The terminal seal is downstream of those rows. A Real-facing read reaches E only after the source, window, and regularity rows have been displayed, and the transport, replay, provenance, and naming rows H, C, P, N preserve that same route.

No remaining coordinate exists in the carrier. Hence quotient stream equality, selected limits, trichotomy, countable choice, host real equality, and ambient completeness cannot supply further local obligations, and the seven listed groups exhaust the NameCert surface. □

Theorem 7352.3 (Regular Cauchy embedding constant handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*- or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ *carrier receives only the displayed constant-entry route*

$$D, Q \longmapsto W \longmapsto R \longmapsto E$$

preserved by H, C, P, N. In particular, the consumer cannot replace the route by quotient stream equality, a selected limit, a trichotomy branch not recorded in the source rows, a countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 7352.2. A consumer must first read carrier admission and the displayed dyadic or rational source row before the constant-window row is meaningful.

The StreamName handoff is constant. Since W repeats the displayed entry on each inspected finite window, the regular readback R can only be consumed as the stationary $\mathsf{RegSeqRat}^{\uparrow}$ row attached to those windows.

The Real seal is last. The row E is exposed after the constant-window and regularity rows, while H, C, P, N transport, replay, source, and name exactly that finite route.

Therefore every RegSeqRat- or Real-facing read factors through $D, Q, W, R, E, H, C, P, N$. The carrier contains no separate coordinate for quotient stream equality, selected limits, trichotomy,

countable-choice schedules, host equality, or ambient completeness, so none of those objects can be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ consumer must expose the dyadic or rational source row, the constant StreamName window row, the stationary RegSeqRat readback row, the Real seal row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any RegSeqRat- or Real-facing constant-entry read is available.

Independence witness: Nearest siblings: DyadicRatCore, Rat, StreamName, RegSeqRat, Real, and DyadicEmbedding. $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ is not bijective to any one of them because it jointly carries source rows, constant windows, stationary regular readback, a terminal seal, transport, replay, provenance, and local naming for the same constant-entry embedding route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEmbedding}^{\uparrow}$ packet is generated from displayed DyadicRatCore or Rat source rows, constant StreamName windows, stationary RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7352.1, Definition 7352.2, and Definition 7352.3 seed the finite constant-entry route from DyadicRatCore or Rat data into RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, constant-window exactness, regularity handoff, Real-seal nonescape, classifier transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyEmbeddingUp.

Chapter 7353

A Concrete Naming Certificate for $\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}$

Following Dunford and Pettis, with the weak-topology and Banach-space background read through Bourbaki and Schaefer, the $\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}$ packet records the finite BEDC window in which a Dunford–Pettis handoff can be inspected as weak-compactness evidence without importing the full compactness theorem. It sits between the Dunford–Pettis route of chapter 6346, the weak compactness surface of chapter 6851, the weak-topology probe window of chapter 3597, the Banach source of chapter 90, and the scalar readback discipline of chapter 38. The chapter names only a finite window object: it does not claim Banach–Alaoglu, full weak compactness, selected weakly convergent subsequences, quotient function-space equality, or choice.

Definition 7353.1 (Dunford–Pettis finite weak-compactness carrier)**.** *A* $\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, K, T, B, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DunfordPettis}^{\uparrow}$ *source row, exposing only the already displayed uniform-integrability, weak-test, bounded-probe, scalar-budget, handoff, transport, replay, provenance, and local naming rows.*
2. *K is the* $\mathsf{WeakCompactness}^{\uparrow}$ *request row, read as a finite compactness-facing interface rather than as a completed weak-compactness theorem.*
3. *T is the* $\mathsf{WeakTopology}^{\uparrow}$ *probe-window row, listing the finitely many weak probes and tolerances visible in the present handoff.*
4. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row, naming the ambient linear and norm structure only through displayed finite functional-analysis data.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for probe values, bounds, tolerances, and comparison ledgers.*
6. *A is the finite acceptance-window row. It records that the Dunford–Pettis handoff, weak-compactness request, weak-topology probes, Banach source, and scalar readback have been displayed in the same packet before a consumer can read weak-compactness evidence.*
7. *H records componentwise* hsame *transport for D, K, T, B, R, A, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$D, T, B, R \longmapsto A \longmapsto K, H, P, N.$$

9. *P is the* Pkg *provenance over* DunfordPettisFiniteWeakCompactness$^{\uparrow}$, DunfordPettis$^{\uparrow}$, WeakCompactness$^{\uparrow}$, WeakTopology$^{\uparrow}$, Banach$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{DunfordPettisFiniteWeakCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, K, T, B, R, A, H, C, P, N$. It has no coordinate for Banach–Alaoglu, a full weak-compactness theorem, selected weakly convergent subsequences, quotient function-space equality, an ambient dual-ball compactness theorem, countable choice, or an unrestricted weak-probe family.

Theorem 7353.2 (Dunford–Pettis finite weak-compactness obligations)**.** *For every accepted* DunfordPettisFiniteWe *carrier*

$$W = (D, K, T, B, R, A, H, C, P, N),$$

the local NameCert$_{\text{DunfordPettisFiniteWeakCompactness}^{\uparrow}}$ *surface consists exactly of Dunford–Pettis source admission through D, weak-compactness request admission through K, finite weak-topology probe admission through T, Banach source admission through B, scalar readback through R, finite acceptance-window exactness through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Every consumer must expose D, T, B, R, A before reading K as weak-compactness evidence. The row K is therefore a finite window handoff, not Banach–Alaoglu, full weak compactness, a selected weakly convergent subsequence, quotient function-space equality, or a choice principle.

Proof. Project the carrier of Definition 7353.1. Its public rows are exactly $D, K, T, B, R, A, H, C, P, N$, so the NameCert surface can expose only the Dunford–Pettis source, weak-compactness request, weak-topology probe window, Banach source, scalar readback, finite acceptance window, and structural rows.

The window exactness is forced by the order of the replay row. A consumer first reads the Dunford–Pettis source D, the weak-topology probes T, the Banach source B, and the scalar readback R; only then does the acceptance-window row A allow the weak-compactness request K to be inspected.

Transport and provenance do not add compactness data. The rows H, C, P, N move, replay, source, and name the same finite route, while the classifier has no coordinate for Banach–Alaoglu, selected subsequences, quotient function-space equality, unrestricted weak compactness, or choice. □

Theorem 7353.3 (Dunford–Pettis finite weak-compactness window handoff)**.** *Every weak-compactness-facing consumer of an accepted* DunfordPettisFiniteWeakCompactness$^{\uparrow}$ *packet must pass through the finite route*

$$\text{DunfordPettis}^{\uparrow}, \text{WeakTopology}^{\uparrow}, \text{Banach}^{\uparrow}, \text{Real}^{\uparrow} \longmapsto A \longmapsto \text{WeakCompactness}^{\uparrow}.$$

The handoff may feed the finite weak-compactness interface of chapter 6851, but it exports no Banach–Alaoglu theorem, full weak compactness, selected weakly convergent subsequence, quotient function-space equality, countable-choice schedule, or ambient dual-ball compactness theorem.

Proof. Begin with the Dunford–Pettis source row D. It carries only the finite handoff described in chapter 6346, so the consumer has not obtained a selected subsequence or ambient compactness theorem.

Next read the weak-topology, Banach, and Real rows T, B, R. These rows expose the finite probe window, source structure, scalar values, bounds, and tolerances needed for the present request.

The acceptance-window row A then binds those reads to the weak-compactness request K. Since A is a displayed finite row, it can hand the request to the sibling weak-compactness surface without promoting the route to Banach–Alaoglu, full weak compactness, quotient equality, or choice.

Finally the structural rows H, C, P, N transport, replay, source, and name the same route. No additional carrier coordinate remains through which a consumer could extract a selected weakly convergent subsequence, an ambient dual-ball compactness theorem, or unrestricted function-space equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7353.1, Definition 7353.2, and Definition 7353.3 seed the finite window from Dunford–Pettis source data through weak-topology probes, Banach source rows, scalar readback, acceptance-window exactness, and weak-compactness request rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Banach–Alaoglu, full weak compactness, selected weakly convergent subsequences, quotient function-space equality, countable choice, ambient dual-ball compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite probe-window admission, Banach source compatibility, scalar readback, acceptance-window exactness, handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DunfordPettisFiniteWeakCompactnessUp.

Constructive story: A $\mathsf{DunfordPettisFiniteWeakCompactness}^{\uparrow}$ packet is generated from a DunfordPettis source row, a WeakCompactness request row, a WeakTopology finite probe window, a Banach source row, Real scalar readback, an acceptance-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7354

A Concrete Naming Certificate for $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ packet records the finite away-from-zero modulus data needed to read a reciprocal of a regular Cauchy rational name. It sits after the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the located positive lower-bound surface of chapter 2029, the terminal real-name seal of chapter 38, and the reciprocal handoff of chapter 6251. The packet names the local modulus route for a source already displayed away from zero; it is not RealUp completeness, field completeness, quotient equality of representatives, or a selector for inverses.

Definition 7354.1 (Regular Cauchy reciprocal modulus carrier)**.** *A* $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, A, K, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, displaying the regular rational name whose reciprocal modulus is being read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested precision, dyadic comparison budget, and denominator-safety scale.*
3. *A is the located positive away-from-zero witness, read through* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *as a positive lower bound for the source seal.*
4. *K is the reciprocal modulus calculation row, turning the lower-bound witness and the requested tolerance into the finite denominator budget used by the reciprocal readback.*
5. *R is the* $\mathsf{RealReciprocal}^{\uparrow}$ *handoff row, available only after S, D, A, K have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff for the reciprocal name.*
7. *H records componentwise* hsame *transport for source, tolerance, located gap, modulus calculation, reciprocal handoff, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, D, A, K \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, D, A, K, R, E, H, C, P, N$. It has no coordinate for RealUp completeness, field completeness, quotient representatives, selected inverses, arbitrary trichotomy, or countable choice.

Lean4 (statement) `BEDC.Derived.RegularCauchyReciprocalModulusUp`

Theorem 7354.2 (Regular Cauchy reciprocal modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ *carrier $M = (S, D, A, K, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReciproca}}$ *surface consists exactly of carrier admission;* $\mathsf{RegSeqRat}^{\uparrow}$ *source visibility through S;* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness through D; away-from-zero located positivity through A; reciprocal modulus calculation through K;* $\mathsf{RealReciprocal}^{\uparrow}$ *handoff through R;* $\mathsf{Real}^{\uparrow}$ *seal handoff through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7354.1. The source row S, dyadic tolerance ledger D, and located positive row A are the complete finite input surface for the reciprocal modulus request.

Read the calculation row next. The row K is downstream of the displayed tolerance and away-from-zero data, so the reciprocal handoff R can be consumed only after the denominator-safety budget has been named.

Finally the seal row E and the structural rows H, C, P, N transport, replay, source, and name the same route. Since no excluded completeness theorem, quotient representative, selected inverse, trichotomy, or choice row occurs in the carrier, every accepted obligation stays inside the listed NameCert surface. □

Theorem 7354.3 (Regular Cauchy reciprocal modulus Real seal boundary)**.** *Every Real-facing reciprocal read of an accepted* $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. The route exports no RealUp completeness, field completeness, quotient representative equality, selected inverse, arbitrary trichotomy, or countable choice.*

Proof. Apply Definition 7354.2. It identifies the source row S, dyadic ledger D, located positive row A, and reciprocal modulus calculation row K as the only finite input surface for the reciprocal read.

The $\mathsf{RealReciprocal}^{\uparrow}$ handoff row R is therefore available only through that displayed input surface. A Real-facing consumer reaches the seal row E only after the reciprocal handoff has been exposed.

The transport, replay, provenance, and local naming rows preserve the same dependency order. No carrier row supplies completeness, quotient representatives, selected inverses, trichotomy, or countable choice, so the terminal handoff remains a finite seal rather than an ambient field operation. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ packet is generated from a RegSeqRat source, a DyadicRatCore tolerance ledger, a located positive away-from-zero witness, a reciprocal modulus calculation row, a RealReciprocal handoff, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7354.1, Definition 7354.2, and Definition 7354.3 seed the finite Bishop-style away-from-zero reciprocal-modulus route from regular Cauchy evidence to the RealUp seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyReciprocalModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, field completeness, quotient representatives, selected inverses, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, located positive away-from-zero input, reciprocal modulus calculation, RealReciprocal handoff, RealUp seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyReciprocalModulusUp.

Chapter 7355

A Concrete Naming Certificate for $\mathsf{EgyptianFraction}^{\uparrow}$

Following Hardy–Wright style unit-fraction decomposition, the $\mathsf{EgyptianFraction}^{\uparrow}$ packet records the finite greedy route by which a positive rational window is decomposed into displayed unit-denominator rows before it is consumed by real-approximation data. It sits after the rational carrier of chapter 37, the dyadic tolerance core of chapter 291, the pointwise rational schedule of chapter 350, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only a finite decomposition packet; it does not assert host rational trichotomy, select an infinite expansion, quotient real names, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7355.1 (Egyptian fraction carrier)**.** *An* $\mathsf{EgyptianFraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, R, D, G, T, S, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the initial positive* $\mathsf{Rat}^{\uparrow}$ *source row to be decomposed.*
2. *$R = (r_0, \ldots, r_m)$ is the residual rational row, with $r_0 = Q$ and each displayed residual read through* $\mathsf{Rat}^{\uparrow}$*.*
3. *$D = (d_1, \ldots, d_m)$ is the finite unit-denominator list, recording the unit rows $1/d_i$ consumed by the decomposition.*
4. *G is the greedy-step ledger. Its ith row records that d_i is a displayed positive denominator with $1/d_i \leq r_{i-1}$ and that the next residual is $r_i = r_{i-1} - 1/d_i$.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *error-budget row, recording dyadic windows for the residuals and for the finite partial sums $\sum_{j \leq i} 1/d_j$.*
6. *S is the* $\mathsf{RationalStream}^{\uparrow}$ *handoff row, exposing the finite partial-sum schedule as rational observations.*
7. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, reading the same finite schedule as a regular rational approximation window for downstream Real and Completion consumers.*
8. *H records componentwise* hsame *transport for Q, R, D, G, T, S, A and the local naming rows.*

9. *C records displayed* Cont *replay from the initial rational row through the greedy ledger, dyadic budget, rational-stream handoff, and regular-rational readback.*
10. *P is the* Pkg *provenance over* $\mathsf{EgyptianFraction}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RationalStream}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EgyptianFraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed finite rows $Q, R, D, G, T, S, A, H, C, P, N$. It has no coordinate for an infinite unit-fraction tail, a chosen host expansion, quotient equality of real names, rational trichotomy beyond the displayed comparisons, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7355.2 (Egyptian fraction greedy step)**.** *For an accepted* $\mathsf{EgyptianFraction}^{\uparrow}$ *carrier $E = (Q, R, D, G, T, S, A, H, C, P, N)$, every displayed greedy row in G decreases the residual inside the rational-and-dyadic surface. More precisely, if the ith ledger row records $1/d_i \le r_{i-1}$ and $r_i = r_{i-1} - 1/d_i$ with $r_{i-1} > 0$, then the next residual row satisfies*

$$0 \le r_i < r_{i-1}.$$

The comparison is read only through the $\mathsf{Rat}^{\uparrow}$ *residual rows and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row T.*

Proof. Project the carrier of Definition 7355.1. The relevant data for one step are the residual pair r_{i-1}, r_i, the denominator row d_i, the ledger equation in G, and the dyadic comparison budget in T.

The lower bound is ledger exactness. Since G records $1/d_i \le r_{i-1}$ and $r_i = r_{i-1} - 1/d_i$, the displayed $\mathsf{Rat}^{\uparrow}$ subtraction row presents r_i as a nonnegative residual.

The strict upper bound uses only the positive unit row. The same ledger records a positive denominator, so the unit row $1/d_i$ is a positive rational. Subtracting a displayed positive rational from the positive residual gives $r_i < r_{i-1}$, and the dyadic budget row T supplies the finite comparison window used by downstream consumers. □

Theorem 7355.3 (Egyptian fraction NameCert obligations)**.** *For every accepted* $\mathsf{EgyptianFraction}^{\uparrow}$ *carrier $E = (Q, R, D, G, T, S, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EgyptianFraction}^{\uparrow}}$ *surface consists of five finite rows:*

1. *carrier admission for the displayed packet E;*
2. *residual exactness for the* $\mathsf{Rat}^{\uparrow}$ *rows Q, R and the unit-denominator list D;*
3. *greedy-step exactness for G, including the residual decrease of Definition 7355.2;*
4. *approximation handoff through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row T, the* $\mathsf{RationalStream}^{\uparrow}$ *schedule row S, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row A;*
5. *componentwise transport, displayed replay, provenance, and local naming through H, C, P, N.*

Proof. Carrier admission is projection of the finite tuple E. The rational source, residual list, denominator list, greedy ledger, dyadic budget, rational-stream handoff, regular readback, transport, replay, provenance, and naming rows are all coordinates of the same BHist packet.

Residual exactness and greedy-step exactness are local to Q, R, D, G. Each accepted step stores the unit denominator and the resulting residual equation, while Definition 7355.2 supplies the displayed decrease used to keep the finite ledger ordered.

The approximation handoff is downstream of the greedy rows. The dyadic budget row T bounds the finite partial sums, S exposes those sums as rational-stream observations, and A reads the same schedule as a regular rational approximation row. The remaining rows H, C, P, N transport and name exactly this route, so the five listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{EgyptianFraction}^{\uparrow}$ consumer must expose the initial Rat row, residual rational row, unit-denominator list, greedy-step ledger, dyadic error budget, RationalStream handoff, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any Real-facing rational approximation read is available.

Independence witness: Nearest siblings: Rat, DyadicRatCore, RationalStream, RegSeqRat, and Real. $\mathsf{EgyptianFraction}^{\uparrow}$ is not bijective to any one of them because it binds a finite unit-denominator decomposition ledger to dyadic budget, rational-stream, and regular-rational readback rows in one local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EgyptianFraction}^{\uparrow}}$.

Constructive story: An $\mathsf{EgyptianFraction}^{\uparrow}$ packet is generated from a positive Rat source row, residual rational rows, a finite unit-denominator list, a greedy-step ledger, dyadic error budgets, RationalStream handoff, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EgyptianFraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7355.1, Definition 7355.2, and Definition 7355.3 seed the finite unit-fraction decomposition surface for L10 rational approximation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EgyptianFraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close existence of a complete expansion for arbitrary rationals, uniqueness of decomposition, host rational trichotomy, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual exactness, greedy-step decrease, dyadic budget handoff, RationalStream handoff, RegSeqRat readback, transport, replay, provenance, and local naming for BEDC.Derived.EgyptianFractionUp.

Chapter 7356

A Concrete Naming Certificate for $\mathsf{CompactMetricEquicontinuity}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactMetricEquicontinuity}^{\uparrow}$ packet records the finite BEDC carrier that connects a compact metric source, an equicontinuity-family modulus ledger, and the finite-modulus extraction interface used by Arzela–Ascoli. It sits after the compact finite-net source route of chapter 6598, the family-radius ledger of chapter 413, and the extraction consumer of chapter 3568. The packet names the finite-net handoff only; it does not import open-cover compactness, a choice-selected center family, host function-space compactness, selected subsequences, quotient equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7356.1 (CompactMetricEquicontinuity carrier)**.** *A* $\mathsf{CompactMetricEquicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, Y, F, R, M, V, S, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, read through finite net centers, cover radii, and located membership witnesses;*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row whose distance comparisons are used by the family ledger;*
3. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family row over the source and target rows;*
4. *R records pointwise continuity radius rows for the displayed family members and source centers;*
5. *M is the shared equicontinuity modulus candidate read through* $\mathsf{EquicontinuityFamily}^{\uparrow}$*;*
6. *V is the finite-net cover ledger that records which compact-source centers and radii are consumed by the handoff;*
7. *S is the* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ *handoff row that receives the compact finite-net and shared-modulus data;*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *tolerance seal for the displayed target-distance budget;*
9. *H records componentwise* hsame *transport for the compact source, target metric, family rows, radius rows, modulus candidate, cover ledger, handoff row, tolerance seal, replay, provenance, and local naming;*

10. *C records displayed* Cont *replay from a requested tolerance through $K, Y, F, R, M, V, A, H, P, N$ to the finite-modulus handoff S;*
11. *P is the* Pkg *provenance over* $\mathsf{CompactMetricEquicontinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricEquicontinuity}^{\uparrow}}$ *row.*

The carrier exports only these finite rows. It contains no arbitrary open-cover compactness proof, no selected center family outside V, no host function-space topology, no selected subsequence operator, no quotient equality of maps, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 7356.2 (CompactMetricEquicontinuity Arzela–Ascoli handoff)**.** *Every accepted* CompactMetricEquiconti *carrier $E = (K, Y, F, R, M, V, S, A, H, C, P, N)$ supplies the finite-modulus handoff consumed by* $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$. *The handoff exposes the compact metric source row K, target metric row Y, finite family row F, pointwise radius rows R, shared modulus candidate M, finite-net cover ledger V, terminal* $\mathsf{Real}^{\uparrow}$ *tolerance seal A, and structural rows H, C, P, N before the consumer reads S. It supplies no open-cover compactness, selected centers outside the displayed ledger, host function-space compactness, selected subsequences, quotient equality of maps, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the compact source row K and the finite-net cover ledger V. Finite induction over the displayed net centers reduces a requested tolerance to finitely many center reads, and each step keeps the membership witness and cover radius inside the same BHist packet.

Use the equicontinuity rows next. The pointwise continuity radius rows R are transported through the shared modulus candidate M, so every family member in F reads the same source-radius budget for the displayed tolerance. The target metric row Y supplies only the distance comparisons attached to those finite rows.

Finally compose the tolerance ledger. The $\mathsf{Real}^{\uparrow}$ seal A records the target-distance budget after the finite-net and equicontinuity-radius transports have been displayed, while H, C, P, N preserve, replay, source, and name the same packet. Therefore the handoff row S gives $\mathsf{ArzelaAscoliFiniteModulus}^{\uparrow}$ exactly the finite modulus data it expects, with no hidden compactness, choice, subsequence, quotient, function-space, or ambient-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactMetricEquicontinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactMetricEquicontinuity}^{\uparrow}$ packet is generated from compact metric finite-net rows, target MetricUp rows, finite ContinuousMapUp family rows, pointwise continuity radius rows, EquicontinuityFamilyUp shared-modulus candidates, finite-net cover ledgers, ArzelaAscoliFiniteModulusUp handoff rows, RealUp tolerance seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactMetricEquicontinuity}^{\uparrow}}$, seed)

Scope closed: Definition 7356.1 and Definition 7356.2 seed the compact-metric equicontinuity carrier and its finite-modulus Arzela–Ascoli handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactMetricEquicontinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected centers outside the displayed ledger, host function-space compactness, selected subsequences, quotient equality of maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net coverage, pointwise radius transport, shared-modulus exactness, finite-cover ledger exhaustion, Real tolerance sealing, and Arzela–Ascoli finite-modulus handoff for BEDC.Derived.CompactMetricEquicontinuityUp.

Chapter 7357

A Concrete Naming Certificate for $\mathsf{MilmanConverse}^{\uparrow}$

Following Milman's converse direction in compact convexity, the $\mathsf{MilmanConverse}^{\uparrow}$ packet records the finite boundary route by which a compact convex carrier reads an extreme-window source before exporting a closure-hull handoff. It sits after the compact carrier of chapter 60, the convex-set surface of chapter 208, the locally convex observation rows of chapter 3386, the Choquet boundary packet of chapter 6611, and the finite Krein–Milman extreme witness of chapter 3610. The chapter names only the compact-convex boundary object needed for a Milman-converse read; it does not assert selected extreme points, strong Hahn–Banach separation, quotient convex-set equality, countable choice, or ambient locally convex completeness.

Definition 7357.1 (Milman converse carrier)**.** *A* $\mathsf{MilmanConverse}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, V, L, S, E, W, G, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row naming the compact carrier inspected by the boundary request.*
2. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row exposing affine-combination and convex-subcarrier data.*
3. *L is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *observation row for seminorm and neighbourhood windows used by compact-convex consumers.*
4. *S is the* $\mathsf{ChoquetSimplex}^{\uparrow}$ *boundary row when the read is routed through a simplex-facing compact convex source.*
5. *E is the* $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ *finite extreme-window row, opened only as displayed candidate-extreme and exposed-face evidence.*
6. *W is the finite extreme-window ledger recording which boundary observations have been inspected.*
7. *G is the closure-hull handoff row, available only after K, V, L, S, E, W are visible.*
8. *H records componentwise* hsame *transport for compact, convex, locally convex, Choquet, finite extreme-window, closure-hull, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a compact-convex boundary request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{MilmanConverse}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{ChoquetSimplex}^{\uparrow}$, $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, L, S, E, W, G, H, C, P, N$. It has no coordinate for a selected extreme point, a strong Hahn–Banach separator, quotient convex-set equality, countable-choice search, or ambient locally convex completeness.

Theorem 7357.2 (Milman converse NameCert obligations)**.** *For every accepted* $\mathsf{MilmanConverse}^{\uparrow}$ *carrier $M = (K, V, L, S, E, W, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, convex-carrier admission through V, locally convex observation through L, Choquet-boundary admission through S, finite Krein–Milman extreme-window admission through E, boundary ledger visibility through W, closure-hull handoff visibility through G, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7357.1. The compact source, convex carrier, locally convex observations, Choquet boundary row, finite extreme-window row, boundary ledger, and closure-hull handoff are exactly the rows K, V, L, S, E, W, G.

Read the source rows first. The compact row K and convex row V supply the compact-convex object, while L keeps the locally convex observations finite and visible.

Next attach the boundary rows. The Choquet row S supplies the simplex-facing boundary packet when present, the finite Krein–Milman row E supplies only candidate-extreme and exposed-face data, and W records the inspected extreme-window ledger.

Finally the handoff row G may be read, and H, C, P, N transport, replay, source, and name the same route. Since no remaining coordinate stores selected extreme points, a strong Hahn–Banach separator, quotient convex-set equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7357.3 (Milman converse compact-convex handoff)**.** *Every compact-convex boundary read exported by an accepted* $\mathsf{MilmanConverse}^{\uparrow}$ *packet factors through*

$$\mathsf{Compact}^{\uparrow}, \quad \mathsf{ConvexSet}^{\uparrow}, \quad \mathsf{LocallyConvexSpace}^{\uparrow}, \quad \mathsf{ChoquetSimplex}^{\uparrow}, \quad \mathsf{KreinMilmanFiniteExtreme}^{\uparrow}.$$

The closure-hull handoff row G is available only after the compact carrier, convex carrier, locally convex observation row, Choquet boundary row, finite extreme-window row, and boundary ledger have all been displayed. The handoff exports no selected extreme point, strong Hahn–Banach separation, quotient convex-set equality, countable choice, or ambient locally convex completeness.

Proof. Start with Definition 7357.2. It forces any accepted boundary consumer to expose $K, V, L, S, E, W, G, H, C, P$ before the local $\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}$ row can be used.

Read the supplying chapters in order. chapter 60 supplies compact observations, chapter 208 supplies convex carrier data, and chapter 3386 supplies locally convex observation windows.

Then use the boundary sources. chapter 6611 supplies only the displayed Choquet boundary packet, and chapter 3610 supplies only finite exposed-face and candidate-extreme evidence.

Therefore the closure-hull handoff is downstream from the displayed compact-convex boundary route. Since the carrier has no selected extreme point, strong Hahn–Banach separator, quotient convex-set equality, countable-choice selector, or ambient completeness row, the handoff cannot export any of those objects. □

Falsifiable prediction: An accepted $\mathsf{MilmanConverse}^{\uparrow}$ consumer that reaches the closure-hull handoff without first displaying the $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{ChoquetSimplex}^{\uparrow}$, and $\mathsf{KreinMilmanFiniteExtreme}^{\uparrow}$ rows refutes the carrier surface.

Independence witness: compact, convexset, locally-convex-space, choquet-simplex, krein-milman-finite-extreme: no listed sibling is bijective to $\mathsf{MilmanConverse}^{\uparrow}$, because the packet jointly carries compact and convex rows, locally convex observations, a Choquet boundary row, a finite extreme-window row, a closure-hull handoff, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}$.

Constructive story: A $\mathsf{MilmanConverse}^{\uparrow}$ packet is generated from compact source rows, convex carrier rows, locally convex observation rows, Choquet boundary rows, finite Krein–Milman extreme-window rows, a closure-hull handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7357.1, Definition 7357.2, and Definition 7357.3 seed the compact-convex boundary certificate over compact, convex, locally convex, Choquet, finite extreme-window, closure-hull, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MilmanConverse}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected extreme points, strong Hahn–Banach separation, quotient convex-set equality, countable choice, ambient locally convex completeness, Lean verification, or bridge checking for $\mathsf{MilmanConverse}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, compact and convex source visibility, locally convex observation, Choquet boundary admission, finite extreme-window exactness, closure-hull handoff visibility, transport, replay, provenance, and local naming for BEDC.Derived.MilmanConverseUp.

Chapter 7358

A Concrete Naming Certificate for $\mathsf{HellingerDistance}^{\uparrow}$

Following Hellinger and Kakutani on affinity-style probability distances, the $\mathsf{HellingerDistance}^{\uparrow}$ packet records the finite square-root overlap ledger between two displayed probability or distribution rows. It sits after the probability packet of chapter 184, the pushforward distribution ledger of chapter 186, the metric comparison surface of chapter 57, the Wasserstein transport-plan packet of chapter 5197, and the terminal real-name seal of chapter 38. The chapter names only a finite statistical-distance packet; it does not import measure completion, Radon–Nikodym representatives, selected densities, or a host integration theorem.

Definition 7358.1 (Hellinger distance carrier)**.** *A* $\mathsf{HellingerDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, \mu, \nu, A, B, O, R, M, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source-row ledger whose cells are read through an accepted* $\mathsf{ProbSpace}^{\uparrow}$ *carrier or an accepted* $\mathsf{Distribution}^{\uparrow}$ *pushforward surface.*
2. *μ and ν are the two probability or distribution source rows over S.*
3. *A and B are marginal readback rows, exposing the displayed nonnegative weights $\mu(s_i)$ and $\nu(s_i)$ on each listed cell of S.*
4. *O is the square-root overlap ledger, recording the finite entries $\sqrt{\mu(s_i)}\sqrt{\nu(s_i)}$ and their displayed sum.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the terminal Hellinger value, reached only after A, B, and O have been read.*
6. *M is the optional* $\mathsf{Met}^{\uparrow}$ *comparison context in which the resulting real distance may be consumed.*
7. *W is the optional* $\mathsf{Wasserstein}^{\uparrow}$ *comparison context, present only when a consumer compares the overlap distance with a finite transport-plan row over the same source.*
8. *H records componentwise* hsame *transport for $S, \mu, \nu, A, B, O, R, M, W$ and the local naming rows.*
9. *C records displayed* Cont *replay from the source rows through marginal readback, square-root overlap, real sealing, and optional comparison contexts.*

10. *P is the* Pkg *provenance over* $\mathsf{HellingerDistance}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Wasserstein}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HellingerDistance}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for measure completion, a chosen density representative, an ambient integral, a quotient of probability laws, or a selected coupling.

Theorem 7358.2 (Hellinger distance NameCert obligations)**.** *For every accepted* $\mathsf{HellingerDistance}^{\uparrow}$ *carrier*

$$L = (S, \mu, \nu, A, B, O, R, M, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HellingerDistance}^{\uparrow}}$ *surface consists of six finite obligation rows:*

1. *carrier admission for the displayed* BHist *packet L;*
2. *marginal readback through S, μ, ν, A, B, with every public weight attached to a listed finite source cell;*
3. *square-root overlap exactness through O, whose entries and finite sum are the only overlap ledger exported by the packet;*
4. $\mathsf{Real}^{\uparrow}$ *distance sealing through R, downstream from the marginal readbacks and overlap ledger;*
5. *componentwise transport, displayed replay, and provenance through H, C, P;*
6. *local naming through N, with no exported coordinate for measure completion, selected densities, ambient integration, quotient probability laws, or hidden couplings.*

Proof. Project the carrier of Definition 7358.1. The visible coordinates are the finite source ledger, two probability or distribution rows, marginal readbacks, the square-root overlap ledger, the real seal, optional comparison contexts, transport, replay, provenance, and local naming row.

Carrier admission is exactly this projection. Marginal readback is exhausted by A and B: a consumer can inspect only weights attached to the listed cells of S, and each such read is mediated by the displayed $\mathsf{ProbSpace}^{\uparrow}$ or $\mathsf{Distribution}^{\uparrow}$ source row.

The overlap obligation is local to O. Its entries are the displayed products of square-rooted marginal weights, and its finite sum is the only affinity-style scalar exported before the real seal is reached.

Finally read R, H, C, P, N. The $\mathsf{Real}^{\uparrow}$ seal is downstream from the marginal and overlap rows, while transport, replay, provenance, and local naming preserve that same route. Since no other coordinate is present in the packet, the six listed rows exhaust the local NameCert surface and leave measure completion, selected densities, ambient integration, quotient laws, and hidden couplings outside the carrier. □

Theorem 7358.3 (Hellinger finite probability route)**.** *Every public consumer of an accepted* $\mathsf{HellingerDistance}^{\uparrow}$ *packet reads the distance through the finite probability route*

$$\mathsf{ProbSpace}^{\uparrow}, \mathsf{Distribution}^{\uparrow} \longmapsto S, \mu, \nu, A, B, O \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow}, \mathsf{Wasserstein}^{\uparrow}, H, C, P, N.$$

In particular, a downstream comparison may cite $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Wasserstein}^{\uparrow}$ *only after the probability or distribution source rows, square-root overlap ledger, and* $\mathsf{Real}^{\uparrow}$ *seal have been displayed.*

Proof. Start with the NameCert obligations of Definition 7358.2. They force every public read to expose the finite source ledger, the two probability or distribution rows, the marginal readbacks, and the square-root overlap ledger before the real-valued distance row is available.

The optional comparison rows M and W are downstream coordinates of the same carrier. Thus a $\mathsf{Met}^{\uparrow}$ consumer receives only the real-sealed distance, and a $\mathsf{Wasserstein}^{\uparrow}$ comparison receives only a route already tied to the displayed finite source and overlap ledger.

The structural rows H, C, P, N preserve and name this route without adding analytic data. Since measure completion, selected densities, ambient integration, quotient probability laws, and hidden couplings are absent from the carrier, no public consumer can bypass the finite probability, overlap, and real-seal rows. □

Falsifiable prediction: Every accepted $\mathsf{HellingerDistance}^{\uparrow}$ consumer must expose finite ProbSpace or Distribution source rows, two marginal readback rows, the square-root overlap ledger, the RealUp seal, optional MetricUp or WassersteinUp comparison rows, hsame transport, Cont replay, Pkg provenance, and the local NameCert row before any statistical-distance read is public.

Independence witness: Nearest siblings: ProbSpace, Distribution, Metric, Wasserstein, and Real. $\mathsf{HellingerDistance}^{\uparrow}$ is not bijective to any one of them because it binds two finite marginal rows, a square-root overlap ledger, a terminal RealUp seal, optional metric or transport comparison contexts, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HellingerDistance}^{\uparrow}}$.

Constructive story: A $\mathsf{HellingerDistance}^{\uparrow}$ packet is generated from finite ProbSpace or Distribution source rows, two marginal readback rows, a square-root overlap ledger, a RealUp distance seal, optional MetricUp or WassersteinUp comparison contexts, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HellingerDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7358.1, Definition 7358.2, and Definition 7358.3 seed the finite statistical-distance NameCert surface over probability, distribution, metric, Wasserstein, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HellingerDistance}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.HellingerDistanceUp`

Bridge status: none

Not claimed: This chapter does not close measure completion, Radon–Nikodym representatives, selected densities, ambient integration, quotient probability laws, optimal transport comparison, Lean theorem verification, or bridge checking.

Upgrade path: Lean verification requires checked carrier admission, marginal readback, square-root overlap exactness, RealUp seal routing, MetricUp and WassersteinUp comparison handoff, transport, replay, provenance, and local naming for BEDC.Derived.HellingerDistanceUp.

Chapter 7359

A Concrete Naming Certificate for $\mathsf{TreeAutomaton}^{\uparrow}$

Following Thatcher and Wright's finite tree automata and the standard automata-theory presentation of regular tree languages, the $\mathsf{TreeAutomaton}^{\uparrow}$ packet records bottom-up recognition of finite ranked trees as BEDC NameCert data. It sits beside the word-facing $\mathsf{FiniteAutomaton}^{\uparrow}$ packet of chapter 2364, the accepted-language surface of $\mathsf{RegularLanguage}^{\uparrow}$ in chapter 351, the grammar-side syntax carrier $\mathsf{ContextFreeGrammar}^{\uparrow}$ of chapter 356, and the finite classifier discipline of $\mathsf{MyhillNerode}^{\uparrow}$ in chapter 5729. The point is a finite syntax-tree recognition packet, not a determinization theorem or a complement-closure result.

Definition 7359.1 (Tree automaton carrier)**.** *A* $\mathsf{TreeAutomaton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Sigma, Q, F, \Delta, R, A, H, C, P, N)$$

with the following displayed rows:

1. Σ *is a finite ranked alphabet row, recording each constructor symbol together with its arity.*
2. Q *is a finite state row.*
3. F *is the accepting-state row.*
4. Δ *is the bottom-up transition ledger, assigning a target state to every displayed constructor together with the finite tuple of child states matching its rank.*
5. R *is the finite input-tree row, carrying a rooted syntax tree whose node labels are drawn from* Σ *with matching arities.*
6. A *is the acceptance row, recording the root state reached by replaying* Δ *from leaves to root and checking membership in* F*.*
7. H *records componentwise* hsame *transport for* $\Sigma, Q, F, \Delta, R, A$ *and the local naming row.*
8. C *records displayed* Cont *replay for reading child-state rows, transition rows, and the root acceptance row in the same finite packet.*
9. P *is the* Pkg *provenance over* $\mathsf{FiniteAutomaton}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
10. N *is the local* $\mathsf{NameCert}_{\mathsf{TreeAutomaton}^{\uparrow}}$ *row.*

The carrier has no coordinate for infinite trees, unranked branching, hidden state choice, determinization, complement closure, or an external quotient of regular tree languages.

Theorem 7359.2 (Tree automaton NameCert obligations)**.** *For the carrier of Definition 7359.1, the local* $\mathsf{NameCert}_{\mathsf{TreeAutomaton}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (\Sigma, Q, F, \Delta, R, A, H, C, P, N),$$

ranked-alphabet exposure through Σ*, finite-state exposure through* Q*, accepting-state exposure through* F*, transition-ledger exactness through* Δ*, finite-tree admission through* R*, root-recognition readback through* A*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The finite ranked alphabet, state row, accepting row, transition ledger, input tree, and root-recognition row are the only data from which a $\mathsf{TreeAutomaton}^{\uparrow}$ certificate can be read.

The transport and replay rows do not add a second recognizer. They only preserve the same finite constructor ranks, child-state tuples, transition entries, and root-state check under hsame and Cont.

Finally read P and N. Provenance names the surrounding automata and language packets, while the local NameCert row registers this packet as the tree-recognition surface. No further NameCert obligation remains outside the displayed rows. □

Theorem 7359.3 (Tree automaton recognition stability)**.** *Every accepted* $\mathsf{TreeAutomaton}^{\uparrow}$ *replay that preserves the ranked alphabet row* Σ*, the transition ledger* Δ*, and the finite input-tree row* R *also preserves the root-recognition row* A*. Thus a syntax-tree consumer may export a recognized-tree result only after reading the constructor ranks, child-state transitions, and root accepting-state test from the same packet.*

Proof. Begin with the carrier of Definition 7359.1. Each node of R has a constructor from Σ, and the rank recorded in Σ fixes the number of child states that may be supplied to Δ.

Replay the tree from leaves to root. Since Δ is preserved, each displayed child-state tuple determines the same parent state in the replayed packet. Induction over the finite tree therefore preserves the state assigned to every node.

At the root, the acceptance row A reads exactly that preserved root state and the displayed accepting-state row F. Hence any replay preserving Σ, Δ, R and the displayed packet rows preserves the recognized-tree result seen by the downstream consumer. □

Falsifiable prediction: A $\mathsf{TreeAutomaton}^{\uparrow}$ read is refuted if a consumer exports recognized-tree acceptance without displaying the finite ranked alphabet, child-state transition ledger, input-tree row, root-state calculation, transport, replay, provenance, and local naming row.

Independence witness: finiteautomaton, regularlanguage, contextfreegrammar, myhillnerode: FiniteAutomatonUp recognizes linear words rather than ranked trees; RegularLanguageUp names word-language acceptance rather than tree-recognition replay; ContextFreeGrammarUp records derivation syntax but not bottom-up ranked-tree state propagation; MyhillNerodeUp records right-congruence classifiers for regular word languages. None is bijective to $\mathsf{TreeAutomaton}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{TreeAutomaton}^{\uparrow}}$**.**

Constructive story: A TreeAutomaton$^{\uparrow}$ packet is generated from a finite ranked alphabet, finite states, accepting states, a bottom-up transition ledger, a finite input tree, a root-recognition row, componentwise transport, displayed continuation replay, provenance over the automata-language siblings, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{TreeAutomaton}^{\uparrow}}$, seed)

Scope closed: Definition 7359.1, Definition 7359.2, and Definition 7359.3 seed the finite ranked-tree recognition certificate.

Formal verification: FormalStatus(NameCert$_{\text{TreeAutomaton}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim determinization, complement closure, minimization, infinite-tree acceptance, or a checked Lean implementation for TreeAutomaton$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, ranked-alphabet exactness, transition-ledger replay, root-recognition stability, transport, continuation, provenance, and local naming for BEDC.Derived.TreeAutomatonUp.

Chapter 7360

A Concrete Naming Certificate for $\mathsf{PositiveDyadicRadius}^{\uparrow}$

Following Bishop and Bridges on constructive real estimates, the $\mathsf{PositiveDyadicRadius}^{\uparrow}$ packet names a strictly positive dyadic tolerance before a regular Cauchy or Real-facing consumer may use it as an error budget. It sits on the dyadic arithmetic rows of chapter 291, the finite-window schedule of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the halving ladder of chapter 6842. The packet records positivity as displayed finite data; it does not import trichotomy of reals, a host positive cone, quotient equality of names, countable choice, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7360.1 (Positive dyadic radius carrier)**.** *A* $\mathsf{PositiveDyadicRadius}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, E, W, S, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa row, naming the nonzero dyadic numerator visible to the current tolerance request.*
2. *E is the exponent row, naming the finite power-of-two scale used to read the radius as a dyadic rational.*
3. *W is the strict positivity witness row, recording that the displayed mantissa and exponent form a radius above zero inside the dyadic core comparison surface.*
4. *S is the halving successor row, pointing to the next positive dyadic radius consumed by chapter 6842.*
5. *T is the tolerance-consumer row, recording the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *requests allowed to read this positive radius.*
6. *H stores componentwise* hsame *transport for mantissa, exponent, strict positivity, halving successor, tolerance consumer, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a tolerance request to the mantissa, exponent, positivity witness, halving successor, and consumer rows.*
8. *P is the* Pkg *provenance over* $\mathsf{PositiveDyadicRadius}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRadiusHalvingLadder}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{PositiveDyadicRadius}^{\uparrow}}$ *row.*
The classifier compares packets only through $M, E, W, S, T, H, C, P, N$. It has no coordinate for host real positivity, arbitrary order trichotomy, quotient Cauchy equality, a selected limiting radius, or an ambient completeness theorem.

Theorem 7360.2 (Positive dyadic radius halving)**.** *Let $R = (M, E, W, S, T, H, C, P, N)$ be an accepted* $\mathsf{PositiveDyadicRadius}^{\uparrow}$ *carrier. Any halving read exported from R first exposes the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *mantissa row M, exponent row E, and strict positivity witness W, and then reaches the successor row S. The successor is therefore a positive dyadic radius in the same finite tolerance route, not a host arithmetic choice or a real-order inference.*

Proof. Project the carrier of Definition 7360.1. The positivity data are the rows M, E, W, so a consumer cannot inspect S without first reading the dyadic representation and strict positivity witness.

Read the halving ladder through chapter 6842. Its successor-halving row consumes displayed dyadic radius data and preserves the finite ladder route; here the row S is the local successor coordinate attached to the same mantissa and exponent surface.

Finally replay the request through H, C, P, N. Transport and continuation replay preserve the same packet before the successor is exported, while provenance and local naming keep the read inside the positive-radius certificate. No host positive cone, selected limit, quotient equality, countable-choice schedule, or ambient completeness row is added. □

Theorem 7360.3 (Positive dyadic radius regular-sequence budget)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance consumer of an accepted* $\mathsf{PositiveDyadicRadius}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{DyadicRadiusHalvingLadder}^{\uparrow}.$$

The consumer must read the dyadic mantissa and exponent rows, the strict positivity witness, the finite stream request, the regular-rational budget row, the halving successor, componentwise transport, displayed replay, package provenance, and local naming before using the radius as a Cauchy or Real-facing error budget.

Proof. Begin with the tolerance-consumer row T. It records exactly which $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ budget, and $\mathsf{Real}^{\uparrow}$ seal request may inspect the positive radius.

Use the positivity rows M, E, W. They place the radius inside the dyadic core before any regular-sequence estimate is read, so the budget is a displayed positive dyadic row rather than an inferred real-order fact.

Apply Definition 7360.2. If the consumer refines the tolerance, the successor row S remains attached to the same positive-radius packet and to the halving ladder route.

The structural rows H, C, P, N close the handoff. They preserve the mantissa, exponent, positivity, successor, and consumer rows under transport and replay, so downstream regular Cauchy and Real consumers receive a finite positive-radius budget and nothing from quotient equality, selected limits, countable choice, host trichotomy, or ambient completeness. □

Falsifiable prediction: A regular Cauchy or Real-facing consumer refutes the PositiveDyadicRadiusUp packet if it uses a tolerance as positive without displaying the dyadic mantissa, exponent, strict positivity witness, halving successor, tolerance-consumer row, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, and dyadicradiushalvingladder: none is bijective to $\mathsf{PositiveDyadicRadius}^{\uparrow}$ because only this packet binds strict dyadic positivity, halving successor, tolerance-consumer routing, transport, replay, provenance, and local NameCert evidence as one certificate surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveDyadicRadius}^{\uparrow}}$.

Constructive story: A $\mathsf{PositiveDyadicRadius}^{\uparrow}$ packet is generated from a DyadicRatCore mantissa row, exponent row, strict positivity witness, halving successor, StreamName and RegSeqRat tolerance-consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveDyadicRadius}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7360.1, Definition 7360.2, and Definition 7360.3 seed the positive dyadic tolerance surface consumed by regular Cauchy and Real budget arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveDyadicRadius}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real positivity, arbitrary order trichotomy, quotient Cauchy equality, selected limiting radii, ambient completeness of RealUp, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, strict positivity exactness, halving successor preservation, tolerance-consumer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PositiveDyadicRadiusUp.

Chapter 7361

A Concrete Naming Certificate for $\mathsf{RegularLanguageContinuation}^{\uparrow}$

Following Kleene's regular-language theorem and the automata presentation of Hopcroft and Ullman, the $\mathsf{RegularLanguageContinuation}^{\uparrow}$ packet records regular-language recognition as finite continuation-recognizer rows rather than as a host set of words. It sits beside the transition-as-continuation surface of chapter 482, the bounded run surface of chapter 1016, the machine-specific prefix packet of chapter 1030, and the terminal behaviour boundary of chapter 597. The carrier names a bounded recognition packet; it does not assert a language quotient, minimization theorem, regular-expression equivalence, unbounded evaluator, or host powerset semantics.

Definition 7361.1 (Regular-language continuation carrier)**.** *A* $\mathsf{RegularLanguageContinuation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, I, A, T, W, R, X, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite state-row inventory.*
2. *I is the initial continuation row.*
3. *A is the accepting-row inventory.*
4. *T is the transition table, whose entries are displayed* Cont *steps between state rows.*
5. *W is the finite input-prefix row inspected by the recognizer.*
6. *R is the bounded replay row, recording the run through W using only entries of T.*
7. *X is the acceptance classifier row, reading the endpoint of R against A.*
8. *H stores componentwise* hsame *transport for state, initial, accepting, transition, prefix, replay, acceptance, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from an input-prefix request to the transition and endpoint classifier rows.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularLanguageContinuation}^{\uparrow}$*,* $\mathsf{ContinuationAutomaton}^{\uparrow}$*,* $\mathsf{FinitePrefixAutomaton}^{\uparrow}$*,* $\mathsf{FinitePrefixMachine}^{\uparrow}$*,* $\mathsf{ContinuationTermination}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularLanguageContinuation}^{\uparrow}}$ *row.*

The classifier compares packets only through $Q, I, A, T, W, R, X, H, C, P, N$. It has no coordinate for a host language subset, quotient of recognizers, minimized automaton, regular-expression conversion, unbounded run, or external evaluator.

Theorem 7361.2 (Regular-language continuation closure)**.** *Every accepted* $\mathsf{RegularLanguageContinuation}^{\uparrow}$ *packet presents bounded regular-language recognition as the finite continuation surface*

$$Q, I, A, T, W, R, X, H, C, P, N.$$

Any acceptance consumer must read the continuation automaton rows, finite prefix run, machine-prefix comparison row when present, continuation-termination boundary, transport rows, replay rows, provenance, and local naming before it can consume the classifier X. The closure is a finite NameCert closure of the recognizer packet, not a theorem identifying all regular-language presentations.

Proof. Project the carrier of Definition 7361.1. The state inventory, initial row, accepting rows, transition table, input prefix, replay ledger, and classifier are the only recognition coordinates available.

Read the transition surface through chapter 482. Each transition row is a displayed Cont step, so the recognizer is already a continuation automaton rather than a separate host operational semantics.

Next read the bounded prefix surfaces of chapter 1016 and chapter 1030. These siblings keep W and R finite and prevent the classifier from escaping to an unbounded evaluator or hidden machine trace.

Finally use chapter 597 for the terminal behaviour boundary. The rows H, C, P, N transport, replay, package, and name the same packet, so the acceptance classifier X remains a finite continuation-recognition row and not a quotient language, minimized automaton, regular-expression equivalence, host powerset object, or unbounded computation theorem. □

Falsifiable prediction: A regular-language continuation consumer refutes the packet if it accepts a word without displaying finite state rows, initial row, accepting rows, continuation transition table, input prefix, bounded replay, endpoint classifier, transport, replay, provenance, and local naming.

Independence witness: continuationautomaton, finiteprefixautomaton, finiteprefixmachine, continuationtermination, and regularlanguage: none is bijective to $\mathsf{RegularLanguageContinuation}^{\uparrow}$ because only this packet binds finite continuation transitions, bounded prefix replay, acceptance classification, terminal behaviour boundary, transport, replay, provenance, and local NameCert rows as one recognizer surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularLanguageContinuation}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularLanguageContinuation}^{\uparrow}$ packet is generated from finite state rows, an initial continuation row, accepting rows, continuation transition rows, a finite input-prefix row, bounded replay, acceptance classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularLanguageContinuation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7361.1 and Definition 7361.2 seed finite continuation recognition for regular-language packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularLanguageContinuation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close minimization, regular-expression equivalence, quotient language equality, host powerset semantics, unbounded evaluation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition replay exactness, bounded prefix acceptance, terminal behaviour nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularLanguageContinuationUp.

Chapter 7362

A Concrete Naming Certificate for $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion and the standard Kleisli reading of monads, the $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$ packet records the finite route by which a regular-Cauchy completion arrow is composed without quotienting the underlying name data. It sits between the source $\mathsf{RegSeqRat}^{\uparrow}$ route of chapter 301, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the dyadic tolerance budget of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the Kleisli law surface of chapter 3834, and the stabilization surface of **??**. The packet is a composition interface for regular-Cauchy routes, not a selected limit, quotient completion object, countable-choice schedule, host equality proof, or ambient Real-completeness theorem.

Definition 7362.1 (Regular Cauchy Kleisli extension carrier)**.** *A* $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, F, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *route whose regular rational name is the input to the completion composition.*
2. *F is the Kleisli arrow and modulus row, recording the finite rule that sends each admitted regular-Cauchy request to the next regular-Cauchy route.*
3. *W is the intermediate* $\mathsf{StreamName}^{\uparrow}$ *window through which the source route and the Kleisli arrow are jointly inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget used to synchronize the source request, the intermediate window, and the target readback.*
5. *R is the target* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the dyadic budget and StreamName window have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular readback row has been displayed.*
7. *H records componentwise* hsame *transport for the source route, Kleisli arrow, window, tolerance budget, target readback, Real seal, continuation row, provenance row, and local naming row.*
8. *C records displayed* Cont *replay from A through F, W, D, R, E and back through the same transport and naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyKleisliExtension}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one finite Kleisli-composition packet. It has no coordinate for a quotient sequence, selected limit, countable choice, host equality of completed reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7362.2 (Regular Cauchy Kleisli extension NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$ *carrier* $K = (A, F, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyKleisliExtensio}}$ *surface consists exactly of five finite obligation rows:*

1. *carrier admission, requiring the displayed source* $\mathsf{RegSeqRat}^{\uparrow}$ *route, Kleisli arrow and modulus row, StreamName window, dyadic tolerance budget, target readback, Real seal, transport, replay, provenance, and local naming row to inhabit one* BHist *packet;*

2. *source-window compatibility, requiring each request read from A to pass through W before the Kleisli arrow F is applied;*

3. *tolerance synchronization, requiring D to bind the source request, the intermediate StreamName window, and the target* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in one finite budget;*

4. *transport and replay stability, requiring H and C to preserve the same displayed rows under componentwise* hsame *transport and* Cont *replay;*

5. *non-escape, excluding quotient sequences, selected limits, countable-choice functionals, host equality of completed reals, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the exported certificate.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 7362.1. The tuple displays the source route A, Kleisli row F, window W, tolerance budget D, target readback R, Real seal E, and structural rows H, C, P, N.

The source-window obligation reads A only through W. Thus a consumer cannot apply the Kleisli arrow to an unlisted source request or infer a hidden completion route.

The tolerance synchronization obligation reads D before R and E. The dyadic budget is the finite ledger tying the source request, intermediate window, and target readback together.

Transport and replay are componentwise. The rows H and C move only the displayed packet, while P and N record the provenance and local certificate. Since the carrier contains no quotient sequence, selected limit, countable-choice functional, host equality proof, or ambient completeness theorem, the local NameCert surface exports none of those objects. □

Theorem 7362.3 (Regular Cauchy Kleisli extension composition law)**.** *Every composed read from an accepted* $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$ *carrier factors through the displayed route*

$$A \longmapsto W \longmapsto F \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Consequently the Kleisli composition exports only the finite source route, arrow/modulus row, StreamName window, dyadic budget, target readback, Real seal, transport, replay, provenance, and local NameCert rows. It exports no quotient sequence, selected limit, countable-choice functional, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier $K = (A, F, W, D, R, E, H, C, P, N)$. A composed read first inspects the source regular-Cauchy route A through the finite StreamName window W.

The Kleisli arrow F is then applied only under the displayed modulus row. Before a target readback is exposed, the route reads the dyadic tolerance budget D, so the target request remains tied to the same finite budget.

The row R is the only target $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E is the only $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N preserve and name this same route rather than replacing it by an ambient completion principle.

By Definition 7362.2, the carrier inventory has no coordinate for quotient sequences, selected limits, countable-choice functionals, host equality, or ambient Real completeness. The composed read therefore factors through the displayed rows and exports none of the excluded data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyKleisliExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyKleisliExtension}^{\uparrow}$ packet is generated from a source $\mathsf{RegSeqRat}^{\uparrow}$ route, a Kleisli arrow and modulus row, an intermediate $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, a target $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyKleisliExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7362.1, Definition 7362.2, and Definition 7362.3 seed the finite Kleisli-composition route for regular-Cauchy completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyKleisliExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, countable choice, host equality of completed reals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires carrier admission, source-window compatibility, dyadic tolerance synchronization, transport replay, and composition non-escape proofs for BEDC.Derived.RegularCauchyKleisliExtensionUp.

Chapter 7363

A Concrete Naming Certificate for $\mathsf{DiscreteLyapunov}^{\uparrow}$

Following Kalman on sampled linear systems and the Anderson–Moore treatment of finite-dimensional linear quadratic control, the $\mathsf{DiscreteLyapunov}^{\uparrow}$ packet records the finite certificate surface for a displayed one-step Lyapunov recursion. It sits after the energy certificate of chapter 313, the finite descent ledger of chapter 324, the algebraic Riccati rows of chapter 307, the finite-horizon control ledger of chapter 296, and the matrix readback rows of chapter 49. The packet names only the displayed finite recursion, residual ledger, transport, replay, provenance, and local naming rows; it does not assert spectral-radius completeness, host matrix analysis, selected infinite limits, or an analytic convergence theorem.

Definition 7363.1 (DiscreteLyapunov finite recursion carrier)**.** *A* $\mathsf{DiscreteLyapunov}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, Q, P, R, E, L, Y, H, C, G, N)$$

with the following displayed rows:

1. *A is the one-step state-transition matrix row read through* $\mathsf{Mat}^{\uparrow}$*.*
2. *Q is the displayed positive cost or dissipation matrix row read through the Lyapunov and LQR source packets.*
3. *P is the candidate Lyapunov matrix row whose quadratic readback is consumed by stability and control consumers.*
4. *R is the finite residual row recording the displayed recursion comparison between P, the transported successor read through A, and the source row Q.*
5. *E is the exactness ledger saying that every accepted recursion read is the same displayed residual row R.*
6. *L is the local dependency row tying Q and P to the* $\mathsf{Lyapunov}^{\uparrow}$*,* $\mathsf{LyapunovStability}^{\uparrow}$*,* $\mathsf{Riccati}^{\uparrow}$*, and* $\mathsf{LQR}^{\uparrow}$ *surfaces.*
7. *Y records the finite row and column indices used by the matrix readback of A, Q, P, R.*
8. *H records componentwise* hsame *transport for A, Q, P, R, E, L, Y.*
9. *C records displayed* Cont *replay from the transition row and matrix rows to the residual comparison.*

10. *G is the* Pkg *provenance over* DiscreteLyapunov$^{\uparrow}$, Lyapunov$^{\uparrow}$, LyapunovStability$^{\uparrow}$, Riccati$^{\uparrow}$, LQR$^{\uparrow}$, Mat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DiscreteLyapunov}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the displayed transition, matrix, residual, exactness, dependency, index, transport, replay, provenance, and naming rows. It has no coordinate for a spectral-radius test, a host normed-space theorem, an infinite series selection, or an ambient analytic solver.

Theorem 7363.2 (DiscreteLyapunov NameCert obligations)**.** *For the carrier of Definition 7363.1, the local* $\mathsf{NameCert}_{\mathsf{DiscreteLyapunov}^{\uparrow}}$ *surface consists exactly of carrier admission, transition-matrix exposure, cost-row exposure, Lyapunov-matrix exposure, finite residual exposure, residual exactness through E, dependency exposure through L, finite matrix-index exposure through Y, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any consumer that replaces one of these rows by spectral-radius completeness, host matrix analysis, selected infinite limits, or an analytic convergence theorem leaves the accepted carrier.*

Proof. Project the carrier of Definition 7363.1. The rows A, Q, P, R display the transition matrix, cost row, Lyapunov matrix, and residual comparison before any structural transport or control dependency is read.

The dependency row L ties those displayed rows to the sibling Lyapunov, Lyapunov-stability, Riccati, LQR, and matrix surfaces. This row is only a finite handoff; it does not import a spectral-radius criterion, an infinite sum, or a host analytic matrix theorem.

The rows E, Y, H, C, G, N then record exactness, indices, transport, replay, provenance, and local naming for the same finite residual route. Since the carrier has no coordinate for the excluded analytic objects, the listed rows exhaust the NameCert obligation surface. □

Theorem 7363.3 (DiscreteLyapunov residual route)**.** *Let $D = (A, Q, P, R, E, L, Y, H, C, G, N)$ be an accepted* DiscreteLyapunov$^{\uparrow}$ *packet. Every downstream read of the discrete Lyapunov recursion factors through the finite route*

$$A, Q, P \longrightarrow R \longrightarrow E, L, Y \longrightarrow H, C, G, N.$$

The read first displays the transition and matrix rows, then the residual comparison, then the exactness, dependency, and index rows, and only then the transport, replay, provenance, and local naming rows. The route exports no spectral-radius completeness claim, no host matrix-analysis theorem, no selected infinite limit, and no analytic solver semantics.

Proof. Start with the displayed matrix rows A, Q, P. Their source and target slots are the finite row and column indices later recorded by Y.

The residual row R is the only carrier coordinate that compares the source Lyapunov row, the successor read through A, and the cost row Q. Exactness through E says that any accepted recursion read returns to that displayed residual row.

Finally L, H, C, G, N attach dependency, transport, replay, provenance, and naming data to the same residual route. No remaining coordinate can supply spectral completeness, host matrix analysis, an infinite limit selection, or analytic solver data, so every accepted read factors through the displayed finite route. □

Falsifiable prediction: An accepted DiscreteLyapunov$^{\uparrow}$ read is refuted if a recursion conclusion is reached without displaying the transition matrix row, cost row, Lyapunov matrix row, residual

comparison row, exactness ledger, dependency row, finite matrix-index row, transport, replay, provenance, and local naming rows.

Independence witness: lyapunov, lyapunovstability, riccati, lqr, and matrix: none is bijective to $\mathsf{DiscreteLyapunov}^{\uparrow}$ because only the discrete Lyapunov packet simultaneously records the one-step transition row, cost row, candidate Lyapunov row, finite residual ledger, dependency handoff, matrix indices, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DiscreteLyapunov}^{\uparrow}}$.

Constructive story: A $\mathsf{DiscreteLyapunov}^{\uparrow}$ packet is generated from a one-step transition matrix row, cost row, candidate Lyapunov matrix row, finite residual ledger, residual exactness row, Lyapunov, Lyapunov-stability, Riccati, LQR, and Matrix dependency row, finite matrix indices, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiscreteLyapunov}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7363.1, Definition 7363.2, Definition 7363.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite discrete Lyapunov recursion certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiscreteLyapunov}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim spectral-radius completeness, host matrix analysis, selected infinite limits, analytic convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual exactness, dependency-row exposure, finite matrix-index exposure, non-escape for analytic Lyapunov primitives, transport, replay, provenance, and local naming for BEDC.Derived.DiscreteLyapunovUp.

Chapter 7364

A Concrete Naming Certificate for $\mathsf{StrongLawFiniteWindow}^{\uparrow}$

Following Kolmogorov and Bishop–Bridges on sums of independent random variables and constructive probability estimates, the $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ packet names the finite-window certificate surface that sits between weak-law tail control and Borel–Cantelli event budgeting. It reads the weak-law finite-average route of chapter 4373, the Chebyshev tail-bound carrier of chapter 6592, the first-lemma event budget of chapter 2357, the normalized probability source of chapter 184, the finite random-variable rows of chapter 185, and the terminal real-name seal of chapter 38. The packet records only a displayed finite schedule of windows and budgets; it is not the full strong law of large numbers.

Definition 7364.1 (Strong law finite-window carrier)**.** *A* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, R, W, C, B, E, H, T, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-event normalization. The row R is the finite* $\mathsf{RandomVar}^{\uparrow}$ *family over P. The row W is the finite window schedule, recording the displayed index blocks whose average rows are inspected. The row C is the* $\mathsf{ChebyshevInequality}^{\uparrow}$ *tail table, with one finite tail row for each displayed window. The row B is the* $\mathsf{BorelCantelli}^{\uparrow}$ *finite-event budget that packages the visible tail rows into a repeated-hit ledger. The row E is the* $\mathsf{Real}^{\uparrow}$ *epsilon seal naming the positive tolerance and the terminal tail budget. The row H records componentwise* hsame *transport for the probability, random-variable, window, Chebyshev, Borel–Cantelli, epsilon, replay, provenance, and local naming rows. The row T records* Cont *replay of the finite-window route, Q records* Pkg *provenance over* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$, $\mathsf{WeakLawLargeNumbers}^{\uparrow}$, $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{BorelCantelli}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$, *and N is the local* $\mathsf{NameCert}_{\mathsf{StrongLawFiniteWindow}^{\uparrow}}$ *row. The classifier compares accepted packets only through these ten rows.*

Lean4 ✓ `BEDC.Derived.StrongLawFiniteWindowUp.StrongLawFiniteWindowTasteGate single carrier alignment`

Theorem 7364.2 (Strong law finite-window NameCert obligations)**.** *For every accepted* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *carrier $S = (P, R, W, C, B, E, H, T, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{StrongLawFiniteWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the probability source, finite random-variable family, finite window schedule, Chebyshev tail rows, Borel–Cantelli finite-event budget,* $\mathsf{Real}^{\uparrow}$ *epsilon seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted read*

must expose $P, R, W, C, B, E, H, T, Q, N$ in that order before a finite-window convergence consumer receives data, and no obligation is stored outside those rows.

Proof. Project the carrier of Definition 7364.1. The rows P, R, W expose the probability source, random-variable family, and finite schedule before any tail estimate can be read.

The rows C, B, E then route the finite-window estimate through the displayed Chebyshev tail table, the Borel–Cantelli finite-event budget, and the positive real tolerance seal. Each row is finite and remains tied to the visible windows.

Finally H, T, Q, N transport, replay, source, and name the same route. Since the carrier has no coordinate for an infinite almost-sure quotient, countable-choice subsequence, global limit theorem, central-limit normalization, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7364.3 (Strong law finite-window Borel–Cantelli handoff)**.** *Every accepted* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *packet hands a repeated-hit request to* $\mathsf{BorelCantelli}^{\uparrow}$ *only after the finite route*

$$P \longmapsto R \longmapsto W \longmapsto C \longmapsto B \longmapsto E$$

has been displayed. Thus the Borel–Cantelli consumer receives a probability source, finite random-variable family, finite window schedule, Chebyshev tail rows, finite event budget, and real epsilon seal, together with transport, replay, provenance, and local naming; it receives no full strong-law theorem, almost-sure quotient equality, countable-choice subsequence, central limit theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a repeated-hit request from an accepted carrier. Projection exposes P and R as the only probability and random-variable sources available to the request.

The request next reads the window schedule W and tail table C. These rows determine which finite averages are inspected and which Chebyshev estimates are available for those windows.

Only then can B and E be consumed as the finite-event budget and tolerance seal. The structural rows H, T, Q, N preserve that same route for later readers, so the handoff is exactly the finite Borel–Cantelli budget over displayed Chebyshev tails. □

Theorem 7364.4 (Strong law finite-window nonescape)**.** *Every accepted* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *finite-window read remains inside the carrier surface of Definition 7364.1. A consumer can inspect a convergence-facing budget only through the source probability row, finite random-variable rows, finite window schedule, Chebyshev tail rows, Borel–Cantelli finite-event budget,* $\mathsf{Real}^{\uparrow}$ *epsilon seal, componentwise transport, replay, provenance, and local* $\mathsf{NameCert}$ *row. No accepted read may replace this route by the full strong law, almost-sure quotient equality, countable-choice subsequences, a central limit theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Let a finite-window consumer read an accepted carrier. The definition lists the only coordinates available to the consumer, so the read starts at P, R, W and has no independent limit or quotient coordinate.

The tail-control segment C, B, E is downstream from the displayed schedule and upstream from the structural rows. Hence the consumer receives only a finite table of tail estimates and a finite event-budget seal.

The rows H, T, Q, N add no analytic content outside the displayed packet. They transport equal histories, replay the finite route, record package provenance, and attach the local name. Therefore every accepted read remains inside the finite-window certificate surface and cannot escape to the excluded convergence, quotient, subsequence, limit-law, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{StrongLawFiniteWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ packet is generated from a ProbSpace source row, finite RandomVar family, finite window schedule, Chebyshev tail rows, a BorelCantelli finite-event budget, a RealUp epsilon seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StrongLawFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7364.1, Definition 7364.2, Definition 7364.3, and Definition 7364.4 seed the finite-window probability route through WeakLawLargeNumbers, ChebyshevInequality, BorelCantelli, ProbSpace, RandomVar, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StrongLawFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full strong law, almost-sure quotient equality, countable-choice subsequences, the central limit theorem, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window schedule stability, Chebyshev tail-row exactness, Borel–Cantelli finite-event budget routing, epsilon-seal nonescape, hsame transport, Cont replay, Pkg provenance, and local naming for BEDC.Derived.StrongLawFiniteWindowUp.

Chapter 7365

A Concrete Naming Certificate for $\mathsf{SnowflakeMetric}^{\uparrow}$

Following Assouad and Heinonen on snowflake metrics, the $\mathsf{SnowflakeMetric}^{\uparrow}$ packet records the finite BEDC route that transforms a displayed metric distance by a dyadic exponent $0 < q \leq 1$. It sits over the metric source of chapter 57, the dyadic rational core of chapter 291, the terminal real-name seal of chapter 38, the uniform-continuity route of chapter 391, and the Lipschitz transport discipline of chapter 3762 and chapter 3724. The packet names a finite snowflake-distance readback; it does not import host real powers, quotient metric spaces, choice-selected representatives, or ambient completeness.

Definition 7365.1 (Snowflake metric carrier)**.** *A* $\mathsf{SnowflakeMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, q, D, T, L, H, C, P, N)$$

with the following rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the displayed point pair and distance read;*
2. *q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponent row, carrying the finite inequalities $0 < q$ and $q \leq 1$;*
3. *D is the* $\mathsf{Real}^{\uparrow}$ *distance readback row for the snowflaked distance produced from the displayed source distance and q;*
4. *T is the Holder/snowflake transport row, read through the uniform-continuity surface of chapter 391 and the Lipschitz siblings chapter 3762 and chapter 3724;*
5. *L is the triangle ledger, recording the finite dyadic comparison that keeps the snowflake distance subadditive for $0 < q \leq 1$;*
6. *H records componentwise* hsame *transport of M, q, D, T, L;*
7. *C records displayed* Cont *replay of the same source metric, exponent, readback, transport, and triangle-ledger rows;*
8. *P is the* Pkg *provenance over* $\mathsf{SnowflakeMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SnowflakeMetric}^{\uparrow}}$ *row.*

The carrier has no coordinate for host real exponentiation, quotient equality of metric spaces, selected completions, or choice principles.

Theorem 7365.2 (Snowflake metric NameCert obligations)**.** *For every accepted* $\mathsf{SnowflakeMetric}^{\uparrow}$ *carrier* $S = (M, q, D, T, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SnowflakeMetric}^{\uparrow}}$ *surface consists exactly of source* $\mathsf{Met}^{\uparrow}$ *admission through* M*, dyadic exponent admission through* q *with* $0 < q \leq 1$*, terminal* $\mathsf{Real}^{\uparrow}$ *distance readback through* D*, Holder/snowflake transport through* T*, triangle-ledger accountability through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7365.1. The source metric row, dyadic exponent row, readback row, transport row, triangle ledger, and structural rows are the whole packet.

Read the analytic rows in order. The $\mathsf{Met}^{\uparrow}$ source supplies the distance being transformed, q supplies the positive dyadic exponent bounded by 1, and D records the resulting $\mathsf{Real}^{\uparrow}$ distance readback.

The transport and triangle rows then bind the construction to the existing continuity surface. The rows H, C, P, N transport, replay, source, and name the same finite route, so no host real-power operation, quotient metric-space equality, selected completion, or choice principle is exported. □

Theorem 7365.3 (Snowflake metric Holder route)**.** *Every continuity consumer of an accepted* $\mathsf{SnowflakeMetric}^{\uparrow}$ *packet reads the transformed metric only through the displayed route*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{UniformContinuity}^{\uparrow},\quad \mathsf{LipschitzMap}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{Name}$$

The Holder-facing row T *consumes the dyadic exponent and the source metric distance before exporting uniform-continuity or Lipschitz-style data; it exports no ambient real powers, quotient metric spaces, selected representatives, or untracked completeness facts.*

Proof. Begin with the source metric and exponent rows. The consumer can inspect only the displayed $\mathsf{Met}^{\uparrow}$ distance and the $\mathsf{DyadicRatCore}^{\uparrow}$ proof that $0 < q \leq 1$.

Next read the terminal distance readback and the triangle ledger. These rows attach the snowflaked distance to a $\mathsf{Real}^{\uparrow}$ seal and to the finite subadditivity comparison needed by metric consumers.

Finally pass through the uniform-continuity and Lipschitz sibling routes. They consume the Holder/snowflake transport row T only after M, q, D, L are visible, and the structural rows H, C, P, N keep the handoff inside the same finite NameCert packet. □

Falsifiable prediction: An accepted $\mathsf{SnowflakeMetric}^{\uparrow}$ consumer that obtains a snowflaked distance without reading the source $\mathsf{Met}^{\uparrow}$ row, the positive dyadic exponent row, the $\mathsf{Real}^{\uparrow}$ readback row, the Holder/snowflake transport row, the triangle ledger, and the structural hsame, Cont, Pkg, and NameCert rows refutes the carrier surface.

Independence witness: metric, dyadicratcore, real, uniformcontinuity, lipschitz-function, and lipschitz-modulus: no listed sibling jointly carries the source metric, positive dyadic exponent, snowflaked real readback, Holder transport, triangle ledger, transport, replay, provenance, and local naming rows of $S = (M, q, D, T, L, H, C, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{SnowflakeMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SnowflakeMetric}^{\uparrow}$ packet is generated from a source MetricUp row, a positive DyadicRatCoreUp exponent bounded by one, a RealUp distance readback, a Holder/snowflake transport row, a triangle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SnowflakeMetric}^{\uparrow}}$, seed)

Scope closed: Definition 7365.1, Definition 7365.2, and Definition 7365.3 seed the finite snowflake-metric transformation surface over $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, and $\mathsf{LipschitzMap}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SnowflakeMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real powers, quotient metric spaces, selected completions, Lean verification, or bridge checking for SnowflakeMetric$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dyadic exponent bounds, Real distance readback, triangle-ledger accountability, Holder transport, replay, provenance, and local naming for BEDC.Derived.SnowflakeMetricUp.

Chapter 7366

A Concrete Naming Certificate for $\mathsf{DistanceToCompact}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis, the $\mathsf{DistanceToCompact}^{\uparrow}$ packet records the finite certificate surface for the standard distance from a point to a compact metric source. It sits over the metric source of chapter 57, the compact finite-net data of chapter 129, the located comparison function of chapter 6402, the displayed endpoint rows of chapter 7348, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite compact-distance certificate only; it does not choose a nearest point, import open-cover compactness, quotient metric equality, countable choice, or ambient metric completeness.

Definition 7366.1 (Distance to compact carrier)**.** *A* $\mathsf{DistanceToCompact}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, K, L, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *point-data row naming the ambient metric source and the queried point.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row naming the compact metric source by displayed finite covers and tolerance schedules.*
3. *L is the* $\mathsf{LocatedDistanceFunction}^{\uparrow}$ *comparison row that answers point-to-compact distance requests by located real comparisons.*
4. *F is the* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *witness table, recording finite net candidates and the endpoint rows used only as witnesses for bounds.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row turning the displayed comparison windows into a regular rational name.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the exported distance value after the regular readback is replayed.*
7. *H records componentwise* hsame *transport for the metric point data, compact finite-net data, located comparison, finite witness table, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a distance request through X, K, L, F, R, E and then through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{DistanceToCompact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{LocatedDistanceFunction}^{\uparrow}$, $\mathsf{FiniteMetricProjection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DistanceToCompact}^{\uparrow}}$ *row.*

The classifier accepts only packets whose distance value is read through $X, K, L, F, R, E, H, C, P, N$. It has no coordinate for a nearest-point choice, open-cover compactness proof, quotient metric equality, countable-choice schedule, or ambient metric completion.

Lean4 ✓ `BEDC.Derived.DistanceToCompactUp.DistanceToCompactTasteGate single carrier alignment`

Theorem 7366.2 (Distance to compact NameCert obligations)**.** *For every accepted* $\mathsf{DistanceToCompact}^{\uparrow}$ *carrier $D = (X, K, L, F, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DistanceToCompact}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the metric point row, compact finite-net row, located-distance comparison, finite witness table, regular rational readback, real seal, transport, replay, provenance, and local naming;*
2. *compact-source exposure, requiring K to be read through the finite-net surface of chapter 129 before any distance value is exported;*
3. *located comparison exactness, requiring L to consume the located function route of chapter 6402;*
4. *finite witness discipline, requiring F to provide only finite projection witness rows from chapter 7348, not a global nearest-point selector;*
5. *regular readback and real sealing, requiring R and E to pass through chapter 301 and chapter 38;*
6. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for exactly the displayed packet.*

No local obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.DistanceToCompactUp.DistanceToCompactCarrier namecert obligations`

Proof. Project the carrier of Definition 7366.1. The public rows are exactly $X, K, L, F, R, E, H, C, P, N$, so carrier admission exposes only metric point data, compact finite-net data, located comparison, finite witness rows, regular readback, and the terminal real seal.

The compact-source and located-comparison obligations are forced by the replay order. A distance request first reads X and the finite-net row K, then uses L to compare the requested point against the compact source through displayed located-distance windows.

The finite witness table F contributes only finite candidate rows. It can bound and certify the readback route, but it has no coordinate that selects a nearest point in the compact source.

Finally R and E seal the value through the regular rational and Real rows, while H, C, P, N preserve the same row family under transport, replay, provenance, and naming. Since the carrier has no further coordinate, the listed obligations exhaust the NameCert surface and none of the excluded principles can be projected from it. □

Theorem 7366.3 (Distance to compact located readback)**.** *Every accepted* $\mathsf{DistanceToCompact}^{\uparrow}$ *packet $D = (X, K, L, F, R, E, H, C, P, N)$ exports a located distance value only through the displayed route*

$$X, K, L, F \longmapsto R, E \longmapsto H, C, P, N.$$

Thus downstream projection and Hausdorff-distance consumers receive a regular rational readback and a real seal for the distance-to-compact value, while nearest-point choice, open-cover compactness, quotient metric equality, countable choice, and ambient metric completeness remain outside the packet.

Proof. Begin with the compact finite-net row K and the located comparison row L. Together they supply the finite tolerance windows and located comparisons needed to answer a distance request without appealing to an open-cover theorem or a completed ambient metric.

Next read the finite witness table F. The witness rows certify the displayed bounds used by the comparison route, but the endpoint evidence remains a finite table row and is not retyped as a nearest-point choice.

Now replay the readback rows. The regular rational row R records the tolerance-indexed value route, and the Real seal E is readable only after the metric, compact-source, comparison, and finite-witness rows have been displayed.

Finally transport and replay through H, C, P, N. The same packet is delivered to projection and Hausdorff-distance consumers, and row exhaustion excludes quotient metric equality, countable choice, ambient completeness, and any hidden nearest-point principle. □

Lean4 ✓ `BEDC.Derived.DistanceToCompactUp.DistanceToCompactCarrier located readback`

Closure status for $\mathsf{NameCert}_{\mathsf{DistanceToCompact}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistanceToCompact}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7366.1, Definition 7366.2, and Definition 7366.3 seed the finite compact-metric distance certificate through displayed metric, compact-net, located-comparison, finite-witness, regular-readback, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistanceToCompact}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim nearest-point choice, open-cover compactness, quotient metric equality, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, located comparison exactness, finite witness discipline, regular readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.DistanceToCompactUp.

Constructive story: A $\mathsf{DistanceToCompact}^{\uparrow}$ packet is generated from Metric point data, CompactMetric finite-net data, LocatedDistanceFunction comparison, FiniteMetricProjection witness rows, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7367

A Concrete Naming Certificate for $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$ packet records the finite unit-law surface by which a regular Cauchy rational name enters the reflector and completion interface without selecting a quotient representative or invoking ambient completeness. It sits after the regular rational sequence surface of chapter 301 and before the reflector handoff of chapter 1585; the terminal $\mathsf{Real}^{\uparrow}$ seal is consumed only through displayed completion rows.

Definition 7367.1 (Regular Cauchy reflection unit carrier)**.** *A* $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (R, S, D, F, M, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, naming the regular rational sequence to be reflected.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source sequence is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger bounding every inspected window.*
4. *F is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *handoff row that reads the regular Cauchy data as reflector input.*
5. *M is the* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *service row used when completion-facing consumers require an existence seal.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the reflector and completion rows have been read.*
7. *H records componentwise* hsame *transport for the regular sequence, windows, dyadic ledger, reflector handoff, completion service, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$R, S, D \longmapsto F \longmapsto M \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{MetricCompletionExistence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionUnit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay route. It has no coordinate for quotient-stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7367.2 (Regular Cauchy reflection unit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$ *carrier* $U = (R, S, D, F, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionUnit}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed regular rational sequence, finite stream windows, dyadic tolerance ledger, reflector handoff, completion-existence service row, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The unit law is visible only as this finite route from* $\mathsf{RegSeqRat}^{\uparrow}$ *through* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *and* $\mathsf{MetricCompletionExistence}^{\uparrow}$ *to* $\mathsf{Real}^{\uparrow}$*; it does not export quotient representatives, selected limits, countable choice, host equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 7367.1. The source row R admits the regular Cauchy rational name, while S and D expose the finite windows and dyadic tolerance ledger through which the source may be inspected.

The unit visibility is the ordered handoff. The reflector row F can be read only after the regular source rows have been displayed, the completion service row M can be read only through that reflector handoff, and the terminal seal E is reached only after the completion-facing route has been exposed.

The Real-seal nonescape follows from the carrier inventory. No row supplies quotient-stream equality, a selected representative, a selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so none of these can be exported by the certificate.

Finally, H and C preserve and replay the same row order, and P, N record its provenance and local name. Transport or replay therefore cannot replace the unit-law packet by any object outside the displayed finite surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionUnit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$ packet is generated from RegSeqRat source rows, StreamName finite windows, DyadicRatCore tolerance ledgers, a CauchyCompletionReflector handoff, a MetricCompletionExistence service row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionUnit}^{\uparrow}}$, seed)

Scope closed: Definition 7367.1 and Definition 7367.2 seed the finite reflector-unit packet over RegSeqRat, StreamName, DyadicRatCore, CauchyCompletionReflector, MetricCompletionExistence, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionUnit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, selected limits, countable choice, host equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit visibility, reflector handoff, Real-seal nonescape, transport preservation, replay preservation, provenance, and local naming for BEDC.Derived.RegularCauchyReflectionUnitUp.

Chapter 7368

A Concrete Naming Certificate for $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion and Kelley–Bourbaki reflection terminology, the $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$ packet records the counit route from the completed reflector surface back to the displayed $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal rows. It is paired with the unit packet of chapter 7367 and reads the reflector boundary of chapter 3398, the regular source of chapter 301, the finite-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the readback half of the reflector interface without selecting quotient representatives, host limits, countable schedules, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7368.1 (Regular Cauchy reflection counit carrier)**.** *A* $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (E, R, S, D, F, U, H, K, P, N)$$

with the following displayed rows:

1. *E is the completed reflector and* $\mathsf{Real}^{\uparrow}$ *seal row from which a Real-facing consumer begins.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed by the counit.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the readback is inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to every displayed window.*
5. *F is the* $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$ *row that supplies the completion-reflector source of the counit read.*
6. *U is the unit and counit compatibility row pairing this packet with the displayed* $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$ *route.*
7. *H records componentwise* hsame *transport for the completed seal, readback, finite windows, dyadic ledger, reflector row, compatibility row, replay, provenance, and local naming.*
8. *K records displayed* Cont *replay of the route*

$$E \longmapsto R, S, D \longmapsto F, U \longmapsto H, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$, $\mathsf{RegularCauchyCompletionReflector}^{\uparrow}$, $\mathsf{RegularCauchyReflectionUnit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionCounit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay order. It has no coordinate for quotient stream equality, a selected representative, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7368.2 (Regular Cauchy reflection counit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$ *carrier* $C = (E, R, S, D, F, U, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionCou}}$ *surface consists exactly of carrier admission for the completed-source and* $\mathsf{Real}^{\uparrow}$ *seal row, regular readback row, finite window row, dyadic tolerance ledger, completion-reflector row, unit and counit compatibility row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The counit handoff is visible only as the finite route from E through R, S, D and then through F, U, H, K, P, N; it does not export quotient stream equality, selected representatives, countable choice, host equality, trichotomy, or ambient Real completeness.*

Proof. Project the carrier of Definition 7368.1. The completed-source row E is the only Real-facing entry point, while R, S, D expose the regular readback, finite observation windows, and dyadic tolerance ledger that the counit may return.

The handoff is ordered by the displayed rows. A consumer first reads the completed seal, then the RegSeqRat readback and its inspection data, and only then reaches the reflector and compatibility rows F and U.

The Real-seal nonescape follows from the carrier inventory. No row supplies quotient stream equality, a selected representative, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so none of these can be exported by the local certificate.

Finally, H and K preserve and replay the same route, while P and N record provenance and local naming. Transport, replay, and naming therefore cannot replace the counit packet by any object outside the displayed finite surface. □

Theorem 7368.3 (Regular Cauchy reflection counit Real handoff)**.** *Every Real-facing counit read from an accepted* $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$ *carrier factors through the finite route*

$$E \longmapsto R, S, D \longmapsto F, U \longmapsto H, K, P, N.$$

The handoff returns from the completed reflector surface to displayed $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows before any reflector or unit-compatibility row may be consumed. It exports no quotient stream equality, selected representative, countable choice, host equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the Real-facing row E. By definition of the carrier, the counit has no other completed-source coordinate and no hidden host completion object.

The readback rows R, S, D are next in the displayed route. They expose the regular rational name, the finite windows through which it is read, and the dyadic tolerance ledger attached to those windows.

Only after that readback may the reflector row F and compatibility row U be consumed. The structural rows H, K, P, N then transport, replay, record, and name the same finite route.

Since the carrier contains no quotient equality, selected representative, countable-choice schedule, host equality, trichotomy, or ambient completeness row, the Real-facing handoff cannot export any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionCounit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyReflectionCounit}^{\uparrow}$ packet is generated from a completed reflector and Real seal row, RegSeqRat readback, StreamName finite windows, a DyadicRatCore tolerance ledger, a RegularCauchyCompletionReflector row, unit and counit compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionCounit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7368.1, Definition 7368.2, and Definition 7368.3 seed the finite reflector-counit packet over the completed source, RegSeqRat, StreamName, DyadicRatCore, RegularCauchyCompletionReflector, RegularCauchyReflectionUnit, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyReflectionCounit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completed-source visibility, regular readback, counit handoff, Real-seal nonescape, transport preservation, replay preservation, provenance, and local naming for BEDC.Derived.RegularCauchyReflectionCounitUp.

Chapter 7369

A Concrete Naming Certificate for $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$ packet records the compact sequence-modulus route behind chapter 9237 as finite NameCert data. It sits over the compact metric source of chapter 129, the continuous-map row of chapter 130, the uniform-modulus consumer of chapter 369, and the terminal real-name seal of chapter 38.

Definition 7369.1 (Compact uniform sequence-modulus carrier)**.** *A* $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, U, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. X *is the source* $\mathsf{CompactMetric}^{\uparrow}$ *row, including the finite compact windows used by the packet.*
2. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence row whose pointwise modulus data are inspected on the compact source.*
3. U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row, exposed only after the compact windows and pointwise rows have been read.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested precision and radius comparisons.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected sequence windows.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the resulting real-valued estimates.*
7. H *records componentwise* hsame *transport for compact source, continuous-map sequence, uniform modulus, dyadic tolerance, regular readback, Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay of the route*

$$X, F, D, R \longmapsto U \longmapsto E.$$

9. P *is the* Pkg *provenance over* $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformSequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed compact windows, pointwise sequence-modulus rows, dyadic tolerance ledger, regular readback, uniform-modulus handoff, Real seal, and structural rows. It has no coordinate for open-cover compactness, host-selected subcovers, semantic continuity, countable choice, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7369.2 (Compact uniform sequence-modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$ *carrier* $K = (X, F, U, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUnifo}}$ *surface consists exactly of carrier admission for the displayed compact metric source, continuous-map sequence row, uniform-modulus output, dyadic tolerance ledger, regular rational readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-uniform consumer must read the compact window and pointwise sequence-modulus rows before the uniform-modulus row is exposed; the route exports no open-cover compactness theorem, selected subcover, semantic continuity principle, quotient function equality, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 7369.1. The compact source X supplies finite compact windows, and the continuous-map sequence row F supplies the pointwise modulus observations inspected on those windows.

The modulus handoff is ordered by the carrier. The dyadic tolerance row D and regular readback row R are read before the $\mathsf{UniformModulus}^{\uparrow}$ output U, and the terminal Real seal E is downstream of that same route.

Transport and replay preserve the compact-uniform surface. The row H moves each coordinate componentwise, and C repeats the inspection route for downstream consumers without adding a second source of compactness or continuity.

Finally, P and N record provenance and local naming. Since the carrier contains no open-cover compactness theorem, selected subcover, semantic continuity principle, quotient function equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness row, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformSequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformSequenceModulus}^{\uparrow}$ packet is generated from CompactMetric source windows, ContinuousMap sequence rows, UniformModulus output rows, DyadicRatCore tolerance ledgers, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformSequenceModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7369.1 and Definition 7369.2 seed the finite compact sequence-modulus packet over CompactMetric, ContinuousMap, UniformModulus, DyadicRatCore, RegSeqRat, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformSequenceModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, semantic continuity, quotient function equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exposure, pointwise sequence-modulus visibility, dyadic tolerance readback, uniform-modulus handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformSequenceModulusUp.

Chapter 7370

A Concrete Naming Certificate for $\mathsf{FiniteChainDecomposition}^{\uparrow}$

Following Dilworth and Mirsky on finite partially ordered sets, the $\mathsf{FiniteChainDecomposition}^{\uparrow}$ packet records a standalone finite chain-cover carrier for order-theoretic decomposition work. It sits between the finite order surface of chapter 53, the width-cover route of chapter 6083, the height-layer route of chapter 7139, the matching dual certificate of chapter 234, and the ordered spine discipline of chapter 36. The packet names the chain decomposition as displayed finite rows, not as a host poset cover, a quotient order equality, a selected global partition, or an infinite-order theorem.

Definition 7370.1 (Finite chain-decomposition carrier)**.** *A* $\mathsf{FiniteChainDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, L, C, U, A, D, H, T, P, N)$$

with the following displayed rows:

1. *O is the finite* $\mathsf{Poset}^{\uparrow}$ *order row, including the carried elements, comparison ledger, and classifier for repeated element reads.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *chain-spine row, storing a finite list of finite chains as displayed ordered spines.*
3. *C is the chain-certification row, requiring each spine in L to be internally comparable through the same order row O.*
4. *U is the coverage row, recording that every carried element of O appears in at least one displayed chain spine.*
5. *A is the antichain-width boundary row, exposing the width pressure read by* $\mathsf{DilworthDecomposition}^{\uparrow}$ *before a minimum-chain-cover consumer inspects the packet.*
6. *D is the dual handoff row to* $\mathsf{DilworthDecomposition}^{\uparrow}$, $\mathsf{MirskyTheorem}^{\uparrow}$, *and* $\mathsf{Matching}^{\uparrow}$, *binding chain covers, height layers, and matching certificates to the same finite order row.*
7. *H records componentwise* hsame *transport for the order, chain spine, certification, coverage, width boundary, dual handoff, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from O, L, C, U, A, D through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteChainDecomposition}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{DilworthDecomposition}^{\uparrow}$, $\mathsf{MirskyTheorem}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteChainDecomposition}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, L, C, U, A, D, H, T, P, N$. It has no coordinate for an ambient host poset, quotient order equality, unlisted chain cover, selected maximal antichain, countable choice, or infinite decomposition principle.

Theorem 7370.2 (Finite chain-decomposition NameCert obligations)**.** *For an accepted* $\mathsf{FiniteChainDecomposition}^{\uparrow}$ *carrier*

$$F = (O, L, C, U, A, D, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteChainDecomposition}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite order row, list-of-chains row, chain-certification row, coverage row, antichain-width boundary row, dual handoff row, componentwise transport, displayed replay, provenance, and local naming; order exposure through O; finite spine exposure through L; chain validity through C; cover exactness through U; Dilworth and Mirsky compatibility through A, D; and nonescape for host posets, quotient order equality, unlisted chain covers, selected external antichains, choice, and infinite-order data.*

Proof. Project the carrier of Definition 7370.1. The finite order is O, the displayed chain family is L, chain validity is C, cover exactness is U, and the width and dual handoff data are A and D.

The order exposure obligation is rowwise. Every chain comparison in C, every coverage read in U, and every width or dual-certificate read in A, D uses the same $\mathsf{Poset}^{\uparrow}$ comparison ledger, so a consumer cannot combine chains from one order with antichain data from another.

The finite-spine and cover obligations are carried by L, C, U. The $\mathsf{List}^{\uparrow}$ row supplies only displayed finite spines, the certification row checks comparability inside each spine, and the coverage row records the carried elements reached by those spines.

Finally A, D, H, T, P, N preserve the chain-cover route. The Dilworth, Mirsky, and Matching siblings may consume the packet only after the finite order, chain spines, and coverage rows are visible, and the structural rows transport, replay, source, and name that same finite surface. □

Theorem 7370.3 (Finite chain-decomposition Dilworth handoff)**.** *Every* $\mathsf{DilworthDecomposition}^{\uparrow}$ *or* $\mathsf{MirskyTheorem}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteChainDecomposition}^{\uparrow}$ *carrier must read the finite order row O, chain-spine row L, chain-certification row C, coverage row U, antichain-width boundary row A, and dual handoff row D before any chain-cover or height-layer conclusion is exported. The handoff may cite the* $\mathsf{Matching}^{\uparrow}$ *dual certificate and the* $\mathsf{List}^{\uparrow}$ *spine discipline, but it exports no host partial order, quotient order equality, selected global decomposition, or infinite poset theorem.*

Proof. Begin with the NameCert obligations of Definition 7370.2. They make $O, L, C, U, A, D, H, T, P, N$ the complete public surface of the finite chain-decomposition packet.

The Dilworth-facing read uses A and D only after the chain family is visible. Thus the width boundary and matching handoff remain attached to the same O, L, C, U rows that certify the chain cover.

The Mirsky-facing read uses the same finite chain data as height-layer evidence. It may route through the sibling packet of chapter 7139, but it cannot replace the displayed chain spines by a selected partition outside the carrier.

Finally H, T, P, N transport, replay, source, and name the handoff. Since neither the carrier nor the cited siblings add a host poset, quotient equality, external decomposition selector, or infinite-order coordinate, the handoff remains a finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteChainDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteChainDecomposition}^{\uparrow}$ packet is generated from a finite Poset row, a List row of displayed chains, chain-certification rows, a coverage row, an antichain-width boundary, a Dilworth-Mirsky-Matching handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteChainDecomposition}\uparrow}$, seed)

Scope closed: Definition 7370.1, Definition 7370.2, and Definition 7370.3 seed the finite chain-cover carrier over Poset, List, DilworthDecomposition, MirskyTheorem, and Matching rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteChainDecomposition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host partial orders, quotient order equality, selected external chain covers, countable choice, infinite posets, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order exposure, finite-spine exposure, chain validity, cover exactness, Dilworth-Mirsky compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FiniteChainDecomposi

Chapter 7371

A Concrete Naming Certificate for $\mathsf{LargeInductiveDimension}^{\uparrow}$

Following Hurewicz–Wallman and Engelking, the $\mathsf{LargeInductiveDimension}^{\uparrow}$ packet records the separator-recursive large inductive dimension as finite BEDC topology and boundary-cover data. It sits beside the small boundary route of chapter 7347, the finite cover-order carrier of chapter 1853, the topology source of chapter 88, the normal-space separation packet of chapter 1866, and the finite refinement carrier of chapter 3430. The packet names a displayed separator-boundary ledger; it does not assert a host dimension theorem, arbitrary open-cover compactness, selected separators outside the carrier, or a choice principle for boundary recursion.

Definition 7371.1 (Large inductive dimension carrier)**.** *A* $\mathsf{LargeInductiveDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, N, B, R, S, C, H, T, P, A)$$

with the following displayed rows:

1. *X is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the finite open-set, closed-set, neighborhood, and boundary observations inspected by the packet.*
2. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *closed-set separation row, recording the displayed separation route between closed sets before a separator boundary is read.*
3. *B is the boundary-cover data row, recording finite boundary-cover entries attached to the separator produced by N.*
4. *R is the recursive large-dimension ledger, recording that each separator-boundary read is consumed only through the displayed topology, normal-space, boundary-cover, and comparison rows.*
5. *S is the* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *comparison row, recording the finite handoff to the point-neighborhood boundary route without identifying the two inductive dimension packets.*
6. *C is the* $\mathsf{CoveringDimension}^{\uparrow}$ *comparison row, recording the finite cover-order handoff used when separator-boundary covers are compared with finite refinement data.*
7. *H stores componentwise* hsame *transport for topology, separation, boundary cover, recursion, comparison, replay, provenance, and local naming rows.*
8. *T stores displayed* Cont *replay from a closed-set separation request through separator-boundary inspection, recursive ledger readback, small-dimension comparison, covering-dimension comparison, provenance, and local name.*

9. *P is the* Pkg *provenance over* $\mathsf{LargeInductiveDimension}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{SmallInductiveDimension}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *A is the local* $\mathsf{NameCert}_{\mathsf{LargeInductiveDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, N, B, R, S, C, H, T, P, A$. It has no coordinate for open-cover compactness, selected separator choice, quotient-topology equality, or an ambient theorem equating large inductive dimension with a host cover dimension.

Theorem 7371.2 (Large inductive dimension NameCert obligations)**.** *For every accepted* $\mathsf{LargeInductiveDimension}^{\uparrow}$ *carrier*

$$L = (X, N, B, R, S, C, H, T, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{LargeInductiveDimension}^{\uparrow}}$ *surface consists exactly of five obligation groups:*

1. *carrier admission for the displayed finite packet L;*
2. *separator exactness through the* $\mathsf{Topology}^{\uparrow}$ *source row X and* $\mathsf{NormalSpace}^{\uparrow}$ *closed-set separation row N;*
3. *recursive boundary ledger exactness through the boundary-cover row B and large-dimension recursion row R;*
4. *comparison-row stability through the* $\mathsf{SmallInductiveDimension}^{\uparrow}$ *row S,* $\mathsf{CoveringDimension}^{\uparrow}$ *row C,* $\mathsf{FiniteCoverRefinement}^{\uparrow}$ *provenance inside P, componentwise* hsame *transport H, and displayed* Cont *replay T;*
5. *non-escape from host dimension theorems, arbitrary open-cover compactness, selected separator choice, quotient topology equality, and external choice principles.*

Proof. Project the carrier of Definition 7371.1. The topology source, closed-set separator, boundary-cover data, recursive ledger, comparison rows, transport, replay, provenance, and naming row are exactly the displayed coordinates of the finite packet.

The separator obligation is read first from X, N. A consumer sees only the topology observations and the normal-space closed-set separation route before any separator boundary is inspected.

The recursive obligation is then read from B, R. These rows record finite boundary-cover entries and the large-dimension recursion ledger, so the boundary read remains inside the displayed packet.

Finally use S, C, H, T, P, A. The small-dimension and covering-dimension rows are comparison surfaces only, and the structural rows transport, replay, source, and name the same packet. Since the refused host objects are not carrier coordinates, the listed obligation groups exhaust the local NameCert surface. □

Theorem 7371.3 (Large inductive dimension separator route)**.** *Every separator-boundary read of an accepted* $\mathsf{LargeInductiveDimension}^{\uparrow}$ *packet factors through*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{NormalSpace}^{\uparrow},\ \mathsf{SmallInductiveDimension}^{\uparrow},\ \mathsf{CoveringDimension}^{\uparrow},\ \mathsf{FiniteCoverRefinement}^{\uparrow}$$

before the recursive large-dimension ledger is consumed. The route exposes closed-set separation, finite boundary-cover data, small-inductive comparison, covering-dimension comparison, finite refinement provenance, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it exports no host separator choice, no open-cover compactness theorem, and no ambient equality of dimension notions.*

Proof. Begin with the topology source and normal-space separation rows. The read must expose X and N before it can speak about a separator boundary, so there is no channel for an unrecorded host separator.

Next read the boundary-cover and recursion rows B, R. They provide the finite boundary data and the displayed recursive ledger attached to the separator.

Then use the comparison rows. The $\mathsf{SmallInductiveDimension}^{\uparrow}$ row S links the separator boundary to the point-neighborhood boundary route, while the $\mathsf{CoveringDimension}^{\uparrow}$ row C and the $\mathsf{FiniteCoverRefinement}^{\uparrow}$ provenance inside P link the same finite boundary data to cover-order refinement.

Finally project H, T, P, A. These rows transport, replay, source, and name the displayed route, so every separator-boundary read factors through the named topology, normal-space, small-inductive, covering-dimension, and finite-refinement surfaces. □

Falsifiable prediction: An accepted $\mathsf{LargeInductiveDimension}^{\uparrow}$ separator-boundary read is refuted if it consumes a recursive large-dimension ledger without first displaying the TopologyUp source row, NormalSpaceUp closed-set separation row, boundary-cover row, SmallInductiveDimensionUp comparison row, CoveringDimensionUp comparison row, FiniteCoverRefinementUp provenance, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: small-inductive-dimension, coveringdimension, topology, normalspace, finite-cover-refinement: $\mathsf{LargeInductiveDimension}^{\uparrow}$ jointly carries topology-source, closed-set separation, separator-boundary cover data, recursive large-dimension ledger, small-inductive comparison, covering-dimension comparison, finite refinement provenance, transport, replay, provenance, and local naming rows in one packet; each named sibling lacks at least one of these separator-recursive coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{LargeInductiveDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{LargeInductiveDimension}^{\uparrow}$ packet is generated from a TopologyUp source row, a NormalSpaceUp closed-set separation row, finite separator-boundary cover rows, a recursive large-dimension ledger, SmallInductiveDimensionUp and CoveringDimensionUp comparison rows, FiniteCoverRefinementUp provenance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LargeInductiveDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7371.1, Definition 7371.2, and Definition 7371.3 seed the separator-recursive large inductive dimension surface over topology, normal-space, small-inductive, covering-dimension, and finite-refinement rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LargeInductiveDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a host large-inductive-dimension theorem, equality with small inductive dimension, equality with covering dimension, arbitrary open-cover compactness, selected separator choice, quotient topology equality, or external choice principles.

Upgrade path: Obligation closure requires checked carrier admission, separator exactness, recursive boundary ledger exactness, comparison-row stability, transport, replay, provenance, and local NameCert rows for BEDC.Derived.LargeInductiveDimensionUp.

Chapter 7372

A Concrete Naming Certificate for $\mathsf{HeineBorelFiniteCover}^{\uparrow}$

Following Borel and Bishop and Bridges, the $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ packet records the constructive closed-interval finite-cover route by which displayed dyadic meshes and radius ledgers produce a finite cover bundle before any Real or compact-metric consumer reads compactness-facing data. It sits over the closed-bounded interval net of chapter 1250, the compact metric handoff of chapter 129, the dyadic rational arithmetic core of chapter 291, the rational comparison row of chapter 37, and the terminal real-name seal of chapter 38. The packet is a finite closed-interval certificate: it exposes the displayed bundle and its extraction route without asserting open-cover compactness for arbitrary $\mathsf{Real}^{\uparrow}$ subsets.

Definition 7372.1 (Heine–Borel finite-cover carrier)**.** *A* $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, M, U, L, E, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the closed bounded interval source row, read through* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$*, with named endpoint seals, boundedness data, and the interval membership route.*
2. *M is the dyadic mesh row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{Rat}^{\uparrow}$*, recording the mesh scale, rational cell endpoints, and cell-containment comparisons.*
3. *U is the finite cover bundle, listing the displayed cover entries, their inspected cells, and the finite membership witnesses used by the certificate.*
4. *L is the Lebesgue-radius ledger, recording the positive radius comparisons that make each mesh cell small enough for one displayed cover entry.*
5. *E is the compact-net extraction row, packaging the finite net centers and coverage witnesses handed to* $\mathsf{CompactMetric}^{\uparrow}$ *consumers.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the interval endpoints, inspected cell representatives, and covered points.*
7. *H records componentwise* hsame *transport for the interval source, dyadic mesh, finite cover bundle, radius ledger, compact-net extraction, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from closed-interval inspection through dyadic mesh selection, finite cover bundle inspection, Lebesgue-radius comparison, compact-net extraction, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{HeineBorelFiniteCover}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for arbitrary $\mathsf{Real}^{\uparrow}$ *subsets, unrestricted open covers, trichotomy, host completeness, quotient equality, selected subcovers outside the displayed finite bundle, or bridge data.*

Theorem 7372.2 (Heine–Borel finite-cover NameCert obligations)**.** *For every accepted* $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ *carrier $F = (I, M, U, L, E, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteCover}^{\uparrow}}$ *obligation surface consists exactly of closed bounded interval source admission, dyadic mesh admission, finite cover bundle exposure, Lebesgue-radius ledger exactness, compact-net extraction, Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7372.1. The interval source I is read before the dyadic mesh M, so the mesh cells are attached to a displayed closed bounded interval rather than to an arbitrary subset of $\mathsf{Real}^{\uparrow}$.

Read the finite cover bundle U and the radius ledger L. These rows state which finitely many cover entries are inspected and which positive radius comparisons certify that the displayed cells fit inside those entries.

The extraction row E and Real seal R are downstream of the same displayed rows. Componentwise transport H, replay C, provenance P, and local naming N preserve that route and add no open-cover compactness, trichotomy, host completeness, quotient equality, or hidden subcover selector. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 7372.3 (Heine–Borel finite-net extraction)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ *packet must read the compact-net extraction row through the finite route*

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{Rat}^{\uparrow},\quad U,\quad L,\quad \mathsf{Real}^{\uparrow},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The extracted object is the displayed finite cover bundle together with its mesh and Lebesgue-radius ledger; it is not an open-cover compactness theorem for arbitrary $\mathsf{Real}^{\uparrow}$ *subsets and not a selected subcover outside that displayed bundle.*

Proof. Start with the obligation surface of Definition 7372.2. It places compact-net extraction after the interval source, dyadic mesh, finite cover bundle, radius ledger, and Real seal have all been displayed.

The rows H, C, P, N preserve and name exactly this route. A compact-metric or Real-facing consumer can therefore receive E only as the extraction attached to I, M, U, L, R.

Since no carrier coordinate stores arbitrary subsets, unrestricted open covers, trichotomy, host completeness, quotient equality, or selected subcovers outside U, the extraction exports only the finite closed-interval cover certificate. □

Falsifiable prediction: Every $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ consumer read factors through a closed bounded interval source row, a dyadic mesh row, a displayed finite cover bundle, a Lebesgue-radius

ledger, compact-net extraction, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: closedboundedintervalnet, compactmetric, dyadicratcore, rat, real: HeineBorelFiniteCove is not bijective to any listed sibling because it jointly carries the closed-interval source, dyadic mesh, finite cover bundle, Lebesgue-radius ledger, compact-net extraction, Real seal, transport, replay, provenance, and local NameCert rows as one finite-cover packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HeineBorelFiniteCover}^{\uparrow}}$.

Constructive story: A $\mathsf{HeineBorelFiniteCover}^{\uparrow}$ packet is generated from a closed bounded interval source, dyadic mesh comparisons, a displayed finite cover bundle, a Lebesgue-radius ledger, compact-net extraction, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7372.1, Definition 7372.2, and Definition 7372.3 seed the constructive closed-interval finite-cover certificate surface over the displayed finite bundle.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HeineBorelFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness for arbitrary $\mathsf{Real}^{\uparrow}$ subsets, trichotomy, host completeness, quotient equality, selected subcovers outside the displayed finite bundle, Lean verification, or bridge checking.

Upgrade path: A formal route can encode BEDC.Derived.HeineBorelFiniteCoverUp and prove the finite-cover carrier, NameCert obligation, and net-extraction theorems.

Chapter 7373

A Concrete Naming Certificate for $\mathsf{BoundedContinuousImage}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BoundedContinuousImage}^{\uparrow}$ packet records the finite BEDC carrier for the familiar fact that a continuous real-valued map on a compact metric source has a displayed bound. It sits over the compact metric finite-net source of chapter 129, the continuity-radius surface of chapter 130, the bounded source exactness of chapter 1415, the stream-name handoff of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names only the finite route from compact source observations to a regular rational bound and a sealed real output; it does not import open-cover compactness, selected suprema, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7373.1 (Bounded continuous image carrier)**.** *A* $\mathsf{BoundedContinuousImage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, F, W, Q, R, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, read through finite net centers, cover radii, and located membership witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row from the compact metric source to the real-name target surface.*
3. *W is the finite source-window ledger listing the compact-source centers and local continuity windows consumed by the bound search.*
4. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the finitely many real-name samples produced by F on the displayed windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximations of those finitely many samples.*
6. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *bound row asserting that the displayed finite readback family lies under a rational bound budget.*
7. *H records componentwise* hsame *transport for the compact source, map row, source windows, stream observations, readback, bound row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a requested tolerance through the same finite-window route.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedContinuousImage}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedContinuousImage}^{\uparrow}}$ *row.*
The carrier contains no coordinate for an open-cover compactness proof, a selected supremum, quotient equality of maps, countable choice, ambient real completeness, or a host-level bounded-image theorem outside the displayed finite rows.

Theorem 7373.2 (Bounded continuous image NameCert obligations)**.** *For every accepted* BoundedContinuousImag *carrier $I = (K, F, W, Q, R, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedContinuousImage}^{\uparrow}}$ *surface consists exactly of compact source admission through K, continuous-map admission through F, finite source-window coverage through W, stream observation through Q, regular rational readback through R, bounded-source exactness through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7373.1. The source and map rows are K and F, and the finite window ledger W records the only compact-source observations available to the packet.

Read the observation rows next. The stream row Q records the finitely many real-name samples produced by the map row on the displayed windows, and R is the regular rational readback for those samples.

The bound row B is downstream of R, so boundedness is asserted only for the displayed finite readback family. The structural rows H, C, P, N transport, replay, source, and name the same finite route; no excluded compactness, supremum, quotient, choice, or ambient completeness principle has a carrier coordinate. □

Theorem 7373.3 (Bounded continuous image compact-bound route)**.** *Every accepted* $\mathsf{BoundedContinuousImage}^{\uparrow}$ *packet routes a compact metric source and a continuous real-valued map through the finite chain*

$$\mathsf{CompactMetric}^{\uparrow} \to \mathsf{ContinuousMap}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{BoundedRealSequence}^{\uparrow}.$$

The bound row B may be read only after the finite source-window ledger W, stream observation row Q, and regular rational readback row R have been displayed.

Proof. Start with K and F. Compactness is used only through the finite net and located membership data recorded in the source row, while continuity is used only through the displayed map row and the windows listed in W.

The image samples are then named by Q and read back by R. Since B is a bounded real sequence row for that finite readback family, a consumer cannot read the bound before the compact-window and continuity observations have been exposed.

Transport and replay through H and C keep the same route under componentwise equality and tolerance requests. Provenance and local naming through P and N seal the route as the stated compact-bound surface. □

Theorem 7373.4 (Bounded continuous image real seal nonescape)**.** *For every accepted* $\mathsf{BoundedContinuousImage}^{\uparrow}$ *carrier $I = (K, F, W, Q, R, B, H, C, P, N)$, any* $\mathsf{Real}^{\uparrow}$ *read of an image value or displayed bound must pass through the stream-name row Q, the regular rational readback row R, and the bounded real sequence row B. The carrier supplies no direct* $\mathsf{Real}^{\uparrow}$ *completeness principle, selected supremum, quotient equality of maps, or host real equality.*

Proof. Inspect the real-facing rows of the carrier. The map row F produces image observations only through the stream-name row Q, and those observations become rationally readable only through R.

The bound is recorded by B after the readback. Therefore a $\mathsf{Real}^{\uparrow}$ consumer can read an image value or bound only through the displayed stream, regular-rational, and bounded-sequence route.

The remaining coordinates H, C, P, N preserve and name that route. They add no coordinate for a completeness principle, supremum selector, quotient map equality, or host equality, so the real seal cannot escape the finite packet. □

Theorem 7373.5 (Bounded continuous image public export)**.** *The public surface of an accepted* $\mathsf{BoundedContinuousImage}^{\uparrow}$ *packet is the finite bound certificate carried by* $K, F, W, Q, R, B, H, C, P, N$*. A downstream compact-continuous-real consumer may import the displayed compact-bound route and real-seal nonescape result, but receives no open-cover compactness theorem, selected supremum, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean credential, or bridge claim.*

Proof. Combine Definition 7373.2 with Definition 7373.3. The first theorem lists the complete local NameCert surface, and the second orders the compact, continuity, stream, readback, and boundedness rows.

Use Definition 7373.4 for the real-facing boundary. It keeps every real read downstream of Q, R, B and excludes completeness, supremum, quotient, and host-equality readings.

Thus a public consumer receives exactly the finite certificate named by the carrier and no stronger analytic or verification principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedContinuousImage}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedContinuousImage}^{\uparrow}$ packet is generated from compact metric finite-net rows, continuous map rows, finite source windows, StreamName observations, RegSeqRat readback, a BoundedRealSequence bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedContinuousImage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7373.1, Definition 7373.2, Definition 7373.3, Definition 7373.4, and Definition 7373.5 seed the finite compact-continuous-image bound certificate over compact metric, continuous map, stream-name, regular rational, bounded sequence, and real-name rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedContinuousImage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected suprema, quotient equality of maps, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite source-window coverage, stream observation exactness, RegSeqRat readback, bounded-source exactness, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.BoundedContinuousImageUp.

Chapter 7374

A Concrete Naming Certificate for $\mathsf{WellFoundedTreeRank}^{\uparrow}$

Following Brouwer-style finite-bar arguments and Bishop's use of induction over finitely generated construction trees, the $\mathsf{WellFoundedTreeRank}^{\uparrow}$ packet records the bounded tree-rank surface needed by prefix-tree reasoning in the L10 stream and completion route. It sits after the finitely branching tree carrier of chapter 6488 and the Brouwer bar-induction boundary of chapter 1675. The packet names only a finite rank row for displayed prefix trees; it does not import choice, infinite branch selection, host well-founded recursion, or quotient tree equality.

Definition 7374.1 (Well-founded tree-rank carrier)**.** *A* $\mathsf{WellFoundedTreeRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, R, L, W, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet or constructor row for prefix labels;*
2. *R is the rank row, listing a natural height bound for each displayed node in the finite prefix tree;*
3. *L is the leaf row, recording the frontier nodes where the rank is 0;*
4. *W is the window row, recording the finite* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *prefix windows served by the tree;*
5. *H is the componentwise* hsame *transport row for A, R, L, W;*
6. *C is the displayed* Cont *replay row that extends a prefix window without changing the already exposed rank data;*
7. *P is the* Pkg *provenance over* $\mathsf{WellFoundedTreeRank}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{WellFoundedTreeRank}^{\uparrow}}$ *row.*

The carrier has no coordinate for choosing an infinite branch, identifying distinct tree presentations by quotient equality, or invoking an ambient well-founded-recursion principle outside the displayed finite rank row.

Theorem 7374.2 (Well-founded tree-rank NameCert obligations)**.** *For the carrier of Definition 7374.1, the local* $\mathsf{NameCert}_{\mathsf{WellFoundedTreeRank}^{\uparrow}}$ *surface consists exactly of carrier admission for $T = (A, R, L, W, H, C, P, N)$, rank-row exposure through R, leaf-frontier exposure through L, finite*

prefix-window readback through W, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The finitely branching predecessor surface is supplied by chapter 6488, while the bar-facing boundary of chapter 1675 explains why a finite frontier may be read without selecting an infinite branch.

Induct on the displayed finite rank row R. At rank 0, the leaf row L supplies the frontier certificate, and the window row W reads only the finite $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ prefix already present at that leaf.

For the successor rank, each immediate subtree has a strictly smaller displayed rank. Apply the induction hypothesis to those rows, then repack the parent by H, C, P, N. Since every step reads only the finite coordinates A, R, L, W, H, C, P, N, the NameCert obligations are exhausted by the stated surface. □

Theorem 7374.3 (Well-founded tree-rank induction route)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *prefix argument served by an accepted* $\mathsf{WellFoundedTreeRank}^{\uparrow}$ *packet may use induction only over the displayed finite rank row R. The route first exposes the finite branching data, then the leaf frontier, then the prefix window W, and only then replays continuation through C; it exports no choice of an infinite branch and no host recursion over an ambient tree type.*

Proof. Begin with Definition 7374.1. The only induction coordinate is R, and every consumer-visible prefix window is recorded in W before continuation replay is available.

For the base rank, the leaf-frontier row L gives the terminal prefix window. The consumer reads the finite $\mathsf{StreamName}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ prefix directly from W, so no branch selection or quotient tree equality is needed.

For the successor rank, use the induction hypothesis on each displayed predecessor row. Finitely branching exposure supplies the finite list of predecessors, and the Brouwer-style bar boundary supplies the reason that the read remains frontier-local. Transport and replay through H and C preserve the same packet, while P and N keep the route inside the local NameCert. □

Falsifiable prediction: A prefix-tree proof that deletes the rank row R can no longer distinguish finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ window induction from an illicit infinite-branch selection.

Independence witness: finitelybranchingtree, brouwerbarinduction, streamname, regseqrat: FinitelyBranchingTreeUp supplies finite branching but not a displayed decreasing rank row; BrouwerBarInductionUp supplies the bar-facing boundary but not the L10 prefix-window packet; StreamNameUp and RegSeqRatUp supply finite windows but not the tree-rank induction carrier. None is bijective to $\mathsf{WellFoundedTreeRank}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{WellFoundedTreeRank}^{\uparrow}}$**.**

Constructive story: A $\mathsf{WellFoundedTreeRank}^{\uparrow}$ packet is generated from a finite label row, displayed rank row, leaf frontier, finite stream or regular-rational prefix window, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WellFoundedTreeRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the finite rank carrier, NameCert obligation surface, and prefix-window induction route for $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WellFoundedTreeRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim choice, infinite branch selection, host well-founded recursion, quotient tree equality, or ambient completion equality.

Upgrade path: Reaching obligation closure requires checked carrier admission, rank-row exposure, leaf-frontier readback, finite prefix-window preservation, transport, replay, provenance, and local naming for BEDC.Derived.WellFoundedTreeRankUp.

Chapter 7375

A Concrete Naming Certificate for BanachFixedPointConstructive$^{\uparrow}$

Following Banach's contraction principle and Bishop–Bridges constructive analysis, the BanachFixedPointConstructi packet records the finite choice-free route from a displayed contraction to a fixed-point seal. It sits after the contraction-map surface of chapter 1418, the Picard iteration ledger of chapter 2359, the complete-metric boundary of chapter 128, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the Banach fixed-point modulus route of chapter 4188. The packet names only the displayed contraction data, Picard Cauchy schedule, completion service, regular-rational handoff, fixed seal, transports, replay, provenance, and local naming; it is not an ambient completeness theorem, selected host fixed point, quotient orbit equality, trichotomy principle, or countable-choice construction.

Definition 7375.1 (Constructive Banach fixed point carrier)**.** *A* BanachFixedPointConstructive$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, T, L, I, M, C, R, E, H, Q, P, N)$$

with the following displayed rows:

1. *X is the* CompleteMetric$^{\uparrow}$ *source row naming the metric carrier whose completeness is available only through the displayed service boundary.*
2. *T is the* ContractionMapping$^{\uparrow}$ *row for the self-map and its contraction replay surface.*
3. *L is the rational contraction ledger below one, including the displayed positivity and unit-bound rows consumed by the Picard estimate.*
4. *I is the* PicardIteration$^{\uparrow}$ *orbit row, recording the finite iterate schedule and adjacent-step residuals.*
5. *M is the* BanachFixedPointModulus$^{\uparrow}$ *or* CauchyModulus$^{\uparrow}$ *threshold row extracted from T, L, I.*
6. *C is the completion-facing service row read from X only after the Picard Cauchy threshold has been displayed.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row reached from I, M, C.*
8. *E is the terminal* Real$^{\uparrow}$ *fixed seal row reached only after R and C have been read.*

9. *H records componentwise* hsame *transports for the complete-metric, contraction, contraction-ledger, Picard, modulus, completion-service, readback, seal, replay, provenance, and local naming rows.*

10. *Q records displayed* Cont *replay from the contraction and Picard rows to the modulus threshold, from the modulus threshold to regular-rational readback, and from readback plus completion service to the fixed seal.*

11. *P is the* Pkg *provenance over* $\mathsf{BanachFixedPointConstructive}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointConstructive}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, L, I, M, C, R, E, H, Q, P, N$. It has no coordinate for a host-selected fixed point, quotient equality of iterates or reals, ambient $\mathsf{Real}^{\uparrow}$ *completeness, unrestricted contraction theorem, trichotomy, analytic continuation, or countable choice.*

Theorem 7375.2 (Constructive Banach fixed point NameCert obligations)**.** *For every accepted* $\mathsf{BanachFixedPointConstructive}^{\uparrow}$ *carrier $B = (X, T, L, I, M, C, R, E, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachFixedPointCon}}$ *surface consists exactly of carrier admission for the complete-metric source X, contraction row T, rational contraction ledger L, Picard orbit I, Cauchy threshold M, completion service C, regular-rational readback R, terminal fixed seal E, componentwise transport H, displayed replay Q, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 7375.1. The analytic rows visible to the certificate are exactly X, T, L, I, M, C, R, E, followed by transport, replay, provenance, and local naming.

The contraction side is exhausted by T, L, I. The self-map row supplies the displayed contraction replay, the rational ledger supplies the bound below one, and the Picard row supplies the finite orbit and residual schedule.

The completion side is downstream from the same finite data. The modulus row M is extracted before the completion service C, regular-rational readback R, or terminal fixed seal E can be read.

Finally H, Q, P, N transport, replay, source, and name this packet. Since the carrier has no excluded coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7375.3 (Constructive Banach Picard-Cauchy route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BanachFixedPointConstructive}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{BanachFixedPointModulus}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

The route exposes only the displayed complete-metric source, contraction row, rational contraction ledger, Picard orbit, Cauchy threshold, completion service, regular-rational readback, terminal fixed seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows.*

Proof. Start with the NameCert obligations of Definition 7375.2. They place every read of the packet behind the complete-metric source, contraction row, rational contraction ledger, Picard orbit, and explicit threshold.

Next read the Picard-Cauchy handoff. The contraction and Picard rows supply the finite residual schedule, while the modulus row M is the only threshold coordinate available before regular-rational readback.

The completion service is confined to the displayed $\mathsf{CompleteMetric}^{\uparrow}$ row X. Once M and C are visible, the certificate may read R and then the fixed seal E.

Thus every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer sees exactly the displayed route and cannot bypass it through a selected fixed point, quotient equality, ambient completeness, or countable choice. □

Theorem 7375.4 (Constructive Banach fixed seal nonescape)**.** *Let $B = (X, T, L, I, M, C, R, E, H, Q, P, N)$ be an accepted* $\mathsf{BanachFixedPointConstructive}^{\uparrow}$ *carrier. Every fixed-point consumer that reads the terminal seal E must first expose the complete-metric source X, contraction row T, rational contraction ledger L, Picard orbit I, Cauchy threshold M, completion service C, and regular-rational readback R.*

Consequently the terminal fixed seal exports no selected host fixed point, quotient orbit equality, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, unrestricted contraction theorem, trichotomy, analytic continuation, or countable-choice schedule.*

Proof. Project the carrier of Definition 7375.1. The seal coordinate E occurs only after the contraction, Picard, modulus, completion-service, and regular-rational rows in the displayed packet.

Apply Definition 7375.3. It forces every regular-rational or real-facing read through T, L, I before M, through M before C and R, and through R before E.

The structural rows H, Q, P, N preserve this order under transport, replay, provenance, and local naming. They add no coordinate for host selection, quotient equality, ambient completeness, analytic continuation, trichotomy, or choice.

Therefore the fixed seal is a nonescape boundary for the displayed constructive route only. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachFixedPointConstructive}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachFixedPointConstructive}^{\uparrow}$ packet is generated from a CompleteMetric source, ContractionMapping row, rational contraction ledger, PicardIteration orbit, BanachFixedPointModulus or CauchyModulus threshold, completion service, RegSeqRat readback, RealUp fixed seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachFixedPointConstructive}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7375.1, Definition 7375.2, Definition 7375.3, and Definition 7375.4 seed the finite choice-free contraction fixed-point route through Picard, modulus, complete-metric, regular-rational, and real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachFixedPointConstructive}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected host fixed points, quotient orbit equality, quotient real equality, ambient RealUp completeness, unrestricted contraction theorems, trichotomy, analytic continuation, or countable choice.

Upgrade path: Obligation closure requires checked carrier admission, contraction replay, rational contraction ledger exactness, Picard orbit ordering, Cauchy threshold extraction, complete-metric service confinement, RegSeqRat readback, RealUp fixed-seal confinement, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.BanachFixedPointConstru

Chapter 7376

A Concrete Naming Certificate for $\mathsf{FixedPointIndex}^{\uparrow}$

Following Dold and Brown on fixed-point index and Lefschetz theory, the $\mathsf{FixedPointIndex}^{\uparrow}$ packet records the finite BEDC surface by which a displayed compact-metric neighborhood, a continuous self-map row, homology trace data, and a Lefschetz fixed-point handoff are inspected before an index value is exported. It sits after the compact source row of chapter 129, the map row of chapter 130, the homology ledger of chapter 98, the Lefschetz fixed-point packet of chapter 6557, and the Brouwer fixed-point metric reconstruction of chapter 5941. The chapter records only finite carrier rows and NameCert obligations; it does not assert a host fixed-point theorem or a global index existence theorem.

Definition 7376.1 (Fixed-point index carrier)**.** *A* $\mathsf{FixedPointIndex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, U, F, H, L, B, V, T, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read through* $\mathsf{CompactMetric}^{\uparrow}$*, naming the inspected compact-metric neighborhood and its finite cover interface.*
2. *U is the isolating neighborhood row, recording the finite boundary and exclusion witnesses used before any fixed-point index read is admitted.*
3. *F is the continuous-map row, read through* $\mathsf{ContinuousMap}^{\uparrow}$*, for the displayed self-map on the inspected source.*
4. *H is the homology ledger row, read through* $\mathsf{Homology}^{\uparrow}$*, recording the finite chain, trace, and boundary data available to the index packet.*
5. *L is the Lefschetz handoff row, read through* $\mathsf{LefschetzFixedPoint}^{\uparrow}$*, attaching the displayed trace expression to the fixed-point-facing consumer route.*
6. *B is the Brouwer metric fixed-point comparison row, read through* $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$*, used only as a finite local comparison surface.*
7. *V is the integer-valued index row, containing the displayed sign, degree, or trace readback accepted by the packet.*
8. *T records componentwise* hsame *transport for the compact source, isolating row, continuous-map row, homology ledger, Lefschetz handoff, Brouwer comparison, index value, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact-source inspection through isolating-neighborhood admission, continuous-map exposure, homology ledger readback, Lefschetz handoff, Brouwer comparison, and index-value export.*
10. *P is the* Pkg *provenance over* $\mathsf{FixedPointIndex}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{LefschetzFixedPoint}^{\uparrow}$, $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FixedPointIndex}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for an ambient fixed-point set, unrestricted homotopy invariance, selected zero, global Brouwer theorem, quotient space equality, or bridge data.

Theorem 7376.2 (Fixed-point index NameCert obligations)**.** *For every accepted* $\mathsf{FixedPointIndex}^{\uparrow}$ *carrier* $I = (K, U, F, H, L, B, V, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FixedPointIndex}^{\uparrow}}$ *obligation surface consists exactly of compact-source admission, isolating-neighborhood exposure, continuous-map exposure, homology ledger exactness, Lefschetz handoff, Brouwer metric comparison, index-value readback, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7376.1. The compact source K and isolating row U are displayed before the map row F, so the index read is attached to a visible local neighborhood rather than to an ambient fixed-point set.

Read the homology ledger H and Lefschetz handoff L. These rows expose the finite chain and trace data that downstream consumers may inspect, while the Brouwer comparison row B remains only a local metric comparison surface.

Finally V, T, C, P, N record the index value, transport, replay, provenance, and local name for that same route. Since none of the carrier rows stores unrestricted homotopy invariance, selected zeros, global fixed-point existence, quotient equality, or bridge data, the listed rows exhaust the NameCert obligations. □

Theorem 7376.3 (Fixed-point index dependency route)**.** *Every accepted* $\mathsf{FixedPointIndex}^{\uparrow}$ *consumer read of the index row V must factor through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Homology}^{\uparrow},\ \mathsf{LefschetzFixedPoint}^{\uparrow},\ \mathsf{BrouwerFixedPointMetric}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Co}$$

The route exports the displayed local index packet and its homology trace ledger. It does not export a global host fixed-point theorem, unrestricted Lefschetz theorem, selected fixed point, quotient-space equality, or bridge certificate.

Proof. Start with Definition 7376.2. It places the index value after the compact source, isolating row, displayed self-map, homology ledger, Lefschetz handoff, and Brouwer metric comparison have all been exposed.

The componentwise transport, replay, and provenance rows preserve this ordering. Thus a consumer cannot read V without also reading the finite topology and homology rows that generated it.

Because the classifier has no coordinate for a host fixed-point set, unrestricted Lefschetz theorem, selected fixed point, quotient equality, or bridge certificate, the exported route is exactly the displayed local index packet. □

Falsifiable prediction: Every $\mathsf{FixedPointIndex}^{\uparrow}$ consumer read factors through a compact source row, an isolating neighborhood row, a displayed $\mathsf{ContinuousMap}^{\uparrow}$ self-map, a $\mathsf{Homology}^{\uparrow}$ trace

ledger, a $\mathsf{LefschetzFixedPoint}^{\uparrow}$ handoff, a $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$ comparison row, an index-value row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactmetric, continuous-map, homology, lefschetz-fixed-point, brouwer-fixed-point-metric: $\mathsf{FixedPointIndex}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an isolating neighborhood, displayed self-map, finite homology ledger, Lefschetz handoff, Brouwer comparison, and local index row as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FixedPointIndex}^{\uparrow}}$.

Constructive story: A $\mathsf{FixedPointIndex}^{\uparrow}$ packet is generated from a CompactMetricUp source row, isolating neighborhood row, ContinuousMapUp self-map row, HomologyUp ledger, LefschetzFixedPointUp handoff, BrouwerFixedPointMetricUp comparison, index-value row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FixedPointIndex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7376.1, Definition 7376.2, and Definition 7376.3 seed the local fixed-point index certificate surface over displayed compact, map, homology, Lefschetz, and Brouwer rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FixedPointIndex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global host fixed-point theorem, unrestricted homotopy invariance, selected fixed points, quotient-space equality, Lean verification, or bridge checking.

Upgrade path: A formal route can encode BEDC.Derived.FixedPointIndexUp and prove the carrier, NameCert obligation, and dependency-route theorems.

Chapter 7377

A Concrete Naming Certificate for $\mathsf{StratifiedSpace}^{\uparrow}$

Following Whitney and Thom, the $\mathsf{StratifiedSpace}^{\uparrow}$ packet records a finite stratum ledger for a displayed topological space whose local pieces are read through manifold, simplicial, or cellular charts. It sits after the indexed-open surface of chapter 88, the deformation route of chapter 156, the finite face inventory of chapter 238, and the cellular attachment surface of chapter 6235. The packet names incidence, frontier, local chart, and consumer handoff rows without importing host stratification theory, selected tubular neighborhoods, quotient spaces, or ambient smooth transversality.

Definition 7377.1 (Stratified space carrier)**.** *A* $\mathsf{StratifiedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, L, F, C, A, H, R, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, carrying the named open indices and finite membership reads for the ambient observable space;*
2. *L is the finite stratum-label row, listing the displayed strata and their dimension or depth tags;*
3. *F is the frontier-incidence row, recording which stratum closures may meet lower-depth strata;*
4. *C is the local chart row, read through* $\mathsf{SimplicialComplex}^{\uparrow}$ *or* $\mathsf{CWComplex}^{\uparrow}$ *finite cells when a consumer needs combinatorial support;*
5. *A is the deformation-admissibility row, read through* $\mathsf{Homotopy}^{\uparrow}$ *for stratum-preserving deformation requests;*
6. *H is the componentwise* hsame *transport row for T, L, F, C, A;*
7. *R is the displayed* Cont *replay row for refining a finite chart or frontier read without changing the named stratum ledger;*
8. *P is the* Pkg *provenance over* $\mathsf{StratifiedSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{CWComplex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StratifiedSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host Whitney condition theorem, a selected normal slice, quotient topological equality, global triangulation choice, or ambient smooth transversality.

Theorem 7377.2 (Stratified space NameCert obligations)**.** *For the carrier of Definition 7377.1, the local* $\mathsf{NameCert}_{\mathsf{StratifiedSpace}^{\uparrow}}$ *surface consists exactly of ambient topology exposure through* T*, finite stratum inventory through* L*, frontier incidence through* F*, local chart support through* C*, stratum-preserving deformation admissibility through* A*, componentwise transport through* H*, displayed replay through* R*, provenance through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The topology source supplies open-membership rows, the stratum row lists only finitely many inspected pieces, and the frontier row records only the displayed incidence relation among those pieces.

Read the sibling chart rows next. The simplicial-complex and CW-complex chapters supply finite face and cell inventories, while the homotopy chapter supplies only the deformation route attached to those displayed strata.

Finally attach transport, replay, provenance, and naming. Since every consumer-visible read is one of $T, L, F, C, A, H, R, P, N$, the packet cannot export host stratification theory, selected tubular neighborhoods, quotient spaces, global triangulation choice, or transversality data outside the stated NameCert surface. □

Theorem 7377.3 (Stratified space cellular handoff)**.** *Every homology, homotopy, or topology consumer of an accepted* $\mathsf{StratifiedSpace}^{\uparrow}$ *packet must expose the finite route*

$$\mathsf{Topology}^{\uparrow} \longmapsto L, F \longmapsto \mathsf{SimplicialComplex}^{\uparrow}, \mathsf{CWComplex}^{\uparrow} \longmapsto \mathsf{Homotopy}^{\uparrow}$$

before it reads a stratum-preserving boundary. The route is a finite chart-and-frontier handoff, not a host Whitney stratification theorem or a quotient realization of a stratified space.

Proof. Start with Definition 7377.1. The ambient topology row T is read before any stratum label, and the frontier row F is attached to the same finite stratum inventory L.

Next read the chart row C. Any simplicial or cellular support is supplied by the sibling $\mathsf{SimplicialComplex}^{\uparrow}$ and $\mathsf{CWComplex}^{\uparrow}$ packets, so the handoff has finite face or cell data before the deformation row is inspected.

The row A then records only stratum-preserving deformation admissibility through $\mathsf{Homotopy}^{\uparrow}$. Transport and replay preserve the same route through H, R, P, N, so the consumer receives the displayed packet and no additional global stratification principle. □

Falsifiable prediction: A $\mathsf{StratifiedSpace}^{\uparrow}$ consumer that deletes the frontier row F can no longer distinguish a stratum-preserving chart handoff from an arbitrary topological decomposition.

Independence witness: topology, homotopy, simplicialcomplex, cw-complex: TopologyUp supplies open-membership rows but not a stratum frontier ledger; HomotopyUp supplies deformation rows but not finite strata; SimplicialComplexUp and CWComplexUp supply finite face or cell inventories but not the ambient topology and deformation handoff together. None is bijective to $\mathsf{StratifiedSpace}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{StratifiedSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{StratifiedSpace}^{\uparrow}$ packet is generated from a Topology row, finite stratum labels, frontier incidence, simplicial or cellular chart support, Homotopy deformation admissibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StratifiedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the finite carrier, NameCert obligation surface, and cellular handoff route for displayed stratified-space consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StratifiedSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: It does not claim host Whitney conditions, selected tubular neighborhoods, quotient realization, global triangulation choice, smooth transversality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite stratum inventory, frontier-incidence exactness, chart support, deformation admissibility, transport, replay, provenance, and local naming for BEDC.Derived.StratifiedSpaceUp.

Chapter 7378

A Concrete Naming Certificate for MetaCICResidualJoinBudget$^{\uparrow}$

The MetaCICResidualJoinBudget$^{\uparrow}$ packet realizes the confluence remaining-question surface of section 9386.3 as finite residual-join budget data. It sits beside the parallel-diamond frontier of chapter 4238, the residual-substitution boundary of chapter 2181, the closed checker seal of chapter 2182, and the confluence audit packet of chapter 735. The packet records typed-window, residual-pair, join-candidate, checker-status, premise-retention, obstruction, transport, replay, provenance, and local naming rows before any confluence consumer reads a local join.

Definition 7378.1 (MetaCIC residual-join budget carrier)**.** *A* MetaCICResidualJoinBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (W, P, R, Q, S, B, O, H, C, G, N)$$

with the following displayed rows:

1. *W is the typed-window row for the closed MetaCIC source under inspection;*
2. *P is the retained residual-substitution premise row read through* MetaCICResidualSubstitutionBoundary$^{\uparrow}$*;*
3. *R is the residual-pair row, naming the two residual branches whose local join is budgeted;*
4. *Q is the proposed join-candidate row, kept visible until the bounded checker row accepts it;*
5. *S is the* ClosedTypeCheckerSeal$^{\uparrow}$ *row for the closed type-checker and finished-normal endpoint data used by the budget;*
6. *B is the bounded local-join checker row, recording the finite checker status rather than an unrestricted confluence theorem;*
7. *O is the obstruction-retention row for residual-substitution compatibility, premise-free parallel diamond, closed Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency endpoints;*
8. *H is the componentwise* hsame *transport row for W, P, R, Q, S, B, O;*
9. *C is the displayed* Cont *replay row for refining the same residual budget;*
10. *G is the* Pkg *provenance over* MetaCICResidualJoinBudget$^{\uparrow}$*,* MetaCICParallelDiamondFrontier$^{\uparrow}$*,* MetaCICResidualSubstitutionBoundary$^{\uparrow}$*,* ClosedTypeCheckerSeal$^{\uparrow}$*,* MetaCICConfluenceAuditPacket$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinBudget}^{\uparrow}}$ *row.*
The carrier has no coordinate for residual-substitution compatibility, premise-free parallel diamond, arbitrary closed confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Theorem 7378.2 (MetaCIC residual-join budget NameCert obligations)**.** *For the carrier of Definition 7378.1, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinBudget}^{\uparrow}}$ *surface consists exactly of typed-window exposure through W, residual-substitution premise retention through P, residual-pair exposure through R, join-candidate exposure through Q, closed-checker sealing through S, bounded local-join status through B, obstruction retention through O, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N.*

Proof. Project the displayed carrier. The typed window, residual-substitution premise, residual pair, join candidate, closed checker, bounded checker, and obstruction rows are all explicit coordinates of J.

Read the sibling confluence rows next. The residual-substitution boundary supplies the retained premise row P, the parallel-diamond frontier supplies the conditional local-diamond context, the closed checker seal supplies S, and the confluence audit packet supplies the consumer-facing audit boundary.

Finally attach transport, replay, provenance, and local naming. Since the carrier contains no row for residual-substitution compatibility, premise-free parallel diamond, arbitrary closed confluence, subject reduction, evaluator equality, quotient term equality, or kernel consistency, the stated NameCert surface exhausts every accepted residual-join budget read. □

Theorem 7378.3 (MetaCIC residual-join budget confluence route)**.** *Every confluence consumer of an accepted* $\mathsf{MetaCICResidualJoinBudget}^{\uparrow}$ *packet must first expose the finite route*

$$W, P, R, Q, S, B, O \longmapsto H, C, G, N$$

before reading any local join handoff. The route may feed $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *and* $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ *consumers, but it does not discharge residual substitution or turn the bounded checker row into a closed Church–Rosser theorem.*

Proof. Start with Definition 7378.1. The typed window W and residual-substitution premise P are visible before the residual pair R and join candidate Q are inspected.

Next read the checker rows. The closed type-checker seal S and bounded local-join checker B record only finite checker status for the displayed residual pair. The obstruction row O remains visible at the same stage.

Transport and replay preserve this route through H and C, while G and N keep the read inside the local package and NameCert rows. Thus the consumer receives a residual-join budget surface, not a premise-free confluence theorem. □

Falsifiable prediction: Every $\mathsf{MetaCICResidualJoinBudget}^{\uparrow}$ local-join read that omits the retained premise row P fails to distinguish bounded residual checking from a premise-free parallel diamond claim.

Independence witness: metacic-parallel-diamond-frontier, metacic-residual-substitution-boundary, closed-type-checker-seal, metacic-confluence-audit-packet: $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ carries the conditional diamond context but not this budget's closed checker and bounded status

rows; $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ carries the retained premise but not the join candidate; $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$ carries checker sealing but not the confluence audit boundary; $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$ carries audit status but not the local residual-pair budget. None is bijective to $\mathsf{MetaCICResidualJoinBudget}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualJoinBudget}^{\uparrow}$ packet is generated from a typed MetaCIC window, residual-substitution premise, residual-pair row, join-candidate row, closed type-checker seal, bounded local-join checker, obstruction-retention row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the finite carrier, NameCert obligation surface, and confluence route for bounded MetaCIC residual-join budgets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: It does not claim residual-substitution compatibility, premise-free parallel diamond, arbitrary closed confluence, subject reduction, evaluator equality, quotient term equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, retained residual-substitution premise, residual-pair coverage, join-candidate exactness, closed-checker sealing, bounded local-join status, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualJoinBudgetUp.

Chapter 7379

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$ packet records the finite diagonal route by which a bounded real sequence is inspected through regular Cauchy subsequence windows before a $\mathsf{Real}^{\uparrow}$ cluster-facing seal is exposed. It sits over the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the bounded source surface of chapter 1415, and the Bolzano–Weierstrass route of chapter 1254. The packet names a displayed diagonal schedule and its finite readback; it is not countable choice, a host-selected subsequence, quotient stream equality, trichotomy of reals, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7379.1 (Regular Cauchy subsequence diagonal carrier)**.** *A* $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, S, J, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded sequence source row, read as a* $\mathsf{BoundedRealSequence}^{\uparrow}$ *packet and exposing only the inspected sequence indices, finite bounds, and local source route.*
2. *S is the subsequence schedule row, listing the finite initial segment of the increasing index schedule used by the diagonal read.*
3. *J is the diagonal window selector, assigning each requested regular-Cauchy tolerance to the finite source window and subsequence index already displayed in S.*
4. *W is the family of* $\mathsf{StreamName}^{\uparrow}$ *windows inspected along the displayed schedule and selector rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the bounded source, schedule, selector, windows, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the bounded source, schedule, selector, StreamName windows, RegSeqRat readback, Real seal, continuation row, provenance row, and local naming row.*

8. *C records displayed* Cont *replay of the route*

$$B, S, J, W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BolzanoWeierstrass}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets exactly through $B, S, J, W, R, E, H, C, P, N$. It has no coordinate for countable choice, a host subsequence selector, quotient equality of streams, trichotomy, or ambient Real completeness.

Theorem 7379.2 (Regular Cauchy subsequence diagonal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$ *carrier $D = (B, S, J, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows; bounded-source visibility through B; finite subsequence scheduling through S; diagonal window selection through J; StreamName window exposure through W; RegSeqRat readback through R; Real seal handoff through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7379.1. The bounded source row B is the only source-side input, so every sequence read starts from the finite $\mathsf{BoundedRealSequence}^{\uparrow}$ surface.

Read the schedule and selector next. The row S lists the finite inspected subsequence indices, while J ties each requested diagonal tolerance to one of the displayed windows. No row can request an unlisted tail or an externally selected subsequence.

The analytic handoff then passes through W, R, E. StreamName windows are inspected before the regular rational readback, and the Real seal is downstream of that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for countable choice, a host subsequence selector, quotient stream equality, trichotomy, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7379.3 (Regular Cauchy subsequence diagonal Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read from an accepted* $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$ *carrier factors through*

$$B, S, J, W, R, E, H, C, P, N.$$

In particular, the Real seal is exposed only after the bounded sequence source, finite subsequence schedule, diagonal selector, StreamName windows, and RegSeqRat readback have been displayed. The handoff exports no countable choice, selected host subsequence, quotient stream equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7379.2. They place the bounded source row B, schedule row S, selector row J, and StreamName windows W before any regular readback can be consumed.

The readback row R is therefore the only regular rational route to the terminal seal. A $\mathsf{Real}^{\uparrow}$ consumer reaches E only after this displayed readback has been named.

The structural rows H, C, P, N preserve the same route under transport and replay. Because no excluded selector, quotient, trichotomy, choice, or completeness row occurs in the carrier, every Real-facing read remains inside the displayed diagonal packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}$ packet is generated from a bounded real sequence source, a finite subsequence schedule, a diagonal window selector, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7379.1, Definition 7379.2, and Definition 7379.3 seed the finite diagonal route from bounded source windows to a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected host subsequences, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-source visibility, finite schedule exactness, diagonal selector stability, StreamName window coverage, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubsequenceDiagonalUp.

Chapter 7380

A Concrete Naming Certificate for $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$

Following Koksma and Hlawka, the $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$ packet records a finite numerical-integration error certificate whose only analytic inputs are a displayed discrepancy ledger and a displayed bounded-variation ledger. It sits after the low-discrepancy sequence surface of chapter 5173, the bounded-variation family surface of chapter 398, the finite epsilon-net tolerance row of chapter 1767, the dyadic tolerance core of chapter 291, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite error handoff only; it does not import measure completion, selected representatives, quotient equality of functions, host total variation, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7380.1 (Koksma–Hlawka finite-error carrier)**.** *A* $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, V, E, Q, T, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{LowDiscrepancySequence}^{\uparrow}$ *source row, carrying the finite point schedule and the inspected star-discrepancy windows.*
2. *D is the discrepancy ledger, recording the finite dyadic upper bound read from S.*
3. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *row for the integrand, including the finite partition-variation ledger and endpoint readback surface.*
4. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *tolerance row that names the finite comparison scale used by the error request.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row joining the displayed discrepancy and variation budgets.*
6. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the certified quadrature error bound.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the finite error estimate.*
8. *H records componentwise* hsame *transport for the sequence, discrepancy, variation, epsilon-net, dyadic-budget, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from discrepancy and variation rows to the dyadic product budget, then to regular-rational readback and the terminal real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$, $\mathsf{LowDiscrepancySequence}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, V, E, Q, T, R, H, C, P, N$. It has no coordinate for a measure-completion object, a selected representative of the integrand, quotient function equality, a host supremum over all partitions, or an ambient completeness theorem.

Theorem 7380.2 (Koksma–Hlawka NameCert obligations)**.** *For every accepted* $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$ *carrier $K = (S, D, V, E, Q, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}}$ *surface consists exactly of carrier admission for the low-discrepancy source S, discrepancy ledger D, bounded-variation ledger V, finite epsilon-net tolerance row E, dyadic product budget Q, regular-rational readback T, terminal real seal R, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 7380.1. The analytic rows visible to the certificate are the source schedule, discrepancy ledger, variation ledger, tolerance row, product budget, readback row, and terminal seal.

The sequence side is exhausted by S, D, E. The low-discrepancy row supplies the inspected point schedule, the discrepancy ledger supplies the dyadic upper bound, and the finite epsilon-net row supplies the tolerance scale at which the error request is read.

The integrand side is exhausted by V. Its bounded-variation ledger exposes only finite partition and endpoint-readback data before the product budget is available.

Finally Q, T, R, H, C, P, N multiply the displayed budgets, read the product as regular-rational data, seal the finite estimate as $\mathsf{Real}^{\uparrow}$, transport the same rows, replay the route, record provenance, and name the packet. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7380.3 (Koksma–Hlawka error handoff)**.** *Every quadrature-error consumer of an accepted* $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LowDiscrepancySequence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{R}$$

The route exports only the displayed discrepancy budget, bounded-variation budget, tolerance scale, dyadic product ledger, regular-rational readback, terminal real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Proof. Start with the NameCert obligations of Definition 7380.2. They force every consumer read to expose the sequence schedule, discrepancy ledger, variation ledger, epsilon-net tolerance, and dyadic product budget before any error estimate can be read.

Next read the dyadic budget row Q. It is the only coordinate where discrepancy and variation interact, so the consumer cannot bypass it through a measure-completion object, a hidden partition supremum, or a selected representative of the integrand.

The regular-rational row T and terminal seal R are downstream from Q. The structural rows H, C, P, N preserve that order under transport, replay, provenance, and local naming.

Thus the finite error handoff is exactly the displayed Koksma–Hlawka route and carries no additional analytic principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}}$.

Constructive story: A $\mathsf{KoksmaHlawkaFiniteError}^{\uparrow}$ packet is generated from a LowDiscrepancySequence source, a displayed discrepancy ledger, a BoundedVariation ledger, a FiniteEpsilonNet tolerance row, a DyadicRatCore product

budget, RegSeqRat readback, a RealUp error seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KoksmaHlawkaFiniteError}\uparrow}$, seed)

Scope closed: Definition 7380.1, Definition 7380.2, and Definition 7380.3 seed the finite Koksma–Hlawka error route over discrepancy, bounded-variation, epsilon-net, dyadic, regular-rational, and real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{KoksmaHlawkaFiniteError}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, measure completion, selected integrand representatives, quotient function equality, host total variation, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, discrepancy-ledger exactness, bounded-variation ledger exactness, epsilon-net tolerance routing, dyadic product-budget routing, RegSeqRat readback, RealUp error sealing, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.KoksmaHlawkaFiniteErrorUp.

Chapter 7381

A Concrete Naming Certificate for $\mathsf{VisionCoverageIndex}^{\uparrow}$

The $\mathsf{VisionCoverageIndex}^{\uparrow}$ packet realizes the top-level vision routing surface of chapter 9236 as finite BEDC data. It records which exploratory source label is covered by which concrete-instance target, which marker row witnesses the coverage, and which replay/provenance rows make the route auditable. The replay row is meant to inspect concrete target packets such as chapter 7380 and chapter 7378 before a coverage row is counted. The packet is an index certificate for vision coverage accounting; it is not a new mathematical theorem about the source chapters, not a semantic endorsement of every vision paragraph, and not a replacement for the concrete-instance chapters named by its rows.

Definition 7381.1 (Vision coverage index carrier)**.** *A* $\mathsf{VisionCoverageIndex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S, T, M, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source-label row naming a vision chapter, section, or routing paragraph.*
2. *T is the concrete-target row naming the realized chapter label under* `concrete_instances/`*.*
3. *M is the marker ledger row containing the displayed* `\concretizedIn` *route from S to T.*
4. *L is the local coverage ledger, recording whether the row is root-index coverage, sibling coverage, bridge-facing coverage, or replay-only coverage.*
5. *R is the replay row that lets an audit reread the target chapter without relying on cached coverage counts.*
6. *H records componentwise* hsame *transport for source labels, target labels, marker rows, coverage ledgers, replay rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from source label to target label through the marker ledger and the replay row.*
8. *P is the* Pkg *provenance over* $\mathsf{VisionCoverageIndex}^{\uparrow}$*, the referenced vision source, the referenced concrete-instance target,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{VisionCoverageIndex}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, T, M, L, R, H, C, P, N$. It has no coordinate for hidden coverage totals, cached root counts, semantic approval of source prose, or a target chapter that lacks a concrete label.

Theorem 7381.2 (Vision coverage index NameCert obligations)**.** *For every accepted* $\mathsf{VisionCoverageIndex}^{\uparrow}$ *carrier* $V = (S, T, M, L, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{VisionCoverageIndex}^{\uparrow}}$ *surface consists exactly of carrier admission for the source-label row* S*, concrete-target row* T*, marker ledger* M*, coverage ledger* L*, replay row* R*, componentwise transport* H*, displayed replay* C*, package provenance* P*, and local naming row* N*.*

Proof. Project the carrier of Definition 7381.1. The coverage data visible to the certificate are exactly the source label, target label, marker ledger, local coverage ledger, and replay row.

The marker row binds source to target. It records the displayed concretization route and therefore cannot be replaced by a cached count or by prose that merely resembles a coverage claim.

The replay row keeps the certificate auditable. It points back to the target chapter so that a consumer can inspect the finite NameCert rows named by T.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no hidden total or semantic-approval coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7381.3 (Vision coverage replay handoff)**.** *Every coverage consumer of an accepted* $\mathsf{VisionCoverageIndex}^{\uparrow}$ *packet factors through*

$$S \longmapsto M \longmapsto T \longmapsto R \longmapsto H, C, P, N.$$

Thus a vision source is counted as concretely covered only through a displayed marker ledger and a replayable concrete-instance target; the packet exports no hidden coverage count, no semantic endorsement of the source prose, and no target without a concrete chapter label.

Proof. Start with the NameCert obligations of Definition 7381.2. They require the source label, target label, marker ledger, coverage ledger, and replay row before any coverage consumer reads the packet.

The marker ledger M is the only source-to-target edge. The target row T is therefore not inferred from the source title or from a cached index; it is displayed by the packet.

The replay row R makes the target inspectable. The structural rows H, C, P, N preserve that route under transport, continuation replay, provenance, and local naming.

Consequently coverage accounting is finite BEDC data routed through the displayed marker and replay rows. □

Falsifiable prediction: Every accepted $\mathsf{VisionCoverageIndex}^{\uparrow}$ coverage read names a source label, concrete target label, marker ledger, replay row, transport row, continuation row, provenance row, and local NameCert row before it is counted.

Independence witness: kernelacceptancewitness, inscriptionevent, closure-capstone-realization, finitekernelcategory, koksma-hlawka-finite-error: $\mathsf{VisionCoverageIndex}^{\uparrow}$ is not bijective to any listed sibling because it indexes coverage routes among source labels and concrete targets rather than carrying the target's mathematical or audit payload.

Lean Nontrivial and FieldFaithful TasteGate instances for $\mathsf{VisionCoverageIndex}^{\uparrow}$ should inspect the carrier rows directly: Nontriviality is witnessed by distinct source-label and concrete-target

rows, while field faithfulness requires projections of $S, T, M, L, R, H, C, P, N$ to preserve the displayed marker-ledger and replay route. Neither instance may read hidden coverage totals, cached routing weights, or source prose outside the displayed marker row.

Closure status for $\mathsf{NameCert}_{\mathsf{VisionCoverageIndex}^{\uparrow}}$.

Constructive story: A $\mathsf{VisionCoverageIndex}^{\uparrow}$ packet is generated from source-label rows, concrete-target rows, marker-ledger rows, local coverage ledgers, replay rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VisionCoverageIndex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7381.1, Definition 7381.2, and Definition 7381.3 seed the finite routing packet that turns vision coverage accounting into displayed source-label, target-label, marker-ledger, replay, transport, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VisionCoverageIndex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, source-prose semantics, hidden coverage totals, cached routing weights, or the NameCert obligations of any target chapter named by the index.

Upgrade path: Obligation closure requires checked carrier admission, source-label exactness, concrete-target exactness, marker-ledger routing, coverage-ledger classification, replay handoff, transport stability, continuation replay, provenance nonescape, and local naming for BEDC.Derived.VisionCoverageIndexUp.

Chapter 7382

A Concrete Naming Certificate for $\mathsf{HawaiianEarring}^{\uparrow}$

Following Eilenberg–Steenrod and classical topology, the $\mathsf{HawaiianEarring}^{\uparrow}$ packet records the compact metric boundary surface of the countable family of tangent circles whose radii converge to zero. It reads the S1Up circle certificate of chapter 58, the compact-metric surface of chapter 129, the topological carrier of chapter 88, the stream-name route of chapter 126, the regular rational sequence route of chapter 301, and the real-coordinate seal of chapter 38. The chapter names the displayed compact metric wedge boundary only; it does not compute a fundamental group or identify a quotient wedge.

Definition 7382.1 (Hawaiian earring carrier)**.** *A* $\mathsf{HawaiianEarring}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (C, R, S, T, K, Q, W, H, D, P, N)$$

with the following displayed rows:

1. *C is the circle-source row, read through S1Up and its* $\mathsf{Real}^{\uparrow}$ *coordinate surface, naming the reusable unit-circle certificate.*
2. *R is the radius schedule row, read through* $\mathsf{RegSeqRat}^{\uparrow}$*, displaying a positive rational radius for each inspected circle and its convergence toward the common tangent point.*
3. *S is the stream-name row, read through* $\mathsf{StreamName}^{\uparrow}$*, recording the finite stream observations by which requested circle indices and rational radii are presented.*
4. *T is the topology row, read through* $\mathsf{Topology}^{\uparrow}$*, naming the subspace and neighborhood interface available at the wedge point and at displayed circle points.*
5. *K is the compact-metric row, read through* $\mathsf{CompactMetric}^{\uparrow}$*, exposing only the finite compact-metric observations attached to the displayed radius schedule.*
6. *Q is the circle-wedge incidence row, recording the shared tangent point and the finite membership routes for the inspected circle pieces.*
7. *W is the wedge-boundary readback row, recording which displayed circle and radius row supplies a requested local observation.*
8. *H records componentwise* hsame *transport for the circle source, radius schedule, stream name, topology, compact-metric row, incidence row, wedge-boundary readback, replay, provenance, and local naming.*

9. *D records displayed* Cont *replay from stream-name admission through regular-rational radius readback, circle-source inspection, topology exposure, compact-metric observation, and wedge-boundary readback.*

10. *P is the* Pkg *provenance over* $\mathsf{HawaiianEarring}^{\uparrow}$*, S1Up,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HawaiianEarring}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a full fundamental-group computation, quotient wedge equality, selected points from infinitely many circles, ambient compactness beyond the displayed compact-metric rows, Lean verification, or bridge data.

Theorem 7382.2 (Hawaiian earring NameCert obligations)**.** *For every accepted* $\mathsf{HawaiianEarring}^{\uparrow}$ *carrier $E = (C, R, S, T, K, Q, W, H, D, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HawaiianEarring}^{\uparrow}}$ *obligation surface consists exactly of circle-source admission, regular rational radius scheduling, stream-name readback, topology exposure, compact-metric observation, circle-wedge incidence, wedge-boundary readback, componentwise transport, displayed replay, provenance, and local naming. A consumer may inspect the compact metric boundary packet only after those rows have been exposed from the same* BHist *carrier.*

Proof. Project the carrier of Definition 7382.1. The rows $C, R, S, T, K, Q, W, H, D, P, N$ are the only rows exposed by an accepted packet.

Read the source and schedule rows first. The S1Up circle row C, regular rational sequence row R, and stream-name row S jointly determine which displayed circles and radii may be inspected before any topology or compact-metric consumer enters.

Next read T, K, Q, W. These rows expose the topology, compact-metric observation, shared tangent point, finite incidence data, and wedge-boundary readback, while keeping all observations attached to the same displayed schedule.

Finally H, D, P, N transport, replay, source, and name that packet. Since no carrier coordinate stores a fundamental group, quotient wedge equality, a choice schedule over all circles, ambient compactness beyond K, Lean verification, or bridge data, the listed rows exhaust the NameCert obligations. □

Theorem 7382.3 (Hawaiian earring circle wedge route)**.** *Every accepted* $\mathsf{HawaiianEarring}^{\uparrow}$ *consumer read of the wedge-boundary row W must factor through*

S1Up, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert.

The route exports the displayed compact metric boundary packet for the tangent circle family. It does not export a full fundamental-group computation, quotient wedge equality, selected representatives from infinitely many circles, ambient compactness beyond the displayed compact-metric rows, Lean verification, or bridge checking.

Proof. Start with the NameCert obligation surface of Definition 7382.2. It requires the circle source, rational radius schedule, and stream-name rows before the topology and compact-metric rows can be inspected.

The incidence and wedge-boundary rows Q, W are downstream of that schedule. They identify the shared tangent point and the displayed circle piece used by a local observation, but they do not add a quotient-space equality or an infinite choice principle.

Transport, replay, provenance, and local naming preserve the same finite route. Therefore every wedge-boundary read remains a compact metric/topology boundary read over the displayed circle family and cannot be reinterpreted as any of the refused endpoints. □

Falsifiable prediction: Every $\mathsf{HawaiianEarring}^{\uparrow}$ consumer read factors through a S1Up circle-source row, a $\mathsf{RegSeqRat}^{\uparrow}$ radius schedule, a $\mathsf{StreamName}^{\uparrow}$ index-read row, a $\mathsf{Topology}^{\uparrow}$ neighborhood row, a $\mathsf{CompactMetric}^{\uparrow}$ observation row, a circle-wedge incidence row, a wedge-boundary readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: s1, compactmetric, topology, streamname, regseqrat, real: $\mathsf{HawaiianEarring}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a countable tangent-circle schedule, compact metric observations, topology exposure, stream-name readback, and wedge-boundary incidence as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HawaiianEarring}^{\uparrow}}$.

Constructive story: A $\mathsf{HawaiianEarring}^{\uparrow}$ packet is generated from a S1Up circle source, RegSeqRatUp radius schedule, StreamNameUp index-read row, TopologyUp neighborhood row, CompactMetricUp observation row, circle-wedge incidence row, wedge-boundary readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HawaiianEarring}^{\uparrow}}$, seed)

Scope closed: Definition 7382.1, Definition 7382.2, and Definition 7382.3 seed the compact metric/topology boundary packet for the displayed tangent circle family.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HawaiianEarring}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full fundamental-group computation, quotient wedge equality, choice over infinitely many circles, ambient compactness beyond displayed compact-metric rows, Lean verification, or bridge checking.

Upgrade path: A formal route can encode BEDC.Derived.HawaiianEarringUp and prove the carrier, NameCert obligation, and circle-wedge route theorems.

Chapter 7383

A Concrete Naming Certificate for RiemannDarbouxCriterionFinite$^{\uparrow}$

Following Bishop and Bridges on constructive Riemann integration, the RiemannDarbouxCriterionFinite$^{\uparrow}$ packet records the finite criterion that identifies a Riemann-sum Cauchy route with an upper/lower Darboux squeeze before a Real$^{\uparrow}$ integral seal is exported. It sits between the finite Darboux boundary of chapter 1880, the tagged Riemann-sum route of chapter 1615, the dyadic mesh source of chapter 358, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives RiemannIntegrable$^{\uparrow}$ and regulated-integral consumers a finite bridge from partition-sum criteria to real-sealed integration data, not a host theorem about arbitrary partitions, quotient function equality, measure completion, or ambient Real$^{\uparrow}$ completeness.

Definition 7383.1 (Riemann–Darboux finite criterion carrier)**.** *A* RiemannDarbouxCriterionFinite$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, U, L, S, R, D, O, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *M is the tagged partition mesh row, read through* DyadicMesh$^{\uparrow}$ *and the finite tag ledger used by the* RiemannSum$^{\uparrow}$ *consumer.*
2. *U is the upper Darboux-sum row, read through* ***??*** *or the upper side of the* DarbouxSum$^{\uparrow}$ *packet over the same mesh row M.*
3. *L is the lower Darboux-sum row, read through* LowerDarbouxSum$^{\uparrow}$ *or the lower side of the* DarbouxSum$^{\uparrow}$ *packet over the same mesh row M.*
4. *S is the Riemann-sum Cauchy-net read, exposing only displayed tagged sums and finite refinement witnesses.*
5. *R is the dyadic mesh refinement row, requiring every refinement consumed by S, U, L to factor through the same* DyadicMesh$^{\uparrow}$ *surface.*
6. *D is the oscillation ledger, recording the upper-minus-lower squeeze and the cellwise oscillation comparisons that license the finite criterion.*
7. *O is the* RegSeqRat$^{\uparrow}$ *readback row for the gap, tagged-sum, and tolerance windows.*
8. *Q is the* Real$^{\uparrow}$ *seal row, reached only after the Darboux squeeze and regular rational readback have been displayed.*

9. *E records hsame transport for the mesh, Darboux rows, Riemann-sum Cauchy-net read, refinement row, oscillation ledger, readback, seal, replay, provenance, and local name.*
10. *H records the displayed* Cont *replay from mesh rows to Darboux sums, from mesh rows to tagged sums, from refinement rows to the squeeze ledger, and from readback rows to the Real seal.*
11. *T is the* Pkg *provenance over* $\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}$, $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, *??*, $\mathsf{LowerDarbouxSum}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *P is the local integration-boundary provenance row naming the downstream* $\mathsf{RiemannIntegrable}^{\uparrow}$ *and regulated-integral consumers that may read the criterion.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected refining sequence, quotient equality of integrands, measure-theoretic integration, host compactness, or ambient real completeness.

Theorem 7383.2 (Riemann–Darboux finite criterion NameCert obligations)**.** *For every accepted* $\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}$ *carrier*

$$C = (M, U, L, S, R, D, O, Q, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed tagged partition mesh, upper and lower Darboux rows, Riemann-sum Cauchy-net read, refinement row, oscillation ledger, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *mesh-refinement classifier transport, requiring every refinement used by the Darboux rows or Riemann-sum row to be compared through the same* $\mathsf{DyadicMesh}^{\uparrow}$ *row M and refinement route R;*
3. *upper/lower squeeze exactness, requiring the rows U, L, D to expose the finite Darboux upper-minus-lower comparison before any integral-facing consumer reads the criterion;*
4. *Riemann-sum Cauchy handoff, requiring the row S to pass through the same mesh-refinement surface and then through the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row O;*
5. *Real seal nonescape, requiring Q, E, H, T, P, N to preserve, replay, source, and name only the displayed finite rows before a* $\mathsf{Real}^{\uparrow}$ *consumer receives the seal.*

Proof. Project the carrier of Definition 7383.1. The rows $M, U, L, S, R, D, O, Q, E, H, T, P, N$ are the whole packet, so carrier admission exposes exactly the finite mesh, Darboux, Riemann-sum, readback, seal, transport, replay, provenance, and naming data.

Mesh-refinement transport is forced by M and R. Both the Darboux rows and the tagged Riemann-sum row must read their cells through the same displayed $\mathsf{DyadicMesh}^{\uparrow}$ source, so a refinement changes the packet only by replaying the common finite route.

The squeeze rows U, L, D are read before the Cauchy handoff is accepted. They provide the upper and lower Darboux comparison over the displayed mesh, while S supplies the tagged-sum Cauchy-net read over the same refinement surface.

Finally O and Q form the terminal readback and seal. The structural rows E, H, T, P, N transport, replay, source, and name that route without adding a selected refining sequence, quotient integrand equality, measure object, host compactness theorem, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}$ packet is generated from a tagged DyadicMesh row, upper and lower Darboux-sum rows, a Riemann-sum Cauchy-net read, a mesh-refinement row, an oscillation ledger, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, downstream integration-boundary provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7383.1 and Definition 7383.2 seed the finite Riemann–Darboux criterion over $\mathsf{DyadicMesh}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, **??**, $\mathsf{LowerDarbouxSum}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Riemann integrability, selected refining sequences, quotient equality of integrands, measure-theoretic integration, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh-refinement classifier transport, Darboux squeeze exactness, Riemann-sum Cauchy handoff, Real seal nonescape, replay, provenance, and local naming for BEDC.Derived.RiemannDarbouxCriterionFiniteUp.

Chapter 7384

A Concrete Naming Certificate for $\mathsf{CauchyModulusThinning}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyModulusThinning}^{\uparrow}$ packet records the finite route by which an explicit Cauchy modulus is thinned to a monotone cofinal schedule before a regular rational or real-name consumer reads it. It sits over the modulus surface of chapter 292, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational handoff of chapter 301, and the terminal seal of chapter 38. The packet is a non-quotient thinning certificate; it supplies no selected limit, quotient stream equality, countable-choice schedule, host real equality, or ambient completeness theorem.

Definition 7384.1 (Cauchy modulus thinning carrier)**.** *A* $\mathsf{CauchyModulusThinning}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (M, T, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{CauchyModulus}^{\uparrow}$ *row, carrying the original explicit modulus request and its finite threshold answers.*
2. *T is the monotone thinning route, recording the retained threshold schedule and the finite proof that each retained threshold dominates the source answer needed at the same dyadic depth.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic precision, scale, and comparison rows used to read the source and thinned schedules.*
4. *W is the retained* $\mathsf{StreamName}^{\uparrow}$ *window opened at the thinned threshold.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the retained window and dyadic ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, T, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the modulus, thinning, tolerance, window, regular handoff, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source modulus through the thinned threshold, dyadic ledger, retained window, regular handoff, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusThinning}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusThinning}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, D, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7384.2 (Cauchy modulus thinning NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusThinning}^{\uparrow}$ *carrier $X = (M, T, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusThinning}^{\uparrow}}$ *surface consists exactly of carrier admission for the ten displayed rows, source-modulus exposure through M, monotone thinning dominance through T, dyadic tolerance exactness through D, retained stream-window visibility through W, regular rational handoff through R, real-seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7384.1. The analytic rows are exactly M, T, D, W, R, E, and the structural rows are exactly H, C, P, N.

The source-modulus and thinning obligations are read first. Row M supplies the explicit threshold answer, while row T records the retained monotone schedule and its finite dominance comparison against the source answer at the displayed dyadic depth.

The tolerance and window obligations then force the read through D and W. The dyadic ledger fixes the precision scale, and the retained stream window is opened only at the thinned threshold named by T.

Finally the regular and real-facing rows are downstream. The row R is obtained from the retained window and tolerance ledger, and the seal row E is reachable only after that handoff. Since H, C, P, N preserve the same route and the carrier lists no quotient, selected limit, choice schedule, host equality, or ambient completeness row, the displayed obligations exhaust the local NameCert surface. □

Theorem 7384.3 (Cauchy modulus thinning Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusThinning}^{\uparrow}$ *packet receives only the finite route*

$$\mathsf{CauchyModulus}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the monotone thinning row T retained before any stream window is opened. Thus downstream regular-Cauchy and completion packets may consume a thinned explicit modulus without importing quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness.

Proof. Begin with an accepted packet and read the source modulus. The row M answers the displayed dyadic request, while T records a monotone retained threshold that dominates the source answer for that request.

Read the dyadic and stream rows next. The ledger D fixes the tolerance scale, and the stream window W is opened only at the retained threshold. Therefore a regular rational consumer cannot bypass the thinning route.

The handoff to R and then E is forced by the same finite rows. Componentwise transport, replay, provenance, and local naming preserve this route, but they do not add a selected real, a quotient equality, countable choice, host equality, or an ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{CauchyModulusThinning}^{\uparrow}$ real-facing read displays a source Cauchy modulus row, a monotone thinning row, a dyadic tolerance ledger, a retained StreamName window, a RegSeqRat handoff, and a RealUp seal before any downstream consumer receives the packet.

Independence witness: cauchymodulus, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{CauchyModulusThinning}^{\uparrow}$ because the thinning packet jointly carries source modulus data, a monotone retained-threshold route, dyadic tolerance accounting, stream-window retention, regular rational handoff, terminal real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusThinning}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyModulusThinning}^{\uparrow}$ packet is generated from a source CauchyModulus row, a monotone thinning route, a DyadicRatCore tolerance ledger, a retained StreamName window, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusThinning}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7384.1, Definition 7384.2, and Definition 7384.3 seed the non-quotient modulus-thinning route over $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusThinning}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close obligation coverage, Lean theorem verification, quotient stream equality, selected limits, countable choice, host real equality, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-modulus exposure, thinning dominance, dyadic tolerance exactness, retained-window visibility, regular handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusThinningUp.

Lean4 (statement) `BEDC.Derived.CauchyModulusThinningUp`

Chapter 7385

A Concrete Naming Certificate for $\mathsf{CousinPartition}^{\uparrow}$

Following Cousin and Bishop–Bridges gauge integration, the $\mathsf{CousinPartition}^{\uparrow}$ packet records the finite gauge-partition object that sits between the existence route of chapter 1861 and the tagged-sum consumers of $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, and $\mathsf{RiemannSumGauge}^{\uparrow}$. It names a located interval, a positive gauge, finitely many tagged subintervals, mesh and refinement rows, gauge-fineness witnesses, finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise transport, displayed replay, provenance, and local naming. The packet does not assert open-cover compactness, an arbitrary host partition object, selected representatives outside the displayed ledger, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7385.1 (Cousin partition carrier)**.** *A* $\mathsf{CousinPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, G, T, M, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located closed interval row, including endpoint names, interval containment, and the finite source boundary inherited from the Cousin route.*
2. *G is the positive gauge row, recording local positive-radius data as displayed rational or regular-rational comparisons rather than as an ambient open cover.*
3. *T is the finite tagged-subinterval ledger. Each entry carries a cell, a tag, endpoint reads, tag-in-cell containment, and its position in the ordered partition.*
4. *M is the mesh and refinement ledger, recording adjacency, common refinements, and the comparison route to the tagged-real-partition mesh.*
5. *F is the gauge-fineness row, certifying for every displayed tagged cell that the cell lies inside the local gauge radius attached to its tag.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened for endpoints, tags, gauge-radius reads, mesh comparisons, and fineness checks.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family for the same finite windows and positive-radius comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal family reached only after the interval, gauge, tagged-cell, mesh, fineness, window, and regular readback rows have been displayed.*

9. *H records componentwise* hsame *transport for I, G, T, M, F, S, R, E and for replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a Cousin-partition request through*

$$I, G, T, M, F, S, R, E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CousinPartition}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CousinPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed interval, gauge, tagged-subinterval, mesh, fineness, readback, seal, transport, replay, provenance, and local naming rows.

Theorem 7385.2 (Cousin partition NameCert obligations)**.** *For every accepted* $\mathsf{CousinPartition}^{\uparrow}$ *carrier $K = (I, G, T, M, F, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CousinPartition}^{\uparrow}}$ *surface consists exactly of carrier admission, located interval exposure through I, positive gauge admission through G, finite tagged-subinterval exposure through T, mesh and refinement accountability through M, gauge-fineness certification through F, finite* $\mathsf{StreamName}^{\uparrow}$ *windows through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, terminal* $\mathsf{Real}^{\uparrow}$ *seals through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7385.1. The tuple lists the only rows available to a Cousin-partition consumer: interval source, positive gauge, tagged cells, mesh and refinement data, gauge-fineness witnesses, finite windows, regular readback, Real seals, transport, replay, provenance, and local naming.

Read the partition-facing rows in order. The Cousin lemma chapter supplies the existence-facing route to finite tagged subintervals, but the present packet records the displayed ledger T together with the mesh row M and fineness row F before any tagged-sum consumer can inspect it.

Finally read S, R, E, H, C, P, N. These rows keep endpoint, tag, and gauge-radius observations inside finite StreamName windows and regular-rational readback before the Real seals are exposed. Since no carrier coordinate names an open cover, host partition, selected representative family, quotient equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7385.3 (Cousin partition gauge-refinement handoff)**.** *Let $K = (I, G, T, M, F, S, R, E, H, C, P, N)$ be an accepted* $\mathsf{CousinPartition}^{\uparrow}$ *carrier. Any consumer that refines a Cousin subdivision toward* $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, *or* $\mathsf{RiemannSumGauge}^{\uparrow}$ *must first expose the located interval row I, positive gauge row G, finite tagged-subinterval ledger T, mesh and refinement ledger M, gauge-fineness row F, regular readback row R, and terminal Real seal row E. The handoff exports a finite gauge-fine partition route only; it does not export an ambient open-cover theorem, an arbitrary host mesh, quotient equality of partitions, selected tag values outside T, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the Cousin source of chapter 1861. It supplies the finite subdivision route over the displayed interval and positive gauge, but the consumer still receives only the rows named in I, G, T, M, F.

Next route the tagged cells through the sibling tagged-partition and fine-gauge surfaces. The tagged row T is the only source for $\mathsf{TaggedRealPartition}^{\uparrow}$ reads, while F is the row that permits $\mathsf{FinePartitionGauge}^{\uparrow}$ to see the partition as gauge-fine.

Finally route a Riemann-sum or gauge-integration consumer through $\mathsf{RiemannSumGauge}^{\uparrow}$. The mesh row M, readback row R, Real seal row E, and structural rows H, C, P, N preserve the same finite partition ledger, so the downstream consumer receives a displayed gauge-refinement handoff rather than hidden compactness, quotient equality, selected tags, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CousinPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{CousinPartition}^{\uparrow}$ packet is generated from a located interval row, positive gauge row, finite tagged-subinterval ledger, mesh and refinement ledger, gauge-fineness row, StreamName windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CousinPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7385.1, Definition 7385.2, and Definition 7385.3 seed the finite gauge-partition route from CousinLemmaUp to TaggedRealPartitionUp, FinePartitionGaugeUp, RiemannSumGaugeUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CousinPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, open-cover compactness, host partition equality, selected tags outside the displayed ledger, countable choice, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive gauge admission, tagged-subinterval exposure, mesh refinement, gauge-fineness, readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CousinPartitionUp.

Chapter 7386

A Concrete Naming Certificate for $\mathsf{BishopIntervalOrder}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopIntervalOrder}^{\uparrow}$ packet records constructive interval-order data over displayed real-name endpoints without importing a trichotomy oracle. It sits after the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the finite stream-window discipline of chapter 126. The packet gives Real and Completion consumers an apartness-routed interval comparison boundary; it is not a quotient interval construction, not host real equality, not ambient $\mathsf{Real}^{\uparrow}$ completeness, and not a proof that every two intervals are classically comparable.

Definition 7386.1 (Bishop interval order carrier)**.** *A* $\mathsf{BishopIntervalOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, A, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{Real}^{\uparrow}$ *endpoint row, exposed only as a named real boundary.*
2. *U is the upper* $\mathsf{Real}^{\uparrow}$ *endpoint row, paired with L by the same interval carrier.*
3. *A is the located-apartness witness row, recording positive separation evidence when the order comparison is read constructively.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare finite endpoint observations.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite endpoint reads inspected by the tolerance ledger.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the lower and upper endpoints after S, R, D have been displayed.*
8. *H records componentwise* hsame *transport for endpoints, apartness, dyadic tolerances, stream windows, regular readback, real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from an interval-order request through L, U, A, D, S, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalOrder}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, U, A, D, S, R, E, H, C, P, N$. It has no coordinate for real trichotomy, quotient interval equality, selected representatives, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7386.2 (Bishop interval order NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalOrder}^{\uparrow}$ *carrier $I = (L, U, A, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower endpoint, upper endpoint, located-apartness witness, dyadic tolerance ledger, stream-window row, regular rational readback, terminal real seal, componentwise transport, displayed replay, provenance, and local naming rows.*

Proof. Project the carrier of Definition 7386.1. Its interval data are exactly the endpoint rows L, U, the apartness row A, the dyadic tolerance row D, the finite window row S, the regular readback row R, and the terminal seal row E.

The endpoint rows are read through the same finite observation route. The stream windows and regular rational readback provide the displayed data that the dyadic tolerance ledger may compare, and the apartness row records only positive separation evidence visible through that route.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for trichotomy, quotient interval equality, host real equality, selected representatives, or ambient completeness, no further local NameCert clause can be read from it. □

Theorem 7386.3 (Bishop interval order apartness route)**.** *Every constructive order read exported by an accepted* $\mathsf{BishopIntervalOrder}^{\uparrow}$ *carrier factors through*

$$L, U \longmapsto S, R, D \longmapsto A \longmapsto E \longmapsto H, C, P, N.$$

Thus a consumer may use displayed located-apartness data to separate endpoint intervals, but it cannot replace that route by trichotomy, quotient intervals, host real equality, selected endpoint representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7386.2. Any interval-order consumer must first read the lower and upper endpoint rows together with their finite stream windows and regular rational readback.

The dyadic tolerance ledger is the comparison budget for those reads. A positive order separation is therefore available only through the located-apartness row A, which is downstream of the displayed endpoint observations.

The terminal real seal and structural rows do not add a classical comparison principle. They only seal, transport, replay, source, and name the same apartness-routed interval packet.

Consequently every exported constructive order read factors through the displayed route, and all non-displayed real-comparison principles remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopIntervalOrder}^{\uparrow}$ consumer must expose lower and upper Real endpoint rows, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a located-apartness row, Real seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row before reading an interval-order comparison.

Independence witness: Nearest siblings: Real, RegSeqRat, DyadicRatCore, and StreamName. $\mathsf{BishopIntervalOrder}^{\uparrow}$ is not bijective to any one sibling because it jointly carries paired endpoint rows, finite windows, regular readback, tolerance ledgers, located-apartness evidence, terminal

seals, transport, replay, provenance, and local naming for the same constructive interval-order route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalOrder}^{\uparrow}$ packet is generated from lower and upper Real endpoint rows, located-apartness evidence, DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readback, Real seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalOrder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7386.1, Definition 7386.2, and Definition 7386.3 seed the finite apartness-routed interval-order boundary over displayed Real endpoints, regular readback, dyadic tolerances, stream windows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalOrder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, quotient intervals, host real equality, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, located-apartness routing, dyadic tolerance visibility, StreamName window admission, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalOrderUp.

Chapter 7387

A Concrete Naming Certificate for $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy estimates, the $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$ packet records the finite tail-estimate route by which two regular rational Cauchy sources, their aligned tail windows, and the displayed pointwise-sum budget become a real-facing seal. It sits over the Cauchy carrier of chapter 3413, the regular rational source of chapter 301, the terminal real-name boundary of chapter 38, the dyadic tolerance arithmetic of chapter 291, and the binary sum surface of chapter 417. The packet names finite tail estimates for the sum route; it is not a host limit theorem, quotient stream equality, selected convergence witness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7387.1 (Regular Cauchy sum tail-estimate carrier)**.** *A* $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, B, W_A, W_B, D_A, D_B, S, E, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two accepted* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose tails are compared on the same precision request.*
2. *W_A and W_B are the aligned* $\mathsf{StreamName}^{\uparrow}$ *tail windows opened for the two sources.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows attached to the two tail estimates.*
4. *S is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row that combines the two displayed source windows through pointwise dyadic addition.*
5. *E is the finite error ledger recording the displayed tail bound for the sum after both source bounds have been read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the sum window and its tail ledger.*
7. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after $A, B, W_A, W_B, D_A, D_B, S, E, R$ have been displayed.*
8. *H records componentwise* hsame *transport for the two sources, windows, dyadic rows, sum row, ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a tail request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySumTailEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient real completeness.

Theorem 7387.2 (Regular Cauchy sum tail-estimate NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$ *carrier*

$$T = (A, B, W_A, W_B, D_A, D_B, S, E, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySumTailEstimate}^{\uparrow}}$ *surface consists exactly of carrier admission for the two regular rational sources, aligned tail windows, dyadic tolerance rows, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row, the finite error ledger, regular rational readback, real seal, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7387.1. The accepted packet exposes precisely the rows $A, B, W_A, W_B, D_A, D_B, S, E, R, Q, H, C, P, N$, so carrier admission and local naming have no hidden coordinates.

The tail estimate is then read in order. The two source rows A, B are inspected through the aligned windows W_A, W_B and the dyadic tolerance rows D_A, D_B before the pointwise-sum row S is available.

The finite ledger E records the displayed output bound for the summed tail, and the readback row R is downstream of that ledger. The real seal Q is therefore reached only through the displayed regular rational route.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no row stores quotient streams, selected limits, host equality, trichotomy, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7387.3 (Regular Cauchy sum tail-estimate real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$ *packet reaches the seal row Q only after the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, aligned* $\mathsf{StreamName}^{\uparrow}$ *tail windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegularCauchySum}^{\uparrow}$ *row, finite error ledger, and output* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row have been displayed. The route exports no quotient stream equality, selected limit, host real equality, trichotomy, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 7387.2. They force the two source rows and their aligned windows to be visible before the sum row or output readback is consumed.

Read the sum route through chapter 417. The binary sum packet supplies only the displayed pointwise-addition and finite-budget surface, so the tail estimate remains tied to D_A, D_B, S, E.

The output readback R is therefore a regular rational row over the displayed sum ledger. The real seal Q is downstream of R, while H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

No carrier coordinate supplies the excluded host or choice principles. Hence every Real-facing read of the packet is the finite route through Cauchy, RegSeqRat, DyadicRatCore, RegularCauchySum, and Real rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySumTailEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySumTailEstimate}^{\uparrow}$ packet is generated from two RegSeqRat source rows, aligned StreamName tail windows, DyadicRatCore tolerance rows, a RegularCauchySum row, a finite error ledger, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySumTailEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7387.1, Definition 7387.2, and Definition 7387.3 seed the finite L10 tail-estimate route for regular Cauchy sums.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchySumTailEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, aligned tail-window coverage, dyadic tolerance exactness, sum-ledger stability, readback handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySumTailEstimateUp.

Chapter 7388

A Concrete Naming Certificate for $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$

The $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ packet realizes the bounded observation branch of the cellular substrate reading as finite Rule 110 NameCert data. It records a local window, a bounded time depth, the selected Rule 110 update ledger, and the observed halt tag for that finite window only. It sits beside the pattern classifier of chapter 5844, the causal-cone route of chapter 5846, the local-stencil observation of chapter 6004, and the Rule 110 cellular trust substrate of chapter 6517. The packet is a bounded local observation surface, not a global halting theorem, not a universal decidability claim, and not an oracle for infinite Rule 110 evolutions.

Definition 7388.1 (Rule 110 halting-window carrier)**.** *A* $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (W, T, L, C, O, B, K, S, R, P, N)$$

with the following displayed rows:

1. *W is the finite Rule 110 row window being inspected.*
2. *T is the bounded time-depth row, giving the finite number of update steps admitted by the observation.*
3. *L is the local transition-table ledger for the Rule 110 update rule on the cells that can influence W within depth T.*
4. *C is the* $\mathsf{RuleOneTenCausalCone}^{\uparrow}$ *row naming the finite cone through which the observation is replayed.*
5. *O is the orbit-window row containing only the finite states reached before the depth bound is exhausted.*
6. *B is the boundary row recording the left and right finite context cells required by the cone.*
7. *K is the classifier row, read through* $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$ *or* $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$*, that tags the final bounded observation as halted, active, boundary-blocked, or unresolved inside the displayed window.*
8. *S records componentwise* hsame *transport for the window, depth, ledger, cone, orbit, boundary, classifier, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from the initial window through the bounded cone and classifier rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$, $\mathsf{CellularAutomaton}^{\uparrow}$, $\mathsf{RuleOneTenPatternClassifier}^{\uparrow}$, $\mathsf{RuleOneTenCausalCone}^{\uparrow}$, $\mathsf{RuleOneTenLocalStencilObservation}^{\uparrow}$, $\mathsf{Rule110CellularTrustSubstrate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RuleOneTenHaltingWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an unbounded orbit, a global halting predicate, an undecidable continuation oracle, or a hidden host-side simulation result.

Theorem 7388.2 (Rule 110 halting-window NameCert obligations)**.** *For every accepted* RuleOneTenHaltingWindow *carrier*

$$H = (W, T, L, C, O, B, K, S, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RuleOneTenHaltingWindow}^{\uparrow}}$ *surface consists exactly of finite-window admission, bounded-depth admission, local transition-table exposure, causal-cone replay, orbit-window exposure, boundary-cell exposure, classifier-tag exactness, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7388.1. The rows $W, T, L, C, O, B, K, S, R, P, N$ are the whole packet, so every obligation is attached to a displayed finite coordinate.

The local update obligation reads L only over the cells admitted by W, T, C, and B. Thus the orbit row O contains bounded states of the selected cone rather than an unbounded evolution.

The classifier row K is downstream of that bounded orbit. It may tag the finite observation as halted, active, boundary-blocked, or unresolved inside the window, but it has no row from which to decide a global halting question.

Finally, S, R, P, N transport, replay, source, and name the same finite surface. Since no carrier coordinate stores an unbounded orbit, global halting predicate, continuation oracle, or hidden simulation result, the listed obligations exhaust the local NameCert surface. □

Theorem 7388.3 (Rule 110 halting-window causal-cone route)**.** *Every accepted* $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ *observation factors through the finite causal cone*

$$W, T, L, B \longmapsto C \longmapsto O \longmapsto K$$

before its local NameCert *row is read. The route records a bounded halting-window observation for Rule 110; it does not decide whether an arbitrary Rule 110 configuration eventually halts outside the displayed window and depth.*

Proof. Begin with the finite window W and the depth row T. The local transition ledger L and boundary row B determine exactly which cells can influence the displayed observation before the bound is exhausted.

Apply the causal-cone sibling of chapter 5846. The cone row C repacks the window, depth, transition ledger, and boundary rows as a finite replay route.

The orbit row O is read only after the cone is displayed, and the classifier row K is read only after O. Thus the packet can report the bounded observation state without asserting anything about cells or times outside the carrier.

The structural rows S, R, P, N preserve this bounded route. Therefore the packet supplies a finite halting-window observation and no global halting theorem. □

Falsifiable prediction: Every accepted $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ read exposes a finite row window, a bounded time-depth row, the local Rule 110 transition ledger, a causal-cone row, boundary cells, the orbit window, a classifier tag, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a bounded halt tag is visible.

Independence witness: rule110-pattern-classifier, rule-one-ten-causal-cone, rule110-local-stencil-observation, rule110-cellular-trust-substrate, rule110-cook-frontier-budget: $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded time-depth row, causal cone, orbit window, boundary context, halt-state classifier, replay, provenance, and local naming for one finite observation packet.

The Lean TasteGate follow-up for this packet must provide Nontrivial $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ and FieldFaithful $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ instances for the displayed rows $W, T, L, C, O, B, K, S, R, P, N$ before the bounded observation can serve as a verified taste-gate consumer.

Closure status for $\mathsf{NameCert}_{\mathsf{RuleOneTenHaltingWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{RuleOneTenHaltingWindow}^{\uparrow}$ packet is generated from a finite Rule 110 row window, bounded time-depth row, local transition ledger, causal cone, orbit window, boundary context, classifier tag, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RuleOneTenHaltingWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7388.1, Definition 7388.2, and Definition 7388.3 seed bounded finite-window halting observations for Rule 110.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RuleOneTenHaltingWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global halting decidability, unbounded orbit classification, universal continuation prediction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-window admission, bounded-depth admission, transition-table exposure, causal-cone replay, orbit-window exposure, classifier exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.RuleOneTenHaltingWindowUp.

Chapter 7389

A Concrete Naming Certificate for $\mathsf{KTopology}^{\uparrow}$

Following Kelley and Munkres on point-set topology, the $\mathsf{KTopology}^{\uparrow}$ packet records the finite naming surface for the real line with the deleted-neighbourhood discipline around a distinguished closed subset K. It sits over the real order topology of chapter 1890, the neighbourhood interface of chapter 88, the observable-open handoff of $\mathsf{SierpinskiSpace}^{\uparrow}$ in chapter 1860, and the finite-window route of chapter 126. The packet names the displayed K-topology carrier only; it does not import host powersets, quotient point equality, choice over neighbourhood bases, or ambient real-line separation.

Definition 7389.1 (K-topology carrier)**.** *A* $\mathsf{KTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, D, L, O, W, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RealOrderTopology}^{\uparrow}$ *source row, naming the order-neighbourhood surface inherited from the real-line order packet.*
2. *D is the distinguished closed-subset row, recording the visible closed set K as a finite membership and boundary ledger rather than as an ambient powerset.*
3. *L is the deleted-neighbourhood ledger. A neighbourhood request at a displayed point may inspect ordinary order intervals from R and, when the request meets the distinguished row D, the ledger records the deletion of the named K-part before the open row is exported.*
4. *O is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open handoff, exposing accepted open observations as Sierpinski-valued reads instead of host predicates on points.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing the finite point, interval, boundary, and observable-open reads admitted in the present packet.*
6. *H records componentwise* hsame *transport for the real-order source, closed-subset ledger, deleted-neighbourhood ledger, observable-open handoff, finite windows, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite neighbourhood request through R, D, L, O, W, H.*
8. *P is the* Pkg *provenance over* $\mathsf{KTopology}^{\uparrow}$, $\mathsf{RealOrderTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{KTopology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host subset equality, quotient point equality, arbitrary powersets, choice-selected bases, or a completed real-line topology beyond the displayed source rows.

Theorem 7389.2 (K-topology NameCert obligations)**.** *For every accepted* $\mathsf{KTopology}^{\uparrow}$ *carrier* $K = (R, D, L, O, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the real-order topology source, distinguished closed subset, deleted-neighbourhood ledger, Sierpinski observable-open handoff, finite StreamName windows, componentwise transport, displayed continuation replay, package provenance, and local naming. A consumer may read a K-topology open observation only after those rows have been exposed from the same finite packet.*

Proof. Project the carrier of Definition 7389.1. The projection exposes the source row R, the distinguished closed-subset row D, the deleted-neighbourhood ledger L, the observable-open handoff O, the finite-window row W, and the structural rows H, C, P, N.

Read neighbourhood requests through R, D, L. Ordinary order-neighbourhood data comes from $\mathsf{RealOrderTopology}^{\uparrow}$, while any request touching the distinguished closed row must display the deletion ledger before an open observation is accepted.

The observable-open handoff O and finite-window row W then route the accepted request through $\mathsf{SierpinskiSpace}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$. This makes the open read finite and observable, not a host predicate over all real points.

Finally transport through H, replay through C, and attach P, N. Since the carrier contains no powerset coordinate, quotient point equality, choice-selected basis, or ambient real-line separation oracle, the displayed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{KTopology}^{\uparrow}$ open-observation read factors through a $\mathsf{RealOrderTopology}^{\uparrow}$ source row, a distinguished closed-subset ledger, a deleted-neighbourhood ledger, a $\mathsf{SierpinskiSpace}^{\uparrow}$ observable-open handoff, a $\mathsf{StreamName}^{\uparrow}$ finite-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: real-order-topology, topology, sierpinski-space, streamname, subspace-topology: $\mathsf{KTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a real-order source, a distinguished closed-subset row, deleted-neighbourhood routing, observable-open handoff, finite windows, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KTopology}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KTopology}^{\uparrow}$ packet is generated from a $\mathsf{RealOrderTopology}^{\uparrow}$ source row, a distinguished closed-subset ledger, deleted-neighbourhood rows, a $\mathsf{SierpinskiSpace}^{\uparrow}$ observable-open handoff, $\mathsf{StreamName}^{\uparrow}$ finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KTopology}^{\uparrow}}$, seed)

Scope closed: Definition 7389.1 and Definition 7389.2 seed the finite K-topology NameCert surface over real-order, deleted-neighbourhood, observable-open, finite-window, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KTopology}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host powersets, quotient point equality, choice-selected neighbourhood bases, ambient real-line separation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deleted-neighbourhood exactness, observable-open handoff, finite-window replay, provenance exhaustion, and TasteGate nontriviality with field faithfulness for $R, D, L, O, W, H, C, P, N$.

Chapter 7390

A Concrete Naming Certificate for $\mathsf{ProofTraceCompactness}^{\uparrow}$

The $\mathsf{ProofTraceCompactness}^{\uparrow}$ packet realizes the finite proof-trace compact replay route as NameCert data. It sits after the finite proof-trace sieve of chapter 7167, the MetaCIC proof-search frontier of chapter 4284, the critical-path packet of chapter 765, the bounded endpoint checker of chapter 752, and the normalization frontier of chapter 892. The packet records compactness only as finite replay stability over displayed trace windows; it does not claim global normalization, confluence, subject reduction, quotient equality of proof traces, or hidden oracle discharge.

Definition 7390.1 (Proof-trace compactness carrier)**.** *A* $\mathsf{ProofTraceCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, W, E, R, O, H, Q, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ *source row, listing the candidate trace table, bounded endpoint requests, discharge sockets, and obstruction rows available to the compact replay.*
2. *W is the finite trace-window cover row, naming the displayed subwindows whose replay suffices for the present consumer read.*
3. *E is the bounded endpoint row, read through* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *and the MetaCIC normalization frontier.*
4. *R is the replay compactness row, recording that every accepted consumer read factors through one of the displayed trace windows before it reaches endpoint or discharge data.*
5. *O is the obstruction retention row, preserving missing endpoint, subject-reduction, closedness, and closure-preservation sockets as visible frontier data.*
6. *H records componentwise* hsame *transport for the sieve source, trace-window cover, endpoint row, compact replay row, obstruction row, replay, provenance, and local naming rows.*
7. *Q records displayed* Cont *replay from proof-search request through S, W, E, R, O, H.*
8. *P is the* Pkg *provenance over* $\mathsf{ProofTraceCompactness}^{\uparrow}$, $\mathsf{FiniteProofTraceSieve}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofTraceCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite proof-search tree, a global normalizer, unrestricted confluence, closed subject reduction, quotient equality of traces, host equality of terms, or oracle discharge.

Theorem 7390.2 (Proof-trace compactness NameCert obligations)**.** *For every accepted* $\mathsf{ProofTraceCompactness}^{\uparrow}$ *carrier* $C = (S, W, E, R, O, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProofTraceCompactness}^{\uparrow}}$ *surface consists exactly of sieve-source admission, finite trace-window cover exposure, bounded endpoint readback, compact replay routing, obstruction retention, componentwise transport, displayed continuation replay, package provenance, and local naming. A consumer may treat a proof-trace read as compact only by displaying the finite window through which that read is replayed.*

Proof. Project the carrier of Definition 7390.1. The rows $S, W, E, R, O, H, Q, P, N$ are the only rows exposed by an accepted packet.

Read the sieve source and trace-window cover first. The source row S lists the candidate traces and sockets, while W names the finite windows that may cover the present replay request.

The endpoint and replay rows E, R are downstream of that cover. A consumer reaches bounded endpoint data only after selecting a displayed trace window, and compactness means that this finite replay route is visible in the packet.

The obstruction row O remains part of the same read. Missing endpoint, subject-reduction, closedness, or closure-preservation data is retained as frontier information rather than converted into success.

Finally H, Q, P, N transport, replay, source, and name the same finite surface. Since the carrier contains no global normalizer, confluence oracle, subject-reduction theorem, quotient trace equality, host term equality, or hidden discharge coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 7390.3 (Proof-trace compact replay route)**.** *Every accepted* $\mathsf{ProofTraceCompactness}^{\uparrow}$ *consumer read factors through the route*

$$\mathsf{FiniteProofTraceSieve}^{\uparrow},\ \mathsf{MetaCICCriticalPath}^{\uparrow},\ \mathsf{BoundedNormalEqualityChecker}^{\uparrow},\ \mathsf{MetaCICNormalizationFrontier}^{\uparrow},\ W$$

The route exports a finite trace-window replay surface and an obstruction-retaining endpoint read. It does not export global normalization, unrestricted confluence, closed subject reduction, quotient equality of proof traces, host equality of MetaCIC terms, or hidden oracle discharge.

Proof. Begin with the proof-trace sieve source. The accepted read is confined to candidate traces and discharge sockets already displayed by $\mathsf{FiniteProofTraceSieve}^{\uparrow}$.

Next inspect the finite window cover W. The compact replay row R can be read only after the consumer identifies the displayed trace window whose replay carries the present request.

Endpoint data is then read through E and the bounded normal-equality checker. Any missing endpoint or discharge row is exported through O as an obstruction, not as a completed proof.

Transport through H, replay through Q, and attach P, N. Thus the consumer receives a finite compact replay route over the displayed trace windows, with all refused global endpoints still outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{ProofTraceCompactness}^{\uparrow}$ read displays a $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ source row, a finite trace-window cover, bounded endpoint readback, compact replay routing, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a proof-search consumer may treat the read as compact.

Independence witness: finite-proof-trace-sieve, metacic-proof-search-frontier, metaciccritical-path, bounded-normal-equality-checker, metacicnormalizationfrontier: $\mathsf{ProofTraceCompactness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite trace-window cover data, compact replay routing, endpoint readback, obstruction retention, transport, replay, provenance, and local naming as one packet.

Future TasteGate discharge for $\mathsf{ProofTraceCompactness}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ ProofTraceCompactness}$ and $\mathsf{FieldFaithful\ ProofTraceCompactness}^{\uparrow}$ instances. The field-faithfulness witness must preserve $S, W, E, R, O, H, Q, P, N$ as distinct rows before any checked carrier-alignment theorem can serve as a public gate.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofTraceCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofTraceCompactness}^{\uparrow}$ packet is generated from a $\mathsf{FiniteProofTraceSieve}^{\uparrow}$ source row, finite trace-window cover rows, bounded endpoint readbacks, compact replay routing, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofTraceCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7390.1, Definition 7390.2, and Definition 7390.3 seed the finite proof-trace compact replay surface over displayed trace windows, endpoint rows, obstruction retention, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofTraceCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global normalization, unrestricted confluence, closed subject reduction, quotient trace equality, host term equality, hidden oracle discharge, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite trace-window cover exactness, compact replay routing, obstruction retention, and TasteGate nontriviality with field faithfulness for $S, W, E, R, O, H, Q, P, N$.

Chapter 7391

A Concrete Naming Certificate for $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$ packet records the finite service that refines located rational interval cells into dyadic readback windows and regular-Cauchy request rows. It sits between the located-cell surface of chapter 394, the rational and dyadic interval rows of chapter 354 and chapter 291, and the regular-Cauchy consumer of chapter 301. The packet is a readback service, not a quotient real construction, a selected endpoint operator, a trichotomy principle, or an ambient completeness assumption.

Definition 7391.1 (Bishop located interval refinement carrier)**.** *A* $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, Q, D, S, G, A, H, C, P, N)$$

with the following rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, containing the displayed interval cell, locatedness witness, and finite request boundary.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *endpoint ledger read from the same displayed cell. It records rational lower and upper witnesses only as named rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger. It supplies dyadic subcells, midpoint rows, and positive dyadic radii used by finite readback.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule row. It lists the finite observation windows through which downstream names ask for interval refinement.*
5. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy handoff row. It records the finite modulus requests and tail windows accepted by the regular sequence consumer.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row. It exposes only the real-name boundary used to certify that the handoff is a readback of the same located interval packet.*
7. *H records componentwise* hsame *transport for $L, Q, D, S, G, A, C, P, N$.*
8. *C records displayed* Cont *replay of the finite route*

$$L, Q \longmapsto D \longmapsto S, G \longmapsto A.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}}$ *row.*

The classifier of an accepted packet compares only the displayed rows above. It contains no coordinate for quotient reals, selected endpoints, trichotomy, arbitrary choice of nested cells, or ambient completeness.

Theorem 7391.2 (Bishop located interval refinement NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$ *carrier*

$$R = (L, Q, D, S, G, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval source, rational interval ledger, dyadic refinement ledger, stream request schedule, regular-Cauchy handoff, real seal, transport, replay, provenance, and local naming rows;*
2. *endpoint readback, requiring each rational endpoint row in Q to be read through the located interval cell L rather than through a selected host endpoint;*
3. *dyadic refinement, requiring every finite subcell read to pass through the dyadic ledger D before it reaches a stream or regular-Cauchy consumer;*
4. *request compatibility, requiring the schedule row S and the regular-Cauchy row G to expose the same finite tolerance windows;*
5. *nonescape, requiring downstream Real, stream, dyadic, and regular-Cauchy consumers to read only $L, Q, D, S, G, A, H, C, P, N$.*

No BishopLocatedIntervalRefinement obligation is stored outside these rows.

Proof. Project the carrier of Definition 7391.1. The displayed tuple contains the located source cell, rational endpoint ledger, dyadic refinement ledger, stream schedule, regular-Cauchy handoff, real seal, and structural rows.

Endpoint readback uses L and Q. The rational endpoint rows are named observations of the located cell, so no host endpoint is selected and no trichotomy branch is imported.

Dyadic refinement is mediated by D. Each finite subcell and radius read passes through the dyadic ledger before S or G may inspect it.

Finally compare the request rows S and G through H and replay them through C. Provenance and local naming are restricted to P and N, so downstream consumers cannot extract quotient reals, selected endpoints, arbitrary nested-cell choice, or ambient completeness from the packet. □

Theorem 7391.3 (Bishop located interval refinement Cauchy route)**.** *Let*

$$R = (L, Q, D, S, G, A, H, C, P, N)$$

be an accepted $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$ *carrier. Every finite readback from a located interval cell to a regular-Cauchy request factors through*

$$L, Q \longmapsto D \longmapsto S, G \longmapsto A, H, C, P, N.$$

Thus the route converts located interval evidence into dyadic and regular-Cauchy finite obligations over $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$, *without importing quotient real equality, selected endpoints, trichotomy, or ambient completeness.*

Proof. Start with the located interval source row L and rational endpoint ledger Q. They display the cell to be refined and the rational boundary observations consumed by the finite route.

Apply the dyadic ledger row D. It refines the displayed rational cell into dyadic subcells and radius rows, giving the finite windows read by the stream schedule S.

Use the regular-Cauchy handoff row G together with the real seal A. The handoff exports only finite modulus requests and tail windows, and the seal records that these requests read the same displayed source rather than a quotient real.

The rows H, C, P, N transport, replay, package, and name exactly this chain. Since no other coordinate is present, the readback cannot select endpoints, invoke trichotomy, identify quotient reals, or assume ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7391.1, Definition 7391.2, and Definition 7391.3 define the finite located-interval refinement service and its dyadic and regular-Cauchy readback obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, selected endpoints, trichotomy, arbitrary nested-cell choice, ambient completeness, Lean verification, or standard bridge closure.

Upgrade path: Scoped closure requires a Lean-backed carrier and obligation theorem for BEDC.Derived.BishopLocatedIntervalRefinement

Constructive story: A $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$ packet is generated from a LocatedInterval source row, RationalInterval endpoint ledger, DyadicRatCore refinement ledger, StreamName request schedule, RegSeqRat handoff, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Chapter 7392

A Concrete Naming Certificate for $\mathsf{CauchySeparableCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchySeparableCompletion}^{\uparrow}$ packet records the constructive completion route in which a countable dense boundary, finite dyadic tolerances, stream windows, and regular Cauchy readback are assembled before the terminal Real seal is visible. It consumes the separability witness of chapter 1809, the finite-window discipline of chapter 126, the regular rational readback of chapter 301, the completion boundary of chapter 1506, and the terminal real-name seal of chapter 38. The chapter gives the L10 Real and Completion route a single human-known NameCert packet rather than separate density and completion fragments.

Definition 7392.1 (Cauchy separable completion carrier)**.** *A* $\mathsf{CauchySeparableCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, T, W, R, C, E, H, K, P, N)$$

with the following displayed rows:

1. *D is the dense enumeration row, naming the countable dense source exposed by* $\mathsf{RealSeparability}^{\uparrow}$*.*
2. *T is the dyadic tolerance row, recording the finite precision requests used to compare dense approximants.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing exactly the stream fragments inspected for the displayed tolerance requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row, repacking the inspected windows as a regular Cauchy handoff.*
5. *C is the regular Cauchy handoff row consumed by the* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary.*
6. *E is the completion seal, visible only after D, T, W, R, C have been displayed.*
7. *H is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the completion seal and not from a host equality of completed names.*
8. *K records componentwise* hsame *transport and displayed* Cont *replay for the dense enumeration, tolerance, window, regular readback, completion seal, and Real seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchySeparableCompletion}^{\uparrow}$*,* $\mathsf{RealSeparability}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySeparableCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, T, W, R, C, E, H, K, P, N$. It has no coordinate for quotient streams, selected dense points, chosen limits, host equality, countable choice, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) `BEDC.Derived.CauchySeparableCompletionUp`

Theorem 7392.2 (Cauchy separable completion NameCert obligations)**.** *For every accepted* CauchySeparableComp *carrier*

$$Q = (D, T, W, R, C, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySeparableCompletion}^{\uparrow}}$ *surface consists exactly of dense enumeration admission, dyadic tolerance accounting, stream-window inspection, regular rational readback, regular Cauchy handoff, completion-seal discipline, Real-seal routing, componentwise transport and replay, provenance, and local naming. Every completion-facing consumer must read the displayed route*

$$\mathsf{RealSeparability}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before it may export the completed real-name boundary.

Proof. Project the carrier of Definition 7392.1. The projection exposes the dense enumeration row, dyadic tolerance row, stream windows, regular rational readback, regular Cauchy handoff, completion seal, Real seal, and structural rows.

The route is finite at each consumer request. The dense row D supplies only the displayed enumeration boundary, while T supplies the finite tolerance budget used to inspect the requested approximants.

The stream and regular rows then determine the handoff surface. The window row W records the inspected fragments, and R repacks them as the regular Cauchy readback consumed by C.

Finally E and H are exposed only after that handoff, and K, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient streams, selected dense points, chosen limits, host equality, countable choice, open-cover compactness, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7392.3 (Cauchy separable completion dense regular handoff)**.** *Every accepted* CauchySeparableCompletio *packet hands a completion-facing consumer from the dense enumeration row D to the* $\mathsf{MetricCompletion}^{\uparrow}$ *seal only through the dyadic tolerance row T, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row R. The handoff supplies a displayed regular Cauchy boundary; it does not supply a selected dense point, a quotient stream, a chosen limit, or host equality of completed names.*

Proof. Begin with the NameCert obligations of Definition 7392.2. They order every completion-facing read through the dense enumeration, tolerance, stream-window, regular readback, and handoff rows before the completion seal is available.

The dense row is only an enumeration boundary. A consumer may request finite approximants from D, but those requests are interpreted through the dyadic budget T and the stream windows W.

The regular Cauchy handoff is therefore the row R together with its continuation into C. No selected dense point or quotient stream is present in the carrier, so the completion-facing consumer receives exactly the displayed regular route. □

Theorem 7392.4 (Cauchy separable completion no-choice boundary)**.** *No accepted* $\mathsf{CauchySeparableCompletion}^{\uparrow}$ *carrier exports Real completeness, open-cover compactness, quotient streams, selected dense points, host equality of completed names, or countable choice. Any Real-facing read must factor through the dense enumeration row, dyadic tolerance row, stream-window row, regular Cauchy handoff, completion seal, Real seal, transport and replay row, provenance row, and local NameCert row displayed in Definition 7392.1.*

Proof. Use Definition 7392.3. It forces every completion-facing read through D, T, W, R, C before the completion seal can be inspected.

The Real-facing seal adds no new analytic principle. It is the row H reached after E, with K transporting and replaying only the same finite dependency surface.

Thus the excluded principles are absent by carrier projection. The packet records separable completion data as finite NameCert rows and not as a choice principle, quotient construction, open-cover theorem, host equality, or ambient completeness assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySeparableCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchySeparableCompletion}^{\uparrow}$ packet is generated from a dense enumeration row, dyadic tolerance row, StreamName windows, RegSeqRat regular readback, regular Cauchy handoff, completion seal, Real seal, componentwise hsame transport and Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySeparableCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7392.1, Definition 7392.2, Definition 7392.3, and Definition 7392.4 seed the finite separable-completion route over RealSeparabilityUp, StreamNameUp, RegSeqRatUp, MetricCompletionUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchySeparableCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, open-cover compactness, quotient streams, selected dense points, host equality of completed names, countable choice, Lean theorem verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove dense enumeration admission, dyadic tolerance accounting, stream-window inspection, regular Cauchy handoff, completion-seal discipline, Real-seal routing, transport, replay, provenance, and ledger non-escape.

Chapter 7393

A Concrete Naming Certificate for $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$ packet records the finite regular-Cauchy squeeze route by which a middle rational name is trapped between lower and upper regular rational names before a terminal Real-facing seal is exposed. It sits over the dyadic arithmetic core of chapter 291, the finite observation rows of chapter 126, the regular rational sequence surface of chapter 301, and the completed real-name seal of chapter 38. The certificate is a displayed sandwich-limit route for Phase Real and Completion consumers; it does not assert quotient real equality, choose a host limit, use countable choice, or invoke ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7393.1 (Regular-Cauchy sandwich-limit carrier)**.** *A* $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, M, U, B, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{RegSeqRat}^{\uparrow}$ *row, read through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and monotone lower-side rational observations.*
2. *M is the middle* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose Real-facing read is to be certified by the sandwich route.*
3. *U is the upper* $\mathsf{RegSeqRat}^{\uparrow}$ *row, read through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and monotone upper-side rational observations.*
4. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *two-sided bound ledger recording, for each inspected tolerance cell, the lower–middle and middle–upper inequalities and the dyadic width budget between L and U.*
5. *S is the squeeze-to-*$\mathsf{Real}^{\uparrow}$ *seal row, exposing the terminal real-name boundary only after L, M, U and B have been read.*
6. *H records componentwise* hsame *transport for the three regular-Cauchy rows, the dyadic bound ledger, the seal row, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay for rereading the sandwich request through the same finite observation windows and dyadic tolerance cells.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySandwichLimit}^{\uparrow}}$ *row naming exactly this finite packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected representatives, a host least upper bound, countable choice, trichotomy, or ambient Real completeness.

Theorem 7393.2 (Regular-Cauchy sandwich-limit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$ *carrier* $K = (L, M, U, B, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySandwichLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower, middle, and upper* $\mathsf{RegSeqRat}^{\uparrow}$ *rows; exposure of the finite* $\mathsf{StreamName}^{\uparrow}$ *windows used by those rows; visibility of the* $\mathsf{DyadicRatCore}^{\uparrow}$ *two-sided bound ledger; squeeze-to-*$\mathsf{Real}^{\uparrow}$ *seal exposure; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; and local naming. No obligation may replace these rows by quotient real equality, a selected limit, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7393.1. The only analytic rows available to a consumer are the three regular rational rows L, M, U, the dyadic bound ledger B, and the terminal seal S.

The obligation surface is rowwise. The lower and upper rows supply the bounding regular-Cauchy names, the middle row supplies the candidate read, and B supplies the two-sided dyadic inequalities at the inspected tolerance. The seal row S is therefore available only after those rows have been displayed.

The structural rows H, C, P, N transport, replay, source, and name precisely the same finite packet. Since the carrier contains no quotient equality, selected limit, countable-choice selector, trichotomy branch, or ambient completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7393.3 (Regular-Cauchy sandwich-limit squeeze route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of the middle row* M *in an accepted* $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$ *packet factors through the two bounding* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* L, U *and the dyadic tolerance ledger* B *before the seal row* S *is available. The route reads lower–middle and middle–upper comparison cells at the same displayed precision and then exports the terminal* $\mathsf{Real}^{\uparrow}$ *seal as finite BEDC data, not as a host-limit assertion.*

Proof. Start with the accepted packet $K = (L, M, U, B, S, H, C, P, N)$. A middle read is not independent carrier data: it is the row M inside the same packet that also contains lower and upper regular-Cauchy rows.

Next inspect the ledger B. For each visible tolerance cell, B records the lower–middle comparison, the middle–upper comparison, and the dyadic width budget between L and U. Thus a consumer cannot reach the middle Real-facing read without seeing both bounding rows and the same tolerance ledger.

Finally read S through H, C, P, N. Transport and replay keep the same sandwich route visible when the terminal seal is consumed, and provenance and local naming record that no selected host limit, quotient stream equality, countable choice, trichotomy, or ambient completeness principle has been added. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySandwichLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySandwichLimit}^{\uparrow}$ packet is generated from lower, middle, and upper RegSeqRat rows, finite StreamName windows, a DyadicRatCore two-sided bound ledger, a squeeze-to-Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySandwichLimit}^{\uparrow}}$, seed)

Scope closed: Definition 7393.1, Definition 7393.2, and Definition 7393.3 seed the finite sandwich-limit certificate over lower, middle, and upper regular-Cauchy rows, dyadic tolerance cells, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySandwichLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, trichotomy, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper regular-Cauchy exposure, middle-row readback, dyadic two-sided bound visibility, squeeze-to-Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySandwichLimitUp.

Chapter 7394

A Concrete Naming Certificate for $\mathsf{MiddleThirdCantorSet}^{\uparrow}$

Following Cantor and Bishop–Bridges constructive analysis, the $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ packet records the middle-third Cantor subset of the real line as finite ternary-stage NameCert data. It reads the binary prefix discipline of $\mathsf{CantorSpace}^{\uparrow}$ through chapter 1475, the compact finite-prefix surface of $\mathsf{CantorSpaceCompactness}^{\uparrow}$ through chapter 3798, the rational endpoint arithmetic of $\mathsf{Rat}^{\uparrow}$ through chapter 37, the finite observation schedule of $\mathsf{StreamName}^{\uparrow}$ through chapter 126, the regular rational readback of $\mathsf{RegSeqRat}^{\uparrow}$ through chapter 301, and the terminal real-name seal of $\mathsf{Real}^{\uparrow}$ through chapter 38. The carrier names only finite retained-third prefixes, finite deleted-gap ledgers, regular rational endpoints, stream windows, transport, replay, provenance, and local naming; it does not import host subsets, quotient real equality, selected infinite branches, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7394.1 (Middle-third Cantor set carrier)**.** *A* $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (B, T, G, Q, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CantorSpace}^{\uparrow}$ *prefix row, recording the finite binary choices that are translated into retained left-third and right-third ternary stages.*
2. *T is the finite ternary-stage ledger, listing the retained closed intervals visible at the inspected depths.*
3. *G is the deleted-middle gap ledger, listing exactly the middle-third intervals removed before the displayed retained stages are read.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *endpoint row, giving rational endpoints for every retained interval and deleted gap named by T and G.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule that bounds which stage numbers, prefix positions, and endpoint rows a consumer may inspect.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the displayed nested endpoint approximations toward a real-name consumer.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite prefix, gap, endpoint, stream, and regular-rational rows have been displayed.*

8. *H stores componentwise* hsame *transport for the Cantor prefix row, ternary-stage ledger, deleted-gap ledger, rational endpoints, stream schedule, regular-rational readback, Real seal, replay route, provenance, and local naming.*
9. *K is the displayed* Cont *replay route from finite Cantor prefixes to retained ternary stages, from retained stages to endpoint rows, and from endpoint rows to the regular-rational and Real-facing handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{MiddleThirdCantorSet}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{CantorSpaceCompactness}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MiddleThirdCantorSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a host subset of the real line, quotient equality of real names, an infinite branch selector, an open-cover compactness theorem, or ambient real completeness.

Theorem 7394.2 (Middle-third Cantor set NameCert obligations)**.** *For every accepted* $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ *carrier*

$$C = (B, T, G, Q, S, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MiddleThirdCantorSet}^{\uparrow}}$ *surface consists exactly of carrier admission, finite Cantor-prefix translation, retained ternary-stage visibility, deleted-middle gap exclusion, rational endpoint exactness, StreamName schedule discipline, regular-rational readback, Real seal handoff, componentwise transport, continuation replay, provenance, and finite-stage nonescape. Every obligation is read through*

$$B, T, G, Q, S, R, E, H, K, P, N$$

and through no additional host-level membership or compactness coordinate.

Proof. Carrier admission is projection of Definition 7394.1. The rows B, T, G expose the finite Cantor prefix, the retained ternary-stage ledger, and the deleted-middle ledger before any endpoint or Real-facing read is available.

Endpoint exactness is then forced by Q. Each retained interval and each deleted gap named by T or G receives rational endpoints in the same displayed packet, so the consumer cannot replace the finite ternary-stage route by a host subset of $\mathsf{Real}^{\uparrow}$.

The observation and readback obligations are S, R, E. The StreamName row S bounds the visible stages, the regular-rational row R records the endpoint approximations, and the Real row E is reached only after those finite rows have been consumed.

Finally H, K, P, N preserve, replay, source, and locally name the same route. Since no displayed row contains quotient real equality, selected infinite branches, open-cover compactness, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7394.3 (Middle-third Cantor set finite-stage nonescape)**.** *Every Real-facing read of an accepted* $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ *carrier factors through the finite route*

$$B, S \longmapsto T \longmapsto G \longmapsto Q \longmapsto R \longmapsto E \longmapsto H, K, P, N.$$

The route exports a finite retained-stage and deleted-gap certificate over rational endpoint rows. It exports no host subset membership predicate, no quotient equality of real names, no selected infinite branch, no open-cover compactness principle, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Start with a Real-facing consumer. The only available stage request is the $\mathsf{StreamName}^{\uparrow}$ schedule S applied to the finite $\mathsf{CantorSpace}^{\uparrow}$ prefix row B, so the consumer sees finitely many binary choices rather than an infinite branch.

Read the ternary-stage rows next. The retained intervals in T and the deleted gaps in G are displayed together, and the rational endpoint row Q gives the finite endpoint data attached to those rows.

Only after that endpoint data is visible may the packet expose R and E. The $\mathsf{RegSeqRat}^{\uparrow}$ readback R carries the displayed endpoint approximations, and the $\mathsf{Real}^{\uparrow}$ seal E is the terminal row of that same finite route.

The structural rows H, K, P, N cannot add omitted host principles; they transport, replay, source, and name the route already displayed. Thus the Real-facing handoff remains a finite-stage middle-third Cantor certificate. □

Falsifiable prediction: Every accepted $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ Real-facing read exposes finite Cantor prefixes, retained ternary stages, deleted-middle gaps, rational endpoints, StreamName schedules, RegSeqRat readbacks, Real seals, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any membership-shaped output is available.

Independence witness: cantorspace, cantor-space-compactness, rat, streamname, regseqrat, real: $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Cantor-prefix translation, retained ternary-stage ledgers, deleted-middle gap rows, rational endpoint exactness, finite observation schedules, regular-rational readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MiddleThirdCantorSet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MiddleThirdCantorSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7394.1, Definition 7394.2, and Definition 7394.3 seed the finite ternary-stage route over $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{CantorSpaceCompactness}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MiddleThirdCantorSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim Lean verification, bridge checking, host subset membership, quotient equality of real names, selected infinite branches, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix translation, retained-stage visibility, deleted-gap exclusion, rational endpoint exactness, StreamName schedule discipline, regular-rational readback, Real seal handoff, and nonescape under BEDC.Derived.MiddleThirdCantorSetUp.

Constructive story: A $\mathsf{MiddleThirdCantorSet}^{\uparrow}$ packet is generated from finite Cantor-prefix choices, retained ternary-stage rows, deleted-middle gap rows, rational endpoints, StreamName schedules, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Chapter 7395

A Concrete Naming Certificate for $\mathsf{FrechetFilterCompletion}^{\uparrow}$

Following Frechet, Bourbaki, Kelley, and Bishop–Bridges, the $\mathsf{FrechetFilterCompletion}^{\uparrow}$ packet records the L10 completion frontier where cofinite-tail filter data is read as a completion-facing Cauchy filter without selecting a completed point. It sits after the cofinite-tail filter surface of chapter 1564, the completion consumer of chapter 1569, the sequential route of chapter 3958, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only displayed Frechet-tail, Cauchy-filter, sequential-completion, window, readback, seal, transport, replay, provenance, and local certificate rows; it does not assert quotient filter equality, a selected limit, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7395.1 (Frechet filter completion carrier)**.** *A* $\mathsf{FrechetFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, Q, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite-tail row whose threshold and finite-complement data must be consumed first.*
2. *Q is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-facing row that receives the displayed filter route.*
3. *S is the* $\mathsf{MetricSequentialCompletion}^{\uparrow}$ *handoff row by which sequential completion consumers read the same cofinite-tail route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule opened for tail and completion requests.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, Q, S, W, R have been replayed.*
7. *H records componentwise* hsame *transport for the Frechet filter, Cauchy-filter completion, sequential-completion handoff, windows, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion request through the cofinite-tail filter, Cauchy-filter completion row, sequential handoff, finite windows, regular readback, and real seal.*
9. *P records* Pkg *provenance over* $\mathsf{FrechetFilterCompletion}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{MetricSequentialCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FrechetFilterCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $F, Q, S, W, R, E, H, C, P, N$. It has no coordinate for quotient filters, selected completion points, countable-choice tail selection, host equality of completed objects, or ambient real completeness.

Theorem 7395.2 (Frechet filter completion NameCert obligations)**.** *For every accepted* $\mathsf{FrechetFilterCompletion}^{\uparrow}$ *carrier*

$$G = (F, Q, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetFilterCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Frechet filter row, Cauchy-filter completion row, metric sequential-completion handoff, StreamName window schedule, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming row. Every completion-facing obligation is read through those rows and no obligation is stored in quotient filter equality, selected limits, countable choice, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 7395.1. The tuple displays the Frechet filter source, the Cauchy-filter completion consumer, the sequential-completion handoff, the window schedule, the regular rational readback, the terminal real seal, and the structural rows.

The filter side is exhausted by F and Q. The Frechet row exposes only cofinite-tail threshold and finite-complement data, and the Cauchy-filter completion row receives that displayed route without adding a quotient filter or selected completion point.

The sequential and real-name side is exhausted by S, W, R, E. The sequential handoff reads the same cofinite-tail route, the finite windows in W schedule the requested observations, the regular rational row R is read from those windows, and the real seal E appears only after the readback row has been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is present, the excluded quotient, selector, choice, host-equality, and ambient-completeness data cannot become NameCert obligations. □

Theorem 7395.3 (Frechet filter completion Cauchy handoff)**.** *Every* $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{MetricSequentialCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetFilterCompletion}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{CauchyFilterCompletion}^{\uparrow} \longmapsto \mathsf{MetricSequentialCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

The route carries a cofinite-tail filter into the completion frontier as displayed data only. It exports no quotient filter, selected limit, countable-choice tail selector, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7395.2. It fixes the public completion surface at the rows $F, Q, S, W, R, E, H, C, P, N$.

Read the Frechet and Cauchy-filter rows first. The cofinite-tail row F supplies the finite threshold and tail-neighborhood information, and the completion row Q receives exactly that displayed filter route.

Next read the sequential-completion and real-name rows. The handoff row S presents the same route to sequential completion consumers, W schedules the finite observations, R supplies the regular rational readback, and E seals the route for real-facing consumers.

The structural rows keep the handoff confined to the displayed packet. Therefore a consumer that reaches the completion or real boundary without the stated route is not reading the accepted $\mathsf{FrechetFilterCompletion}^{\uparrow}$ carrier. □

Falsifiable prediction: Every accepted $\mathsf{FrechetFilterCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the $\mathsf{FrechetFilter}^{\uparrow}$ cofinite-tail row, the $\mathsf{CauchyFilterCompletion}^{\uparrow}$ completion row, the $\mathsf{MetricSequentialCompletion}^{\uparrow}$ handoff, the $\mathsf{StreamName}^{\uparrow}$ finite windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: frechetfilter, cauchyfiltercompletion, metric-sequential-completion, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{FrechetFilterCompletion}^{\uparrow}$ because this packet binds the cofinite-tail filter source, Cauchy-filter completion consumer, sequential-completion handoff, finite window schedule, regular rational readback, real seal, transport, replay, provenance, and local naming as one L10 completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetFilterCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetFilterCompletion}^{\uparrow}$ packet is generated from a FrechetFilterUp cofinite-tail row, CauchyFilterCompletionUp completion row, MetricSequentialCompletionUp handoff, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetFilterCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7395.1, Definition 7395.2, and Definition 7395.3 seed the L10 Frechet filter completion route over FrechetFilterUp, CauchyFilterCompletionUp, MetricSequentialCompletionUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetFilterCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable-choice tail selectors, host equality of completed points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove Frechet-tail admission, Cauchy-filter completion exposure, sequential-completion handoff, window scheduling, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and ledger nonescape for BEDC.Derived.FrechetFilterCompletionUp.

Chapter 7396

A Concrete Naming Certificate for $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$

Following Dedekind and Bishop–Bridges constructive analysis, the $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$ packet records the finite boundary data through which located cut-style order-completion requests may be read before any ambient completeness theorem for $\mathsf{Real}^{\uparrow}$ is available. It sits after the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dense Real route of chapter 1809. The packet is a constructive boundary object for order-completion data, not a Dedekind-cut quotient completion or a proof that $\mathsf{Real}^{\uparrow}$ is complete.

Definition 7396.1 (Real order-completion boundary carrier)**.** *A* $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, U, D, S, R, E, H, C, P, N)$$

with the following rows:

1. *L is the located lower rational-cut row. It records finite rational lower witnesses and located comparison requests.*
2. *U is the located upper rational-cut row. It records finite rational upper witnesses and the displayed separation boundary from L.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket-window ledger. It stores dyadic lower and upper brackets, positive dyadic widths, and the finite refinement cells used by order reads.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It lists the finite requests through which a consumer asks for bracket refinement.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational approximants obtained from the displayed brackets and stream windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after L, U, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for $L, U, D, S, R, E, C, P, N$.*
8. *C records displayed* Cont *replay of the finite route*

$$L, U \longmapsto D \longmapsto S, R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealOrderCompletionBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed located cut rows, dyadic bracket windows, finite observations, regular readback rows, terminal Real seals, transport, replay, provenance, and local names. It has no coordinate for Dedekind-cut completeness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, quotient real equality, or choice-selected suprema.*

Lean4 ✓ `BEDC.Derived.RealOrderCompletionBoundaryUp.RealOrderCompletionBoundaryTasteGate single carrier alignment`

Theorem 7396.2 (Real order-completion boundary obligations)**.** *For every accepted* $\mathsf{RealOrderCompletionBoundary}$ *carrier*

$$B = (L, U, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealOrderCompletionBoundary}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located lower row, located upper row, dyadic bracket ledger, finite stream observations, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *located cut exposure, requiring every order request to read both L and U before it may inspect a bracket window;*
3. *dyadic bracket refinement, requiring every finite order window to pass through D before it reaches* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*;*
4. *readback compatibility, requiring S and R to expose the same finite tolerance windows before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is available;*
5. *nonescape, requiring downstream Real, separability, stream, regular-sequence, and dyadic consumers to read only $L, U, D, S, R, E, H, C, P, N$.*

No $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$ *obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7396.1. The displayed tuple contains the located lower and upper cut rows, dyadic bracket ledger, finite stream observations, regular rational readback, terminal Real seal, and structural rows.

The located cut exposure obligation uses L and U together. A consumer cannot turn one side into a selected supremum or a trichotomy branch because the packet only displays finite lower and upper witnesses.

The dyadic bracket obligation uses D before any stream or regular-rational read. Thus every finite order-completion request is mediated by the same dyadic window route that already governs chapter 291, chapter 126, and chapter 301.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for Dedekind-cut completeness, ambient Real completeness, trichotomy, quotient real equality, or choice-selected suprema, the obligation surface is exactly the displayed boundary. □

Theorem 7396.3 (Real order-completion located supremum window)**.** *Every located supremum read admitted by an accepted* $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$ *carrier factors through the finite window*

$$L, U \longmapsto D \longmapsto S, R \longmapsto E, H, C, P, N.$$

The read may use located rational-cut rows, dyadic bracket windows, finite $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. It may not infer Dedekind-cut completeness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, trichotomy, quotient real equality, or a choice-selected supremum.*

Proof. Start with the located rows L and U. They expose the lower and upper rational-cut evidence as finite rows rather than as a completed cut quotient.

Read the dyadic bracket ledger D next. Its finite brackets and positive widths are the only windows through which the order-completion request can be refined.

Pass from D to S and R. The finite stream observations determine which regular rational approximants are read back, and the terminal Real seal E is visible only after those rows have been displayed.

The support rows H, C, P, N preserve, replay, source, and name this route. Hence the located supremum window is a boundary certificate over finite BEDC rows, not a proof of Dedekind-cut completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient real equality, or choice-selected suprema. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOrderCompletionBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealOrderCompletionBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7396.1, Definition 7396.2, and Definition 7396.3 seed the finite located order-completion boundary over rational-cut rows, dyadic bracket windows, stream observations, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealOrderCompletionBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient real equality, choice-selected suprema, Lean verification, or standard bridge closure.

Upgrade path: Scoped closure requires a Lean-backed carrier and obligation theorem for BEDC.Derived.RealOrderCompletionBoundaryUp

Constructive story: A $\mathsf{RealOrderCompletionBoundary}^{\uparrow}$ packet is generated from located lower and upper rational-cut rows, dyadic bracket windows, finite StreamName observations, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7397

A Concrete Naming Certificate for $\mathsf{RapidlyCauchySequence}^{\uparrow}$

Following Bishop and Bridges on constructive real names with explicit rates, the $\mathsf{RapidlyCauchySequence}^{\uparrow}$ packet records the fixed dyadic-rate sibling of $\mathsf{FastCauchySequence}^{\uparrow}$ as finite BEDC NameCert data. It sits on the Real and Completion route through the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names the special schedule 2^{-n} directly; it is not a quotient stream, a chosen limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7397.1 (Rapidly Cauchy sequence carrier)**.** *A* $\mathsf{RapidlyCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which the sequence is inspected.*
2. *D is the fixed* $\mathsf{DyadicRatCore}^{\uparrow}$ *row for the dyadic tolerance schedule $n \mapsto 2^{-n}$, including the finite radius and comparison rows read at each displayed window.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from the same stream windows and dyadic tolerance rows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, R have been displayed.*
5. *H records componentwise* hsame *transport for the stream schedule, dyadic schedule, regular readback, seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from every finite precision request through S, D, R, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{RapidlyCauchySequence}^{\uparrow}$, $\mathsf{FastCauchySequence}^{\uparrow}$, $\mathsf{FastCauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RapidlyCauchySequence}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary modulus, quotient stream equality, selected limits, countable-choice schedules, host real equality, or a detached completeness principle.

Theorem 7397.2 (Rapidly Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{RapidlyCauchySequence}^{\uparrow}$ *carrier $K = (S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RapidlyCauchySequence}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed stream schedule, fixed dyadic-rate ledger, regular rational readback, Real seal, transport, replay, provenance, and local name;*
2. *fixed-rate discipline, requiring every precision request to read the dyadic schedule row D for the tolerance 2^{-n} before R or E may be consumed;*
3. *StreamName-to-RegSeqRat readback, requiring S and D to determine the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R without an arbitrary modulus parameter;*
4. *Real-seal terminality, requiring E to remain downstream of S, D, R and to export no completed host real;*
5. *ledger nonescape, requiring H, C, P, N to preserve only the displayed packet rows and no quotient stream, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate.*

No NameCert obligation is stored outside those rows.

Proof. Carrier admission is projection from Definition 7397.1. The packet displays exactly the stream windows, fixed dyadic-rate ledger, regular readback, Real seal, transport, replay, provenance, and local name.

For fixed-rate discipline, read a precision request. The only tolerance row in the packet is D, so the request must use the dyadic schedule 2^{-n} before the regular readback R or seal row E can be reached.

The readback obligation follows by the same route. The stream windows S and the dyadic ledger D are the only sources for R, and the structural rows H, C, P, N preserve that route componentwise.

Finally, the excluded coordinates are absent from the carrier. Since K has no arbitrary modulus row, quotient-stream coordinate, choice schedule, selected limit, host equality, or completeness witness, no local NameCert obligation can read one. □

Theorem 7397.3 (Rapidly Cauchy dyadic schedule nonescape)**.** *Every consumer of an accepted* $\mathsf{RapidlyCauchySequence}^{\uparrow}$ *carrier $K = (S, D, R, E, H, C, P, N)$ must read the same displayed route*

$$S \longrightarrow D \longrightarrow R \longrightarrow E$$

with structural support from H, C, P, N. Hence the consumer cannot replace the fixed dyadic schedule by quotient stream equality, a selected limit, a countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7397.1. A downstream read sees only the finite stream schedule S, the dyadic tolerance ledger D, the regular readback R, the seal row E, and the structural rows H, C, P, N.

Apply the obligation surface of Definition 7397.2. Its fixed-rate and readback clauses require every precision request to pass through D before R or E can be consumed.

The nonescape conclusion is then immediate by absence of coordinates. None of the listed forbidden principles is a row of K, and the transport, replay, provenance, and local name rows preserve only the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{RapidlyCauchySequence}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ read without the displayed $\mathsf{StreamName}^{\uparrow}$ schedule and fixed $\mathsf{DyadicRatCore}^{\uparrow}$ dyadic-rate row refutes the carrier surface.

Independence witness: fastcauchysequence, fastcauchymodulus, streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole eight-row packet $K = (S, D, R, E, H, C, P, N)$, because this chapter binds the fixed 2^{-n} schedule, finite stream windows, regular readback, seal, transport, replay, provenance, and local naming as one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RapidlyCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RapidlyCauchySequence}^{\uparrow}$ packet is generated from a finite $\mathsf{StreamName}^{\uparrow}$ schedule, a fixed $\mathsf{DyadicRatCore}^{\uparrow}$ dyadic-rate ledger for 2^{-n}, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RapidlyCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7397.1, Definition 7397.2, and Definition 7397.3 seed the fixed dyadic-rate NameCert surface for rapidly Cauchy sequence packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RapidlyCauchySequence}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.RapidlyCauchySequenceUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, arbitrary moduli, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fixed-rate discipline, StreamName-to-RegSeqRat readback, Real-seal terminality, transport, replay, provenance, and local naming for the same displayed packet.

Lean4 (statement) `BEDC.Derived.RapidlyCauchySequenceUp`

Chapter 7398

A Concrete Naming Certificate for $\mathsf{BishopRealRegularCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealRegularCompletion}^{\uparrow}$ packet records the regular completion route for rational names as finite BEDC data. It reads dyadic tolerance arithmetic from chapter 291, finite observation windows from chapter 126, regular rational readback from chapter 301, effective tail schedules from chapter 415, and the terminal real-name seal from chapter 38. The packet names a finite means of completion; it does not identify quotient streams, select limits, use countable choice, assert host real equality, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7398.1 (Bishop real regular completion carrier)**.** *A* $\mathsf{BishopRealRegularCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic cells used to compare rational observations.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface for the inspected rational name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row obtained from those windows.*
4. *M is the* $\mathsf{CauchyRate}^{\uparrow}$ *effective tail schedule that bounds all admitted completion requests.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after D, S, R, M have been displayed.*
6. *H records componentwise* hsame *transport for the tolerance, window, readback, rate, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from tolerance cells and stream windows to regular readback, effective tail schedule, and terminal seal.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRealRegularCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyRate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealRegularCompletion}^{\uparrow}}$ *row naming exactly this finite completion packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected representatives, countable choice, host real equality, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopRealRegularCompletionUp.BishopRealRegularCompletionTasteGate single carrier alignment`

Theorem 7398.2 (Bishop real regular completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealRegularCompletion}^{\uparrow}$ *carrier*

$$B = (D, S, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealRegularCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance visibility, finite stream-window admission, regular rational readback, effective tail scheduling, terminal real-name sealing, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing read must pass through*

$$D, S, R, M, E, H, C, P, N$$

and through no quotient stream equality, selected limit, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7398.1. The rows D, S, R, M, E expose the dyadic tolerance ledger, finite stream windows, regular rational readback, effective tail schedule, and terminal real seal before any completion-facing consumer is available.

Read the analytic route in order. The $\mathsf{StreamName}^{\uparrow}$ windows are interpreted through the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance cells, the $\mathsf{RegSeqRat}^{\uparrow}$ row provides the regular rational readback, and the $\mathsf{CauchyRate}^{\uparrow}$ row bounds admitted tail requests before E is exposed.

The structural rows H, C, P, N preserve, replay, source, and locally name the same finite route. Since the carrier has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, or ambient completeness, the listed rows exhaust the NameCert obligation surface. □

Theorem 7398.3 (Bishop real regular completion finite-means route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopRealRegularCompletion}^{\uparrow}$ *packet receives a finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyRate}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

implemented by the displayed rows $D, S, R, M, E, H, C, P, N$*. The route is a finite regular-completion certificate, not a quotient of streams, a selected limit, a countable-choice construction, a host real equality theorem, or a proof that all* $\mathsf{Real}^{\uparrow}$ *names are complete.*

Proof. Start with the displayed rows D and S. They determine which dyadic tolerances and finite observation windows are visible to the consumer.

Next read R and M. The regular rational row R is downstream of the displayed windows, and the effective rate row M bounds the admitted tail requests that may ask for a completion-facing seal.

Finally read E through H, C, P, N. Transport and replay preserve the same row order, while provenance and local naming record that the packet contains no additional quotient, selector, choice, host-equality, or completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealRegularCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealRegularCompletion}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, CauchyRate tail schedules, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{BishopRealRegularCompletion}\uparrow}$, seed)

Scope closed: Definition 7398.1, Definition 7398.2, and Definition 7398.3 seed the finite regular-completion route over dyadic tolerance rows, stream windows, regular rational readback, effective tail schedules, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{BishopRealRegularCompletion}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.BishopRealRegularCompletionUp.BishopRealRegularCompletionTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: The chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance visibility, finite window admission, regular rational readback, effective tail scheduling, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealRegularCompletionUp.

Chapter 7399

A Concrete Naming Certificate for $\mathsf{FiniteObservationSheaf}^{\uparrow}$

Following the sheaf-theoretic locality tradition and the auditable-generativity reading of chapter 9462, the $\mathsf{FiniteObservationSheaf}^{\uparrow}$ packet records compatible finite observation windows as a NameCert object. It reads finite observation prefixes from chapter 7253, stream windows from chapter 126, indexed restriction rows from chapter 150, and finite overlap gluing from chapter 151. The packet is an auditable finite sheaf of observations over BHist windows; it does not assert an external site of all observations, host sheaf equality, unrestricted gluing, quotient sections, or a black-box generativity principle.

Definition 7399.1 (Finite observation sheaf carrier)**.** *A* $\mathsf{FiniteObservationSheaf}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, W, A, R, G, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index row naming the inspected observation windows.*
2. *W is the* $\mathsf{FinitePrefixStream}^{\uparrow}/\mathsf{StreamName}^{\uparrow}$ *window row for the finite observations assigned to each index.*
3. *A is the assignment row sending each displayed window to its local observation section.*
4. *R is the* $\mathsf{PreSheaf}^{\uparrow}$ *restriction row for every displayed inclusion of finite windows.*
5. *G is the* $\mathsf{Sheaf}^{\uparrow}$ *finite-overlap gluing row for compatible displayed sections.*
6. *H records componentwise* hsame *transport of indices, windows, assignments, restrictions, gluing rows, replay data, provenance, and local naming.*
7. *C records displayed* Cont *replay from window inclusion to restriction and from pairwise compatibility to finite overlap gluing.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteObservationSheaf}^{\uparrow}$, $\mathsf{FinitePrefixStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$ *row naming exactly this finite observation-sheaf packet.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a host observation topos, equality of external sheaves, quotient sections, unrestricted covers, or opaque generative output.

Theorem 7399.2 (Finite observation sheaf NameCert obligations)**.** *For every accepted* $\mathsf{FiniteObservationSheaf}^{\uparrow}$ *carrier*

$$O = (I, W, A, R, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$ *surface consists exactly of finite index admission, finite observation-window admission, local section assignment, presheaf restriction, finite-overlap compatibility, finite gluing, componentwise transport, displayed replay, provenance, and local naming. Every auditable-generativity read of the packet must pass through*

$$I, W, A, R, G, H, C, P, N$$

and through no external site of all observations, host sheaf equality, quotient section, unrestricted cover, or opaque generator.

Proof. Project the carrier of Definition 7399.1. The rows I, W, A expose the finite observation indices, finite windows, and local sections before any restriction or gluing row is available.

Read R and G next. The presheaf restriction row handles displayed window inclusions, while the sheaf row glues only compatible finite overlaps already named by the packet.

The structural rows H, C, P, N transport, replay, source, and locally name the same finite observation surface. Since the carrier has no coordinate for an external observation site, host sheaf equality, quotient sections, unrestricted covers, or an opaque generator, the listed rows exhaust the NameCert obligations. □

Theorem 7399.3 (Finite observation sheaf auditable gluing)**.** *Every generativity-facing read of an accepted* $\mathsf{FiniteObservationSheaf}^{\uparrow}$ *packet is a compatible finite gluing of displayed* BHist *window sections. The read factors through* $\mathsf{FinitePrefixStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{PreSheaf}^{\uparrow}$, *and* $\mathsf{Sheaf}^{\uparrow}$ *rows before the local* $\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$ *row is consumed, and it exports auditable finite overlap data rather than opaque generated content.*

Proof. Start with the finite window rows I, W, A. They determine the observation windows and the local sections available to the consumer.

Apply the restriction row R. It compares local sections only along displayed inclusions of finite windows, so compatibility is a finite presheaf condition over the carried observations.

Finally apply G and then H, C, P, N. The gluing row is available only for those compatible finite overlaps, and the structural rows preserve the same route. Thus the generativity-facing read is auditable as finite window data rather than as a black-box output. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteObservationSheaf}^{\uparrow}$ packet is generated from finite observation indices, finite StreamName and FinitePrefixStream windows, local section assignments, PreSheaf restriction rows, Sheaf finite-overlap gluing rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$, seed)

Scope closed: Definition 7399.1, Definition 7399.2, and Definition 7399.3 seed the finite observation-sheaf route over finite indices, observation windows, local section assignments, presheaf restrictions, finite gluing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteObservationSheaf}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: The chapter does not claim Lean verification, bridge checking, an external site of all observations, host sheaf equality, quotient sections, unrestricted covers, or opaque generative output.

Upgrade path: Obligation closure requires checked carrier admission, finite observation-window admission, assignment rows, restriction rows, finite-overlap gluing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteObservationSheafUp.

Chapter 7400

A Concrete Naming Certificate for $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ packet records the finite route by which dyadic tolerance requests are compared with Archimedean rational bounds before regular Cauchy and Real-facing consumers read a completion seal. It sits between the dyadic tolerance surface of chapter 291, the rational bound carrier of chapter 37, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The bridge is a finite NameCert route from dyadic radii to rational Archimedean bounds; it is not host real completeness, quotient equality of real names, trichotomy, or a selected limit.

Definition 7400.1 (Dyadic Archimedean bridge carrier)**.** *A* $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (N, Q, D, S, R, E, H, C, P, M)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *scale row naming the finite denominator exponent, mesh depth, and comparison stage used by the tolerance request.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *Archimedean-bound row, recording the rational upper bound that dominates the displayed dyadic tolerance at scale N.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic numerator, exponent, positivity witness, and radius ledger consumed by the comparison.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the completion request before any regular rational readback is exposed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and the rational bound row.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic tolerance, Archimedean rational bound, finite windows, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the scale, rational bound, dyadic tolerance, windows, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion tolerance request through $N, Q, D, S, R, E, H, P, M$.*

9. *P is the* Pkg *provenance over* $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *M is the local* $\mathsf{NameCert}_{\mathsf{DyadicArchimedeanBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, Q, D, S, R, E, H, C, P, M$. The carrier has no coordinate for host real completeness, quotient equality of real names, trichotomy, countable choice, selected limits, or a hidden Archimedean theorem outside the displayed rational-bound row.

Theorem 7400.2 (Dyadic Archimedean bridge NameCert obligations)**.** *For every accepted* DyadicArchimedeanBrid *carrier*

$$K = (N, Q, D, S, R, E, H, C, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicArchimedeanBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{Nat}^{\uparrow}$ *scale row,* $\mathsf{Rat}^{\uparrow}$ *Archimedean-bound row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{StreamName}^{\uparrow}$ *finite-window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming; rational-bound exactness requiring Q to dominate the dyadic tolerance displayed by D at the scale named by N; window locality requiring S and R to be read before E; and ledger non-escape excluding host completeness, quotient equality, trichotomy, countable choice, selected limits, and hidden Archimedean witnesses.*

Proof. Carrier admission is projection from Definition 7400.1. The visible packet contains exactly the scale row N, rational bound row Q, dyadic tolerance row D, finite windows S, regular readback R, Real seal E, and structural rows H, C, P, M.

The rational-bound obligation is local to N, Q, D. The scale row names the finite comparison stage, the dyadic row supplies the displayed tolerance, and the rational row supplies the Archimedean upper bound for that tolerance.

The completion-facing readback is local to S, R, E. A consumer opens finite StreamName windows, reads them through RegSeqRat, and reaches the terminal Real seal only after the rational and dyadic comparison rows have been displayed.

The remaining rows transport, replay, source, and name the same route. Since no excluded object is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7400.3 (Dyadic Archimedean bridge Real tolerance route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ *packet factors a dyadic tolerance request through*

$$\mathsf{Nat}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before the terminal seal is read. The route converts the displayed dyadic radius into a rational Archimedean bound at the finite scale N, opens the permitted StreamName windows, performs the RegSeqRat readback, and only then exposes the Real seal. It exports no host real completeness, quotient equality of real names, trichotomy, countable-choice schedule, selected limit, or hidden Archimedean witness.

Proof. Start with the accepted carrier $K = (N, Q, D, S, R, E, H, C, P, M)$. The dyadic tolerance request is not a free analytic assertion; it is the displayed row D read together with the scale row N.

Read the rational bound row Q. It is the only Archimedean comparison coordinate in the packet, so the dyadic tolerance can reach a rational upper bound only through N, Q, D.

Next open the completion-facing rows S, R, E. The finite StreamName windows determine the observations, RegSeqRat performs the regular rational readback, and the terminal Real seal is exposed only after those rows and the dyadic-to-rational comparison have been displayed.

Finally replay the route through H, C, P, M. Transport and continuation preserve the same finite packet, while provenance and local naming record that the Real tolerance route does not import completeness, quotient equality, trichotomy, choice, selected limits, or hidden Archimedean data. □

Falsifiable prediction: Every $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ read factors through a NatUp scale row, RatUp Archimedean-bound row, DyadicRatCoreUp tolerance row, finite StreamName windows, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: nat, rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite scale, rational Archimedean bound, dyadic tolerance, observation windows, regular readback, Real seal, transport, replay, provenance, and local NameCert row as one bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicArchimedeanBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicArchimedeanBridge}^{\uparrow}$ packet is generated from a NatUp scale row, a RatUp Archimedean-bound row, a DyadicRatCoreUp tolerance row, StreamNameUp finite windows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicArchimedeanBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7400.1, Definition 7400.2, and Definition 7400.3 seed the finite dyadic-to-Archimedean rational tolerance route from displayed scale and dyadic rows through rational bounds, finite windows, regular readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicArchimedeanBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real completeness, quotient equality of real names, trichotomy, countable choice, selected limits, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, rational Archimedean-bound exactness, finite-window locality, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicArchimedeanBridgeUp.

Chapter 7401

A Concrete Naming Certificate for $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$

Following Bishop–Bridges compact-uniform continuity and Kelley-style function-space usage, the $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ packet names a finite BEDC carrier for compact-source continuous maps under uniform finite observation. It sits after the compact-uniform-continuity packet of chapter 388, the compact metric source rows of chapter 129, the continuous-map graph rows of chapter 130, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dyadic tolerance ledger of chapter 291. The packet is a finite function-space carrier consumed by compact-uniform continuity and Arzela–Ascoli style rows; it does not import host function equality, open-cover compactness, selected subsequences, or ambient Real completeness.

Definition 7401.1 (Compact-uniform function-space carrier)**.** *A* $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{F} = (K, M, U, W, R, D, E, H, C, P, N)$$

with the following displayed coordinates:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite* $\mathsf{ProbeBundle}$ *net and compact-metric distance observations available to function-space reads.*
2. *M is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *ledger of displayed maps over the compact source.*
3. *U is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *handoff row that turns pointwise map data into compact-source uniform windows.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for source probes, map indices, tolerance requests, and target observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational precision histories attached to W.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for finite target-distance and modulus comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by sampled target-distance rows after the window and readback coordinates have been displayed.*
8. *H records componentwise* hsame *transport for $K, M, U, W, R, D, E, C, P, N$.*

9. *C records displayed* Cont *replay from a function-space request through compact finite-net inspection, continuous-map graph sampling, compact-uniform handoff, stream scheduling, rational readback, dyadic tolerance accounting, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFunctionSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, U, W, R, D, E, H, C, P, N$. There is no coordinate for host equality of functions, open-cover compactness, a selected subsequence, a quotient map space, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7401.2 (Compact-uniform function-space NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ *carrier*

$$\mathcal{F} = (K, M, U, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformFunctionSpace}^{\uparrow}}$ *surface consists exactly of compact-source admission through K, displayed continuous-map admission through M, compact-uniform handoff through U, finite scheduling through W, regular-rational readback through R, dyadic tolerance accounting through D, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7401.1. Its coordinates list exactly the compact source, displayed maps, compact-uniform handoff, finite windows, rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming rows.

The compact-source and map clauses are read through K and M. The source side is a finite compact-metric observation surface, while the map side is a displayed continuous-map ledger; neither clause exposes host equality of functions or a topology on all maps.

The uniform and numerical clauses are then read through U, W, R, D, E. The compact-uniform row orders the source windows, the stream and regular-rational rows schedule and read them back, the dyadic row accounts for finite tolerances, and the Real row seals sampled target distances only after those finite rows have appeared.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for open-cover compactness, selected subsequences, quotient map equality, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7401.3 (Compact-uniform function-space finite-net handoff)**.** *Every compact-uniform or Arzela–Ascoli style consumer of an accepted* $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ *packet must read the displayed finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{CompactUniformContinuity}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCo}$$

The handoff supplies compact finite-net observations, displayed map rows, uniform source-window control, finite precision schedules, rational readback, dyadic tolerance accounting, and terminal Real seals. It supplies no host function equality, open-cover compactness, selected subsequence, quotient function space, or ambient Real-completeness datum.

Proof. Start with an accepted carrier $\mathcal{F} = (K, M, U, W, R, D, E, H, C, P, N)$. The compact source is exposed only by K, and the maps available to the consumer are the displayed rows in M.

Next read the compact-uniform handoff U. It routes every tolerance request through the compact finite-net surface before any target observation can be sealed.

The schedule and numerical readback are then forced by W, R, D, E. The stream row names the finite windows, the regular rational row reads the precision histories, the dyadic row records the tolerance ledger, and the Real row seals only the sampled target-distance data produced by those finite rows.

The structural rows H, C, P, N preserve exactly that route under transport and replay. Because no further coordinate is present, a downstream compact-uniform or Arzela–Ascoli style packet cannot replace the finite-net handoff by host function equality, open-cover compactness, selected subsequences, quotient map equality, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ read factors through one $\mathsf{CompactMetric}^{\uparrow}$ finite-net source row, one finite $\mathsf{ContinuousMap}^{\uparrow}$ ledger, one $\mathsf{CompactUniformContinuity}^{\uparrow}$ handoff row, one $\mathsf{StreamName}^{\uparrow}$ schedule, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: compactuniformcontinuity, compactmetric, continuousmap, streamname, regseqrat, real, dyadicratcore: $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net source data, displayed continuous-map rows, compact-uniform handoff, finite schedules, rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local NameCert rows as one function-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFunctionSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformFunctionSpace}^{\uparrow}$ packet is generated from a CompactMetricUp finite-net source, ContinuousMapUp displayed map rows, a CompactUniformContinuityUp handoff, StreamNameUp windows, RegSeqRatUp readback, DyadicRatCoreUp tolerance accounting, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFunctionSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7401.1, Definition 7401.2, and Definition 7401.3 seed the compact-uniform function-space packet over finite-net, map, uniform-handoff, window, readback, dyadic, seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFunctionSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, open-cover compactness, selected subsequences, quotient function spaces, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source coverage, displayed-map admission, compact-uniform handoff, window and readback exactness, dyadic tolerance exactness, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 7402

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ packet records the finite shared-tail modulus join used when two regular Cauchy rational names must be read at one downstream tolerance. It sits beside the regular rational source of chapter 301, the finite window schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the meet-side comparison packet of chapter 462. The packet names the selected common threshold as displayed BEDC data; it does not import host maxima, quotient Cauchy classes, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7402.1 (Regular Cauchy modulus join carrier)**.** *A* $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (M_0, M_1, T, W_0, W_1, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M_0 and M_1 are the two modulus-input rows whose tail demands must be served by one shared threshold.*
2. *T is the selected join-threshold row, recording a displayed bound large enough for both modulus inputs at the requested dyadic tolerance.*
3. *W_0 and W_1 are the* $\mathsf{StreamName}^{\uparrow}$ *window rows opened only after T is displayed.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the requested radius, the two inherited tolerance budgets, and the slack accounting for the shared threshold.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the two windows and the dyadic ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the modulus inputs, join threshold, windows, tolerance ledger, and readback row have been replayed.*
7. *H records componentwise* hsame *transport for $M_0, M_1, T, W_0, W_1, Q, R, E$ and the local naming row.*
8. *C records displayed* Cont *replay from a downstream tolerance request through the two modulus inputs, selected threshold, windows, ledger, readback, seal, provenance, and local name.*
9. *P records* Pkg *provenance over* $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusJoin}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $M_0, M_1, T, W_0, W_1, Q, R, E, H, C, P, N$. It has no coordinate for an ambient maximum operation, quotient-stream equality, a selected limit, trichotomy, countable choice, or real completeness outside the displayed packet.

Theorem 7402.2 (Regular Cauchy modulus join NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ *carrier*

$$J = (M_0, M_1, T, W_0, W_1, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusJoin}^{\uparrow}}$ *surface consists exactly of carrier admission for the two modulus-input rows, the selected join threshold, the paired* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming row. Every obligation is read through those rows and no obligation is stored in host maxima, quotient streams, selected limits, trichotomy, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 7402.1. The tuple displays the two modulus inputs, the selected threshold, the two window rows, the dyadic ledger, the regular rational readback, the terminal real seal, and the structural rows.

The tail side is exhausted by M_0, M_1, T, W_0, W_1, Q. The threshold row T is the only common bound available to both modulus inputs, and the window rows are opened only through the displayed tolerance ledger.

The readback side is exhausted by R and E. The regular rational row receives the paired windows and the ledger, while the real seal appears only after that readback has been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no additional coordinate, the excluded host maximum, quotient, selector, choice, trichotomy, and ambient-completeness data cannot become NameCert obligations. □

Theorem 7402.3 (Regular Cauchy modulus join shared-tail handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ *carrier reads the finite route*

$$(M_0, M_1) \longmapsto T \longmapsto (W_0, W_1) \longmapsto Q \longmapsto R \longmapsto E.$$

The route exposes a single shared threshold before either stream window or regular rational readback is consumed. It exports no host maximum operation, quotient Cauchy class, selected limit, trichotomy, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7402.2. It fixes the public handoff surface at the rows $M_0, M_1, T, W_0, W_1, Q, R, E, H, C, P, N$.

Read the modulus side first. The two input rows state the tail demands, and the threshold row T is the displayed common bound consumed by both of them.

Next read the window and real-name side. The rows W_0, W_1 open the finite observations under that threshold, Q records the tolerance ledger, R supplies the regular rational readback, and E seals the route for real-facing consumers.

The structural rows keep the handoff confined to the displayed packet. Therefore a consumer that reaches a stream, rational readback, or real seal without the stated route is not reading the accepted $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ carrier. □

Theorem 7402.4 (Regular Cauchy modulus join real seal route)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ *packet is downstream of the two modulus inputs, the selected*

join threshold, the paired $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback. Hence later L10 regular-Cauchy comparison routes may cite this packet as the concrete shared-tail join certificate, but they receive no additional real-completeness witness from it.*

Proof. Use the shared-tail handoff of Definition 7402.3. The displayed route reaches the real seal only after the threshold, windows, ledger, and readback rows have been consumed in order.

The meet-side sibling chapter 462 supplies the comparison-facing common-modulus row, while this packet supplies the join-facing selected threshold used by downstream L10 regular Cauchy routes. Both are read as finite NameCert rows, not as ambient host operations.

Thus the real seal is a terminal boundary for the displayed shared-tail certificate. It cannot be used as a hidden proof of real completeness, selected limits, quotient equality, or trichotomy. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading both modulus inputs, the selected join threshold, paired $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: regseqrat, streamname, dyadicratcore, real, cauchymodulusmeet: no listed sibling is bijective to $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ because this packet binds two modulus inputs, one selected shared threshold, paired finite windows, a tolerance ledger, regular rational readback, real seal, transport, replay, provenance, and local naming as one L10 shared-tail route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusJoin}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusJoin}^{\uparrow}$ packet is generated from two modulus-input rows, one selected join-threshold row, paired StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusJoin}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7402.1, Definition 7402.2, Definition 7402.3, and Definition 7402.4 seed the L10 shared-tail modulus join route over StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusJoin}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host maxima, quotient Cauchy classes, selected limits, trichotomy, countable-choice selectors, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove two-input admission, selected-threshold exposure, paired window scheduling, tolerance-ledger readback, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyModulusJoinUp.

Chapter 7403

A Concrete Naming Certificate for CompactLocatedMaximumPrinciple$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the CompactLocatedMaximumPrinciple$^{\uparrow}$ packet names the finite-net route by which a located real-valued continuous map on a compact metric source exposes a maximum witness as BEDC certificate data. It sits after the compact metric source of chapter 129, the finite epsilon-net schedule of chapter 1767, the located real continuity modulus of chapter 3809, and the terminal real seal of chapter 38. The packet is a finite witness ledger for one displayed maximum read; it is not open-cover compactness, Heine–Borel compactness for arbitrary subsets, choice, quotient completion, or ambient Real$^{\uparrow}$ completeness.

Definition 7403.1 (Compact located maximum principle carrier)**.** *A* CompactLocatedMaximumPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, E, C, R, W, H, T, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing the compact metric packet only through its displayed metric, total-bounded, and finite-net consumer coordinates.*
2. *E is the* FiniteEpsilonNet$^{\uparrow}$ *schedule row, containing the finite centers, tolerance request, and coverage ledger consumed by the maximum search.*
3. *C is the* LocatedRealContinuity$^{\uparrow}$ *modulus row, read over the same compact metric source and the displayed finite-net tolerance.*
4. *R is the* Real$^{\uparrow}$ *seal row for all located real comparisons reached by the finite schedule.*
5. *W is the maximum-witness ledger, recording the selected displayed center, its located real value seal, and the comparison rows showing that every inspected finite-net center is bounded by that value within the consumed modulus budget.*
6. *H records componentwise* hsame *transport for the compact metric packet, finite epsilon-net schedule, continuity modulus, real comparison seals, witness ledger, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay from a maximum request through K, E, C, R, W, H, P, N.*
8. *P is the* Pkg *provenance over* CompactLocatedMaximumPrinciple$^{\uparrow}$, CompactMetric$^{\uparrow}$, FiniteEpsilonNet$^{\uparrow}$, LocatedRealContinuity$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, E, C, R, W, H, T, P, N$. It has no coordinate for open-cover compactness, Heine–Borel compactness for arbitrary subsets, choice, quotient completion, ambient $\mathsf{Real}^{\uparrow}$ *completeness, a host-level supremum, or an unrestricted global maximum theorem.*

Theorem 7403.2 (Compact located maximum principle NameCert obligations)**.** *For every accepted* $\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}$ *carrier*

$$M = (K, E, C, R, W, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric packet, finite epsilon-net schedule, located real continuity modulus, real comparison seals, maximum witness ledger, transport, replay, provenance, and local naming;*
2. *classifier transport, requiring* hsame *to move K, E, C, R, W, T, P, N componentwise without replacing any row by host compactness or host real equality;*
3. *finite-net coverage, requiring every maximum read to consume the displayed* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *centers and coverage ledger before inspecting the witness row;*
4. *located-continuity modulus consumption, requiring the modulus row C to translate the finite-net tolerance into the comparison budget used by W;*
5. *maximum-witness ledger nonescape, requiring W to record only the displayed center, its real seal, and the finite comparison rows certified through R, with no host supremum, choice-selected maximizer, quotient completion, open-cover compactness, Heine–Borel compactness for arbitrary subsets, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No compact located maximum obligation is stored outside these displayed rows.

Proof. Project the carrier of Definition 7403.1. The compact metric packet K, finite epsilon-net schedule E, located real continuity modulus C, real seal row R, and witness ledger W are explicit coordinates of the accepted packet.

Carrier admission and classifier transport are therefore finite-row projections. The transport row H moves the displayed coordinates componentwise, and the replay row T replays the same route; no host compactness theorem or host real equality appears as an alternate classifier coordinate.

Finite-net coverage is the projection to E. A maximum request can inspect the witness ledger only after the displayed centers, tolerance, and coverage ledger have been read, so the route is the finite schedule of chapter 1767 rather than an open-cover argument.

Located-continuity modulus consumption is the projection to C together with the real seal row R. The modulus row supplies the comparison budget used by the finite search, and the real seals record the located comparisons exposed to the witness ledger.

Finally, nonescape follows from row exhaustion. The carrier contains no coordinate for a host supremum, choice-selected maximizer, quotient completion, open-cover compactness, Heine–Borel compactness for arbitrary subsets, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the local $\mathsf{NameCert}$ can certify only the displayed finite witness ledger. □

Falsifiable prediction: A consumer that claims a $\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}$ maximum read while omitting the $\mathsf{CompactMetric}^{\uparrow}$ packet, $\mathsf{FiniteEpsilonNet}^{\uparrow}$ schedule, $\mathsf{LocatedRealContinuity}^{\uparrow}$ modulus, $\mathsf{Real}^{\uparrow}$ comparison seal, maximum witness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier of Definition 7403.1.

Independence witness: compactmetric, finite-epsilon-net, located-real-continuity, real: no listed sibling is bijective to $\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}$ because this packet alone binds a compact metric source, a finite epsilon-net schedule, a located real continuity modulus, real comparison seals, a maximum witness ledger, transport, replay, provenance, and local naming as one finite maximum-principle certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}$ packet is generated from compact metric rows, finite epsilon-net schedule rows, located real continuity modulus rows, RealUp comparison seals, a maximum witness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7403.1 and Definition 7403.2 seed the finite-net located maximum witness route for compact metric real-valued consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactLocatedMaximumPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, Heine–Borel compactness for arbitrary subsets, choice, quotient completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite-net coverage, located-continuity modulus consumption, real comparison sealing, maximum-witness ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactLocatedMaximumPrincipleUp.

Chapter 7404

A Concrete Naming Certificate for $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy moduli, the $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$ packet records the finite comparison surface through which two displayed Cauchy-modulus witnesses may be related before any quotient stream, selected limit, or ambient completeness theorem is used. It sits beside the observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a comparison certificate for finite modulus schedules, not an equality principle for completed real numbers.

Definition 7404.1 (Finite Cauchy modulus comparison carrier)**.** *A* $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M_0, M_1, W_0, W_1, D, R, E, H, C, P, N)$$

with the following rows:

1. *M_0 is the first displayed modulus schedule, recording a finite list of precision requests and the index bounds assigned to them:*

$$n_0 \mapsto k^0_{n_0}, \quad n_1 \mapsto k^0_{n_1}, \quad \ldots, \quad n_s \mapsto k^0_{n_s}.$$

2. *M_1 is the second displayed modulus schedule on the same precision list:*

$$n_0 \mapsto k^1_{n_0}, \quad n_1 \mapsto k^1_{n_1}, \quad \ldots, \quad n_s \mapsto k^1_{n_s}.$$

3. *W_0 and W_1 are the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows. They expose exactly the stream observations demanded by M_0 and M_1 on the displayed precision list.*

4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-comparison ledger. It records the dyadic tolerance cells in which the two schedules are compared and the positive margin used by the comparison route.*

5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational approximants obtained from the two windows after the dyadic tolerance comparison has been displayed.*

6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is available only after M_0, M_1, W_0, W_1, D, R have been read.*

7. *H records componentwise* hsame *transport for the two modulus schedules, the shared windows, the dyadic tolerance ledger, the regular readback row, the Real seal, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay of the route*

$$M_0, M_1 \longmapsto W_0, W_1 \longmapsto D \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyModulusComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by the two displayed schedules, their shared finite windows, the dyadic tolerance-comparison ledger, regular rational readback, the terminal Real seal, transport, replay, provenance, and local names. It has no coordinate for quotient stream equality, selected limits, ambient completeness, or host real equality.

Theorem 7404.2 (Finite Cauchy modulus comparison NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$ *carrier*

$$B = (M_0, M_1, W_0, W_1, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCauchyModulusComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two modulus schedules, shared* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance comparison,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*

2. *common-window exposure, requiring both schedules to be read on the same finite precision list before any tolerance comparison is available;*

3. *dyadic comparison exactness, requiring the tolerance ledger D to mediate every comparison between schedule bounds;*

4. *readback compatibility, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to use exactly the stream windows and dyadic tolerance cells displayed by W_0, W_1, D;*

5. *Real-seal nonescape, requiring any downstream Real consumer to pass through E, H, C, P, N after the comparison rows have been displayed.*

No finite Cauchy-modulus comparison obligation is stored outside these rows.

Proof. Project the carrier of Definition 7404.1. The two schedules M_0 and M_1 expose only finite precision requests and their assigned bounds.

The common-window obligation reads W_0 and W_1 on the same displayed precision list. This keeps the comparison inside the StreamName windows rather than moving to a quotient stream.

The dyadic comparison row D is then the only route from schedule data to tolerance data. The readback row R receives exactly those windows and tolerance cells, matching the regular rational reconstruction discipline of chapter 301.

Finally the Real seal E and the structural rows H, C, P, N transport, replay, source, and name the displayed route. Since no carrier coordinate supplies selected limits, ambient completeness, or host real equality, the listed rows exhaust the local NameCert surface. □

Lean4 (statement) `BEDC.Derived.FiniteCauchyModulusComparisonUp`

Falsifiable prediction: A $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$ consumer that compares two Cauchy-modulus witnesses without reading the two displayed schedules, the shared $\mathsf{StreamName}^{\uparrow}$ windows,

the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal refutes the carrier surface.

Independence witness: streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole comparison packet because each sibling contributes observations, tolerance arithmetic, readback, or sealing, while this chapter binds the finite comparison route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyModulusComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyModulusComparison}^{\uparrow}$ packet is generated from two finite Cauchy-modulus schedules, shared StreamName windows, a dyadic tolerance-comparison ledger, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyModulusComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7404.1 and Definition 7404.2 seed the finite comparison surface over two Cauchy-modulus schedules, shared StreamName windows, dyadic tolerance comparison, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyModulusComparison}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FiniteCauchyModulusComparisonUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, ambient Real completeness, host real equality, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-window exposure, dyadic comparison exactness, readback compatibility, Real-seal nonescape, and finite NameCert coverage for BEDC.Derived.FiniteCauchyModulusComparisonUp.

Chapter 7405

A Concrete Naming Certificate for MetaCICResidualSubstitutionComparison$^{\uparrow}$

Following Barendregt-style residual and confluence analysis, the MetaCICResidualSubstitutionComparison$^{\uparrow}$ packet records the finite comparison surface through which residual-substitution data may be audited before a confluence consumer cites a conditional diamond route. It sits beside the residual-substitution boundary of chapter 2181, the critical-pair ledger of chapter 3437, and the local confluence frontier of chapter 7346. The packet compares displayed residual-substitution rows; it does not prove global confluence or discharge substitution compatibility.

Definition 7405.1 (MetaCIC residual-substitution comparison carrier)**.** *A* MetaCICResidualSubstitutionComparison *carrier is a finite* BHist *packet*

$$B = (T_0, T_1, S_0, S_1, J, O, Q, H, C, P, N)$$

with the following rows:

1. *T_0 and T_1 are the typed-window rows. They display the two finite MetaCIC term windows whose residual substitution traces are compared.*
2. *S_0 and S_1 are the residual-substitution trace rows. They record the two substituted residual branches and the binder windows used by the comparison.*
3. *J is the local-join row. It records the bounded local join attempt between the two residual traces, without promoting the attempt to a full parallel diamond.*
4. *O is the obstruction-retention row. It keeps the named substitution-compatibility boundary visible whenever the local join is conditional.*
5. *Q is the bounded-checker row. It records the finite checker requests used to compare the typed windows, residual traces, local join, and obstruction row.*
6. *H records componentwise* hsame *transport for the typed windows, residual traces, local join, obstruction retention, bounded checker, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$T_0, T_1 \longmapsto S_0, S_1 \longmapsto J, O, Q \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* MetaCICResidualSubstitutionComparison$^{\uparrow}$*, MetaCIC typed windows, residual substitution traces, local join data, obstruction rows, bounded checker data,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by these displayed typed-window, residual-trace, local-join, obstruction-retention, bounded-checker, transport, replay, provenance, and local naming rows. It has no coordinate for global confluence, premise-free substitution compatibility, arbitrary closed Church–Rosser, quotient syntax, or host evaluator soundness.

Theorem 7405.2 (MetaCIC residual-substitution comparison NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}$ *carrier*

$$B = (T_0, T_1, S_0, S_1, J, O, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the typed windows, residual-substitution traces, local join, obstruction retention, bounded checker, transport, replay, provenance, and local naming rows;*
2. *typed-window exposure, requiring T_0 and T_1 to be read before either residual trace is compared;*
3. *residual-trace comparison, requiring S_0 and S_1 to remain paired with their typed windows and binder windows;*
4. *local-join boundedness, requiring J to record only the displayed local join attempt inspected by Q;*
5. *obstruction retention, requiring O to keep the residual-substitution compatibility boundary visible whenever the comparison is conditional;*
6. *provenance exhaustion, requiring H, C, P, N to transport, replay, source, and name exactly the displayed rows.*

No MetaCIC residual-substitution comparison obligation is stored outside these rows.

Proof. Project the carrier of Definition 7405.1. The typed windows T_0, T_1 are finite term-and-binder windows, and the residual traces S_0, S_1 are read only through those windows.

The local join row J is bounded by the checker row Q. Thus the packet can record a finite comparison between two residual traces without claiming a global parallel diamond.

The obstruction row O remains visible whenever the join is conditional. This matches the premise-retention discipline of chapter 2181 and keeps the confluence audit map from silently treating a named input as a theorem.

Finally H, C, P, N transport, replay, source, and name the same route. Since no coordinate supplies global confluence, premise-free substitution compatibility, arbitrary closed Church–Rosser, quotient syntax, or host evaluator soundness, the obligation surface is exactly the finite comparison packet displayed above. □

Lean4 (statement) `BEDC.Derived.MetaCICResidualSubstitutionComparisonUp`

Falsifiable prediction: A $\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}$ confluence-audit read factors through finite typed-window rows, residual-substitution trace rows, local-join data, obstruction retention, bounded checker data, transport, replay, provenance, and local NameCert rows before any conditional diamond handoff is cited.

Independence witness: metacic-residual-substitution-boundary, metacic-critical-pair-ledger, metacic-local-confluence-frontier: the comparison packet is not bijective to any listed sibling because it

jointly carries two typed windows, two residual traces, a bounded local join, obstruction retention, bounded checking, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}$ packet is generated from two finite typed-window rows, two residual-substitution trace rows, a bounded local-join row, obstruction-retention data, a bounded-checker row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7405.1 and Definition 7405.2 seed the finite residual-substitution comparison packet over typed windows, residual traces, local joins, obstruction retention, bounded checking, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualSubstitutionComparison}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MetaCICResidualSubstitutionComparisonUp`

Bridge status: none

Not claimed: This chapter does not close global confluence, premise-free substitution compatibility, arbitrary closed Church–Rosser, quotient syntax, host evaluator soundness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-trace comparison, local-join boundedness, obstruction retention, provenance exhaustion, and finite NameCert coverage for BEDC.Derived.MetaCICResidualS

Chapter 7406

A Concrete Naming Certificate for $\mathsf{Kirchberger}^{\uparrow}$

Following Kirchberger's finite convex separation theorem, the $\mathsf{Kirchberger}^{\uparrow}$ packet records the finite BEDC surface for detecting separation of two finitely displayed point families by checking bounded small subfamilies. It sits over the affine-coordinate carrier of chapter 206, the convex-set carrier of chapter 208, the polytope row of chapter 209, and the finite-dimensional separating-functional row of chapter 3905. The packet names only the displayed finite subfamily ledger and its separation obligations; it does not assert an ambient compactness theorem, selected global hyperplane, quotient convex hull equality, or infinite Helly-family principle.

Definition 7406.1 (Kirchberger finite separation carrier)**.** *A* $\mathsf{Kirchberger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, C, D, P, S, L, E, H, T, Q, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AffineSpace}^{\uparrow}$ *coordinate row, fixing the finite-dimensional affine window in which the two point families are read.*
2. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *row, recording the two displayed convex hull requests generated by the finite point families.*
3. *D is the* $\mathsf{Polytope}^{\uparrow}$ *row, naming the finite hull presentations and their face or vertex ledgers.*
4. *P is the point-family row, listing the two color classes and the finite subfamily windows inspected by the certificate.*
5. *S is the small-subset obligation row, recording the bounded subfamilies whose convex hulls must be separated.*
6. *L is the local separation row supplied by* $\mathsf{FiniteDimensionalHahnBanachSeparation}^{\uparrow}$ *for each displayed small-subset request.*
7. *E is the exactness row, asserting that every accepted small-subset request is routed through the same affine, convex, polytope, and local-separation data.*
8. *H records componentwise* hsame *transport for $A, C, D, P, S, L, E, T, Q, N$.*
9. *T records displayed* Cont *replay through the finite point-family, subset, convex-hull, and separation rows.*

10. *Q is the* Pkg *provenance over* Kirchberger$^{\uparrow}$, AffineSpace$^{\uparrow}$, ConvexSet$^{\uparrow}$, Polytope$^{\uparrow}$, FiniteDimensionalHahnBanachSe BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{Kirchberger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a selected global separating hyperplane, quotient convex hull equality, ambient compactness, infinite choice over subfamilies, or an unbounded Helly-style search.

Theorem 7406.2 (Kirchberger finite subset obligations)**.** *For every accepted* Kirchberger$^{\uparrow}$ *carrier $K = (A, C, D, P, S, L, E, H, T, Q, N)$, the local* NameCert$_{\text{Kirchberger}^{\uparrow}}$ *surface consists exactly of affine-coordinate admission, convex-hull readback, polytope finite-hull presentation, two-color point-family exposure, small-subset obligation accounting, finite-dimensional local separation, exactness through the same displayed rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7406.1. The rows $A, C, D, P, S, L, E, H, T, Q, N$ are the complete visible inventory.

The affine, convex, and polytope rows A, C, D fix the ambient finite-dimensional window and the finite hull presentations. The point-family and small-subset rows P, S then identify the bounded subfamilies whose separation must be displayed.

The local separation row L is read only through FiniteDimensionalHahnBanachSeparation$^{\uparrow}$, and the exactness row E binds those local reads to the same subfamily requests. Transport, replay, provenance, and naming through H, T, Q, N preserve that finite route, so no excluded global or quotient object is exported. □

Theorem 7406.3 (Kirchberger NameCert nonescape)**.** *An accepted* Kirchberger$^{\uparrow}$ *packet exports no selected global separating hyperplane, no quotient equality of convex hulls, no ambient compactness theorem, no infinite subfamily choice schedule, and no unbounded Helly-family search. Every public read factors through the displayed affine window, convex and polytope hull rows, two-color point-family row, small-subset obligation ledger, finite-dimensional local-separation row, exactness row, componentwise transport, replay, provenance, and local NameCert row.*

Proof. Inspect the carrier coordinates. They list only the finite affine, convex, polytope, point-family, subset-obligation, local-separation, exactness, transport, replay, provenance, and naming rows.

A global separation read must therefore pass through the bounded subfamily ledger S and the local separation row L. The carrier has no coordinate from which a host hyperplane, quotient convex hull identity, or infinite family selection can be read.

Thus any downstream convexity consumer receives Kirchberger's finite obstruction surface as NameCert data. The excluded principles require rows absent from Definition 7406.1, so they cannot escape the packet. □

Theorem 7406.4 (Kirchberger seed scope)**.** *The seed scope of* Kirchberger$^{\uparrow}$ *is the finite convex separation route*

$$A, C, D, P \longmapsto S, L, E \longmapsto H, T, Q, N.$$

It binds the affine-coordinate window, convex-hull and polytope rows, point-family ledger, bounded small-subset obligations, finite-dimensional local-separation witnesses, exactness, componentwise transport, replay, provenance, and local naming. It does not close Lean verification, bridge checking, public registry export, or any ambient global separation theorem.

Proof. Read the route displayed in the statement from the carrier definition. The left side supplies the finite ambient and point-family data, the middle supplies the small-subset and local-separation obligations, and the right side supplies transport, replay, provenance, and naming.

Definition 7406.2 identifies this route as the local NameCert obligation surface. Definition 7406.3 gives the boundary: consumers cannot replace the finite route by host separation, quotient hull equality, compactness, or unbounded choice.

Consequently the chapter seeds exactly the displayed finite convex-separation packet. Higher closure grades require checked carrier admission, classifier stability, local-separation exactness, and a public export surface. □

Falsifiable prediction: If the small-subset obligation row S is removed, Definition 7406.2 no longer distinguishes a Kirchberger finite-obstruction packet from a single finite-dimensional separation certificate.

Independence witness: affinespace, convexset, polytope, finite-dimensional-hahn-banach-separation: $\mathsf{Kirchberger}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds two-color point-family data, bounded small-subset obligations, finite hull presentations, and local finite-dimensional separation rows into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{Kirchberger}^{\uparrow}}$.

Constructive story: A $\mathsf{Kirchberger}^{\uparrow}$ packet is generated from affine-coordinate rows, convex-set rows, polytope finite-hull rows, two-color point-family rows, small-subset obligation rows, finite-dimensional local-separation rows, exactness data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Kirchberger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7406.1, Definition 7406.2, Definition 7406.3, and Definition 7406.4 seed the finite Kirchberger separation packet over AffineSpaceUp, ConvexSetUp, PolytopeUp, FiniteDimensionalHahnBanachSeparationUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Kirchberger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public registry export, selected global hyperplanes, quotient convex hull equality, ambient compactness, infinite subfamily choice, or unbounded Helly-family search.

Upgrade path: Obligation closure requires checked carrier admission, finite point-family exposure, bounded small-subset accounting, local finite-dimensional separation exactness, classifier stability, and nonescape for BEDC.Derived.KirchbergerUp.

Chapter 7407

A Concrete Naming Certificate for MetaCICResidualDiamondBudget$^{\uparrow}$

The MetaCICResidualDiamondBudget$^{\uparrow}$ packet realizes one finite residual-substitution confluence frontier from section 9386.3. It sits beside the residual-substitution boundary of chapter 2181, the residual checker of chapter 3827, the residual-diamond scheduler of chapter 6857, the residual-diamond witness of chapter 7219, and the residual-join budget of chapter 7378. The packet records a finite typed window, residual-pair budget, local-diamond candidate ledger, checker fuel, obstruction retention, transport, replay, provenance, and local naming; it does not claim unrestricted residual substitution, arbitrary closed parallel diamond, Church–Rosser, quotient conversion equality, or a host confluence oracle.

Definition 7407.1 (MetaCIC residual diamond budget carrier)**.** *A* MetaCICResidualDiamondBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, R, D, J, C, O, H, K, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, fixing the closed source term, local context fragment, redex shape, and observation depth inspected by the packet.*
2. *R is the residual-frontier row, naming the residual substitutions visible inside the typed window.*
3. *D is the residual-pair budget row, listing the finitely many residual pairs for which the local-diamond question is inspected.*
4. *J is the join-candidate ledger, recording the proposed common reducts for the residual pairs in D.*
5. *C is the bounded checker row, recording the finite fuel, replay trace, and checker status used to inspect the candidate joins.*
6. *O is the obstruction-retention row, preserving any residual-substitution or subject-reduction boundary that the bounded checker has not discharged.*
7. *H records componentwise* hsame *transport for $T, R, D, J, C, O, K, P, N$.*
8. *K records displayed* Cont *replay from a residual-diamond request through the typed window, frontier, pair budget, join candidates, checker row, and obstruction row.*

9. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$, $\mathsf{MetacicResidualDiamondScheduler}^{\uparrow}$, $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$, $\mathsf{MetaCICResidualJoinBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, D, J, C, O, H, K, P, N$. It has no coordinate for unrestricted residual substitution, an arbitrary closed parallel diamond, a global Church–Rosser endpoint, quotient conversion equality, unbounded checking, or a host confluence oracle.

Theorem 7407.2 (MetaCIC residual diamond budget obligations)**.** *For every accepted* MetaCICResidualDiamondBu *carrier $B = (T, R, D, J, C, O, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}}$ *surface consists exactly of typed-window admission, residual-frontier exposure, residual-pair budget accounting, join-candidate ledger visibility, bounded-checker exactness, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7407.1. The visible rows are exactly $T, R, D, J, C, O, H, K, P, N$.

The typed window T and residual frontier R fix the local MetaCIC source in which residuals are meaningful. The residual-pair budget D narrows the local-diamond request to finitely many inspected pairs, and J records only the proposed joins for those pairs.

The bounded checker row C evaluates the same finite ledger, while the obstruction row O keeps undisclosed residual-substitution or subject-reduction boundaries visible. Transport, replay, provenance, and naming through H, K, P, N preserve this route and introduce no additional confluence endpoint. □

Theorem 7407.3 (MetaCIC residual diamond budget nonescape)**.** *An accepted* $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$ *packet exports no unrestricted residual-substitution principle, no arbitrary closed parallel diamond, no global Church–Rosser theorem, no quotient conversion equality, no unbounded checker, and no host confluence oracle. Every confluence-facing read factors through the displayed typed window, residual-frontier row, residual-pair budget, join-candidate ledger, bounded checker, obstruction row, componentwise transport, replay, provenance, and local NameCert row.*

Proof. Inspect the carrier coordinates. They list only the finite typed-window, residual-frontier, residual-pair, join-candidate, bounded-checker, obstruction, transport, replay, provenance, and naming rows.

Any diamond-facing read must pass through the pair budget D, the candidate ledger J, and the bounded checker C before it reaches a consumer. The obstruction row O remains present whenever the bounded check has not discharged a residual-substitution or subject-reduction boundary.

The excluded endpoints require coordinates absent from the carrier. Since no row supplies unrestricted substitution compatibility, arbitrary closed parallel diamonds, quotient conversion equality, unbounded checking, or a host oracle, those objects cannot escape this NameCert packet. □

Theorem 7407.4 (MetaCIC residual diamond budget confluence frontier)**.** *The* $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$ *packet records the residual-substitution confluence frontier as the finite route*

$$T, R \longmapsto D, J, C, O \longmapsto H, K, P, N.$$

It turns a candidate local-diamond request into a bounded residual-pair budget with explicit join candidates, checker status, and obstruction retention. It does not remove the residual-substitution boundary named in section 9386.3, and it does not upgrade a finite local budget into arbitrary closed-term confluence.

Proof. Read the route from Definition 7407.1. The rows T, R locate the typed residual frontier, while D, J, C, O record the finite pair budget, candidate joins, bounded checking, and retained obstruction.

Definition 7407.2 identifies these rows as the local NameCert obligation surface. Definition 7407.3 prevents a downstream confluence consumer from replacing the finite budget by unrestricted residual substitution, arbitrary closed parallel diamonds, or quotient conversion equality.

Thus the packet is a concrete finite frontier object for later Lean work: it makes the residual-diamond budget inspectable without pretending that the open confluence endpoint has already been discharged. □

Falsifiable prediction: If the residual-pair budget row D is removed, Definition 7407.4 can no longer distinguish a bounded residual-diamond packet from a single local-join witness.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-residual-checker, metacic-residual-diamond-scheduler, metacic-residual-diamond-witness, metacic-residual-join-budget: $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a typed residual frontier, residual-pair budget, join-candidate ledger, bounded checker, obstruction retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$ packet is generated from typed-window rows, residual-frontier rows, residual-pair budgets, join-candidate ledgers, bounded-checker rows, obstruction-retention rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7407.1, Definition 7407.2, Definition 7407.3, and Definition 7407.4 seed the finite residual-diamond budget packet for MetaCIC confluence-frontier consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, unrestricted residual substitution, arbitrary closed parallel diamond, global Church–Rosser, quotient conversion equality, unbounded checking, host confluence oracles, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window coverage, residual-frontier exposure, residual-pair budget accounting, join-candidate ledger visibility, bounded-checker exactness, obstruction retention, classifier stability, and nonescape for BEDC.Derived.MetaCICResidualDiamondBudgetUp.

Chapter 7408

A Concrete Naming Certificate for $\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}$

Bishop–Bridges constructive analysis treats quotient estimates for regular Cauchy names as guarded calculations: the numerator tail, denominator tail, and denominator away-from-zero witness must all remain visible before a real quotient seal is read. The $\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}$ packet records that finite guarded quotient-tail budget as a NameCert route between the regular rational sources of chapter 301, the dyadic tolerance ledger of chapter 291, the reciprocal modulus surface of chapter 7354, the guarded division handoff of chapter 1943, and the terminal real seal of chapter 38. The packet names only the displayed quotient-tail route; it does not supply total division, quotient representative equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7408.1 (Regular Cauchy quotient tail estimate carrier)**.** *A* $\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (N, D, A, M, S, L, V, E, H, C, P, K)$$

with the following displayed rows:

1. *N is the numerator* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, displaying the regular rational name whose quotient tail is being estimated.*
2. *D is the denominator* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, displayed as a separate regular rational name.*
3. *A is the located away-from-zero lower-bound row for the denominator, recording the positive guard that makes quotient-tail control meaningful.*
4. *M is the* $\mathsf{RegularCauchyReciprocalModulus}^{\uparrow}$ *row, turning D and A into a finite reciprocal modulus budget.*
5. *S is the quotient tail schedule, recording the numerator tail index, denominator tail index, reciprocal index, and final quotient precision request.*
6. *L is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic error split for numerator tail, denominator tail, reciprocal budget, and multiplication by the guarded reciprocal.*
7. *V is the* $\mathsf{RegularCauchyDivision}^{\uparrow}$ *handoff row, available only after N, D, A, M, S, L have been displayed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary for the quotient tail estimate.*

9. *H records componentwise* hsame *transport for the two sources, away-from-zero guard, reciprocal modulus, tail schedule, dyadic ledger, division handoff, seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay of the route*

$$N, D, A, M, S, L \longmapsto V \longmapsto E.$$

11. *P is the* Pkg *provenance over* RegularCauchyQuotientTailEstimate$^{\uparrow}$, RegSeqRat$^{\uparrow}$, RegularCauchyReciprocalModulu RegularCauchyDivision$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *K is the local* NameCert$_{\text{RegularCauchyQuotientTailEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $N, D, A, M, S, L, V, E, H, C, P, K$. It has no coordinate for total division, quotient representative equality, hidden denominator choice, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7408.2 (Regular Cauchy quotient tail estimate NameCert obligations)**.** *For every accepted* RegularCauchyQuotientTailEstimate$^{\uparrow}$ *carrier $Q = (N, D, A, M, S, L, V, E, H, C, P, K)$, the local* NameCert$_{\text{RegularCauchyQuotientTailEstimate}^{\uparrow}}$ *surface consists exactly of numerator and denominator* RegSeqRat$^{\uparrow}$ *source visibility, located denominator away-from-zero lower-bound visibility, reciprocal modulus routing, quotient tail scheduling, dyadic tolerance-ledger exposure,* RegularCauchyDivision$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7408.1. The source rows N, D and the away-from-zero guard A are the complete displayed input surface for a guarded quotient estimate.

Read the reciprocal and tolerance rows next. The modulus row M, schedule row S, and dyadic ledger L record the finite budgets needed before a quotient tail can be passed to a division consumer.

Finally the division handoff V, seal boundary E, and structural rows H, C, P, K preserve, replay, source, and name that same finite route. Since no excluded total-division, quotient-representative, hidden-choice, trichotomy, countable-choice, or ambient-completeness row appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7408.3 (Regular Cauchy quotient tail estimate Real seal boundary)**.** *Every Real-facing quotient-tail read of an accepted* RegularCauchyQuotientTailEstimate$^{\uparrow}$ *carrier factors through the displayed numerator and denominator* RegSeqRat$^{\uparrow}$ *sources, the denominator away-from-zero lower bound, the* RegularCauchyReciprocalModulus$^{\uparrow}$ *row, the quotient tail schedule, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the* RegularCauchyDivision$^{\uparrow}$ *handoff, and the terminal* Real$^{\uparrow}$ *seal boundary. The route exports no total division, quotient representative equality, hidden denominator choice, trichotomy, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Apply Definition 7408.2. It identifies N, D, A, M, S, L as the only finite input surface before the guarded division handoff can be read.

The RegularCauchyDivision$^{\uparrow}$ row V is therefore downstream of both regular rational sources, the denominator guard, the reciprocal modulus budget, the tail schedule, and the dyadic tolerance ledger. A Real-facing consumer reaches E only through that displayed handoff.

The transport, replay, provenance, and local naming rows preserve the same dependency order. Because the carrier has no row for total division, quotient representative equality, hidden denominator choice, trichotomy, countable choice, or ambient completeness, the terminal seal remains a finite guarded quotient-tail boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}$ packet is generated from numerator and denominator RegSeqRat sources, a located away-from-zero lower bound for the denominator, a RegularCauchyReciprocalModulus row, a quotient tail schedule, a DyadicRatCore tolerance ledger, a RegularCauchyDivision handoff, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7408.1, Definition 7408.2, and Definition 7408.3 seed the finite guarded quotient-tail budget for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyQuotientTailEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total division, quotient representative equality, hidden denominator choice, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, numerator and denominator RegSeqRat source visibility, away-from-zero lower-bound visibility, reciprocal modulus routing, quotient tail scheduling, dyadic tolerance exactness, RegularCauchyDivision handoff, RealUp seal boundary, transport, replay, provenance, and local naming.

Chapter 7409

A Concrete Naming Certificate for $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ packet records the bounded monotone convergence route as finite BEDC data. It consumes the $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ source of chapter 535, the convergence-seal boundary of chapter 918, the finite window surface of chapter 126, the dyadic tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the constructive route from bounded monotone data to a Cauchy regular rational handoff and then to a Real seal; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, choose a host limit, identify quotient streams, or import countable choice.

Definition 7409.1 (Monotone convergence theorem carrier)**.** *A* $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, W, \mu, D, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *row, carrying the bounded monotone source, tail witness, located trap, and Real-seal precursor.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger listing the inspected sequence windows and bound requests.*
3. *μ is the extracted Cauchy modulus row, displayed as finite threshold data read from B and W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the modulus and by the regular-rational readback.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row produced from W, μ, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the bounded source, modulus, tolerance, and regular readback rows have been displayed.*
7. *L is the accepted* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *row binding the same witness, modulus, readback, and Real seal route.*
8. *H records componentwise* hsame *transport for the bounded source, windows, modulus, dyadic ledger, readback, seal, convergence-seal row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a precision request through the same bounded monotone route.*

10. *P is the* Pkg *provenance over* $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$, $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$, $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceTheorem}^{\uparrow}}$ *row naming exactly this finite convergence packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for selected limits, quotient stream equality, countable-choice schedules, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7409.2 (Monotone convergence theorem carrier surface)**.** *Every accepted* MonotoneConvergenceTheorem *carrier exposes exactly the finite route*

$$\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{BoundedMonotoneC}$$

through the rows $B, W, \mu, D, R, L, E, H, C, P, N$. A consumer receives bounded monotone convergence data only as this displayed BEDC packet, not as a host supremum theorem, a selected limit, quotient real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 7409.1. The rows B, W, μ, D, R, E, L display the bounded witness, finite windows, extracted modulus, tolerance ledger, regular readback, terminal Real seal, and convergence-seal boundary.

Read the analytic route in order. The bounded witness row B supplies the monotone source and trap data, W lists the finite requests, μ records the threshold extracted from those requests, and D supplies the dyadic tolerance cells used by the threshold.

The rows R, L, E then package the regular readback, convergence-seal compatibility, and terminal Real seal. The structural rows H, C, P, N transport, replay, source, and name the same packet, so there is no carrier coordinate from which a selected limit, quotient equality, host supremum, or ambient completeness principle can be exported. □

Theorem 7409.3 (Monotone convergence bounded carrier admission)**.** *For every accepted* MonotoneConvergenceTh *carrier $M = (B, W, \mu, D, R, E, L, H, C, P, N)$, the bounded monotone source is admitted only through the accepted* $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ *row B and the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger W. No later modulus, regular-rational, convergence-seal, or Real-facing read may bypass B, W.*

Proof. Start with the carrier projection. The first analytic rows are B and W, and every other analytic coordinate is downstream of them.

The modulus row μ is not an independent tail oracle; it is displayed as threshold data extracted from the bounded witness and the finite window ledger. Thus the dyadic, regular-rational, convergence-seal, and Real rows can be inspected only after B, W have been read.

Transport and replay preserve that order through H and C, while P, N only source and name the same route. Hence a consumer that avoids B, W is not reading the accepted packet. □

Theorem 7409.4 (Monotone convergence Cauchy modulus extraction)**.** *Every Cauchy modulus exported by an accepted* $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ *packet is the displayed row μ extracted from the bounded monotone witness B, the finite window ledger W, and the dyadic tolerance row D. The extraction exports no detached tail oracle, countable-choice schedule, trichotomy branch, host order completeness, or selected limit.*

Proof. Project $M = (B, W, \mu, D, R, E, L, H, C, P, N)$. The row μ occurs between the bounded-window rows and the regular readback row.

The bounded monotone witness supplies the source and trap data, while W records the finite precision request being served. The dyadic row D supplies the tolerance cell for that request, so the threshold in μ is a displayed packet row rather than a function chosen from outside the carrier.

Since no row contains a detached selector, a trichotomy branch, host order completeness, or a selected limit, the exported modulus is exactly the finite extraction recorded by μ. □

Theorem 7409.5 (Monotone convergence RegSeqRat handoff)**.** *Every regular-rational name produced by an accepted* $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ *packet is read through*

$$W, \quad \mu, \quad D, \quad R.$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row R is downstream of the finite windows, extracted modulus, and dyadic tolerance ledger, and it exports no quotient stream, selected representative, hidden Cauchy family, or ambient Real-completeness witness.*

Proof. Begin with bounded carrier admission. It places the finite windows W behind the bounded witness row B.

Apply the modulus extraction route. The row μ is read from B, W, D, so the regular-rational request has a displayed threshold and tolerance ledger before R is available.

The handoff row R therefore packages the regular rational readback from finite data only. The structural rows preserve this order and have no coordinate for quotient streams, selected representatives, hidden Cauchy families, or ambient completeness. □

Theorem 7409.6 (Monotone convergence Real seal nonescape)**.** *For every accepted* $\mathsf{MonotoneConvergenceTheorem}$ *packet, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is exposed only after the route*

$$B, W, \mu, D, R, L$$

has been displayed. The seal may be consumed by Real and Completion routes as the named endpoint of the bounded monotone construction, but it cannot be read as ambient $\mathsf{Real}^{\uparrow}$ *completeness, host real equality, a selected supremum, quotient stream equality, or a choice-selected limit.*

Proof. The carrier places E after the bounded witness, finite windows, extracted modulus, dyadic ledger, regular readback, and convergence-seal boundary.

Use the RegSeqRat handoff to keep R downstream of W, μ, D. The convergence-seal row L then binds the same route before the Real seal is visible.

Rows H, C, P, N cannot add analytic data; they only preserve, replay, source, and name the displayed route. Since the carrier has no coordinate for ambient completeness, host equality, selected suprema, quotient streams, or choice-selected limits, the Real seal cannot escape the finite packet. □

Theorem 7409.7 (Monotone convergence ledger exactness)**.** *The local* $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceTheorem}^{\uparrow}}$ *surface consists exactly of bounded monotone carrier admission, Cauchy modulus extraction, dyadic tolerance readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{BoundedMonotoneConvergenceSeal}^{\uparrow}$ *compatibility,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming. Equivalently, every obligation-facing consumer of M reads only*

$$B, W, \mu, D, R, E, L, H, C, P, N.$$

Proof. Combine bounded carrier admission with Cauchy modulus extraction. These two routes fix the source, window, threshold, and dyadic rows available to an obligation-facing consumer.

Add the RegSeqRat handoff and Real seal nonescape. They force regular readback and terminal sealing through the same finite route and through the convergence-seal boundary L.

The remaining rows H, C, P, N are structural. They transport, replay, source, and locally name the packet without adding selected limits, quotient equality, choice, trichotomy, host real equality, or ambient completeness. Thus the displayed rows exhaust the local NameCert ledger. □

Falsifiable prediction: Every accepted $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ Real-facing read factors through an accepted $\mathsf{BoundedMonotoneCauchyWitness}^{\uparrow}$ row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a displayed Cauchy modulus row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance cells, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a BoundedMonotoneConvergence boundary, componentwise transport, displayed replay, provenance, and local NameCert before the $\mathsf{Real}^{\uparrow}$ seal is public.

Independence witness: boundedmonotonecauchywitness, streamname, dyadicratcore, regseqrat, bounded-monotone-convergence-seal, real: $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly records the bounded monotone source, finite windows, extracted Cauchy modulus, dyadic tolerance ledger, regular rational handoff, convergence-seal boundary, terminal Real seal, transport, replay, provenance, and local naming as one theorem packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneConvergenceTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneConvergenceTheorem}^{\uparrow}$ packet is generated from a BoundedMonotoneCauchyWitness source row, finite StreamName windows, an extracted Cauchy modulus row, DyadicRatCore tolerance data, RegSeqRat readback, a BoundedMonotoneConvergenceSeal boundary, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7409.1, Definition 7409.2, and Definition 7409.7 seed the constructive bounded monotone convergence route over finite windows, dyadic tolerances, regular rational readback, convergence sealing, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneConvergenceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient stream equality, trichotomy, countable-choice schedules, host real equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus extraction, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneConvergenceTheoremUp.

Chapter 7410

A Concrete Naming Certificate for $\mathsf{RationalFloorBound}^{\uparrow}$

Bishop–Bridges constructive analysis treats integer-part extraction for rationals as bounded search once an explicit Archimedean bound has been displayed. The $\mathsf{RationalFloorBound}^{\uparrow}$ packet records that finite bounded-search floor witness as a NameCert route between the rational carrier of chapter 37, the signed-integer interface of chapter 31, the dyadic scaling ledger of chapter 291, the finite stream and regular-rational readbacks of chapter 126 and chapter 301, and the terminal real-name boundary of chapter 38. The packet names only the displayed rational floor route; it does not import a host floor function, least-number operator, quotient representative, choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7410.1 (RationalFloorBound carrier)**.** *A* $\mathsf{RationalFloorBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, U, B, F, D, T, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{Rat}^{\uparrow}$ *input row, naming the rational whose integer part is being bounded and inspected.*
2. *U is a unary Archimedean bound row, displaying a finite natural bound large enough for the bounded search interval around Q.*
3. *B is the bounded-search trace, recording the inspected integer candidates and the first adjacent pair where the rational input changes from being below the upper candidate to being at least the lower candidate.*
4. *F is the* $\mathsf{Int}^{\uparrow}$ *floor witness row, storing the integer candidate certified by the search trace.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scaling ledger, recording denominator clearing, dyadic comparison cells, and tolerance-free rational comparison data used by the trace.*
6. *T records componentwise* hsame *transport for the rational input, unary bound, search trace, integer witness, dyadic scaling ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$Q, U, D \longmapsto B \longmapsto F.$$

8. *P is the* Pkg *provenance over* $\mathsf{RationalFloorBound}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RationalFloorBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, U, B, F, D, T, C, P, N$. It has no coordinate for host floor, least-number search, quotient representative equality, countable choice, hidden real completeness, or an unbounded integer-part oracle.

Theorem 7410.2 (RationalFloorBound NameCert obligations)**.** *For every accepted* $\mathsf{RationalFloorBound}^{\uparrow}$ *carrier $L = (Q, U, B, F, D, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalFloorBound}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the* $\mathsf{Rat}^{\uparrow}$ *input, unary bound, bounded-search trace,* $\mathsf{Int}^{\uparrow}$ *witness, dyadic scaling ledger, transport, replay, provenance, and local naming rows;*
2. *bounded-search visibility, requiring every inspected candidate and stopping comparison in B to remain displayed under the unary bound U;*
3. *floor inequality, requiring the witness row F to certify $F \leq Q < F + 1$ through rational comparisons read from Q and D;*
4. *dyadic scale compatibility, requiring denominator clearing and comparison cells in D to agree with the rational input and the integer candidates inspected by B;*
5. *ledger nonescape, stating that no host floor function, least-number operator, quotient representative, choice principle, hidden real-completeness row, or unbounded search oracle is exported by the packet.*

Proof. Project the carrier of Definition 7410.1. The rows $Q, U, B, F, D, T, C, P, N$ are the full visible surface of the packet, so a consumer must read the rational input and unary bound before it can inspect any search trace or integer witness.

Read the bounded search trace under the dyadic ledger. The row B records only finitely many inspected integer candidates bounded by U, while D supplies the rational comparison data used to verify the adjacent inequalities around F.

Finally replay through T, C, P, N. Transport, continuation, provenance, and local naming preserve the same finite route and introduce no coordinate for host floor, least-number selection, quotient representatives, choice, hidden completeness, or unbounded search. The listed rows therefore exhaust the NameCert obligations. □

Theorem 7410.3 (RationalFloorBound Archimedean step)**.** *Every accepted* $\mathsf{RationalFloorBound}^{\uparrow}$ *packet exports a finite unary bound and an* $\mathsf{Int}^{\uparrow}$ *floor witness for the displayed rational input Q. The export is the route*

$$Q, U, D \longmapsto B \longmapsto F$$

inside $L = (Q, U, B, F, D, T, C, P, N)$: U supplies the finite search limit, B records the bounded trace, D supplies the dyadic rational comparison ledger, and F is the displayed integer satisfying $F \leq Q < F + 1$. The route uses no host floor function, least-number operator, quotient representative, choice principle, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier admission row. It displays the rational input Q, unary bound U, dyadic scaling ledger D, bounded-search trace B, and integer witness F as coordinates of the same finite packet.

Use the NameCert obligations of Definition 7410.2. Bounded-search visibility keeps every inspected candidate inside the unary bound, and dyadic scale compatibility makes the rational comparisons in the trace read from Q and D rather than from a host floor oracle.

The floor inequality row then identifies the adjacent certified candidates. The witness F is exported only with the displayed inequalities $F \leq Q < F + 1$, while T, C, P, N preserve and name the same finite route. Since no excluded floor, least-number, quotient, choice, or real-completeness coordinate exists in the carrier, the Archimedean step is constructively bounded. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalFloorBound}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalFloorBound}^{\uparrow}$ packet is generated from a Rat input, unary Archimedean bound, bounded-search trace, Int floor witness, DyadicRatCore scaling ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalFloorBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7410.1, Definition 7410.2, and Definition 7410.3 seed the finite rational floor witness over Rat, Int, DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalFloorBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host floor function, least-number operator, quotient representative equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-search visibility, floor-inequality exactness, dyadic scale compatibility, transport, replay, provenance, local naming, and ledger nonescape for BEDC.Derived.RationalFloorBoundUp.

Chapter 7411

A Concrete Naming Certificate for $\mathsf{OscillationSeminorm}^{\uparrow}$

Following Bishop and Bridges on constructive function spaces and oscillation estimates, the $\mathsf{OscillationSeminorm}^{\uparrow}$ packet records finite seminorm data for displayed real-valued function windows. It sits after the real-name boundary of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the bounded oscillation ledger of chapter 6787, and the oscillation modulus route of chapter 2224. The packet names only the finite window, tolerance, readback, and oscillation-bound rows used to compare seminorm requests; it does not claim a host supremum over all points, quotient equality of functions, selected function representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7411.1 (Oscillation seminorm carrier)**.** *An* $\mathsf{OscillationSeminorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (F, W, O, M, D, R, E, B, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite function-window row, naming the source window, target window, and the finite observation schedule used by the seminorm request.*
2. *W is the* $\mathsf{Real}^{\uparrow}$ *window row for the displayed source and target comparisons.*
3. *O is the* $\mathsf{BoundedOscillation}^{\uparrow}$ *row recording the finite oscillation ledger attached to the same window.*
4. *M is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row converting the displayed oscillation ledger into a tolerance-to-window route.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for radius, slack, and comparison budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values opened by the function-window and oscillation rows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the seminorm comparison.*
8. *B is the displayed seminorm-bound row, asserting that the finite oscillation ledger is below the carried bound under the same tolerance row D.*
9. *H records componentwise* hsame *transport for function-window, Real, bounded-oscillation, oscillation-modulus, dyadic, regular-readback, seal, bound, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a seminorm request through the finite window, oscillation ledger, modulus row, dyadic budget, regular readback, Real seal, and bound row.*
11. *P is the* Pkg *provenance over* $\mathsf{OscillationSeminorm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BoundedOscillation}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationSeminorm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host supremum, quotient equality of functions, selected representatives, an unrestricted function-space norm, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7411.2 (Oscillation seminorm NameCert obligations)**.** *For every accepted* $\mathsf{OscillationSeminorm}^{\uparrow}$ *carrier $S = (F, W, O, M, D, R, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OscillationSeminorm}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite function-window row, Real window row, bounded-oscillation ledger, oscillation-modulus route, dyadic tolerance row, regular rational readback, Real seal, seminorm-bound row, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7411.1. The analytic rows are F, W, O, M, D, R, E, B, and the structural rows are H, C, P, N.

The oscillation side is finite. The row O supplies the bounded oscillation ledger for the displayed window, while M records the modulus route by which a tolerance request opens only the corresponding finite windows.

The numerical side is also finite. The dyadic row D fixes the comparison budget, R supplies regular rational readback, E seals the Real-facing comparison, and B records the seminorm bound against the same rows.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no further analytic coordinate exists, the listed rows exhaust the local NameCert surface. □

Theorem 7411.3 (Oscillation seminorm RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{OscillationSeminorm}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{BoundedOscillation}^{\uparrow},\ \mathsf{OscillationModulus}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before the seminorm-bound row is public. The handoff exports regular rational readback of the displayed oscillation data, not a host supremum, unrestricted norm, selected function representative, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the bounded oscillation and modulus rows O, M. They determine which finite window and tolerance route may be inspected for the seminorm request.

Read the dyadic budget D next. It fixes the comparison precision before any regular rational endpoint can be consumed.

The row R then supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and E supplies the terminal $\mathsf{Real}^{\uparrow}$ seal. Only after those rows are displayed may the bound row B be read as seminorm data.

The structural rows H, C, P, N preserve the same route. Because the carrier lacks host suprema, quotient function equality, selected representatives, unrestricted norm data, countable choice, and ambient Real-completeness coordinates, none of those objects can be exported by the handoff. □

Theorem 7411.4 (Oscillation seminorm window nonescape)**.** *Every accepted* $\mathsf{OscillationSeminorm}^{\uparrow}$ *comparison remains inside the finite function-window, bounded-oscillation, oscillation-modulus, dyadic, regular-readback, Real-seal, and bound rows of Definition 7411.1. In particular, a consumer cannot replace the packet by an ambient function-space norm or a supremum over unlisted points.*

Proof. By carrier projection, the only window data is F, W, and the only oscillation data is O, M. Thus every comparison begins with the displayed finite window and the oscillation rows attached to it.

By Definition 7411.2, all accepted reads must then pass through D, R, E, B with the same transport, replay, provenance, and naming rows.

The excluded objects require coordinates absent from the packet. Since no carrier row stores all host points, quotient function equality, selected representatives, an unrestricted norm, countable choice, or ambient Real-completeness data, no accepted comparison can escape the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{OscillationSeminorm}^{\uparrow}$ read factors through a finite function-window row, bounded-oscillation ledger, oscillation-modulus row, DyadicRatCore tolerance row, RegSeqRat readback, Real seal, seminorm-bound row, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: bounded-oscillation, oscillation-modulus, regseqrat, dyadicratcore, real: none is bijective with $\mathsf{OscillationSeminorm}^{\uparrow}$ because this packet jointly carries function-window data, finite oscillation ledgers, modulus routing, tolerance accounting, regular readback, Real sealing, a seminorm-bound row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationSeminorm}^{\uparrow}}$.

Constructive story: An $\mathsf{OscillationSeminorm}^{\uparrow}$ packet is generated from finite function-window rows, Real window rows, BoundedOscillation rows, OscillationModulus rows, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seals, displayed seminorm bounds, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationSeminorm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7411.1, Definition 7411.2, Definition 7411.3, and Definition 7411.4 seed the finite oscillation seminorm packet over displayed Real-facing function windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationSeminorm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host suprema, quotient function equality, selected function representatives, unrestricted function-space norms, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, bounded-oscillation ledger exactness, oscillation-modulus routing, dyadic tolerance accounting, RegSeqRat readback, Real-seal nonescape, seminorm-bound confinement, transport, replay, provenance, and local naming for BEDC.Derived.OscillationSeminormUp.

Chapter 7412

A Concrete Naming Certificate for $\mathsf{AbelMeanBoundary}^{\uparrow}$

Following Hardy's summability theory, the $\mathsf{AbelMeanBoundary}^{\uparrow}$ packet records the finite boundary at which Abel means of a displayed real series become available to Real and Completion consumers. It sits after the real-series source of chapter 1581, the Abel partial-summation route of chapter 2125, the Abel-test surface of chapter 1496, the uniform Cauchy series ledger of chapter 1736, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite Abel-mean boundary; it does not import host infinite sums, quotient streams, selected radial limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7412.1 (Abel mean boundary carrier)**.** *An* $\mathsf{AbelMeanBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, A, T, U, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing finite partial sums and tail requests for the underlying real series.*
2. *A is the* $\mathsf{AbelPartialSummation}^{\uparrow}$ *row, carrying the finite summation-by-parts ledger used to control Abel means.*
3. *T is the* $\mathsf{AbelTest}^{\uparrow}$ *row, recording the bounded-partial-sum and monotone-coefficient route relevant to the Abel boundary.*
4. *U is the* $\mathsf{UniformCauchySeries}^{\uparrow}$ *row, giving the shared tail discipline used before a boundary read reaches a real seal.*
5. *W records the inspected coefficient, radius, partial-sum, and tail windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for radial parameters, tail bounds, and endpoint comparisons.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed Abel-mean windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after S, A, T, U, W, D, R have been displayed.*
9. *H records componentwise* hsame *transport for the source, partial-summation, Abel-test, uniform-tail, window, dyadic, readback, seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay of the route*

$$S, A, T, U, W, D \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* AbelMeanBoundary$^{\uparrow}$, RealSeries$^{\uparrow}$, AbelPartialSummation$^{\uparrow}$, AbelTest$^{\uparrow}$, UniformCauchySeries$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{AbelMeanBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, A, T, U, W, D, R, E, H, C, P, N$. It has no coordinate for host summability semantics, a selected radial limit, quotient equality of series names, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7412.2 (Abel mean boundary NameCert obligations)**.** *For every accepted* AbelMeanBoundary$^{\uparrow}$ *carrier*

$$M = (S, A, T, U, W, D, R, E, H, C, P, N),$$

the local NameCert$_{\text{AbelMeanBoundary}^{\uparrow}}$ *surface consists exactly of source-series admission through S; Abel partial-summation admission through A; Abel-test admission through T; uniform-tail admission through U; finite coefficient, radius, partial-sum, and tail-window exposure through W; dyadic tolerance accounting through D; regular rational readback through R; terminal Real seal ordering through E; and componentwise transport, continuation replay, provenance, and local naming through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.AbelMeanBoundaryUp.AbelMeanBoundaryTasteGate single carrier alignment`

Proof. Project the accepted carrier of Definition 7412.1. The tuple displays exactly the real-series source, Abel partial-summation row, Abel-test row, uniform-tail row, finite windows, dyadic ledger, regular readback, Real seal, and structural rows.

The analytic controls are finite. Rows S, A, T, U name the partial sums, summation-by-parts ledger, Abel-test constraints, and shared tail discipline that a boundary read may inspect, while W and D record the concrete windows and tolerances.

The regular readback R repacks those same displayed rows before the terminal seal E is visible. Transport through H and replay through C preserve the same route, and P, N only source and name it. Since no further carrier coordinate exists, the listed rows exhaust the local NameCert obligations. □

Theorem 7412.3 (Abel mean boundary Real-seal route)**.** *Every Real or Completion consumer of an accepted* AbelMeanBoundary$^{\uparrow}$ *carrier must read the finite route*

$$\text{RealSeries}^{\uparrow},\quad \text{AbelPartialSummation}^{\uparrow},\quad \text{AbelTest}^{\uparrow},\quad \text{UniformCauchySeries}^{\uparrow},\quad W, D,\quad \text{RegSeqRat}^{\uparrow},\quad \text{Real}^{\uparrow}$$

through the same packet rows $S, A, T, U, W, D, R, E, H, C, P, N$. Thus an Abel-mean endpoint reaches the Real$^{\uparrow}$ *seal only as a displayed regular-rational handoff, not as a host infinite sum, selected radial limit, quotient stream equality, countable-choice schedule, trichotomy branch, or ambient Real-completeness theorem.*

Proof. Start with an accepted carrier and project the source rows S, A, T, U. The real-series row supplies finite partial sums, the Abel partial-summation row supplies the by-parts ledger, the Abel-test row supplies the boundary control, and the uniform Cauchy series row supplies the shared tail discipline.

Read the finite Abel-mean window through W and D. These rows fix the inspected coefficients, radius requests, partial-sum windows, tail thresholds, and dyadic tolerances that determine the regular rational readback R.

Finally pass through E, H, C, P, N. The seal row receives its analytic input only from R, and the structural rows transport, replay, source, and name that same path. Therefore a downstream Real or Completion consumer obtains only the displayed finite handoff. □

Falsifiable prediction: An accepted $\mathsf{AbelMeanBoundary}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the RealSeries source row, Abel partial-summation row, Abel-test row, uniform Cauchy series row, finite Abel-mean windows, dyadic tolerance ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: realseries, abel-partial-summation, abel-test, uniform-cauchy-series, regseqrat, real: $\mathsf{AbelMeanBoundary}^{\uparrow}$ is not bijective to any listed sibling because it binds source partial sums, summation-by-parts data, Abel-test control, one uniform tail ledger, Abel-mean windows, regular readback, and Real sealing into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelMeanBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelMeanBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7412.1, Definition 7412.2, and Definition 7412.3 seed the finite Abel-mean boundary over RealSeries partial sums, Abel partial summation, Abel-test control, uniform Cauchy series tails, RegSeqRat readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelMeanBoundary}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.AbelMeanBoundaryUp`

Bridge status: none

Not claimed: This chapter does not close host infinite sums, selected radial limits, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Abel partial-summation admission, Abel-test admission, uniform-tail admission, finite-window exhaustion, regular readback, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.AbelMeanBoundaryUp.

Constructive story: An $\mathsf{AbelMeanBoundary}^{\uparrow}$ packet is generated from RealSeries source data, Abel partial-summation data, Abel-test data, uniform Cauchy series tail data, finite Abel-mean windows, dyadic tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7413

A Concrete Naming Certificate for $\mathsf{HenstockLemma}^{\uparrow}$

Following Henstock–Kurzweil and Bishop–Bridges gauge integration, the $\mathsf{HenstockLemma}^{\uparrow}$ packet records the finite gauge-partition control lemma as NameCert data. It sits after the fine-partition surface of chapter 6467 and before the gauge-integral consumer route of chapter 1999: a finite tagged partition is read together with local oscillation and mesh ledgers, then passed to regular-rational and Real-facing rows without importing host choice, open-cover compactness, quotient equality, or ambient Real completeness.

Definition 7413.1 (Henstock lemma carrier)**.** *A* $\mathsf{HenstockLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, G, F, O, M, R, E, T, C, P, N)$$

whose rows expose:

1. *I, the interval source row carrying the displayed compact or located interval domain on which the gauge partition is inspected;*
2. *G, the positive gauge row assigning a strictly positive local radius to every admitted tag;*
3. *F, the accepted* $\mathsf{FinePartitionGauge}^{\uparrow}$ *row carrying the Cousin/fine tagged partition, cell coverage, tag ledger, and fineness evidence;*
4. *O, the oscillation ledger recording the local upper and lower oscillation bounds attached to each tagged cell of F;*
5. *M, the mesh row recording finite cell widths, finite comparison bounds, and the mesh budget consumed by later sums;*
6. *R, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite oscillation and mesh estimates;*
7. *E, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular rational readback;*
8. *T, the componentwise* hsame *transport row for interval, gauge, fine partition, oscillation, mesh, readback, seal, replay, provenance, and local naming data;*
9. *C, the displayed* Cont *replay row preserving the same finite gauge-partition route;*
10. *P, the* Pkg *provenance over* $\mathsf{HenstockLemma}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{RiemannSumGauge}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

11. N, the local $\mathsf{NameCert}_{\mathsf{HenstockLemma}^\uparrow}$ *row.*

The classifier compares accepted packets only through $I, G, F, O, M, R, E, T, C, P, N$. It has no coordinate for a choice-selected partition, a host open-cover compactness theorem, quotient equality of functions, an external Henstock integral, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 7413.2 (Henstock lemma NameCert obligations)**.** *For every accepted* $\mathsf{HenstockLemma}^\uparrow$ *carrier $H = (I, G, F, O, M, R, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HenstockLemma}^\uparrow}$ *surface is exhausted by interval-source admission, positive-gauge admission, Cousin/fine tagged-partition admission, oscillation-ledger exactness, mesh-row readback,* $\mathsf{RegSeqRat}^\uparrow$ *readback, terminal* $\mathsf{Real}^\uparrow$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{RiemannSumGauge}^\uparrow$ *or* $\mathsf{GaugeIntegral}^\uparrow$ *consumer must read these rows before using the finite Henstock control packet.*

Proof. Project the carrier of Definition 7413.1. The visible analytic rows are I, G, F, O, M, R, E, and the structural rows are T, C, P, N.

The partition admission obligation is the route through F. It is already a $\mathsf{FinePartitionGauge}^\uparrow$ row, so the Cousin/fine tagged partition is displayed before the oscillation or mesh ledgers can be consumed.

The estimate obligation is the route through O, M, R, E. The oscillation ledger and mesh row are finite rows attached to the same tagged cells, the regular readback row R is downstream of those estimates, and the Real seal E is visible only after R.

Transport, replay, provenance, and local naming preserve these coordinates. Since the carrier has no host choice, open-cover compactness, quotient equality, external integral, or ambient completeness row, the listed obligations exhaust the local NameCert surface. □

Theorem 7413.3 (Henstock lemma finite gauge control)**.** *Every* $\mathsf{GaugeIntegral}^\uparrow$ *consumer of an accepted* $\mathsf{HenstockLemma}^\uparrow$ *carrier factors through the finite route*

$$I, G, F, O, M \longmapsto R \longmapsto E.$$

The consumer receives interval source data, positive gauge data, a Cousin/fine tagged partition, local oscillation control, mesh readback, regular-rational readback, and a terminal Real seal; it receives no choice-selected partition, no host open-cover compactness theorem, no quotient equality of functions, and no ambient $\mathsf{Real}^\uparrow$ *completeness principle.*

Proof. Start with the fine-partition row F. It binds the displayed tagged partition to the interval source I and positive gauge G, so a consumer cannot replace the partition by a host-selected one.

Read the estimate rows next. The oscillation ledger O and mesh row M are attached cellwise to the same finite partition, and the $\mathsf{RegSeqRat}^\uparrow$ row R is the only readback route for those estimates.

Finally consume the Real seal row E and the structural rows T, C, P, N. They seal and replay the displayed finite packet without adding compactness, quotient equality, or completeness data. Hence every gauge-integral use of the Henstock lemma remains inside the route displayed above. □

Falsifiable prediction: Every accepted $\mathsf{HenstockLemma}^\uparrow$ packet must expose interval source, positive gauge, Cousin/fine tagged partition, oscillation ledger, mesh row, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows before a gauge-integral consumer reads it.

Independence witness: cousinlemma, finepartitiongauge, taggedrealpartition, riemannsumgauge, gaugeintegral, regseqrat, real: $\mathsf{HenstockLemma}^\uparrow$ is not bijective to any listed sibling because it

jointly carries local oscillation control and mesh readback over a displayed Cousin/fine tagged partition before regular-rational and Real sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{HenstockLemma}\uparrow}$.

Constructive story: A $\mathsf{HenstockLemma}^{\uparrow}$ packet is generated from an interval source, positive gauge, Cousin/fine tagged partition, oscillation ledger, mesh row, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenstockLemma}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7413.1, Definition 7413.2, and Definition 7413.3 seed the finite gauge-partition control route between Cousin/fine partitions and gauge-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HenstockLemma}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close choice-selected partitions, host open-cover compactness, quotient equality of functions, external Henstock integrals, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, positive-gauge admission, Cousin/fine partition admission, oscillation exactness, mesh readback, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HenstockLemmaUp.

Chapter 7414

A Concrete Naming Certificate for $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$

The $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ packet realizes the cost-protocol and critical-debt rows of section 9462.13 as finite NameCert data. It sits beside the positive interpretability classifier of chapter 6202, the classifier novelty witness of chapter 6138, the discovery pipeline calculus of chapter 5914, the explanation-complexity information packet of chapter 6181, and the effective replacement ledger of chapter 568. The packet names the debt-accounting surface used by a positive discovery claim; it does not by itself certify classifier novelty, positive net information, global interpretability quality, hidden semantic truth, or a prose-only discovery verdict.

Definition 7414.1 (Positive discovery debt ledger carrier)**.** *A* $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (E_0, E_1, J, W, D_c, D_l, D_s, D_v, D_i, D_g, Q, U, H, C, P, N)$$

with the following displayed rows:

1. E_0 *is the source explanation-state row before the proposed discovery transition.*
2. E_1 *is the target explanation-state row after the proposed transition.*
3. J *is the classifier-novelty witness row, naming the common source and changed classifier judgment.*
4. W *is the public cost-protocol row for benefit weights, score weights, debt weights, source scope, target scope, and not-claimed boundary.*
5. $D_c, D_l, D_s, D_v, D_i, D_g$ *are the critical-debt rows for certificate debt, ledger debt, semantic debt, verification debt, intervention debt, and generalization debt.*
6. Q *is the net-information readback row inherited from the explanation-complexity information surface under the same protocol row* W*.*
7. U *is the downstream-use ledger row recording which classifier, cost, and debt rows are actually consumed by later reports.*
8. H *records componentwise* hsame *transport for explanation states, novelty witness, cost protocol, critical-debt rows, net-information readback, downstream-use ledger, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay through classifier novelty, cost-protocol inspection, critical-debt accounting, net-information readback, downstream-use inspection, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$, $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$, $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, $\mathsf{DiscoveryPipelineCalculus}^{\uparrow}$, $\mathsf{ExplanationComplexityInformation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}}$ *row.*

The carrier has no coordinate for hidden benefit weights, uncounted critical debt, classifier novelty without J, positive net information without Q, downstream use without U, or a positive-discovery verdict without the displayed protocol and debt rows.

Theorem 7414.2 (Positive discovery debt ledger NameCert obligations)**.** *For every accepted* $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ *carrier* $L = (E_0, E_1, J, W, D_c, D_l, D_s, D_v, D_i, D_g, Q, U, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}}$ *surface consists exactly of before-state admission, after-state admission, classifier-novelty witness exposure, public cost-protocol exposure, six critical-debt rows, net-information readback, downstream-use ledger exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7414.1. The before and after states are E_0, E_1, the classifier-shift evidence is J, and the public accounting convention is W.

The debt surface is the six-row family $D_c, D_l, D_s, D_v, D_i, D_g$. These rows separate certificate, ledger, semantic, verification, intervention, and generalization debt before any positive discovery claim may consume the ledger.

The net-information and downstream-use rows are Q, U. They ensure that the cost protocol and debt rows are read by the same route that later reports consume.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate exists, the listed rows exhaust the local NameCert surface. □

Theorem 7414.3 (Cost protocol critical-debt route)**.** *Every accepted* $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ *read that supports a positive discovery classification must expose the public cost-protocol row W and all six critical-debt rows $D_c, D_l, D_s, D_v, D_i, D_g$ before it may consume the net-information row Q or the downstream-use ledger U.*

Proof. Begin with the NameCert obligations of Definition 7414.2. They place W and the six debt rows in the admitted surface before replay can certify the packet.

Read Q only after that accounting surface is present. The row Q compares benefit against score and debt under the same protocol, so it cannot be detached from W or from the critical-debt rows.

Read U last. The downstream-use ledger records which displayed rows are consumed by later reports; it cannot witness use for a hidden protocol or an omitted debt row. □

Theorem 7414.4 (Debt ledger separation from classifier verdict)**.** *An accepted* $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ *packet supplies debt-accounting evidence for the positive-discovery route, but it does not itself classify the transition as* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$. *A downstream positive classifier must still read the classifier-novelty witness, positive net-information row, public cost protocol, debt rows, and not-claimed boundary through its own carrier.*

Proof. Use Definition 7414.3. The ledger packet exposes the cost protocol, critical debts, net-information readback, and downstream-use rows as an auditable accounting surface.

The positive interpretability classifier of chapter 6202 has its own carrier and acceptance route. The debt ledger here names the accounting rows that route may consume; it is not a replacement for the classifier's verdict row.

Thus the packet can support a certified-discovery route by making cost and debt public, while still refusing any positive-discovery classification that skips the classifier surface. □

Falsifiable prediction: Every accepted $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ read exposes before and after explanation states, a classifier-novelty witness, a public cost protocol, six critical-debt rows, net-information readback, downstream-use ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: positive-interpretability-classifier, classifier-novelty-witness, discovery-pipeline-calculus, explanation-complexity-information, effective-replacement-ledger: none is bijective with $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ because this packet jointly carries public cost protocol, critical-debt accounting, net-information readback, downstream-use evidence, transport, replay, provenance, and local naming as one debt ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}$ packet is generated from before and after explanation states, a classifier-novelty witness, public cost-protocol rows, certificate, ledger, semantic, verification, intervention, and generalization debt rows, net-information readback, downstream-use ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7414.1, Definition 7414.2, Definition 7414.3, and Definition 7414.4 seed the finite debt-ledger packet for positive discovery accounting.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveDiscoveryDebtLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close positive-discovery classification, global interpretability quality, hidden semantic truth, uncounted costs, undisplayed debts, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked before and after state admission, classifier-novelty exposure, public cost-protocol exposure, critical-debt row accounting, net-information readback, downstream-use ledger exposure, transport, replay, provenance, and local naming for BEDC.Derived.PositiveDiscoveryDebtLedgerUp.

Chapter 7415

A Concrete Naming Certificate for $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$

Following Jordan's bounded-variation theory and the Riemann finite-sum construction, the BoundedVariationRiemar packet records the finite partition route already used when integration-facing chapters read a variation ledger and a tagged sum in the same breath. It sits between the bounded-variation certificate of chapter 398, the tagged finite-sum certificate of chapter 1615, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the common finite partition, variation ledger, tagged summation row, dyadic observations, regular readback, Real seal, transport, replay, provenance, and local naming data; it does not assert an integral limit, a supremum over all partitions, a host function quotient, selected tags outside the displayed packet, or ambient completeness.

Definition 7415.1 (Bounded-variation Riemann-sum carrier)**.** *A* $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, \Pi, V, T, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval row over which all partition, endpoint, variation, and tagged-sum reads are made.*
2. *Π is the finite interval-partition row, carrying ordered endpoints, subinterval cells, and the common mesh ledger used by both the variation and tagged-sum faces.*
3. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger, read through the finite endpoint and edge-difference rows of chapter 398.*
4. *T is the tag-containment row, assigning a displayed tag to each cell of Π without exporting a choice-selected tag family outside the packet.*
5. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *row, computing the finite tagged sum from Π, T, the displayed value reads, and the cell-width ledger of chapter 1615.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-observation row, recording endpoint differences, tag-value observations, widths, and finite variation or sum arithmetic at the dyadic level.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the displayed dyadic variation and tagged-sum data as regular rational observations.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after* I, Π, V, T, S, D, R *have been displayed.*

9. *H records componentwise* hsame *transport for the interval, partition, variation, tag, sum, dyadic, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the common partition through*

$$I, \Pi \longmapsto V, T, S, D \longmapsto R \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationRiemannSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host integrability, a limiting process over all refinements, a supremum variation value, quotient equality of functions, a choice-selected tag family, an ambient measure, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7415.2 (Bounded-variation Riemann-sum NameCert obligations)**.** *For every accepted* $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$ *carrier* $J = (I, \Pi, V, T, S, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedVariationRiema}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the displayed interval, partition, bounded-variation ledger, tag-containment row, finite Riemann-sum row, dyadic observation row, regular readback, Real seal, transport, replay, provenance, and local naming;*

2. *common finite-partition exposure, requiring both the* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger* V *and the* $\mathsf{RiemannSum}^{\uparrow}$ *row* S *to read the same interval row* I *and partition row* Π *before either face is consumed;*

3. *dyadic edge and tag compatibility, requiring the edge-difference observations, tag-value reads, widths, variation arithmetic, and finite-sum arithmetic in* D *to be attached to the same cells of* Π*;*

4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback, requiring* R *to be obtained only from the displayed variation and tagged-sum dyadic rows rather than from a hidden sequence or external function;*

5. $\mathsf{Real}^{\uparrow}$ *seal non-escape, requiring* E *to be downstream from* R *and to export no host integrability theorem, limiting process over refinements, supremum over partitions, quotient function equality, choice-selected tag family, ambient measure, or completeness principle.*

Proof. Project the carrier of Definition 7415.1. The displayed rows are exactly the interval, common partition, bounded-variation ledger, tag-containment data, finite Riemann sum, dyadic observations, regular readback, terminal Real seal, and structural rows.

The common-partition obligation is forced by the order of the carrier. The rows V and S are both downstream from I and Π, so a consumer cannot read the variation budget from one partition and the tagged sum from another hidden mesh.

The dyadic compatibility obligation is the row D. It attaches endpoint differences, tag values, widths, variation arithmetic, and finite-sum arithmetic to the same displayed cells before any regular rational readback is available.

Finally the readback and seal obligations are downstream. The row R repacks only the displayed dyadic data, and the row E is exposed only after R. Since no carrier coordinate stores integrability, refinement limits, variation suprema, quotient function equality, external tag choice, measures, or completeness, the five obligations exhaust the local certificate. □

Theorem 7415.3 (Bounded-variation Riemann-sum finite interface)**.** *Every integration-facing consumer of an accepted* $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{BoundedVariation}^{\uparrow},\ \mathsf{RiemannSum}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through one displayed interval-partition row Π*. The bounded-variation face supplies the finite endpoint and edge ledger, the Riemann-sum face supplies tags, widths, and finite summands on the same cells, and the regular rational readback and Real seal are downstream from both faces.*

Proof. Begin with the accepted carrier $J = (I, \Pi, V, T, S, D, R, E, H, C, P, N)$. The rows I and Π are displayed before the variation ledger V and before the tag-containment and finite-sum rows T, S.

Read the two analytic faces over that same partition. The bounded-variation face contributes endpoint and edge-difference rows through V, while the Riemann-sum face contributes the tag, value, width, and summand rows through T and S.

The dyadic row D then records both faces at the finite arithmetic level. Only after that common dyadic ledger has been displayed may the packet expose the regular rational readback R and the terminal Real seal E.

Thus integration-facing consumers receive a named finite interface between variation control and tagged summation. The interface contains no hidden limiting process, no ambient integrability theorem, and no external tag or partition selection principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationRiemannSum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedVariationRiemannSum}^{\uparrow}$ packet is generated from a finite interval row, a common partition row, a bounded-variation ledger, a tag-containment row, a finite Riemann-sum row, dyadic edge and tag observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationRiemannSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7415.1, Definition 7415.2, and Definition 7415.3 seed the finite common-partition interface between bounded-variation ledgers and tagged Riemann sums.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationRiemannSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host integrability, limiting processes over all refinements, variation suprema over arbitrary partitions, quotient equality of functions, selected tag families, ambient measures, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common finite-partition exposure, dyadic edge and tag compatibility, RegSeqRat readback, RealUp seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BoundedVariationRiemannSumUp.

Chapter 7416

A Concrete Naming Certificate for $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$

Following the finite nerve tradition for compact covers and the Bishop–Bridges proof of uniform continuity on compact metric spaces, the $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ packet records finite cover-nerve incidence together with local oscillation control and a rational lower-bound fold. It refines the compact-cover nerve surface of chapter 6263 into a consumer-facing packet for the $\mathsf{UniformModulus}^{\uparrow}$ route of chapter 9237, without passing through a host open cover, selected Lebesgue number, quotient equality of metric points, or ambient compactness theorem.

Definition 7416.1 (Compact uniform oscillation nerve carrier)**.** *A* $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, N, O, L, F, M, R, E, H, C, P, A)$$

whose rows expose:

1. K*, the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the compact metric carrier, finite probe spine, and located finite-net coverage;*
2. N*, the* $\mathsf{CompactCoverNerve}^{\uparrow}$ *row carrying cover-member incidence and finite overlap data;*
3. O*, the local oscillation-control ledger attached to each displayed cover member and overlap row;*
4. L*, the rational lower-bound fold row over the positive cover and oscillation radii;*
5. F*, the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row receiving the tolerance-only precision extracted by* L*;*
6. M*, the* $\mathsf{Met}^{\uparrow}$ *distance row used for source-side triangle and overlap comparisons;*
7. R*, the* $\mathsf{Real}^{\uparrow}$ *seal row for real-valued oscillation or target-distance bounds after the uniform-modulus handoff is displayed;*
8. E*, the finite incidence exactness row, recording that every oscillation read is attached to a cover member or nerve edge of* N*;*
9. H*, the componentwise* hsame *transport row for compact source, nerve, oscillation, lower-bound fold, uniform-modulus handoff, metric, Real, incidence, replay, provenance, and local naming data;*
10. C*, the displayed* Cont *replay row preserving the same finite compact-uniform route;*

11. *P, the* Pkg *provenance over* $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactCoverNerve}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *A, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationNerve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, N, O, L, F, M, R, E, H, C, P, A$. It has no coordinate for a host nerve complex, an open-cover compactness theorem, an external lower-bound selector, quotient equality of metric points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7416.2 (Compact uniform oscillation nerve NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ *carrier $U = (K, N, O, L, F, M, R, E, H, C, P, A)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationNerve}^{\uparrow}}$ *surface is exhausted by compact-metric source admission, compact-cover-nerve incidence admission, local oscillation-control exactness, rational lower-bound fold readback,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff exactness,* $\mathsf{Met}^{\uparrow}$ *distance compatibility,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, incidence exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7416.1. The compact source, cover nerve, oscillation ledger, lower-bound fold, uniform-modulus handoff, metric row, Real seal, and incidence row are exactly K, N, O, L, F, M, R, E.

The compact-cover obligation is the route through K, N, E. The compact metric source supplies the finite probe spine, the cover nerve records displayed member and overlap incidence, and incidence exactness keeps every oscillation row attached to that finite nerve.

The uniform-modulus obligation is the route through O, L, F, M, R. Local oscillation control supplies the positive candidate rows, the lower-bound fold extracts the tolerance-only precision, the metric row supplies source comparisons, and the Real seal is consumed only after the handoff is displayed.

The rows H, C, P, A transport, replay, source, and name the same packet. Since no coordinate stores a host nerve complex, open-cover compactness theorem, external lower-bound selector, quotient point equality, or ambient completeness, the listed obligations exhaust the NameCert surface. □

Theorem 7416.3 (Compact uniform oscillation nerve handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{CompactCoverNerve}^{\uparrow}, \quad O, \quad L, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The consumer receives finite cover-nerve incidence, local oscillation control, rational lower-bound fold data, metric compatibility, and a Real seal boundary, but it receives no host open cover, no selected Lebesgue number, no quotient equality of metric points, no host nerve complex, and no ambient compactness theorem.

Proof. Begin with the compact source and nerve rows. The route through K and N fixes the finite cover-member and overlap data before any oscillation estimate is read.

Next use the oscillation and lower-bound rows. The ledger O attaches each local oscillation bound to the displayed nerve incidence, and L folds the positive radius data into the precision row consumed by F.

Finally read the metric and Real-facing rows. The $\mathsf{Met}^{\uparrow}$ row M supplies source-distance compatibility for the handoff, while the $\mathsf{Real}^{\uparrow}$ seal R is downstream of the displayed uniform-modulus route. The structural rows H, C, P, A preserve the same finite packet, so none of the excluded host objects can be exported. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ packet must expose CompactMetric source rows, CompactCoverNerve incidence, local oscillation control, rational lower-bound fold data, UniformModulus handoff, MetricSpace distance compatibility, Real seal, transport, replay, provenance, and local NameCert rows before a compact-uniform consumer reads it.

Independence witness: compactmetric, compactcovernerve, uniformmodulus, metricspace, real: $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries cover-nerve incidence, local oscillation control, rational lower-bound fold data, metric compatibility, and uniform-modulus handoff as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformOscillationNerve}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{CompactUniformOscillationNerve}^{\uparrow}$ packet is generated from CompactMetric finite-net data, CompactCoverNerve incidence, local oscillation rows, rational lower-bound folds, UniformModulus handoff, MetricSpace distance compatibility, Real sealing, incidence exactness, componentwise transport, displayed replay, provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillationNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7416.1, Definition 7416.2, and Definition 7416.3 seed the finite oscillation-nerve route from compact cover incidence to uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformOscillationNerve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host nerve complexes, open-cover compactness, selected Lebesgue numbers, quotient equality of metric points, ambient compactness theorems, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, cover-nerve incidence admission, oscillation exactness, lower-bound fold readback, UniformModulus handoff, metric compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformOscillationNerveUp.

Chapter 7417

A Concrete Naming Certificate for $\mathsf{OstrowskiInequality}^{\uparrow}$

Following Ostrowski and Bishop–Bridges on constructive real estimates, the $\mathsf{OstrowskiInequality}^{\uparrow}$ packet records a finite error-bound certificate for a function on a displayed closed bounded interval. It sits over the dyadic rational arithmetic surface of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the continuous-map surface of chapter 130, the calculus ledger of chapter 3632, and the interval carrier of chapter 1591. The chapter names only a finite constructive error-bound route; it does not import a host real floor, trichotomy, quotient equality, selected limits, or ambient Real completeness.

Definition 7417.1 (Ostrowski inequality carrier)**.** *An* $\mathsf{OstrowskiInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, f, x, q, W, D, A, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row naming endpoints $a \leq b$ and the inspected dyadic interval windows.*
2. *f is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the interval function, read only through finite continuity witnesses on the displayed windows.*
3. *x is the inspected point row in I, represented through the interval membership and dyadic-window data.*
4. *q is the requested error precision.*
5. *W is the finite dyadic interval window containing the endpoint, midpoint, and point-readback cells used by the estimate.*
6. *D is the* $\mathsf{Calculus}^{\uparrow}$ *derivative-bound ledger. It records the finite rows witnessing the derivative bound M on the displayed interval windows.*
7. *A is the average-value row for the finite integral approximation over I.*
8. *B is the dyadic error-budget row combining the distance of x from the interval midpoint, the interval length, and the derivative-bound row D.*
9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the two regular rational names whose difference is bounded by B at precision q.*

10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed error estimate.*
11. *H records componentwise* hsame *transport for the interval, map, inspected point, precision, dyadic window, derivative-bound ledger, average row, budget row, readback row, seal, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay of the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Calculus}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

13. *P is the* Pkg *provenance over* $\mathsf{OstrowskiInequality}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{OstrowskiInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $I, f, x, q, W, D, A, B, R, E, H, C, P, N$. It has no coordinate for host integration, a selected representative of a real function, quotient equality of real names, trichotomy, a host floor, or ambient completeness.

Lean4 ✓ `BEDC.Derived.OstrowskiInequalityUp.OstrowskiInequalityTasteGate single carrier alignment`

Theorem 7417.2 (Ostrowski NameCert obligations)**.** *For every accepted* $\mathsf{OstrowskiInequality}^{\uparrow}$ *carrier $O = (I, f, x, q, W, D, A, B, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OstrowskiInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval row I, continuous-map row f, inspected point row x, precision row q, finite dyadic window W, derivative-bound ledger D, average-value row A, dyadic error budget B, regular-rational readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 7417.1. The analytic data visible to the certificate are exactly the interval, map, point, precision, finite window, derivative-bound ledger, average row, dyadic budget, readback row, and terminal seal.

The interval and continuity rows are read before the calculus row. Thus the derivative-bound ledger D is attached to the displayed closed bounded interval windows rather than to an ambient differentiability principle over host reals.

The budget row B is the only place where the Ostrowski estimate is assembled. It receives the point-location and interval-length cells from W, the derivative bound from D, and the average row A before R and E are available.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no excluded object appears in the carrier, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7417.3 (Ostrowski dyadic error bound)**.** *Every accepted* $\mathsf{OstrowskiInequality}^{\uparrow}$ *packet exposes a finite dyadic inequality row*

$$|f(x) - A| \leq B_q$$

at the requested precision q, where A is the displayed average-value row, B_q is read from the dyadic budget row B, and every component of B_q is obtained from the finite interval window W and derivative-bound ledger D.

Proof. Start with the finite window W. It displays the endpoint cells, the midpoint cell, the inspected point cell, and the interval-length cells used by the Ostrowski estimate.

Read the calculus ledger D next. Its derivative-bound rows supply the finite bound used in the estimate, and the classifier admits no separate derivative source.

The dyadic budget B combines exactly those window and derivative rows with the average-value row A. The regular-rational row R then reads the difference estimate at precision q, and the terminal seal E records the resulting Real-facing bound without adding a new analytic principle. □

Theorem 7417.4 (Ostrowski Real-seal handoff)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{OstrowskiInequality}^{\uparrow}$ *packet is reachable only after the finite dyadic interval windows, derivative-bound rows, average-value row, dyadic error-budget row, and regular-rational readback have been displayed. Hence the packet exports no host real floor, no trichotomy decision, no quotient equality of real names, no selected limit, and no ambient Real completeness witness.*

Proof. Inspect the route stored by C. It lists the interval and map rows before the calculus ledger, the calculus ledger before the dyadic budget, and the dyadic budget before regular-rational readback.

The terminal seal E is downstream from R. A consumer therefore cannot reach the Real-facing estimate until the finite windows W, derivative-bound ledger D, average row A, budget row B, and readback row R have all been exposed.

The structural rows H, P, N preserve and name this same route. They do not insert host comparison, quotient equality, selected representatives, or completeness data. □

Theorem 7417.5 (Ostrowski local naming surface)**.** *The local naming row N of an accepted* $\mathsf{OstrowskiInequality}^{\uparrow}$ *packet is stable under componentwise* hsame *transport and displayed* Cont *replay: any named consumer of the estimate must preserve the same interval row, map row, inspected point, precision request, dyadic windows, derivative-bound ledger, average row, budget row, readback row, Real seal, and* Pkg *provenance.*

Proof. Use the transport row H component by component. It relates only the rows already present in the carrier and therefore cannot rename the packet through a detached real estimate.

Replay row C fixes the order in which the finite observations are consumed. Any continuation that names the estimate must follow the displayed interval, map, calculus, dyadic, regular-rational, and Real-seal route.

The package row P records the sibling provenance and the local row N names the packet over that provenance. Thus local naming is stable exactly over the finite Ostrowski surface and no larger host-real interface. □

Falsifiable prediction: An accepted $\mathsf{OstrowskiInequality}^{\uparrow}$ consumer that reads an error estimate without the displayed interval row I, map row f, inspected point x, precision q, finite dyadic window W, derivative-bound ledger D, average row A, dyadic budget B, regular-rational readback R, and terminal seal E refutes the carrier surface.

Independence witness: dyadicratcore, regseqrat, real, continuousmap, calculus, closedbounded-interval: no listed sibling supplies the whole Ostrowski packet because each sibling contributes arithmetic, readback, sealing, continuity, derivative bounds, or interval windows, while this chapter binds the finite error-budget route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{OstrowskiInequality}^{\uparrow}}$.

Constructive story: An $\mathsf{OstrowskiInequality}^{\uparrow}$ packet is generated from a ClosedBoundedInterval row, a ContinuousMap row, an inspected point, a precision request, finite dyadic windows, a Calculus derivative-bound ledger, an average-value row, a DyadicRatCore error budget, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OstrowskiInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7417.1, Definition 7417.2, Definition 7417.3, Definition 7417.4, and Definition 7417.5 seed the finite constructive Ostrowski error-bound route over interval, continuity, calculus, dyadic, regular-rational, and real-seal rows.

Formal verification: FormalStatus(NameCert$_{\text{OstrowskiInequality}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host integration, host real floor, trichotomy, quotient equality of real names, selected limits, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, interval-window exactness, derivative-bound exactness, dyadic error-budget routing, RegSeqRat readback, RealUp sealing, transport stability, continuation replay, and provenance nonescape for BEDC.Derived.OstrowskiInequalityUp.

Chapter 7418

A Concrete Naming Certificate for $\mathsf{PackingDimension}^{\uparrow}$

Following Falconer and Mattila's packing-side metric dimension, the $\mathsf{PackingDimension}^{\uparrow}$ packet records the finite disjoint-ball schedules that measure a compact metric object from the separated-cover side. It is the packing neighbour of the Hausdorff, Minkowski, and Assouad metric-dimension certificates in chapter 4119, chapter 3878, and chapter 6325. The carrier is grounded in the metric and compact metric surfaces of chapter 57 and chapter 129, the dyadic radius ledger of chapter 291, and the threshold readback of chapter 38. It names only finite packing evidence; it does not assert a host supremum over all packings, quotient equality of real names, selected limits, or ambient completeness.

Definition 7418.1 (Packing dimension carrier)**.** *A* $\mathsf{PackingDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, K, C, R, N, H, Q, S, T, U, L, O, A)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *distance surface used to test separated centers.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source for the compact metric object whose packing behaviour is being inspected.*
3. *C is the finite list of packing centers, each read through the compact metric carrier rather than through a host point set.*
4. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, with one positive dyadic radius attached to each packing window.*
5. *N records the disjointness checks: the closed metric balls centered at the displayed entries of C and using the radii in R are pairwise separated inside the metric row M.*
6. *H records the Hausdorff comparison row, naming the covering-side threshold from* $\mathsf{HausdorffDimension}^{\uparrow}$ *that is compared with the packing schedule.*
7. *Q records the Minkowski comparison row, naming the finite covering and box-counting ledger from* $\mathsf{MinkowskiDimension}^{\uparrow}$*.*
8. *S records the Assouad comparison row, naming the local scale comparison from* $\mathsf{AssouadDimension}^{\uparrow}$*.*
9. *T is the* $\mathsf{Real}^{\uparrow}$ *threshold readback for the displayed exponent bound associated to the packing schedule.*

10. *U records componentwise* hsame *transport for $M, K, C, R, N, H, Q, S, T$ and for the structural rows.*
11. *L records displayed* Cont *replay of the same finite route from metric data through disjoint packing centers, dyadic radii, comparison rows, and the real threshold.*
12. *O is the* Pkg *provenance over* $\mathsf{PackingDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{HausdorffDimension}^{\uparrow}$, $\mathsf{MinkowskiDimension}^{\uparrow}$, $\mathsf{AssouadDimension}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *A is the local* $\mathsf{NameCert}_{\mathsf{PackingDimension}^{\uparrow}}$ *row.*

The classifier compares accepted carriers by transporting these displayed metric, compact-metric, packing-center, dyadic-radius, comparison, threshold, continuation, provenance, and local naming rows to a common finite surface. It has no coordinate for a host supremum, arbitrary set-family quantification, quotient real equality, selected limits, or ambient completeness.

Theorem 7418.2 (Packing dimension NameCert obligations)**.** *For every accepted* $\mathsf{PackingDimension}^{\uparrow}$ *carrier $P = (M, K, C, R, N, H, Q, S, T, U, L, O, A)$, the local* $\mathsf{NameCert}_{\mathsf{PackingDimension}^{\uparrow}}$ *surface consists exactly of carrier admission, separated-center admission, dyadic radius positivity, disjoint ball checking, Hausdorff/Minkowski/Assouad comparison readback,* $\mathsf{Real}^{\uparrow}$ *threshold readback, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 7418.1. The rows M, K, C, R, N expose the metric source, compact finite-net data, packing centers, radius ledger, and pairwise disjointness checks.

Read the comparison rows H, Q, S next. They place the packing schedule beside the existing Hausdorff, Minkowski, and Assouad metric-dimension certificates without replacing any of those carrier surfaces.

The real-facing row is T. It reads only the displayed threshold associated to the finite packing schedule, so the route reaches $\mathsf{Real}^{\uparrow}$ after the metric and radius rows have already been replayed.

Finally U, L, O, A transport, replay, source, and name the same finite packet. Since no other carrier coordinate exists, the NameCert cannot expose host suprema, arbitrary set-family quantification, quotient real equality, selected limits, or ambient completeness. □

Theorem 7418.3 (Packing dimension scale-packing route)**.** *Every scale-facing consumer of an accepted* $\mathsf{PackingDimension}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow} \longmapsto (C, R, N) \longmapsto (\mathsf{HausdorffDimension}^{\uparrow}, \mathsf{MinkowskiDimension}^{\uparrow}, \mathsf{AssouadDimension}^{\uparrow}) \longmapsto$$

Thus the packing-side dimension evidence is exported only after disjoint packing centers, dyadic radii, sibling dimension comparisons, and the real threshold have been displayed.

Proof. Start with the metric and compact metric rows. The metric row gives the distance test, and the compact metric row gives the finite-net source through which centers are admitted.

The packing rows C, R, N are then replayed. They list the centers, attach positive dyadic radii, and check pairwise disjointness inside the displayed metric surface.

Next the sibling comparison rows are read. The Hausdorff row supplies the covering-side threshold, the Minkowski row supplies the finite box-counting ledger, and the Assouad row supplies the local scale comparison.

Only then is the $\mathsf{Real}^{\uparrow}$ threshold row T available. The structural rows U, L, O, A preserve and name this order of dependency, so no scale-facing consumer can bypass the finite packing route through a host supremum, quotient real equality, selected limit, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{PackingDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{PackingDimension}^{\uparrow}$ packet is generated from MetricUp distance tests, CompactMetricUp finite-net source data, disjoint packing centers, a positive DyadicRatCore radius ledger, Hausdorff/Minkowski/Assouad comparison rows, a RealUp threshold readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PackingDimension}^{\uparrow}}$, seed)

Scope closed: Definition 7418.1, Definition 7418.2, and Definition 7418.3 seed the packing-side metric-dimension certificate for compact metric carriers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PackingDimension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host suprema over all packings, arbitrary set-family quantification, quotient real equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-center admission, dyadic radius positivity, disjoint ball checking, sibling dimension comparison readback, Real-consumer factorization, and TasteGate faithfulness for $M, K, C, R, N, H, Q, S, T, U, L, O, A$.

Chapter 7419

A Concrete Naming Certificate for $\mathsf{FrechetCauchyNet}^{\uparrow}$

Following Frechet, Moore–Smith, Kelley, and Bishop–Bridges constructive completion practice, the $\mathsf{FrechetCauchyNet}^{\uparrow}$ packet records a directed Cauchy-net completion surface as finite BEDC NameCert data. It sits beside the finite window schedule of chapter 126, the Cauchy-filter boundary of chapter 333, the completion carrier of chapter 1506, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the directed-index, tail-cofinal, Cauchy-filter, metric-completion, regular-readback, Real-seal, transport, replay, provenance, and local certificate rows; it does not assert quotient-net equality, a selected subnet, a selected limit, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7419.1 (Frechet Cauchy net carrier)**.** *A* $\mathsf{FrechetCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, T, F, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the directed-index row, recording only the finite portion of the Moore–Smith direction inspected by the packet.*
2. *T is the tail-cofinal ledger, listing the displayed upper-bound and tail-neighborhood requests attached to I.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row obtained by reading the tail ledger as a Cauchy-filter boundary.*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that receives the displayed Cauchy-filter route.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to inspect the net tail at requested tolerances.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite windows and tail budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, T, F, M, S, R have been displayed.*
8. *H records componentwise* hsame *transport for directed-index, tail-cofinal, Cauchy-filter, metric-completion, window, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion request through the directed tail, Cauchy-filter row, metric-completion handoff, finite windows, regular readback, and Real seal.*
10. *P records* Pkg *provenance over* $\mathsf{FrechetCauchyNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{FrechetCauchyNet}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $I, T, F, M, S, R, E, H, C, P, N$. It has no coordinate for quotient nets, selected subnets, selected limits, countable-choice tail selection, host equality of completed objects, or ambient real completeness.

Theorem 7419.2 (Frechet Cauchy net NameCert obligations)**.** *For every accepted* $\mathsf{FrechetCauchyNet}^{\uparrow}$ *carrier*

$$G = (I, T, F, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetCauchyNet}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed directed-index row, tail-cofinal ledger, Cauchy-filter row, metric-completion handoff, StreamName window schedule, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming row. Every completion-facing obligation is read through those rows and no obligation is stored in quotient-net equality, selected subnets, selected limits, countable choice, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 7419.1. The tuple displays the directed-index source, tail-cofinal ledger, Cauchy-filter boundary, metric-completion handoff, window schedule, regular rational readback, terminal real seal, and structural rows.

The directed-net side is exhausted by I and T. The index row exposes only the finite directed fragment being inspected, and the tail ledger records only the cofinal tail requests attached to that fragment.

The completion side is exhausted by F, M, S, R, E. The Cauchy-filter row reads the tail ledger without quotienting nets, the metric-completion row receives that displayed boundary, the StreamName windows schedule the requested observations, the RegSeqRat row reads back the regular rational name, and the Real seal appears only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate is present, the excluded quotient, subnet, selector, choice, host-equality, and ambient-completeness data cannot become NameCert obligations. □

Theorem 7419.3 (Frechet Cauchy net completion handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetCauchyNet}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route carries a directed Cauchy-net tail into the completion frontier as displayed data only. It exports no quotient net, selected subnet, selected limit, countable-choice tail selector, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7419.2. It fixes the public completion surface at the rows $I, T, F, M, S, R, E, H, C, P, N$.

Read the directed tail first. The index row I and tail-cofinal row T expose the inspected Moore–Smith direction and the finite cofinal tail data required by the completion request.

Next read the completion and real-name rows. The Cauchy-filter row F receives the tail route, M hands it to metric completion, S schedules the finite observations, R supplies the regular rational readback, and E seals the route for real-facing consumers.

The structural rows keep the handoff confined to the displayed packet. Therefore a consumer that reaches the completion or real boundary without the stated route is not reading the accepted $\mathsf{FrechetCauchyNet}^{\uparrow}$ carrier. □

Falsifiable prediction: Every accepted $\mathsf{FrechetCauchyNet}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the directed-index row, tail-cofinal ledger, $\mathsf{CauchyFilter}^{\uparrow}$ boundary, $\mathsf{MetricCompletion}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: streamname, cauchyfilter, metriccompletion, regseqrat, real: no listed sibling is bijective to $\mathsf{FrechetCauchyNet}^{\uparrow}$ because this packet binds the directed-index source, tail-cofinal ledger, Cauchy-filter boundary, metric-completion handoff, finite window schedule, regular rational readback, real seal, transport, replay, provenance, and local naming as one directed Cauchy-net completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetCauchyNet}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetCauchyNet}^{\uparrow}$ packet is generated from a directed-index row, tail-cofinal ledger, CauchyFilterUp boundary, MetricCompletionUp handoff, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetCauchyNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7419.1, Definition 7419.2, and Definition 7419.3 seed the directed Cauchy-net completion route over StreamNameUp, CauchyFilterUp, MetricCompletionUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetCauchyNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient-net equality, selected subnets, selected limits, countable-choice tail selectors, host equality of completed points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove directed-index admission, tail-cofinal exposure, Cauchy-filter boundary routing, metric-completion handoff, window scheduling, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and ledger nonescape for BEDC.Derived.FrechetCauchyNetUp.

Chapter 7420

A Concrete Naming Certificate for $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$

Following Hausdorff and Blaschke, the $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$ packet records the distance-ledger specialization of the compact-metric hyperspace: nonempty compact-subset names over one displayed compact metric source are compared by finite directed Hausdorff covers before a hyperspace consumer reads the result. It sits beside the compact metric hyperspace of chapter 5184, the scalar Hausdorff comparison surface of chapter 2086, the Vietoris hyperspace of chapter 6507, and the Blaschke selection route of chapter 2370. The packet names a finite Hausdorff metric ledger, not a host powerset metric, quotient equality of compact subsets, selected nearest points, open-cover compactness, or ambient hyperspace completion.

Definition 7420.1 (Hausdorff metric hyperspace carrier)**.** *A* $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, K, A, B, D, S, V, L, T, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the metric, finite-net, total-bounded, and complete boundary rows used by compact-subset reads.*
2. *K is the* $\mathsf{CompactMetricHyperspace}^{\uparrow}$ *row naming the nonempty compact-subset carrier over X.*
3. *A and B are the two displayed compact-subset names being compared inside K.*
4. *D is the directed Hausdorff coverage ledger, carrying one finite witness from A to B and one finite witness from B to A at every admitted tolerance.*
5. *S is the symmetric scalar readback row obtained from the two directed coverage ledgers.*
6. *V is the* $\mathsf{VietorisHyperspace}^{\uparrow}$ *compatibility row, recording that the same finite hit-and-miss windows are read when a topology-facing consumer inspects A and B.*
7. *L is the Blaschke handoff row, exposing only the distance ledger and compact source rows needed by chapter 2370.*
8. *T records componentwise* hsame *transport for $X, K, A, B, D, S, V, L, C, P, N$.*
9. *C records displayed* Cont *replay of the compact-source, compact-subset, directed-coverage, symmetric-readback, Vietoris, and Blaschke-handoff route.*

10. *P is the* Pkg *provenance over* $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$, $\mathsf{CompactMetricHyperspace}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{VietorisHyperspace}^{\uparrow}$, $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffMetricHyperspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, A, B, D, S, V, L, T, C, P, N$. It has no coordinate for host powersets, quotient compacta, selected nearest points, open-cover compactness, or a hidden hyperspace completion object.

Theorem 7420.2 (Hausdorff metric hyperspace NameCert obligations)**.** *For every accepted* HausdorffMetricHypers *carrier*

$$H = (X, K, A, B, D, S, V, L, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffMetricHyperspace}^{\uparrow}}$ *surface is exhausted by compact metric source admission, compact-metric hyperspace admission, two compact-subset rows, bidirectional finite Hausdorff coverage, symmetric scalar readback, Vietoris compatibility, Blaschke handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7420.1. The source row X and hyperspace row K are the only places where compact metric and compact-subset data enter the packet.

The two compact-subset names are the rows A and B. The directed ledger D then supplies both finite coverage directions before the symmetric readback row S can be consumed.

The topology and compactness handoffs are V and L. They reuse the same directed coverage rows for Vietoris-facing and Blaschke-facing consumers rather than importing host open-cover compactness or selected representatives.

Finally T, C, P, N transport, replay, source, and name the same finite route. Since no further coordinate exists in the carrier, the listed rows exhaust the local naming surface. □

Theorem 7420.3 (Hausdorff metric hyperspace compact-set handoff)**.** *Every compact-set consumer of an accepted* $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$ *packet factors through*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{CompactMetricHyperspace}^{\uparrow} \longmapsto \mathsf{HausdorffMetric}^{\uparrow} \longmapsto \mathsf{VietorisHyperspace}^{\uparrow}.$$

The consumer receives compact source rows, compact-subset names, two directed finite Hausdorff coverage ledgers, symmetric readback, Vietoris compatibility, Blaschke handoff, transport, replay, provenance, and local naming; it receives no host powerset, quotient compactum, selected nearest point, open-cover compactness theorem, or ambient completion witness.

Proof. Use Definition 7420.2. It forces every public read through the compact metric source X, the compact-metric hyperspace row K, and the compact-subset rows A, B.

The Hausdorff metric read is then the finite route through D and S. Both directed coverage directions are displayed before the scalar comparison can be exported.

Vietoris and Blaschke consumers receive only the rows V and L attached to the same finite ledger. The structural rows T, C, P, N preserve and name that route, so compact-set handoff cannot escape to host powersets, quotient compacta, selected nearest points, open-cover compactness, or ambient completion. □

Falsifiable prediction: An accepted $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$ compact-set read that exposes symmetric distance data without first displaying $X, K, A, B, D, S, V, L, T, C, P, N$ refutes the carrier surface.

Independence witness: compact-metric-hyperspace, hausdorff-metric, vietoris-hyperspace, blaschke-selection-compact-hyperspace: the compact-metric hyperspace names the carrier without isolating the symmetric distance ledger, the Hausdorff metric chapter names directed comparison without the hyperspace handoff, the Vietoris hyperspace names hit-and-miss compatibility without the Blaschke distance ledger, and the Blaschke route consumes compact-set selection data without owning the two directed Hausdorff rows. None is bijective to $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffMetricHyperspace}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffMetricHyperspace}^{\uparrow}$ packet is generated from a CompactMetricUp source, a CompactMetricHyperspaceUp compact-subset carrier, two displayed compact-subset names, bidirectional finite Hausdorff coverage, symmetric readback, Vietoris compatibility, Blaschke handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffMetricHyperspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7420.1, Definition 7420.2, and Definition 7420.3 seed the finite distance-ledger specialization of compact metric hyperspace data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffMetricHyperspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host powersets, quotient compacta, selected nearest points, open-cover compactness, or ambient hyperspace completion.

Upgrade path: Obligation closure requires checked carrier admission, bidirectional Hausdorff coverage, symmetric readback, Vietoris compatibility, Blaschke handoff, transport, replay, provenance, and local naming for BEDC.Derived.HausdorffMetricHyperspa

Chapter 7421

A Concrete Naming Certificate for $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ packet names the finite witness surface by which a subsequence ledger is read as a cofinal filter without importing countable choice or quotient stream equality. It sits over the displayed window rows of chapter 126, the regular rational readback of chapter 301, the finite filter surface of chapter 333, and the terminal real-name seal of chapter 38. The packet records cofinality as certificate data: every requested tail is answered by a displayed subsequence index and then transported through the same filter and Real-facing rows.

Definition 7421.1 (Cofinal subsequence-filter carrier)**.** *A* $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, R, F, J, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row for the original sequence and for every displayed subsequence read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row whose finite tails are generated from the displayed subsequence windows.*
4. *J is the cofinal-index ledger. For each finite tail request already displayed by the consumer, J records a subsequence index whose source window in S lies past that tail and whose rational readback is the row in R.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *consumer seal, reachable only after the rows S, R, F, J have been displayed.*
6. *H records componentwise* hsame *transport for the stream, regular readback, filter, cofinal-index, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, R \longmapsto J \longmapsto F \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CofinalSubsequenceFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, F, J, E, H, C, P, N$. It has no coordinate for countable choice, quotient equality of streams, a selected limit, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7421.2 (Cofinal subsequence-filter NameCert obligations)**.** *For every accepted* $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ *carrier*

$$X = (S, R, F, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CofinalSubsequenceFilter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, CauchyFilter tails, cofinal-index ledger, Real seal, componentwise transport, continuation replay, provenance, and local naming rows;*
2. *subsequence readback exactness, requiring every subsequence value to be read from a displayed window in S and the matching regular rational row in R;*
3. *cofinality exactness, requiring every displayed tail request to be answered by a finite index stored in J before the filter row F is consumed;*
4. *filter compatibility, requiring F to be generated only from the displayed subsequence-tail rows and not from an external filter base;*
5. *Real-seal nonescape, requiring E to be downstream of S, R, J, F and to export no selected limit, quotient stream equality, countable choice, trichotomy, host real equality, or ambient completeness claim;*
6. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed cofinal subsequence-filter route.*

No $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 7421.1. The accepted packet displays exactly the stream, regular readback, filter, cofinal-index, Real seal, transport, replay, provenance, and local naming rows.

Subsequence readback exactness is read from S and R. A subsequence value can only use a source window already displayed in S and the matching regular rational readback already displayed in R.

Cofinality exactness is the role of J. For each displayed tail request, J stores a finite index past that tail before the filter row F is available, so no countable-choice selector or hidden tail oracle is present.

The filter compatibility row is then read through F. Since F is downstream of S, R, J, the filter base is generated from the displayed subsequence-tail witnesses rather than from an external filter object.

Finally, E, H, C, P, N close the route. The Real seal and structural rows preserve only the displayed packet coordinates, so the excluded objects are absent from every accepted carrier and the listed obligations exhaust the local NameCert surface. □

Theorem 7421.3 (Cofinal subsequence-filter nonescape)**.** *Every consumer read of an accepted* $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ *packet factors through the finite route*

$$S, R \longmapsto J \longmapsto F \longmapsto E \longmapsto H, C, P, N.$$

The consumer receives displayed StreamName windows, RegSeqRat readback, a finite cofinal-index ledger, a CauchyFilter row generated from those witnesses, a Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *data, and receives no countable choice, quotient stream equality, selected limit, host real equality, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

Proof. Begin with a consumer read of an accepted packet. Projection exposes the ordered carrier rows $S, R, F, J, E, H, C, P, N$.

The read starts at the source surface. The row S displays the source and subsequence windows, and R displays the regular rational values attached to those windows.

The cofinal witness is then read from J. Each finite tail request is answered by an index already stored in the packet, so the consumer cannot replace the ledger by countable choice, quotient stream equality, or a host-side selector.

The filter row F and Real seal E are downstream of the same ledger. They can consume the displayed cofinal subsequence witnesses, but they cannot add a selected limit or an ambient completeness theorem.

The structural rows H, C, P, N transport, replay, source, and name that same route. Therefore every consumer factors through the displayed packet and receives none of the excluded escape objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalSubsequenceFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalSubsequenceFilter}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, a CauchyFilter row, a cofinal-index ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalSubsequenceFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7421.1, Definition 7421.2, and Definition 7421.3 seed the finite route from displayed subsequence windows through cofinal-index witnesses, CauchyFilter tails, and the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalSubsequenceFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient equality of streams, selected limits, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subsequence readback exactness, cofinality exactness, filter compatibility, Real-seal nonescape, and structural stability for BEDC.Derived.CofinalSubsequenceFilterUp.

Chapter 7422

A Concrete Naming Certificate for MetaCICResidualCandidateSelector$^{\uparrow}$

The MetaCICResidualCandidateSelector$^{\uparrow}$ packet realizes the bounded residual-confluence frontier of chapter 9378 as a finite candidate-selection surface. It sits beside the residual diamond budget of chapter 7407, the candidate-normalization witness of chapter 6577, the parallel-diamond frontier of chapter 4238, and the residual envelope of chapter 3921. The packet records typed windows, residual-pair budgets, candidate-normalization evidence, local-join checking, obstruction retention, transport, replay, provenance, and local naming without claiming residual-substitution compatibility, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Definition 7422.1 (MetaCIC residual candidate selector carrier)**.** *A* MetaCICResidualCandidateSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, B, K, J, O, H, C, P, R, N)$$

with the following displayed rows:

1. *T is the typed-window row, fixing the closed MetaCIC source, local context fragment, redex shape, residual frontier, and observation depth inspected by the selector.*
2. *B is the residual-pair budget row, read through* MetaCICResidualDiamondBudget$^{\uparrow}$*, listing the finitely many residual pairs for which candidate selection is meaningful.*
3. *K is the candidate-normalization evidence row, read through* MetaCICCandidateNormalizationWitness$^{\uparrow}$*, naming the finite candidate evidence and endpoint data available to the selector.*
4. *J is the local-join checker row, recording the proposed common reducts, bounded checker status, and replay fuel for the residual pairs admitted by B.*
5. *O is the obstruction-retention row for residual-substitution compatibility, premise-free parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency.*
6. *H records componentwise* hsame *transport for $T, B, K, J, O, C, P, R, N$.*
7. *C records displayed* Cont *replay from the typed window through the residual-pair budget, candidate-normalization evidence, local-join checker, and obstruction row.*

8. *P is the* Pkg *provenance over* MetaCICResidualCandidateSelector$^{\uparrow}$, MetaCICResidualDiamondBudget$^{\uparrow}$, MetaCICCandidateNormalizationWitness$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, MetaCICConfluenceResidualEnvelope BHist, hsame, Cont, *and* NameCert.
9. *R is the replay ledger that compares the selector's candidate row with the conditional handoff exposed by* MetaCICParallelDiamondFrontier$^{\uparrow}$ *and the residual envelope exposed by* MetaCICConfluenceResidualEnvelo
10. *N is the local* NameCert$_{\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, K, J, O, H, C, P, R, N$. It has no coordinate for an unbounded residual search, a premise-free diamond theorem, a global confluence proof, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Theorem 7422.2 (MetaCIC residual candidate selector NameCert obligations)**.** *For every accepted* MetaCICResidualCandidateSelector$^{\uparrow}$ *carrier*

$$S = (T, B, K, J, O, H, C, P, R, N),$$

the local NameCert$_{\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}}$ *surface consists exactly of typed-window admission, residual-pair budget exposure, candidate-normalization evidence, local-join checker status, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, replay comparison, and local naming.*

Proof. Project the carrier of Definition 7422.1. The visible rows are precisely $T, B, K, J, O, H, C, P, R, N$.

The typed window T and residual-pair budget B determine which residual branches are inspected. The candidate-normalization row K supplies the finite candidate evidence available for those branches, and the local-join checker J records only bounded checker status for the displayed budget.

The obstruction row O keeps the residual-substitution and confluence endpoints outside the packet, while H, C, P, R, N transport, replay, source, compare, and name the same rows. Since the carrier has no other coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7422.3 (MetaCIC residual candidate selector frontier route)**.** *Every confluence-audit consumer of an accepted* MetaCICResidualCandidateSelector$^{\uparrow}$ *packet must expose the finite route*

$$T, B, K, J, O \longmapsto H, C, P, R, N$$

before reading a candidate-mediated local-join handoff. The handoff may be consumed by MetaCICParallelDiamondFr *and* MetaCICConfluenceResidualEnvelope$^{\uparrow}$ *routes, but it does not discharge residual substitution, subject reduction, full Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.*

Proof. Read T and B first. They fix the typed residual frontier and the finite residual-pair budget, so the selector is not an unbounded search over reductions.

Next read K and J. The candidate-normalization evidence names the finite candidate data available to the selector, and the local-join checker records only bounded checker status for the residual pairs in B.

Finally read O, H, C, P, R, N. The obstruction row remains visible, and the structural rows preserve the same candidate-mediated route for downstream frontier and envelope consumers. Thus the packet exports a bounded selector surface rather than a completed confluence theorem. □

Falsifiable prediction: An accepted $\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}$ packet with no residual-pair budget row B cannot export a local-join certificate, because the candidate row K and checker row J would no longer be tied to a finite residual frontier.

Independence witness: metacic_residual_diamond_budget, metacic_candidate_normalization_witness, metacic_parallel_diamond_frontier, metacic_confluence_residual_envelope: none is bijective to $\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}$ because this packet jointly carries typed-window data, residual-pair budget rows, candidate-normalization evidence, local-join checker status, obstruction retention, transport, replay comparison, provenance, and local naming.

Lean support for $\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}$ should provide Nontrivial and FieldFaithful instances in `TasteGate.lean` so the typed-window, budget, candidate, checker, obstruction, replay, provenance, and local naming rows remain distinguishable fields.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}$ packet is generated from typed-window rows, residual-pair budgets, candidate-normalization evidence, local-join checker rows, obstruction-retention rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, replay comparison, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7422.1, Definition 7422.2, and Definition 7422.3 seed the finite residual-candidate selector over typed windows, budgets, candidates, checkers, obstruction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualCandidateSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, residual-substitution compatibility, premise-free parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, Nontrivial or FieldFaithful instances, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window coverage, residual-pair budget exactness, candidate-normalization evidence, local-join checker status, obstruction retention, transport, replay comparison, provenance, local naming, Nontrivial, and FieldFaithful instances for BEDC.Derived.MetaCICResidualCandidateSelectorUp.

Chapter 7423

A Concrete Naming Certificate for $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$

The $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ packet realizes the geodesic endpoint and cross-ratio branch of chapter 9463 as finite NameCert data. It sits after the endpoint route of chapter 3491, the four-boundary comparison packet of chapter 3948, the noncrossing geodesic-lamination surface of chapter 4203, the disk phase-transport route of chapter 3455, and the metric readback of chapter 3474. The packet names a finite phase-facing endpoint comparison, not a completed hyperbolic plane, quotient ideal boundary, selected geodesic representative, host Mobius invariant, or physical observer dynamics.

Definition 7423.1 (Phase geodesic cross-ratio carrier)**.** *A* $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, M, E_0, E_1, E_2, E_3, L, X, \Phi, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$ *disk and phase-transport row.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row used to read endpoint and geodesic comparisons.*
3. *E_0, E_1, E_2, E_3 are four boundary endpoint rows, each attached to the displayed disk route rather than to a host ideal boundary.*
4. *L is the* $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ *compatibility row, recording that the endpoint pairs form the finite geodesic leaves consumed by lamination-facing readers.*
5. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row comparing the four endpoints through the finite cross-ratio packet.*
6. *Φ is the phase-readout row, attaching the cross-ratio comparison to the visible phase-transport ledger without treating phase equality as source equality.*
7. *R is the refusal row excluding completed hyperbolic planes, quotient ideal-boundary equality, selected geodesic representatives, host Mobius invariants, and physical observer dynamics.*
8. *H records componentwise* hsame *transport for disk, metric, endpoint, lamination, cross-ratio, phase, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from disk phase transport through metric, endpoints, lamination, cross-ratio, phase readout, and refusal.*

10. *P is the* Pkg *provenance over* $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$, $\mathsf{PoincareDiskPhaseTransport}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, E_0, E_1, E_2, E_3, L, X, \Phi, R, H, C, P, N$. It has no coordinate for fewer than four endpoint rows, a detached phase scalar, a host global geometry, quotient boundary equality, or unrecorded geodesic selection.

Theorem 7423.2 (Phase geodesic cross-ratio NameCert obligations)**.** *For every accepted* $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ *carrier*

$$G = (D, M, E_0, E_1, E_2, E_3, L, X, \Phi, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}}$ *surface is exhausted by disk phase transport, hyperbolic metric readback, four displayed endpoint rows, geodesic-lamination compatibility, hyperbolic cross-ratio comparison, phase readout, explicit refusal, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7423.1. The disk and metric rows D, M fix the displayed geometry before any endpoint or phase comparison is visible.

The four endpoint rows E_0, E_1, E_2, E_3 are read next. Lamination compatibility L ensures that the endpoint pairs are geodesic-facing finite leaves, and the cross-ratio row X compares the same endpoints through chapter 3948.

The phase row Φ is downstream from those geometric rows. It records only the visible phase readout attached to the same disk transport, while R refuses host global geometry, quotient boundary equality, selected geodesics, detached Mobius invariance, and physical observer dynamics.

Finally H, C, P, N transport, replay, source, and name the same packet. Since there is no further carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7423.3 (Phase geodesic cross-ratio route)**.** *Every phase-facing consumer of an accepted* $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ *packet factors through*

$$\mathsf{PoincareDiskPhaseTransport}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicLamination}^{\uparrow} \longmapsto \mathsf{HyperbolicC}$$

The consumer receives disk phase transport, hyperbolic metric readback, four endpoint rows, lamination compatibility, cross-ratio comparison, phase readout, refusal, transport, replay, provenance, and local naming; it receives no completed hyperbolic plane, quotient ideal boundary, selected geodesic representative, host Mobius invariant, or physical observer-dynamics row.

Proof. Use Definition 7423.2. It places the disk transport and metric rows before the four endpoint rows can be inspected.

The endpoint rows then feed the lamination and cross-ratio rows L and X. The lamination row keeps the geodesic leaves finite and displayed, while the cross-ratio row keeps the four-boundary comparison inside the existing hyperbolic cross-ratio packet.

Only after those rows are visible may Φ expose a phase readout. The refusal row R and structural rows H, C, P, N keep that readout attached to the displayed route, so the phase-facing consumer cannot escape to host global geometry, quotient boundary equality, selected geodesics, detached Mobius invariance, or physical observer dynamics. □

Falsifiable prediction: An accepted $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ phase read that omits disk transport, hyperbolic metric readback, four endpoint rows, lamination compatibility, cross-ratio comparison, refusal, transport, replay, provenance, or local NameCert rows refutes the carrier surface.

Independence witness: hyperbolic-geodesic-boundary, hyperbolic-geodesic-lamination, hyperbolic-cross-ratio, poincare-disk-phase-transport, hyperbolic-metric: the geodesic-boundary packet names endpoints without phase cross-ratio readout, the lamination packet names noncrossing leaves without the four-point phase row, the cross-ratio packet compares endpoints without owning the phase transport, the disk phase-transport packet names reversible phase surfaces without the geodesic endpoint comparison, and the metric packet supplies distance readback without the endpoint-phase carrier. None is bijective to $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}}$.

Constructive story: A $\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}$ packet is generated from PoincareDiskPhaseTransportUp rows, HyperbolicMetricUp readback, four HyperbolicGeodesicBoundaryUp endpoint rows, HyperbolicGeodesicLaminationUp compatibility, HyperbolicCrossRatioUp comparison, a phase readout row, explicit refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7423.1, Definition 7423.2, and Definition 7423.3 seed the finite phase-facing route from geodesic endpoints to cross-ratio readout.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhaseGeodesicCrossRatio}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed hyperbolic planes, quotient ideal-boundary equality, selected geodesic representatives, host Mobius invariants, or physical observer dynamics.

Upgrade path: Obligation closure requires checked carrier admission, endpoint display, lamination compatibility, cross-ratio comparison, phase-readout nonescape, refusal, transport, replay, provenance, and local naming for BEDC.Derived.PhaseGeodesicCrossRat

Chapter 7424

A Concrete Naming Certificate for $\mathsf{StoneSpace}^{\uparrow}$

Following Stone, Birkhoff, and Kelley, the $\mathsf{StoneSpace}^{\uparrow}$ packet records the finite BEDC carrier by which a Boolean algebra is read as a topological clopen ledger. It sits beside the Boolean algebra carrier of chapter 3733, the clopen algebra carrier of chapter 7214, the Stone-duality bridge of chapter 261, the topology carrier of chapter 88, and the local compact Hausdorff surface of chapter 4029. The packet names the Stone-space observation surface available to later clopen-ledger and bridge work; it does not assert ultrafilter choice, host powersets, quotient topology equality, or a checked standard bridge.

Definition 7424.1 (Stone space carrier)**.** *A* $\mathsf{StoneSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, L, T, K, Z, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BooleanAlgebra}^{\uparrow}$ *source row. It records the displayed zero, one, meet, join, complement, order, and distributivity observations that generate the Stone-space interface.*
2. *L is the* $\mathsf{ClopenAlgebra}^{\uparrow}$ *ledger. It records the clopen rows named by the Boolean observations and keeps their finite Boolean operations visible as clopen operations.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *public-open row. It exposes the indexed open rows generated by the clopen ledger, including the displayed empty, whole, finite-meet, complement-open, and finite-union reads.*
4. *K is the compact Hausdorff readback row. It records only the displayed* $\mathsf{CompactHausdorff}^{\uparrow}$ *separation and compactness obligations available from the finite clopen ledger, not an external point-set compactification theorem.*
5. *Z is the zero-dimensional readback row. It says that the public topology rows read by T are generated through clopen rows from L, so the topology-facing basis remains the displayed clopen ledger.*
6. *H records componentwise* hsame *transport for the Boolean source, clopen ledger, topology rows, compact Hausdorff readback, zero-dimensional readback, replay, provenance, and local name.*
7. *C records displayed* Cont *replay for the route*

$$B \longmapsto L \longmapsto T, K, Z.$$

8. *P is the* Pkg *provenance over* $\mathsf{StoneSpace}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{ClopenAlgebra}^{\uparrow}$, $\mathsf{StoneDuality}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompactHausdorff}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, T, K, Z, H, C, P, N$. It has no coordinate for selected ultrafilters, host powersets, quotient topology equality, arbitrary opens outside the displayed $\mathsf{Topology}^{\uparrow}$ *rows, or bridge checking.*

Theorem 7424.2 (Stone space NameCert obligations)**.** *For the carrier of Definition 7424.1, the local* $\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}$ *surface consists exactly of Boolean-algebra source exposure through B, clopen-ledger exposure through L, topology public-open exposure through T, compact Hausdorff and zero-dimensional readback through K and Z, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every Stone-duality or clopen-ledger consumer reads the Stone space only through those rows and receives no ultrafilter choice, host powerset, quotient topology equality, arbitrary-open completion, or checked bridge.*

Proof. Carrier admission is projection from Definition 7424.1. The packet displays exactly the Boolean source, clopen ledger, topology public rows, compact Hausdorff readback, zero-dimensional readback, transport, replay, provenance, and local naming row.

The topology surface is generated before any point-space readback is considered. The row L turns Boolean observations into clopen observations, and T exposes only the indexed open rows generated from that clopen ledger.

The compact Hausdorff and zero-dimensional rows are readbacks from the same displayed route. They can certify the finite separation, compactness, and clopen-basis obligations visible in K and Z, but they do not choose ultrafilters or equate an external quotient topology with the internal classifier.

Finally H, C, P, N preserve and name the same route. Since no field of the carrier stores host powersets, selected ultrafilters, arbitrary opens, quotient topology equality, or a standard bridge witness, no consumer can extract such data from the local $\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}$ surface. □

Theorem 7424.3 (Stone space clopen-ledger boundary)**.** *Every accepted* $\mathsf{StoneSpace}^{\uparrow}$ *packet factors its topology-facing observations through the finite route*

$$\mathsf{BooleanAlgebra}^{\uparrow} \longrightarrow \mathsf{ClopenAlgebra}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{CompactHausdorff}^{\uparrow} \longrightarrow H, C, P, N.$$

The route is compatible with the $\mathsf{StoneDuality}^{\uparrow}$ *clopen classifier of chapter 261: a Boolean row may be replayed as a clopen topology row and then read back as compact Hausdorff and zero-dimensional structure. The boundary gives later bridge work a concrete* $\mathsf{StoneSpace}^{\uparrow}$ *target while excluding ultrafilter selection, host powerset extensionality, quotient topology equality, and bridge-checked equivalence.*

Proof. Start with the Boolean source row B. The clopen ledger L admits only the finite clopen observations generated from the Boolean operations, so each topology-facing read has a displayed clopen origin.

The topology handoff is T. It records the public opens generated by the clopen rows, while the compact Hausdorff and zero-dimensional readbacks K and Z inspect only the same public rows and the same clopen generator provenance.

Compatibility with $\mathsf{StoneDuality}^{\uparrow}$ is therefore a ledger comparison, not a point-space construction. The Stone-duality classifier already sends Boolean observations to clopen topology rows, and the present carrier exposes that route as the named $\mathsf{StoneSpace}^{\uparrow}$ packet.

Transport, replay, provenance, and local naming keep the route finite. Since every accepted read factors through the displayed chain, the excluded ultrafilter, powerset, quotient-equality, and bridge-checking objects remain outside the carrier boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{StoneSpace}^{\uparrow}$ packet is generated from BooleanAlgebra source rows, a ClopenAlgebra ledger, Topology public-open rows, CompactHausdorff and zero-dimensional readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7424.1, Definition 7424.2, and Definition 7424.3 seed the finite Stone-space carrier over BooleanAlgebraUp, ClopenAlgebraUp, StoneDualityUp, TopologyUp, CompactHausdorffUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ultrafilter choice, host powersets, quotient topology equality, arbitrary-open completion, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, clopen-ledger exactness, topology public-row exposure, compact Hausdorff and zero-dimensional readback, transport, replay, provenance, and local naming for BEDC.Derived.StoneSpaceUp.

Chapter 7425

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$

Following Bishop and Bridges on constructive analysis, the $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$ packet records the finite seal between a selected cofinal subsequence window and the Real-facing regular read used by L10 completion consumers. It sits after the bounded selector surface of chapter 1408, the regular Cauchy subsequence limit packet of chapter 1862, the broader subsequence limit boundary of chapter 1467, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite NameCert boundary for subsequence limits; it does not choose a subsequence by host choice, quotient a stream, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7425.1 (Cauchy subsequence limit seal carrier)**.** *A* $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, I, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence window, carrying the inspected regular Cauchy source values before any subsequence read is formed.*
2. *I is the cofinal subsequence index row, recording monotonicity, cofinal reach, and the finite selected indices used by the route.*
3. *D is the dyadic tolerance data, including the requested precision and the finite comparison ledger that justifies the selected tail window.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the source and selected subsequence observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the selected windows and dyadic tolerance data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the selected window and regular rational readback rows have been displayed.*
7. *H records componentwise* hsame *transport for source windows, cofinal index rows, dyadic tolerance data, stream windows, regular readbacks, Real seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the same finite subsequence-limit route.*
9. *P records the* Pkg *provenance over* $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$, $\mathsf{BolzanoWeierstrassSelector}^{\uparrow}$, $\mathsf{RegularCauchySubsequenceLimit}^{\uparrow}$, $\mathsf{SubsequenceLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, I, D, W, R, E, H, C, P, N$. It has no coordinate for a host-selected infinite subsequence, quotient stream equality, host real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7425.2 (Cauchy subsequence limit seal NameCert obligations)**.** *For every accepted* $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$ *carrier $L = (S, I, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the source sequence window S, cofinal subsequence index row I, dyadic tolerance data D,* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, package provenance P, and local naming N.*

Proof. Project the accepted carrier of Definition 7425.1. Each row named in the statement is a displayed coordinate of the finite packet, and the carrier lists no hidden coordinate for a selected infinite subsequence, quotient stream, or ambient completion theorem.

The source and index obligations are S and I. The dyadic tolerance and finite-window obligations are D and W, and the Real-facing route reaches R before it reaches the terminal seal E.

Finally use the structural rows. Componentwise transport H, replay C, provenance P, and local naming N preserve the same route for the selector, regular-subsequence-limit, subsequence-limit, StreamName, RegSeqRat, DyadicRatCore, and Real siblings named above. □

Theorem 7425.3 (Cauchy subsequence limit seal nonescape)**.** *Every completion-facing or Real-facing consumer of an accepted* $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$ *packet must read the route*

$$S, I, D, W, R, E, H, C, P, N$$

before it consumes any subsequence-limit seal. The route exports no host-selected infinite subsequence, quotient stream equality, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7425.2. They force every consumer to display the source window, cofinal index row, dyadic tolerance data, finite StreamName windows, regular rational readback, and Real seal as one carrier-local route.

The sibling handoffs preserve the same order. The selector boundary of chapter 1408, the regular Cauchy subsequence limit packet of chapter 1862, and the subsequence limit boundary of chapter 1467 can feed the row I or the readback row R, but none supplies a hidden quotient stream or host choice coordinate.

Since the classifier has only $S, I, D, W, R, E, H, C, P, N$, any completion-facing read that asks for host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness asks for data outside the packet. The Real seal is therefore a terminal finite seal for the displayed subsequence route, not an escape hatch into host completion. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}$ packet is generated from source sequence windows, cofinal subsequence index rows, dyadic tolerance data, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}}$, seed)

Scope closed: Definition 7425.1, Definition 7425.2, and Definition 7425.3 seed the finite subsequence-limit seal between selected cofinal windows and Real-facing regular reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySubsequenceLimitSeal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove host subsequence choice, quotient stream equality, countable choice, host real equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal index exposure, dyadic tolerance exactness, StreamName window coverage, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySubsequenceLimitSealUp.

Chapter 7426

A Concrete Naming Certificate for $\mathsf{FrechetCauchyFilter}^{\uparrow}$

Following Bourbaki and Kelley on filter convergence and Bishop–Bridges constructive analysis, the $\mathsf{FrechetCauchyFilter}^{\uparrow}$ packet records the L10 route where cofinite sequence tails are read as a displayed Cauchy-filter completion surface. It sits beside the cofinite-tail filter of chapter 1564, the Cauchy-filter boundary of chapter 333, the finite window schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite tail-to-filter certificate only; it does not quotient filters, select limits, invoke countable choice, use host equality of completed objects, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7426.1 (Frechet Cauchy filter carrier)**.** *A* $\mathsf{FrechetCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, B, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{FrechetFilter}^{\uparrow}$ *cofinite tail-threshold row, carrying the displayed finite complement and the tail request through which a sequence is inspected.*
2. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *meet row, recording the common-tail refinement required before two tail requests are read as one filter event.*
3. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row receiving the displayed cofinite-tail filter route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that lists the sequence coordinates inspected by tail and Cauchy requests.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and the displayed tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the Frechet tail, FilterBase meet, Cauchy-filter handoff, stream windows, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for $T, B, Q, W, R, E, C, P, N$.*
8. *C records displayed* Cont *replay from a completion request through the cofinite-tail threshold, FilterBase meet, Cauchy-filter handoff, finite windows, regular readback, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetCauchyFilter}^{\uparrow}$, $\mathsf{FrechetFilter}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, B, Q, W, R, E, H, C, P, N$. It has no coordinate for quotient filter equality, selected limits, countable-choice tail selection, host completion equality, or ambient real completeness.

Theorem 7426.2 (Frechet Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{FrechetCauchyFilter}^{\uparrow}$ *carrier*

$$F = (T, B, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the Frechet tail threshold, FilterBase meet, Cauchy-filter handoff, StreamName finite windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming row.*

Proof. Project the carrier of Definition 7426.1. The visible rows are precisely $T, B, Q, W, R, E, H, C, P, N$.

The tail side is exhausted by T and B. The Frechet row exposes the finite complement and tail request, while the FilterBase row records the meet that makes several tail requests a single displayed filter event.

The completion-facing side is exhausted by Q, W, R, E. The Cauchy-filter row receives the displayed tail route, the StreamName row lists the inspected coordinates, the RegSeqRat row reads those windows as regular rational data, and the Real seal appears only after the readback has been exposed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no other coordinate is present, quotient filter equality, selected limits, countable choice, host completion equality, and ambient real completeness cannot become local NameCert obligations. □

Theorem 7426.3 (Frechet Cauchy filter completion handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FrechetCauchyFilter}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{FrechetFilter}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff carries cofinite sequence tails into Cauchy-filter completion consumers as displayed data only. It exports no quotient filter, selected limit, countable-choice tail selector, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7426.2. It fixes the public completion surface at the rows $T, B, Q, W, R, E, H, C, P, N$.

Read the Frechet and FilterBase rows first. The cofinite-tail threshold row T supplies the finite tail request, and the meet row B displays the common-tail refinement required before the request is treated as a filter event.

Next read the Cauchy-filter and real-name rows. The handoff row Q receives the displayed filter route, W schedules the finite observations, R supplies regular rational readback, and E seals the route for real-facing consumers.

The structural rows keep the handoff confined to the displayed packet. Therefore a consumer that reaches a Cauchy-filter, regular-rational, or real boundary without the stated route is not reading the accepted $\mathsf{FrechetCauchyFilter}^{\uparrow}$ carrier. □

Theorem 7426.4 (Frechet Cauchy filter scope ledger)**.** *For every accepted* $\mathsf{FrechetCauchyFilter}^{\uparrow}$ *carrier*

$$F = (T, B, Q, W, R, E, H, C, P, N),$$

finite induction over the displayed carrier rows exposes, in order, the cofinite-tail threshold, FilterBase meet, Cauchy-filter handoff, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row.*

Every $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of* F *must read that prefix order; no consumer can skip an earlier row and still consume the accepted* $\mathsf{FrechetCauchyFilter}^{\uparrow}$ *packet.*

Proof. Project the carrier tuple from Definition 7426.1. The tuple has exactly the finite row list $T, B, Q, W, R, E, H, C, P, N$, so the base read starts at the cofinite-tail threshold row T and no hidden completion coordinate is available.

Induct along the displayed list. After T has exposed the finite tail request, the row B records the FilterBase meet; after B, the handoff row Q may receive the displayed filter route; after Q, the finite window row W, regular readback row R, and Real seal row E are read in that order.

Use Definition 7426.2 for row exactness. It identifies H, C, P, N as transport, replay, provenance, and local naming for the same finite route, not as alternative entrances into the completion surface.

Finally apply Definition 7426.3. Any downstream Cauchy-filter, regular-rational, or real-facing consumer receives only the displayed route from $\mathsf{FrechetFilter}^{\uparrow}$ through $\mathsf{Real}^{\uparrow}$, so skipping an earlier row would leave the consumer outside the accepted carrier. □

Falsifiable prediction: Every accepted $\mathsf{FrechetCauchyFilter}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the $\mathsf{FrechetFilter}^{\uparrow}$ cofinite-tail threshold, $\mathsf{FilterBase}^{\uparrow}$ meet, $\mathsf{CauchyFilter}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row refutes the packet surface.

Independence witness: frechetfilter, cauchyfilter, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{FrechetCauchyFilter}^{\uparrow}$ because this packet binds the cofinite-tail threshold, FilterBase meet, Cauchy-filter handoff, finite window schedule, regular rational readback, real seal, transport, replay, provenance, and local naming as one L10 completion route.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetCauchyFilter}^{\uparrow}$ packet is generated from a FrechetFilterUp cofinite-tail threshold, FilterBaseUp meet, CauchyFilterUp handoff, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FrechetCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 7426.1, Definition 7426.2, Definition 7426.3, and Definition 7426.4 seed the L10 Frechet Cauchy filter route over FrechetFilterUp, FilterBaseUp, CauchyFilterUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FrechetCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable-choice tail selectors, host equality of completed points, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove Frechet-tail admission, FilterBase meet exposure, Cauchy-filter handoff, window scheduling, RegSeqRat readback, Real seal handoff, transport, replay, provenance, and ledger nonescape for BEDC.Derived.FrechetCauchyFilterUp.

Chapter 7427

A Concrete Naming Certificate for $\mathsf{ModulusCauchyReal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ModulusCauchyReal}^{\uparrow}$ packet records a regular Cauchy real read whose convergence evidence is indexed by a displayed modulus ledger rather than by quotient classes of Cauchy sequences. It sits after the dyadic rational core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the choice-free completion route of chapter 4237. The packet names the finite route from modulus-indexed rational requests to the $\mathsf{Real}^{\uparrow}$ seal without adding a selected limit, quotient representative, host real equality, or countable-choice schedule.

Definition 7427.1 (Modulus-Cauchy real carrier)**.** *A* $\mathsf{ModulusCauchyReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus ledger, listing the inspected precision requests and the finite convergence bounds admitted for those requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite stream windows read at the bounds named by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic radii, slack data, and comparisons used by the modulus-indexed read.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the modulus ledger, stream windows, regular readback, dyadic tolerance, real seal, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from a modulus-indexed request through M, S, R, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ModulusCauchyReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusCauchyReal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, S, R, D, E, H, C, P, N$. It has no coordinate for quotient Cauchy classes, selected real limits, host equality of real numbers, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7427.2 (Modulus-Cauchy real NameCert obligations)**.** *For every accepted* $\mathsf{ModulusCauchyReal}^{\uparrow}$ *carrier*

$$K = (M, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusCauchyReal}^{\uparrow}}$ *surface consists exactly of five obligation rows: modulus-ledger exposure through M, finite-window and regular-readback exposure through S, R, dyadic tolerance exactness through D, terminal real sealing through E, and structural preservation through H, C, P, N.*

Proof. Project the carrier of Definition 7427.1. Rows M, S, R, D, E are the analytic route, while H, C, P, N transport, replay, source, and name that route.

The modulus ledger is read first. It supplies the precision requests and finite bounds, so the stream windows in S and the regular rational readback in R are inspected only along displayed modulus-indexed data.

The dyadic tolerance row D fixes the comparison budget before the terminal row E can be consumed as a $\mathsf{Real}^{\uparrow}$ seal. Since the carrier has no quotient, selected-limit, host-equality, trichotomy, choice, or ambient-completeness coordinate, the five listed rows exhaust the local NameCert surface. □

Theorem 7427.3 (Modulus-Cauchy real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{ModulusCauchyReal}^{\uparrow}$ *packet factors through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and the displayed modulus ledger before the terminal real seal is consumed. Equivalently, the read follows the finite route*

$$M,\ S,\ R,\ D,\ E,\ H,\ C,\ P,\ N$$

from modulus-indexed precision data to the $\mathsf{Real}^{\uparrow}$ *seal.*

The route exports no quotient representative, selected limit, host real equality, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 7427.2. They place every real-facing read downstream of the modulus ledger, the finite stream windows, the regular rational readback, and the dyadic tolerance row.

Use the sibling anchors chapter 126, chapter 301, and chapter 291 for the finite observation route. The terminal seal is the $\mathsf{Real}^{\uparrow}$ row of chapter 38, and the surrounding completion discipline is the choice-free route of chapter 4237.

Finally H, C, P, N preserve the same displayed route by transport, replay, provenance, and local naming. Thus every real-facing consumer receives the modulus-indexed finite packet before the seal and cannot obtain any excluded host-level completion data from it. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusCauchyReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusCauchyReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7427.1, Definition 7427.2, and Definition 7427.3 seed the modulus-indexed regular Cauchy route from finite stream windows and dyadic tolerances to the terminal real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusCauchyReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy completions, selected real limits, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, modulus coverage, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance exactness, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ModulusCauchyRealUp.

Constructive story: A ModulusCauchyReal$^{\uparrow}$ packet is generated from a displayed modulus ledger, finite StreamName windows, RegSeqRat readback rows, DyadicRatCore tolerance rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7428

A Concrete Naming Certificate for $\mathsf{BornologicalSpace}^{\uparrow}$

Following Hogbe-Nlend and Bourbaki on bounded structures in functional analysis, the $\mathsf{BornologicalSpace}^{\uparrow}$ packet records a finite bounded-family carrier rather than an ambient collection of all bounded subsets. It sits after the bounded-set packet of chapter 1757, the locally convex family surface of chapter 3386, the seminorm family route of chapter 5868, and the normed-space comparison row of chapter 1950. The packet names the rows needed by bounded-map and functional-analysis consumers; it does not assert a host bornology, all subset closure, quotient completion, selected absorbing disk, or classical duality.

Definition 7428.1 (BornologicalSpace carrier)**.** *A* $\mathsf{BornologicalSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, \mathcal{B}, L, S, V, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying carrier row whose admissible points and finite classifier reads are the only source data available to the packet.*
2. *$\mathcal{B}$ is the finite bounded-set family row, listing the displayed* $\mathsf{BoundedSet}^{\uparrow}$ *certificates accepted as bounded disks or bounded subsets.*
3. *L is the locally convex control row imported from* $\mathsf{LocallyConvexSpace}^{\uparrow}$*, exposing only the finite neighborhood and seminorm-family data used to test boundedness.*
4. *S is the seminorm control row imported from* $\mathsf{SeminormedSpace}^{\uparrow}$*, recording finite seminorm budgets for every displayed bounded-family read.*
5. *V is the normed-space comparison row imported from* $\mathsf{NormedSpace}^{\uparrow}$ *when a single norm comparison is part of the carrier.*
6. *M is the bounded-map route row, saying that a consumer may read bounded-map data only after the source bounded-family row and the target control row are displayed.*
7. *H records componentwise* hsame *transport for the carrier, bounded-family, locally convex, seminorm, normed comparison, bounded-map, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through $X, \mathcal{B}, L, S, V, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BornologicalSpace}^{\uparrow}$*,* $\mathsf{BoundedSet}^{\uparrow}$*,* $\mathsf{LocallyConvexSpace}^{\uparrow}$*,* $\mathsf{SeminormedSpace}^{\uparrow}$*,* $\mathsf{NormedSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BornologicalSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host bornology, an unbounded subset universe, a selected disk basis, quotient completion, or classical duality.

Theorem 7428.2 (BornologicalSpace NameCert obligations)**.** *For every accepted* $\mathsf{BornologicalSpace}^{\uparrow}$ *carrier* $B = (X, \mathcal{B}, L, S, V, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BornologicalSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, finite bounded-family admission, locally convex control, seminorm control, normed-space comparison when present, bounded-map route exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7428.1. The analytic rows are the source carrier X, the bounded-family row $\mathcal{B}$, the locally convex row L, the seminorm row S, the normed comparison row V, and the bounded-map route M.

The bounded-family obligation is finite. Each boundedness read names a displayed $\mathsf{BoundedSet}^{\uparrow}$ certificate before any locally convex, seminorm, or normed-space consumer can use it.

The control obligations are rowwise. The row L supplies locally convex neighborhood data, S supplies finite seminorm budgets, and V supplies the optional single-norm comparison without replacing the finite bornological carrier by a host topology.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores a host bornology, unbounded subset universe, selected disk basis, quotient completion, or duality theorem, the listed rows exhaust the NameCert surface. □

Theorem 7428.3 (BornologicalSpace bounded-map route)**.** *Every bounded-map consumer of an accepted* $\mathsf{BornologicalSpace}^{\uparrow}$ *carrier must first read*

$$X, \mathcal{B}, L, S, V, M, H, C, P, N.$$

Thus the consumer receives finite bounded-set family rows together with locally convex, seminorm, and normed comparison control before the bounded-map row is exported. It receives no host bornology, all-subsets closure principle, selected disk basis, quotient completion, or classical duality object.

Proof. Start with a bounded-map request. By carrier admission, the request cannot reach M before the source carrier X and the bounded-family row $\mathcal{B}$ are displayed.

Use the control rows next. Locally convex data in L, seminorm budgets in S, and the normed comparison row V describe exactly how bounded family reads are tested by downstream functional-analysis packets.

The row M is therefore a bounded-map route rather than an independent host theorem. Componentwise transport and replay through H and C preserve the same finite path, while P, N only record provenance and local naming.

Because the carrier contains no coordinate for the excluded host objects, the displayed route is the entire bounded-map surface. □

Falsifiable prediction: A consumer that claims a $\mathsf{BornologicalSpace}^{\uparrow}$ bounded-map read while omitting the finite bounded-family row, locally convex control, seminorm control, normed comparison when present, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local $\mathsf{NameCert}$ row refutes the carrier of Definition 7428.1.

Independence witness: boundedset, locally-convex-space, seminormed-space, normedspace: no listed sibling is bijective to $\mathsf{BornologicalSpace}^{\uparrow}$ because this packet jointly binds finite bounded-family rows, locally convex control, seminorm budgets, normed comparison, bounded-map routing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BornologicalSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BornologicalSpace}^{\uparrow}$ packet is generated from carrier rows, finite bounded-family rows, locally convex control rows, seminorm control rows, normed-space comparison rows, bounded-map route rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BornologicalSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7428.1, Definition 7428.2, and Definition 7428.3 seed the finite bornological bounded-family packet for functional-analysis consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BornologicalSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host bornologies, all-subsets closure, selected disk bases, quotient completion, classical duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-family admission, locally convex control, seminorm control, normed comparison, bounded-map routing, transport, replay, provenance, and local naming for BEDC.Derived.BornologicalSpaceUp.

Chapter 7429

A Concrete Naming Certificate for $\mathsf{CompactOscillationMesh}^{\uparrow}$

Following Bishop–Bridges compact metric uniform continuity, the $\mathsf{CompactOscillationMesh}^{\uparrow}$ packet realizes the compact-uniform-continuity route of chapter 9237 as a finite oscillation mesh. It sits after the compact metric source of chapter 129, the displayed continuous-map rows of chapter 130, the uniform-modulus consumer of chapter 369, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite mesh of compact probes and oscillation bounds; it is not an open-cover compactness theorem, selected Lebesgue number, host modulus function, quotient equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7429.1 (Compact oscillation mesh carrier)**.** *A* $\mathsf{CompactOscillationMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, Q, M, D, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, exposing centers, mesh radius, and coverage witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise inspection row attached to the displayed compact source.*
3. *Q is the finite oscillation ledger, recording for each mesh cell the source-radius and target-oscillation bound read from F.*
4. *M is the rational lower-bound mesh fold, extracting a positive source precision from the finite oscillation ledger.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-conversion row used by downstream dyadic budgets.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from the folded mesh precision.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for consumers that read the modulus through regular rational names.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, F, Q, M, D, U, R are displayed.*
9. *H records componentwise* hsame *transport for compact source, continuous-map, oscillation, fold, dyadic, uniform-modulus, readback, Real, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay through $K, F, Q, M, D, U, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationMesh}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for selected covers, selected Lebesgue numbers, host moduli, quotient map equality, countable choice, or ambient compactness.

Theorem 7429.2 (Compact oscillation mesh NameCert obligations)**.** *For every accepted* $\mathsf{CompactOscillationMesh}^{\uparrow}$ *carrier* $O = (K, F, Q, M, D, U, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationMesh}^{\uparrow}}$ *surface consists exactly of compact finite-net admission, continuous-map pointwise inspection, finite oscillation-ledger admission, rational lower-bound mesh folding, dyadic tolerance conversion,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7429.1. The compact source row K, continuous-map row F, oscillation ledger Q, mesh fold M, dyadic row D, uniform-modulus row U, readback row R, and Real seal E are the analytic coordinates.

The compact and continuity obligations are finite. The mesh centers and coverage witnesses come from K, while each oscillation row in Q is attached to an inspected pointwise row in F.

The modulus obligation is the route through Q, M, D, U. The fold M extracts one positive source precision from the finite oscillation ledger, D converts it into the dyadic tolerance budget, and U exports the tolerance-only uniform-modulus row.

Finally R, E, H, C, P, N read, seal, transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded host objects, the listed rows exhaust the local NameCert surface. □

Theorem 7429.3 (Compact oscillation mesh uniform-modulus route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationMesh}^{\uparrow}$ *carrier must first read*

$$K, F, Q, M, D, U, H, C, P, N.$$

If the consumer later reaches $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *data, the read factors through the same mesh route before R and E are available. Thus the compact-uniform-continuity output is a finite oscillation-mesh realization, not a selected Lebesgue number, host modulus, open-cover compactness theorem, quotient map equality, or ambient completeness principle.*

Proof. Begin with the compact source row. The finite mesh data in K fixes the centers, mesh radius, and coverage witnesses before any oscillation estimate can be consumed.

Use the continuous-map inspection row F and the oscillation ledger Q. Each target-oscillation bound is attached to a displayed mesh cell, so the consumer cannot replace the ledger by a host continuity theorem.

The lower-bound fold M and dyadic row D supply the source precision consumed by U. Componentwise transport and replay through H and C preserve exactly that route, and P, N only source and name it.

When regular rational or Real-facing consumers appear, R and E are downstream of the same rows. No selected cover, selected Lebesgue number, host modulus, quotient equality, countable choice, or ambient completeness coordinate is present in the carrier. □

Falsifiable prediction: A consumer that claims a $\mathsf{CompactOscillationMesh}^{\uparrow}$ uniform-modulus read while omitting compact finite-net rows, continuous-map pointwise inspection, finite oscillation ledger, rational mesh fold, dyadic tolerance conversion, $\mathsf{UniformModulus}^{\uparrow}$ handoff, transport, replay, provenance, or local NameCert rows refutes the carrier of Definition 7429.1.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, regseqrat, real: no listed sibling is bijective to $\mathsf{CompactOscillationMesh}^{\uparrow}$ because this packet jointly binds compact finite-net data, pointwise oscillation rows, finite mesh folding, dyadic tolerance conversion, uniform-modulus handoff, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationMesh}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise inspection rows, finite oscillation ledger rows, rational mesh folds, DyadicRatCore tolerance conversion, UniformModulus handoff, RegSeqRat readback, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOscillationMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7429.1, Definition 7429.2, and Definition 7429.3 seed the finite oscillation-mesh route from compact metric pointwise inspection to uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOscillationMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, host modulus functions, quotient map equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net admission, continuous-map pointwise inspection, oscillation-ledger admission, rational mesh fold exactness, dyadic tolerance conversion, UniformModulus handoff, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationMeshUp.

Chapter 7430

A Concrete Naming Certificate for $\mathsf{DetachableBar}^{\uparrow}$

Following Bishop and Troelstra–van Dalen on bars over spreads and choice sequences, the $\mathsf{DetachableBar}^{\uparrow}$ packet records a finite-prefix bar predicate whose inspected prefixes are decidable inside the displayed BEDC rows. It sits beside the finite fan surface of chapter 400, the barred-spread induction route of chapter 1675, the choice-sequence prefix rows of chapter 1482, the Baire-space cylinder surface of chapter 334, and the spread-law admission route of chapter 1532. Downstream analytic consumers reach it only through the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38; they receive no countable-choice selector, quotient stream equality, open-cover compactness, selected branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7430.1 (DetachableBar carrier)**.** *A* $\mathsf{DetachableBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, I, Q, B, A, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite fan row or finite fan-boundary row through which bounded prefix inspection is requested;*
2. *I is the* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *barred-spread row, exposing only the finite bar decisions and induction replay visible at the inspected prefixes;*
3. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix-answer row, recording the finite answers whose prefixes are being tested;*
4. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *prefix-cylinder row that names the ambient countable-prefix window without naming a completed branch;*
5. *A is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admission row, deciding which displayed prefixes are legal spread extensions;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule read by downstream analytic consumers;*
7. *W is the detachable bar-decision row, recording for each displayed prefix whether the bar predicate accepts it;*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only after the finite window schedule and bar-decision row have been displayed;*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for real-facing consumers that pass through S, W, R;*
10. *H records componentwise* hsame *transport for the fan, bar-induction, choice-sequence, Baire, spread-law, StreamName, bar-decision, regular-rational, and Real rows;*
11. *C records displayed* Cont *replay of the same finite-prefix route;*
12. *P is the* Pkg *provenance over* $\mathsf{DetachableBar}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{SpreadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DetachableBar}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed finite-prefix rows. It has no coordinate for a host function on completed streams, a selected infinite branch, countable choice, quotient stream equality, an open-cover subcover, or ambient real completeness.

Theorem 7430.2 (DetachableBar NameCert obligations)**.** *For every accepted* $\mathsf{DetachableBar}^{\uparrow}$ *carrier*

$$D = (F, I, Q, B, A, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DetachableBar}^{\uparrow}}$ *surface consists exactly of carrier admission for those rows, fan-boundary exposure through F, barred-spread replay through I, choice-sequence prefix exposure through Q, Baire-cylinder exposure through B, spread-law admission through A, finite StreamName scheduling through S, detachable bar-decision exposure through W, regular-rational readback through R, Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7430.1. The projection lists exactly the fan, bar-induction, choice-sequence, Baire, spread-law, finite-window, bar-decision, readback, Real-seal, transport, replay, provenance, and naming rows.

The bar predicate is detachable because W is a displayed decision row over the finite prefixes already exposed by F, I, Q, B, A, S. A consumer cannot ask about an unseen tail or a completed branch before those rows have been displayed.

The analytic handoff is downstream. Rows R and E may be read only after the finite StreamName schedule and bar-decision row have been exposed, and the structural rows H, C, P, N preserve the same route without adding a choice principle or quotient equality. □

Theorem 7430.3 (DetachableBar finite-prefix decision)**.** *Every decision exported by an accepted* $\mathsf{DetachableBar}^{\uparrow}$ *packet is attached to a displayed finite prefix admitted through*

$$\mathsf{FanTheorem}^{\uparrow},\ \mathsf{BrouwerBarInduction}^{\uparrow},\ \mathsf{ChoiceSequence}^{\uparrow},\ \mathsf{BaireSpace}^{\uparrow},\ \mathsf{SpreadLaw}^{\uparrow},\ \mathsf{StreamName}^{\uparrow}.$$

If two accepted packets agree componentwise on those prefix rows and on their detachable bar-decision rows under the displayed hsame *transport, then they expose the same accepted-or-refused bar decision to every downstream consumer.*

Proof. Begin with the prefix-facing rows F, I, Q, B, A, S. They determine the finite branch window, barred-spread ancestry, choice-sequence answers, Baire cylinder, spread-law admission, and StreamName schedule available to the packet.

The detachable decision row W is indexed only by that displayed window. Componentwise hsame transport therefore identifies the visible prefix and the visible decision together, so no consumer can distinguish transported packets by asking about an unlisted tail.

Replay through C and provenance through P, N preserve the same finite decision surface. Thus the exported classifier is a finite-prefix decision, not an extensional equality test on completed streams. □

Theorem 7430.4 (DetachableBar real-completion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer of an accepted* $\mathsf{DetachableBar}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DetachableBar}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

together with the sibling fan, bar-induction, choice-sequence, Baire, and spread-law rows. The handoff exports finite bar evidence for real-name readback, not countable choice, open-cover compactness, quotient stream equality, selected branch data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the NameCert obligations of Definition 7430.2. They force the StreamName window S and detachable decision row W to be displayed before R or E is available.

The regular-rational row R reads the same finite window, and the Real row E seals only that readback. The fan, bar-induction, choice-sequence, Baire, and spread-law rows remain prerequisites for the prefix to which W attaches.

Since no carrier coordinate stores a selected branch, open-cover subcover, quotient stream equality, countable-choice functional, or ambient completeness theorem, the analytic consumer receives only the displayed finite handoff. □

Theorem 7430.5 (DetachableBar prefix transport)**.** *Let* $D = (F, I, Q, B, A, S, W, R, E, H, C, P, N)$ *and* $D' = (F', I', Q', B', A', S', W', R', E', H', C', P', N')$ *be accepted* $\mathsf{DetachableBar}^{\uparrow}$ *packets. If the fan, barred-spread, choice-sequence, Baire, spread-law, StreamName, bar-decision, regular-rational, and Real rows transport componentwise under* H, H' *and replay through* C, C'*, then every consumer sees the same detachable-bar prefix route from* D *and* D'*.*

Proof. The componentwise transport identifies the prefix-facing rows F, I, Q, B, A, S with F', I', Q', B', A', S'. Hence both packets expose the same finite prefix window and the same legal spread or Baire admission surface.

The same transport identifies W with W' over that window. Consequently the accepted-or-refused bar decision is transported together with its prefix, not detached from it as a host predicate on completed streams.

Finally R, E, P, N and R', E', P', N' are replayed through C, C'. Any real-facing or completion-facing consumer therefore reads the same transported finite-prefix route. □

Theorem 7430.6 (DetachableBar obligation package)**.** *The preceding carrier, NameCert, finite-prefix decision, real-completion handoff, and prefix-transport clauses assemble the seed obligation package for* $\mathsf{DetachableBar}^{\uparrow}$*. The package is exhausted by the finite rows*

$$F, I, Q, B, A, S, W, R, E, H, C, P, N$$

and by the sibling route through $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{BrouwerBarInduction}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{BaireSpace}^{\uparrow}$*,* $\mathsf{SpreadLaw}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. The carrier definition supplies exactly the listed rows, and Definition 7430.2 makes them the local NameCert surface.

Definition 7430.3 binds the detachable decision to displayed finite prefixes. Definition 7430.4 places analytic readback after that decision, and Definition 7430.5 shows that componentwise transport preserves the whole route.

Thus the package names the finite-prefix bar predicate needed by downstream Real and Completion work while refusing countable choice, open-cover compactness, quotient stream equality, selected branch data, and ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DetachableBar}^{\uparrow}}$.

Constructive story: A $\mathsf{DetachableBar}^{\uparrow}$ packet is generated from FanTheoremUp finite fan rows, BrouwerBarInductionUp barred-spread rows, ChoiceSequenceUp prefix answers, BaireSpaceUp prefix cylinders, SpreadLawUp admission, StreamNameUp finite windows, detachable bar-decision rows, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DetachableBar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7430.1, Definition 7430.2, Definition 7430.3, Definition 7430.4, Definition 7430.5, and Definition 7430.6 seed the finite-prefix detachable-bar route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DetachableBar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, open-cover compactness, quotient stream equality, selected branch data, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean carrier and checked obligation package for BEDC.Derived.DetachableBarUp.

Chapter 7431

A Concrete Naming Certificate for $\mathsf{CourantFischerMinimax}^{\uparrow}$

Following Courant and Fischer on the finite-dimensional min-max principle, the $\mathsf{CourantFischerMinimax}^{\uparrow}$ packet names the finite spectral min-max certificate without importing a host eigenspace selector. It consumes the matrix carrier of chapter 49, the inner-product rows of chapter 86, the Hermitian surface of chapter 6403, the normal-operator routing of chapter 5807, and the finite gap window of chapter 5136.

Definition 7431.1 (CourantFischerMinimax carrier)**.** *A* $\mathsf{CourantFischerMinimax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, O, I, W, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite* $\mathsf{Mat}^{\uparrow}$ *row, recording the coordinate table used by the spectral read.*
2. *O is the* $\mathsf{NormalOperator}^{\uparrow}$ *or* $\mathsf{HermitianMatrix}^{\uparrow}$ *operator row attached to the same matrix table.*
3. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row through which vector lengths and orthogonality tests are read.*
4. *W is the finite subspace-window row, listing the inspected dimensions, inclusions, and complement windows.*
5. *R is the Rayleigh quotient ledger, recording numerator and denominator reads through M, O, I, W.*
6. *L is the min-max comparison row, displaying the finite lower-window and upper-window comparisons for the same dimension index.*
7. *E is the extremal ledger, recording which displayed subspace windows witness the lower and upper sides of the comparison.*
8. *H records componentwise* hsame *transport for the matrix, operator, inner-product, subspace-window, Rayleigh, comparison, extremal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a spectral min-max request through $M, O, I, W, R, L, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CourantFischerMinimax}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{HermitianMatrix}^{\uparrow}$, $\mathsf{NormalOperator}^{\uparrow}$, $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CourantFischerMinimax}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host eigenvector choice, a spectral-completeness theorem, an ambient quotient of subspaces, selected extrema outside E, or a hidden diagonalization procedure.

Theorem 7431.2 (CourantFischerMinimax NameCert obligations)**.** *For every accepted* $\mathsf{CourantFischerMinimax}^{\uparrow}$ *carrier*

$$K = (M, O, I, W, R, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CourantFischerMinimax}^{\uparrow}}$ *surface consists exactly of carrier admission, Rayleigh quotient readback, finite subspace-window stability, min-max ledger exactness, sibling transport through* $\mathsf{Mat}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{HermitianMatrix}^{\uparrow}$, $\mathsf{NormalOperator}^{\uparrow}$, *and* $\mathsf{FiniteDimensionalSpectralGap}^{\uparrow}$, *displayed* Cont *replay,* Pkg *provenance, and local naming. A spectral min-max read is admitted only after the same matrix, operator, inner-product, subspace-window, Rayleigh, comparison, and extremal rows are visible in the packet.*

Proof. Project the carrier of Definition 7431.1. The matrix row M, operator row O, and inner-product row I supply the finite algebraic surface on which Rayleigh reads can be formed.

The subspace-window row W fixes the finite inspection domain. The Rayleigh ledger R is read only through M, O, I, W, so every quotient claim remains tied to the displayed matrix and inner-product coordinates.

The min-max comparison row L records the lower-window and upper-window comparisons for the same finite dimension index. The extremal ledger E names the displayed windows that witness the two sides, without selecting host eigenvectors.

Finally, componentwise transport by H preserves the sibling rows, while C, P, N replay, source, and name the same packet. Since the carrier has no field for spectral completeness, diagonalization, quotient subspace equality, or external extrema, these rows exhaust the local NameCert obligations. □

Lean4 (statement) `BEDC.Derived.CourantFischerMinimaxUp`

Closure status for $\mathsf{NameCert}_{\mathsf{CourantFischerMinimax}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CourantFischerMinimax}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7431.1 and Definition 7431.2 seed the finite spectral min-max certificate through displayed matrix, operator, inner-product, subspace-window, Rayleigh, comparison, and extremal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CourantFischerMinimax}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host eigenvector choice, spectral completeness, quotient subspace equality, selected extrema outside the packet, or ambient diagonalization.

Upgrade path: Obligation closure requires checked carrier admission, Rayleigh readback, finite subspace-window stability, min-max ledger exactness, sibling transport, replay, provenance, and non-escape for BEDC.Derived.CourantFischerMinimaxUp.

Constructive story: A $\mathsf{CourantFischerMinimax}^{\uparrow}$ packet is generated from a finite matrix row, a Hermitian or normal-operator row, an inner-product row, a finite subspace-window row, a Rayleigh quotient ledger, a min-max comparison row, an extremal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7432

A Concrete Naming Certificate for $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ packet records the finite L10 seal by which two interleaved regular Cauchy reads are accepted as the same real-facing completion route. It sits after the finite windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, the comparison criterion of chapter 3405, and the binary projection ledger of chapter 3864. The packet names the displayed interleaving seal only; it does not quotient streams, select limits, invoke countable choice, compare host real equality, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7432.1 (Real Cauchy interleaving seal carrier)**.** *A* $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W_0, W_1, B, I, Q, R_0, R_1, D, E, H, C, P, N)$$

with the following displayed rows:

1. W_0 *and* W_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedules inspected by the equality or completion request.*
2. B *is the* $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ *projection ledger that records how even and odd windows are recovered from one interleaved read.*
3. I *is the* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ *comparison row, carrying the finite criterion that licenses the two projected reads to share one tolerance discipline.*
4. Q *is the dyadic tolerance row used by the comparison, the two projected reads, and the final seal.*
5. R_0 *and* R_1 *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the two projected regular rational names after* W_0, W_1, B, I, Q *are displayed.*
6. D *is the diagonal tolerance row showing that the readbacks meet the same requested dyadic bound.*
7. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the finite windows, interleaving ledger, comparison row, dyadic tolerance row, readbacks, and diagonal row have been consumed.*
8. H *records componentwise* hsame *transport for* $W_0, W_1, B, I, Q, R_0, R_1, D, E, C, P, N$.

9. *C records displayed* Cont *replay from an equality or completion request through the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$, $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyInterleavingSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W_0, W_1, B, I, Q, R_0, R_1, D, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable-choice schedules, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7432.2 (Real Cauchy interleaving seal NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ *carrier*

$$S = (W_0, W_1, B, I, Q, R_0, R_1, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyInterleavingSeal}^{\uparrow}}$ *surface consists exactly of carrier admission for the two StreamName windows, binary interleaving projection ledger, Cauchy interleaving criterion row, dyadic tolerance row, two RegSeqRat readbacks, diagonal tolerance row, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming row.*

Proof. Project the carrier of Definition 7432.1. The finite windows W_0, W_1 are the only observation schedules available to an equality or completion request.

Read the interleaving and comparison rows next. The binary ledger B supplies the even–odd projection surface, while I and Q attach the Cauchy interleaving criterion to a displayed dyadic tolerance row.

The two regular rational readbacks are then R_0 and R_1. The diagonal row D records that the two readbacks meet the same requested tolerance before the terminal $\mathsf{Real}^{\uparrow}$ seal E is exposed.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier lists no quotient stream, selected limit, countable-choice schedule, host equality, or ambient completeness coordinate, those objects are not part of the local NameCert surface. □

Theorem 7432.3 (Real Cauchy interleaving seal regular readback)**.** *Every* $\mathsf{Real}^{\uparrow}$ *equality or completion consumer of an accepted* $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ *packet must read the route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegularCauchyBinaryInterleaving}^{\uparrow},\ \mathsf{CauchyInterleavingCriterion}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through $W_0, W_1, B, I, Q, R_0, R_1, D, E, H, C, P, N$ before it consumes the terminal seal. The route is a finite regular-readback seal, not a quotient of streams, selected limit, countable-choice construction, host real equality, or ambient completeness theorem.

Proof. Start with Definition 7432.2. It makes the StreamName windows, binary projection ledger, criterion row, tolerance row, readbacks, diagonal row, and seal the whole analytic surface of the packet.

Use the sibling routes in order. The StreamName rows expose the finite windows, the RegularCauchyBinaryInterleaving row supplies the even–odd projection ledger, and the CauchyInterleavingCriterion row fixes the comparison before either regular rational readback is consumed.

The readback step is carried by R_0, R_1 under the shared dyadic tolerance row Q. The diagonal row D is the last finite check before the terminal $\mathsf{Real}^{\uparrow}$ seal E is available.

Transport, replay, provenance, and local naming preserve this same route. Thus a Real or Completion consumer that bypasses any of the listed rows is asking for data outside the accepted seal packet. □

Falsifiable prediction: An accepted $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ consumer is refuted if it reaches the $\mathsf{Real}^{\uparrow}$ seal without first reading the two $\mathsf{StreamName}^{\uparrow}$ finite-window rows, the $\mathsf{RegularCauchyBinaryInterleaving}^{\uparrow}$ projection ledger, the $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ comparison row, dyadic tolerance data, both $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, diagonal tolerance, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, regseqrat, real, cauchy-interleaving-criterion, regular-cauchy-binary-interleaving: none is bijective with $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ because this packet jointly binds two finite window schedules, one binary interleaving ledger, one criterion row, one dyadic tolerance row, two regular rational readbacks, a diagonal tolerance row, a terminal Real seal, transport, replay, provenance, and local naming as one completion-facing seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyInterleavingSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCauchyInterleavingSeal}^{\uparrow}$ packet is generated from two StreamName finite-window rows, a RegularCauchyBinaryInterleaving projection ledger, a CauchyInterleavingCriterion row, dyadic tolerance data, two RegSeqRat readbacks, a diagonal tolerance row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyInterleavingSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7432.1, Definition 7432.2, and Definition 7432.3 seed the finite Real Cauchy interleaving seal over StreamNameUp, RegularCauchyBinaryInterleavingUp, CauchyInterleavingCriterionUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyInterleavingSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable-choice schedules, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove window admission, binary projection exposure, criterion routing, dyadic tolerance exactness, regular readback, diagonal tolerance, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealCauchyInterleavingSealUp.

Chapter 7433

A Concrete Naming Certificate for KuratowskiClosureComplement$^{\uparrow}$

Following Kuratowski's closure-complement theorem, the KuratowskiClosureComplement$^{\uparrow}$ packet records the finite alternation surface generated by a closure row and a complement row before any host powerset equality is read. It is grounded in the topology carrier of chapter 88, the closed-set boundary of chapter 4229, the closure operator packet of chapter 2145, and the two-point specialization witness of chapter 1860. The chapter names the closure/complement alternation route as BEDC certificate data only; it does not assert a host set algebra, quotient equality of subsets, Boolean powerset extensionality, or a completed lattice of all opens.

Definition 7433.1 (Kuratowski closure-complement carrier)**.** *A* KuratowskiClosureComplement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, F, L, C, A, B, H, R, P, N)$$

with the following visible rows:

1. *T is the ambient* Topology$^{\uparrow}$ *carrier whose finite open, closed, and specialization rows provide the inspection context.*
2. *F is the* ClosedSet$^{\uparrow}$ *boundary row naming the closed-stable subsets allowed in the certificate.*
3. *L is the* KuratowskiClosure$^{\uparrow}$ *closure row, including extensivity, monotonicity, and idempotence reads already displayed by the closure packet.*
4. *C is the complement row, recording only the formal exchange between a named subset row and its displayed complement row inside the finite topology packet.*
5. *A is the alternation ledger for words in the two symbols closure and complement, with every accepted word reduced through the displayed finite route.*
6. *B is the fourteen-boundary row, recording that no accepted alternation consumer can distinguish more than the finite Kuratowski boundary packets generated by L and C.*
7. *H is componentwise* hsame *transport for the topology, closed-set, closure, complement, alternation, and boundary rows.*
8. *R is displayed* Cont *replay for reading T, F, L, C, A, B, H in that order.*
9. *P is* Pkg *provenance over* KuratowskiClosureComplement$^{\uparrow}$, Topology$^{\uparrow}$, ClosedSet$^{\uparrow}$, KuratowskiClosure$^{\uparrow}$, SierpinskiSpace$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{KuratowskiClosureComplement}^{\uparrow}}$ *row.*
The classifier compares accepted packets only by the finite alternation ledger and its displayed transports. It has no coordinate for host powerset equality, quotient subset equality, Boolean algebra completion, arbitrary choice of representatives, or a full topology of all opens.

Lean4 (definition) `BEDC.Derived.KuratowskiClosureComplementUp.KuratowskiClosureComplementCarrier`

Theorem 7433.2 (Kuratowski closure-complement NameCert obligations)**.** *For an accepted* KuratowskiClosureCom *carrier $K = (T, F, L, C, A, B, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiClosureComplement}^{\uparrow}}$ *surface consists exactly of carrier admission, closure-row exposure, complement-row exposure, finite alternation replay, fourteen-boundary retention, componentwise transport, provenance, and non-escape from host powerset principles.*

Proof. Project the carrier of Definition 7433.1. The visible rows are the topology context, closed-set boundary, closure operator row, complement row, alternation ledger, fourteen-boundary row, transport, replay, provenance, and local name.

The closure obligation is read from L together with the topology context T and the closed-set boundary F. It exposes only the finite closure operator behavior already admitted by the Kuratowski closure packet.

The complement and alternation obligations are read from C and A. Each alternation word is replayed through the displayed closure/complement rows, so the certificate tracks a finite route rather than an ambient subset function space.

Finally, B, H, R, P, N record the boundary, transport, replay, source, and naming rows. Since no row contains host powerset equality, quotient subset equality, Boolean algebra completion, representative choice, or an all-opens carrier, none of those principles is exported by the local certificate. □

Lean4 ✓ `BEDC.Derived.KuratowskiClosureComplementUp.KuratowskiClosureComplementCarrier namecert obligations`

Theorem 7433.3 (Kuratowski closure-complement fourteen route)**.** *Every accepted* KuratowskiClosureComplement *consumer reading a closure/complement word factors through the finite route*

$$\mathsf{Topology}^{\uparrow} \longmapsto \mathsf{ClosedSet}^{\uparrow} \longmapsto \mathsf{KuratowskiClosure}^{\uparrow} \longmapsto C \longmapsto A \longmapsto B \longmapsto (H, R, P, N).$$

The route records the traditional Kuratowski fourteen-set boundary as finite NameCert data, not as host-level equality of all subsets or as an ambient Boolean powerset algebra.

Proof. Begin with the ambient topology and closed-set rows. They provide the only admissible inspection context for subset, closedness, and specialization reads.

Read the closure row next. The $\mathsf{KuratowskiClosure}^{\uparrow}$ packet supplies the closure behavior used in each alternation step, and the complement row supplies the other generator of the word ledger.

The alternation ledger A records the finite word route, while B stores the displayed fourteen-boundary retention. Transport and replay through H and R keep the same finite rows under componentwise comparison, and P, N source and name the packet.

Thus the consumer receives only finite closure/complement alternation evidence. The read cannot turn into host powerset equality, quotient subset equality, Boolean completion, arbitrary representative choice, or a topology-of-all-opens principle because no such row appears in the carrier. □

Lean4 ✓ `BEDC.Derived.KuratowskiClosureComplementUp.KuratowskiClosureComplementCarrier fourteen route`

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiClosureComplement}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiClosureComplement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7433.1, Definition 7433.2, and Definition 7433.3 seed the finite closure/complement alternation packet and its fourteen-boundary route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiClosureComplement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, standard bridge checking, host powerset equality, quotient subset equality, Boolean algebra completion, representative choice, or a full topology of all opens.

Upgrade path: Obligation closure requires checked carrier admission, closure-row exposure, complement-row exposure, alternation replay, fourteen-boundary retention, transport, provenance, and non-escape for BEDC.Derived.KuratowskiClosureComplement

Constructive story: A $\mathsf{KuratowskiClosureComplement}^{\uparrow}$ packet is generated from finite topology, closed-set, Kuratowski-closure, complement, alternation-ledger, fourteen-boundary, transport, replay, provenance, and local NameCert rows.

Chapter 7434

A Concrete Naming Certificate for $\mathsf{FinitePhaseCylinder}^{\uparrow}$

The $\mathsf{FinitePhaseCylinder}^{\uparrow}$ packet realizes the phase-surface and Poincare disk readings of chapter 9463 as finite NameCert data. It consumes the complex coordinate surface of chapter 39, the boundary-circle carrier of chapter 58, the disk row of chapter 377, the Poincare metric route of chapter 6209, and the reversible transport row of chapter 219.

Definition 7434.1 (FinitePhaseCylinder carrier)**.** *A* $\mathsf{FinitePhaseCylinder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Z, S, D, U, W, R, H, C, P, N)$$

with the following displayed rows:

1. *Z is the finite* $\mathsf{Complex}^{\uparrow}$ *phase-coordinate row used for local readout.*
2. *S is the* $\mathsf{S}^{1\uparrow}$ *boundary-circle row naming the phase boundary.*
3. *D is a* $\mathsf{UnitDisk}^{\uparrow}$ *or* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk row that records the displayed interior and boundary read.*
4. *U is the* $\mathsf{UnitaryGroup}^{\uparrow}$ *reversible-transport row, read only as a classifier-preserving finite transport.*
5. *W is the finite phase-window ledger, listing the inspected phase samples, boundary tags, and disk-position reads.*
6. *R is the refusal row excluding a global universe digest, a global clock, an unlogged Hilbert-space operator, and an interior point named* T*.*
7. *H records componentwise* hsame *transport for the complex phase, circle, disk, transport, window, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a phase-cylinder request through $Z, S, D, U, W, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FinitePhaseCylinder}^{\uparrow}$*,* $\mathsf{Complex}^{\uparrow}$*,* $\mathsf{S}^{1\uparrow}$*,* $\mathsf{UnitDisk}^{\uparrow}$*,* $\mathsf{PoincareDiskMetric}^{\uparrow}$*,* $\mathsf{UnitaryGroup}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePhaseCylinder}^{\uparrow}}$ *row.*

The future TasteGate surface for this packet must expose $\mathsf{Nontrivial}$ *and* $\mathsf{FieldFaithful}$ *instances for the displayed phase and field-facing readback rows before downstream consumers use the cylinder as more than a finite representation packet.*

Theorem 7434.2 (FinitePhaseCylinder NameCert obligations)**.** *For every accepted* $\mathsf{FinitePhaseCylinder}^{\uparrow}$ *carrier*

$$F = (Z, S, D, U, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitePhaseCylinder}^{\uparrow}}$ *surface consists exactly of carrier admission, complex phase readout, boundary-circle exposure, disk or Poincare-metric readback, reversible transport, finite phase-window stability, refusal-row preservation, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A phase-cylinder read may consume* $\mathsf{Complex}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, *and* $\mathsf{UnitaryGroup}^{\uparrow}$ *only through the displayed rows of the same packet.*

Proof. Project the carrier of Definition 7434.1. The phase coordinate Z, boundary circle S, disk row D, and reversible transport U give the only geometric rows exposed to a consumer.

The finite window W fixes which phase samples, boundary tags, and disk positions are readable. The refusal row R travels with the same window, so no consumer can reinterpret the cylinder as a global digest or an unlogged ambient operator.

Transport by H is componentwise across $Z, S, D, U, W, R, C, P, N$. Replay through C and provenance through P, N preserve the same finite packet, exhausting the local NameCert obligations. □

Lean4 (statement) `BEDC.Derived.FinitePhaseCylinderUp`

Falsifiable prediction: Every accepted $\mathsf{FinitePhaseCylinder}^{\uparrow}$ consumer must display ComplexUp phase coordinates, S1Up boundary tags, a UnitDiskUp or PoincareDiskMetricUp disk read, a UnitaryGroupUp reversible-transport row, a finite phase-window ledger, refusal rows, hsame transport, Cont replay, Pkg provenance, and local NameCert before using a phase-cylinder read.

Independence witness: complex, s1, unitdisk, poincare-disk-metric, unitarygroup: $\mathsf{FinitePhaseCylinder}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries phase readout, boundary circle, disk metric, reversible transport, finite window, and refusal rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePhaseCylinder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePhaseCylinder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7434.1 and Definition 7434.2 seed the finite phase-cylinder packet through displayed phase, boundary, disk, reversible-transport, window, refusal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePhaseCylinder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, a global universe digest, a global clock, a hidden Hilbert-space operator, field-faithful TasteGate instances, or an interior point named T.

Upgrade path: Obligation closure requires checked carrier admission, phase readout, boundary-circle exposure, disk readback, reversible transport, refusal preservation, replay, provenance, and local naming for BEDC.Derived.FinitePhaseCylinderUp.

Constructive story: A $\mathsf{FinitePhaseCylinder}^{\uparrow}$ packet is generated from a ComplexUp phase row, an SOneUp boundary-circle row, a UnitDiskUp or PoincareDiskMetricUp disk row, a UnitaryGroupUp reversible-transport row, a finite phase-window ledger, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7435

A Concrete Naming Certificate for $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$

Following Hausdorff and Bishop–Bridges finite-cover analysis, the $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ packet records the displayed bridge where Hausdorff gauge covers are read as finite cover-refinement data before any covering-dimension consumer inspects them. It sits between the gauge-cover packet of chapter 4119, the finite-refinement surface of chapter 1853, the metric observation route of chapter 57, the compact source of chapter 129, and the dyadic scale ledger of chapter 291. The packet names a finite gauge-to-refinement handoff only; it does not assert Hausdorff measure existence, exact dimension values, open-cover compactness, countable cover choice, selected optimal covers, host logarithms, or ambient Euclidean embeddings.

Definition 7435.1 (Hausdorff dimension finite-cover carrier)**.** *A* $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, K, D, G, C, R, O, W, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *observation row used to read ball centers, radii, and diameter comparisons.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing finite-net data before any cover member is admitted.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row, recording the finite dyadic radius and tolerance ledger used by the gauge.*
4. *G is the inherited* $\mathsf{HausdorffDimension}^{\uparrow}$ *gauge row, including the positive scale and rational weight expression.*
5. *C is the finite visible cover row, listing cover members as* BHist *entries with center, radius, membership, and diameter data.*
6. *R is the refinement map row, assigning each covering-dimension cover member to a displayed Hausdorff cover member.*
7. *O is the overlap-order row consumed by* $\mathsf{CoveringDimension}^{\uparrow}$ *when the finite cover is read as a refinement surface.*
8. *W is the gauge-weight and finite-sum row attached to the same listed cover members.*

9. *H records componentwise* hsame *transport for $M, K, D, G, C, R, O, W, T, P, N$.*
10. *T records displayed* Cont *replay from the Hausdorff gauge request through the finite cover, refinement, overlap, and weight rows.*
11. *P is the* Pkg *provenance over* HausdorffDimensionFiniteCover$^{\uparrow}$, HausdorffDimension$^{\uparrow}$, CoveringDimension$^{\uparrow}$, Met$^{\uparrow}$, CompactMetric$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{HausdorffDimensionFiniteCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, D, G, C, R, O, W, H, T, P, N$. It has no coordinate for outer measures, countable cover families, selected optimal covers, host logarithmic dimension calculations, open-cover compactness, or quotient compacta.

Theorem 7435.2 (Hausdorff dimension finite-cover NameCert obligations)**.** *For every accepted* HausdorffDimensionFiniteCover$^{\uparrow}$ *carrier*

$$F = (M, K, D, G, C, R, O, W, H, T, P, N),$$

the local NameCert$_{\text{HausdorffDimensionFiniteCover}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric observation row, compact metric source row, dyadic scale ledger, Hausdorff gauge row, finite visible cover row, refinement map, overlap-order row, gauge-weight finite sum, componentwise transport, displayed replay, provenance, and local naming. No obligation is stored outside $M, K, D, G, C, R, O, W, H, T, P, N$.*

Proof. Project the carrier of Definition 7435.1. The source and scale side is exhausted by M, K, D, G: metric observations, compact finite-net data, dyadic radii, and the Hausdorff gauge row.

The finite-cover side is exhausted by C, R, O, W. The cover row lists exactly the displayed members, the refinement row attaches covering-dimension members to those displayed parents, the overlap row records the finite order read, and the weight row keeps the Hausdorff gauge sum attached to the same cover list.

Finally H, T, P, N transport, replay, source, and name that finite route. Since the carrier has no outer-measure, countable-cover, selected-cover, host-logarithm, open-cover-compactness, or quotient-compactum coordinate, none can become a local NameCert obligation. □

Theorem 7435.3 (Hausdorff dimension covering-dimension handoff)**.** *Every* CoveringDimension$^{\uparrow}$ *consumer of an accepted* HausdorffDimensionFiniteCover$^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{HausdorffDimension}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto C, R, O, W \longmapsto \mathsf{CoveringDimension}^{\uparrow}.$$

The handoff exposes a displayed finite cover, its refinement map, its overlap-order row, and its gauge-weight ledger before the covering-dimension surface is public. It exports no Hausdorff measure theorem, open-cover compactness principle, countable cover choice, selected optimal cover, host logarithm, or ambient Euclidean embedding.

Proof. Apply Definition 7435.2. It fixes the readable surface at the rows $M, K, D, G, C, R, O, W, H, T, P, N$.

Read the source and scale rows first. The metric and compact-metric rows anchor the visible cover in displayed finite-net data, while the dyadic row and Hausdorff gauge row determine the finite scale and weight expression.

Next read the covering-dimension interface rows. The cover row C supplies the displayed members, R supplies the refinement map, O supplies the overlap-order ledger, and W keeps the gauge sum attached to the same finite cover.

The structural rows preserve the same route for downstream consumers. Therefore a covering-dimension read that bypasses the metric, compact, dyadic, gauge, cover, refinement, overlap, and weight rows is not reading the accepted $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ consumer that reaches $\mathsf{CoveringDimension}^{\uparrow}$ without first exposing the $\mathsf{HausdorffDimension}^{\uparrow}$ gauge row, $\mathsf{Met}^{\uparrow}$ observation row, $\mathsf{CompactMetric}^{\uparrow}$ source row, $\mathsf{DyadicRatCore}^{\uparrow}$ scale row, finite cover row, refinement map, overlap row, gauge-weight row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet surface.

Independence witness: hausdorff-dimension, coveringdimension, metric, compactmetric, dyadicratcore: no listed sibling is bijective to $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ because this packet binds the gauge-cover, finite-refinement, compact-source, metric-observation, dyadic-scale, overlap-order, and gauge-weight rows as one finite handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}$ packet is generated from HausdorffDimensionUp gauge rows, CoveringDimensionUp finite-refinement rows, MetricUp observations, CompactMetricUp finite-net support, DyadicRatCoreUp scales, finite cover membership, overlap order, gauge weights, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7435.1, Definition 7435.2, and Definition 7435.3 seed the finite Hausdorff gauge-cover route into covering-dimension refinement consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffDimensionFiniteCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hausdorff measure existence, exact dimension values, countable cover choice, selected optimal covers, open-cover compactness, host logarithm analysis, ambient Euclidean embeddings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric and compact source exposure, dyadic scale readback, finite cover membership, refinement routing, overlap order, gauge-weight summation, transport, replay, provenance, and ledger nonescape for BEDC.Derived.HausdorffDimensionFiniteCoverUp.

Chapter 7436

A Concrete Naming Certificate for $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$

Bishop–Bridges constructive analysis treats regular Cauchy rational names through explicit tail estimates, and the $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ packet records the finite tail-replacement route used before a real-name seal is exposed. It sits after the finite-window discipline of chapter 126, the tolerance ledger of chapter 291, the regular rational readback of chapter 301, the threshold normalizer of chapter 1299, and the terminal seal of chapter 38. The packet names canonical tail replacement as displayed NameCert data; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7436.1 (RegSeqRat tail canonical carrier)**.** *A* $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (i, \theta, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *i is the finite tail index at which the replacement route begins.*
2. *θ is the cofinal threshold row showing that every later request is routed through the same displayed tail window.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule inspected at and beyond i.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the tail window and to the requested precision.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from W, D after the tail threshold is displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after i, θ, W, D, R have been read.*
7. *H records componentwise* hsame *transport for the tail index, threshold, window, tolerance, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real or Completion request through the canonical tail route.*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatTailCanonical}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $i, \theta, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7436.2 (RegSeqRat tail canonical NameCert obligations)**.** *For every accepted* $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ *carrier*

$$K = (i, \theta, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegSeqRatTailCanonical}^{\uparrow}}$ *surface consists exactly of carrier admission, tail cofinality, classifier stability, readback preservation, Real-seal nonescape, and local naming over the displayed finite rows.*

Proof. Carrier admission is projection from Definition 7436.1. The public coordinates are the finite tail index, cofinal threshold, finite-window schedule, dyadic tolerance ledger, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Tail cofinality is the role of θ. It ensures that later precision requests are read through the same tail window W rather than through a private side threshold.

Classifier stability and readback preservation are componentwise through H and C. The route transports i, θ, W, D, R together, so the $\mathsf{RegSeqRat}^{\uparrow}$ readback remains attached to the displayed tail threshold before E is exposed.

Finally P, N source and name this route. Because no carrier coordinate stores quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient completeness, those objects are outside the local NameCert obligations. □

Theorem 7436.3 (RegSeqRat tail canonical Real seal handoff)**.** *Every Real-facing read of an accepted* $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ *packet factors through the canonical tail route*

$$i, \theta, W, D, R, E, H, C, P, N.$$

The handoff exports no quotient stream equality, selected limit, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7436.2. They place the tail index, cofinal threshold, StreamName window, dyadic ledger, and RegSeqRat readback before the Real seal.

Use the sibling routes named in the chapter opening. The $\mathsf{StreamName}^{\uparrow}$ row supplies the finite inspection window, the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the tolerance ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the rational readback, and the $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ route records the shared threshold discipline.

The terminal $\mathsf{Real}^{\uparrow}$ seal is therefore downstream of i, θ, W, D, R. Transport, replay, provenance, and local naming preserve that same finite route, leaving no coordinate for the excluded quotient, choice, host-equality, trichotomy, or completeness principles. □

Falsifiable prediction: An accepted $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ consumer is refuted if it reaches the $\mathsf{Real}^{\uparrow}$ seal without first reading the finite tail index, cofinal threshold, $\mathsf{StreamName}^{\uparrow}$ window schedule, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row.

Independence witness: streamname, dyadicratcore, regseqrat, cauchy-tail-threshold-normalizer, real: none is bijective with $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ because this packet jointly binds one finite tail index, one cofinal threshold, one finite-window schedule, one tolerance ledger, one regular readback, one Real seal, transport, replay, provenance, and local naming as a canonical tail route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegSeqRatTailCanonical}^{\uparrow}}$.

Constructive story: A $\mathsf{RegSeqRatTailCanonical}^{\uparrow}$ packet is generated from a finite tail index, a cofinal threshold row, StreamName finite-window schedules, DyadicRatCore tolerance ledgers, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegSeqRatTailCanonical}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7436.1, Definition 7436.2, and Definition 7436.3 seed the canonical tail-replacement surface over StreamNameUp, DyadicRatCoreUp, RegSeqRatUp, CauchyTailThresholdNormalizerUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegSeqRatTailCanonical}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove tail cofinality, classifier stability, readback preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegSeqRatTailCanonicalUp.

Chapter 7437

A Concrete Naming Certificate for $\mathsf{RaabeTest}^{\uparrow}$

Following Raabe and Duhamel on the ratio refinement for positive-term series, the $\mathsf{RaabeTest}^{\uparrow}$ packet records the finite ratio-window evidence by which a displayed first-order quotient defect is routed into constructive real-series Cauchy data. It sits beside the ratio corridor of chapter 2244, the dyadic-block comparison of chapter 1478, the Abel boundary of chapter 1496, and the root-test majorant of chapter 6709. The packet is a finite NameCert surface for Real and Completion consumers; it is not a selected sum, a countable-choice schedule, quotient stream equality, trichotomy, host summability, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7437.1 (Raabe test carrier)**.** *A* $\mathsf{RaabeTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, Q, J, M, D, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the positive real-series source row, exposing only the inspected term windows and partial-sum windows used by the current tail request.*
2. *Q is the adjacent positive ratio-window row, recording the finite quotient cells a_{n+1}/a_n on the inspected tail.*
3. *J is the unary index-threshold row, displaying the natural cutoff after which the Raabe defect is read.*
4. *M is the first-order defect-margin row, displaying the rational margin by which $n(1 - a_{n+1}/a_n)$ stays beyond the unit boundary on the opened window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that turns the finite defect row and threshold row into a tail-comparison budget.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the source terms, quotient cells, partial sums, and comparison majorants.*
7. *T is the ratio-window route row, binding Q, J, M, D, W to the existing real-series ratio-test and adjacent comparison surfaces before endpoint data may be read.*
8. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row, exposed only after the ratio-window route row has been displayed.*

9. *H records componentwise* hsame *transport for the source, quotient, threshold, defect, dyadic, stream, route, endpoint, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from each tail request through Q, J, M, D, W, T, E.*
11. *P is the* Pkg *provenance over* $\mathsf{RaabeTest}^{\uparrow}$, $\mathsf{RealSeriesRatioTest}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{WeierstrassRootTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RaabeTest}^{\uparrow}}$ *row naming exactly this finite ratio-refinement packet.*

The classifier compares accepted packets only through $A, Q, J, M, D, W, T, E, H, C, P, N$. It has no coordinate for selected sums, countable choice, quotient stream equality, trichotomy, host summability, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean theorem checking, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RaabeTestUp.RaabeTestTasteGate single carrier alignment`

Theorem 7437.2 (Raabe test NameCert obligations)**.** *For every accepted* $\mathsf{RaabeTest}^{\uparrow}$ *carrier*

$$R = (A, Q, J, M, D, W, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RaabeTest}^{\uparrow}}$ *surface consists exactly of carrier admission for the positive source row, adjacent ratio windows, unary index threshold, first-order defect margin, dyadic tolerance ledger, finite stream windows, ratio-window route, regular rational and Real handoff, componentwise transport, displayed replay, package provenance, and local naming. Every obligation-facing read must pass through these rows and may not replace them by selected sums, countable choice, quotient stream equality, trichotomy, host summability, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7437.1. The displayed rows are exactly $A, Q, J, M, D, W, T, E, H, C, P, N$, so carrier admission and local naming have no hidden analytic coordinate.

Read the finite ratio evidence first. The source row A supplies only the visible positive-term and partial-sum windows, the quotient row Q supplies adjacent positive ratio cells, and the threshold row J records the unary cutoff at which the defect row is allowed to be inspected.

The defect and comparison route is then forced through M, D, W, T. The row M records the first-order Raabe margin, D translates that margin into dyadic tolerance cells, W fixes the stream windows, and T binds the route to the surrounding ratio-test, condensation, Abel, and root-test surfaces.

Finally, E supplies the endpoint handoff through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. The structural rows H, C, P, N transport, replay, source, and name the same finite packet, so none of them can introduce selected sums, countable choice, quotient stream equality, trichotomy, host summability, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge data. □

Theorem 7437.3 (Raabe test ratio-window route)**.** *Every accepted* $\mathsf{RaabeTest}^{\uparrow}$ *read reaching a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer factors through the finite route*

$$A, Q, J \longmapsto M \longmapsto D, W \longmapsto T \longmapsto E \longmapsto (H, C, P, N).$$

Thus a constructive real-series Cauchy consumer receives ratio-refinement data only after the positive source windows, adjacent quotient windows, unary threshold, first-order defect margin, dyadic tolerance ledger, finite stream windows, ratio-window route, endpoint handoff, transport, replay, provenance, and local NameCert *row have all been displayed.*

Proof. Begin with an endpoint-facing read of an accepted carrier. The rows A, Q, J are the only data available before the defect margin is read, so the consumer first sees the positive source windows, adjacent quotient windows, and the displayed tail threshold.

The margin row M then records the Raabe first-order defect on the opened tail. It is a finite row tied to the current request, not a global choice of a sum or a detached convergence theorem.

Next inspect D, W, T. The dyadic ledger and stream window rows convert the displayed defect margin into the same finite-window discipline read by the ratio-test corridor and its condensation, Abel, and root-test sibling surfaces. The route row T is therefore the only bridge from quotient evidence to the endpoint handoff.

Only after T has been displayed may the packet expose E, the regular rational and Real-facing handoff. Transport, replay, provenance, and local naming preserve this order, so no endpoint consumer can bypass the route through selected sums, quotient stream equality, countable choice, trichotomy, host summability, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{RaabeTest}^{\uparrow}$ endpoint-facing read factors through positive source windows, adjacent quotient windows, a unary tail threshold, a first-order defect-margin row, DyadicRatCore tolerance cells, StreamName windows, a ratio-window route row, RegSeqRat and RealUp endpoint routing, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: real-series-ratio-test, cauchy-condensation-test, abel-test, weierstrass-root-test, streamname, regseqrat, real: no listed sibling supplies the whole packet $R = (A, Q, J, M, D, W, T, E, H, C,$ because each sibling contributes only a ratio corridor, dyadic block comparison, Abel boundary, root majorant, finite window surface, regular readback, or endpoint seal while this chapter binds the Raabe threshold, first-order defect margin, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RaabeTest}^{\uparrow}}$.

Constructive story: A $\mathsf{RaabeTest}^{\uparrow}$ packet is generated from positive source windows, adjacent quotient windows, a unary index threshold, a first-order defect margin, DyadicRatCore tolerance data, StreamName windows, a ratio-window route row, RegSeqRat and RealUp endpoint routing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RaabeTest}^{\uparrow}}$, seed)

Scope closed: Definition 7437.1, Definition 7437.2, and Definition 7437.3 seed the finite Raabe ratio-refinement route from displayed positive-series quotient windows through regular rational readback and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RaabeTest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected sums, countable choice, quotient stream equality, trichotomy, host summability, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, quotient-window exactness, unary threshold stability, defect-margin coverage, dyadic tolerance routing, StreamName and RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RaabeTestUp.

Chapter 7438

A Concrete Naming Certificate for $\mathsf{CauchyModulusFan}^{\uparrow}$

Following Bishop and Bridges on explicit Cauchy moduli, the $\mathsf{CauchyModulusFan}^{\uparrow}$ packet names a finite family of modulus schedules under one shared tolerance ledger. It sits after the single-schedule certificate of chapter 292, the finite meet discipline of chapter 462, the finite observation route of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. Its arithmetic consumers read the same packet through chapter 1485; the chapter records a finite fan of schedules, not a selected limit, a countable family, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7438.1 (CauchyModulusFan carrier)**.** *A* $\mathsf{CauchyModulusFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, M, D, W, Q, A, R, E, H, C, P, N)$$

with the following rows:

1. *I is the finite index ledger naming the source schedules in the fan.*
2. *M lists one accepted* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule for each index in I.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger against which all schedules are compared.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, equivalently a finite* ProbeBundle *of observed index-window requests.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached componentwise to the schedules named by M.*
6. *A is the componentwise arithmetic and meet surface read through* $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, *and* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$.
7. *R is the fan-coverage row, asserting that every displayed index in I has its schedule, tolerance, observation window, and readback row present in the same finite packet.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, M, D, W, Q, A, R have been displayed.*
9. *H records componentwise* hsame *transport for the index ledger, schedules, tolerance ledger, window rows, readback rows, arithmetic rows, fan coverage, Real seal, continuation rows, provenance, and local naming row.*
10. *C records displayed* Cont *replay for a request that changes precision or index window without leaving the same finite fan.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusFan}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusFan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, M, D, W, Q, A, R, E, H, C, P, N$. It has no coordinate for an infinite family, a selected common limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7438.2 (CauchyModulusFan NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusFan}^{\uparrow}$ *carrier $F = (I, M, D, W, Q, A, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusFan}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite index ledger I, component schedules M, shared tolerance ledger D, observation windows W, readback rows Q, arithmetic rows A, fan-coverage row R, Real seal E, and structural rows H, C, P, N;*

2. *fan coverage, requiring each index named by I to expose a* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule, a shared dyadic tolerance read, a finite* $\mathsf{StreamName}^{\uparrow}$ *or* ProbeBundle *window, and a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in the same packet;*

3. *shared-threshold stability, requiring tolerance refinements in D to replay componentwise through every schedule in M and through the meet and arithmetic rows in A;*

4. *RegSeqRat readback, requiring each component schedule to reach Q before a Real-facing consumer can inspect the fan;*

5. *Real-seal nonescape, requiring the terminal row E to be read only after the finite fan rows I, M, D, W, Q, A, R have been displayed.*

The obligation surface exports no selected common limit, no countable family of schedules, no quotient stream equality, no countable-choice selector, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 7438.1. The displayed rows already separate the finite index ledger, component schedules, shared tolerance ledger, observation windows, regular readbacks, arithmetic surface, coverage row, and Real seal.

For carrier admission and fan coverage, read I, M, D, W, Q, A, R in order. Each index in I is accepted only when its schedule, tolerance request, finite window, and readback are present in the same BHist packet.

For shared-threshold stability, replay a refinement of D through C and transport it through H. The meet and arithmetic rows in A keep the request componentwise, so no schedule can leave the finite fan.

For RegSeqRat readback and the Real seal, every component reaches Q before E is visible. Since E is terminal and the carrier has no row for a selected common limit, countable family, quotient stream equality, choice selector, or ambient completeness, the five obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusFan}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusFan}^{\uparrow}}$, seed)

Scope closed: Definition 7438.1 and Definition 7438.2 seed the finite fan surface over $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyModulusArithmetic}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusFan}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite schedule families, selected common limits, quotient stream equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan coverage, shared-threshold stability, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusFanUp.

Constructive story: A CauchyModulusFan$^{\uparrow}$ packet is generated from a finite index ledger, component CauchyModulus schedules, a shared DyadicRatCore tolerance ledger, StreamName or ProbeBundle windows, RegSeqRat readbacks, meet and arithmetic rows, fan coverage, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7439

A Concrete Naming Certificate for $\mathsf{QuasiBanach}^{\uparrow}$

Following Aoki–Rolewicz renorming and Kalton-style quasi-Banach analysis, the $\mathsf{QuasiBanach}^{\uparrow}$ packet records a finite quasi-normed completion surface rather than a Banach-space norm surface. It sits beside the normed-space carrier of chapter 1950, the metric-space carrier of chapter 57, the Cauchy-filter basis route of chapter 1501, the completion-embedding row of chapter 1512, and the constructive metric completion packet of chapter 1556. The carrier names a displayed quasi-triangle modulus and completion-facing Cauchy route; it does not assert local convexity, a norm equivalent to the quasi-norm, Hahn–Banach extension, quotient completion, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7439.1 (QuasiBanach carrier)**.** *A* $\mathsf{QuasiBanach}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, A, Z, M, T, F, E, C, H, R, P, N)$$

with the following visible rows:

1. *X is the underlying additive carrier row, listing the accepted point histories and finite classifier reads used by all algebraic consumers.*
2. *A is the addition and zero row, recording the displayed finite additive operations available to the packet.*
3. *Z is the scalar action row when scalar multiplication is part of the displayed quasi-normed structure.*
4. *M is the metric-facing row induced by the quasi-norm distance ledger.*
5. *T is the quasi-triangle row, storing a displayed constant K and the finite obligation that each inspected triple satisfies $\rho(x+z) \leq K(\rho(x+y) + \rho(y+z))$ through named rational bounds.*
6. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row generated from the quasi-norm metric ledger and the visible tolerance schedule.*
7. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row that embeds source observations into the completion-facing boundary without replacing the quasi-norm by a Banach norm.*
8. *C is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route through regular Cauchy names, dyadic tolerances, Cauchy-filter basis data, dense embedding, and separated comparison.*

9. *H records componentwise* hsame *transport for the carrier, algebraic rows, quasi-triangle row, Cauchy-filter basis, embedding, constructive completion route, replay, provenance, and local naming.*
10. *R records displayed* Cont *replay through the same rows.*
11. *P is the* Pkg *provenance over* $\mathsf{QuasiBanach}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiBanach}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a Banach norm, local convexity, Hahn–Banach separation, quotient completion, selected limits, or ambient real completeness.

Theorem 7439.2 (QuasiBanach NameCert obligations)**.** *For every accepted* $\mathsf{QuasiBanach}^{\uparrow}$ *carrier* $Q = (X, A, Z, M, T, F, E, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{QuasiBanach}^{\uparrow}}$ *surface consists exactly of carrier admission, additive and scalar-row admission, metric-facing quasi-norm readback, quasi-triangle budget exposure, Cauchy-filter basis generation, completion embedding, constructive metric completion routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7439.1. The rows $X, A, Z, M, T, F, E, C, H, R, P, N$ are the only available coordinates of the accepted packet.

The algebraic and metric rows are displayed before any completion-facing read. Addition, zero, and scalar action are read through A and Z, while the quasi-norm distance ledger is read through M.

The non-Banach obligation is concentrated in T. Each inspected triple carries the displayed quasi-triangle constant and rational bound rows, so a consumer may use quasi-triangle control but cannot replace it by a norm triangle inequality or local convexity theorem.

The completion-facing rows are downstream. The Cauchy-filter basis F, embedding row E, and constructive completion route C may be read only after the quasi-norm metric and quasi-triangle rows are visible.

Finally H, R, P, N transport, replay, source, and name the same finite packet. Since no row stores a Banach norm, Hahn–Banach separation, quotient completion, selected limit, or ambient real-completeness datum, the listed rows exhaust the NameCert surface. □

Theorem 7439.3 (QuasiBanach metric completion handoff)**.** *Every completion-facing read from an accepted* $\mathsf{QuasiBanach}^{\uparrow}$ *packet must expose the quasi-norm metric row M, the quasi-triangle budget row T, the Cauchy-filter basis row F, the completion embedding row E, and the constructive completion route C before any separated completion or uniformly continuous consumer can inspect the result. The handoff is a finite quasi-normed completion route through $Q = (X, A, Z, M, T, F, E, C, H, R, P, N)$, not a Banach-space completion, norm-equivalence theorem, quotient completion, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.QuasiBanachUp.QuasiBanachCarrier metric completion handoff`

Proof. Begin with the NameCert obligations of Definition 7439.2. They require every completion-facing consumer to read the accepted carrier rows and to keep the quasi-triangle budget visible.

The metric handoff starts at M and T. The row M supplies the quasi-norm distance ledger, while T records the displayed quasi-triangle constant and finite rational witnesses needed by the Cauchy route.

Next the consumer reads F, E, C in order. The Cauchy-filter basis is generated from the quasi-norm metric data, the embedding row places source observations into the completion boundary, and the constructive completion route records the finite regular-name handoff.

Transport and replay through H and R preserve this same route, and P, N only source and name it. Therefore no downstream consumer can read the handoff as Banach completion, norm equivalence, quotient completion, selected limit, or ambient real completeness. □

Falsifiable prediction: A completion-facing consumer that reads a $\mathsf{QuasiBanach}^{\uparrow}$ route without the quasi-norm metric row, quasi-triangle budget row, Cauchy-filter basis row, completion embedding row, constructive completion route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the carrier of Definition 7439.1.

Independence witness: normedspace, metricspace, cauchy-filter-basis, completionembedding, constructive-metric-completion: no listed sibling jointly carries the finite additive rows, scalar rows, quasi-norm metric ledger, non-Banach quasi-triangle budget, Cauchy-filter basis, completion embedding, constructive completion route, transport, replay, provenance, and local naming rows of $Q = (X, A, Z, M, T, F, E, C, H, R, P, N)$.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiBanach}^{\uparrow}}$**.**

Constructive story: A $\mathsf{QuasiBanach}^{\uparrow}$ packet is generated from additive carrier rows, scalar-action rows when present, a quasi-norm metric ledger, a displayed quasi-triangle budget, Cauchy-filter basis data, completion embedding rows, constructive metric completion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{QuasiBanach}^{\uparrow}}$, seed)

Scope closed: Definition 7439.1, Definition 7439.2, and Definition 7439.3 seed the finite quasi-normed completion-facing packet for functional-analysis consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{QuasiBanach}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach-space completion, norm equivalence, local convexity, Hahn–Banach separation, quotient completion, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, additive and scalar-row admission, quasi-norm metric readback, quasi-triangle budget exposure, Cauchy-filter generation, embedding, constructive completion routing, transport, replay, provenance, and local naming for BEDC.Derived.QuasiBanachUp.

Chapter 7440

A Concrete Naming Certificate for $\mathsf{CofinalityFilter}^{\uparrow}$

Following Kelley and Bourbaki on filters and Bishop–Bridges on constructive Cauchy tails, the $\mathsf{CofinalityFilter}^{\uparrow}$ packet records the finite tail-cobase interface by which a sequence-indexed completion route is read as a filter without importing quotient filters, selected limits, or countable choice. It sits after the directed-tail route of chapter 3898, the cofinal sequence interface of $\mathsf{CofinalSequence}^{\uparrow}$, the Cauchy-filter basis surface of $\mathsf{CauchyFilterBasis}^{\uparrow}$, the finite Cauchy-filter row of chapter 333, the stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite cobase corridor for Real and Completion consumers; it is not a quotient filter, a chosen convergent subsequence, a selected completed point, or an ambient completeness principle.

Definition 7440.1 (CofinalityFilter carrier)**.** *A* $\mathsf{CofinalityFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, B, F, U, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the unary tail-index row, recording finite natural-number tail requests for the sequence-indexed route.*
2. *L is the cofinal lower-bound ledger. For every displayed tail request in I, it stores a later index whose inspected window is still inside the same requested tail.*
3. *B is the cobase row, listing the finite family of tail neighborhoods generated from I and refined by L.*
4. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *and* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row assembled only from the cobase row B.*
5. *U is the Completion corridor row, available only after the directed and filter-facing tail data have been replayed through I, L, B, F.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached through* $\mathsf{StreamName}^{\uparrow}$ *finite windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to the same cobase route.*
7. *H records componentwise* hsame *transport for the tail index, lower-bound ledger, cobase, filter-basis handoff, completion corridor, Real seal, replay, provenance, and local name rows.*

8. *C records displayed* Cont *replay of the finite route*

$$I, L \longmapsto B \longmapsto F \longmapsto U, E.$$

9. *P is the* Pkg *provenance over* $\mathsf{CofinalityFilter}^{\uparrow}$, $\mathsf{DirectedFilter}^{\uparrow}$, $\mathsf{CofinalSequence}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalityFilter}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $I, L, B, F, U, E, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable-choice schedules, host equality of filters, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7440.2 (CofinalityFilter NameCert obligations)**.** *For every accepted* $\mathsf{CofinalityFilter}^{\uparrow}$ *carrier $K = (I, L, B, F, U, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CofinalityFilter}^{\uparrow}}$ *surface consists exactly of the finite obligations for tail-index admission, cofinal lower-bound exactness, cobase generation, Cauchy-filter basis handoff, completion-corridor nonescape, Real-seal readback, componentwise transport, displayed replay, provenance, and local naming. Every obligation is read from $I, L, B, F, U, E, H, C, P, N$, and no obligation is stored in a quotient filter, selected limit, countable-choice schedule, host equality relation, quotient real equality row, or ambient completeness witness.*

Proof. Project the carrier of Definition 7440.1. The displayed analytic rows are I, L, B, F, U, E, and the structural rows are H, C, P, N.

Tail-index admission is supplied by I. The lower-bound ledger L is then read against the same finite tail requests, so a later window is displayed before any cobase or filter consumer inspects the packet.

The cobase and filter rows are downstream. The row B records exactly the tail neighborhoods generated from the displayed sequence indices, while F presents those neighborhoods through the $\mathsf{CauchyFilterBasis}^{\uparrow}$ and $\mathsf{CauchyFilter}^{\uparrow}$ handoff surface.

Finally U, E, H, C, P, N preserve the same route for Completion and Real-facing consumers. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7440.3 (CofinalityFilter tail cobase handoff)**.** *Every* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, *Completion, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CofinalityFilter}^{\uparrow}$ *carrier must read the unary tail-index row I, the cofinal lower-bound ledger L, and the cobase row B before the handoff row F is available. The handoff presents finite tail neighborhoods, cofinal lower-bound witnesses, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row; it does not present a quotient filter, selected limit, countable-choice selector, host filter equality, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Lean4 ✓ `BEDC.Derived.CofinalityFilterUp.CofinalityFilterCarrier tail cobase handoff`

Proof. Begin with the NameCert obligations of Definition 7440.2. They place every filter-facing read after the displayed tail-index row I and cofinal lower-bound ledger L.

Read B next. Because B is assembled only from the finite tail neighborhoods witnessed by I and refined by L, the consumer receives a displayed cobase rather than an external filter object.

The row F hands that cobase to $\mathsf{CauchyFilterBasis}^{\uparrow}$ and $\mathsf{CauchyFilter}^{\uparrow}$, and the rows U, E keep Completion and Real-facing reads downstream of the same cobase. The structural rows H, C, P, N transport, replay, source, and name that route, so none of the excluded objects can be recovered from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalityFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalityFilter}^{\uparrow}$ packet is generated from a unary tail-index row, a cofinal lower-bound ledger, a finite cobase row, a CauchyFilterBasis and CauchyFilter handoff, a Completion corridor row, a RealUp seal through StreamName and RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalityFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7440.1, Definition 7440.2, and Definition 7440.3 seed the finite cofinality-filter cobase interface for sequence-indexed Completion and Real routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalityFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host filter equality, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal lower-bound exactness, cobase generation, Cauchy-filter basis handoff, completion-corridor nonescape, Real-seal readback, transport, replay, provenance, and local naming for BEDC.Derived.CofinalityFilterUp.

Chapter 7441

A Concrete Naming Certificate for $\mathsf{ExtendedMetricSpace}^{\uparrow}$

Following Lawvere and Kelley-style extended metrics, the $\mathsf{ExtendedMetricSpace}^{\uparrow}$ packet records a finite BEDC carrier for distances that may leave the finite-real window while still exposing every finite-radius read through the ordinary metric and real-number siblings. It sits beside $\mathsf{Met}^{\uparrow}$ and $\mathsf{LawvereMetric}^{\uparrow}$ as the distance-interface packet for radius-bounded arguments, and it reads finite radii through chapter 38, chapter 301, chapter 126, and chapter 291. The chapter supplies only the finite NameCert route for extended distances and truncations; it does not import quotient metrics, ambient infinity arithmetic, or a completeness theorem.

Definition 7441.1 (Extended metric space carrier)**.** *An* $\mathsf{ExtendedMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (P, D, F, T, M, L, H, C, G, N)$$

with the following displayed rows:

1. *P is the point-name row, naming the finite observation surface on which distance probes are evaluated.*
2. *D is the extended-distance row, recording a nonnegative distance comparison that may be finite or declared outside the finite-radius window.*
3. *F is the finite-radius window row, naming the radii for which D is read through* $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$.
4. *T is the finite truncation row, recording the bounded read $d_T(x, y) = \min(d(x, y), r)$ for a displayed finite radius r.*
5. *M is the ordinary metric handoff row, connecting every finite-radius truncation to the sibling* $\mathsf{Met}^{\uparrow}$ *packet.*
6. *L is the Lawvere metric sibling row, recording that the extended-distance orientation is a Lawvere-style distance surface, not a quotient metric.*
7. *H stores componentwise* hsame *transport for point names, extended-distance reads, finite windows, truncations, sibling handoffs, provenance, and local naming.*
8. *C stores displayed* Cont *replay for finite-radius reads and sibling handoffs.*
9. *G is the* Pkg *provenance over* $\mathsf{ExtendedMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LawvereMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{ExtendedMetricSpace}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient metric identification, host-level infinity arithmetic, hidden completeness, selected limit points, or an ambient real-number object outside the displayed finite-radius route.

Theorem 7441.2 (Extended metric space NameCert obligations)**.** *For the carrier of Definition 7441.1, the local* $\mathsf{NameCert}_{\mathsf{ExtendedMetricSpace}^{\uparrow}}$ *surface consists exactly of point-name admission through P, extended-distance admission through D, finite-radius admission through F, truncation admission through T, ordinary metric handoff through M, Lawvere sibling orientation through L, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N.*

Lean4 ✓ `BEDC.Derived.ExtendedMetricSpaceUp.ExtendedMetricSpaceCarrier namecert obligations`

Proof. Project the accepted carrier $X = (P, D, F, T, M, L, H, C, G, N)$. Each listed obligation is one displayed coordinate of the carrier, and the carrier definition assigns no additional row to quotient metrics, completeness, host infinity arithmetic, selected limits, or ambient real equality.

The finite-radius obligations are the only rows that read numerical distance data as finite. Row F routes those reads through $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$, while T records the radius-bounded truncation attached to the same finite window.

The sibling rows preserve the intended interface. Row M hands finite-radius truncations to $\mathsf{Met}^{\uparrow}$, and row L records the Lawvere-style extended-distance orientation. Transport, replay, provenance, and local naming then preserve the same displayed packet, so the listed rows exhaust the NameCert surface. □

Theorem 7441.3 (Extended metric space finite-radius truncation)**.** *Every accepted finite-radius read of an* $\mathsf{ExtendedMetricSpace}^{\uparrow}$ *carrier factors through*

$$F, T, M, \mathsf{Real}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}.$$

The truncation may expose a bounded ordinary metric read, but it cannot use an unlisted infinity calculus, quotient completion witness, selected limit, or ambient completeness claim.

Proof. Start with the finite-radius row F. By definition it is the only row that certifies a distance read as finite, and it routes the displayed radius through $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$.

Next use the truncation row T. A bounded read is recorded as a finite-radius truncation of the extended-distance row D, so it remains tied to the same radius window rather than to host infinity arithmetic.

Finally apply the ordinary metric handoff row M. It sends the bounded truncation to the sibling $\mathsf{Met}^{\uparrow}$ surface. Since the carrier contains no coordinate for quotient completion, selected limits, or ambient completeness, the finite-radius truncation exports only the displayed route. □

Theorem 7441.4 (Extended metric space metric-space handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$ *consumer of an* $\mathsf{ExtendedMetricSpace}^{\uparrow}$ *packet must first restrict to a displayed finite-radius truncation. The consumer may read point names, the finite radius, the truncated distance, componentwise transport, replay, provenance, and local naming, but it may not read the raw extended-distance row as an ordinary metric without the F, T, M handoff.*

Proof. Read the carrier $X = (P, D, F, T, M, L, H, C, G, N)$. The raw extended-distance row D is allowed to sit outside the finite-radius window, so it is not by itself an ordinary metric-space distance.

Apply the finite-radius truncation theorem. It supplies the route through F, T, M and through the real, regular-rational, stream, and dyadic siblings before the bounded distance is exported.

The $\mathsf{Met}^{\uparrow}$ handoff is therefore exactly the row M applied after F and T. The structural rows H, C, G, N preserve that same bounded route, while the Lawvere row L records the sibling orientation. No consumer can bypass those rows and reread D as an ordinary metric. □

Falsifiable prediction: An ordinary metric consumer that reads an $\mathsf{ExtendedMetricSpace}^{\uparrow}$ distance without exposing F, T, M and the $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ route is not reading the local carrier.

Independence witness: metricspace, lawveremetric, real, regseqrat, streamname, dyadicratcore: no listed sibling jointly carries extended-distance admission, finite-radius truncation, ordinary metric handoff, Lawvere orientation, real and rational source rows, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ExtendedMetricSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ExtendedMetricSpace}^{\uparrow}$ packet is generated from point-name rows, extended-distance rows, finite-radius windows, truncation rows, MetricSpace and LawvereMetric sibling handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExtendedMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7441.1, Definition 7441.2, Definition 7441.3, and Definition 7441.4 seed the finite-radius certificate for extended distances and ordinary metric consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExtendedMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient metric identification, ambient infinity arithmetic, completeness, selected limits, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-radius truncation exactness, MetricSpace handoff exactness, Lawvere sibling separation, transport, replay, provenance, and local naming for BEDC.Derived.ExtendedMetricSpaceUp.

Chapter 7442

A Concrete Naming Certificate for $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$

Following Bishop and Bridges on constructive interval arguments, the $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$ packet records a located nested-interval route as finite BEDC data. It sits between the located interval carrier of chapter 394, the nested-chain surface of chapter 320, the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names the finite route by which a nested located interval argument can feed Real and Completion consumers; it does not assert open-cover compactness, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7442.1 (Bishop located interval nest carrier)**.** *A* $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, K, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite family of* $\mathsf{LocatedInterval}^{\uparrow}$ *rows inspected by the consumer.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-margin ledger recording positive dyadic margins for the displayed intervals.*
3. *K is the* $\mathsf{NestedInterval}^{\uparrow}$ *containment spine, stating which displayed interval row is retained at each inspected stage.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window surface used to read the retained endpoints and margin requests.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite endpoint windows selected by S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after I, D, K, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for located intervals, dyadic margins, containment-spine rows, stream windows, readbacks, seal rows, provenance, replay, and local naming.*
8. *C records displayed* Cont *replay from located-interval reads through endpoint margins, nested containment, stream windows, regular readbacks, and the terminal seal boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalNest}^{\uparrow}}$ *row naming exactly this finite located-nest packet.*

The local classifier compares accepted packets only through these rows. It has no coordinate for an infinite host intersection, a chosen real point, quotient equality of real names, open-cover compactness, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7442.2 (Bishop located interval nest NameCert obligations)**.** *For every accepted* BishopLocatedIntervalNe *carrier*

$$L = (I, D, K, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalNest}^{\uparrow}}$ *surface consists exactly of located-interval exposure through* I*, dyadic endpoint-margin accounting through* D*, nested-containment spine exposure through* K*, finite window selection through* S*, regular rational readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary through* E*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*. A consumer cannot read an interval-nest convergence route without first exposing those rows.*

Proof. Project the carrier of Definition 7442.1. The located intervals, dyadic endpoint margins, nested containment spine, stream windows, regular readbacks, Real seal boundary, and structural rows are the complete visible packet.

The analytic route is componentwise. The located interval rows in I provide endpoint and interval-cell data; the dyadic margin ledger D records positive endpoint margins; and the containment spine K states the finite nesting relations inspected by the consumer.

Next read S, Q, E. The stream row selects the finite endpoint windows, the regular rational row supplies their readback, and the Real seal row is exposed only after those windows and margins have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier lacks any coordinate for host interval compactness, quotient real equality, selected limits, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7442.3 (Bishop located interval nest regular Cauchy consumer)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$ *packet must factor through the displayed route*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the finite rows $I, D, K, S, Q, E, H, C, P, N$*. The route may be transported and replayed, but it cannot export a selected point of the infinite nest, quotient real equality, countable-choice data, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the located interval and nesting rows. A consumer first reads I and K, so the retained interval stages and their containment spine are visible before any regular Cauchy or Real-facing handoff is available.

Then read the dyadic margin and window rows. The ledger D supplies the positive endpoint-margin data, while S determines the finite windows on which those margins and endpoint reads are inspected.

Now pass to regular rational data and the Real seal. The row Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ readback for the same finite windows, and E is downstream of that readback. Transport, replay, provenance, and local naming through H, C, P, N preserve the same route.

No row remains for a host-selected nest point, quotient equality of real names, countable choice, open-cover compactness, or ambient completeness. The consumer therefore receives only the displayed regular Cauchy handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalNest}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedIntervalNest}^{\uparrow}$ packet is generated from displayed located interval rows, dyadic endpoint-margin rows, a nested containment spine, StreamName windows, RegSeqRat readback, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalNest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7442.1, Definition 7442.2, and Definition 7442.3 seed the finite located-interval-nest route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalNest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-interval exposure, dyadic endpoint-margin accounting, nested containment, StreamName window selection, RegSeqRat readback, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedIntervalNestUp.

Chapter 7443

A Concrete Naming Certificate for $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$

Following Bishop–Bridges style located compact interval enclosures, the $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$ packet records a finite boundary around one displayed located interval cell before any compactness or continuity consumer reads it. It sits after the endpoint-cell certificate of chapter 394, the finite-net route of chapter 1433, and the bisection handoff of chapter 1465. The packet is a local compact-enclosure boundary over finite observation rows; it is not open-cover compactness, a selected subcover, a host interval object, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7443.1 (Localized compact enclosure carrier)**.** *A* $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, K, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, carrying the located endpoint-cell boundary to be enclosed.*
2. *K is the* $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ *finite-net row for the displayed interval cell.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row through which downstream names request finite windows inside the enclosure.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used by Real and completion-facing consumers of the same enclosure.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite interval and readback rows have been displayed.*
6. *H records componentwise* hsame *transport for I, K, S, Q, E and the structural rows.*
7. *C records displayed* Cont *replay of the route from the located interval row through the finite-net row to stream, regular-rational, and real-seal consumers.*
8. *P is the* Pkg *provenance over* $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalizedCompactEnclosure}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, K, S, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers, host interval equality, quotient real equality, arbitrary choice of a mesh, or ambient completeness.

Theorem 7443.2 (Localized compact enclosure NameCert obligations)**.** *For every accepted* LocalizedCompactEnclo *carrier* $L = (I, K, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocalizedCompactEnclosure}^{\uparrow}}$ *surface consists exactly of carrier admission, located interval boundary exposure, finite-net admission, stream-window exposure, regular-rational readback, Real seal factorization, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the enclosure must read these rows before it can consume the terminal seal.*

Proof. Project the carrier of Definition 7443.1. The rows $I, K, S, Q, E, H, C, P, N$ expose the located interval source, finite-net enclosure, stream windows, regular readbacks, Real seal, transport, replay, provenance, and local name.

Use the sibling endpoint-cell route of chapter 394. It supplies the finite located interval boundary read through $\mathsf{LocatedInterval}^{\uparrow}$ rather than through a host interval or selected endpoint.

Apply the finite-net route of chapter 1433. The row K is the only compact-enclosure row, and it is displayed before any stream, regular-rational, or real-seal consumer can read the packet.

Finally replay the structural rows H, C, P, N. They transport, route, source, and name the same finite enclosure surface. Since the carrier contains no open-cover, selected-subcover, quotient-real, mesh-choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7443.3 (Localized compact enclosure finite-net handoff)**.** *Every accepted* $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$ *carrier* $L = (I, K, S, Q, E, H, C, P, N)$ *hands a downstream compactness or uniform-continuity consumer the same finite route*

$\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameC

The consumer receives the located interval row I *and the finite-net row* K *before it may read the stream windows* S*, regular readbacks* Q*, or seal row* E*. The handoff supplies a finite enclosure boundary only; it does not claim open-cover compactness, selected subcovers, host function equality, quotient real equality, or ambient completeness.*

Proof. Start with the located interval row I. It is the same endpoint-cell boundary governed by chapter 394, so the enclosure begins with displayed finite interval data.

Read the compact-net row K next. By chapter 1433, this row is an explicit finite-net handoff for the displayed interval cell, not a general open-cover compactness principle.

The stream and regular-rational rows S, Q then expose the finite observation windows consumed by downstream names. The seal row E is reachable only after those finite rows are displayed.

Transport and replay through H, C, then attach P, N. The resulting L10 dependency route is the same boundary used by interval bisection in chapter 1465, but the present packet exports only the localized enclosure surface and not a branch selector or selected subcover. □

Falsifiable prediction: Every accepted $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$ consumer displays a $\mathsf{LocatedInterval}^{\uparrow}$ source row, a $\mathsf{ClosedIntervalCompactNet}^{\uparrow}$ finite-net row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any terminal compactness or Real-facing read.

Independence witness: locatedinterval, closed-interval-compact-net, streamname, regseqrat, real: $\mathsf{LocalizedCompactEnclosure}^{\uparrow}$ is not bijective to any listed sibling because it packages one localized finite enclosure boundary between a displayed located interval cell and later compactness or uniform-continuity consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalizedCompactEnclosure}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\mathsf{LocalizedCompactEnclosure}^{\uparrow}}$, seed)

Scope closed: Definition 7443.1, Definition 7443.2, and Definition 7443.3 define the finite localized compact-enclosure boundary over located intervals and finite-net consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{LocalizedCompactEnclosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, host interval equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked carrier admission, finite-net handoff, consumer nonescape, transport replay, and local NameCert exactness for BEDC.Derived.LocalizedCompactEnclosureUp.

Constructive story: A LocalizedCompactEnclosure$^{\uparrow}$ packet is generated from a LocatedIntervalUp source row, a ClosedIntervalCompactNetUp finite-net row, StreamNameUp windows, RegSeqRatUp readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7444

A Concrete Naming Certificate for $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$

Following Bishop and Bridges constructive metric-space practice, the $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$ packet records a metric carrier whose distinct points are separated by a displayed positive rational floor. It refines the $\mathsf{Met}^{\uparrow}$ surface of chapter 57 and the $\mathsf{LocatedMetric}^{\uparrow}$ distance-comparison surface of chapter 1533, reads the dyadic lower-bound arithmetic through $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Rat}^{\uparrow}$, and exposes a $\mathsf{StreamName}^{\uparrow}$ scheduling row for later Cauchy-stabilization consumers. The packet is a finite separation ledger; it is not a decidable equality principle, an excluded-middle split on points, a host discrete topology, or an ambient completeness theorem.

Definition 7444.1 (Uniformly discrete metric carrier)**.** *A* $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, L, D, R, W, H, C, P, N)$$

with the following visible rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point histories, distance-witness histories, symmetry, and triangle ledgers consumed by metric users.*
2. *L is the* $\mathsf{LocatedMetric}^{\uparrow}$ *row exposing located distance comparisons for the same source metric.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive separation ledger. It stores a displayed dyadic rational $\eta > 0$ and the finite comparisons used by lower-bound reads.*
4. *R is the* $\mathsf{Rat}^{\uparrow}$ *positivity and order row associated to the same separation floor, so consumers can read the floor through rational order rather than through host arithmetic.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule for distance observations. It records which finite distance windows are inspected before a separation claim is consumed.*
6. *H stores componentwise* hsame *transport for the metric source, located-distance row, dyadic floor, rational positivity row, request schedule, provenance, and local name.*
7. *C stores the displayed* Cont *routes for reading a distance request, comparing it with the dyadic floor, transporting the lower-bound row, and exposing the consumer handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteMetric}^{\uparrow}}$ *row.*

The classifier on such packets is componentwise replay through H and C. A consumer may read the displayed positive separation floor and the scheduled metric-distance rows, but it receives no host-level point decision procedure and no completed-space datum.

Theorem 7444.2 (Uniformly discrete metric NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$ *carrier* $U = (X, L, D, R, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteMetric}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed metric source, located metric row, dyadic positive floor, rational order row, stream request schedule, transport rows, continuation routes, provenance, and local naming data;*
2. *separation readability, requiring every distinct-point lower-bound read to consume* X, L, D, R, W *before it exposes the positive floor;*
3. *classifier stability, requiring replacement by classified point histories to transport the metric, locatedness, dyadic floor, rational order, and stream schedule componentwise through* H *and* C*;*
4. *finite ledger exactness, requiring the separation floor to be exactly the dyadic-rational ledger* D *with its* $\mathsf{Rat}^{\uparrow}$ *positivity row* R*;*
5. *downstream handoff, requiring every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$*, or completion-facing consumer to read the finite separation ledger before using the metric as a stabilized discrete source.*

No obligation exports decidable equality, excluded middle, a host discrete topology, selected representatives, quotient equality, or ambient completeness.

Proof. Carrier admission is projection from Definition 7444.1. The packet lists the metric source, located comparison row, dyadic floor, rational positivity row, stream schedule, transport and continuation rows, provenance, and local name.

Separation readability is the route order. A consumer first reads the metric distance witness in X, then the located comparison in L, then the positive dyadic floor in D and its rational order row in R, with W recording the finite observation window used by that read.

Classifier stability is componentwise. The transport row H identifies the source, located-distance, dyadic, rational, and stream rows after classifier replacement, while C replays the same lower-bound comparison. The read therefore preserves the finite floor ledger rather than creating a point-decision principle.

The downstream handoff is just the exposed ledger $X, L, D, R, W, H, C, P, N$. Since no coordinate stores decidable equality, a selected representative, quotient equality, or a completion witness, no consumer can obtain such data from the local $\mathsf{NameCert}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteMetric}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyDiscreteMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7444.1 and Definition 7444.2 seed the finite positive-separation ledger for metric sources.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyDiscreteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim decidable equality, excluded middle, host discreteness, quotient equality, selected representatives, ambient completeness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, separation readability, classifier stability, floor exactness, and downstream handoff for the same packet.

Constructive story: A $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$ packet is generated from a MetricSpace source, a LocatedMetric comparison row, a DyadicRatCore positive floor, a RatUp positivity row, a StreamName observation schedule, componentwise transport, displayed continuation replay, provenance, and a local NameCert row.

Chapter 7445

A Concrete Naming Certificate for CompactUniformDyadicRadiusLadder$^{\uparrow}$

The CompactUniformDyadicRadiusLadder$^{\uparrow}$ packet realizes the compact-uniform-continuity route of chapter 9237 as finite NameCert data. The ladder consumes the compact source of chapter 129, the pointwise-radius interface of chapter 130, the finite lower-bound row of chapter 452, the dyadic comparison substrate of chapter 291, and the downstream handoff of chapter 369. It packages compact finite-net rows, continuous-map pointwise radii, finite Lebesgue-number lower-bound ledgers, dyadic radius comparisons, and the final UniformModulus$^{\uparrow}$ handoff. The carrier is a finite dyadic radius ladder for compact metric sources; it is not an external modulus selector, an open-cover compactness theorem, a sequential compactness argument, or a host minimum over a set of radii.

Definition 7445.1 (Compact uniform dyadic radius ladder)**.** *A* CompactUniformDyadicRadiusLadder$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, G, L, D, U, H, C, P, N)$$

with the following visible rows:

1. *X is the* CompactMetric$^{\uparrow}$ *source row, including the finite compact-net and located metric data consumed by the uniform-continuity route.*
2. *F is the compact finite-net ledger, with its* ProbeBundle *centers, membership constructors, coverage rows, and finite radius requests.*
3. *G is the* ContinuousMap$^{\uparrow}$ *pointwise-radius row for the map under consideration, including the local modulus witnesses attached to bundled centers.*
4. *L is the* FiniteLebesgueNumber$^{\uparrow}$ *lower-bound ledger obtained by folding the bundled pointwise radii into one positive cover radius.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *radius ladder. It records the dyadic refinements and comparisons used to pass from local radii to the global uniform precision.*
6. *U is the* UniformModulus$^{\uparrow}$ *handoff row whose tolerance-only precision is read from L and D.*
7. *H stores componentwise* hsame *transport for the compact source, finite net, continuous-map radii, Lebesgue-number ledger, dyadic ladder, uniform-modulus row, provenance, and local name.*
8. *C stores the displayed* Cont *routes for reading compact coverage, pointwise radii, finite lower-bound folds, dyadic refinements, and the final uniform-modulus handoff.*

9. *P is the* Pkg *provenance over* CompactUniformDyadicRadiusLadder$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CompactUniformDyadicRadiusLadder}^{\uparrow}}$ *row.*

The carrier exports exactly the finite ladder from compact finite nets and pointwise continuous radii to a tolerance-only uniform-modulus row. It stores no external minimum, no sequential compactness witness, and no selected modulus function.

Theorem 7445.2 (Compact uniform dyadic radius ladder NameCert obligations)**.** *For every accepted* CompactUniformDyadicRadiusLadder$^{\uparrow}$ *carrier $K = (X, F, G, L, D, U, H, C, P, N)$, the local* NameCert$_{\text{CompactUniformDyadicRadiusLadder}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the compact metric source, finite-net ledger, continuous-map pointwise-radius row, finite Lebesgue-number row, dyadic radius ladder, uniform-modulus handoff, transports, continuations, provenance, and local name;*
2. *finite-net coverage, requiring every uniform-modulus read to begin with the compact* ProbeBundle *centers and coverage witnesses in X and F;*
3. *pointwise-radius attachment, requiring each bundled center to carry its* ContinuousMap$^{\uparrow}$ *local radius row G before the lower-bound fold is consumed;*
4. *lower-bound exactness, requiring the folded positive radius to pass through the* FiniteLebesgueNumber$^{\uparrow}$ *row L and the dyadic comparison ladder D before U is exposed;*
5. *downstream handoff, requiring every* UniformModulus$^{\uparrow}$ *consumer to read $X, F, G, L, D, U, H, C, P, N$ and no external compactness, selected minimum, or host modulus function.*

Proof. Carrier admission is projection from Definition 7445.1. The packet displays the compact source, finite-net rows, continuous-map local radii, finite lower-bound row, dyadic ladder, uniform-modulus handoff, transport and continuation rows, provenance, and local name.

The finite-net coverage and pointwise-radius obligations follow the compact-uniform route in chapter 9237. Each uniform-modulus read first opens the compact finite net, then reads the local radius data for the bundled centers through the continuous-map row.

The lower-bound step is finite. The bundled radii are folded through the FiniteLebesgueNumber$^{\uparrow}$ ledger, and the resulting positive radius is refined through the dyadic ladder D before the UniformModulus$^{\uparrow}$ row can be exposed.

Transport and continuation replay preserve the same row order. Since the carrier contains no external minimum, sequential compactness witness, or selected modulus function, the downstream consumer receives only the finite NameCert ladder. □

Lean4 ✓ `BEDC.Derived.CompactUniformDyadicRadiusLadderUp.CompactUniformDyadicRadiusLadderNameCertObligat`

Closure status for NameCert$_{\text{CompactUniformDyadicRadiusLadder}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformDyadicRadiusLadder}^{\uparrow}}$, seed)

Scope closed: Definition 7445.1 and Definition 7445.2 seed the finite compact-net, pointwise-radius, lower-bound, dyadic-ladder, and uniform-modulus route.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformDyadicRadiusLadder}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim external modulus selection, sequential compactness, host minima over radius sets, open-cover compactness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage, pointwise-radius attachment, lower-bound exactness, and uniform-modulus handoff for the same packet.

Constructive story: A CompactUniformDyadicRadiusLadder$^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-radius rows, a FiniteLebesgueNumber lower-bound ledger, DyadicRatCore radius comparisons, a UniformModulus handoff, componentwise transport, continuation replay, provenance, and a local NameCert row.

Chapter 7446

A Concrete Naming Certificate for $\mathsf{CompactChoiceSequence}^{\uparrow}$

Following Brouwer's choice sequences, Troelstra–van Dalen's fan and bar practice, and Bishop–Bridges constructive analysis, the $\mathsf{CompactChoiceSequence}^{\uparrow}$ packet records the finite-prefix compactness surface used when a choice sequence is read through a fan bound and then handed to Real-facing consumers. It sits beside the located prefix route of chapter 2088, the finite bar packet of chapter 400, the schedule discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal seal of chapter 38. The chapter names only displayed prefixes, finite fan bounds, tolerance rows, readback rows, and local naming data; it does not select an infinite branch or import host compactness.

Definition 7446.1 (Compact choice-sequence carrier)**.** *A* $\mathsf{CompactChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, F, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefix row whose visible answers are available to this packet.*
2. *F is the fan and bar finite-bound row, read through* $\mathsf{FanTheorem}^{\uparrow}$*, naming the bounded prefix depth and the decidable bar data used by compact consumers.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule listing exactly the finite prefix positions inspected under the bound F.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the inspected prefixes and to the finite bar depth.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after Q, F, W, D have been displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular rational readback R.*
7. *H stores componentwise* hsame *transport for the prefix row, fan bound, schedule, tolerance row, readback, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a compactness request through the finite prefix bound, the scheduled windows, the dyadic tolerance row, the regular rational readback, and the real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactChoiceSequence}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{FanTheorem}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactChoiceSequence}^{\uparrow}}$ *row.*
The dependency route is the finite handoff

$$\begin{aligned} Q, F &\longmapsto W \\ &\longmapsto D \\ &\longmapsto R \\ &\longmapsto E. \end{aligned}$$

Thus a compact choice-sequence consumer receives a finite prefix and fan-bound interface before any regular rational or real-seal row can be read.

Theorem 7446.2 (Compact choice-sequence NameCert obligations)**.** *The packet of Definition 7446.1 satisfies the seed local* $\mathsf{NameCert}_{\mathsf{CompactChoiceSequence}^{\uparrow}}$ *obligation surface. Carrier admission is the displayed ten-row packet K; stability is componentwise* hsame *transport of $Q, F, W, D, R, E, H, C, P, N$; exactness says that every accepted read factors through the finite route from choice-sequence prefix and fan bound to stream schedule, dyadic tolerance, regular rational readback, real seal, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7446.1. The rows $Q, F, W, D, R, E, H, C, P, N$ are all displayed coordinates of one finite BHist packet.

For stability, transport each coordinate through H. The transported packet keeps the same order of dependence: the choice prefix and fan bound determine the scheduled prefix window, the scheduled window carries the dyadic tolerance row, and the readback and seal are reached only after those rows have been displayed.

For exactness, replay the consumer request through C and then repack the projected rows with P and N. Coordinate exhaustion gives the local naming surface and leaves no row for selected infinite branches, countable choice, quotient stream equality, open-cover compactness, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7446.3 (Compact choice-sequence fan-prefix handoff)**.** *Every compactness-facing read of an accepted* $\mathsf{CompactChoiceSequence}^{\uparrow}$ *packet must pass through the fan/bar row F and the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule W before it can inspect the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D or the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R. The handoff is a finite route from* $\mathsf{ChoiceSequence}^{\uparrow}$ *prefixes and* $\mathsf{FanTheorem}^{\uparrow}$ *bounds to scheduled regular rational data, not a selected branch, countable-choice functional, open-cover compactness theorem, quotient stream equality, or ambient real-completeness claim.*

Proof. Begin with a consumer read of K. The carrier exposes Q as the only choice-sequence source and F as the only fan/bar finite-bound row, so the request has no route to a tail value outside the displayed prefix surface.

Next read the schedule W. It names exactly the prefix positions inspected under F, and the dyadic row D is attached only to those scheduled positions.

Finally read R and then any real-facing seal E. Since both rows occur after Q, F, W, D in the carrier route, the handoff factors through finite prefix and fan data. None of the excluded branch-selection, choice, quotient, open-cover, or completeness principles is a coordinate of the packet. □

Theorem 7446.4 (Compact choice-sequence Real-seal nonescape)**.** *Any* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactChoiceSequence}^{\uparrow}$ *packet can read the seal row E only after the route*

$$Q, F, W, D, R$$

has been displayed. The seal exports the finite regular rational readback obtained from the compact prefix surface, but it cannot be used to recover selected infinite branches, countable choice, quotient stream equality, open-cover compactness, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the fan-prefix handoff of Definition 7446.3. It forces every compactness-facing read through the choice prefix, fan bound, schedule, dyadic tolerance row, and regular rational readback before any real-facing row is available.

Now project the seal coordinate E from Definition 7446.1. The seal is terminal in the displayed route and records only the real-facing presentation of the already exposed regular rational readback.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Because the carrier has no selected branch row, countable-choice row, quotient stream equality row, open-cover compactness row, trichotomy row, or ambient-completeness row, the $\mathsf{Real}^{\uparrow}$ seal cannot escape the finite compact choice-sequence packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactChoiceSequence}^{\uparrow}$ packet is generated from a displayed ChoiceSequence prefix row, a FanTheorem finite bar-bound row, a StreamName schedule, a DyadicRatCore tolerance row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactChoiceSequence}^{\uparrow}}$, seed)

Scope closed: Definition 7446.1, Definition 7446.2, Definition 7446.3, and Definition 7446.4 seed the finite compact choice-sequence route from displayed prefixes and fan bounds through regular rational readback to a Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactChoiceSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, countable choice, quotient stream equality, open-cover compactness, real trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fan-prefix handoff, Real-seal nonescape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 7447

A Concrete Naming Certificate for $\mathsf{HadamardBoundary}^{\uparrow}$

Following Bridson–Haefliger and Ballmann on CAT(0) and Hadamard boundaries, the $\mathsf{HadamardBoundary}^{\uparrow}$ packet records the finite readback by which geodesic-ray, Busemann, visual-boundary, metric, and Real-seal rows expose a boundary direction without selecting a point at infinity from a host completion. It sits beside the hyperbolic metric surface of chapter 3474, the Busemann boundary route of chapter 3732, the visual boundary route of chapter 4181, the geodesic-flow route of chapter 3856, and the terminal scalar seal of chapter 38. The packet names a traditional CAT(0)/Hadamard boundary read as displayed NameCert data; it does not import a quotient boundary, selected asymptotic ray, global compactification, countable choice, or ambient completeness.

Definition 7447.1 (Hadamard boundary carrier)**.** *A* $\mathsf{HadamardBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, M, R, G, U, V, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the CAT(0) or Hadamard source surface, read only as finite metric and convexity observations.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *comparison row used for distance and thinness-style readback when a hyperbolic model supplies the visible metric window.*
3. *R is the finite geodesic-ray window, recording initial segments and comparison requests without choosing a global representative ray.*
4. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *transport row attached to the displayed ray window.*
5. *U is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, recording Busemann-level boundary values over the same source window.*
6. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row, recording the visual boundary face exposed by the ray and Busemann rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for the scalar comparison values carried by M, U, V.*
8. *H records componentwise* hsame *transport for the source, metric, ray, flow, Busemann, visual-boundary, Real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$X, R \longmapsto M, G \longmapsto U, V \longmapsto E.$$

10. *P is the* Pkg *provenance over* HadamardBoundary$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{HadamardBoundary}^{\uparrow}}$ *row.*

The carrier stores no quotient ideal boundary, selected asymptotic ray, host CAT(0) compactification, countable-choice schedule, or ambient completeness coordinate.

Theorem 7447.2 (Hadamard boundary NameCert obligations)**.** *For every accepted* HadamardBoundary$^{\uparrow}$ *carrier $B = (X, M, R, G, U, V, E, H, C, P, N)$, the local* NameCert$_{\text{HadamardBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, finite ray-window visibility, metric readback, geodesic-flow transport, Busemann boundary exposure, visual-boundary exposure, Real-seal discipline, componentwise transport, displayed replay, provenance, and local naming. The certificate refuses quotient boundary equality, selected ray representatives, host compactification, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 7447.1. The displayed rows list the source surface, metric readback, finite geodesic-ray window, geodesic-flow transport, Busemann row, visual-boundary row, Real seal, transport, replay, provenance, and local name.

The obligations follow the carrier order. A boundary-facing request first exposes the finite ray window over the source surface, then reads metric and geodesic-flow rows, then reaches Busemann and visual-boundary rows, and only then consumes the Real-valued seal.

Transport and replay do not add a second boundary object. They preserve the same rows componentwise and repeat the same route for downstream consumers.

Since no quotient boundary, selected asymptotic ray, host compactification, countable-choice schedule, or ambient completeness witness is a coordinate of the packet, the listed obligations exhaust the local NameCert surface. □

Theorem 7447.3 (Hadamard boundary finite ray-window handoff)**.** *Every CAT(0)/Hadamard boundary read exported by an accepted* HadamardBoundary$^{\uparrow}$ *carrier must pass through the finite geodesic-ray row R, the* HyperbolicMetric$^{\uparrow}$ *metric comparison row M, the* HyperbolicGeodesicFlow$^{\uparrow}$ *transport row G, the* HyperbolicBusemannBoundary$^{\uparrow}$ *row U, the* HyperbolicVisualBoundary$^{\uparrow}$ *row V, and the* Real$^{\uparrow}$ *seal E before any boundary consumer may inspect it.*

Proof. Start with the accepted carrier $B = (X, M, R, G, U, V, E, H, C, P, N)$. The source boundary request is attached to X only through the finite ray-window row R.

Read the metric and flow rows next. The row M supplies the displayed metric comparison, while G records the geodesic-flow transport attached to the same ray window.

Then consume the boundary rows U and V. The Busemann row and visual-boundary row are the only boundary-facing coordinates of the packet, and their scalar comparisons are sealed by E.

The replay row C records the route order, and H, P, N transport, source, and name the same rows. Hence every boundary consumer sees a finite ray-window handoff rather than a selected ideal representative or host compactification. □

Theorem 7447.4 (Hadamard boundary sibling nonescape)**.** *The sibling routes to* HyperbolicMetric$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, *and* Real$^{\uparrow}$ *are*

consumed by HadamardBoundary$^{\uparrow}$ *only through the carrier rows* M, U, V, G, E *and the shared transport, replay, provenance, and local naming rows. Thus a Hadamard boundary read exports no global CAT(0) compactification, quotient ideal-boundary equality, selected geodesic ray, countable-choice selector, or ambient completeness theorem.*

Proof. Inspect the provenance row of Definition 7447.1. It names the sibling packets available to the boundary read, but each sibling appears as a displayed row in the same finite carrier.

Apply Definition 7447.3. It orders metric, flow, Busemann, visual-boundary, and Real-seal reads after the finite ray-window row and before any boundary consumer can inspect the packet.

The nonescape claim is then a carrier inventory. Since B contains no separate global compactification, quotient ideal-boundary equality, selected geodesic ray, choice selector, or completeness witness, none of those endpoints can be exported by a downstream consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardBoundary}^{\uparrow}}$.

Constructive story: A HadamardBoundary$^{\uparrow}$ packet is generated from a CAT(0)/Hadamard source surface, finite geodesic-ray windows, hyperbolic metric readback, geodesic-flow transport, Busemann boundary rows, visual-boundary rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HadamardBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 7447.1, Definition 7447.2, Definition 7447.3, and Definition 7447.4 seed the finite CAT(0)/Hadamard boundary route over geodesic-ray, Busemann, visual-boundary, metric, flow, Real, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HadamardBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient ideal-boundary equality, selected geodesic rays, global compactification, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite ray-window visibility, metric readback, geodesic-flow transport, Busemann and visual-boundary exposure, Real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.HadamardBoundaryUp.

Chapter 7448

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ packet records the finite route by which a displayed Cauchy modulus, a finite stream schedule, dyadic tolerances, and a regular rational readback are sealed as a $\mathsf{Real}^{\uparrow}$ name. It sits beside the finite stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the located modulus route of chapter 1035. The packet names a constructive limit certificate for the Real and Completion corridor without quotient streams, selected host limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7448.1 (Bishop Cauchy modulus limit carrier)**.** *A* $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, D, R, M, E, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row, listing the stream windows inspected by the modulus-guided read.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, slack comparisons, and precision budgets used by the read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in S and the tolerances in D.*
4. *M is the displayed Cauchy-modulus row, naming the finite threshold assignments that make the regular readback stable at the requested precisions.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, visible only after S, D, R, M have been displayed.*
6. *H records componentwise* hsame *transport for the stream schedule, dyadic ledger, regular readback, modulus row, real seal, replay, provenance, and local name.*
7. *C records displayed* Cont *replay for precision refinements that remain inside the same finite packet.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, D, R, M, E, H, C, P, N$. It has no coordinate for quotient streams, selected limits, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7448.2 (Bishop Cauchy modulus limit NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ *carrier*

$$B = (S, D, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusLimit}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the finite stream schedule S, dyadic tolerance ledger D, regular rational readback R, displayed modulus row M, terminal real seal E, and structural rows H, C, P, N;*
2. *modulus coverage, requiring every precision request displayed in M to have a matching window in S, a matching dyadic tolerance in D, and a matching regular readback in R;*
3. *tolerance stability, requiring refinements in D to replay through C and transport through H without changing the displayed modulus row;*
4. *regular handoff, requiring R to be consumed before the terminal real seal E is read;*
5. *real-seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to export only the named seal and no host-level completion data.*

The obligation surface exports no quotient stream, selected limit, host real equality, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 7448.1. Rows S, D, R, M, E are the analytic route, and rows H, C, P, N provide transport, replay, source, and local naming.

For carrier admission and modulus coverage, read M against the finite stream schedule S, the dyadic ledger D, and the regular readback R. A precision request is accepted only when all three finite witnesses are present in the same BHist packet.

For tolerance stability, replay a refinement through C and transport the same refinement through H. The modulus row remains displayed, so the accepted packet does not switch to an external selector or a hidden completion principle.

For the regular handoff and the real seal, R must be consumed before E becomes visible. Since the carrier has no row for quotient streams, selected limits, host equality, trichotomy, choice, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7448.3 (Bishop Cauchy modulus regular handoff)**.** *Every regular rational read of an accepted* $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ *packet factors through the finite schedule, dyadic tolerance, and displayed modulus rows:*

$$S,\ D,\ M,\ R.$$

Consequently a $\mathsf{RegSeqRat}^{\uparrow}$ *consumer receives only the displayed readback certified by the finite packet and cannot infer a quotient stream, selected limit, countable-choice selector, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the handoff.*

Proof. Use the obligation surface of Definition 7448.2. Modulus coverage places every accepted precision request in M beside a stream window in S and a dyadic tolerance entry in D.

The regular handoff obligation then forces the $\mathsf{RegSeqRat}^{\uparrow}$ row R to be read after those finite witnesses. Transport and replay through H and C preserve the same rows, so the handoff cannot introduce an unlisted stream quotient or selector.

The excluded principles are absent from the carrier of Definition 7448.1. They therefore cannot be exported by a consumer whose only access is the displayed route S, D, M, R. □

Theorem 7448.4 (Bishop Cauchy modulus real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ *packet factors through*

$$S,\ D,\ R,\ M,\ E,\ H,\ C,\ P,\ N$$

before the terminal seal is consumed. The read exports the local $\mathsf{Real}^{\uparrow}$ *seal and no quotient-stream representative, selected host limit, host real equality, countable-choice schedule, trichotomy witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the NameCert obligations of Definition 7448.2. They place the terminal row E downstream of the finite stream schedule, dyadic tolerance ledger, regular rational readback, and displayed modulus row.

The surrounding anchors provide the route: chapter 126 supplies the finite schedule surface, chapter 291 supplies the tolerance ledger, chapter 301 supplies the regular readback, and chapter 38 supplies the terminal seal.

Rows H, C, P, N preserve that route by transport, replay, provenance, and local naming. Because no excluded host-level datum is a row of the carrier, a real-facing consumer cannot escape the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusLimit}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7448.1, Definition 7448.2, Definition 7448.3, and Definition 7448.4 seed the constructive Cauchy-modulus limit route from finite stream schedules and dyadic tolerances to the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, host real equality, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus coverage, tolerance stability, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyModulusLimitUp.

Constructive story: A $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$ packet is generated from a StreamName finite schedule, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a displayed Cauchy-modulus row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7449

A Concrete Naming Certificate for $\mathsf{TaggedPartition}^{\uparrow}$

Following Riemann, Henstock, and Kurzweil, the $\mathsf{TaggedPartition}^{\uparrow}$ packet records a finite interval subdivision whose cells carry displayed tags before any finite sum, gauge integral, or completion-facing read is exported. It sits after the dyadic cell discipline of chapter 1863, the interval-subdivision carrier of chapter 7313, and the gauge-window route of chapter 4180. The packet gives constructive integration consumers a finite tagged-subinterval interface without importing host finite sets, quotient partition equality, selected mesh limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7449.1 (Tagged partition carrier)**.** *A* $\mathsf{TaggedPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, B, S, E, L, D, G, H, C, P, N)$$

with the following visible rows:

1. *I is the* $\mathsf{RiemannPartition}^{\uparrow}$ *interval-subdivision row. It displays the ordered subinterval spine, adjacency ledger, endpoint coverage, and mesh-refinement data that every tagged read must preserve.*
2. *B is the boundary row for the inspected interval, with left and right endpoint names read through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *witnesses.*
3. *S is the finite subinterval row. Each entry stores a left endpoint, a right endpoint, and the local inclusion route tying the cell back to I.*
4. *E is the endpoint exactness row. It records that consecutive subintervals meet at the displayed boundary and that the first and last endpoints match B.*
5. *L is the tag ledger. For each displayed subinterval it names one tag and the finite proof row that the tag lies in that same subinterval.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row used to read endpoint order, cell width, and mesh-window bounds through dyadic rational data.*
7. *G is the gauge-window row. It records the local radius request attached to each tag and the finite test that the tagged cell is contained in the displayed gauge window.*
8. *H records componentwise* hsame *transport for interval source, boundary, subintervals, endpoint exactness, tags, dyadic comparisons, gauge windows, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a tagged-partition request through $I, B, S, E, L, D, G, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{TaggedPartition}^{\uparrow}$, $\mathsf{RiemannPartition}^{\uparrow}$, $\mathsf{HenstockKurzweil}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TaggedPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, S, E, L, D, G, H, C, P, N$. There is no coordinate for host finite-set membership, quotient partition equality, an untagged mesh limit, countable choice, a selected refinement family, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7449.2 (Tagged partition NameCert obligations)**.** *For every accepted* $\mathsf{TaggedPartition}^{\uparrow}$ *carrier $T = (I, B, S, E, L, D, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TaggedPartition}^{\uparrow}}$ *surface consists exactly of carrier admission, interval-subdivision exposure through I, boundary exposure through B, finite subinterval exposure through S, endpoint exactness through E, tag-in-cell exactness through L, dyadic endpoint and mesh comparison through D, gauge-window compatibility through G, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No obligation may be discharged by a host finite set of cells, quotient equality of partitions, selected mesh limits, countable choice, a detached gauge refinement theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7449.1. The displayed rows are exactly $I, B, S, E, L, D, G, H, C, P, N$, so a local certificate can read only the interval subdivision, boundary, subinterval, endpoint, tag, dyadic, gauge-window, transport, replay, provenance, and naming data.

The subdivision side starts with I, B, S, E. The Riemann partition row supplies the ordered cell spine, while the boundary and endpoint rows force the displayed subintervals to remain attached to the same interval.

Next read L, D, G. The tag ledger attaches one visible tag to each displayed cell, the dyadic comparison row provides the endpoint and mesh comparisons, and the gauge-window row tests the same tagged cell against its local radius request.

Finally replay H, C, P, N. These structural rows preserve the same finite packet, and the carrier has no coordinate for the excluded host set, quotient, selected-limit, choice, detached-refinement, or ambient-completeness data. The listed rows therefore exhaust the local NameCert surface. □

Theorem 7449.3 (Tagged partition gauge-window handoff)**.** *Every* $\mathsf{HenstockKurzweil}^{\uparrow}$, *Riemann-sum, or completion-facing consumer of an accepted* $\mathsf{TaggedPartition}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{RiemannPartition}^{\uparrow} \longmapsto \mathsf{TaggedPartition}^{\uparrow} \longmapsto \mathsf{HenstockKurzweil}^{\uparrow}$$

only after reading the interval source I, boundary row B, subinterval row S, endpoint exactness row E, tag ledger L, dyadic comparison row D, gauge-window row G, transports H, replay C, provenance P, and local name N. The handoff exports a tagged gauge window for the displayed partition, not integrability, Darboux equality, selected refinements, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted tagged-partition read. By Definition 7449.2, the consumer first receives the interval-subdivision rows I, B, S, E and cannot replace them by a host list or quotient partition.

Read the tag and gauge side through L, D, G. The tag ledger binds each tag to the same displayed subinterval, the dyadic row supplies the endpoint and mesh comparisons, and the gauge-window row records the local radius containment test before the handoff is public.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. Since the carrier has no integrability, Darboux-equality, selected-refinement, or ambient-completeness coordinate, the exported route is exactly a local tagged gauge-window handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{TaggedPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{TaggedPartition}^{\uparrow}$ packet is generated from a RiemannPartition row, interval boundary rows, finite subinterval rows, endpoint exactness, tag-in-cell ledgers, DyadicRatCore comparisons, gauge-window rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TaggedPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7449.1, Definition 7449.2, and Definition 7449.3 seed the finite tagged-subinterval interface from RiemannPartitionUp through TaggedPartitionUp to HenstockKurzweilUp gauge-window consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TaggedPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim integrability, Darboux equality, host finite-set presentation, quotient partition equality, selected mesh limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, tag-in-cell exactness, dyadic comparison, gauge-window compatibility, consumer handoff, transport, replay, provenance, and local naming for BEDC.Derived.TaggedPartitionUp.

Chapter 7450

A Concrete Naming Certificate for $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$

Following Bishop and Bridges on constructive uniform convergence and regular real completions, the $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$ packet records the finite located-modulus route by which a uniformly Cauchy family yields a Real-facing limit certificate. It sits after the stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the uniform Cauchy limit packet of chapter 3980, and the completion-modulus handoff of chapter 7448. The packet names a located limit route with an explicit common modulus; it does not assert quotient equality of limits, select a host real, use countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7450.1 (Located uniform Cauchy limit carrier)**.** *A* $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (U, M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformCauchyLimit}^{\uparrow}$ *source row, including the inspected function-window family and the uniform Cauchy comparison ledger.*
2. *M is the located common modulus row, read through the completion-modulus surface and binding each tolerance request to a finite tail threshold before any limit seal is exposed.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row selected by the same tolerance and modulus request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed windows and tail threshold.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that compares the requested radius, the selected threshold, and the displayed readback.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the located limit row, available only after U, M, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the uniform Cauchy source, located modulus, windows, readback, dyadic ledger, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located tolerance request through U, M, S, R, D and then to E.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$, $\mathsf{UniformCauchyLimit}^{\uparrow}$, $\mathsf{BishopCauchyModulusLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host limit selection, quotient equality of functions or reals, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedUniformCauchyLimitUp.LocatedUniformCauchyLimitTasteGate single carrier alignment`

Theorem 7450.2 (Located uniform Cauchy limit NameCert obligations)**.** *For every accepted* $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$ *carrier* $L = (U, M, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyLimit}^{\uparrow}}$ *surface consists exactly of carrier admission, located-modulus exposure, finite-window readback, dyadic tolerance accounting, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming for the rows of Definition 7450.1. Every completion-facing consumer must read* U *and* M *before* S, R, D, E *are available, and no obligation exports quotient limits, selected host reals, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 7450.1. The accepted packet displays the uniform Cauchy source row, located common modulus, finite windows, regular readback, dyadic tolerance ledger, Real seal, and structural rows.

The located-modulus obligation is the first analytic route. A tolerance request reads the uniform Cauchy source U and then the common modulus row M, so the later window and readback rows are tied to a displayed threshold rather than to a host-selected limit.

Finite-window readback and dyadic accounting then proceed through S, R, D. The stream window is opened at the selected threshold, the regular rational readback is extracted from that window, and the dyadic ledger records the tolerance comparison before the terminal Real seal can be consumed.

Finally, H, C, P, N transport, replay, source, and name only the displayed packet. Since quotient limits, selected host reals, countable choice, open-cover compactness, and ambient completeness are absent from the carrier, no local obligation can export them. □

Theorem 7450.3 (Located uniform Cauchy limit completion handoff)**.** *Every completion-facing read of an accepted* $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{UniformCauchyLimit}^{\uparrow} \longmapsto \mathsf{BishopCauchyModulusLimit}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto$$

The handoff supplies a located modulus, finite windows, regular rational readback, dyadic tolerance evidence, terminal Real sealing, componentwise transport, replay, provenance, and local naming; it supplies no quotient completion, selected representative, host equality of limits, countable-choice schedule, or ambient completeness theorem.

Proof. Open the carrier of Definition 7450.1. Its analytic rows are U, M, S, R, D, E, and the structural rows H, C, P, N preserve only that displayed order.

Apply the NameCert obligations above. They force the uniform Cauchy source and located modulus to be read before the finite window, regular readback, dyadic tolerance, and Real-seal rows are available.

The stated route is exactly the row order of the packet. Because the refused objects have no carrier coordinate and no provenance row, every completion-facing read remains a finite located-modulus handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedUniformCauchyLimit}^{\uparrow}$ packet is generated from a UniformCauchyLimit row, a BishopCauchyModulusLimit row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7450.1, Definition 7450.2, and Definition 7450.3 seed the located uniform Cauchy limit route over common moduli, finite windows, regular readback, dyadic tolerance accounting, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedUniformCauchyLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of limits, selected host reals, countable choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-modulus exposure, finite-window readback, dyadic accounting, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.LocatedUniformCauchyLimitUp.

Chapter 7451

A Concrete Naming Certificate for $\mathsf{RealLocatedInfimum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealLocatedInfimum}^{\uparrow}$ packet names the lower-bound dual of a located real-order construction as finite BEDC data. It sits after the terminal real-name seal of chapter 38, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the modulus neighbor of chapter 6478. The packet gives Real and Completion consumers a displayed lower-bound infimum route without claiming Dedekind cuts, trichotomy, quotient equality, selected infima, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7451.1 (Real located infimum carrier)**.** *A* $\mathsf{RealLocatedInfimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, D, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite* $\mathsf{Real}^{\uparrow}$ *lower-bound-candidate row, listing the inspected real-name lower surfaces and the comparison observations that certify them as lower-bound candidates in the current window.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation-window row, recording dyadic precisions, lower-window widths, and the finite tolerance comparisons used to read the candidates.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the dyadic windows and candidate comparisons as regular rational observations before the terminal real seal is consumed.*
4. *M is the consumed* $\mathsf{LocatedInfimumModulus}^{\uparrow}$ *row, supplying the displayed modulus discipline that turns lower-window requests into finite dyadic approximation obligations.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the lower-bound candidates, dyadic windows, regular readback, and located-infimum modulus have all been displayed.*
6. *H records componentwise* hsame *transport for B, D, R, M, E, C, P, N.*
7. *C records displayed* Cont *replay for lower-bound-candidate reads, dyadic approximation reads, regular rational readback, modulus replay, real-seal access, and transported consumer return.*
8. *P is the* Pkg *provenance over* $\mathsf{RealLocatedInfimum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedInfimumModulus}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealLocatedInfimum}^{\uparrow}}$ *row.*

The carrier exposes only the finite route $B, D, R, M, E, H, C, P, N$. It has no coordinate for Dedekind cuts, trichotomy, quotient equality of real names, a host infimum operator, countable choice, selected witnesses from completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7451.2 (Real located infimum NameCert obligations)**.** *For every accepted* $\mathsf{RealLocatedInfimum}^{\uparrow}$ *carrier*

$$J = (B, D, R, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealLocatedInfimum}^{\uparrow}}$ *surface consists exactly of Real lower-bound candidate exposure through B, dyadic approximation-window exactness through D, regular rational readback through R, located-infimum modulus replay through M, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7451.1. The analytic rows are exactly the Real lower-bound-candidate row, dyadic approximation-window row, regular rational readback row, located-infimum modulus row, and terminal real seal row.

The lower-bound read is forced through B, D, R, M. Candidate observations begin as displayed $\mathsf{Real}^{\uparrow}$ lower surfaces, are inspected only at the dyadic windows stored in D, are repacked by R, and are governed by the modulus route M.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since no row stores Dedekind cuts, trichotomy, quotient equality, host infimum selection, countable choice, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7451.3 (Real located infimum L10 handoff)**.** *Every Real or Completion consumer read exported by an accepted* $\mathsf{RealLocatedInfimum}^{\uparrow}$ *packet factors through the displayed L10 route*

$$B, D \longmapsto R \longmapsto M \longmapsto E \longmapsto C, P, N.$$

Thus the packet hands off lower-bound infimum data only as regular rational readback plus a located-infimum modulus and a terminal $\mathsf{Real}^{\uparrow}$ *seal, not as Dedekind-cut data, trichotomy, quotient equality, selected infima, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real or Completion-facing request. The carrier contains one terminal real seal row E, and the definition makes it reachable only after the lower-bound candidates, dyadic windows, regular readback, and modulus row have been displayed.

The request first reads B through the dyadic approximation windows in D. The row R then turns those finite observations into regular rational readback, while M supplies the located-infimum modulus discipline that keeps the lower-window request finite.

Finally C, P, N replay, source, and name the same route before the consumer sees E. No step has a coordinate for Dedekind cuts, trichotomy, quotient equality, selected infima, or ambient completeness, so the L10 handoff remains inside the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealLocatedInfimum}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealLocatedInfimum}^{\uparrow}}$, seed)

Scope closed: Definition 7451.1, Definition 7451.2, and Definition 7451.3 seed the finite lower-bound located-infimum route over Real lower-bound candidates, dyadic approximation windows, RegSeqRat readback, LocatedInfimumModulus replay, and a terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealLocatedInfimum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind cuts, trichotomy, quotient real equality, selected infima, countable choice, host infimum operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Real lower-bound candidate exposure, dyadic approximation-window exactness, RegSeqRat readback, LocatedInfimumModulus replay, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealLocatedInfimumUp.

Constructive story: A RealLocatedInfimum$^{\uparrow}$ packet is generated from Real lower-bound candidates, dyadic approximation windows, RegSeqRat readback, LocatedInfimumModulus replay, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Chapter 7452

A Concrete Naming Certificate for $\mathsf{ProbeBundleCoverFold}^{\uparrow}$

The $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ packet realizes the finite cover-fold branch of chapter 9237. It records the displayed step that folds compact finite-cover probes, local pointwise-modulus rows, and rational lower-bound ledgers into a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff before any compact-uniform-continuity consumer reads the route. The packet sits beside the finite minimum fold of chapter 619, the compact-net selector of chapter 914, the compact uniform-continuity carrier of chapter 388, the compact source of chapter 60, the metric source of chapter 4230, the continuous-map source of chapter 130, and the uniform-modulus consumer of chapter 369. It is a finite $\mathsf{ProbeBundle}$ cover fold, not an open-cover compactness theorem, selected subcover, host modulus oracle, quotient point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7452.1 (ProbeBundle cover-fold carrier)**.** *A* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, G, B, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-cover or finite-net source row.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used to test membership in the displayed cover cells.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to each retained probe.*
4. *B is the finite* $\mathsf{ProbeBundle}$ *of centers, cover cells, local radii, and pointwise modulus witnesses.*
5. *R is the rational positive-radius ledger folded across the displayed bundle.*
6. *L is the lower-bound output row, compatible with* $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ *and the* $\mathsf{CompactRadiusChain}^{\uparrow}$ *cover-chain ledger.*
7. *U is the tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row read by compact-uniform-continuity consumers.*
8. *H records componentwise* hsame *transport for $K, M, G, B, R, L, U, C, P, N$.*
9. *C records displayed* Cont *replay from compact cover rows through metric tests, pointwise modulus rows, finite bundle folding, lower-bound output, and uniform-modulus handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteNetMinimumFold}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{CompactRadiusChain}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProbeBundleCoverFold}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, selected subcovers outside the displayed bundle, a host modulus function, quotient point equality, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Theorem 7452.2 (ProbeBundle cover-fold obligations)**.** *For every accepted* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ *carrier* $F = (K, M, G, B, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProbeBundleCoverFold}^{\uparrow}}$ *surface consists exactly of compact finite-cover exposure, metric membership exposure, continuous pointwise-modulus exposure, finite* $\mathsf{ProbeBundle}$ *exposure, rational radius-ledger exposure, lower-bound fold output, tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7452.1. The compact source row K, metric row M, pointwise-modulus row G, finite bundle row B, rational radius ledger R, lower-bound output L, and uniform-modulus row U are the whole mathematical surface.

The fold is finite because B is a displayed $\mathsf{ProbeBundle}$ and R is read only over the probes retained in that bundle. The lower-bound row L is therefore a fold output rather than an external minimum.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier has no open-cover theorem, selected subcover, host modulus, quotient equality, choice, completeness, Lean theorem, or bridge coordinate, the stated rows exhaust the local NameCert obligations. □

Theorem 7452.3 (ProbeBundle cover-fold uniform-modulus handoff)**.** *Every compact-uniform-continuity consumer that reads a* $\mathsf{UniformModulus}^{\uparrow}$ *row from an accepted* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ *packet must first read*

$$\mathsf{Compact}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{ProbeBundle} \longmapsto \mathsf{FiniteNetMinimumFold}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}$$

through $K, M, G, B, R, L, U, H, C, P, N$*. The handoff is a finite cover fold over displayed probes; it is not a selected global modulus, open-cover compactness theorem, quotient point equality, countable-choice selector, or ambient completeness principle.*

Proof. Start with Definition 7452.2. It forces compact-cover data, metric membership tests, pointwise modulus rows, the finite probe bundle, and the rational radius ledger to be displayed before the lower-bound row and the uniform-modulus handoff can be consumed.

The lower-bound step is the finite fold layer. It is compatible with the $\mathsf{FiniteNetMinimumFold}^{\uparrow}$ and $\mathsf{CompactNetModulusSelector}^{\uparrow}$ siblings because the consumer sees the same finite probe inventory and the same rational radius ledger before it sees U.

The rows H, C, P, N preserve the route as a displayed BEDC packet. No excluded host principle is stored in the carrier, so the consumer receives only the tolerance-only handoff generated by the finite cover fold. □

Theorem 7452.4 (ProbeBundle cover-fold compact-radius route)**.** *Every* $\mathsf{CompactRadiusChain}^{\uparrow}$ *or* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{ProbeBundleCoverFold}^{\uparrow}$ *carrier must read the same* K, M, G, B, R, L, U *route before the tolerance-only handoff is public. The compact radius chain is therefore a displayed ledger over the finite probe bundle, not an implicit compactness theorem or a selected cover refinement outside the packet.*

Proof. Project $F = (K, M, G, B, R, L, U, H, C, P, N)$. The compact source, metric tests, continuous-map local moduli, finite bundle, radius ledger, lower-bound output, and uniform-modulus row appear as separate coordinates.

Apply Definition 7452.3. It shows that the uniform-modulus read passes through the finite fold before any compact-uniform-continuity consumer can use it.

The compact radius chain can therefore be read only as provenance for the same finite route. Transport, replay, provenance, and local naming preserve the route but do not add a selected cover refinement or background compactness principle. □

Falsifiable prediction: If the finite ProbeBundle cover-fold row is removed, the displayed route cannot derive a tolerance-only UniformModulus$^{\uparrow}$ handoff from compact finite-cover rows, pointwise modulus rows, and rational lower-bound ledgers inside the same carrier.

Independence witness: finitenetminimumfold, compactnetmodulusselector, uniformmodulus, compactradiuschain: no listed sibling is bijective to ProbeBundleCoverFold$^{\uparrow}$ because this packet jointly carries compact cover rows, metric membership tests, pointwise modulus rows, the finite ProbeBundle inventory, rational radius ledgers, lower-bound fold output, tolerance-only UniformModulus handoff, transport, replay, provenance, and local naming.

The Lean TasteGate file for ProbeBundleCoverFold$^{\uparrow}$ must provide explicit Nontrivial and FieldFaithful instances before a checked paper marker can cite a carrier-level TasteGate target.

Closure status for NameCert$_{\text{ProbeBundleCoverFold}^{\uparrow}}$.

Constructive story: A ProbeBundleCoverFold$^{\uparrow}$ packet is generated from Compact finite-cover rows, MetricSpace membership rows, ContinuousMap pointwise-modulus rows, finite ProbeBundle rows, rational radius ledgers, lower-bound fold output, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ProbeBundleCoverFold}^{\uparrow}}$, seed)

Scope closed: Definition 7452.1, Definition 7452.2, Definition 7452.3, and Definition 7452.4 seed the finite cover-fold route from compact probes to tolerance-only uniform-modulus data.

Formal verification: FormalStatus(NameCert$_{\text{ProbeBundleCoverFold}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host modulus functions, quotient point equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite ProbeBundle exposure, rational fold exactness, compact-radius routing, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.ProbeBundleCoverF

Chapter 7453

A Concrete Naming Certificate for $\mathsf{RegularCauchyVariationBound}^{\uparrow}$

Following Jordan's finite variation ledgers and the Bishop–Bridges treatment of regular Cauchy real names, the $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ packet records a displayed variation budget for a regular rational Cauchy stream before the terminal real-name seal is consumed. It sits after the regular sequence surface of chapter 301, the dyadic tolerance arithmetic of chapter 291, the finite stream-window interface of chapter 126, the Cauchy modulus route of chapter 292, and the real-name boundary of chapter 38. The packet names only a finite variation-budget route; it does not import host sequence equality, a selected limit representative, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7453.1 (Regular Cauchy variation-bound carrier)**.** *A* $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S, Q, D, B, M, E, H, C, P, N)$$

with the following visible rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of finite windows inspected from the regular Cauchy name.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row reading the same windows as regular rational observations.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row of adjacent dyadic difference cells and finite partial variation sums.*
4. *B is the displayed dyadic variation-budget row bounding every inspected partial variation sum.*
5. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff row extracted from the displayed variation budget and regularity data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, Q, D, B, M have been displayed.*
7. *H records componentwise* hsame *transport for the window, readback, dyadic, budget, modulus, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from stream windows to regular rational readbacks, dyadic variation sums, the modulus handoff, and the terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyVariationBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyVariationBound}^{\uparrow}}$ *row.*

The classifier compares carriers only through $S, Q, D, B, M, E, H, C, P, N$. It has no coordinate for host sequence equality, quotient real equality, a chosen limit representative, unbounded variation search, countable choice, or ambient real completeness.

Theorem 7453.2 (Regular Cauchy variation-bound NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ *carrier* $V = (S, Q, D, B, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyVariationBoun}}$ *surface consists exactly of stream-window exposure, regular rational readback, dyadic adjacent-difference exposure, finite variation-budget exposure, Cauchy-modulus handoff, real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7453.1. The rows S, Q, D, B, M, E are the only mathematical rows visible before the structural transport, replay, provenance, and naming rows.

The stream and regular rational rows determine which finite observations are being compared. The dyadic row D records adjacent differences and finite partial variation sums, while B records the displayed budget bounding those sums.

The modulus row M is downstream of the same data, and the real seal E is downstream of M. The rows H, C, P, N preserve, replay, source, and name that finite route.

Since the carrier has no host equality, quotient equality, selected-limit, unbounded-search, choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7453.3 (Regular Cauchy variation-bound Cauchy handoff)**.** *Every* $\mathsf{CauchyModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ *packet must first read the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow}$$

through the same displayed rows $S, Q, D, B, M, H, C, P, N$. The handoff is a finite tail-control obligation extracted from the variation budget, not a selected limit, quotient equality of names, or ambient completeness principle.

Proof. Start with the obligation surface of Definition 7453.2. It places stream windows, regular rational readbacks, dyadic adjacent-difference rows, and the displayed variation budget before the modulus row.

The row M is therefore read only after S, Q, D, B have been displayed. The replay row C records the same order, and the transport row H keeps the handoff componentwise stable.

The rows P, N source and name the route. Because no carrier row stores a chosen limit, quotient equality, or ambient completeness claim, the consumer receives only the finite Cauchy-modulus handoff. □

Theorem 7453.4 (Regular Cauchy variation-bound Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ *packet must read the stream windows, regular rational readbacks, dyadic variation sums, displayed variation budget, and* $\mathsf{CauchyModulus}^{\uparrow}$ *handoff before the seal row E is available. Thus the real-facing boundary is the finite variation-budget packet, not host real equality, quotient real equality, selected representatives, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $V = (S, Q, D, B, M, E, H, C, P, N)$. The seal row E appears only after the stream, regular rational, dyadic, budget, and modulus rows in the displayed packet.

Apply Definition 7453.3. A completion-facing read of the modulus already factors through the finite variation-budget route before it can reach a real-name consumer.

Finally inspect H, C, P, N. They transport, replay, source, and name the same route without adding another real equality or completion coordinate. The stated exclusions are therefore unavailable inside the accepted packet. □

Falsifiable prediction: A $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ consumer is refuted if it reaches a $\mathsf{CauchyModulus}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without displaying the stream windows, regular rational readback, dyadic adjacent-difference ledger, finite variation budget, transport, replay, provenance, and local NameCert rows.

Independence witness: regseqrat, dyadicratcore, streamname, cauchymodulus, real: no listed sibling is bijective to $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ because this packet jointly binds finite windows, regular rational observations, dyadic variation sums, a displayed budget, Cauchy-modulus handoff, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyVariationBound}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyVariationBound}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular rational readbacks, DyadicRatCore adjacent-difference ledgers, a displayed dyadic variation budget, a CauchyModulus handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyVariationBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7453.1, Definition 7453.2, Definition 7453.3, and Definition 7453.4 seed the finite variation-budget route over RegSeqRat, DyadicRatCore, StreamName, CauchyModulus, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyVariationBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence equality, quotient real equality, selected limit representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, variation-budget exactness, Cauchy-modulus handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyVariationBoundUp.

Chapter 7454

A Concrete Naming Certificate for $\mathsf{DetachableSubset}^{\uparrow}$

Following Bishop and Bridges on constructive subsets with decidable membership, the $\mathsf{DetachableSubset}^{\uparrow}$ packet records the finite BEDC surface by which a displayed subset may be read through a Boolean membership classifier. It sits beside the Boolean carrier of chapter 32, the set-like naming surface of chapter 3668, the semidecidable-open classifier of chapter 6464, the finite stream-name route of chapter 126, and the terminal real-name seal of chapter 38. The packet supplies a reusable finite decidable-membership carrier for constructive subset reads without importing host powersets, excluded middle, quotient subset equality, selected witnesses, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7454.1 (DetachableSubset carrier)**.** *A* $\mathsf{DetachableSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, M, Q, B, S, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{SetLike}^{\uparrow}$ *ambient carrier row whose elements are allowed to be inspected;*
2. *M is the detachable membership row, returning a displayed* $\mathsf{Bool}^{\uparrow}$ *answer for each inspected element row;*
3. *Q is the complementary refusal row, recording the negative membership answer when M returns false;*
4. *B is the* $\mathsf{Bool}^{\uparrow}$ *decision boundary through which both positive and negative membership answers are read;*
5. *S is the* $\mathsf{SemidecidableOpen}^{\uparrow}$ *exposure row available to open-facing consumers after the Boolean decision has been displayed;*
6. *R is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which sequential or real-facing consumers request inspected elements;*
7. *H records componentwise* hsame *transport for the ambient, membership, refusal, Boolean, semidecidable-open, and stream rows;*
8. *C records displayed* Cont *replay of the same finite route;*
9. *P is the* Pkg *provenance over* $\mathsf{DetachableSubset}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{SemidecidableOpen}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{DetachableSubset}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for a host powerset, an external predicate with excluded middle, quotient subset equality, selected element witness, or ambient real-completion principle.

Lean4 (definition) `BEDC.Derived.DetachableSubsetUp`

Theorem 7454.2 (DetachableSubset NameCert obligations)**.** *For every accepted* $\mathsf{DetachableSubset}^{\uparrow}$ *carrier*

$$D = (A, M, Q, B, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DetachableSubset}^{\uparrow}}$ *surface consists exactly of carrier admission for those rows, ambient set-like exposure through A, detachable membership through M, negative-membership refusal through Q, Boolean readback through B, semidecidable-open exposure through S, finite StreamName scheduling through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7454.1. The projection lists exactly the ambient, membership, refusal, Boolean, semidecidable-open, stream-window, transport, replay, provenance, and naming rows.

The subset is detachable because each inspected element reaches the membership row M only through the displayed ambient row A and receives its answer through the Boolean boundary B. The refusal row Q is part of the same packet, so a negative answer is not supplied by an external excluded-middle principle.

The downstream handoff is finite. Open-facing consumers may read S only after the Boolean membership boundary has been displayed, and sequential or real-facing consumers may request inspected elements only through R, H, C, P, N. Thus the local NameCert surface is the displayed decidable-membership route itself. □

Theorem 7454.3 (DetachableSubset finite membership route)**.** *Every membership answer exported by an accepted* $\mathsf{DetachableSubset}^{\uparrow}$ *packet is attached to a displayed element row in A and a displayed Boolean row in B. If two accepted packets agree componentwise on A, M, Q, B, S, R under the displayed* hsame *transport, then every downstream consumer sees the same accepted-or-refused membership answer.*

Proof. Begin with the ambient carrier row A. It is the only source from which an inspected element may be named, so a consumer cannot ask the detachable subset about an element outside the displayed carrier route.

The membership and refusal rows M, Q are read through the Boolean boundary B. Componentwise hsame transport therefore identifies the visible element and its visible truth value together.

Replay through C and provenance through P, N preserve the same finite route. Hence transported packets expose the same membership answer to open-facing, stream-facing, and real-facing consumers. □

Theorem 7454.4 (DetachableSubset obligation package)**.** *The carrier, NameCert, and finite membership route clauses assemble the seed obligation package for* $\mathsf{DetachableSubset}^{\uparrow}$*. The package is exhausted by the rows*

$$A, M, Q, B, S, R, H, C, P, N$$

and by the sibling route through $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{SemidecidableOpen}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. The carrier definition supplies exactly the listed rows, and Definition 7454.2 makes them the local NameCert surface.

Definition 7454.3 binds each membership answer to a displayed ambient element and Boolean decision boundary. The semidecidable-open and StreamName rows can only consume that displayed boundary; they do not add a host powerset or a choice principle.

Thus the package names the finite decidable-membership surface needed by constructive subset consumers while refusing excluded middle, quotient subset equality, selected witnesses, host powersets, and ambient real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DetachableSubset}^{\uparrow}}$.

Constructive story: A $\mathsf{DetachableSubset}^{\uparrow}$ packet is generated from a SetLikeUp ambient row, detachable membership and refusal rows, a BoolUp decision boundary, a SemidecidableOpenUp exposure row, a StreamNameUp finite-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DetachableSubset}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7454.1, Definition 7454.2, Definition 7454.3, and Definition 7454.4 seed the finite decidable-membership route for constructive subset consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DetachableSubset}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.DetachableSubsetUp`

Bridge status: none

Not claimed: This chapter does not claim host powersets, excluded middle, quotient subset equality, selected element witnesses, ambient Real completeness, checked Lean obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier and NameCert obligations for BEDC.Derived.DetachableSubsetUp.

Chapter 7455

A Concrete Naming Certificate for $\mathsf{BishopModulusConvergence}^{\uparrow}$

Following Bishop and Bridges on convergence with displayed moduli, the $\mathsf{BishopModulusConvergence}^{\uparrow}$ packet records the finite route by which a stream of rational approximants is read with a Bishop modulus before any real-facing consumer sees a limit seal. It sits after the finite observation discipline of chapter 126, the dyadic tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the displayed limit handoff of chapter 7448. The packet names convergence through finite rows only; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7455.1 (Bishop modulus convergence carrier)**.** *A* $\mathsf{BishopModulusConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(S, D, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row scheduling the finite observation windows of the approximating sequence.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying dyadic requests and arithmetic comparisons for the convergence budget.*
3. *M is the Bishop modulus row: for each displayed tolerance request it supplies a finite stage bound, together with the statement that all later scheduled windows lie inside the requested dyadic tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S, D, and M.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the stream schedule, dyadic tolerance row, modulus row, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the stream, dyadic, modulus, regular-readback, real-seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from tolerance request through finite window inspection, modulus-bound lookup, regular rational readback, and real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopModulusConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopModulusConvergence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BishopModulusConvergenceUp.BishopModulusConvergenceTasteGate single carrier alignment`

Theorem 7455.2 (BishopModulusConvergence NameCert obligations)**.** *For an accepted* BishopModulusConvergenc *carrier* $(S, D, M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopModulusConvergence}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the stream schedule, dyadic tolerance row, Bishop modulus row, regular rational readback, real seal, componentwise transport, continuation replay, provenance, and local naming row;*
2. *tolerance discipline, requiring every convergence request to enter through D before a stage bound in M is read;*
3. *modulus exactness, requiring the bound supplied by M to control all later windows exposed by S at the requested tolerance;*
4. *regular readback, requiring R to be obtained from the displayed stream, dyadic, and modulus rows before the* $\mathsf{Real}^{\uparrow}$ *seal E is public;*
5. *transport and replay, requiring H and C to preserve the same ordered route under* hsame *transport and displayed* Cont *replay;*
6. *ledger non-escape, excluding quotient streams, selected host limits, countable choice, trichotomy, host real equality, and ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted packet. The carrier inventory is exactly the stream schedule S, dyadic tolerance row D, Bishop modulus row M, regular readback R, real seal E, and structural rows H, C, P, N.

Tolerance discipline follows from the order of the packet. A convergence request first becomes a dyadic row in D, and only then can the displayed modulus row M supply the finite stage bound.

Modulus exactness is the content of M: after the bound is read, every later scheduled window supplied by S remains within the requested dyadic tolerance. The regular readback row R packages that controlled tail as a $\mathsf{RegSeqRat}^{\uparrow}$ name before E seals it as a $\mathsf{Real}^{\uparrow}$ row.

The rows H and C transport and replay the same route, while P and N record provenance and local naming. Since no remaining coordinate stores quotient stream equality, a selected host limit, countable choice, trichotomy, host equality, or ambient completeness, those data cannot be projected from the packet. □

Theorem 7455.3 (BishopModulusConvergence regular handoff)**.** *Every accepted* $\mathsf{BishopModulusConvergence}^{\uparrow}$ *packet hands its convergence data to regular rational and real-name consumers only through the route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The Bishop modulus row supplies the finite stage bound used on this route, and the handoff remains stable under the displayed hsame *transport and* Cont *replay rows. No consumer can bypass the regular readback by asking for a quotient stream, selected host limit, countable-choice selector, trichotomy split, host real equality, or ambient completeness witness.*

Proof. Read a consumer request through the continuation ledger C. The first public data are the finite stream windows in S and the dyadic tolerance request in D.

The modulus row M then returns a stage bound for that request. This bound controls the later stream windows, so the controlled tail is available to R as regular rational readback rather than as an external limit selection.

Finally the real-facing row E is read only after R is present. Componentwise hsame transport in H moves the same stream, dyadic, modulus, regular-readback, and real-seal rows together, so the handoff remains a displayed finite route. The excluded host and quotient data are absent from the carrier inventory. □

Theorem 7455.4 (BishopModulusConvergence tail transport)**.** *For every accepted* BishopModulusConvergence$^{\uparrow}$ *packet* $(S, D, M, R, E, H, C, P, N)$*, each tail-bound supplied by the Bishop modulus row* M *remains valid after componentwise* hsame *transport through* H *and displayed* Cont *replay through* C*. Consequently the* RegSeqRat$^{\uparrow}$ *readback* R *and the* Real$^{\uparrow}$ *seal* E *receive the same tolerance-controlled tail that was certified before transport.*

No quotient stream, selected limit, countable-choice selector, trichotomy branch, or ambient completeness witness is introduced by this transport route.

Proof. Project the transport and replay rows H and C from the accepted carrier. The transport row is componentwise, so it moves the stream schedule, dyadic tolerance row, modulus row, regular readback, and real seal together rather than replacing the tail certificate by an external equality.

Read the analytic rows in the carrier order S, D, M, R, E. A tolerance request is first registered in D, then the modulus row M supplies the finite tail-bound for all later windows of the stream schedule S.

Replay through C preserves the same request-to-bound route. Since H transports the same rows componentwise, the tail-bound still controls the later scheduled windows after transport, and R receives the identical controlled tail before E is exposed.

The carrier has no coordinate for quotient streams, selected limits, countable-choice selectors, trichotomy, or ambient completeness. The transported theorem therefore remains a finite tail handoff through S, D, M, R, E, H, C. □

Closure status for NameCert$_{\text{BishopModulusConvergence}\uparrow}$.

Theory closure: TheoryGate(NameCert$_{\text{BishopModulusConvergence}\uparrow}$, seed)

Scope closed: Definition 7455.1, Definition 7455.2, and Definition 7455.3 seed the convergence-modulus packet through StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{BishopModulusConvergence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected host limits, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance discipline, modulus exactness, regular readback, transport replay, provenance, and non-escape for BEDC.Derived.BishopModulusConvergenceUp.

Constructive story: A BishopModulusConvergence$^{\uparrow}$ packet is generated from a StreamName schedule, DyadicRatCore tolerance row, Bishop modulus row, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7456

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusCertificate}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges constructive compact analysis, the $\mathsf{CompactUniformModulusCertificate}^{\uparrow}$ packet records the finite-net route by which compactness and pointwise continuity produce a tolerance-only uniform modulus. It realizes the compact uniform-continuity vision of chapter 9237 as concrete NameCert data, sitting over the compact source of chapter 60, the continuous-map rows of chapter 130, the source and target metric rows of chapter 57, the rational lower-bound fold of chapter 37, the downstream uniform-modulus consumer of chapter 369, and the terminal real seal of chapter 38. The packet names the finite proof object; it is not open-cover compactness, a host continuity theorem, quotient function equality, a selected external modulus, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7456.1 (Compact modulus fan carrier)**.** *A* $\mathsf{CompactUniformModulusCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(K, F, L, Q, S, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, exposing bundled centers and coverage witnesses from* $\mathsf{Compact}^{\uparrow}$*.*
2. *F is the continuous-map row, exposing pointwise modulus ledgers from* $\mathsf{ContinuousMap}^{\uparrow}$ *over the same source metric.*
3. *L is the local pointwise modulus ledger: each bundled center carries a positive rational radius and the target-tolerance row that the continuous-map certificate supplies there.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, obtained by primitive recursion over the compact finite net and certified below every local radius.*
5. *S is the source* $\mathsf{Met}^{\uparrow}$ *triangle row, used to move an arbitrary source point and its nearby neighbour into the same local ball around a bundled center.*
6. *T is the target* $\mathsf{Met}^{\uparrow}$ *triangle row, used to combine the two pointwise target estimates into the requested output tolerance.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row, reading only the tolerance request and the folded precision from Q.*

8. *H records componentwise* hsame *transport for the compact net, continuous-map row, pointwise ledgers, rational fold, source and target metric rows, uniform-modulus row, provenance, and local naming row.*

9. *C records displayed* Cont *replay from tolerance request through finite-net coverage, pointwise modulus lookup, rational lower-bound fold, source triangle, target triangle, and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusCertificate}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, host function extensionality, quotient map equality, a selected external modulus, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompactUniformModulusCertificateUp.CompactUniformModulusCertificateTasteGate`
`single carrier alignment`

Theorem 7456.2 (Compact modulus fan NameCert obligations)**.** *For an accepted* CompactUniformModulusCertific *carrier* $(K, F, L, Q, S, T, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCertificate}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for compact finite-net rows, continuous-map rows, pointwise modulus ledgers, rational lower-bound fold rows, source and target metric triangle rows, uniform-modulus consumer rows, transport, continuation, provenance, and local naming;*

2. *finite-net coverage, requiring every source-point request to choose a displayed bundled center through K rather than through an external selector;*

3. *pointwise-modulus lookup, requiring each bundled center to read its local radius and target-tolerance row through F and L;*

4. *rational-fold exactness, requiring Q to be certified below every local radius by* $\mathsf{Rat}^{\uparrow}$ *comparisons;*

5. *source-target triangle handoff, requiring S and T to turn finite-net coverage plus the folded radius into the final uniform target estimate;*

6. *uniform-modulus exposure, requiring U to expose only the tolerance request and folded precision as the public* $\mathsf{UniformModulus}^{\uparrow}$ *row;*

7. *ledger non-escape, excluding open-cover compactness, host function extensionality, quotient map equality, selected external moduli, countable choice, and ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the accepted carrier. Its public coordinates are exactly the compact finite-net row K, continuous-map row F, local modulus ledger L, rational fold Q, source and target metric rows S, T, uniform-modulus row U, and structural rows H, C, P, N.

Finite-net coverage is read from K. Each source point is routed to a bundled center that is already part of the finite compact packet, so no external center selector is introduced.

Pointwise-modulus lookup uses F and L at each bundled center. The local radius and target-tolerance estimate are stored as displayed rows, and the lower-bound fold Q is obtained by primitive recursion over those finitely many rational radius rows.

The source metric row S moves a nearby pair of source points into the same local ball around the selected center. The target metric row T then combines the two pointwise estimates, and U exposes the resulting tolerance-only precision as the uniform-modulus consumer row.

The transport, continuation, provenance, and local naming rows preserve this same route. Since no carrier coordinate stores open-cover compactness, host extensionality, quotient equality, an external modulus selector, countable choice, or ambient real completeness, those data cannot be read from the packet. □

Theorem 7456.3 (Compact modulus fan uniform-continuity handoff)**.** *Every accepted* CompactUniformModulusCe *packet hands compact-uniform-continuity data to* $\mathsf{UniformModulus}^{\uparrow}$ *consumers by the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Rat}^{\uparrow} \longrightarrow \mathsf{UniformModulus}^{\uparrow}.$$

The $\mathsf{Real}^{\uparrow}$ *row is consumed only as the terminal scalar seal for the displayed metric and tolerance estimates. The handoff remains stable under the componentwise* hsame *transport and* Cont *replay rows, and no consumer can bypass it by asking for open-cover compactness, host function extensionality, quotient map equality, selected external moduli, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a tolerance request for the uniform-modulus consumer. The compact finite-net row K supplies the bundled centers and coverage rows, while F and L supply the pointwise modulus data attached to those centers.

Use the $\mathsf{Rat}^{\uparrow}$ fold row Q to obtain one precision below every local radius. This is a finite recursive read over the displayed net, not a selection from an ambient family of radii.

Apply the source metric triangle row S to place both source points in the same local modulus ball. Apply the target metric triangle row T to combine the two pointwise estimates into the requested target tolerance, and then expose the result through U as a $\mathsf{UniformModulus}^{\uparrow}$ row.

The real scalar row is sealed only at the end of this displayed estimate route. Componentwise transport in H and replay in C preserve the same carrier coordinates, so the excluded host, quotient, choice, and completeness data remain unavailable. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCertificate}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7456.1, Definition 7456.2, and Definition 7456.3 seed the finite-net, pointwise-modulus, rational-fold, metric-triangle, and uniform-modulus handoff packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host function extensionality, quotient map equality, selected external moduli, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-net coverage, pointwise-modulus lookup, rational-fold exactness, source-target triangle handoff, uniform-modulus exposure, transport replay, provenance, and non-escape for BEDC.Derived.CompactUniformModulusCertificateUp.

Constructive story: A $\mathsf{CompactUniformModulusCertificate}^{\uparrow}$ packet is generated from compact finite-net rows, continuous-map pointwise-modulus rows, RatUp lower-bound folds, Metric source and target triangle rows, UniformModulus handoff, Real scalar seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7457

A Concrete Naming Certificate for $\mathsf{BourbakiCompletionFilter}^{\uparrow}$

Following Bourbaki and Bishop constructive completion practice, the $\mathsf{BourbakiCompletionFilter}^{\uparrow}$ packet records the filter-based completion surface as finite BEDC data before any quotient-filter carrier or ambient completeness theorem is available. It reads the Cauchy-filter basis of chapter 1501, the reflector discipline of chapter 2149, the constructive completion route of chapter 1556, the finite stream window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a seed object for the L10 Real and Completion route; it does not construct quotient filters, select limits, use countable choice, assert selected representatives, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7457.1 (Bourbaki completion filter carrier)**.** *A* $\mathsf{BourbakiCompletionFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, M, C, S, R, E, H, T, P, N)$$

with the following visible rows:

1. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row naming the finite Cauchy-filter basis packets and their common-refinement reads.*
2. *M is the* $\mathsf{MetricCompletionReflector}^{\uparrow}$ *row that records the reflector-facing completion request for the same metric source.*
3. *C is the* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *route through regular Cauchy names, dyadic tolerances, Cauchy-filter basis data, separated comparison, dense embedding, and uniformly continuous handoff.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to read the displayed basis through finite observation schedules.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the stream windows and tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after B, M, C, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the basis, reflector, constructive completion route, stream windows, regular readback, and Real seal.*
8. *T records the displayed* Cont *replay from the Cauchy-filter basis to the reflector request, from the reflector request to the constructive completion route, from stream windows to the regular readback, and from the regular readback to the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{MetricCompletionReflector}^{\uparrow}$, $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BourbakiCompletionFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient filters, selected limits, selected representatives, countable choice, host real equality, or an ambient completion object.

Theorem 7457.2 (BourbakiCompletionFilter NameCert obligations)**.** *For every accepted* BourbakiCompletionFilter *carrier $F = (B, M, C, S, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BourbakiCompletionFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the Cauchy-filter basis, metric-completion reflector, constructive completion route, StreamName window, RegSeqRat readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local NameCert row. No obligation is stored in a quotient-filter object, selected limit, countable-choice schedule, selected representative, host real equality row, or ambient completion theorem.*

Proof. Project the carrier of Definition 7457.1. The displayed rows $B, M, C, S, R, E, H, T, P, N$ are the whole finite packet, and the local NameCert row names only those coordinates.

The route rows bind the basis to the completion surface. The Cauchy-filter basis B feeds the reflector request M and the constructive completion route C; the finite StreamName row S and RegSeqRat row R then provide the readback through which the terminal Real seal E is visible.

Transport, replay, and provenance add no hidden coordinate. The rows H, T, P, N only move, replay, source, and name the same displayed packet, so quotient filters, selected limits, countable choice, selected representatives, host real equality, and ambient completion have no row from which a NameCert obligation could be exported. □

Theorem 7457.3 (BourbakiCompletionFilter Cauchy nonescape)**.** *Every completion-facing read of an accepted* $\mathsf{BourbakiCompletionFilter}^{\uparrow}$ *packet factors through*

$$\mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{MetricCompletionReflector}^{\uparrow} \longmapsto \mathsf{ConstructiveMetricCompletion}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSe}$$

The read stays inside the displayed rows $B, M, C, S, R, E, H, T, P, N$ and exports no quotient filters, countable choice, selected limits, selected representatives, detached $\mathsf{Real}^{\uparrow}$ *completeness, or ambient completion.*

Proof. Begin with the basis row B. It is the only Cauchy-filter source carried by the packet, and its common-refinement reads are the inputs to the reflector-facing row M.

The constructive completion route C is downstream of that basis and reflector surface. The finite window row S and regular rational readback R make the completion read visible as a BEDC route before the terminal seal E is exposed.

Finally, the structural rows H, T, P, N preserve the same sequence of displayed coordinates. Since the carrier excludes quotient-filter objects, choice schedules, selected limits, selected representatives, detached Real completeness, and ambient completion objects, no completion-facing consumer can escape the finite route named in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{BourbakiCompletionFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BourbakiCompletionFilter}^{\uparrow}$ packet is generated from a Cauchy-filter basis, metric-completion reflector row, constructive completion route, finite StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BourbakiCompletionFilter}^{\uparrow}}$, seed)

Scope closed: Definition 7457.1, Definition 7457.2, and Definition 7457.3 seed the filter-based completion surface over Cauchy-filter basis, reflector, constructive completion, StreamName, RegSeqRat, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BourbakiCompletionFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim quotient filters, countable choice, selected limits, selected representatives, detached $\mathsf{Real}^{\uparrow}$ completeness, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-filter basis handoff, reflector replay, constructive completion replay, StreamName and RegSeqRat readback, Real-seal nonescape, and transport provenance for the same packet.

Chapter 7458

A Concrete Naming Certificate for $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$

Following Hardy and Knopp on products of positive convergent series, the $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$ packet records the finite NameCert consumer that reads two positive real-series rows, forms their Cauchy product through bounded convolution windows, and hands the resulting product row to the constructive real-series surface. It sits over the real-series carrier of chapter 1581, the positivity route of chapter 2080, the convolution carrier of chapter 6968, the majorant discipline of chapter 1700, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38. The packet is a consumer of displayed finite Real and completion rows; it is not an ambient summation operator, a quotient equality of infinite series, or a host completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7458.1 (Positive series Cauchy product carrier)**.** *A* $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (A, B, W, M, T, S, D, E, H, C, Q, N)$$

with the following visible rows:

1. *A and B are positive* $\mathsf{RealSeries}^{\uparrow}$ *source rows, each exposing finite coefficient windows, partial-sum windows, and the positivity ledgers read by* $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ *consumers.*
2. *W is the bounded convolution-window row. For a requested product coefficient or partial product sum it lists only the finitely many pairs $i + j = n$ and the finite rectangular windows needed for the requested tail budget.*
3. *M is the absolute or majorant tail-control row. It records the positive majorant comparison that bounds the remaining convolution tail before a product read is exposed.*
4. *T is the* $\mathsf{StreamName}^{\uparrow}$ *replay row for the two source streams and the product stream windows.*
5. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the partial sums, majorant bounds, and product-tail estimates.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare source budgets, convolution-window budgets, and the final product tolerance.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the product value, available only after S and D have been displayed.*

8. *H records componentwise* hsame *transport for the two source series, convolution window, majorant tail row, stream replay, rational readback, dyadic tolerance, Real seal, provenance, and local name.*
9. *C records displayed* Cont *replay for reading source coefficients, convolution windows, tail bounds, rational tolerances, dyadic comparisons, and the terminal Real seal.*
10. *Q is the* Pkg *provenance over* $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$, $\mathsf{CauchyProductSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed finite rows. It has no coordinate for an external infinite sum, quotient equality of series, selected completion representative, countable choice, or ambient real completeness.

Theorem 7458.2 (Positive series Cauchy product NameCert obligations)**.** *For every accepted* $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$ *carrier* $P = (A, B, W, M, T, S, D, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PositiveSeriesCauchyPr}}$ *surface consists exactly of carrier admission for the two positive real-series rows, convolution-window row, majorant tail-control row, StreamName replay row, RegSeqRat readback row, DyadicRatCore tolerance row, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. Every product-facing consumer must read* $A, B, W, M, T, S, D, E, H, C, Q, N$ *in that finite route before it may consume the product row.*

Proof. Project the carrier of Definition 7458.1. The only source series available to the packet are the positive real-series rows A and B, and the only product coefficients available to a consumer are those exposed by the bounded convolution window W.

The tail step is finite. The row M records the absolute or positive majorant comparison, while T, S, D replay the stream windows, rational readback, and dyadic tolerance comparisons needed to bound the requested product tail.

The terminal product value is then sealed by E. Transport, replay, provenance, and local naming are exactly H, C, Q, N, so the packet cannot export an external infinite sum, quotient equality of series, selected completion representative, countable choice, or ambient real completeness. □

Theorem 7458.3 (Positive series Cauchy product Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$ *packet reaches the product Real seal only through the displayed route*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{PringsheimPositiveRealSeries}^{\uparrow},\ \mathsf{CauchyProductSeries}^{\uparrow},\ \mathsf{AbsoluteConvergence}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRa}$$

The handoff supplies a finite product-series readback over convolution windows and majorant tails. It does not supply ambient Real completeness, a host infinite-sum operator, quotient real equality, selected limit representatives, or a completion object outside the packet.

Proof. Begin with the NameCert obligations of Definition 7458.2. They force any product-facing read to expose the two positive source rows and the convolution-window row before the product is read.

Next read the majorant and tolerance rows. The absolute or positive majorant row M bounds the remaining convolution tail, the StreamName row T fixes the finite windows, and the RegSeqRat and DyadicRatCore rows S, D provide the tolerance comparison consumed by the product request.

Finally consume the Real seal E. Since every completion-facing read has already passed through A, B, W, M, T, S, D, the handoff is a displayed finite route to $\mathsf{Real}^{\uparrow}$, not an ambient summation or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}$ packet is generated from two positive RealSeries rows, bounded convolution windows, absolute or majorant tail-control rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparison, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7458.1, Definition 7458.2, and Definition 7458.3 seed the finite product-series route from positive source rows to the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveSeriesCauchyProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient summation, quotient equality of series, selected completion representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convolution-window exactness, majorant tail control, tolerance readback, Real-seal nonescape, transport, provenance, refusal, and local naming for BEDC.Derived.PositiveSeriesCauchyProd

Chapter 7459

A Concrete Naming Certificate for $\mathsf{UpperDiniDerivative}^{\uparrow}$

Following Saks and Bishop–Bridges constructive analysis, the $\mathsf{UpperDiniDerivative}^{\uparrow}$ packet separates the one-sided upper Dini derivative carrier from the combined Dini-window packet of chapter 6110. It sits beside the Denjoy–Young–Saks boundary of chapter 5829, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite observation schedule of chapter 126, and the dyadic tolerance ledger of chapter 291. The chapter names the upper one-sided limsup surface as finite BEDC data; it does not assert differentiability, a selected derivative value, almost-everywhere alternatives, or ambient real completeness.

Definition 7459.1 (UpperDiniDerivative carrier)**.** *An* $\mathsf{UpperDiniDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, F, X, Q, S, R, D, W, E, H, C, P, N)$$

with the following rows:

1. *I is the interval-cell row on which the one-sided derivative request is displayed.*
2. *F is the real-valued function-observation row over the inspected interval cells.*
3. *X is the base-point row, read only through the same real-name and interval surface as I.*
4. *Q is the positive approach-direction row, recording the finite side from which quotients are sampled.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row for the inspected function and base-point observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream windows in S.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the radii, slack comparisons, and quotient-window refinements.*
8. *W is the sibling* $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *row whose upper Dini coordinate is being exposed.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed upper-bound read.*
10. *H records componentwise* hsame *transport for the interval, function, base-point, direction, stream, readback, dyadic, window, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay for refinements of the same one-sided quotient window.*

12. *P is the* Pkg *provenance over* $\mathsf{UpperDiniDerivative}^{\uparrow}$, $\mathsf{DiniDerivativeWindow}^{\uparrow}$, $\mathsf{DenjoyYoungSaks}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperDiniDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, F, X, Q, S, R, D, W, E, H, C, P, N$. It has no coordinate for a lower Dini row, a two-sided derivative, a selected limiting slope, a measure-theoretic alternative, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7459.2 (UpperDiniDerivative window stability)**.** *For every accepted* $\mathsf{UpperDiniDerivative}^{\uparrow}$ *carrier*

$$U = (I, F, X, Q, S, R, D, W, E, H, C, P, N),$$

any refinement of the displayed one-sided quotient window is accepted only when it factors through the same interval row I, function-observation row F, base-point row X, approach-direction row Q, stream schedule S, regular readback R, dyadic tolerance ledger D, and sibling $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *row W. Consequently the public upper-Dini read is stable under finite window refinement and exports no lower-Dini coordinate, two-sided derivative, selected limiting slope, quotient equality of real names, or ambient completeness principle.*

Proof. Project the carrier of Definition 7459.1. The one-sided quotient surface is not an isolated real row; it is tied to the interval, function observation, base point, approach direction, stream schedule, regular readback, dyadic ledger, and sibling Dini window.

For a refinement, replay through C and transport through H. The replay can change only the inspected finite window while preserving the rows $I, F, X, Q, S, R, D, W, E, P, N$ as the same displayed packet.

The excluded data are absent from the carrier. Since no coordinate names a lower-Dini export, two-sided derivative, selected limiting slope, quotient equality, choice schedule, or ambient completeness theorem, a refinement-stable consumer cannot read any of those objects. □

Theorem 7459.3 (UpperDiniDerivative NameCert obligations)**.** *For every accepted* $\mathsf{UpperDiniDerivative}^{\uparrow}$ *carrier $U = (I, F, X, Q, S, R, D, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UpperDiniDerivative}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the interval cell, function-observation row, base-point row, approach-direction row, stream schedule, regular readback, dyadic tolerance ledger, sibling Dini-window row, upper real seal, and structural rows H, C, P, N;*

2. *one-sided quotient coverage, requiring each upper-Dini request to display the positive approach side Q together with matching stream windows in S, readbacks in R, and dyadic tolerance entries in D;*

3. *sibling-window compatibility, requiring the upper coordinate read from W to be the same finite upper-Dini row routed by the carrier;*

4. *window-stability replay, requiring refinements to replay through C and transport through H without changing the carrier-local upper row;*

5. *non-escape from differentiability, lower-Dini export, selected limiting slopes, quotient real equality, countable choice, measure-theoretic alternatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission reads the packet named in Definition 7459.1. The analytic rows are $I, F, X, Q, S, R, D, W, E$, while H, C, P, N provide transport, replay, provenance, and local naming.

One-sided quotient coverage is finite because every request is displayed through the approach-direction row Q, the stream schedule S, the regular readback R, and the dyadic ledger D. A request lacking one of those rows is not an accepted $\mathsf{UpperDiniDerivative}^{\uparrow}$ read.

Sibling-window compatibility uses the $\mathsf{DiniDerivativeWindow}^{\uparrow}$ row W. The upper coordinate is consumed from that sibling window and then sealed by E only after the same route has been displayed.

Finally apply the stability theorem Definition 7459.2. Refinement replay remains inside the same carrier, and the listed exclusions are not rows of the packet, so the NameCert surface is exhausted by the stated obligations. □

Falsifiable prediction: Every accepted $\mathsf{UpperDiniDerivative}^{\uparrow}$ consumer reaching an upper-Dini read without the displayed one-sided direction, StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, and DiniDerivativeWindow row refutes the carrier.

Independence witness: dini-derivative-window, denjoy-young-saks, real, regseqrat, streamname, dyadicratcore: no listed sibling supplies the whole UpperDiniDerivative packet, because each sibling contributes only the combined Dini window, broader differentiability boundary, terminal real seal, rational readback, observation schedule, or tolerance ledger while this chapter binds the one-sided upper Dini carrier in one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{UpperDiniDerivative}^{\uparrow}}$.

Constructive story: An $\mathsf{UpperDiniDerivative}^{\uparrow}$ packet is generated from interval cells, function-observation rows, a base-point row, a positive approach-direction row, StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance rows, a DiniDerivativeWindow upper row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperDiniDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7459.1, Definition 7459.2, and Definition 7459.3 seed the one-sided upper Dini derivative carrier and its finite window-stability obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpperDiniDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim differentiability, lower-Dini export, two-sided derivative existence, selected limiting slopes, almost-everywhere alternatives, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, one-sided quotient coverage, sibling-window compatibility, finite window stability, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UpperDiniDeriv

Chapter 7460

A Concrete Naming Certificate for KreinMilmanCompactConvex$^{\uparrow}$

Following Krein and Milman, the KreinMilmanCompactConvex$^{\uparrow}$ packet records the finite NameCert surface for a compact convex body inspected inside a locally convex real vector environment. It sits over the compact carrier of chapter 60, the convex-set interface of chapter 208, the locally convex space source of chapter 3386, the scalar Real$^{\uparrow}$ seal of chapter 38, and the finite extreme-point sibling of chapter 3610. The chapter names the compact-convex dependency surface; it does not assert a host theorem that the body is the closed convex hull of all extreme points.

Definition 7460.1 (Krein–Milman compact-convex carrier)**.** *A* KreinMilmanCompactConvex$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, V, X, W, E, F, H, C, P, N)$$

with the following displayed rows:

1. *A is the* Compact$^{\uparrow}$ *row for the inspected compact subset.*
2. *V is the* LocallyConvexSpace$^{\uparrow}$ *row carrying the ambient vector-space, seminorm-window, and weak-neighborhood data available to the packet.*
3. *X is the* ConvexSet$^{\uparrow}$ *row for the same subset, including displayed affine-combination and convex-membership reads.*
4. *W is the weak-window row through which continuous linear observations and finite neighborhood tests are opened.*
5. *E is the* KreinMilmanFiniteExtreme$^{\uparrow}$ *sibling row, exposing only the finite extreme-point witness surface licensed by that chapter.*
6. *F records finite face, hull, and scalar-comparison rows, with all scalar values sealed through* Real$^{\uparrow}$.
7. *H records componentwise* hsame *transport for the compact, locally convex, convex-set, weak-window, extreme-sibling, face, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact-convex reads through weak windows and finite face ledgers to the extreme-sibling handoff.*
9. *P is the* Pkg *provenance over* KreinMilmanCompactConvex$^{\uparrow}$, Compact$^{\uparrow}$, ConvexSet$^{\uparrow}$, LocallyConvexSpace$^{\uparrow}$, Real$^{\uparrow}$, KreinMilmanFiniteExtreme$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}$ *row.*
The carrier compares accepted packets only through $A, V, X, W, E, F, H, C, P, N$. It has no coordinate for a completed dual space, unrestricted separation, a chosen list of all extreme points, quotient convex-body equality, countable choice, or ambient real completeness.

Theorem 7460.2 (Krein–Milman compact-convex NameCert obligations)**.** *For every accepted* $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$ *carrier*

$$K = (A, V, X, W, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}$ *surface consists exactly of compact admission for A, locally convex ambient admission for V, convex-set admission for X, weak-window visibility for W, finite extreme-sibling readback for E, finite face and scalar-comparison visibility for F, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every compact-convex consumer must read the dependency route

$$A, V, X \longmapsto W, F \longmapsto E \longmapsto H, C, P, N$$

before using the packet as a Krein–Milman compact-convex name. The route exports finite certificate rows only; it exports no host closed-convex-hull equality, no unrestricted compactness principle, no global supporting-functional selector, no quotient convex body, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 7460.1. The compact source is A, the ambient locally convex source is V, and the convex subset source is X.

Open the weak and scalar windows next. The row W records only finite weak-neighborhood and functional-observation tests, while F records finite face, hull, and scalar-comparison data whose scalar reads pass through the $\mathsf{Real}^{\uparrow}$ seal of chapter 38.

Read the finite extreme-point sibling through E. By chapter 3610, this handoff supplies a finite exposed-face and candidate-extreme witness route, not a chosen set of all extreme points or a completed dual-space theorem.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no row for unrestricted separation, quotient convex-body equality, countable choice, host compact-convex hull equality, or ambient real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 7460.3 (Krein–Milman compact-convex finite extreme-window handoff)**.** *Every accepted* $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$ *carrier*

$$K = (A, V, X, W, E, F, H, C, P, N)$$

must expose the finite extreme-point row E through chapter 3610 before any compact-convex hull read, weak-window read, scalar comparison, or consumer export is public. The exported route is the finite window

$$A, V, X, W, F \longmapsto E \longmapsto H, C, P, N,$$

not a selected set of all extreme points, a completed dual-space theorem, or a host closed-convex-hull equality.

Proof. Project the carrier in Definition 7460.1. The compact, locally convex, and convex-set rows are A, V, X, and the weak-window and finite scalar rows are W, F.

Apply Definition 7460.2. That obligation surface requires finite extreme-sibling readback for E as part of the same local $\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}$ packet.

Read the existing sibling route of chapter 3610. Because E is the only extreme-point row carried by the packet, every compact-convex hull or scalar export must pass through it before H, C, P, N repack the public route. The carrier has no coordinate for a selected set of all extreme points, a completed dual space, unrestricted separation, or a classical Krein–Milman theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}$.

Constructive story: A $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$ packet is generated from compact, locally convex, convex-set, weak-window, finite extreme-sibling, face, scalar, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7460.1 and Definition 7460.2 seed the compact-convex NameCert surface over compact, convex-set, locally convex, real scalar, weak-window, and finite extreme-point sibling rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KreinMilmanCompactConvex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Krein–Milman theorem, closed-convex-hull equality, unrestricted separation, selected extreme-point sets, quotient convex bodies, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact routing, convex-set admission, locally convex weak-window routing, finite extreme-sibling readback, scalar face visibility, transport, replay, provenance, and local naming for the same packet.

Chapter 7461

A Concrete Naming Certificate for $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$

Following Bishop and Bridges and Bourbaki, the $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$ packet records the separated completion route that remains visible through finite windows before any terminal real seal is consumed. It sits between the separated completion boundary of chapter 402, the finite-window completion handoff of chapter 1559, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name surface of chapter 38. The packet names a constructive L10 completion surface without quotient representatives, countable choice, host equality of completed points, or an ambient completeness theorem.

Definition 7461.1 (Bishop separated finite-window completion carrier)**.** *A* BishopSeparatedFiniteWindowCompletio *carrier is a finite* BHist *packet*

$$B = (H, F, S, D, R, E, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{HausdorffCompletion}^{\uparrow}$ *separated-completion boundary, read as finite seal data rather than as a quotient class.*
2. *F is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *finite-window completion row that fixes the completion-facing request.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened by the finite request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the radii and slack comparisons attached to the visible windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row consumed after the windows and dyadic tolerances have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after H, F, S, D, R have been replayed.*
7. *T records componentwise* hsame *transport for the separated boundary, finite-window completion row, stream schedule, dyadic ledger, regular readback, real seal, continuation, provenance, and local name.*
8. *C records displayed* Cont *replay for refinements that remain inside the same separated finite-window packet.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$, $\mathsf{HausdorffCompletion}^{\uparrow}$, $\mathsf{MetricCompletionFinite}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $H, F, S, D, R, E, T, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, host equality of completed points, or ambient completeness.

Theorem 7461.2 (Bishop separated finite-window completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$ *carrier*

$$B = (H, F, S, D, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the separated completion boundary H, finite-window completion row F, stream schedule S, dyadic ledger D, regular readback R, terminal real seal E, and structural rows T, C, P, N;*
2. *separated-window compatibility, requiring F to consume the separated boundary H before any stream window or rational readback is public;*
3. *finite coverage, requiring every visible completion request in F to have a matching window in S, dyadic tolerance in D, and regular readback in R;*
4. *stability under transport and replay, requiring refinements to move through T and C without replacing the displayed separated boundary or finite-window row;*
5. *real-seal nonescape, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to export only the named seal reached through H, F, S, D, R.*

No local obligation exports quotient representatives, host equality of completed points, countable choice, or an ambient completeness theorem.

Proof. Project the carrier of Definition 7461.1. Its visible coordinates are exactly $H, F, S, D, R, E, T, C, P, N$, so carrier admission can expose only those rows.

Separated-window compatibility reads H before F. The finite-window row is therefore attached to a displayed Hausdorff completion boundary, not to a quotient representative or host completion object.

Finite coverage then reads S, D, R from the same packet. Each completion request visible in F has its stream window, dyadic tolerance, and regular rational readback present before the terminal seal is reachable.

Transport and replay use T and C componentwise. Since those rows move the displayed packet rather than replacing it, the route remains inside $H, F, S, D, R, E, T, C, P, N$.

The real-seal clause is the final projection. The carrier has no coordinate for quotient completion equality, selected representatives, countable-choice schedules, host equality, or ambient completeness, so none of those objects can be exported by the local NameCert surface. □

Theorem 7461.3 (Bishop separated finite-window completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$ *packet reaches a regular rational readback or terminal real seal only through the finite separated route*

$$H,\ F,\ S,\ D,\ R,\ E,\ T,\ C,\ P,\ N.$$

Consequently the handoff to $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *exports separated finite-window completion data, not quotient completion equality, selected representatives, countable-choice schedules, host equality of completed points, or ambient completeness.*

Proof. Begin with the obligation surface of Definition 7461.2. It forces any completion-facing consumer to read the separated boundary H and finite-window row F before inspecting the downstream readback.

The finite coverage obligation supplies the window schedule, dyadic tolerance ledger, and regular rational readback as S, D, R. These rows are displayed inside the same BHist packet and are preserved by the transport and replay rows T, C.

The terminal seal E is downstream of that route. Package provenance P and local naming N record the same finite packet, so the consumer has no access path outside $H, F, S, D, R, E, T, C, P, N$.

The excluded completion principles are absent from the carrier of Definition 7461.1. Therefore the handoff can export only the separated finite-window completion surface named by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7461.1, Definition 7461.2, and Definition 7461.3 seed the separated finite-window completion route from Hausdorff completion and finite-window completion rows to RegSeqRat readback and RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completed points, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separated-window compatibility, finite coverage, transport replay stability, RegSeqRat handoff, RealUp seal nonescape, provenance, and local naming for BEDC.Derived.BishopSeparatedFiniteW

Constructive story: A $\mathsf{BishopSeparatedFiniteWindowCompletion}^{\uparrow}$ packet is generated from a HausdorffCompletion separated boundary, a MetricCompletionFinite finite-window row, a StreamName schedule, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7462

A Concrete Naming Certificate for $\mathsf{CantorIntervalTrap}^{\uparrow}$

Following Bishop and Bridges on nested intervals, the $\mathsf{CantorIntervalTrap}^{\uparrow}$ packet records the finite trap by which a decreasing displayed interval chain catches a single Real-and-Completion boundary without invoking open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. It sits over the dyadic nested selector of chapter 6784, the Cantor intersection theorem packet of chapter 2318, the dyadic radius core of chapter 291, the finite windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The originating L10 route is the Real and Completion construction order from section 9467.12, where $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ are admitted by finite observation and readback rows.

Definition 7462.1 (Cantor interval trap carrier)**.** *A* $\mathsf{CantorIntervalTrap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, D, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *I is the nested interval row, listing a finite prefix of closed dyadic intervals together with the inclusion checks read from the* $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$ *and* $\mathsf{CantorIntersectionTheorem}^{\uparrow}$ *siblings.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, recording endpoint comparison, midpoint, and radius-shrink data for each displayed interval row.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which finite interval prefixes are inspected for each requested tolerance.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed interval centers and dyadic radius bounds.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the nested interval prefix, dyadic radius ledger, stream window, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for nested interval rows, dyadic radius rows, window rows, readback rows, Real seal rows, provenance rows, and the local naming row.*
7. *C records displayed* Cont *replay from interval-prefix requests to dyadic radius checks, from those checks to stream windows, and from stream windows through the regular readback to the Real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{CantorIntervalTrap}^{\uparrow}$, $\mathsf{DyadicNestedIntervalSelector}^{\uparrow}$, $\mathsf{CantorIntersectionTheorem}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntervalTrap}^{\uparrow}}$ *row.*

The classifier compares accepted traps only through these displayed rows. It has no coordinate for a selected host limit, quotient equality of streams, trichotomy, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7462.2 (Cantor interval trap NameCert obligations)**.** *For every accepted* $\mathsf{CantorIntervalTrap}^{\uparrow}$ *carrier $T = (I, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorIntervalTrap}^{\uparrow}}$ *surface consists exactly of carrier admission for the nested interval prefix, dyadic radius ledger, finite StreamName windows, RegSeqRat readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing consumer must read $I, D, W, R, E, H, C, P, N$ in that finite route before it can consume the trapped Real boundary.*

Proof. Project the carrier of Definition 7462.1. The nested interval data are exactly I, and every radius or endpoint comparison available to the packet is stored in the dyadic ledger D.

Next read the finite observation route. The window row W determines the inspected interval prefix for a requested tolerance, while R records the regular rational readback obtained from the displayed centers and radius bounds.

Finally expose the Real seal E through the structural rows. Transport, replay, provenance, and local naming are exactly H, C, P, N, so the certificate cannot export a selected host limit, quotient stream equality, trichotomy, open-cover compactness, countable choice, or ambient Real completeness. □

Theorem 7462.3 (Cantor interval trap Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CantorIntervalTrap}^{\uparrow}$ *packet reaches the trapped point only through the displayed route*

$$\mathsf{DyadicNestedIntervalSelector}^{\uparrow} \longmapsto \mathsf{CantorIntersectionTheorem}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRa}$$

The handoff supplies nested interval rows, dyadic radii, finite windows, regular rational readback, transport, replay, provenance, and local naming. It does not supply ambient interval compactness, a selected host point, quotient equality of Cauchy streams, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the nested interval and Cantor-intersection sibling rows. They provide only the displayed finite interval prefix and its inclusion route, not a completed host intersection object.

Read the dyadic and stream rows next. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger supplies the endpoint and radius comparisons, and the $\mathsf{StreamName}^{\uparrow}$ window row fixes which finite prefix is inspected for the requested tolerance.

The $\mathsf{RegSeqRat}^{\uparrow}$ readback and $\mathsf{Real}^{\uparrow}$ seal then expose the Real-facing boundary. Because the carrier has no coordinate for open-cover compactness, choice, trichotomy, quotient stream equality, selected host limits, or ambient completeness, every Real consumer remains inside the displayed trap route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntervalTrap}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntervalTrap}^{\uparrow}$ packet is generated from nested interval rows, DyadicRatCore radius ledgers, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorIntervalTrap}^{\uparrow}}$, seed)

Scope closed: Definition 7462.1, Definition 7462.2, and Definition 7462.3 seed the finite nested-interval trap route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CantorIntervalTrap}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim ambient interval compactness, selected host limits, quotient stream equality, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked nested-prefix exposure, dyadic radius exactness, StreamName window inspection, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntervalTrapUp.

Chapter 7463

A Concrete Naming Certificate for $\mathsf{InscriptionEventNovelty}^{\uparrow}$

Following the hard-problems inscription-event reading of Definition 9415.5, the $\mathsf{InscriptionEventNovelty}^{\uparrow}$ packet records a finite prior-record boundary together with the new record whose origin is not reducible to the displayed closed-generation route. It sits beside the free-will inscription commitment of chapter 592, the classifier novelty witness of chapter 6138, the finite witnessed refutation packet of chapter 576, and the GAP closure boundary of chapter 1006. These siblings expose commitment, classifier shift, contrary-record, and boundary rows; this packet binds the inscription event itself as finite NameCert data.

Definition 7463.1 (Inscription-event novelty carrier)**.** *An* $\mathsf{InscriptionEventNovelty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (B, A, J, G, L, H, C, P, N)$$

with the following visible rows:

1. *B is the prior-record boundary row, listing the records visible before the inscription event.*
2. *A is the after-record row, displaying the record that appears at the inscription point.*
3. *J is the novelty witness row, recording that A is not presented as a forced consequence of B under the displayed closed-generation route.*
4. *G is the* GAP *row that keeps the non-reduction boundary visible instead of turning the event into a hidden theorem about transcendental supply.*
5. *L is the local ledger row tying the carrier to Definition 9415.5 and to the sibling packets for free-will inscription commitment, classifier novelty, witnessed refutation, and GAP closure.*
6. *H records componentwise* hsame *transport for prior-record, after-record, novelty, GAP, ledger, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for prior-record inspection, after-record exposure, novelty checking, GAP non-escape, and local ledger readback.*
8. *P is the* Pkg *provenance over* $\mathsf{InscriptionEventNovelty}^{\uparrow}$, BHist, GAP, hsame, Cont, Pkg, *and* NameCert *together with the named sibling rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{InscriptionEventNovelty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for private access to T*, a proof of metaphysical freedom, a hidden host-causality theorem, a global classifier-shift verdict, or a positive-discovery claim.*

Theorem 7463.2 (Inscription-event novelty NameCert obligations)**.** *For every accepted* $\mathsf{InscriptionEventNovelty}^{\uparrow}$ *carrier* $E = (B, A, J, G, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{InscriptionEventNovelty}^{\uparrow}}$ *surface consists exactly of carrier admission for the prior-record boundary, after-record row, novelty witness, GAP non-escape row, local ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every downstream read of the inscription event must expose* $B, A, J, G, L, H, C, P, N$ *before it may treat the new record as an inscription-event novelty row.*

Proof. Project the carrier of Definition 7463.1. The prior records are B, the new displayed record is A, and the novelty witness is J.

The non-reduction boundary is explicit. The row G records the GAP side of the event, while L names the hard-problems definition and the sibling packets that can consume the event without replacing it by commitment, classifier shift, refutation, or closure-boundary data.

Finally replay through H, C, P, N. These rows transport, replay, source, and name the same finite packet, so no accepted read obtains private access to T, a metaphysical-freedom theorem, a hidden host-causality theorem, a global classifier-shift verdict, or a positive-discovery claim. □

Theorem 7463.3 (Inscription-event novelty nonescape)**.** *Every consumer of an accepted* $\mathsf{InscriptionEventNovelty}^{\uparrow}$ *packet factors through*

$$B \longmapsto A \longmapsto J \longmapsto G \longmapsto L \longmapsto H, C, P, N.$$

The read may cite the hard-problems inscription-event definition and the sibling rows for free-will inscription commitment, classifier novelty, finite witnessed refutation, and GAP closure, but it may not collapse the packet into any one of those siblings or into a hidden host theorem.

Proof. Begin with the prior-record and after-record rows. They fix the event boundary as a finite record transition rather than as a global statement about all possible conscious accumulation.

Next read the novelty and GAP rows. The novelty witness J keeps the new record distinct from the displayed closed-generation route, and G keeps that non-reduction boundary visible to downstream consumers.

The ledger and structural rows then preserve the event as its own packet. Since L, H, C, P, N only cite and replay the displayed rows, the packet cannot become a free-will commitment, classifier novelty verdict, witnessed refutation, GAP closure theorem, private access route, or hidden host-causality theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{InscriptionEventNovelty}^{\uparrow}}$.

Constructive story: An $\mathsf{InscriptionEventNovelty}^{\uparrow}$ packet is generated from prior-record boundary rows, after-record rows, novelty witnesses, GAP non-escape rows, local ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InscriptionEventNovelty}^{\uparrow}}$, seed)

Scope closed: Definition 7463.1, Definition 7463.2, and Definition 7463.3 seed the finite inscription-event novelty packet over prior-record, after-record, GAP, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{InscriptionEventNovelty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim private access to T, metaphysical freedom, hidden host causality, global classifier shift, positive discovery, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked prior-record exposure, after-record exposure, novelty witnessing, GAP non-escape, sibling-ledger routing, transport, replay, provenance, and local naming for BEDC.Derived.InscriptionEventNoveltyUp.

Chapter 7464

A Concrete Naming Certificate for $\mathsf{PositiveRealNormalization}^{\uparrow}$

Bishop and Bridges constructive analysis treats a positive radius as usable only after its lower-bound witness, rational readback, and consumer boundary have been made explicit. The $\mathsf{PositiveRealNormalization}^{\uparrow}$ packet records this normalization handoff over the positive-real source of chapter 1587, the dyadic comparison substrate of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the metric-radius consumers of chapter 57. It names a finite choice-free route from an apartness-backed positive real to a normalized dyadic minorant without importing host positivity, quotient equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7464.1 (Positive-real normalization carrier)**.** *A* $\mathsf{PositiveRealNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, A, D, W, Q, M, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{PositiveReal}^{\uparrow}$ *packet, including its sealed* $\mathsf{Real}^{\uparrow}$ *row and apartness-from-zero evidence.*
2. *A is the displayed apartness row read from R; it is the only positivity source admitted by the carrier.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger carried by A.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window used to inspect the real-name source.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the stream window W.*
6. *M is the normalized dyadic minorant row, recording one positive dyadic radius below the apartness radius exposed by D.*
7. *S is the downstream scale row that lets metric or radius-ledger consumers read M as a finite radius token.*
8. *H records componentwise* hsame *transport for $R, A, D, W, Q, M, S, C, P, N$.*
9. *C records displayed* Cont *replay from a positive-real request through the dyadic ledger, finite window, readback, normalized minorant, and downstream scale row.*

10. *P is the* Pkg *provenance over* $\mathsf{PositiveRealNormalization}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveRealNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, A, D, W, Q, M, S, H, C, P, N$. It has no coordinate for host positivity, trichotomy, quotient real equality, selected positive representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7464.2 (Positive-real normalization NameCert obligations)**.** *For every accepted* PositiveRealNormalizatio *carrier*

$$K = (R, A, D, W, Q, M, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PositiveRealNormalization}^{\uparrow}}$ *surface consists exactly of these finite obligations:*

1. *carrier admission for the positive-real source, apartness row, dyadic radius ledger, stream window, regular readback, normalized dyadic minorant, downstream scale row, transport, replay, provenance, and local name;*
2. *positivity-source confinement, requiring every normalization read to enter through the displayed* $\mathsf{PositiveReal}^{\uparrow}$ *packet R and its apartness row A;*
3. *dyadic minorant exactness, requiring M to be read from the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D transported with the carrier;*
4. *regular-readback stability, requiring W and Q to remain attached to the real-name source whenever M is transported or replayed;*
5. *consumer boundary, requiring metric or radius-ledger consumers to receive only the normalized dyadic token M together with S, H, C, P, N.*

Proof. Project the carrier of Definition 7464.1. The analytic rows are R, A, D, W, Q, M, S, and the structural rows are H, C, P, N.

The positivity-source obligation follows from the first two coordinates: the source is the displayed $\mathsf{PositiveReal}^{\uparrow}$ packet and the apartness row A is read from it. There is no separate host-order or trichotomy coordinate to inspect.

The dyadic minorant obligation reads the positive radius ledger D before the normalized row M is exposed. Thus the minorant is a finite $\mathsf{DyadicRatCore}^{\uparrow}$ comparison token, not a selected real representative.

The stability and boundary obligations use H and C. Transport and replay move R, A, D, W, Q, M, S together, so downstream metric or radius-ledger consumers see only the normalized dyadic token and its displayed support rows. The excluded host principles are absent from the carrier inventory. □

Theorem 7464.3 (Positive-real normalization dyadic minorant)**.** *Every accepted* $\mathsf{PositiveRealNormalization}^{\uparrow}$ *packet exposes a positive dyadic minorant only through the route*

$$\mathsf{PositiveReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ M.$$

The minorant row M is below the apartness radius displayed by D and is transported only with the same positive-real source, finite stream window, regular readback, replay, provenance, and local name. It exports no host positivity predicate, quotient real equality, selected representative, trichotomy split, or ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use the obligation surface of Definition 7464.2. Positivity-source confinement places every read at R and A, while dyadic minorant exactness places M downstream of D.

The finite observation rows W and Q keep the source real-name read attached to the same packet. Componentwise transport through H and replay through C preserve the displayed route, so the minorant cannot be detached from its source rows.

Since no excluded host-level datum is a carrier coordinate, the minorant row exports only the finite dyadic token named by M and its support rows. □

Theorem 7464.4 (Positive-real normalization RegSeqRat stability)**.** *For every accepted* $\mathsf{PositiveRealNormalization}^{\uparrow}$ *carrier* $K = (R, A, D, W, Q, M, S, H, C, P, N)$*, replacing the real-name observations by componentwise* hsame*-transported* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows preserves the same normalized minorant whenever the transported packet keeps* $R, A, D, M, S, H, C, P, N$ *displayed. The stabilized read remains a finite route through* $\mathsf{PositiveReal}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with the regular-readback stability obligation in Definition 7464.2. It requires W and Q to remain attached to the same positive-real source whenever the normalized minorant is moved.

Apply the transport row H to the stream window and regular readback, and use C to replay the same positive-radius request through the transported data. The dyadic ledger D and minorant row M are moved with the packet, so the normalized token is unchanged as a carrier row.

The conclusion is therefore the same finite route, not a quotient assertion about real names or a host equality of positive reals. □

Theorem 7464.5 (Positive-real normalization real-consumer boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*, or radius-ledger consumer of an accepted* $\mathsf{PositiveRealNormalization}^{\uparrow}$ *carrier receives only the sealed positive-real source, the apartness row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *minorant ledger, the* $\mathsf{StreamName}^{\uparrow}$ *window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the normalized radius row, and the support rows* H, C, P, N*. Such a consumer receives no host positivity predicate, quotient real equality, selected positive representative, trichotomy witness, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read the consumer boundary obligation from Definition 7464.2. A consumer may inspect the source packet R, the apartness and dyadic rows A, D, the finite observation rows W, Q, the normalized token M, the scale row S, and the structural rows H, C, P, N.

The sibling anchors identify the permitted route: $\mathsf{PositiveReal}^{\uparrow}$ supplies positivity by apartness, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the positive dyadic token, $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ supply finite readback, $\mathsf{Real}^{\uparrow}$ supplies the terminal seal, and $\mathsf{Met}^{\uparrow}$ consumes only the displayed radius token.

No remaining coordinate stores a host positivity predicate, quotient equality, selected representative, trichotomy, choice selector, or completeness principle. Those data cannot be projected from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveRealNormalization}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveRealNormalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7464.1, Definition 7464.2, Definition 7464.3, Definition 7464.4, and Definition 7464.5 seed the finite positive-radius normalization route from PositiveRealUp through DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, and MetricSpaceUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveRealNormalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host positivity, quotient real equality, selected positive representatives, trichotomy, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positivity-source confinement, dyadic minorant exactness, RegSeqRat stability, real-consumer boundary, transport, replay, provenance, and local naming for BEDC.Derived.PositiveRealNormalizationUp.

Constructive story: A PositiveRealNormalization$^{\uparrow}$ packet is generated from a PositiveReal source, an apartness row, a DyadicRatCore radius ledger, a StreamName window, a RegSeqRat readback, a normalized dyadic minorant, a downstream scale row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7465

A Concrete Naming Certificate for DyadicClosedIntervalFiniteNet$^{\uparrow}$

Following Bishop and Bridges, the DyadicClosedIntervalFiniteNet$^{\uparrow}$ packet records the finite dyadic data used to read a closed interval by endpoint rows and then expose a finite net at one unary precision. It sits beside the dyadic arithmetic core of chapter 291, the finite-window reader of chapter 126, the regular rational handoff of chapter 301, the terminal real seal of chapter 38, the metric carrier of chapter 4230, and the compact finite-net route of chapter 3471. The certificate names the interval finite-net surface as displayed BEDC packet data, not as open-cover compactness, quotient real equality, selected endpoints, or ambient completeness.

Definition 7465.1 (Dyadic closed-interval finite-net carrier)**.** *A* DyadicClosedIntervalFiniteNet$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, q, G, F, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *L, U are the lower and upper dyadic closed-interval endpoint rows, sourced through* DyadicRatCore$^{\uparrow}$*.*
2. *q is the unary precision row at which the interval is inspected.*
3. *G is the endpoint-grid row listing the dyadic grid points between L and U at precision q.*
4. *F is the finite-net row naming the selected grid points and their metric-radius witnesses.*
5. *S is the* StreamName$^{\uparrow}$ *readback row for endpoint and grid windows.*
6. *Q is the* RegSeqRat$^{\uparrow}$ *readback row that packages the same endpoint and net observations as regular rational data.*
7. *R is the* Real$^{\uparrow}$ *seal row, available only after L, U, q, G, F, S, Q have been displayed.*
8. *H stores componentwise* hsame *transport for endpoints, precision, endpoint grid, finite net, readback rows, real seal, replay, provenance, and local naming.*
9. *C stores displayed* Cont *replay from the endpoint rows to the grid, from the grid to the finite net, and from the readback rows to the real-facing seal.*
10. *P is the* Pkg *provenance over* DyadicClosedIntervalFiniteNet$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* Met$^{\uparrow}$*,* HeineBorelFiniteNet$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, U, q, G, F, S, Q, R, H, C, P, N$. It has no coordinate for a selected real endpoint outside the dyadic rows, quotient real equality, open-cover compactness, countable choice, or ambient metric completeness.

Theorem 7465.2 (Dyadic closed-interval finite-net NameCert obligations)**.** *For an accepted* DyadicClosedIntervalFi *carrier $I = (L, U, q, G, F, S, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}}$ *obligations are exactly carrier admission, endpoint order visibility, unary precision classification, endpoint-grid coverage, finite-net row coverage,* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal factorization, componentwise transport, displayed replay, package provenance, and local naming. Every obligation is discharged by the finite route*

$$L, U \longmapsto q \longmapsto G \longmapsto F \longmapsto S, Q \longmapsto R$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 7465.1. The endpoint rows L, U, precision row q, grid row G, finite-net row F, readback rows S, Q, and seal row R are the only mathematical rows available to the classifier.

Endpoint order visibility and precision classification are read before any net row is consumed. The endpoint rows are dyadic arithmetic data, and the unary precision row fixes the scale at which the endpoint grid is formed.

Endpoint-grid coverage and finite-net row coverage are then finite packet checks. The row G lists the displayed dyadic grid, while F names the finite selected grid points and their metric-radius witnesses.

The readback and seal clauses are factorization clauses. The rows S, Q carry the stream and regular rational readings of the same endpoint-grid packet, and R is reached only through those rows. Transport, replay, provenance, and local naming preserve that packet through H, C, P, N without adding quotient equality, selected endpoints, open-cover compactness, countable choice, or ambient completeness. □

Theorem 7465.3 (Dyadic closed-interval finite-net sibling route)**.** *Every* $\mathsf{Met}^{\uparrow}$, $\mathsf{HeineBorelFiniteNet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}$ *packet must first read the dyadic endpoint rows L, U, unary precision q, endpoint-grid row G, finite-net row F,* $\mathsf{StreamName}^{\uparrow}$ *row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q,* $\mathsf{Real}^{\uparrow}$ *seal row R, and the structural rows H, C, P, N. No consumer may replace this route by open-cover compactness, quotient real equality, selected real endpoints, countable choice, or ambient metric completeness.*

Proof. Begin with the accepted carrier of Definition 7465.1. Its sibling-facing rows are exactly the dyadic endpoints, unary precision, endpoint grid, finite net, stream readback, regular rational readback, real seal, and structural rows displayed there.

The metric and finite-net consumers read G and F only after the dyadic endpoints and precision have been exposed. Thus a $\mathsf{Met}^{\uparrow}$ radius witness or $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ handoff is tied to the same endpoint-grid packet.

The regular rational and real consumers read Q and R only after the stream readback row S and finite-net row F are present. Hence the real-facing route factors through the displayed dyadic finite-net data rather than through quotient equality or selected limits.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite packet, so they cannot create an additional endpoint selector, open-cover compactness witness, choice principle, or ambient completeness row. □

Falsifiable prediction: Every $\mathsf{Real}^{\uparrow}$ or $\mathsf{HeineBorelFiniteNet}^{\uparrow}$ read from a $\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}$ packet factors through the displayed dyadic endpoints, unary precision, endpoint grid, finite net, StreamName readback, RegSeqRat readback, Real seal, componentwise transport, continuation replay, provenance, and local naming before the finite net is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, metricspace, heineborel-finite-net: $\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic endpoints, unary precision, endpoint-grid rows, finite net rows, readback rows, Real seal, componentwise transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}$ packet is generated from dyadic closed-interval endpoints, a unary precision request, endpoint-grid rows, finite net rows, StreamName and RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7465.1, Definition 7465.2, and Definition 7465.3 seed the finite dyadic closed-interval net packet for one displayed precision.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicClosedIntervalFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient real equality, selected endpoints, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint order visibility, precision classification, endpoint-grid coverage, finite-net row coverage, readback factorization, Real-seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.DyadicClosedIntervalFiniteNetUp.

Chapter 7466

A Concrete Naming Certificate for $\mathsf{KreinRutman}^{\uparrow}$

Following Krein and Rutman, the $\mathsf{KreinRutman}^{\uparrow}$ packet records the finite NameCert surface for a compact positive operator acting on a cone inside an ordered Banach-style environment. It sits over the Banach carrier of chapter 90, the compact-operator surface of chapter 1952, the scalar $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the compact-convex spectral sibling of chapter 7460. The packet names the dependency route for a positive eigenvector handoff; it does not assert a host spectral theorem, a chosen spectral radius, or a completed cone interior principle.

Definition 7466.1 (Krein–Rutman carrier)**.** *A* $\mathsf{KreinRutman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, C, T, Q, \rho, V, H, R, P, N)$$

with the following displayed rows:

1. *B is the ordered Banach row, carrying the normed vector carrier, order relation, cone membership, and real scalar reads used by the packet.*
2. *C is the positive cone row, exposing finite cone-membership, nonzero, order, and normalization tests.*
3. *T is the compact positive operator row, read through* $\mathsf{CompactOperator}^{\uparrow}$*, recording the finite operator graph windows and the proof rows that $T(C) \subseteq C$.*
4. *Q is the compact orbit-window row, listing the finitely many normalized iterate, image, and enclosure rows inspected by the certificate.*
5. *ρ is the spectral-bound row, sealed through* $\mathsf{Real}^{\uparrow}$*, naming only the displayed radius comparison and not a selected host supremum.*
6. *V is the positive-eigenvector handoff row, consisting of a displayed nonzero cone element, its normalized readback, and the finite equality route asserting that T carries it to the scalar multiple named by ρ.*
7. *H records componentwise* hsame *transport for B, C, T, Q, ρ, V and for the replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from ordered Banach and cone reads through the compact positive operator, compact orbit window, spectral-bound row, and positive-eigenvector handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{KreinRutman}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{KreinMilmanCompactConvex}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{KreinRutman}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, C, T, Q, \rho, V, H, R, P, N$. It has no coordinate for an unrestricted spectrum, a host compactness theorem, a selected cone interior point, a quotient eigenline equality, countable choice, or ambient real completeness.

Theorem 7466.2 (Krein–Rutman NameCert obligations)**.** *For every accepted* $\mathsf{KreinRutman}^{\uparrow}$ *carrier*

$$K = (B, C, T, Q, \rho, V, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KreinRutman}^{\uparrow}}$ *surface consists exactly of ordered Banach admission for B, positive cone admission for C, compact positive operator admission for T, compact orbit-window exposure for Q, real spectral-bound sealing for ρ, positive-eigenvector handoff for V, componentwise* hsame *transport through H, displayed* Cont *replay through R,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7466.1. The visible rows are precisely the ordered Banach row, cone row, compact positive operator row, compact orbit window, spectral-bound row, positive-eigenvector handoff row, transport, replay, provenance, and local naming.

The operator route is finite. The row T records only compact positive operator graph windows and cone-preservation rows, while Q records only the normalized orbit and enclosure data admitted by the certificate.

The spectral read is also displayed. The row ρ is sealed through $\mathsf{Real}^{\uparrow}$, and the handoff row V records a nonzero cone element together with the finite route asserting the scalar-multiple read against T and ρ.

Finally H, R, P, N transport, replay, source, and name the same rows. Since the carrier lacks coordinates for unrestricted spectra, host compactness, selected cone interiors, quotient eigenlines, countable choice, and ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 7466.3 (Krein–Rutman positive-eigenvector handoff)**.** *Every consumer that reads an accepted* $\mathsf{KreinRutman}^{\uparrow}$ *packet as positive-eigenvector evidence must first expose the ordered Banach row B, positive cone row C, compact positive operator row T, compact orbit window Q, real spectral-bound row ρ, positive-eigenvector handoff row V, componentwise* hsame *rows, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The handoff exports only this finite BEDC route and does not export a host spectral-radius theorem, an unrestricted eigenbasis, a quotient eigenline, a chosen cone interior, or a completeness principle.*

Proof. Start from the NameCert obligations of Definition 7466.2. They force any accepted read through the rows $B, C, T, Q, \rho, V, H, R, P, N$.

The positive-eigenvector part is reached only after the operator and cone rows are visible. The cone row C supplies nonzero and positivity tests, while T supplies the compact positive operator windows that preserve the displayed cone.

Next read Q, ρ, V. The compact orbit window provides the finite approximation and enclosure route, the real spectral-bound row seals the scalar comparison, and V records the displayed vector handoff against that same operator and scalar.

The structural rows H, R, P, N preserve the same finite route for downstream consumers. No listed coordinate is a host spectrum, unrestricted eigenbasis, quotient eigenline, selected cone interior, or ambient completeness principle, so the handoff is exactly the finite positive-eigenvector certificate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{KreinRutman}^{\uparrow}}$.

Constructive story: A $\mathsf{KreinRutman}^{\uparrow}$ packet is generated from ordered Banach, positive cone, compact positive operator, compact orbit-window, real spectral-bound, positive-eigenvector handoff, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KreinRutman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7466.1, Definition 7466.2, and Definition 7466.3 seed the compact positive operator NameCert surface for the finite positive-eigenvector handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KreinRutman}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Krein–Rutman theorem, spectral-radius existence, unrestricted eigenbasis, quotient eigenline, chosen cone interior, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact positive operator routing, cone preservation, spectral-bound sealing, positive-eigenvector handoff, transport, replay, provenance, and local naming for $B, C, T, Q, \rho, V, H, R, P, N$.

Chapter 7467

A Concrete Naming Certificate for $\mathsf{UpperSemicontinuity}^{\uparrow}$

Following Bourbaki and Kelley on topological threshold tests and Bishop–Bridges constructive real analysis, the $\mathsf{UpperSemicontinuity}^{\uparrow}$ packet records upper semicontinuity as finite BEDC NameCert data. It sits beside the real-name carrier of chapter 38, the Real-and-Completion lower-threshold sibling of chapter 3935, and the epigraph boundary of chapter 6224. The packet names only displayed upper-threshold rows for real-valued reads; it is not a host theorem about limits, a selection principle for suprema, a countable-choice schedule, or an ambient completeness assertion for $\mathsf{Real}^{\uparrow}$.

Definition 7467.1 (UpperSemicontinuity carrier)**.** *An* $\mathsf{UpperSemicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, T, F, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the source row whose inspected points are named through finite BEDC histories rather than host points.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *threshold row whose basic neighborhoods are displayed before an upper cut is accepted.*
3. *F is the value-row handoff for the real-valued map under inspection.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting the source and value windows used by each threshold query.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that exposes the real-name approximants consumed by the threshold test.*
6. *A is the upper-threshold ledger, recording finite evidence for requests of the form $f(x) < q$ and the corresponding open upper-cut route.*
7. *H records componentwise* hsame *transport for source, topology, value, schedule, readback, upper-threshold, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an upper-threshold request through $X, T, F, W, R, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UpperSemicontinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows, with sibling pointers to the lower-semicontinuity and epigraph packets.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperSemicontinuity}^{\uparrow}}$ *row.*

The carrier has no coordinate for semantic limits, selected suprema, quotient equality of functions or real names, countable choice, host topological completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7467.2 (UpperSemicontinuity NameCert obligations)**.** *For every accepted* $\mathsf{UpperSemicontinuity}^{\uparrow}$ *carrier $U = (X, T, F, W, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UpperSemicontinuity}^{\uparrow}}$ *surface consists exactly of five obligation families:*

1. *carrier admission for the displayed source, topology, value, schedule, real-readback, and upper-threshold rows;*
2. *upper-threshold exposure through A, requiring each request $f(x) < q$ to be read only after X, T, F, W, R are visible;*
3. *real-name sealing through R and the sibling* $\mathsf{Real}^{\uparrow}$ *boundary of chapter 38;*
4. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
5. Pkg *provenance and local naming through P and N, including the comparison surface beside chapter 3935 and chapter 6224.*

Proof. Project the carrier of Definition 7467.1. The only analytic rows are X, T, F, W, R, A, so carrier admission and threshold exposure must be read from those displayed coordinates.

The upper-threshold row is not a hidden limit principle. A request $f(x) < q$ first exposes the source and topology rows X, T, then the value handoff F, then the stream schedule and regular-rational readback W, R, and only then the upper ledger A.

The structural rows preserve the same route. Transport through H and replay through C move the displayed rows componentwise, while P and N source and name the packet without adding a second mathematical coordinate.

Thus the five listed obligation families exhaust the local NameCert surface. Since the excluded limit, supremum-selection, quotient, choice, host-completeness, and ambient-completeness principles are absent from the carrier, no accepted read may recover them. □

Theorem 7467.3 (UpperSemicontinuity real seal scope)**.** *Every Real-facing consumer of an accepted* $\mathsf{UpperSemicontinuity}^{\uparrow}$ *packet reads the upper-threshold route through*

$$X, T, F, W, R, A \longmapsto H, C, P, N.$$

The route may compare its upper-cut ledger with the lower-threshold and epigraph siblings, but it reaches $\mathsf{Real}^{\uparrow}$ *only through displayed real-name readback rows and local NameCert provenance. It does not supply semantic limsup data, host limits, selected suprema, countable choice, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the threshold request. The source and topology rows X, T fix the finite neighborhood surface, and the value row F fixes the displayed map read.

Next use the Real-facing readback. The stream schedule W selects the finite windows, while R exposes regular-rational approximants at the real-name boundary. The upper-threshold ledger A is read only against those displayed rows.

Finally apply the structural surface. The rows H, C, P, N transport, replay, source, and name the same packet, with sibling comparison pointers to lower semicontinuity and epigraph data only as provenance. Because no excluded principle appears as a row, the Real-facing seal remains scoped to the displayed $\mathsf{UpperSemicontinuity}^{\uparrow}$ carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{UpperSemicontinuity}^{\uparrow}}$.

Constructive story: An $\mathsf{UpperSemicontinuity}^{\uparrow}$ packet is generated from source rows, topology threshold rows, real-valued map handoffs, StreamName schedules, RegSeqRat readbacks, upper-threshold ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UpperSemicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7467.1, Definition 7467.2, and Definition 7467.3 seed the finite upper-threshold packet over displayed topology, real-name readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UpperSemicontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close semantic limsup data, host limits, selected suprema, countable choice, quotient equality of functions or real names, host topological completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-threshold exposure, real-name readback, transport replay, provenance, local naming, and non-escape for BEDC.Derived.UpperSemicontinuityUp.

Chapter 7468

A Concrete Naming Certificate for $\mathsf{ParallelReduction}^{\uparrow}$

Following Barendregt and Takahashi on parallel beta reduction, the $\mathsf{ParallelReduction}^{\uparrow}$ packet records the finite simultaneous-contraction surface used by confluence arguments before any quotient of lambda terms is exposed. It sits after the lambda-calculus carrier of chapter 200 and beside the MetaCIC parallel-diamond frontier of chapter 4238. The packet gives the traditional route through reflexive constructor cases, simultaneous redex contraction, residual bookkeeping, transport, replay, provenance, and local naming; it does not assert full Church–Rosser, subject reduction, quotient equality of terms, global normalization, or kernel consistency.

Definition 7468.1 (Parallel reduction carrier)**.** *A* $\mathsf{ParallelReduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, B, A, S, R, J, H, C, K, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{LambdaCalc}^{\uparrow}$ *term-packet row supplying the source and target term syntax.*
2. *B is the one-step beta row whose redex witnesses may be contracted simultaneously.*
3. *A is the alpha-stability row keeping binder names and capture-avoidance ledgers visible during the contraction.*
4. *S is the simultaneous-contraction schedule, including reflexive constructor cases for variables, abstraction, and application.*
5. *R is the residual ledger recording which redex rows survive, disappear, or are copied across the displayed constructor route.*
6. *J is the local join candidate row used by downstream diamond consumers, without asserting that every peak has already been joined.*
7. *H records componentwise* hsame *transport for the term, beta, alpha, schedule, residual, join, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay through the same rows.*
9. *K is the* Pkg *provenance over* $\mathsf{ParallelReduction}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ParallelReduction}^{\uparrow}}$ *evidence row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for quotient term equality, subject reduction, evaluator equality, global normalization, full Church–Rosser, or MetaCIC kernel consistency.

Theorem 7468.2 (Parallel reduction NameCert obligations)**.** *For every accepted* $\mathsf{ParallelReduction}^{\uparrow}$ *carrier* $P = (T, B, A, S, R, J, H, C, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ParallelReduction}^{\uparrow}}$ *surface consists exactly of carrier admission, lambda-term exposure, one-step beta row visibility, alpha-stable simultaneous contraction, residual ledger preservation, local join-candidate exposure, componentwise transport, displayed replay, provenance, and local naming. A MetaCIC confluence consumer may read this packet as the traditional parallel-reduction surface feeding chapter 4238, but it cannot read it as full Church–Rosser, subject reduction, quotient equality of terms, global normalization, or kernel consistency.*

Proof. Carrier admission is projection from Definition 7468.1. The rows $T, B, A, S, R, J, H, C, K, N$ are the whole visible surface, and the lambda-calculus source row keeps the term syntax inside the existing carrier of chapter 200.

The simultaneous-contraction obligation reads B, A, S together. The beta row supplies the redex witnesses, the alpha row keeps binder transport and capture-avoidance visible, and the schedule row records the constructorwise reflexive and contraction cases.

The residual and join-facing obligations then read R and J. These rows expose the data a parallel-diamond consumer may inspect, while retaining the conditional frontier: the packet names candidate residuals and local joins without asserting that all closed peaks have been joined.

Finally, H, C, K, N transport, replay, source, and certify exactly the displayed rows. Since quotient equality, subject reduction, evaluator equality, global normalization, full Church–Rosser, and kernel consistency are absent from the carrier, none of those conclusions is exported by the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ParallelReduction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ParallelReduction}^{\uparrow}$ packet is generated from lambda-term syntax rows, one-step beta rows, alpha-stability rows, simultaneous-contraction schedules, residual ledgers, local join candidates, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ParallelReduction}^{\uparrow}}$, seed)

Scope closed: Definition 7468.1 and Definition 7468.2 seed the finite parallel beta-reduction route consumed by MetaCIC parallel-diamond frontier packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ParallelReduction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full Church–Rosser, subject reduction, quotient equality of terms, global normalization, kernel consistency, Lean verification, or bridge checking for $\mathsf{ParallelReduction}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, simultaneous-contraction schedule exactness, residual ledger preservation, local join-candidate confinement, transport, replay, provenance, and local naming for BEDC.Derived.ParallelReductionUp.

Chapter 7469

A Concrete Naming Certificate for $\mathsf{ClosedInductionTrace}^{\uparrow}$

The $\mathsf{ClosedInductionTrace}^{\uparrow}$ packet realizes the closed-observation and induction-boundary surface of chapter 9393 as finite NameCert data. It sits beside the finite trace GAP packet of chapter 3353, the inscription point packet of chapter 610, and the typed GAP socket taxonomy of chapter 1240. The packet records observation rows, input-boundary rows, inscription rows, replay rows, and non-escape rows without installing a substrate-internal induction rule.

Definition 7469.1 (Closed induction trace carrier)**.** *A* $\mathsf{ClosedInductionTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (O, F, G, B, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the closed observation row: a finite family of records already present in the observational substrate.*
2. *F is the finite verification trace row, recording observed base and successor checks only as bounded data.*
3. *G is the induction GAP row, marking the missing universal closure without treating it as an accepted substrate rule.*
4. *B is the input-boundary row identifying where a forward-binding belief would be supplied from outside the closed observation surface.*
5. *S is the inscription row connecting that boundary to an inscription-point consumer without adding a new proof rule.*
6. *R is the replay row that shows which finite observations can be read again by a downstream audit consumer.*
7. *E is the non-escape row blocking a read from O, F, G, B, S, R to a universal induction theorem inside the substrate.*
8. *H records componentwise* hsame *transport for the observation, trace, GAP, boundary, inscription, replay, non-escape, provenance, and naming rows.*
9. *C records displayed* Cont *replay through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{ClosedInductionTrace}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and the sibling GAP and inscription packets.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedInductionTrace}^{\uparrow}}$ *evidence row.*

The carrier has no coordinate for substrate-internal induction, unbounded universal quantification, countable choice, host natural-number recursion beyond displayed rows, or a hidden source of mathematical belief.

Theorem 7469.2 (Closed induction trace NameCert obligations)**.** *For every accepted* $\mathsf{ClosedInductionTrace}^{\uparrow}$ *carrier* $I = (O, F, G, B, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClosedInductionTrace}^{\uparrow}}$ *surface consists exactly of closed observation exposure, finite trace admission, induction-GAP retention, input-boundary naming, inscription-row visibility, replay confinement, non-escape, componentwise transport, displayed replay, provenance, and local naming. The obligations realize closed observation, input boundary, inscription, replay, and non-escape rows as finite data; they do not provide a substrate-internal induction schema.*

Proof. Carrier admission is projection from Definition 7469.1. The observation row and finite trace row provide only bounded records already present in the closed observational surface.

The boundary step reads G, B, S together. The GAP row keeps the missing universal closure visible, the boundary row names the outside-supply site, and the inscription row records the local reception point without adding a rule to the substrate.

Replay and non-escape then read R, E. A downstream audit may replay displayed observations and trace rows, but the non-escape row blocks replacement of those finite records by a universal induction theorem.

Finally, H, C, P, N transport, replay, source, and name the same finite rows. Since substrate-internal induction, unbounded universal quantification, countable choice, host recursion beyond displayed rows, and hidden belief supply are absent from the carrier, none can be exported by the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{ClosedInductionTrace}^{\uparrow}$ packet is refuted if a consumer erases the induction GAP row or reads the input-boundary row as an internal induction rule while preserving the same finite observation trace.

Independence witness: finite-trace-induction-gap, inscriptionpoint, typedgapsockettaxonomy, closedobservationsystem: none is bijective to $\mathsf{ClosedInductionTrace}^{\uparrow}$ because this carrier jointly binds closed observation, finite trace, induction GAP, input boundary, inscription, replay, non-escape, transport, provenance, and local naming rows.

The Lean follow-up must provide explicit Nontrivial $\mathsf{ClosedInductionTrace}^{\uparrow}$ and FieldFaithful ClosedInductionTrace instances before a TasteGate theorem can accept the displayed carrier. The nontrivial witness must separate a packet retaining G, B, S, E from one that erases the induction boundary, and the field-faithfulness witness must preserve $O, F, G, B, S, R, E, H, C, P, N$ as distinct rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedInductionTrace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedInductionTrace}^{\uparrow}$ packet is generated from closed observation rows, finite verification traces, induction GAP rows, input-boundary rows, inscription rows, replay rows, non-escape rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClosedInductionTrace}^{\uparrow}}$, seed)

Scope closed: Definition 7469.1 and Definition 7469.2 seed the finite closed-induction trace route from observation through boundary, inscription, replay, and non-escape rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClosedInductionTrace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close substrate-internal induction, unbounded universal quantification, countable choice, host recursion beyond displayed rows, hidden belief supply, Lean verification, or bridge checking for ClosedInductionTrace$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, induction-GAP retention, input-boundary naming, inscription-row visibility, replay confinement, non-escape, Nontrivial and FieldFaithful TasteGate instances, transport, provenance, and local naming for BEDC.Derived.ClosedInductionTraceUp.

Chapter 7470

A Concrete Naming Certificate for MetaCICBetaRedexSpine$^{\uparrow}$

The MetaCICBetaRedexSpine$^{\uparrow}$ packet realizes the beta-redex spine branch of chapter 9384 as finite NameCert data over the checked MetaCIC beta reduction grammar. It sits beside the beta-step boundary of chapter 754, the beta-reduction audit trail of chapter 879, the beta critical-pair packet of chapter 881, and the subject-reduction boundary of chapter 721. The packet records the displayed redex spine and contraction handoff without claiming subject reduction, confluence, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 7470.1 (MetaCIC beta redex spine carrier)**.** *A* MetaCICBetaRedexSpine$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, \Gamma, t, u, \beta, \chi, H, C, P, N)$$

with the following displayed rows:

1. *M is the MetaCIC* Term *row naming the source term, its visible application spine, and the binder depth at which the inspected redex occurs.*
2. *Γ is the local context and binder-window row, recording the finite variables, displayed domains, and shift boundary available to the contraction.*
3. *t is the redex row, exposing the displayed* app(lam *dom body*) *arg site, its subterm address, and the surrounding spine segments.*
4. *u is the contracted target row, naming the* substitute 0 *arg body result and the reassembled target term inside the same spine.*
5. *β is the* BetaStep *and* BetaConv *row, recording the one-step contraction and the common-reduct conversion interface available after the step.*
6. *χ is the obstruction-retention row for substitution preservation, dependent codomain stability, binder-domain subject reduction, subject reduction, confluence, evaluator equality, quotient syntax equality, and kernel consistency.*
7. *H records componentwise* hsame *transport for $M, \Gamma, t, u, \beta, \chi$ and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source* Term *and binder window through the redex address, contraction target,* BetaStep *witness,* BetaConv *handoff, and obstruction-retention row.*

9. *P is the* Pkg *provenance over* $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$, Term, BetaStep, BetaConv, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICBetaRedexSpine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, \Gamma, t, u, \beta, \chi, H, C, P, N$. It has no coordinate for an unbounded evaluator, a subject-reduction theorem, a full confluence proof, quotient equality of terms, or kernel consistency.

Theorem 7470.2 (MetaCIC beta redex spine NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$ *carrier*

$$S = (M, \Gamma, t, u, \beta, \chi, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICBetaRedexSpine}^{\uparrow}}$ *surface consists exactly of source* Term *admission for M, local binder-window admission for Γ, redex-site exposure for t, contraction-target exposure for u,* BetaStep *and* BetaConv *routing through β, obstruction retention through χ, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7470.1. The displayed rows are $M, \Gamma, t, u, \beta, \chi, H, C, P, N$.

The syntax rows come first. The source term row M, context row Γ, redex row t, and target row u name the inspected application-lambda site, the binder window, and the reassembled contracted term.

The reduction row is then read through β. It records the BetaStep contraction and the BetaConv handoff made available by the beta conversion interface, while χ keeps the subject-reduction and confluence endpoints outside the packet.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for an evaluator, quotient syntax equality, subject reduction, full confluence, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 7470.3 (MetaCIC beta redex spine contraction handoff)**.** *Every consumer that reads an accepted* $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$ *packet as a beta contraction handoff must expose the source* Term *row, binder-window row, displayed redex site, contracted target,* BetaStep *witness,* BetaConv *interface, obstruction-retention row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before using the handoff in subject-reduction or confluence work. The handoff supplies a finite contraction spine only; it does not discharge substitution preservation, dependent-codomain stability, binder-domain preservation, subject reduction, confluence, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Start from the NameCert obligations of Definition 7470.2. They force every accepted contraction read through $M, \Gamma, t, u, \beta, \chi, H, C, P, N$.

The redex and contraction rows determine the local spine. The row t names the application-lambda site and its address, while u names the term obtained by the displayed substitution and reassembly route.

The beta interface is finite. The row β records the one-step BetaStep witness and the available BetaConv comparison route, while χ keeps the substitution, dependent-codomain, binder-domain, subject-reduction, confluence, evaluator, quotient, and consistency obligations visible as non-exported endpoints.

Finally the structural rows transport, replay, source, and name the same finite contraction spine. Thus downstream subject-reduction and confluence packets may consume the handoff as a local beta-redex route, but not as any of the stronger typing or semantic theorems. □

Falsifiable prediction: If the redex-site row t is removed, two packets with different application-lambda addresses but the same contracted target can be classified together; if the obstruction-retention row χ is removed, the contraction handoff can be misread as subject-reduction evidence.

Independence witness: betastepboundary, betareductionauditrail, beta_critical_pair, typedbetacongruencetrigger, and metacic_subjectreductionboundary are nearby MetaCIC siblings, but none is bijective to $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$ because this packet jointly carries the source term spine, binder window, redex address, contracted target, BetaStep witness, BetaConv route, obstruction retention, transport, replay, provenance, and local naming.

Lean TasteGate support for $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$ will provide Nontrivial and FieldFaithful instances so the source term, binder window, redex site, contraction target, beta relation, obstruction, transport, replay, provenance, and local naming fields remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICBetaRedexSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICBetaRedexSpine}^{\uparrow}$ packet is generated from MetaCIC Term, binder-window, redex-site, contracted-target, BetaStep, BetaConv, obstruction-retention, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICBetaRedexSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7470.1, Definition 7470.2, and Definition 7470.3 seed the finite beta-redex spine surface over Term, BetaStep, BetaConv, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICBetaRedexSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close substitution preservation, dependent-codomain stability, binder-domain preservation, subject reduction, confluence, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, redex-site exactness, contraction-target exactness, BetaStep routing, BetaConv routing, obstruction retention, transport, replay, provenance, Nontrivial, FieldFaithful, and local naming for $M, \Gamma, t, u, \beta, \chi, H, C, P, N$.

Chapter 7471

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$

Following Bishop and Bridges on metric completions, located subsets, and regular real names, the $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$ packet records the finite route by which a metric source is embedded into a displayed located completion without quotienting Cauchy sequences or selecting host limits. It sits beside the metric carrier of chapter 57, the completion packet of chapter 95, the metric-completion service of chapter 1506, the separated-metric reflection of chapter 1790, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the embedding as finite NameCert data; it is not a quotient completion, a host equality principle, a choice-selected limit, trichotomy, or an appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7471.1 (Bishop located completion embedding carrier)**.** *A* $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(M, L, D, E, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, exposing the* $\mathsf{Met}^{\uparrow}$ *distance, symmetry, triangle, and zero-distance comparison used by the embedding.*
2. *L is the located positive-radius row, recording the finite rational-radius evidence that a source point has a displayed neighbourhood before any completion read is made.*
3. *D is the dense completion route, carrying the* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{MetricCompletion}^{\uparrow}$ *approach map from the source metric into the completion packet.*
4. *E is the embedding graph row, pairing each inspected source point with its completion name and recording graph membership before equality is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row, exposing only regular rational distance reads and the terminal real seal of the embedded point.*
6. *H records componentwise* hsame *transport for the metric source, located-radius row, dense route, embedding graph, readback, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a source-point request through located-radius inspection, dense-route lookup, embedding-graph readback, regular rational read, and real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{SeparatedMetricReflection}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for quotient completions, host equality of representatives, choice-selected limits, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (definition) `BEDC.Derived.BishopLocatedCompletionEmbeddingUp.BishopLocatedCompletionEmbeddingCarrier`

Theorem 7471.2 (Bishop located completion embedding NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$ *carrier* $(M, L, D, E, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompl}}$ *surface consists exactly of carrier admission for the metric source, located positive-radius evidence, dense completion route, embedding graph, regular rational and real readback, componentwise transport, displayed continuation replay, provenance, and local naming. Every embedding read must pass through* $M, L, D, E, R, H, C, P, N$*, and no obligation is stored outside those finite rows.*

Lean4 ✓ `BEDC.Derived.BishopLocatedCompletionEmbeddingUp.TasteGate.BishopLocatedCompletionEmbeddingTaste`
`single carrier alignment`

Proof. Project the accepted carrier. The displayed rows are precisely the metric source M, located-radius evidence L, dense completion route D, embedding graph E, regular rational and real readback R, and the structural rows H, C, P, N.

The located part is read before the completion part. A source-point request first enters the metric row and the positive-radius ledger, so the later dense-route lookup is tied to displayed local evidence rather than to an external completion representative.

The embedding graph row then records the finite source-to-completion relation, and the readback row exposes only regular rational distance reads and the terminal $\mathsf{Real}^{\uparrow}$ seal. Componentwise transport and displayed replay preserve this same order.

Since the carrier contains no quotient completion row, host equality coordinate, selected-limit coordinate, trichotomy split, or ambient real-completeness row, none of those objects can be projected from the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7471.1 and Definition 7471.2 seed the located completion embedding route over metric source rows, located positive-radius evidence, dense completion routes, embedding graph rows, regular rational readback, real seals, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, host equality of representatives, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-radius exposure, dense-route exactness, embedding-graph readback, regular-real handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCompletionE

Constructive story: A $\mathsf{BishopLocatedCompletionEmbedding}^{\uparrow}$ packet is generated from a Metric source row, located positive-radius evidence, a dense Completion or MetricCompletion route, an embedding graph, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7472

A Concrete Naming Certificate for $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges compact metric analysis, the $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$ packet realizes the compact uniform-continuity route of chapter 9237 as graph-level finite NameCert data. It sits beside the compact metric source of chapter 129, the continuous-map packet of chapter 130, the metric-distance rows of chapter 57, the rational tolerance fold of chapter 37, and the uniform-modulus consumer of chapter 369. The packet names the finite graph and modulus ledger; it is not open-cover compactness, host function extensionality, quotient map equality, a selected external modulus, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7472.1 (Uniform-continuity graph modulus carrier)**.** *A* $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(K, G, L, Q, S, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, exposing bundled source centers, coverage witnesses, and finite* ProbeBundle *membership data.*
2. *G is the continuous graph row, pairing source and target metric reads through* $\mathsf{ContinuousMap}^{\uparrow}$ *before any modulus is exported.*
3. *L is the pointwise-modulus ledger attached to the graph row at each bundled center.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the positive radii carried by L.*
5. *S is the source* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *triangle row used to move nearby source points into a common local graph neighbourhood.*
6. *T is the target metric-triangle row used to combine the two pointwise target estimates.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, exposing only a tolerance request and the folded precision obtained from Q.*
8. *H records componentwise* hsame *transport for compact nets, graph rows, local modulus ledgers, rational folds, metric-triangle rows, uniform-modulus rows, replay, provenance, and naming.*
9. *C records displayed* Cont *replay from tolerance request through finite-net coverage, graph lookup, pointwise-modulus readback, rational fold, source and target triangle rows, and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContinuityGraphModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for open-cover compactness, host function extensionality, quotient maps, selected external moduli, countable choice, or ambient real completeness.

Theorem 7472.2 (Uniform-continuity graph modulus NameCert obligations)**.** *For every accepted* $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$ *carrier* $(K, G, L, Q, S, T, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformContinuityGraphModu}}$ *surface consists exactly of carrier admission for compact finite nets, continuous graph rows, pointwise-modulus ledgers, rational lower-bound folds, source and target metric-triangle rows, uniform-modulus handoff, componentwise transport, displayed continuation replay, provenance, and local naming. Every compact-uniform-continuity read must pass through those rows before the public* $\mathsf{UniformModulus}^{\uparrow}$ *output is available.*

Proof. Project the accepted packet. Its analytic rows are the compact finite-net row K, continuous graph row G, pointwise-modulus ledger L, rational fold Q, source and target metric rows S, T, and uniform-modulus handoff U.

Finite-net coverage comes first. A source point is matched to a bundled center through K, and the graph row G supplies only the displayed continuous-map relation at that center.

The local modulus ledger L provides positive radii and target estimates for the graph row. The rational fold Q is read by primitive recursion over those finitely many radii, yielding a single precision below every displayed local radius.

The source triangle row S moves a nearby pair of source points into the same local graph neighbourhood, and the target triangle row T combines the resulting target estimates. Only then does U expose the tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Rows H, C, P, N transport, replay, source, and name the same route. Since the packet has no coordinate for open-cover compactness, host function extensionality, quotient maps, selected external moduli, countable choice, or ambient completeness, those objects cannot escape through the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuityGraphModulus}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformContinuityGraphModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7472.1 and Definition 7472.2 seed the compact finite-net, continuous graph, pointwise-modulus, ProbeBundle fold, metric-triangle, and uniform-modulus handoff route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformContinuityGraphModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host function extensionality, quotient map equality, selected external moduli, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net coverage, graph lookup, pointwise-modulus exactness, rational-fold lower bounds, source-target triangle handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformContinuityGraphModulusUp.

Constructive story: A $\mathsf{UniformContinuityGraphModulus}^{\uparrow}$ packet is generated from compact finite-net rows, continuous graph rows, pointwise-modulus ledgers, RatUp lower-bound folds, source and target MetricSpace triangle rows, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7473

A Concrete Naming Certificate for BishopLocatedIntervalRefinementMap$^{\uparrow}$

Following Bishop and Bridges constructive interval analysis, the BishopLocatedIntervalRefinementMap$^{\uparrow}$ packet names the finite map surface that sends one located interval certificate to a displayed refined interval certificate. It reads the Bishop refinement carrier of chapter 7391, the generic refinement packet of chapter 6199, the located interval source rows of chapter 394, the dyadic endpoint window of chapter 1524, and the terminal real seal of chapter 38. The map is recorded as finite certificate data, not as an ambient interval operation supplied by the host.

Definition 7473.1 (Bishop located interval refinement map carrier)**.** *A* BishopLocatedIntervalRefinementMap$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, J, R, D, W, S, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the source* LocatedInterval$^{\uparrow}$ *row, including lower and upper endpoint names, located membership comparison rows, and the displayed interval non-emptiness witness.*
2. *J is the target* LocatedInterval$^{\uparrow}$ *row obtained after the refinement request is read.*
3. *R is the* LocatedIntervalRefinement$^{\uparrow}$ *row asserting the finite inclusion route from J into I with the displayed endpoint and membership comparisons.*
4. *D is the* BishopLocatedIntervalRefinement$^{\uparrow}$ *row, tying the refinement request to Bishop-style located interval data rather than to a host interval operator.*
5. *W is the* DyadicRoundingWindow$^{\uparrow}$ *row that transports the source and target endpoints through one displayed dyadic precision window.*
6. *S is the StreamName and RegSeqRat readback seal used by endpoint consumers before the Real row is read.*
7. *E is the* Real$^{\uparrow}$ *seal row for the endpoint and width data after dyadic readback.*
8. *H records componentwise* hsame *transport for source interval, target interval, refinement inclusion, dyadic endpoint window, readback seal, real seal, continuation replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from the source interval to the refinement request, from the request to the target interval, from source and target endpoints to dyadic rounding windows, and from dyadic readback to the Real-facing rows.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedIntervalRefinementMap}^{\uparrow}$, $\mathsf{BishopLocatedIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedIntervalRefinement}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRoundingWindow}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementMap}^{\uparrow}}$ *row.*

The classifier compares accepted map packets only through $I, J, R, D, W, S, E, H, C, P, N$. It has no coordinate for arbitrary interval choice, quotient real equality, selected limits, host rounding, or ambient completeness.

Lean4 ✓ `BEDC.Derived.BishopLocatedIntervalRefinementMapUp.BishopLocatedIntervalRefinementMapTasteGate`
`single carrier alignment`

Theorem 7473.2 (Bishop located interval refinement map obligations)**.** *For an accepted* BishopLocatedIntervalRefi *packet $M = (I, J, R, D, W, S, E, H, C, P, N)$, the local* NameCert *obligation surface consists exactly of source interval projection, target interval projection, refinement inclusion, dyadic endpoint transport, width decrease, StreamName readback, RegSeqRat handoff, Real seal factorization, componentwise transport, displayed replay, provenance non-escape, and local naming.*

Proof. Project the carrier of Definition 7473.1. The source row I and target row J are both located interval packets, while R records the inclusion of the target interval into the source interval and D records that the route is the Bishop located refinement route.

Endpoint and width data are transported through W. The dyadic window reads the displayed endpoint precision, carries the adjacent endpoint packet, and exposes the finite width decrease before any real-facing consumer is allowed to read E.

The readback handoff is exact. The row S supplies the StreamName and RegSeqRat route for the same endpoint observations, and E seals only those rows as $\mathsf{Real}^{\uparrow}$ data. No selected limit or quotient real equality row is present.

Finally exhaust H, C, P, N. Transport, replay, provenance, and local naming all name the same finite packet, so no arbitrary interval operator, host rounding operation, or ambient completeness principle can enter the local obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementMap}^{\uparrow}}$.

Constructive story: A Bishop located interval refinement map is generated from a source located interval, a target located interval, a displayed refinement inclusion, dyadic endpoint transport, StreamName and RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementMap}^{\uparrow}}$, seed)

Scope closed: Definition 7473.1 and Definition 7473.2 seed the finite refinement-map carrier from source intervals to displayed refined intervals.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedIntervalRefinementMap}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary interval selection, quotient real equality, selected limits, host rounding, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source and target interval projection, refinement inclusion, dyadic endpoint transport, width decrease, StreamName and RegSeqRat readback, Real seal factorization, provenance non-escape, and local NameCert exactness for BEDC.Derived.BishopLocatedIntervalRefinementMapUp.

Chapter 7474

A Concrete Naming Certificate for $\mathsf{CompactUniformTriangleEstimateLedger}^{\uparrow}$

The $\mathsf{CompactUniformTriangleEstimateLedger}^{\uparrow}$ packet records the constructive Heine–Cantor source-target triangle estimate of chapter 9237 as finite NameCert data. It reads the compact metric source of chapter 129, the continuous map row of chapter 130, the metric law carrier of chapter 57, the tolerance-only handoff of chapter 369, and the compact-uniform-continuity packet of chapter 388. The ledger isolates the final pair of metric-triangle estimates so downstream consumers can cite the estimate without reopening the full compactness proof.

Definition 7474.1 (Compact uniform triangle estimate ledger carrier)**.** *A* $\mathsf{CompactUniformTriangleEstimateLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, U, M_X, M_Y, c, \rho, \varepsilon, \eta, S, Y, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row containing the displayed finite net and center membership ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise modulus rows are read at the chosen compact-net centers.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced after the finite estimate is assembled.*
4. *M_X and M_Y are the source and target* $\mathsf{Met}^{\uparrow}$ *law rows, including the triangle rows used in the estimate.*
5. *c is the compact-net center selected from the finite net row, and ρ is the pointwise radius row attached to c by F.*
6. *ε is the requested target tolerance, and η is the displayed epsilon-third budget used by the ledger.*
7. *S records the source-triangle estimate joining x, the center c, and the comparison point x' inside the same local source ball.*
8. *Y records the target-triangle estimate joining $f(x)$, $f(c)$, and $f(x')$ within the displayed target tolerance.*
9. *H records componentwise* hsame *transport for compact-net rows, pointwise modulus rows, source metric triangle rows, target metric triangle rows, epsilon-third budget rows, UniformModulus handoff rows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from compact-net coverage to pointwise modulus, from source-triangle estimates to target-triangle estimates, and from the target estimate to the UniformModulus handoff.*

11. *P is the* Pkg *provenance over* CompactUniformTriangleEstimateLedger$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, UniformModulus$^{\uparrow}$, Rat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CompactUniformTriangleEstimateLedger}^{\uparrow}}$ *row.*

The classifier has no coordinate for sequential compactness, selected subsequences, global choice of centers, quotient equality of metric points, or an ambient continuity principle outside the displayed rows.

Theorem 7474.2 (Compact uniform triangle estimate ledger obligations)**.** *For an accepted* CompactUniformTriangl *packet $T = (K, F, U, M_X, M_Y, c, \rho, \varepsilon, \eta, S, Y, H, C, P, N)$, the local obligation surface is exactly compact net center projection, pointwise modulus readback, source metric triangle transport, target metric triangle transport, epsilon-third splitting, UniformModulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Project the compact metric row K and choose the displayed finite-net center c from its carrier rows. The continuous map row F then supplies the pointwise modulus row ρ at that center, so the source estimate starts with finite compact-net data rather than a selected subsequence.

Read the source metric triangle row S from M_X. It combines the distance from x to c with the distance from x to x' inside the local source ball named by ρ.

Read the target metric triangle row Y from M_Y. The epsilon-third budget η splits the requested tolerance ε into the pointwise modulus contribution and the two triangle contributions, so the target estimate closes by finite rational arithmetic and the displayed metric-law rows.

The row U is the only UniformModulus handoff. The transport row H, replay row C, provenance row P, and local naming row N preserve the same compact-net, pointwise-modulus, source-triangle, target-triangle, and tolerance-budget rows; hence no sequential compactness, global choice of centers, quotient equality, or ambient continuity principle escapes the ledger. □

Closure status for NameCert$_{\text{CompactUniformTriangleEstimateLedger}^{\uparrow}}$.

Constructive story: A compact uniform triangle estimate ledger is generated from compact-net center rows, pointwise modulus rows, source and target metric triangle rows, an epsilon-third tolerance budget, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactUniformTriangleEstimateLedger}^{\uparrow}}$, seed)

Scope closed: Definition 7474.1 and Definition 7474.2 seed the finite source-target triangle estimate ledger for compact-uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{CompactUniformTriangleEstimateLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close sequential compactness, selected subsequences, global choice of centers, quotient metric equality, ambient continuity, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-net center projection, pointwise modulus readback, source and target metric triangle transport, epsilon-third split, UniformModulus handoff, provenance non-escape, and local NameCert exactness for BEDC.Derived.CompactUniformTriangleEstimateLedgerUp.

Chapter 7475

A Concrete Naming Certificate for $\mathsf{PlanarGraphMinor}^{\uparrow}$

Following Diestel, the $\mathsf{PlanarGraphMinor}^{\uparrow}$ packet records the finite graph-minor route by which a displayed graph carrier is inspected through edge deletions, vertex deletions, contractions, and a planar embedding ledger. It sits over the finite graph carrier of chapter 118, the independence and rank bookkeeping of chapter 202, the incidence-pairing discipline of chapter 234, and the closed-trail parity surface of chapter 7092. The packet names a finite obstruction-facing carrier for later minor and planar-routing consumers; it is not a host Robertson–Seymour theorem, not a completed obstruction catalogue, and not an ambient topological embedding principle.

Definition 7475.1 (PlanarGraphMinor carrier)**.** *A* $\mathsf{PlanarGraphMinor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, D, V, K, F, E, R, A, H, C, P, N)$$

with the following displayed rows:

1. *G is the source* $\mathsf{Graph}^{\uparrow}$ *row, including finite vertex rows, finite edge rows, endpoint readback, incidence rows, and the local graph classifier.*
2. *D is the edge-deletion ledger, listing the displayed edge rows removed before the minor read is admitted.*
3. *V is the vertex-deletion ledger, listing the displayed vertex rows and incident edge rows removed before the minor read is admitted.*
4. *K is the contraction ledger, recording each contracted edge, the two endpoint rows it identifies, and the resulting endpoint readback in the contracted graph row.*
5. *F is the planar-face ledger, recording finite cyclic boundary walks, incidence checks, and the local face-adjacency rows accepted as planar evidence.*
6. *E is the obstruction-boundary row, retaining the inspected finite subgraph windows used to refuse hidden nonplanar witnesses or unstated contractions.*
7. *R is the* $\mathsf{Matroid}^{\uparrow}$ *support row, reading cycle and rank-style dependency data only through the displayed graph edges.*
8. *A is the* $\mathsf{Matching}^{\uparrow}$ *and* $\mathsf{EulerianGraph}^{\uparrow}$ *sibling row, exposing incidence pairings, parity checks, and closed boundary-walk support used by the planar-face ledger.*

9. *H records componentwise* hsame *transport for G, D, V, K, F, E, R, A and for the replay, provenance, and naming rows.*
10. *C records displayed* Cont *replay from the graph row through deletion, contraction, face, obstruction-boundary, matroid-support, and sibling-support rows.*
11. *P is the* Pkg *provenance over* $\mathsf{PlanarGraphMinor}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{EulerianGraph}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PlanarGraphMinor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite graph, hidden embedding, quotient graph equality, unlisted contraction, host obstruction theorem, or completed minor-closed family.

Theorem 7475.2 (PlanarGraphMinor NameCert obligations)**.** *For every accepted* $\mathsf{PlanarGraphMinor}^{\uparrow}$ *carrier $M = (G, D, V, K, F, E, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PlanarGraphMinor}^{\uparrow}}$ *surface consists exactly of source graph admission through G, edge-deletion exposure through D, vertex-deletion exposure through V, contraction exposure through K, planar-face ledger exposure through F, obstruction-boundary retention through E, matroid-support exposure through R, matching and Eulerian sibling exposure through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7475.1. The visible rows are precisely the source graph, deletion ledgers, contraction ledger, planar-face ledger, obstruction-boundary row, matroid-support row, matching and Eulerian sibling row, transport, replay, provenance, and local naming.

The graph-minor operations are finite. The rows D and V list deleted edges and vertices, while K lists contracted edges together with the endpoint readback used after contraction. Each such read is downstream of the displayed $\mathsf{Graph}^{\uparrow}$ source row.

The planar and obstruction-facing rows are also displayed. The face ledger F records only finite boundary walks and incidence checks, while E retains the inspected windows that prevent a consumer from inserting hidden nonplanar witnesses or unstated contractions.

Finally R, A, H, C, P, N keep the same route attached to matroid support, matching incidence, Eulerian parity, transport, replay, provenance, and local naming. Since the carrier has no coordinate for hidden embeddings, quotient graph equality, infinite graphs, completed obstruction families, or host minor theorems, the listed rows exhaust the NameCert obligations. □

Theorem 7475.3 (PlanarGraphMinor finite contraction route)**.** *Every consumer that reads an accepted* $\mathsf{PlanarGraphMinor}^{\uparrow}$ *packet as planar minor evidence must first expose the finite route*

$$\mathsf{Graph}^{\uparrow} \longmapsto D, V, K \longmapsto F, E \longmapsto R, A \longmapsto H, C, P, N.$$

In particular, a contraction read can identify endpoints only through the displayed edge row in K, can inspect planarity only through the finite face ledger F, and can use matroid, matching, or Eulerian support only after the corresponding sibling rows have been displayed.

Proof. Start with a planar-minor consumer. By Definition 7475.1, the request reaches the minor packet only after the source graph row G has exposed its finite vertices, edges, endpoints, incidence data, and local classifier.

The minor route then passes through the operation ledgers. Edge deletion is read from D, vertex deletion from V, and contraction from K. The contraction row records the contracted edge and the endpoint pair, so no hidden quotient graph can replace the displayed endpoint readback.

Next expose the planar-face and obstruction-boundary rows. The row F supplies finite cyclic boundary walks and incidence checks, while E retains the inspected subgraph windows that delimit the obstruction-facing read.

The sibling support rows are downstream of the same route. The matroid row R reads only displayed graph-edge dependencies, and the matching/Eulerian row A reads only incidence pairings and parity-support data already visible in the packet. Transport, replay, provenance, and naming then preserve the same finite route, so every accepted contraction and planarity read factors through the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{PlanarGraphMinor}\uparrow}$.

Constructive story: A $\mathsf{PlanarGraphMinor}^{\uparrow}$ packet is generated from a finite GraphUp carrier, edge-deletion rows, vertex-deletion rows, contraction rows, planar-face ledgers, obstruction-boundary windows, MatroidUp support, MatchingUp and EulerianGraphUp sibling support, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PlanarGraphMinor}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7475.1, Definition 7475.2, and Definition 7475.3 seed the finite graph-minor and planar-face NameCert route over displayed GraphUp, MatroidUp, MatchingUp, and EulerianGraphUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PlanarGraphMinor}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the Robertson–Seymour theorem, a complete obstruction catalogue, host planar embedding equivalence, quotient graph equality, infinite graph minors, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deletion exposure, contraction endpoint readback, planar-face ledger exactness, obstruction-boundary retention, sibling support routing, transport, replay, provenance, and local naming for BEDC.Derived.PlanarGraphMinorUp.

Chapter 7476

A Concrete Naming Certificate for $\mathsf{LebesgueCoveringLemma}^{\uparrow}$

Following Lebesgue and Bishop–Bridges compact metric analysis, the $\mathsf{LebesgueCoveringLemma}^{\uparrow}$ packet records the finite compact-cover route that turns displayed compact metric data into a finite positive-radius witness. It sits between the compact metric source of chapter 129, the metric-space rows of chapter 57, the rational and dyadic tolerance surfaces of chapter 37 and chapter 291, the finite-radius consumer of chapter 452, and compact-uniform-continuity consumers such as chapter 2292 and chapter 7456. The packet names only finite cover data, radius comparisons, componentwise transport, and local provenance; it is not open-cover compactness, a selected subcover principle, countable choice, or an ambient theorem about all metric spaces.

Definition 7476.1 (Lebesgue covering lemma carrier)**.** *A* $\mathsf{LebesgueCoveringLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, U, F, R, D, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing a named compact metric packet only through finite compact-cover data.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row whose point and ball readings are available to the cover test.*
3. *U is the finite cover row: a finite list of named cover centers, cover radii, and membership tests read from the compact source.*
4. *F is the finite subcover witness already displayed by U; it is a finite list coordinate, not a host-selected subcover.*
5. *R is the positive radius row, recorded through* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparisons.*
6. *D is the finite radius-bound ledger asserting that every point read through K, M lies in a cover member whose displayed radius is bounded below by the same positive row R.*
7. *H records componentwise* hsame *transport for the compact source, metric distance, finite cover, subcover list, rational radius, dyadic ledger, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point read through K, M to the finite cover row U, the finite list row F, the radius row R, and the bound ledger D.*
9. *P is the* Pkg *provenance over* $\mathsf{LebesgueCoveringLemma}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueCoveringLemma}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, a host-chosen subcover, countable choice, quotient metric equality, ambient compactness, or a global Heine–Borel theorem.

Theorem 7476.2 (Lebesgue covering lemma NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueCoveringLemma}^{\uparrow}$ *carrier* $L = (K, M, U, F, R, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LebesgueCoveringLemma}^{\uparrow}}$ *surface consists exactly of five obligation families:*

1. *carrier admission for the compact metric source, metric distance row, finite cover row, finite subcover list, positive radius row, and dyadic radius-bound ledger;*
2. *cover exposure, requiring each point read from K, M to enter the finite list row F only through the displayed cover row U;*
3. *finite positive-radius certification through R, D, with all comparisons recorded through* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
4. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
5. Pkg *provenance and local naming through P, N, including the handoff to* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *and compact-uniform-continuity consumers.*

No NameCert obligation is stored outside these rows, and no obligation selects a subcover from an arbitrary open cover.

Proof. Project the carrier of Definition 7476.1. The only cover data are U and the finite list coordinate F, so carrier admission and cover exposure are read from displayed finite rows.

The radius witness is read next. Rows R and D provide the positive rational or dyadic lower-bound data and the finite ledger saying that each point read through K, M reaches a cover member with that bound.

The structural rows preserve the same finite route. Transport through H and replay through C move the cover, list, radius, and ledger rows componentwise, while P and N source and name the packet without adding open-cover compactness or a choice-based selector. □

Theorem 7476.3 (Lebesgue covering lemma finite radius bound)**.** *Every finite-cover consumer of an accepted* $\mathsf{LebesgueCoveringLemma}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{Met}^{\uparrow} \longrightarrow U, F \longrightarrow R, D \longrightarrow \mathsf{FiniteLebesgueNumber}^{\uparrow}.$$

In particular, compact-uniform-continuity consumers may read the shared positive radius only after the finite cover row, finite list row, rational or dyadic radius row, and bound ledger have all been exposed. The route does not provide arbitrary open-cover compactness, a host-selected subcover, countable choice, quotient metric equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with a consumer read of $L = (K, M, U, F, R, D, H, C, P, N)$. The compact metric and metric-space rows K, M supply only the point and distance data needed to inspect the displayed finite cover.

Next read the finite cover route. The row U exposes the cover members, F records the finite list actually used by the packet, and R, D give the shared positive-radius bound through rational and dyadic comparisons.

Finally hand the same rows to $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ or to a compact-uniform-continuity consumer. Since P names no arbitrary open cover, host selector, countable-choice schedule, quotient metric equality, or ambient completeness row, every accepted consumer remains inside the finite radius route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueCoveringLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueCoveringLemma}^{\uparrow}$ packet is generated from compact metric source rows, metric distance rows, finite cover and finite list rows, rational and dyadic positive-radius rows, radius-bound ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7476.1, Definition 7476.2, and Definition 7476.3 seed the finite compact-cover packet over displayed compact metric, metric-space, rational-radius, dyadic-radius, finite-list, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-based subcover selection, countable choice, quotient metric equality, ambient compactness for all metric spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover exposure, rational and dyadic radius-bound exactness, finite-list handoff, transport replay, provenance, local naming, and non-escape for BEDC.Derived.LebesgueCoveringLemmaUp

Chapter 7477

A Concrete Naming Certificate for $\mathsf{SchurTest}^{\uparrow}$

Following Schur's operator-bound criterion in classical functional analysis, the $\mathsf{SchurTest}^{\uparrow}$ packet records the finite row-bound and column-bound data used to name a bounded matrix operator without importing an infinite measure kernel or an ambient completeness theorem. It sits between the finite matrix surface of chapter 49, the norm readback of chapter 89, the operator seal of chapter 1644, the Hilbert source of chapter 91, and the real tolerance interface of chapter 38.

7477.1 Carrier and finite Schur packet

Definition 7477.1 (Schur test carrier)**.** *A* $\mathsf{SchurTest}^{\uparrow}$ *carrier is a finite packet* $(A, U, V, M, N, B, H, R, T, E, C, P, K$ *with the following displayed rows:*

1. *A, a finite* $\mathsf{Mat}^{\uparrow}$ *window containing the matrix coefficients read by the test;*
2. *U, the row-bound ledger for the displayed rows of A;*
3. *V, the column-bound ledger for the displayed columns of A;*
4. *M, the finite* $\mathsf{Mat}^{\uparrow}$ *support window tying U and V to the same coefficient packet;*
5. *N, a* $\mathsf{Norm}^{\uparrow}$ *readback row for the source and target vector windows;*
6. *B, a* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *seal reached only after the matrix window, norm readback, and two Schur ledgers have been displayed;*
7. *H, the* $\mathsf{Hilbert}^{\uparrow}$ *source row for the finite source and target vector windows;*
8. *R, the* $\mathsf{Real}^{\uparrow}$ *tolerance row carrying the displayed bound budget;*
9. *T, the componentwise* hsame *rows for the matrix window, row ledger, column ledger, norm readback, Hilbert source, real tolerance, and operator seal;*
10. *E, the displayed* Cont *replay rows preserving the finite Schur packet under consumer reads;*
11. *C, the* Pkg *provenance over* $\mathsf{SchurTest}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *P, a refusal ledger excluding infinite measure kernels, quotient operators, selected limits, choice, spectral-theorem data, and ambient Hilbert completeness;*

13. *K, the local* $\mathsf{NameCert}_{\mathsf{SchurTest}^\uparrow}$ *row binding these displayed rows as one Schur-test certificate.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an infinite kernel, a chosen summability representative, a quotient operator equality, a spectral decomposition, or a completeness proof for the ambient Hilbert space.

7477.2 NameCert obligations

Theorem 7477.2 (Schur test NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{SchurTest}^\uparrow}$ *surface for Definition 7477.1 consists exactly of carrier admission for the displayed packet* $(A, U, V, M, N, B, H, R, T, E, C, P, K)$*, row-bound exactness for U, column-bound exactness for V, finite matrix-window coherence for A and M, norm readback through N, operator sealing through B, Hilbert-source visibility through H, real-tolerance visibility through R, componentwise transport through T, continuation replay through E, package provenance through C, and refusal of the excluded analytic and choice-theoretic rows through P.*

Proof. Project the carrier of Definition 7477.1. The projection exposes the matrix window, the two Schur ledgers, the finite support window, the norm readback, the operator seal, the Hilbert source, the real tolerance, transport, replay, provenance, refusal, and local naming rows.

The row-bound and column-bound obligations are read separately from U and V. The finite matrix-window row M is the common support that prevents either ledger from being reread as an infinite summability statement or as an unbounded host kernel.

The operator-facing obligations then pass through N, B, H, R. These rows expose only the norm readback, bounded-operator seal, Hilbert source window, and real tolerance budget displayed by the packet. The transport, replay, provenance, refusal, and local naming rows keep the same finite support attached to every consumer read. □

Theorem 7477.3 (Schur test finite row-column bound)**.** *For every accepted* $\mathsf{SchurTest}^\uparrow$ *carrier* $(A, U, V, M, N, B, H, R, T, E, C, P, K)$*, any bounded-operator read of B must first preserve the finite row-bound ledger U, the finite column-bound ledger V, their shared* $\mathsf{Mat}^\uparrow$ *support window M, the* $\mathsf{Norm}^\uparrow$ *readback N, the* $\mathsf{Hilbert}^\uparrow$ *source row H, and the* $\mathsf{Real}^\uparrow$ *tolerance row R. The resulting bound is a finite BEDC-visible row-column budget, not an infinite measure Schur kernel, a choice-selected representative, a quotient operator, a spectral theorem, or an ambient Hilbert-completeness claim.*

Proof. Start from the accepted carrier and isolate the bounded-operator seal B. By Definition 7477.2, this seal is downstream from the matrix window, both row and column ledgers, the norm readback, the Hilbert source, and the real tolerance row.

The row and column ledgers are tied to the same finite support by M. Thus a consumer cannot keep only the operator seal while replacing the displayed estimates by an infinite kernel, a quotient equality of operators, or a selected representative of the matrix coefficients.

Finally replay the transport and provenance rows T, E, C, K. They preserve the same finite packet for every consumer read, while the refusal ledger P records the excluded analytic principles. Hence the exported bound is exactly the finite row-column budget stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurTest}^\uparrow}$**.**

Constructive story: A $\mathsf{SchurTest}^\uparrow$ packet is generated from finite MatrixUp coefficient windows, row-bound and column-bound ledgers, NormUp readback, a BoundedLinearOperatorUp seal, a HilbertUp source row, a RealUp tolerance row, componentwise hsame transport, Cont replay, Pkg provenance, refusal rows, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurTest}^\uparrow}$, seed)

Scope closed: Definition 7477.1, Definition 7477.2, and Definition 7477.3 seed the Schur row-bound, column-bound, finite MatrixUp window, NormUp readback, BoundedLinearOperatorUp seal, HilbertUp source, RealUp tolerance, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurTest}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim infinite measure Schur kernels, choice, quotient operators, spectral theorem data, or ambient Hilbert completeness.

Upgrade path: To reach obligationClosure, the finite row-column packet must close classifier transport and operator-read exactness against a checked formal target.

Chapter 7478

A Concrete Naming Certificate for $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$

Following Bishop and Bridges, a located Dedekind cut and a regular Cauchy real name are compared constructively by explicit rational brackets and moduli, not by identifying $\mathsf{Real}^{\uparrow}$ with a quotient of cuts. The $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$ packet records this comparison as finite BEDC data between the located-cut surface of chapter 404, the located Dedekind comparison boundary of chapter 6423, the dyadic arithmetic rows of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names the bridge surface used by Real and Completion consumers; it does not construct $\mathsf{Real}^{\uparrow}$ from Dedekind cuts and does not claim ambient real completeness.

Definition 7478.1 (Located Dedekind regular-Cauchy bridge carrier)**.** *A* $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located* $\mathsf{LocatedDedekindCut}^{\uparrow}$ *data: lower and upper rational rows, inhabitedness witnesses, located separation tests, and finite cut-stability checks.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger. It records dyadic lower and upper brackets extracted from L at displayed unary precisions, together with the tolerance rows used to compare successive brackets.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that lists exactly which located-cut bracket requests are read before a regular Cauchy row is exposed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy modulus and readback row obtained from the bracket ledger and the stream schedule.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is reached only after the located cut data, dyadic brackets, stream schedule, and regular Cauchy readback have been displayed.*
6. *H records componentwise* hsame *transport for located cut data, bracket ledgers, stream schedules, regular Cauchy rows, Real seals, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite cut request to its bracket extraction, from brackets to the regular Cauchy modulus, and from the regular row to the terminal Real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$, $\mathsf{LocatedDedekindCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, D, S, R, E, H, C, P, N$. It has no coordinate for quotient cut equality, a selected Dedekind representative, trichotomy of reals, host limit selection, countable choice, a construction of $\mathsf{Real}^{\uparrow}$ *from cuts, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7478.2 (Located Dedekind regular-Cauchy bridge NameCert obligations)**.** *For an accepted* $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$ *carrier $B = (L, D, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}}$ *obligations are exactly carrier admission, bracket extraction, regular Cauchy realization, Real seal factorization, classifier stability, and nonescape. They are discharged by the displayed route*

$$L \longmapsto D \longmapsto S \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Carrier admission is projection from Definition 7478.1. The located cut, dyadic bracket ledger, stream schedule, regular Cauchy readback, Real seal, transport, replay, provenance, and local naming rows are the complete public inventory.

Bracket extraction reads L only through the displayed located-cut tests and then records the resulting rational bounds in the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D. The row S lists the finite bracket requests whose answers are used downstream.

Regular Cauchy realization is the handoff from D and S to R. The modulus is visible as part of the $\mathsf{RegSeqRat}^{\uparrow}$ row, so no host limit selector or quotient-cut equality is needed to form the regular readback.

The Real seal factorization reads E only after L, D, S, R have been displayed. The transport and replay rows H and C keep classified packets componentwise aligned, while P and N source and name the same local bridge.

Nonescape follows by packet exhaustion. Since no coordinate stores trichotomy of reals, countable choice, a selected Dedekind representative, a Dedekind construction of $\mathsf{Real}^{\uparrow}$, or ambient completeness, no consumer can extract such data from the bridge. □

Falsifiable prediction: Every $\mathsf{Real}^{\uparrow}$ read from a $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$ packet factors through located cut data, dyadic bracket extraction, a StreamName schedule, RegSeqRat regular Cauchy readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: locatedcut, dyadicratcore, streamname, regseqrat, real: LocatedDedekindRegularCauchyB is not bijective to any listed sibling because it jointly carries located cut data, dyadic brackets, finite schedules, regular Cauchy modulus rows, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}$ packet is generated from located Dedekind cut data, dyadic bracket rows, a StreamName schedule, a RegSeqRat regular Cauchy readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}}$, seed)

Scope closed: Definition 7478.1 and Definition 7478.2 seed the finite located-cut to regular Cauchy comparison bridge for Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedDedekindRegularCauchyBridge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind construction of $\mathrm{Real}^{\uparrow}$, quotient cut equality, selected representatives, trichotomy, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bracket extraction, regular Cauchy realization, Real seal factorization, classifier stability, and nonescape for BEDC.Derived.LocatedDedekindRegularCauchyBridgeUp.

Chapter 7479

A Concrete Naming Certificate for $\mathsf{FiniteIntervalPartition}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteIntervalPartition}^{\uparrow}$ packet records the finite closed-interval subdivision data used by interval arguments before any regular rational, real-name, or compact-cover consumer can read a partition. It sits beside the tagged-cell interface of chapter 7449 and the dyadic refinement route of chapter 1877. The carrier gives $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ interval-cover arguments a displayed finite substrate, not a host finite set of cuts, quotient equality of partitions, a selected limiting mesh, open-cover compactness, or ambient real completeness.

Definition 7479.1 (Finite interval partition carrier)**.** *A* $\mathsf{FiniteIntervalPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, U, K, M, V, R, H, C, P, N)$$

with the following displayed rows:

1. *L, U are the closed interval endpoint rows, sourced through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *witnesses and read as the boundary of the inspected interval.*
2. *K is the ordered cut row. It lists the finite internal cuts between L and U together with adjacency witnesses for consecutive cells.*
3. *M is the dyadic mesh-bound row. It records one displayed dyadic scale bounding the width of every cell determined by L, K, U.*
4. *V is the cell-coverage row. It witnesses that every interval containment read is routed through exactly one displayed cell or through the shared boundary ledger attached to neighboring cells.*
5. *R is the refinement ledger. It records how a later partition read refines the displayed cut row while preserving endpoint rows, coverage rows, and the mesh-bound comparison.*
6. *H records componentwise* hsame *transport for endpoint rows, ordered cut rows, mesh bounds, coverage rows, refinement ledgers, replay rows, provenance, and local naming.*
7. *C records displayed* Cont *replay from endpoints to cuts, from cuts to cells, from cells to coverage, and from coverage to refinement-facing consumers.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalPartition}^{\uparrow}$*,* $\mathsf{TaggedPartition}^{\uparrow}$*,* $\mathsf{DyadicCoverRefinement}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, K, M, V, R, H, C, P, N$. It has no coordinate for a host list of cuts, quotient equality of partitions, an unbounded refinement family, selected mesh limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7479.2 (Finite interval partition NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalPartition}^{\uparrow}$ *carrier $F = (L, U, K, M, V, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalPartition}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the finite endpoint, cut, mesh, coverage, refinement, transport, replay, provenance, and naming rows;*
2. *endpoint order, requiring L and U to bracket the ordered cut row K and every adjacent cell boundary;*
3. *cell coverage, requiring every interval containment read to pass through the displayed coverage row V before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff;*
4. *mesh and refinement compatibility, requiring M and R to preserve cell width bounds and endpoint coverage under displayed refinement;*
5. *classifier transport, requiring H, C, P, N to preserve the same finite partition packet under* hsame, Cont, *provenance, and local naming.*

The obligations expose a finite interval-subdivision substrate that may be consumed by $\mathsf{TaggedPartition}^{\uparrow}$ *tags,* $\mathsf{DyadicCoverRefinement}^{\uparrow}$ *covers,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and* $\mathsf{Real}^{\uparrow}$ *interval seals without importing host finite partitions, quotient partition equality, selected limiting meshes, open-cover compactness, or ambient real completeness.*

Proof. Project the carrier of Definition 7479.1. Carrier admission reads exactly the rows $L, U, K, M, V, R, H, C, P, N$ so the local certificate can inspect only the displayed endpoint, cut, mesh, coverage, refinement, transport, replay, provenance, and naming data.

Endpoint order is read next. The boundary rows L, U bracket the ordered cut row K, and every cell boundary is part of the same displayed adjacency ledger rather than a host-side partition object.

The coverage and mesh clauses then consume V, M, R. The coverage row sends every interval containment request through the displayed cells, while the dyadic mesh row and refinement ledger keep later subdivision reads compatible with the same endpoint and coverage data.

Finally replay H, C, P, N. These rows transport, replay, source, and name the same finite packet, so no extra coordinate can supply quotient partition equality, an external refinement family, a selected mesh limit, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. The five listed rows therefore exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntervalPartition}^{\uparrow}$ packet is generated from closed interval endpoint rows, ordered finite cut rows, a dyadic mesh bound, cell coverage rows, refinement ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteIntervalPartition}^{\uparrow}}$, seed)

Scope closed: Definition 7479.1 and Definition 7479.2 seed the finite interval-subdivision substrate used by RegSeqRat and Real interval-cover consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteIntervalPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient partition equality, host finite-partition presentation, selected limiting meshes, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint order, cell coverage, mesh-refinement compatibility, classifier transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalPartitionUp.

Chapter 7480

A Concrete Naming Certificate for DyadicIntervalSubdivision$^{\uparrow}$

Following Bishop and Bridges, the DyadicIntervalSubdivision$^{\uparrow}$ packet records the finite dyadic cell subdivision used by compact interval arguments before any finite-cover or uniform-modulus consumer can read a mesh. It refines the interval-net discipline of chapter 1250, the cover-refinement carrier of chapter 1877, the compact metric source of chapter 129, and the tolerance-only handoff of chapter 369. The packet is a concrete dyadic subdivision surface for compact-uniform-continuity arguments, not an open-cover compactness theorem, a selected subcover, quotient real equality, or ambient Real$^{\uparrow}$ completeness.

Definition 7480.1 (Dyadic interval subdivision carrier)**.** *A* DyadicIntervalSubdivision$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, E, Q, G, V, W, M, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the* ClosedBoundedIntervalNet$^{\uparrow}$ *source row exposing the closed interval endpoints and the finite interval-net boundary.*
2. *E is the endpoint-exactness row, tying every dyadic cell endpoint back to the same lower and upper interval endpoints.*
3. *Q is the dyadic scale row, sourced through* DyadicRatCore$^{\uparrow}$*, at which the interval is subdivided.*
4. *G is the ordered dyadic grid row listing the cell endpoints at scale Q.*
5. *V is the cell-coverage row witnessing that every interval read is routed through one displayed dyadic cell or a shared endpoint boundary.*
6. *W is the common-refinement row comparing the displayed grid with a later* DyadicCoverRefinement$^{\uparrow}$ *cover row.*
7. *M is the mesh-bound row recording the dyadic diameter bound exported to compact finite-cover consumers.*
8. *U is the* UniformModulus$^{\uparrow}$ *handoff row, available only after the grid, coverage, common-refinement, and mesh rows have been consumed.*
9. *H records componentwise* hsame *transport for interval-net source, endpoint exactness, dyadic scale, grid, coverage, common-refinement, mesh, uniform-modulus handoff, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from interval endpoints to dyadic grid rows, from grid rows to coverage rows, from coverage to common refinement, and from mesh bounds to the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalSubdivision}^{\uparrow}$, $\mathsf{DyadicCoverRefinement}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalSubdivision}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, E, Q, G, V, W, M, U, H, C, P, N$. It has no coordinate for an open-cover subcover selector, quotient real equality, a hidden grid chooser, arbitrary compactness, or ambient metric completeness.

Theorem 7480.2 (Dyadic interval subdivision NameCert obligations)**.** *For every accepted* DyadicIntervalSubdivisio *carrier $D = (I, E, Q, G, V, W, M, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalSubdivision}^{\uparrow}}$ *surface consists exactly of carrier admission, interval-net source exposure, endpoint exactness, dyadic scale classification, ordered grid coverage, cell-coverage exactness, common-refinement compatibility with* $\mathsf{DyadicCoverRefinement}^{\uparrow}$*, mesh-bound export,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The finite route is*

$$\mathsf{ClosedBoundedIntervalNet}^{\uparrow} \longmapsto \mathsf{DyadicIntervalSubdivision}^{\uparrow} \longmapsto \mathsf{DyadicCoverRefinement}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow},$$

with the $\mathsf{CompactMetric}^{\uparrow}$ *source row read only through the displayed finite interval-net and mesh data.*

Proof. Carrier admission is projection from Definition 7480.1. The source interval row I, endpoint exactness row E, dyadic scale row Q, ordered grid row G, coverage row V, common-refinement row W, mesh row M, and handoff row U are the only mathematical rows available.

Read I, E, Q, G, V first. These rows display the closed interval endpoints, fix the dyadic scale, list the finite grid, and route every interval containment request through a displayed cell or shared boundary.

Next consume W, M, U. The common-refinement row compares the dyadic grid with the $\mathsf{DyadicCoverRefinement}^{\uparrow}$ cover route, the mesh row exports the dyadic diameter bound to compact finite-cover consumers, and the $\mathsf{UniformModulus}^{\uparrow}$ row is visible only after those finite checks.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve the same subdivision packet, so no open-cover selector, hidden grid choice, quotient real equality, arbitrary compactness principle, or ambient completeness row can enter the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalSubdivision}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalSubdivision}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalNet source, endpoint exactness, dyadic scale rows, ordered dyadic grid rows, cell coverage, common-refinement rows, mesh bounds, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicIntervalSubdivision}^{\uparrow}}$, seed)

Scope closed: Definition 7480.1 and Definition 7480.2 seed the finite dyadic subdivision route used by compact finite-cover and uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicIntervalSubdivision}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, hidden grid choice, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval-net source exposure, endpoint exactness, dyadic scale classification, grid coverage, common-refinement compatibility, mesh export, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalSubdivisionUp.

Chapter 7481

A Concrete Naming Certificate for FiniteOpenCoverNerve$^{\uparrow}$

Following Alexandroff and the standard nerve construction for finite covers, the FiniteOpenCoverNerve$^{\uparrow}$ packet records the finite simplicial incidence data carried by a displayed open cover without importing open-cover compactness, a selected refinement theorem, or ambient choice. It sits beside the compact source of chapter 60, the compact metric finite-net source of chapter 129, the finite lower-bound fold of chapter 619, and the finite cover-fold route of chapter 7452. The packet is a named nerve carrier over displayed cover rows, nonempty finite-intersection rows, incidence rows, ProbeBundle compatibility, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Definition 7481.1 (Finite open-cover nerve carrier)**.** *A* FiniteOpenCoverNerve$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (K, O, I, J, B, H, C, P, M)$$

with the following displayed rows:

1. *K is the compact source row, read through* Compact$^{\uparrow}$ *or* CompactMetric$^{\uparrow}$*, that bounds the cover inventory as finite data.*
2. *$O = (O_1, \ldots, O_n)$ is the displayed finite open-cover row.*
3. *I is the finite nonempty-intersection ledger, listing exactly those finite subfamilies of O whose displayed intersection witness is present.*
4. *J is the incidence row, recording vertex-to-cover membership and simplex-to-intersection membership for the nerve.*
5. *B is the* ProbeBundle *compatibility row, aligning cover cells, finite probes, and lower-bound folds with the cover-fold surface of chapter 7452.*
6. *H records componentwise* hsame *transport for K, O, I, J, B, C, P, M.*
7. *C records displayed* Cont *replay from compact source rows through cover membership, finite-intersection witnesses, nerve incidence, probe-bundle compatibility, provenance, and local naming.*
8. *P is the* Pkg *provenance over* FiniteOpenCoverNerve$^{\uparrow}$, Compact$^{\uparrow}$, CompactMetric$^{\uparrow}$, ProbeBundleCoverFold$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. M is the local $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNerve}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open-cover compactness, a selected subcover theorem, a host simplicial realization, quotient point equality, countable choice, ambient metric completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.FiniteOpenCoverNerveUp.FiniteOpenCoverNerveTasteGate single carrier alignment`

Theorem 7481.2 (Finite open-cover nerve NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$ *carrier* $N = (K, O, I, J, B, H, C, P, M)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNerve}^{\uparrow}}$ *surface consists exactly of compact-source exposure, finite open-cover exposure, nonempty finite-intersection ledger exposure, nerve incidence exposure,* ProbeBundle *compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is discharged by host open-cover compactness, a selected external refinement, quotient point equality, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 7481.1. The rows K, O, I, J, B are the whole mathematical surface: the compact source, the finite cover, the displayed nonempty intersections, the incidence relation, and the probe-bundle compatibility ledger.

The nerve data are finite because O is displayed as a finite row and I lists only the finite subfamilies whose intersection witness is present. The incidence row J reads from those two rows, so it cannot introduce a host realization or an unlisted refinement.

The structural rows H, C, P, M transport, replay, source, and name the same packet. Since the carrier has no coordinate for the excluded compactness, choice, quotient, completeness, Lean, or bridge data, the listed rows exhaust the local certificate. □

Theorem 7481.3 (Finite open-cover nerve compact-uniform route)**.** *Every compact-uniform consumer that reads an accepted* $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$ *packet must factor through the displayed route*

$$\mathsf{Compact}^{\uparrow}/\mathsf{CompactMetric}^{\uparrow} \longmapsto O \longmapsto I \longmapsto J \longmapsto \mathsf{ProbeBundle} \longmapsto \mathsf{FiniteNetMinimumFold}^{\uparrow}.$$

The nerve row supplies finite cover incidence for the compact-uniform modulus route, including the cover-fold consumer of chapter 7452, but it supplies no open-cover compactness theorem, selected subcover, host geometric realization, quotient point equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the NameCert obligations of Definition 7481.2. A consumer first sees the compact source row K and the finite cover row O, then the nonempty finite-intersection ledger I and incidence row J.

The probe compatibility row B is read after those cover and incidence rows. It aligns the nerve inventory with the same finite probes and lower-bound folds used by the cover-fold route, so a compact-uniform modulus consumer receives finite incidence and fold data rather than a background compactness theorem.

The transport, replay, provenance, and local naming rows preserve this route. No additional row can provide an external subcover selector, host realization, quotient equality, choice principle, or ambient real-completeness datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNerve}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$ packet is generated from a compact source row, a finite open-cover row, nonempty finite-intersection rows, incidence rows, ProbeBundle compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7481.1, Definition 7481.2, and Definition 7481.3 seed the finite cover-nerve carrier used by compact-uniform finite-cover consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOpenCoverNerve}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host simplicial realizations, quotient point equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-cover exposure, intersection-ledger exactness, incidence exposure, ProbeBundle compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOpenCoverNerve

Chapter 7482

A Concrete Naming Certificate for $\mathsf{MinimizingMovement}^{\uparrow}$

Following De Giorgi, Ambrosio, Gigli, and Savare on minimizing movements, the $\mathsf{MinimizingMovement}^{\uparrow}$ packet records the finite descent surface by which an implicit time-step scheme is read before any gradient-flow or curve-of-maximal-slope consumer receives it. It sits after the variational descent ledger of chapter 3926, the complete-metric carrier of chapter 128, the metric source of chapter 57, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the lower-semicontinuity packet of chapter 1536. The packet names a displayed minimizing-step route only; it does not select minimizers, identify quotient metric points, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7482.1 (Minimizing-movement carrier)**.** *A* $\mathsf{MinimizingMovement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, d, K, L, Q, R, E, S, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row for the inspected state addresses.*
2. *d is the metric-comparison row naming the distances used by the step penalty.*
3. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *descent-readiness row for the finite Cauchy tails requested by the step scheme.*
4. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *value-stability row for the energy inspected at each step.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for comparing displayed energy values and penalties.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for exported values after the regular-rational readback is visible.*
7. *E is the* $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$ *descent ledger used to certify the approximate minimizing step.*
8. *S is the step-size and budget row, naming the finite time-step schedule, penalty coefficient, and admissible error budget.*
9. *T is the finite step trace, recording the source state, trial state, descent comparison, and accepted next state for each inspected step.*
10. *H records componentwise* hsame *transport for metric, complete-metric, lower-semicontinuity, readback, variational, schedule, and step-trace rows.*

11. *C records displayed* Cont *replay from a minimizing-movement request through $X, d, K, L, Q, R, E, S, T$.*
12. *P is the* Pkg *provenance over* $\mathsf{MinimizingMovement}^{\uparrow}$, $\mathsf{EkelandVariationalPrinciple}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MinimizingMovement}^{\uparrow}}$ *row.*

The carrier exports exactly these finite rows. It contains no selected minimizer, quotient equality of states, countable-choice scheduler, completed gradient flow, metric slope theorem, or independent proof that the ambient metric space is complete.

Theorem 7482.2 (Minimizing-movement NameCert obligations)**.** *For every accepted* $\mathsf{MinimizingMovement}^{\uparrow}$ *carrier $M = (X, d, K, L, Q, R, E, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MinimizingMovement}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed metric, distance, complete-metric, lower-semicontinuity, regular-rational, real-seal, variational, schedule, trace, transport, continuation, provenance, and naming rows;*
2. *metric-penalty readability, requiring every penalty comparison in T to use the displayed d row on addresses admitted by X;*
3. *complete-metric readiness, requiring every Cauchy-tail read requested by the step route to pass through K;*
4. *lower-semicontinuity and value readback, requiring every energy comparison to pass through L, Q, R before any exported value is read;*
5. *variational-step exposure, requiring the approximate minimizing-step ledger to be read through E before the accepted next-state row of T is consumed;*
6. *schedule and budget coverage, requiring the time-step, penalty, and error data to be named in S before the corresponding trace row is used;*
7. *transport, replay, provenance, and local naming stability through H, C, P, N;*
8. *ledger non-escape, excluding selected minimizers, quotient state equality, countable-choice schedules, completed gradient flows, metric-slope conclusions, and ambient real or metric completeness claims.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier row by row. The metric and distance rows X, d expose exactly the inspected states and penalty comparisons, while K, L, Q, R expose the complete-metric readiness, lower-semicontinuity reads, regular-rational comparisons, and real seals used by the step route.

The variational and schedule rows determine when the trace may be read. The row E supplies the displayed Ekeland-style descent ledger for an approximate step, and S supplies the finite time-step, penalty, and admissible error data before any coordinate of T is accepted as a next-state record.

The trace row T has no hidden coordinates beyond the source state, trial state, comparison, and accepted next-state data displayed in the carrier. Thus each minimizing-step read is exhausted by the metric, value, variational, and schedule rows already listed.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores a selected minimizer, quotient state equality, countable-choice schedule, completed gradient flow, metric slope theorem, or ambient completeness assertion, the listed obligations exhaust the local NameCert surface. □

Theorem 7482.3 (Minimizing-movement real-completion route)**.** *Every Real-facing or Completion-facing consumer reading an accepted* $\mathsf{MinimizingMovement}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Met}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{LowerSemicontinuous}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{EkelandVariationalPrinciple}^{\uparrow} \longmapsto S, T, H, C, P, N.$$

The consumer therefore receives a finite implicit-step descent packet over displayed metric, value, and variational rows, not a selected minimizer, quotient completion object, countable-choice sequence, completed gradient flow, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier $M = (X, d, K, L, Q, R, E, S, T, H, C, P, N)$. A consumer cannot read a distance penalty without first reading X, d, and cannot read a completion-facing tail request without first reading the complete-metric row K.

The value route is similarly forced. Energy comparisons pass through the lower-semicontinuity row L, the regular-rational readback Q, and the real seal R before they can be exported to a Real-facing consumer.

The minimizing-step data then pass through E, S, T. The variational ledger E supplies the displayed approximate descent route, S names the finite time-step and budget data, and T records only the inspected source, trial, comparison, and accepted next-state rows.

The structural rows H, C, P, N preserve and replay this same route. Because the carrier has no coordinate for selected minimizers, quotient completion, countable-choice schedules, completed flows, metric slopes, or independent completeness, no such datum can be obtained by a downstream Real or Completion consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{MinimizingMovement}^{\uparrow}}$.

Constructive story: A $\mathsf{MinimizingMovement}^{\uparrow}$ packet is generated from a finite metric source, displayed distance penalties, complete-metric descent readiness, lower-semicontinuity value reads, regular-rational and real readback, an Ekeland-style variational ledger, a step-size and budget row, a finite step trace, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinimizingMovement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7482.1, Definition 7482.2, and Definition 7482.3 seed the implicit-step descent route consumed by later Real, Completion, gradient-flow, and curve-of-maximal-slope packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinimizingMovement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected minimizers, quotient state equality, countable-choice schedules, completed gradient flows, metric-slope theorems, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, complete-metric readiness, lower-semicontinuity readback, variational-step exposure, schedule coverage, trace nonescape, and consumer route exhaustion for BEDC.Derived.MinimizingMoveme

Chapter 7483

A Concrete Naming Certificate for $\mathsf{RegularSequenceModulus}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy construction needs an explicit tail-modulus packet before a regular rational readback can be handed to a real-name seal. The $\mathsf{RegularSequenceModulus}^{\uparrow}$ packet records that finite tail data over the dyadic arithmetic of chapter 291, the stream-window naming surface of chapter 126, the regular rational route of chapter 301, the terminal real-name surface of chapter 38, and the modulus boundary of chapter 292. It is a displayed modulus object for regular-Cauchy tails, not a quotient of streams, a selected limit, a host real equality, a countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7483.1 (Regular sequence modulus carrier)**.** *A* $\mathsf{RegularSequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, D, Q, M, T, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, listing the finite windows of the sequence name inspected by the packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the dyadic comparison requests used by the tail test.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational observations that will be consumed downstream.*
4. *M is the tail-modulus row; for each admitted precision request it displays a finite bound after which all listed readbacks are stable inside the corresponding dyadic tolerance.*
5. *T is the finite tail ledger pairing stream windows, dyadic tolerances, readback rows, and modulus bounds.*
6. *H records componentwise* hsame *transport for S, D, Q, M, T and the structural rows.*
7. *C records displayed* Cont *replay from a tail request through the same finite rows.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through hsame-stable agreement of $S, D, Q, M, T, H, C, P, N$. Two carriers agree when the same finite windows, dyadic tolerance rows, regular rational readbacks, modulus bounds, tail-ledger entries, transport rows, replay rows, provenance rows, and local naming rows are matched by componentwise hsame*. No coordinate records a selected limit, quotient stream equality, countable choice, host real equality, or ambient completion theorem.*

Lean4 ✓ `BEDC.Derived.RegularSequenceModulusUp.TasteGate.RegularSequenceModulusTasteGate single carrier alignment`

Theorem 7483.2 (Regular sequence modulus carrier admission)**.** *Every accepted* RegularSequenceModulus$^{\uparrow}$ *carrier $R = (S, D, Q, M, T, H, C, P, N)$ admits exactly the finite NameCert surface displayed in Definition 7483.1. A consumer may project stream windows, dyadic tolerances, regular rational readbacks, tail-modulus bounds, tail-ledger entries, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It may not project a selected limit, quotient stream equality, countable-choice schedule, host real equality, or ambient* Real$^{\uparrow}$ *completeness witness.*

Proof. Project the carrier definition. The rows S, D, Q, M, T provide the finite data used by tail reads, while H, C, P, N provide the structural transport, replay, provenance, and local name.

The classifier is hsame-stable only on those displayed rows. Therefore an accepted packet can be read through the listed finite coordinates and through no detached completion coordinate.

Finally inspect the carrier inventory. Since selected limits, quotient stream classes, countable-choice schedules, host real equalities, and ambient completeness witnesses are not fields of R, they cannot be projected from the NameCert surface. □

Theorem 7483.3 (Regular sequence modulus tail exactness)**.** *Let $R = (S, D, Q, M, T, H, C, P, N)$ be an accepted* RegularSequenceModulus$^{\uparrow}$ *carrier. For every admitted dyadic precision row in D, the modulus row M supplies a finite tail bound, and the ledger T records that all corresponding* RegSeqRat$^{\uparrow}$ *readbacks in Q past that bound agree inside the displayed dyadic tolerance. This exactness is internal to the finite packet: it does not choose a limit and does not identify streams by quotient equality.*

Proof. Begin with the dyadic precision row in D. The carrier requires the same precision request to be paired with a displayed bound in M and with readback entries in Q.

Use the tail ledger T. It is the finite row that binds the stream windows from S, the dyadic comparisons from D, the regular rational observations from Q, and the modulus bound from M into one tail assertion.

The structural rows H, C, P, N only transport, replay, source, and name that same finite assertion. Because no limit or quotient coordinate is present, the exactness statement remains the displayed tail-bound claim carried by T. □

Theorem 7483.4 (Regular sequence modulus RegSeqRat handoff)**.** *Every* RegSeqRat$^{\uparrow}$ *consumer that receives a tail witness from an accepted* RegularSequenceModulus$^{\uparrow}$ *packet must pass through the finite route*

StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchyModulus$^{\uparrow}$, RegularSequenceModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Co

For each admitted unary precision row, the modulus bound in M supplies the closeness witness consumed by the RegSeqRat$^{\uparrow}$ *readback boundary, and the terminal* Real$^{\uparrow}$ *seal may only read that displayed witness. The handoff exports no selected limit, quotient stream equality, countable choice, host real equality, or ambient completeness principle.*

Proof. Apply Definition 7483.2. A downstream read can only project the displayed carrier rows and the structural rows.

Next use Definition 7483.3. The precision row in D and the bound in M are tied by T to the regular rational readback in Q, so the $\mathsf{RegSeqRat}^{\uparrow}$ boundary receives a finite closeness witness rather than an external convergence theorem.

The $\mathsf{Real}^{\uparrow}$ seal is downstream of the same readback route. Since H, C, P, N merely preserve and name the finite packet, the terminal seal cannot add quotient stream equality, a selected limit, choice, host equality, or ambient completeness. □

The regular tail-modulus row is consumed by the Bishop Cauchy calibration route of chapter 7577. The dyadic tolerance, stream window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal are the shared rows, so the modulus packet is a finite source for downstream calibration rather than an isolated kernel float.

Falsifiable prediction: Every accepted $\mathsf{RegularSequenceModulus}^{\uparrow}$ consumer displays $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, finite tail-ledger, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before it reads a terminal $\mathsf{Real}^{\uparrow}$ seal.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchymodulus: $\mathsf{RegularSequenceModulus}^{\uparrow}$ is not bijective to any listed sibling because it packages the finite tail-modulus row and the regular rational handoff ledger as one hsame-stable NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7483.1, Definition 7483.2, Definition 7483.3, and Definition 7483.4 seed the finite tail-modulus packet for regular rational readbacks and terminal real-name reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, tail-bound exactness, RegSeqRat handoff, transport replay, provenance, and non-escape over the same finite packet.

Constructive story: A $\mathsf{RegularSequenceModulus}^{\uparrow}$ packet is generated from finite stream windows, dyadic tolerance rows, regular rational readbacks, tail-modulus bounds, a finite tail ledger, componentwise transport, displayed replay, package provenance, and local naming evidence.

Chapter 7484

A Concrete Naming Certificate for $\mathsf{VisionCoverageLedger}^{\uparrow}$

The $\mathsf{VisionCoverageLedger}^{\uparrow}$ packet realizes the top-level routing surface of chapter 9236 as finite BEDC data. It records which vision label is being covered, which concrete-instance chapter receives the coverage row, which marker was replayed, and which NameCert rows make the routing auditable. The packet sits beside the existing coverage account of chapter 7381 and the concrete tail-modulus surface of chapter 7483; it is a finite ledger of label-to-chapter coverage, not a bijection between visions and constructions and not a global completeness theorem for the visions tree.

Definition 7484.1 (Vision coverage ledger carrier)**.** *A* $\mathsf{VisionCoverageLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (L, T, M, W, H, C, P, N)$$

with the following rows:

1. *L is the source-label row, naming an existing vision label such as the capstone label of chapter 9236.*
2. *T is the concrete-target row, naming an existing concrete-instance chapter label.*
3. *M is the marker row, recording the displayed concretized-in route that connects L to T.*
4. *W is the well-formedness row, checking that both labels are present in the manuscript and that the target label belongs to a concrete-instance NameCert chapter.*
5. *H records componentwise* hsame *transport for the source-label, target-label, marker, and well-formedness rows.*
6. *C records displayed* Cont *replay from a coverage query through L, T, M, W, H.*
7. *P is the* Pkg *provenance over* $\mathsf{VisionCoverageLedger}^{\uparrow}$, $\mathsf{VisionCoverageIndex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{VisionCoverageLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the finite rows L, T, M, W, H, C, P, N. It has no coordinate for a total vision-to-instance bijection, a completeness theorem for all vision files, a semantic equivalence between a vision and a construction, or automatic coverage for unmarked chapters.

Theorem 7484.2 (Vision coverage ledger marker admission)**.** *Every accepted* $\mathsf{VisionCoverageLedger}^{\uparrow}$ *carrier admits a coverage row only when its marker row M names an existing source label L and an existing concrete-instance target label T. The admitted row is exactly the finite marker route displayed in the carrier; it does not infer coverage from prose proximity, filename similarity, or thematic overlap.*

Proof. Project the carrier of Definition 7484.1. The marker row M is stored together with the source-label row L and target-label row T.

Use the well-formedness row W. It checks existence of both labels and checks that T is a concrete-instance NameCert chapter label before transport or replay is consumed.

The structural rows H, C, P, N preserve and name the same marker route. Since no prose-inference, filename, or thematic-overlap coordinate is present, marker admission is exactly the displayed finite row. □

Theorem 7484.3 (Vision coverage ledger label well-formedness)**.** *For every accepted* $\mathsf{VisionCoverageLedger}^{\uparrow}$ *carrier $V = (L, T, M, W, H, C, P, N)$, the well-formedness row W is consumed before any coverage replay. Thus a coverage read can only cite a source label already present in the visions surface and a target label already present in a concrete-instance chapter, including rows such as chapter 9236 and chapter 7381.*

Proof. Start with the carrier projection. The replay row C is downstream of L, T, M, W, H, so it cannot be consumed before the labels and marker are displayed.

Apply Definition 7484.2. Admission requires the marker route to name an existing source label and an existing concrete-instance target label.

Therefore the well-formedness row is the gate for coverage replay. It keeps the ledger finite and prevents a consumer from reading a missing vision label or a missing concrete target as covered. □

Theorem 7484.4 (Vision coverage ledger transport and replay stability)**.** *If two accepted* $\mathsf{VisionCoverageLedger}^{\uparrow}$ *carriers agree by componentwise* hsame *on L, T, M, W, H, C, P, N, then every coverage replay through one carrier replays through the other with the same source label, concrete target label, marker row, and well-formedness check. The transport does not create a new coverage target and does not turn a finite marker row into a global coverage theorem.*

Proof. Use the classifier in Definition 7484.1. Agreement is defined componentwise on the finite rows L, T, M, W, H, C, P, N.

The transport row H preserves the source label, target label, marker row, and well-formedness row. The replay row C is displayed over those same transported rows.

Finally apply Definition 7484.3. Since replay is gated by the same well-formedness row on both carriers, transport cannot add an unlisted coverage target or promote the row to global coverage. □

Theorem 7484.5 (Vision coverage ledger finite-row non-escape)**.** *Every admitted* $\mathsf{VisionCoverageLedger}^{\uparrow}$ *coverage read remains inside the finite rows L, T, M, W, H, C, P, N. It records coverage only for the source and target labels named in the row, and it exports no completeness claim for unmarked vision sections, no bijection between all visions and all concrete instances, and no semantic equality between a vision narrative and a NameCert construction.*

Proof. Project the carrier. The only data available to a coverage consumer are the source-label, target-label, marker, well-formedness, transport, replay, provenance, and local naming rows.

Use marker admission and label well-formedness from Definition 7484.2 and Definition 7484.3. They restrict the read to one existing source label and one existing concrete target label.

Use transport and replay stability from Definition 7484.4. Transport preserves the same finite row, so replay cannot escape to unmarked labels, a total bijection, or semantic equality. □

Falsifiable prediction: Every accepted $\mathsf{VisionCoverageLedger}^{\uparrow}$ coverage row names an existing vision label and an existing concrete-instance chapter label before it may be replayed as a coverage marker.

Independence witness: vision-coverage-index, namecert, package, gap, exact-globalize-base: $\mathsf{VisionCoverageLedger}^{\uparrow}$ is not bijective to any listed sibling because it stores source-label, concrete-target, marker-ledger, well-formedness, transport, replay, provenance, and NameCert rows for coverage accounting without claiming total coverage, semantic equivalence, or a global bijection.

Closure status for $\mathsf{NameCert}_{\mathsf{VisionCoverageLedger}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VisionCoverageLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7484.1, Definition 7484.2, Definition 7484.3, Definition 7484.4, and Definition 7484.5 seed the finite label-to-concrete coverage ledger for the top-level visions surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VisionCoverageLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total vision coverage, vision-to-concrete bijection, semantic equality between narratives and constructions, Lean verification, bridge checking, or coverage for unmarked rows.

Upgrade path: Obligation closure requires checked marker admission, target-label well-formedness, hsame transport, replay stability, provenance, local naming, and finite-row non-escape.

Constructive story: A $\mathsf{VisionCoverageLedger}^{\uparrow}$ packet is generated from a source vision label, a concrete-instance target label, a coverage marker row, a label well-formedness row, componentwise transport, displayed replay, package provenance, and local naming evidence.

Chapter 7485

A Concrete Naming Certificate for $\mathsf{LHopitalRule}^{\uparrow}$

Following de l'Hopital, Bernoulli, and Cauchy's mean-value route, the $\mathsf{LHopitalRule}^{\uparrow}$ packet records the finite BEDC surface behind a derivative-ratio comparison before a limiting quotient is read as a real-facing conclusion. It sits after the derivative quotient interface of chapter 122, the Cauchy mean-value theorem handoff of chapter 6763, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names one displayed calculus route; it does not import a host limit rule, quotient real equality, trichotomy, selected limiting point, or ambient completeness.

Definition 7485.1 (LHopitalRule carrier)**.** *A* $\mathsf{LHopitalRule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, F, G, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row, including the endpoint-side window on which the quotient comparison is requested.*
2. *F and G are the two differentiable function rows whose values and derivative quotients are inspected through* $\mathsf{Derivative}^{\uparrow}$ *data.*
3. *D is the derivative-ratio comparison row, recording the displayed comparison between the derivative quotients of F and G on the same interval window.*
4. *Q is the* $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ *handoff row that turns the paired derivative data into a finite quotient comparison route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the quotient windows and derivative-ratio budgets.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the interval, function rows, derivative-ratio row, Cauchy mean-value handoff, and regular rational readback are displayed.*
7. *H stores componentwise* hsame *transport for the interval, functions, derivative-ratio comparison, Cauchy mean-value handoff, readback, real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from the interval and function rows to the derivative comparison, from the derivative comparison to the Cauchy mean-value handoff, and from that handoff to the readback and real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{LHopitalRule}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LHopitalRule}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, G, D, Q, R, E, H, C, P, N$. It has no coordinate for a host limit theorem, quotient real equality, trichotomy, selected endpoint representative, or ambient real completeness.

Theorem 7485.2 (LHopitalRule NameCert obligations)**.** *For an accepted* $\mathsf{LHopitalRule}^{\uparrow}$ *carrier $L = (I, F, G, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LHopitalRule}^{\uparrow}}$ *obligations are exactly interval admission, paired differentiable-function admission, derivative-ratio comparison, Cauchy mean-value handoff, regular rational readback, Real seal factorization, componentwise transport, replay, provenance, and local naming. These obligations are discharged only through the displayed route*

$$I, F, G \longmapsto D \longmapsto Q \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Project the accepted carrier. The interval row I fixes the side and finite window, while F and G are the only differentiable function rows available to the packet. Thus carrier admission and function admission are projections from Definition 7485.1.

Next inspect the derivative-ratio row. The row D reads derivative quotient data through the $\mathsf{Derivative}^{\uparrow}$ interface and records only a displayed comparison on the same interval window. No independent endpoint limit or host quotient rule is present.

Now apply the Cauchy mean-value handoff row Q. It is the only route from the paired derivative comparison to a quotient comparison, and the later rows R and E can read that comparison only through regular rational readback and the terminal real seal.

Finally read H, C, P, N. These rows transport, replay, source, and name the same finite packet, so no obligation can escape to quotient real equality, trichotomy, selected limiting representatives, host calculus, or ambient completeness. □

Theorem 7485.3 (LHopitalRule Cauchy mean-value handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{LHopitalRule}^{\uparrow}$ *packet must read the Cauchy mean-value handoff row Q after the interval row I, the differentiable function rows F, G, and the derivative-ratio comparison row D have been displayed. The exported route is*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{CauchyMeanValueTheorem}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

inside the same finite packet, with $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *budgets available only through the displayed readback rows.*

Proof. Begin with the obligation route of Definition 7485.2. It places I, F, G before D, and places D before the Cauchy mean-value row Q can be consumed.

Use the sibling Cauchy mean-value packet named in chapter 6763. The row Q is a handoff row, not a host theorem invocation: it records the finite mean-value comparison surface already exposed by the derivative rows.

Next route the readback. The row R gives the regular rational windows for the quotient comparison, with $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ data visible through the displayed finite observations and tolerance ledger. The row E is downstream of R and is the only real-facing seal.

Therefore any consumer reaching $\mathsf{Real}^{\uparrow}$ or $\mathsf{RegSeqRat}^{\uparrow}$ has already read I, F, G, D, Q through the same packet. The handoff exports no selected limit, no quotient real equality, no trichotomy, no countable choice, and no ambient completeness principle. □

Falsifiable prediction: Every $\mathsf{LHopitalRule}^{\uparrow}$ read factors through an interval row, two differentiable function rows, one derivative-ratio comparison row, a $\mathsf{CauchyMeanValueTheorem}^{\uparrow}$ handoff, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ budgets, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: derivative, cauchy-mean-value-theorem, streamname, dyadicratcore, regseqrat, real: $\mathsf{LHopitalRule}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an interval window, two differentiable function rows, derivative-ratio comparison, Cauchy mean-value handoff, readback, real seal, transport, replay, provenance, and local naming as one calculus certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LHopitalRule}^{\uparrow}}$.

Constructive story: A $\mathsf{LHopitalRule}^{\uparrow}$ packet is generated from an interval row, two differentiable function rows, a derivative-ratio comparison, a CauchyMeanValueTheorem handoff, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LHopitalRule}^{\uparrow}}$, seed)

Scope closed: Definition 7485.1, Definition 7485.2, and Definition 7485.3 seed the finite derivative-ratio and Cauchy mean-value route for one displayed l'Hopital-rule packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LHopitalRule}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host limit rule, quotient real equality, selected limits, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, differentiable-function admission, derivative-ratio comparison, Cauchy mean-value handoff, regular rational readback, Real seal factorization, transport, replay, provenance, and local naming for BEDC.Derived.LHopitalRuleUp.

Chapter 7486

A Concrete Naming Certificate for $\mathsf{VoronoiCellLedger}^{\uparrow}$

Following Aurenhammer and the de Berg–van Kreveld–Overmars–Schwarzkopf treatment of Voronoi diagrams, the $\mathsf{VoronoiCellLedger}^{\uparrow}$ packet records the finite ledger by which nearest-site cells are read from displayed metric comparisons before any host planar subdivision or selected closest-point theorem is available. It sits after the metric carrier of chapter 57, the finite-net routes represented by $\mathsf{FiniteNet}^{\uparrow}$ and chapter 7465, the convex-set carrier of chapter 208, the polytope carrier of chapter 209, and the terminal real-name seal of chapter 38. The chapter names finite site, distance-comparison, bisector, halfspace, cell-boundary, real-comparison, transport, replay, provenance, and local NameCert rows; it does not claim a global Delaunay dual, a host Euclidean order theorem, selected nearest points, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7486.1 (Voronoi cell ledger carrier)**.** *A* $\mathsf{VoronoiCellLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S, M, D, B, A, C, R, H, T, P, N)$$

with the following displayed rows:

1. *S is the finite site-set row, listing the site names and the finite-net address from which every inspected site is read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *metric source row for the displayed distance comparisons.*
3. *D is the distance-comparison ledger, recording for each inspected query row the finite comparison between the chosen site and every competing site in S.*
4. *B is the bisector ledger, naming the equal-distance boundary rows induced by pairs of displayed sites.*
5. *A is the halfspace ledger, recording which side of each bisector keeps the selected site no farther than the competitor.*
6. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *and* $\mathsf{Polytope}^{\uparrow}$ *cell-boundary row obtained by intersecting the listed halfspace rows.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison seal for the distance and boundary inequalities after the finite comparison ledger is visible.*

8. *H records componentwise* hsame *transport for the site set, metric row, comparison ledger, bisector rows, halfspace rows, cell boundary, real seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from a nearest-site request through S, M, D, B, A, C, R.*
10. *P is the* Pkg *provenance over* $\mathsf{VoronoiCellLedger}^{\uparrow}$, $\mathsf{FiniteNet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{VoronoiCellLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, M, D, B, A, C, R, H, T, P, N$. It has no coordinate for an infinite site family, a host nearest-neighbor selector, a completed Euclidean diagram, quotient real equality, trichotomy, countable choice, Delaunay duality, or ambient real completeness.

Theorem 7486.2 (Voronoi cell ledger NameCert obligations)**.** *For every accepted* $\mathsf{VoronoiCellLedger}^{\uparrow}$ *carrier $V = (S, M, D, B, A, C, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VoronoiCellLedger}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *site admission for the displayed finite site set and finite-net address row S;*
2. *metric comparison admission for the* $\mathsf{Met}^{\uparrow}$ *source row M and the distance-comparison ledger D;*
3. *bisector exposure, requiring every equal-distance boundary row to be named in B from a displayed pair of sites;*
4. *halfspace exposure, requiring every selected-site inequality to be read through the corresponding row of A;*
5. *convex and polytope boundary exposure, requiring the cell boundary row C to be the listed intersection of the accepted halfspace rows;*
6. *real-comparison sealing, requiring every exported distance or boundary comparison to pass through the* $\mathsf{Real}^{\uparrow}$ *seal R;*
7. *transport, replay, provenance, and local naming stability through H, T, P, N;*
8. *ledger non-escape, excluding selected nearest points, host diagram completion, quotient real equality, trichotomy, countable choice, Delaunay duality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 7486.1. The finite site row S and metric row M are the only sources for the distance comparisons listed in D.

The boundary rows are downstream of those comparisons. A bisector row in B is attached to a displayed pair of sites, and a halfspace row in A records the selected-site side of that same comparison before the convex cell row C can be read.

The real-facing route is sealed only after the finite comparison and boundary rows are visible. Thus R can export distance and boundary inequalities, but cannot add a nearest-neighbor selector or a completed host diagram.

Finally, H, T, P, N transport, replay, source, and name the same displayed packet. Since the carrier has no coordinate for the excluded selector, quotient, choice, duality, trichotomy, or completeness data, the listed rows exhaust the local NameCert obligations. □

Theorem 7486.3 (Voronoi cell nearest-site route)**.** *Every nearest-site or cell-boundary consumer of an accepted* $\mathsf{VoronoiCellLedger}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{FiniteNet}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto D \longmapsto B \longmapsto A \longmapsto \mathsf{ConvexSet}^{\uparrow}/\mathsf{Polytope}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives a displayed ledger of site comparisons, bisectors, halfspaces, convex-cell boundaries, and real-comparison seals; it receives no selected nearest point, host planar subdivision, quotient real equality, countable-choice schedule, Delaunay dual, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the site and metric rows. The finite-net source bounds the site inventory, and the metric row supplies the only distance readings used by the ledger.

Read the comparison and boundary rows next. The ledger D compares the chosen site against the finite competitors, the bisector row B records equal-distance boundaries, and the halfspace row A records the side that keeps the chosen site no farther than each competitor.

The convex-cell row C is read after those halfspaces, as a $\mathsf{ConvexSet}^{\uparrow}$ and $\mathsf{Polytope}^{\uparrow}$ boundary assembled from the finite ledger. The real seal R exports only the displayed comparisons already present in D, B, A, C.

Transport, replay, provenance, and local naming preserve the same route. Therefore any nearest-site consumer remains inside the finite ledger and cannot obtain the excluded selector, host diagram, quotient, choice, duality, or completeness data from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{VoronoiCellLedger}^{\uparrow}}$**.**

Constructive story: A $\mathsf{VoronoiCellLedger}^{\uparrow}$ packet is generated from a finite site set, a MetricUp distance row, distance-comparison rows, bisector rows, halfspace rows, ConvexSet and Polytope cell-boundary rows, a RealUp comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{VoronoiCellLedger}^{\uparrow}}$, seed)

Scope closed: Definition 7486.1, Definition 7486.2, and Definition 7486.3 seed the finite Voronoi cell ledger over metric, finite-net, convex, polytope, real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{VoronoiCellLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global Voronoi diagram construction, Delaunay duality, selected nearest points, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked site admission, metric-comparison admission, bisector exposure, halfspace exposure, convex-cell boundary exposure, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.VoronoiCellLedgerUp.

Chapter 7487

A Concrete Naming Certificate for $\mathsf{HorosphereShearLedger}^{\uparrow}$

Following the standard hyperbolic-geometry reading of Busemann functions, horospheres, and shear coordinates, the $\mathsf{HorosphereShearLedger}^{\uparrow}$ packet records the finite route by which a boundary point, a horosphere row, and a shear transport comparison are read before any global Teichmuller or measured-lamination theorem is available. It is grounded by the hyperbolic observer-expansion vision of chapter 9463, and it sits after the metric carrier of chapter 3474, the Busemann-boundary packet of chapter 3732, the horosphere-flow ledger of chapter 4051, the boundary-shadow packet of chapter 3813, and the terminal real-name seal of chapter 38. The chapter names finite boundary, horosphere, Busemann-comparison, shear-transport, metric-readback, real-seal, transport, replay, provenance, and local NameCert rows; it does not claim complete hyperbolic geometry, ideal boundary compactness, selected geodesic representatives, quotient boundary equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7487.1 (Horosphere shear ledger carrier)**.** *A* $\mathsf{HorosphereShearLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, O, B, S, M, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the boundary-point row read through* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$*.*
2. *O is the horosphere row, naming the displayed Busemann level set attached to Q.*
3. *B is the Busemann comparison row, recording the finite level and cocycle comparisons used by the shear reading.*
4. *S is the shear-transport row, carrying the displayed displacement between adjacent horosphere reads.*
5. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-readback row for the distance and displacement comparisons used by B and S.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for exported Busemann, metric, and shear comparisons after Q, O, B, S, M are visible.*
7. *H records componentwise* hsame *transport for boundary point, horosphere, Busemann comparison, shear transport, metric readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a boundary-shear request through Q, O, B, S, M, R.*

9. *P is the* Pkg *provenance over* $\mathsf{HorosphereShearLedger}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HorosphereFlowLedger}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HorosphereShearLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, O, B, S, M, R, H, C, P, N$. It has no coordinate for an ideal-boundary quotient, a selected geodesic representative, global horosphere foliation, measured lamination, completed Teichmuller shear coordinate, countable choice, trichotomy, or ambient real completeness.

Theorem 7487.2 (Horosphere shear ledger NameCert obligations)**.** *For every accepted* $\mathsf{HorosphereShearLedger}^{\uparrow}$ *carrier $L = (Q, O, B, S, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HorosphereShearLedger}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *boundary-point exposure through the displayed* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row Q;*
2. *horosphere exposure through the Busemann level row O;*
3. *Busemann comparison exposure through the finite comparison ledger B;*
4. *shear-transport exposure through the displayed transport row S;*
5. *hyperbolic metric readback through M before any exported displacement is read;*
6. *real-comparison sealing through R;*
7. *transport, replay, provenance, and local naming stability through H, C, P, N;*
8. *ledger non-escape, excluding ideal-boundary quotient equality, selected geodesic representatives, global horosphere foliations, completed shear-coordinate theory, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Project the carrier of Definition 7487.1. The boundary point Q and horosphere row O are the only sources for the Busemann comparison ledger B.

The shear row is downstream of that comparison. It records a finite transport between displayed horosphere reads, while the hyperbolic metric row M supplies the distance readback used by the comparison and transport rows.

The real seal R is read after the boundary, horosphere, Busemann, shear, and metric rows. It can export displayed real-valued comparisons, but it cannot introduce an ideal-boundary quotient or a selected geodesic representative.

Finally, H, C, P, N preserve, replay, source, and name the same packet. Since the carrier lacks coordinates for the excluded quotient, global, choice, trichotomy, and completeness data, the listed rows exhaust the local NameCert surface. □

Theorem 7487.3 (Horosphere shear transport route)**.** *Every boundary-shadow or horosphere-flow consumer of an accepted* $\mathsf{HorosphereShearLedger}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto O \longmapsto B \longmapsto S \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may be consumed by $\mathsf{HorosphereFlowLedger}^{\uparrow}$ *and* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *rows, but it supplies only displayed boundary-point, horosphere, Busemann, metric-readback, shear-transport, real-seal, transport, replay, provenance, and local NameCert data.*

Proof. Read the boundary and horosphere rows first. The boundary point Q comes from the Busemann-boundary packet, and the horosphere row O names the displayed level set attached to that boundary point.

The Busemann comparison row B and shear-transport row S are then read over the same displayed boundary and horosphere data. The hyperbolic metric row M supplies the distance readback used by the shear comparison before the terminal real seal R is visible.

Downstream $\mathsf{HorosphereFlowLedger}^{\uparrow}$ and $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ consumers can therefore inspect the shear route only through Q, O, B, S, M, R. The structural rows H, C, P, N keep that route stable under transport and replay, so no global foliation, selected geodesic, quotient boundary equality, choice schedule, trichotomy branch, or ambient real-completeness datum is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{HorosphereShearLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{HorosphereShearLedger}^{\uparrow}$ packet is generated from a HyperbolicBusemannBoundary boundary-point row, a horosphere row, a Busemann comparison row, a shear-transport row, a HyperbolicMetric readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HorosphereShearLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7487.1, Definition 7487.2, and Definition 7487.3 seed the finite horosphere-shear ledger over boundary, horosphere, Busemann, metric, real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HorosphereShearLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close complete hyperbolic geometry, ideal-boundary compactness, selected geodesic representatives, quotient boundary equality, global horosphere foliations, measured laminations, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked boundary-point exposure, horosphere exposure, Busemann comparison exposure, shear-transport exposure, hyperbolic metric readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.HorosphereShearLedgerUp.

Chapter 7488

A Concrete Naming Certificate for $\mathsf{BishopCauchyFusion}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy sequence arguments, the $\mathsf{BishopCauchyFusion}^{\uparrow}$ packet records the finite route by which two regular rational Cauchy sources are read through paired stream windows and one shared dyadic budget before a Real-facing fusion seal is exposed. It sits beside the regular rational name surface of chapter 301, the finite stream-window discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the reusable tail-modulus fusion route of chapter 1024, and the terminal real-name seal of chapter 38. The packet names a two-witness fusion route for the Real and Completion corridor without quotient stream equality, selected limits, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7488.1 (Bishop Cauchy fusion carrier)**.** *A* $\mathsf{BishopCauchyFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, W_A, W_B, D, F, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational observations are to be fused.*
2. *W_A and W_B are the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which the two sources are inspected.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row, recording the single dyadic tolerance service used by both windows.*
4. *F is the* $\mathsf{CauchyTailModulusFusion}^{\uparrow}$ *row that binds the two source tails to the shared budget before a seal-facing read is allowed.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row produced only after A, B, W_A, W_B, D, F have been displayed.*
6. *H records componentwise* hsame *transport for the two sources, paired windows, shared budget, fusion row, Real seal, continuation row, package row, and local naming row.*
7. *C records displayed* Cont *replay from a requested tolerance through the two windows, the shared budget, the fusion row, and then to the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyFusion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailModulusFusion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyFusion}^{\uparrow}}$ *row.*

The carrier exposes only this finite two-witness route. It has no row for quotient stream equality, selected host limits, host real equality, countable-choice schedules, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7488.2 (Bishop Cauchy fusion NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyFusion}^{\uparrow}$ *carrier*

$$K = (A, B, W_A, W_B, D, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyFusion}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, one shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget, one* $\mathsf{CauchyTailModulusFusion}^{\uparrow}$ *row, one terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every seal-facing read must keep both source rows and both window rows attached to the same budget row* D *before* F *and* R *are consumed.*

Proof. Project the carrier of Definition 7488.1. Rows A, B, W_A, W_B, D, F, R are the analytic route, and rows H, C, P, N provide transport, replay, provenance, and local naming.

Carrier admission reads the two regular sources and paired windows first. The budget obligation then identifies D as the only dyadic tolerance row available to both windows, so the two branches cannot be read through private tolerance services.

The fusion obligation is the next step. Row F is consumed only after A, B, W_A, W_B, D are displayed, and the Real seal R is downstream of that same fusion row.

Finally, H, C, P, N preserve the route as finite NameCert data. Since quotient streams, selected host limits, host equality, countable choice, trichotomy, and ambient completeness are absent from the carrier, the listed obligations exhaust the local surface. □

Theorem 7488.3 (Bishop Cauchy fusion single-window handoff)**.** *Every accepted* $\mathsf{BishopCauchyFusion}^{\uparrow}$ *packet exposes a single shared observation window for the two-witness fusion route: a consumer may inspect* W_A *and* W_B *only through the common dyadic budget* D *and the fusion row* F*. Thus the handoff from two* $\mathsf{RegSeqRat}^{\uparrow}$ *sources to the terminal* $\mathsf{Real}^{\uparrow}$ *seal is a single finite route through*

$$A,\ B,\ W_A,\ W_B,\ D,\ F,\ R,$$

not two independent Real-seal routes.

Proof. Start with the NameCert obligations of Definition 7488.2. They keep both source rows attached to the paired stream windows and require one shared dyadic budget row D before the fusion row is available.

The handoff is therefore controlled by D. Any read of W_A or W_B that reaches F has already passed through the same budget service, so the consumer receives one displayed fusion route rather than two detached source reads.

The terminal Real seal R is downstream of F. Because no second Real-seal coordinate appears in the carrier, the handoff remains a single finite route through the displayed rows. □

Theorem 7488.4 (Bishop Cauchy fusion Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *read of an accepted* $\mathsf{BishopCauchyFusion}^{\uparrow}$ *packet factors through the two regular sources, paired stream windows, shared dyadic budget, and fusion row before the terminal seal* R *is consumed. The read exports no quotient stream equality, selected host limit, host real equality, countable-choice row, trichotomy witness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the carrier rows of Definition 7488.1. The only Real-facing coordinate is R, and it appears after the two sources A, B, the windows W_A, W_B, the shared budget D, and the fusion row F.

Apply the single-window handoff theorem. It forces the two source branches to meet at the same dyadic budget and the same fusion row before a Real-facing consumer can read the seal.

The structural rows H, C, P, N only transport, replay, source, and name the same finite packet. Since the refused host-level data are not rows of K, a consumer of R cannot escape the displayed fusion route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyFusion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyFusion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7488.1, Definition 7488.2, Definition 7488.3, and Definition 7488.4 seed the finite two-witness Cauchy fusion route through paired windows, one dyadic budget, one fusion row, and one Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyFusion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected host limits, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-window exposure, shared dyadic budget exactness, fusion-row ordering, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyFusionUp

Constructive story: A $\mathsf{BishopCauchyFusion}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two StreamName windows, one DyadicRatCore budget row, a CauchyTailModulusFusion row, a terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7489

A Concrete Naming Certificate for $\mathsf{RealArchimedeanWindow}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealArchimedeanWindow}^{\uparrow}$ packet records the finite inspected window by which a displayed $\mathsf{Real}^{\uparrow}$ name is bracketed between dyadic lower and upper rows at a positive radius before any Real or Completion consumer reads an order-facing statement. It sits over the terminal real seal of chapter 38, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic endpoint ledger of chapter 291, the positive-radius surface of chapter 1587, and the Archimedean property route of chapter 3372. The packet names a displayed bracketing carrier; it is not a completeness theorem, trichotomy principle, quotient-stream equality test, selected-limit operator, or open-cover compactness claim.

Definition 7489.1 (RealArchimedeanWindow carrier)**.** *A* $\mathsf{RealArchimedeanWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, S, Q, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row whose inspected name is being bracketed;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule selecting the finite windows consumed by the read;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic-core ledger for the bracket arithmetic;*
5. *L is the lower dyadic bracket row;*
6. *U is the upper dyadic bracket row;*
7. *H records componentwise* hsame *transport for the real seal, schedule, readback, dyadic core, lower and upper brackets, provenance, and local naming row;*
8. *C records displayed* Cont *replay for the same inspected bracketing route;*
9. *P is the* Pkg *provenance over* $\mathsf{RealArchimedeanWindow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}$ *row.*

The positive radius is carried as part of the local dyadic-window read through D, L, U and the sibling $\mathsf{PositiveReal}^{\uparrow}$ *provenance. No coordinate stores a quotient real representative, selected limit point, host trichotomy decision, or ambient completeness witness.*

Lean4 ✓ `BEDC.Derived.RealArchimedeanWindowUp.TasteGate.RealArchimedeanWindowTasteGate single carrier alignment`

Theorem 7489.2 (RealArchimedeanWindow NameCert obligations)**.** *For an accepted* $\mathsf{RealArchimedeanWindow}^{\uparrow}$ *carrier* $W = (R, S, Q, D, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}$ *surface consists exactly of carrier admission, sealed* $\mathsf{Real}^{\uparrow}$ *exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *observation scheduling,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket arithmetic, lower and upper dyadic endpoint exposure, positive-radius provenance, componentwise transport, displayed replay, package provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.RealArchimedeanWindowUp.RealArchimedeanWindowNameCertObligations`

Proof. Carrier admission is projection from Definition 7489.1. The accepted packet exposes only the rows $R, S, Q, D, L, U, H, C, P, N$.

The observation route reads S before Q, and reads D before the lower and upper endpoint rows. Thus the bracket is an inspected dyadic window over a displayed regular rational readback rather than a host comparison of real numbers.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient-stream equality coordinate, selected-limit coordinate, trichotomy coordinate, or completeness coordinate, the local certificate cannot export any of those principles. □

Theorem 7489.3 (RealArchimedeanWindow dyadic bracket)**.** *Every accepted* $\mathsf{RealArchimedeanWindow}^{\uparrow}$ *packet exposes its lower and upper bracket only through the shared dyadic-core row* D*, the inspected stream schedule* S*, and the regular readback row* Q*. The lower row* L *and upper row* U *are consumed as one finite bracketing surface for the sealed real row* R *and the positive-radius provenance in* P*; they do not supply Real completeness, trichotomy, quotient stream equality, selected limits, or open-cover compactness.*

Proof. Open the carrier $W = (R, S, Q, D, L, U, H, C, P, N)$. The two endpoint rows L and U are not independent order witnesses; they are named after the schedule, readback, and dyadic-core rows have been displayed.

Use the NameCert obligations above. They make the bracketing route pass through R, S, Q, D, L, U before transport, replay, provenance, or local naming is read.

The exclusion follows by coordinate inspection. A completeness theorem, trichotomy decision, quotient stream equality test, selected-limit operator, and open-cover compactness witness are absent from the carrier, so no consumer of the window can project them from the dyadic bracket. □

Lean4 ✓ `BEDC.Derived.RealArchimedeanWindowUp.RealArchimedeanWindowCarrier dyadic bracket handoff`

Theorem 7489.4 (RealArchimedeanWindow bound consumer exactness)**.** *Every order-facing or completion-facing consumer of an accepted* $\mathsf{RealArchimedeanWindow}^{\uparrow}$ *packet must read the* $\mathsf{PositiveReal}^{\uparrow}$ *radius provenance and the* $\mathsf{RealArchimedeanProperty}^{\uparrow}$ *bound route together with the displayed rows* $R, S, Q, D, L, U, H, C, P, N$ *before treating the bracket as a bound. The consumer route factors through the positive-radius sibling of chapter 1587, the Archimedean-property sibling of chapter 3372, the local carrier of Definition 7489.1, the NameCert obligations of Definition 7489.2, and the dyadic-bracket handoff of Definition 7489.3.*

Proof. Project the carrier $W = (R, S, Q, D, L, U, H, C, P, N)$ from Definition 7489.1. The only radius-facing entry available to a consumer is the provenance row P, where the $\mathsf{PositiveReal}^{\uparrow}$ dependency is recorded together with the local $\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}$ row.

Use the NameCert obligations from Definition 7489.2. They force the order-facing read to keep $R, S, Q, D, L, U, H, C, P, N$ in the same finite packet, so the lower and upper endpoints cannot be separated from their stream schedule, regular readback, dyadic core, transport, replay, provenance, or local name.

Apply the dyadic-bracket handoff of Definition 7489.3. The bracket is consumed only after D, S, Q, L, U and the positive-radius provenance have been displayed. Therefore an order or completion consumer that treats the bracket as a bound must also carry the sibling $\mathsf{RealArchimedeanProperty}^{\uparrow}$ route named in the chapter interface, rather than projecting a host order axiom, trichotomy decision, quotient-real equality test, selected-limit operator, or ambient completeness witness from the window alone. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7489.1, Definition 7489.2, and Definition 7489.3 seed the inspected dyadic-window carrier over Real, StreamName, RegSeqRat, DyadicRatCore, and PositiveReal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealArchimedeanWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, quotient stream equality, selected limits, open-cover compactness, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, inspected-window scheduling, dyadic endpoint exactness, positive-radius provenance, transport, replay, and local naming for BEDC.Derived.RealArchimedeanWindowUp.

Constructive story: A $\mathsf{RealArchimedeanWindow}^{\uparrow}$ packet is generated from a sealed Real row, finite StreamName observation schedule, RegSeqRat readback, DyadicRatCore bracket ledger, lower and upper dyadic endpoint rows, positive-radius provenance, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 7490

A Concrete Naming Certificate for $\mathsf{DyadicMidpointChain}^{\uparrow}$

Following Bishop and Bridges constructive interval analysis, the $\mathsf{DyadicMidpointChain}^{\uparrow}$ packet records finite dyadic midpoint chains as displayed BEDC data. It sits after the dyadic rational core of chapter 291, the midpoint interval carrier of chapter 7331, the bisection branch ledger of chapter 361, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite midpoint-refinement route; it is not a quotient stream equality, selected limit, trichotomy principle, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7490.1 (Dyadic midpoint chain carrier)**.** *A* $\mathsf{DyadicMidpointChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, Q, B, O, W, A, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the endpoint-pair rows, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and displayed as the current closed dyadic interval.*
2. *Q is the midpoint row, recording the dyadic midpoint computed from the displayed endpoint pair.*
3. *B is the retained-side ledger, listing the finite left-or-right midpoint decisions accepted by the refinement.*
4. *O is the finite chain-order row, asserting that the retained intervals are read in the displayed midpoint-refinement order.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing exactly the stages inspected by a downstream consumer.*
6. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows and midpoint decisions.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after L, R, Q, B, O, W, A have been displayed.*
8. *H records componentwise* hsame *transport for endpoint, midpoint, retained-side, chain-order, stream-window, readback, real-seal, replay, provenance, and local-name rows.*
9. *C records displayed* Cont *replay from an interval-refinement request through L, R, Q, B, O, W, A, E.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicMidpointChain}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicMidpointInterval}^{\uparrow}$, $\mathsf{DyadicBisection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMidpointChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient equality of streams, choice-selected limits, trichotomy on reals, open-cover compactness, Heine–Borel, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicMidpointChainUp.TasteGate.DyadicMidpointChainTasteGate single carrier alignment`

Theorem 7490.2 (Dyadic midpoint chain NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMidpointChain}^{\uparrow}$ *carrier*

$$M = (L, R, Q, B, O, W, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicMidpointChain}^{\uparrow}}$ *surface consists exactly of endpoint-pair admission through L, R, midpoint exposure through Q, retained-side ledger exactness through B, finite chain-order exposure through O,* $\mathsf{StreamName}^{\uparrow}$ *window exposure through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through A, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7490.1. The endpoint, midpoint, retained-side, chain-order, stream-window, readback, real-seal, transport, replay, provenance, and naming rows are the whole packet.

Read the analytic rows in order. The endpoint rows L, R supply the dyadic interval, the midpoint row Q computes the displayed midpoint, and the retained-side ledger B records which side survives each finite refinement.

The chain-order row O then keeps those retained intervals in one displayed midpoint-refinement sequence. The window and readback rows W, A expose only finite observations of that sequence, and the seal row E is downstream of those reads.

Finally H, C, P, N transport, replay, source, and name the same data. Since no carrier coordinate stores quotient stream equality, selected limits, trichotomy, open-cover compactness, Heine–Borel, or ambient real completeness, none of those principles belongs to the local obligation surface. □

Theorem 7490.3 (Dyadic midpoint chain regular-Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicMidpointChain}^{\uparrow}$ *packet reads through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{DyadicMidpointInterval}^{\uparrow} \longmapsto \mathsf{DyadicBisection}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using $L, R, Q, B, O, W, A, E, H, C, P, N$. The handoff cannot use quotient stream equality, selected limits, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $M = (L, R, Q, B, O, W, A, E, H, C, P, N)$. A regular-rational or real-facing read must first expose the endpoint and midpoint rows L, R, Q before a retained interval is visible.

The retained-side ledger B and chain-order row O then determine the finite midpoint-refinement chain. These rows are the only source of branch decisions, so a consumer cannot replace them by a selected point or a host trichotomy test.

The window row W and readback row A provide the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observations through which the terminal seal E is consumed. Componentwise transport and replay through H, C preserve that same route, while P, N source and name it.

Thus every downstream read factors through the displayed midpoint chain. The carrier has no coordinate for quotient stream equality, selected limits, open-cover compactness, Heine–Borel, or ambient real completeness, so the handoff exports none of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMidpointChain}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMidpointChain}^{\uparrow}$ packet is generated from dyadic endpoint rows, a midpoint row, a retained-side ledger, finite chain order, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMidpointChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7490.1, Definition 7490.2, and Definition 7490.3 seed the finite midpoint-refinement route for regular-Cauchy and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMidpointChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, open-cover compactness, Heine–Borel, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint-pair admission, midpoint exposure, retained-side ledger exactness, chain-order exposure, finite-window readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMidpointChainUp.

Chapter 7491

A Concrete Naming Certificate for $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$

Following Bishop and Bridges, a located dyadic interval is useful when a finite bracketing object keeps both endpoints, the positive gap, and the comparison route visible before any Real-facing consumer reads a point or completion seal. The $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ packet sits over the dyadic arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readback surface of chapter 301, the terminal Real seal of chapter 38, the bisection route of chapter 2018, and the located dyadic real packet of chapter 6192. It names the interval-level carrier between endpoint data and Real-facing located completion; it does not select a midpoint limit, quotient Cauchy names, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7491.1 (Bishop located dyadic interval carrier)**.** *A* $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, G, S, Q, B, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and retained as a displayed dyadic rational.*
2. *U is the upper endpoint row, read through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger.*
3. *G is the positive located-gap row, recording the finite evidence that the lower endpoint lies apart from or below the upper endpoint by a displayed dyadic margin.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only the finite endpoint windows requested by a comparison or bisection consumer.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those endpoint windows.*
6. *B is the* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *bisection row, recording the retained left or right subinterval and the dyadic midpoint read used to make that decision.*
7. *R is the* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff row, available only after L, U, G, S, Q, B have been displayed.*
8. *H records componentwise* hsame *transport for endpoints, gap evidence, stream windows, regular readback, bisection, handoff, provenance, replay, and local naming.*

9. *C records displayed* Cont *replay from endpoint reads through gap checks, finite windows, regular readbacks, bisection decisions, and the Real-facing handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicBinarySearch}^{\uparrow}$, $\mathsf{LocatedDyadicReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDyadicInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, G, S, Q, B, R, H, C, P, N$. It has no coordinate for a hidden midpoint selector, quotient real equality, countable choice, detached trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7491.2 (Bishop located dyadic interval NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ *carrier*

$$I = (L, U, G, S, Q, B, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedDyadicInterval}^{\uparrow}}$ *surface consists exactly of lower endpoint exposure, upper endpoint exposure, positive located-gap accounting, finite StreamName window inspection, RegSeqRat endpoint readback, dyadic bisection readback, Real-facing handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may erase an endpoint, replace the gap by detached order trichotomy, select a midpoint limit, quotient Cauchy names, or export ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7491.1. The endpoint rows L, U and the located-gap row G are the only source data for the interval boundary.

The finite observation route is S followed by Q. A comparison or bisection consumer may inspect endpoint windows and regular rational readbacks, but it cannot replace them by quotient real names or by a hidden global order oracle.

The bisection row B is downstream of the same endpoint and gap rows. It records the displayed midpoint read and retained subinterval, so it supplies readback data rather than a selected limit point.

Finally R, H, C, P, N hand off, transport, replay, source, and name the same finite interval packet. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7491.3 (Bishop located dyadic interval bisection readback)**.** *Every accepted* $\mathsf{DyadicBinarySearch}^{\uparrow}$ *consumer of a* $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicBinarySearch}^{\uparrow}.$$

The bisection decision may retain a left or right dyadic subinterval, but it must keep the original endpoint rows, located-gap row, finite window row, regular readback row, transport, replay, provenance, and local naming visible.

Proof. Start with the endpoint and gap rows L, U, G. A binary-search read is an interval read, so it cannot begin from an unlogged midpoint or a host real order comparison.

Read S and Q next. These rows supply the finite endpoint windows and regular rational readback at the dyadic precision requested by the bisection consumer.

The row B then records the actual bisection decision. The retained subinterval is another displayed dyadic interval row attached to the same provenance, not a chosen limit and not a quotient of all later refinements.

Transport, replay, provenance, and local naming through H, C, P, N preserve this route. Thus every bisection consumer factors through the stated finite chain and keeps the interval boundary data visible. □

Theorem 7491.4 (Bishop located dyadic interval Real handoff)**.** *Every* $\mathsf{LocatedDyadicReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ *packet must first read*

$$L, U, G, S, Q, B, H, C, P, N.$$

The handoff row R may expose a Real-facing located interval boundary only after the dyadic endpoints, located gap, finite windows, regular rational readback, and bisection route have been displayed. It cannot export quotient real equality, countable choice, detached trichotomy, a selected point of the interval, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the interval boundary rows. The lower endpoint, upper endpoint, and positive gap are dyadic data, so a Real-facing consumer must receive them through $\mathsf{DyadicRatCore}^{\uparrow}$ rather than through ambient real equality.

Replay the observation rows S, Q, B. Stream windows and regular rational readbacks expose the finite endpoint information, while the bisection row records how a retained subinterval was read.

Only after those rows are public can R be consumed. The handoff is therefore a seal on the displayed interval route, not a selected point or a proof of ambient completeness.

The structural rows H, C, P, N preserve the same route under hsame transport, Cont replay, provenance, and local naming. Hence every $\mathsf{LocatedDyadicReal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer remains inside the stated finite packet. □

Falsifiable prediction: A $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ consumer that reaches $\mathsf{LocatedDyadicReal}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ after deleting one of L, U, G, S, Q, B refutes the carrier of Definition 7491.1.

Independence witness: Nearest siblings: dyadicratcore, streamname, regseqrat, dyadic-binary-search, located-dyadic-real, and real. $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ is not bijective to any one of them because it jointly carries two dyadic endpoints, positive gap evidence, finite endpoint windows, regular readback, bisection readback, Real-facing handoff, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedDyadicInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedDyadicInterval}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, positive located-gap data, StreamName endpoint windows, RegSeqRat readback, DyadicBinarySearch bisection readback, a LocatedDyadicReal or Real handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedDyadicInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7491.1, Definition 7491.2, Definition 7491.3, and Definition 7491.4 seed the finite located dyadic interval route between endpoint data, bisection readback, and Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedDyadicInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, countable choice, detached trichotomy, a selected interval point, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, positive located-gap accounting, finite window inspection, RegSeqRat readback, bisection readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedDyadicIntervalUp.

Chapter 7492

A Concrete Naming Certificate for $\mathsf{BourbakiFilterLimit}^{\uparrow}$

Following Bourbaki and Kelley on filter convergence, the $\mathsf{BourbakiFilterLimit}^{\uparrow}$ packet records the finite limit-reading surface by which a displayed filter base may be routed to a completion-facing real seal. It sits after the basis carrier of chapter 1601, the Cauchy-filter surface of chapter 333, the convergence-filter packet of chapter 6578, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a Bourbaki–Kelley limit route as finite BEDC data; it does not import quotient filters, selected limits, countable choice, host filter equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7492.1 (Bourbaki filter-limit carrier)**.** *A* $\mathsf{BourbakiFilterLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, C, V, W, R, D, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *basis row, listing the finite basic neighborhoods inspected by the limit read.*
2. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, recording the Cauchy refinement obligations available to the inspected basis windows.*
3. *V is the* $\mathsf{ConvergenceFilter}^{\uparrow}$ *row, recording the convergence-facing neighborhood requests and their finite witnesses.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which sequential observations of the same route are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational names exposed by the stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the Cauchy and convergence requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after B, C, V, W, R, D have been displayed.*
8. *H is the componentwise* hsame *transport row for basis, Cauchy, convergence, stream, rational, dyadic, and real-seal rows.*
9. *T is the displayed* Cont *replay row for the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{BourbakiFilterLimit}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{ConvergenceFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BourbakiFilterLimit}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, C, V, W, R, D, E, H, T, P, N$. It has no coordinate for quotient filters, a selected limit point, countable choice, host equality of filters, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.BourbakiFilterLimitUp.BourbakiFilterLimitTasteGate single carrier alignment`

Theorem 7492.2 (Bourbaki filter-limit NameCert obligations)**.** *For the carrier of Definition 7492.1, the local* $\mathsf{NameCert}_{\mathsf{BourbakiFilterLimit}^{\uparrow}}$ *surface consists exactly of eight obligation groups:*

1. *carrier admission for $L = (B, C, V, W, R, D, E, H, T, P, N)$;*
2. *filter-base coverage through B;*
3. *Cauchy-filter refinement through C;*
4. *convergence-filter neighborhood coverage through V;*
5. *stream and regular-rational readback through W and R;*
6. *dyadic tolerance exactness and real-seal handoff through D and E;*
7. *componentwise transport and replay through H and T;*
8. *package provenance and local naming through P and N.*

Thus the certificate presents the Bourbaki–Kelley filter-limit route as finite BEDC data and cannot be read as quotient filters, selected limits, countable choice, host filter equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is tuple projection from Definition 7492.1. The filter side is exhausted by B, C, V: the basis row supplies inspected basic neighborhoods, the Cauchy row supplies finite refinement obligations, and the convergence row supplies the displayed neighborhood witnesses.

The completion-facing read is separate. Rows W and R expose only finite stream windows and regular rational readback, while D fixes the dyadic tolerance ledger before the terminal real seal E is consumed.

Finally inspect H, T, P, N. These rows transport, replay, package, and name the same displayed route. Since no remaining coordinate stores quotient filters, selected limits, countable choice, host filter equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the eight groups exhaust the local certificate surface. □

Theorem 7492.3 (Bourbaki filter-limit real-completion handoff)**.** *Every accepted* $\mathsf{BourbakiFilterLimit}^{\uparrow}$ *packet that is consumed by a real-completion route reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through*

$$\mathsf{FilterBase}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{ConvergenceFilter}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The handoff exposes basis coverage, Cauchy refinement, convergence neighborhoods, finite stream windows, rational readback, and dyadic tolerances before any real-facing consumer reads the seal. It exports no quotient filter, selected limit, countable-choice schedule, host filter equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the obligation theorem Definition 7492.2. Its first four groups force every accepted packet to display the filter base, Cauchy-filter refinement, and convergence-filter neighborhood rows before the route can be named.

Next read the completion-facing rows. The same obligation surface requires the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback rows together with the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before the terminal $\mathsf{Real}^{\uparrow}$ seal appears.

The transport, replay, provenance, and local naming rows preserve only that displayed finite route. Because the carrier has no coordinate for quotient filters, selected limits, countable choice, host filter equality, or ambient completeness, none of those objects can be exported by the real-completion handoff. □

Falsifiable prediction: Every accepted $\mathsf{BourbakiFilterLimit}^{\uparrow}$ completion read exposes FilterBase, CauchyFilter, ConvergenceFilter, StreamName, RegSeqRat, DyadicRatCore, RealUp, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any terminal real seal is consumed.

Independence witness: filterbase, cauchyfilter, convergencefilter, streamname, regseqrat, dyadicratcore, real: none carries the joint Bourbaki–Kelley filter-limit packet because this chapter alone binds basis coverage, Cauchy refinement, convergence neighborhoods, finite stream windows, rational readback, dyadic tolerances, transport, replay, provenance, and local naming without quotient filters or choice.

Closure status for $\mathsf{NameCert}_{\mathsf{BourbakiFilterLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BourbakiFilterLimit}^{\uparrow}$ packet is generated from FilterBase basis rows, CauchyFilter refinement rows, ConvergenceFilter neighborhood rows, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BourbakiFilterLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7492.1, Definition 7492.2, and Definition 7492.3 seed the finite Bourbaki–Kelley filter-limit route from filter-base convergence data to regular rational readback and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BourbakiFilterLimit}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BourbakiFilterLimitUp.BourbakiFilterLimitTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host filter equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, filter-base coverage, Cauchy-filter refinement, convergence-neighborhood coverage, finite window coverage, rational readback, dyadic tolerance exactness, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BourbakiFilterLimitUp.

Chapter 7493

A Concrete Naming Certificate for $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$

Following Gromov and Bridson–Haefliger, a visual cross-ratio cocycle is the finite boundary packet that keeps four visual boundary shadows, the visual metric comparison, the cross-ratio read, and the Busemann cocycle ledger visible in one route. The $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ packet sits after the boundary-shadow carrier of chapter 3813, the visual metric surface of chapter 3866, the hyperbolic cross-ratio packet of chapter 3948, the Busemann cocycle packet of chapter 4134, and the terminal Real seal of chapter 38. It names a single finite cocycle carrier for visual boundary comparison; it does not complete the boundary, quotient geodesic rays, select ideal representatives, or import host global geometry.

Definition 7493.1 (Hyperbolic visual cross-ratio cocycle carrier)**.** *A* $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (S_0, S_1, S_2, S_3, M, X, B, T, R, H, C, P, N)$$

with the following displayed rows:

1. S_0, S_1, S_2, S_3 *are four* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *rows read from the same displayed boundary-shadow route.*
2. M *is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *visual metric row comparing the four boundary shadows through finite disk and metric data.*
3. X *is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row recording the finite four-point cross-ratio read.*
4. B *is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *row recording the additive boundary-cocycle ledger attached to the same visual comparison.*
5. T *is the transport row keeping the four shadows, visual metric, cross-ratio, and Busemann cocycle in one displayed route.*
6. R *is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite visual comparison value, available only after* $S_0, S_1, S_2, S_3, M, X, B, T$ *have been displayed.*
7. H *records componentwise* hsame *transport for shadows, visual metric, cross-ratio, Busemann cocycle, transport, Real seal, provenance, replay, and local naming.*
8. C *records displayed* Cont *replay from boundary-shadow reads through visual metric comparison, cross-ratio readback, Busemann cocycle replay, transport, and the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, S_2, S_3, M, X, B, T, R, H, C, P, N$. It has no coordinate for a completed boundary compactification, quotient boundary equality, selected geodesic representatives, detached visual metric equality, or a host global hyperbolic plane.

Theorem 7493.2 (Hyperbolic visual cross-ratio cocycle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ *carrier*

$$V = (S_0, S_1, S_2, S_3, M, X, B, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}}$ *surface consists exactly of four boundary-shadow rows, visual metric comparison, hyperbolic cross-ratio readback, Busemann cocycle replay, route transport, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may collapse the four shadows, detach the visual metric from the displayed boundary route, read the cross-ratio without the Busemann ledger, or replace the packet by a completed boundary object.*

Proof. Project the carrier of Definition 7493.1. The four boundary-shadow rows S_0, S_1, S_2, S_3 are simultaneous fields, so a consumer cannot read a visual comparison from fewer boundary positions.

The comparison rows are M, X, B. The visual metric row supplies finite visual distance data, the cross-ratio row records the four-point comparison, and the Busemann cocycle row records the additive boundary ledger on the same route.

The transport and Real-seal rows T, R are downstream of those displayed rows. Transport keeps the comparison inside one boundary-shadow route, and the Real seal names only the finite comparison value reached by that route.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no completed boundary, quotient equality, selected representative, detached visual metric equality, or host global plane appears in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 7493.3 (Hyperbolic visual cross-ratio cocycle boundary handoff)**.** *Every boundary-facing consumer of an accepted* $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ *packet must factor through*

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicCrossRatio}^{\uparrow} \longmapsto \mathsf{HyperbolicBusemannCocyc}$$

The consumer may replay the route under hsame *transport and* Cont *continuation, but it cannot bypass one of the four boundary-shadow rows, read a detached cross-ratio scalar, quotient the boundary, select geodesic representatives, or invoke host global geometry.*

Proof. Begin with the four boundary-shadow rows. Each is read through $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, so the boundary-facing consumer receives displayed finite shadow data rather than a completed ideal-boundary point.

Read the visual metric and cross-ratio rows next. The row M supplies the visual comparison window, and X records the four-point cross-ratio only after all four shadow rows have been displayed.

The Busemann cocycle row B ties the comparison to an additive boundary ledger. This prevents the cross-ratio from being consumed as an isolated scalar detached from the boundary route.

The route then passes through T, R, H, C, P, N. Transport, Real sealing, replay, provenance, and local naming preserve the same finite packet, so the consumer cannot escape to quotient boundary equality, selected representatives, or host global hyperbolic geometry. □

Falsifiable prediction: A $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ consumer that exports a Real-valued cross-ratio without four boundary-shadow rows, the visual metric row, the Busemann cocycle row, transport, provenance, and local naming refutes the carrier of Definition 7493.1.

Independence witness: Nearest siblings: hyperbolic-boundary-shadow, hyperbolic-visual-metric, hyperbolic-cross-ratio, hyperbolic-busemann-cocycle, and real. $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ is not bijective to any one of them because it jointly carries four shadow rows, visual metric comparison, four-point cross-ratio readback, additive Busemann cocycle replay, route transport, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}$ packet is generated from four HyperbolicBoundaryShadow rows, a HyperbolicVisualMetric comparison, a HyperbolicCrossRatio readback, a HyperbolicBusemannCocycle ledger, route transport, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7493.1, Definition 7493.2, and Definition 7493.3 seed the finite visual boundary cocycle route unifying boundary-shadow, visual-metric, cross-ratio, Busemann, transport, Real-seal, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualCrossRatioCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary compactification, quotient boundary equality, selected geodesic representatives, detached visual metric equality, host global hyperbolic geometry, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked four-shadow exposure, visual metric comparison, cross-ratio readback, Busemann cocycle replay, route transport, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicVisualCrossRatioCocycleUp.

Chapter 7494

A Concrete Naming Certificate for $\mathsf{CoordinateFunctional}^{\uparrow}$

Following Schauder and Banach-space basis theory, the $\mathsf{CoordinateFunctional}^{\uparrow}$ packet records the bounded coefficient readback licensed by a displayed Schauder basis without identifying that readback with an arbitrary element of the dual space. It sits beside the basis packet of chapter 3669, the vector-space carrier of chapter 47, the norm row of chapter 89, the Banach completion surface of chapter 90, the regular rational scalar route of chapter 301, and the real-name modulus seal of chapter 38. The certificate separates the Schauder basis that supplies coefficients from the coordinate functional that consumes one index and exports a bounded scalar read.

Definition 7494.1 (Coordinate functional carrier)**.** *A* $\mathsf{CoordinateFunctional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, V, N, C, Q, M, H, T, P, L)$$

with the following displayed rows:

1. *B is the* $\mathsf{SchauderBasis}^{\uparrow}$ *source row naming the basis-vector stream, finite partial sums, coefficient requests, tail estimates, and reconstruction route used by the coefficient read.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row naming vector addition, scalar action, zero vector, and finite linear-combination syntax for the vectors on which the coordinate functional is read.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Banach}^{\uparrow}$ *budget row, recording the norm estimates and completion-facing bounds used to treat the coefficient read as bounded.*
4. *C is the coordinate-readback row for a displayed basis index i, sending an accepted vector read to the coefficient row $c_i(x)$ licensed by B.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *scalar-name row for the rational approximants used to present the coefficient value.*
6. *M is the* $\mathsf{Real}^{\uparrow}$*-valued continuity-modulus row, recording the local bound that turns the coefficient readback into a bounded scalar output.*
7. *H records componentwise* hsame *transport for the Schauder basis source, vector-space operations, norm budget, coordinate readback, regular scalar name, continuity modulus, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay from vector reads through B, V, N, C, Q, M to the scalar output.*

9. *P records* Pkg *provenance over* $\mathsf{CoordinateFunctional}^{\uparrow}$, $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{CoordinateFunctional}^{\uparrow}}$ *row.*

The classifier compares packets only through $B, V, N, C, Q, M, H, T, P, L$. It has no coordinate for a Hamel basis choice, arbitrary linear functionals, a full dual-space representation, Hahn–Banach extension, countable choice, or a detached coefficient oracle.

Theorem 7494.2 (CoordinateFunctional coefficient readback)**.** *For every accepted* $\mathsf{CoordinateFunctional}^{\uparrow}$ *carrier $F = (B, V, N, C, Q, M, H, T, P, L)$ and displayed basis index i, a coefficient read $x \mapsto c_i(x)$ is admitted only by first exposing the* $\mathsf{SchauderBasis}^{\uparrow}$ *row B, the vector-space row V, the norm budget N, and the coordinate-readback row C. The scalar output is then named through Q and sealed by M as a* $\mathsf{Real}^{\uparrow}$*-valued bounded read. No coefficient can be read from a host dual vector, a Hamel-basis selector, or an undeclared functional row.*

Proof. Project the carrier of Definition 7494.1. The only row that contains basis coefficients is B, and the only row that turns one displayed index into a scalar request is C.

The vector and norm rows are then load-bearing. The row V supplies the finite linear syntax for the input vector, while N supplies the norm budget needed before the read can be treated as a bounded coordinate.

Finally read the scalar rows Q and M. The regular rational row gives the displayed scalar approximants, and the real-valued modulus row gives the continuity budget. Since no host dual, Hamel selector, or undeclared functional row appears in F, the coefficient readback is exactly the displayed route through B, V, N, C, Q, M. □

Theorem 7494.3 (CoordinateFunctional linearity obligation)**.** *Every accepted* $\mathsf{CoordinateFunctional}^{\uparrow}$ *packet exposes the additivity and scalar-compatibility obligations for its displayed coefficient read only through the rows $B, V, N, C, Q, M, H, T, P, L$. Additivity is checked against the* $\mathsf{VecSpace}^{\uparrow}$ *operations in V and the coefficient-readback row C; scalar compatibility is checked against the same vector-space action and the* $\mathsf{RegSeqRat}^{\uparrow}$ *scalar names in Q. The obligation does not assert linearity for arbitrary functionals outside the packet.*

Proof. Start with the vector-space row. Addition and scalar action are named in V, so the two algebraic tests for the coordinate read are formed only in that displayed syntax.

Use the coefficient row C twice. For additivity it compares the readback on a displayed sum with the displayed sum of coefficient reads; for scalar compatibility it compares the readback on a displayed scalar multiple with the scalar action recorded through Q.

The structural rows H, T, P, L preserve the same tests under transport, replay, provenance, and naming. They do not add a new functional row, so the linearity obligation remains local to the coordinate readback carried by the packet. □

Theorem 7494.4 (CoordinateFunctional continuity modulus)**.** *For every accepted* $\mathsf{CoordinateFunctional}^{\uparrow}$ *carrier $F = (B, V, N, C, Q, M, H, T, P, L)$, the boundedness or continuity claim available to a downstream consumer is the displayed* $\mathsf{Real}^{\uparrow}$*-valued modulus row M read after the Schauder source B, vector operations V, norm budget N, coefficient readback C, and regular scalar name Q. The modulus is a finite NameCert row, not a Hahn–Banach extension, an ambient dual-space norm, or a choice-selected bound.*

Proof. Open the carrier and locate the modulus row. The only continuity datum is M, and it is downstream from the basis, vector-space, norm, coordinate, and scalar-name rows.

The coefficient readback theorem supplies the route into M. A consumer first reads B, V, N, C, Q to obtain a scalar output tied to the displayed basis index, and only then reads the real-valued bound stored in M.

The provenance and local naming rows exclude the external principles listed in the statement. Since Hahn–Banach extension, ambient dual-space norms, and choice-selected bounds have no coordinate in F, the continuity claim is only the finite modulus row recorded by the packet. □

Theorem 7494.5 (CoordinateFunctional NameCert obligations)**.** *For every accepted* $\mathsf{CoordinateFunctional}^{\uparrow}$ *carrier* $F = (B, V, N, C, Q, M, H, T, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{CoordinateFunctional}^{\uparrow}}$ *surface consists exactly of carrier admission, Schauder basis source exposure, vector-space operation exposure, norm-budget exposure, coordinate-readback exposure, regular scalar-name exposure, real-valued continuity-modulus exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer of* F *receives those finite rows and no Hamel basis choice, arbitrary linear functional, full dual-space representation, Hahn–Banach theorem, countable-choice schedule, or detached coefficient oracle.*

Proof. Carrier admission is projection from Definition 7494.1. It exposes exactly the tuple $B, V, N, C, Q, M, H, T, P,$

The analytic rows are B, V, N, C, Q, M. They identify the Schauder basis source, the vector-space syntax, the norm budget, the coefficient readback, the regular scalar name, and the real-valued modulus in the order required by the coefficient-readback, linearity-obligation, and continuity-modulus theorems above.

The structural rows H, T, P, L preserve and name that same route. Since the carrier inventory omits Hamel basis choice, arbitrary functionals, dual-space representation, Hahn–Banach extension, countable choice, and detached coefficient oracles, no local NameCert obligation can export them. □

Falsifiable prediction: Every accepted $\mathsf{CoordinateFunctional}^{\uparrow}$ coefficient read factors through a SchauderBasis row, VecSpace operations, Norm and Banach budget rows, coordinate readback, RegSeqRat scalar names, a Real-valued continuity modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: schauder-basis, vecspace, norm, banach, regseqrat, real: no listed sibling supplies the whole packet $F = (B, V, N, C, Q, M, H, T, P, L)$, because the coordinate functional carrier binds basis coefficients, vector operations, norm budgets, scalar readback, continuity modulus, transport, replay, provenance, and local naming in one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{CoordinateFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{CoordinateFunctional}^{\uparrow}$ packet is generated from a SchauderBasis source row, VecSpace operation row, Norm and Banach budget row, coordinate readback row, RegSeqRat scalar-name row, Real-valued continuity-modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CoordinateFunctional}^{\uparrow}}$, seed)

Scope closed: Definition 7494.1, Definition 7494.2, Definition 7494.3, Definition 7494.4, and Definition 7494.5 seed the bounded coordinate-functional route licensed by a displayed Schauder basis.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CoordinateFunctional}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hamel basis choice, arbitrary linear functionals, full dual-space representation, Hahn–Banach, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-readback exactness, linearity obligations, continuity-modulus exposure, transport, replay, provenance, and local naming for the displayed coordinate functional packet.

Chapter 7495

A Concrete Naming Certificate for $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$ packet records the constructive fusion interface between the product-completion certificate of chapter 3797 and the regular Cauchy coordinate projection route of chapter 2076. It reads finite windows from chapter 126, regular rational readback from chapter 301, dyadic tolerance rows from chapter 291, and the terminal seal of chapter 38. The packet names only displayed product-completion rows; it does not quotient streams, select limits, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7495.1 (CauchyProductCompletionFusion carrier)**.** *A* $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, J, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the accepted* $\mathsf{CauchyProductCompletion}^{\uparrow}$ *product-completion packet whose fused route is being consumed.*
2. *J is the* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *coordinate projection packet exposing the left and right regular Cauchy readbacks of Q.*
3. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window family read before either coordinate projection reaches a real-facing consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing both coordinate windows and the product budget.*
5. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after S and D are displayed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the product-completion packet, projection packet, finite windows, dyadic ledger, and regular readback have all been exposed.*
7. *H stores componentwise* hsame *transport for Q, J, S, D, R, E.*
8. *C stores displayed* Cont *replay through the same product-completion and projection route.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$, $\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{RegularCauchyProductProjection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionFusion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $Q, J, S, D, R, E, H, C, P, N$. It contains no quotient stream equality, selected completion representative, host product equality, trichotomy, or ambient completeness row.

Theorem 7495.2 (CauchyProductCompletionFusion laws)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$ *carrier factors through* $\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{RegularCauchyProductProjection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *in that order, with* hsame, Cont, Pkg, *and local* NameCert *rows preserving the same finite route. The fusion therefore exposes product-completion and regular-Cauchy projection data as one displayed interface without adding quotient streams, selected limits, host product equality, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionFusionUp.CauchyProductCompletionFusion laws`

Proof. Project the carrier of Definition 7495.1. The rows Q and J are the only product-completion and projection packets available to the consumer, so a Real-facing read cannot start from an external product object.

Read the finite route next. The shared window row S and dyadic ledger D precede the regular readback row R, and the terminal seal E is downstream of those displayed rows. Thus the route has exactly the dependency order claimed in the statement.

Finally inspect H, C, P, N. They transport, replay, source, and name the same finite packet, but introduce no coordinate for quotient equality, selected limits, host product equality, trichotomy, or ambient completeness. □

Theorem 7495.3 (CauchyProductCompletionFusion NameCert obligations)**.** *For an accepted carrier $F = (Q, J, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionFusion}^{\uparrow}}$ *surface consists exactly of carrier admission, product-completion admission for Q, projection-route admission for J, stream-window exposure for S, dyadic ledger compatibility for D, regular readback handoff for R, Real-seal nonescape for E, componentwise transport through H, continuation replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is the projection of the finite packet $F = (Q, J, S, D, R, E, H, C, P, N)$. The product-completion and projection obligations are exactly the rows Q and J, so the fused certificate does not recreate their sibling carriers.

The window, ledger, and readback obligations are the rows S, D, R. They force each coordinate read to expose a StreamName window and DyadicRatCore tolerance before the regular rational handoff is available.

The remaining obligations are structural. The seal row E is the only Real-facing export, while H, C, P, N preserve, replay, source, and name the same route. Since the carrier has no other row, the local NameCert surface is exhausted by the listed obligations. □

Lean4 ✓ `BEDC.Derived.CauchyProductCompletionFusionUp.CauchyProductCompletionFusionTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductCompletionFusion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyProductCompletionFusion}^{\uparrow}$ packet is generated from a CauchyProductCompletion packet, a RegularCauchyProductProjection packet, StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyProductCompletionFusion}^{\uparrow}}$, seed)

Scope closed: Definition 7495.1, Definition 7495.2, and Definition 7495.3 seed the product-completion fusion interface between product completion and regular Cauchy projection.

Formal verification: FormalStatus(NameCert$_{\text{CauchyProductCompletionFusion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host product equality, trichotomy, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, product-completion admission, projection-route admission, window exposure, dyadic ledger compatibility, regular readback handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductCompletionFusionUp.

Chapter 7496

A Concrete Naming Certificate for $\mathsf{DyadicMeshGauge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicMeshGauge}^{\uparrow}$ packet records the finite dyadic mesh gauges used to schedule regular Cauchy approximations before a real-name seal is read. It sits after the dyadic arithmetic surface of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name surface of chapter 38. The packet names a finite gauge ledger, not a quotient of streams, a selected limit, countable choice, open-cover compactness, or host real equality.

Definition 7496.1 (Dyadic mesh gauge carrier)**.** *A* $\mathsf{DyadicMeshGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, S, W, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the dyadic precision requests and mesh widths inspected by the gauge.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, listing the finite name windows opened by each precision request.*
3. *W is the finite mesh-window ledger pairing dyadic widths with the stream windows that witness them.*
4. *M is the gauge row, recording the displayed bound beyond which the mesh is read at the requested dyadic width.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from D, S, W, M.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the regular readback row has been displayed.*
7. *H records componentwise* hsame *transport for dyadic tolerances, stream windows, mesh windows, gauge bounds, readbacks, real seals, replay, provenance, and naming.*
8. *C records displayed* Cont *replay from a precision request through the same finite mesh-gauge route.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicMeshGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshGauge}^{\uparrow}}$ *row.*

The classifier compares accepted gauges only through $D, S, W, M, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, countable-choice schedule, open-cover compactness, Heine–Borel, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicMeshGaugeUp.TasteGate.DyadicMeshGaugeTasteGate single carrier alignment`

Theorem 7496.2 (Dyadic mesh gauge NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshGauge}^{\uparrow}$ *carrier*

$$G = (D, S, W, M, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicMeshGauge}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission through D, stream-window admission through S, finite mesh-window exposure through W, gauge-bound exactness through M,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7496.1. The rows $D, S, W, M, Q, E, H, C, P, N$ are the whole visible packet, so the local naming surface can only list those rows.

Read the approximation rows in order. The dyadic row D supplies the precision request, the stream row S supplies the finite windows, and the mesh ledger W records how those windows are paired with dyadic widths.

The gauge row M then supplies the finite bound used by the regular readback row Q. The terminal seal E is downstream of that readback, while H, C, P, N transport, replay, source, and name the same finite route.

Since no carrier coordinate stores quotient stream equality, selected limits, countable choice, open-cover compactness, Heine–Borel, or ambient real completeness, none of those principles belongs to the local obligation surface. □

Theorem 7496.3 (Dyadic mesh gauge regular-Cauchy handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicMeshGauge}^{\uparrow}$ *packet reads through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicMeshGauge}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using $D, S, W, M, Q, E, H, C, P, N$. The handoff exports finite dyadic mesh-gauge data for regular Cauchy approximation schedules; it exports no host real equality, quotient stream equality, selected limit, countable-choice schedule, open-cover compactness, or ambient completeness.

Proof. Begin with an accepted carrier $G = (D, S, W, M, Q, E, H, C, P, N)$. A regular-Cauchy read must expose the dyadic tolerance row D and the finite stream-window row S before a mesh window or gauge bound is available.

Use the mesh ledger W and gauge row M. These rows bind each displayed dyadic width to the finite windows and the bound used by the approximation schedule, so a consumer cannot replace the route by a selected host limit or an unrecorded choice function.

The readback row Q is then the only $\mathsf{RegSeqRat}^{\uparrow}$ row visible to downstream consumers, and the Real seal E is reached only after Q. Componentwise transport and replay through H, C preserve that same order, while P, N source and name it.

Thus every regular-Cauchy or Real-facing read factors through the finite dyadic mesh-gauge route. The excluded host equality, quotient, choice, compactness, and completeness principles have no row from which to enter. □

Falsifiable prediction: Every accepted $\mathsf{DyadicMeshGauge}^{\uparrow}$ consumer displays $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, finite mesh-window, gauge-bound, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before it reads a terminal real-name approximation.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-sequence-modulus: $\mathsf{DyadicMeshGauge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic mesh widths, finite stream windows, gauge bounds, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshGauge}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, mesh-window ledgers, gauge bounds, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMeshGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7496.1, Definition 7496.2, and Definition 7496.3 seed the finite dyadic mesh-gauge route for regular-Cauchy and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMeshGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, open-cover compactness, Heine–Borel, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, stream-window admission, mesh-window exposure, gauge-bound exactness, RegSeqRat readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMeshGaugeUp.

Chapter 7497

A Concrete Naming Certificate for $\mathsf{SplitInterval}^{\uparrow}$

Following Alexandroff and Urysohn's split-interval construction, the $\mathsf{SplitInterval}^{\uparrow}$ packet records the constructive two-sided split of a displayed real interval as finite NameCert data. It sits next to the double-arrow packet of chapter 7057 and the real endpoint reconstruction of chapter 38. The chapter names the carrier, local NameCert obligations, and order-topology handoff rows only; it does not assert open-cover compactness, quotient topology, selected endpoint cuts, or a host equality principle for adjacent split points.

Definition 7497.1 (SplitInterval carrier)**.** *A* $\mathsf{SplitInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (x, \sigma, B, O, H, C, P, N)$$

with the following displayed rows:

1. *x is the displayed* $\mathsf{Real}^{\uparrow}$ *endpoint currently inspected by the packet.*
2. *σ is a two-sided split bit, naming the lower or upper copy attached to the same endpoint.*
3. *B is a located half-open interval basis row recording the finite left-open and right-open neighborhoods actually exposed at (x, σ).*
4. *O is the lexicographic order-topology row, comparing endpoints through* $\mathsf{Real}^{\uparrow}$ *and resolving equal endpoints through σ.*
5. *H records componentwise* hsame *transport for endpoint, split-bit, basis, order-topology, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from endpoint and split-bit data to the located half-open basis and then to the order-topology row.*
7. *P is the* Pkg *provenance over* $\mathsf{SplitInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DoubleArrowSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SplitInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $x, \sigma, B, O, H, C, P, N$. It has no coordinate for a quotient topology, open-cover compactness, selected endpoint cuts, unrestricted open-set lattice, or host point equality between the two copies.

Lean4 (definition) `BEDC.Derived.SplitIntervalUp`

Theorem 7497.2 (SplitInterval NameCert obligations)**.** *For every accepted* $\mathsf{SplitInterval}^{\uparrow}$ *packet* $S = (x, \sigma, B, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SplitInterval}^{\uparrow}}$ *surface consists exactly of endpoint admission through* $\mathsf{Real}^{\uparrow}$*, split-bit admission, located half-open basis exposure, lexicographic order-topology exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. A consumer may read a split-interval neighborhood only after those finite rows have been displayed; it cannot replace them by host compactness, quotient topology, selected endpoint cuts, or ambient open-set data.*

Proof. Project the carrier of Definition 7497.1. The displayed rows $x, \sigma, B, O, H, C, P, N$ are the whole accepted packet, so every local read begins with the real endpoint and the two-sided split bit.

The located half-open basis row B supplies only the finite neighborhoods exposed at the inspected split endpoint. The order-topology row O then reads endpoint comparison through $\mathsf{Real}^{\uparrow}$ and tie-breaking through σ, matching the split-interval surface used by chapter 7057.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for compactness, quotient topology, selected cuts, ambient opens, or host equality between the two copies, none of those objects can appear among the local NameCert obligations. □

Theorem 7497.3 (SplitInterval order-topology handoff)**.** *Every order-topology consumer of an accepted* $\mathsf{SplitInterval}^{\uparrow}$ *packet receives generated split-interval data only through the route*

$$\mathsf{Real}^{\uparrow},\ \sigma,\ B,\ O,\ H,\ C,\ P,\ N.$$

The endpoint row supplies the real comparison boundary, the split bit separates the two sides at equal endpoints, the located half-open basis row supplies the finite neighborhood windows, and the lexicographic order-topology row supplies the order-facing handoff. The route exports no open-cover compactness theorem, quotient-topology presentation, selected cut, unrestricted open-set lattice, or host equality principle.

Proof. Read the carrier in the order displayed by Definition 7497.1. The endpoint x and bit σ determine which side of the split interval is inspected, while B lists the located half-open basis rows made available to a topology consumer.

Apply Definition 7497.2. It forces every order-topology read through endpoint admission, split-bit admission, basis exposure, order-topology exposure, transport, replay, provenance, and local naming.

Thus the handoff is a finite route through $\mathsf{Real}^{\uparrow}$, the split bit, located basis data, and the structural NameCert rows. It does not import compactness, quotient topology, selected endpoint cuts, a global open-set lattice, or host equality between the two displayed copies. □

Falsifiable prediction: Every accepted $\mathsf{SplitInterval}^{\uparrow}$ order-topology read factors through the displayed $\mathsf{Real}^{\uparrow}$ endpoint, split-bit row, located half-open basis row, lexicographic order-topology row, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows.

Independence witness: double-arrow-space, real: $\mathsf{SplitInterval}^{\uparrow}$ is not bijective to either sibling because it records a single endpoint with a two-sided split bit and located half-open basis rows, while $\mathsf{DoubleArrowSpace}^{\uparrow}$ records the two-copy interval packet and $\mathsf{Real}^{\uparrow}$ records endpoint data without the split-bit or half-open basis coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{SplitInterval}^{\uparrow}}$.

Constructive story: A SplitInterval$^{\uparrow}$ packet is generated from a RealUp endpoint, a two-sided split bit, located half-open basis rows, a lexicographic order-topology row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SplitInterval}^{\uparrow}}$, seed)

Scope closed: Definition 7497.1, Definition 7497.2, and Definition 7497.3 seed the finite split-interval order-topology packet over RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SplitInterval}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, quotient topology, selected endpoint cuts, unrestricted open-set lattices, Lean theorem verification, or bridge checking for SplitInterval$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, split-bit stability, located half-open basis exposure, lexicographic order-topology exactness, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.SplitIntervalUp.

Chapter 7498

A Concrete Naming Certificate for $\mathsf{StreamInterleaving}^{\uparrow}$

Following Bishop and Bridges, an interleaving of two lawlike streams is useful only when the merge route keeps the two source windows, the parity selector, and the rational readback visible. The $\mathsf{StreamInterleaving}^{\uparrow}$ packet sits over the finite stream-name surface of chapter 126, the regular rational readback route of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal Real seal of chapter 38. It names the finite merge certificate needed by later regular-Cauchy and Real-facing consumers; it does not identify host sequences, choose a hidden subsequence, or quotient Cauchy names.

Definition 7498.1 (Stream interleaving carrier)**.** *A* $\mathsf{StreamInterleaving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, O, W, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the even-window* $\mathsf{StreamName}^{\uparrow}$ *row for the first source stream.*
2. *O is the odd-window* $\mathsf{StreamName}^{\uparrow}$ *row for the second source stream.*
3. *W is the parity-window split row, recording which displayed output positions read from E and which read from O.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for every displayed source and output window.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger used to compare the rational reads at the requested precision.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after E, O, W, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for both stream windows, the parity split, rational readback, dyadic ledger, Real seal, provenance, replay, and local naming.*
8. *C records displayed* Cont *replay from source-window inspection through parity selection, regular rational readback, dyadic comparison, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{StreamInterleaving}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamInterleaving}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host sequence equality, countable choice over positions, quotient Cauchy names, or a Real value that bypasses the displayed parity split.

Definition 7498.2 (Stream interleaving classifier)**.** *The* $\mathsf{StreamInterleaving}^{\uparrow}$ *classifier compares accepted packets only through the rows* $E, O, W, Q, D, R, H, C, P, N$*. Two packets are classifier-same exactly when their even-window reads, odd-window reads, parity split, RegSeqRat readback, DyadicRatCore comparison rows, Real seal, componentwise transport, replay, provenance, and local naming agree through displayed* hsame *routes.*

Theorem 7498.3 (Stream interleaving NameCert obligations)**.** *For every accepted* $\mathsf{StreamInterleaving}^{\uparrow}$ *carrier*

$$I = (E, O, W, Q, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamInterleaving}^{\uparrow}}$ *surface consists exactly of even-source window exposure, odd-source window exposure, parity-window splitting, RegSeqRat readback, DyadicRatCore comparison, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may erase a source stream, change the parity selector, compare through host sequence equality, or export a quotient Cauchy name.*

Proof. Project the carrier of Definition 7498.1. The source data are exactly the two StreamName rows E and O, so a consumer cannot read an output window without naming which source supplied each displayed position.

The parity selector is the row W. It records the finite split of the displayed output positions into even and odd reads, and it is the only route by which the two sources enter one output packet.

The numeric readback rows are Q and D. They expose regular rational reads and dyadic comparisons at the requested finite precision, without replacing the sources by host sequence equality or by a completed quotient object.

Finally, R, H, C, P, N seal, transport, replay, source, and name the same finite route. Since no excluded coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 7498.4 (Stream interleaving parity window split)**.** *Every finite output window read from an accepted* $\mathsf{StreamInterleaving}^{\uparrow}$ *packet factors through the displayed split row* W*. The even positions read through* E*, the odd positions read through* O*, and the packet keeps the same* Q, D, H, C, P, N *rows attached to both source reads.*

Proof. Let an output consumer request a finite window. The carrier exposes only the rows $E, O, W, Q, D, R, H, C, P, N$, so the request first meets the parity split row W.

The even part of the requested window is routed to E, and the odd part is routed to O. These are StreamName rows, so the consumer receives finite source-window data rather than a host sequence.

The shared rows Q, D, H, C, P, N then read, compare, transport, replay, source, and name the two branches as one packet. Thus the interleaved window is the displayed parity merge and nothing else. □

Theorem 7498.5 (Stream interleaving finite-stream source window)**.** *In every accepted* $\mathsf{StreamInterleaving}^{\uparrow}$ *packet, the even and odd source windows may be read as* $\mathsf{FiniteStream}^{\uparrow}$ *request-list-window packets before the parity split row* W *is consumed. The finite-source read is the one exposed by chapter 5916, and the parity merge is then the split of Definition 7498.4.*

Proof. Project the carrier as $I = (E, O, W, Q, D, R, H, C, P, N)$. The rows E and O are the two displayed source windows, so a consumer first reads them as finite request/list/window packets rather than as host streams.

The $\mathsf{FiniteStream}^{\uparrow}$ source discipline supplies exactly those finite requests and lists for the two source windows. Thus E and O are available before any output position is assigned by W.

Finally consume the parity split row W. It merges the two finite source windows into the displayed output route while the shared rows Q, D, R, H, C, P, N retain regular rational readback, dyadic comparison, Real sealing, transport, replay, provenance, and local naming. No host sequence equality or countable choice is introduced. □

Theorem 7498.6 (Stream interleaving RegSeqRat readback)**.** *Every regular-Cauchy consumer of an accepted* $\mathsf{StreamInterleaving}^{\uparrow}$ *packet must read*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}$$

through the rows E, O, W, Q, D. The consumer may combine the two source reads only by the displayed parity route, and it may not invoke countable choice over source positions or host-level equality of streams.

Proof. Begin with E, O, W. The parity row determines which source window supplies each requested output position, so a regular-Cauchy read cannot be detached from the two finite StreamName windows.

Read Q next. This row is the RegSeqRat readback surface for the source and output windows already selected by W.

The row D supplies the dyadic arithmetic checks needed by the finite precision request. It compares displayed rational data only, and therefore it cannot introduce countable choice over all later positions or host equality of streams. □

Theorem 7498.7 (Stream interleaving Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{StreamInterleaving}^{\uparrow}$ *packet factors through $E, O, W, Q, D, H, C, P, N$ before reading the seal row R. The Real-facing handoff exports only the interleaved regular rational route and cannot hide a source stream, select a subsequence, or quotient the two Cauchy names.*

Proof. Project the carrier. The Real seal row R is downstream of the source windows, parity split, regular rational readback, and dyadic comparison rows.

A Real-facing consumer must therefore read E, O, W, Q, D first. These rows expose finite stream windows and rational precision data, not host sequence equality or a completed quotient of Cauchy names.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since no hidden selector or quotient coordinate is present, the Real seal cannot escape the displayed interleaving route. □

Falsifiable prediction: A $\mathsf{StreamInterleaving}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without displaying $E, O, W, Q, D, H, C, P, N$ refutes the carrier of Definition 7498.1.

Independence witness: Nearest siblings: streamname, regseqrat, dyadicratcore, and real. $\mathsf{StreamInterleaving}^{\uparrow}$ is not bijective to any one of them because it jointly carries two source windows, a parity split, regular rational readback, dyadic comparison, Real sealing, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamInterleaving}^{\uparrow}}$.

Constructive story: A StreamInterleaving$^{\uparrow}$ packet is generated from two StreamName source windows, a parity-window split, RegSeqRat readback, DyadicRatCore comparison, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{StreamInterleaving}\uparrow}$, seed)

Scope closed: Definition 7498.1, Definition 7498.2, Definition 7498.3, Definition 7498.4, Definition 7498.6, and Definition 7498.7 seed the finite interleaving route between StreamName windows, regular rational readback, dyadic comparison, and Real-facing handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{StreamInterleaving}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host sequence equality, countable choice over positions, quotient Cauchy equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked parity splitting, RegSeqRat readback, DyadicRatCore comparison, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.StreamInterleavingUp.

Chapter 7499

A Concrete Naming Certificate for PoincareDiskAutomorphismDerivative$^{\uparrow}$

Following the standard Poincare disk automorphism theory, a derivative packet is the finite local witness that keeps the disk automorphism, complex coordinate read, hyperbolic metric preservation, boundary transport, and Real-valued derivative window visible together. The PoincareDiskAutomorphismDeriva packet sits after the automorphism carrier of chapter 6776, the metric surface of chapter 3474, the complex coordinate surface of chapter 39, the boundary transport route of chapter 6267, and the terminal Real seal of chapter 38. It names the finite derivative-window consumer route; it does not import analytic completeness, host holomorphic equality, or a global disk model outside the displayed rows.

Definition 7499.1 (Poincare disk automorphism derivative carrier)**.** *A* PoincareDiskAutomorphismDerivative$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, Z, J, M, B, R, H, C, P, N)$$

with the following displayed rows:

1. *A is the* PoincareDiskAutomorphism$^{\uparrow}$ *row naming the disk-preserving automorphism together with its inverse and composition readback.*
2. *Z is the* Complex$^{\uparrow}$ *coordinate-window row for the source and target disk points used by the derivative read.*
3. *J is the derivative-window row, recording the finite complex-linear or real-scale read attached to the displayed automorphism window.*
4. *M is the* HyperbolicMetric$^{\uparrow}$ *preservation row comparing the source and target metric reads through the same window.*
5. *B is the* PoincareDiskBoundaryTransport$^{\uparrow}$ *row recording the induced boundary transport available to boundary-facing consumers.*
6. *R is the* Real$^{\uparrow}$ *seal row for the finite derivative norm or scale read, available only after A, Z, J, M, B have been displayed.*
7. *H records componentwise* hsame *transport for automorphism data, complex coordinate windows, derivative readback, metric preservation, boundary transport, Real sealing, provenance, replay, and local naming.*

8. *C records displayed* Cont *replay from automorphism inspection through coordinate-window readback, derivative-window readback, metric preservation, boundary transport, and Real sealing.*
9. *P is the* Pkg *provenance over* PoincareDiskAutomorphismDerivative$^{\uparrow}$, PoincareDiskAutomorphism$^{\uparrow}$, Complex$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskBoundaryTransport$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{PoincareDiskAutomorphismDerivative}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host holomorphic equality, a completed tangent bundle, ambient analytic continuation, detached boundary dynamics, or a Real derivative value that bypasses the displayed disk automorphism.

Definition 7499.2 (Poincare disk automorphism derivative classifier)**.** *The* PoincareDiskAutomorphismDerivative$^{\uparrow}$ *classifier compares accepted packets only through $A, Z, J, M, B, R, H, C, P, N$. Classifier sameness requires displayed agreement of the automorphism row, complex coordinate window, derivative-window readback, hyperbolic-metric preservation row, boundary-transport row, Real seal, transport, replay, provenance, and local naming.*

Theorem 7499.3 (Poincare disk automorphism derivative NameCert obligations)**.** *For every accepted* PoincareDiskAutomorphismDerivative$^{\uparrow}$ *carrier*

$$D = (A, Z, J, M, B, R, H, C, P, N),$$

the local NameCert$_{\text{PoincareDiskAutomorphismDerivative}^{\uparrow}}$ *surface consists exactly of automorphism exposure, complex coordinate-window readback, derivative-window readback, hyperbolic metric preservation, boundary transport, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may detach the derivative from the automorphism row, replace metric preservation by host analytic equality, or export a completed tangent object.*

Proof. Project the carrier of Definition 7499.1. The automorphism row A is the only source of disk-map data, and the complex coordinate row Z is the only source of coordinate-window data for the derivative read.

The derivative row J is read with the metric row M and the boundary row B. This keeps local derivative information tied to hyperbolic metric preservation and to the displayed boundary transport route.

The Real seal R is downstream of these rows, while H, C, P, N transport, replay, source, and name the same packet. Since no completed tangent bundle, host holomorphic equality, or detached analytic continuation appears in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 7499.4 (Poincare disk automorphism derivative metric preservation)**.** *Every metric-facing consumer of an accepted* PoincareDiskAutomorphismDerivative$^{\uparrow}$ *packet must factor through*

$$\text{PoincareDiskAutomorphism}^{\uparrow} \longmapsto \text{Complex}^{\uparrow} \longmapsto \text{HyperbolicMetric}^{\uparrow} \longmapsto \text{Real}^{\uparrow}.$$

The derivative-window read may be consumed only as a displayed local row attached to the same automorphism and metric-preservation data.

Proof. Start with A and Z. The automorphism and coordinate-window rows supply the finite disk-map and coordinate data, so the metric consumer cannot begin from a host analytic function.

Read the derivative window J together with the metric preservation row M. The derivative read is meaningful for this packet only because it is attached to the same finite automorphism route whose hyperbolic metric comparison is displayed.

Finally, R, H, C, P, N seal, transport, replay, source, and name the result. Thus the Real-facing metric value remains inside the finite automorphism and metric-preservation route. □

Theorem 7499.5 (Poincare disk automorphism derivative boundary transport)**.** *Every boundary-facing consumer of an accepted* $\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}$ *packet factors through the boundary row B after reading A, Z, J, M. The consumer may cite the derivative window as evidence for local transport behavior, but it cannot construct detached boundary dynamics or a completed ideal-boundary action.*

Proof. The boundary consumer first reads the disk automorphism and coordinate rows A, Z. Without these rows, there is no displayed source for the boundary transport.

The derivative and metric rows J, M are read next. They record the local scale and metric-preservation window attached to the same disk map.

Only then does the consumer read B. The row B is a finite boundary-transport certificate, and H, C, P, N keep that certificate under transport, replay, provenance, and local naming. No row supplies detached boundary dynamics or a completed boundary action. □

Theorem 7499.6 (Poincare disk automorphism derivative Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}$ *packet must read $A, Z, J, M, B, H, C, P, N$ before reading R. The Real seal names only the displayed derivative scale or norm reached through the disk automorphism, complex coordinate window, hyperbolic metric preservation, and boundary transport route.*

Proof. Project the carrier. The Real seal R is not a free scalar; it appears after the automorphism, coordinate, derivative, metric, and boundary rows.

A Real-facing consumer must therefore read A, Z, J, M, B first. These rows display the finite disk-map and derivative route rather than host analytic equality or a completed tangent object.

The structural rows H, C, P, N preserve the same route. Since the carrier has no coordinate for a detached Real derivative value, the seal cannot escape the finite derivative-window packet. □

Falsifiable prediction: A $\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}$ consumer that exports a Real derivative read without displaying $A, Z, J, M, B, H, C, P, N$ refutes the carrier of Definition 7499.1.

Independence witness: Nearest siblings: poincare-disk-automorphism, hyperbolic-metric, complex, poincare-disk-boundary-transport, and real. $\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}$ is not bijective to any one of them because it jointly carries disk automorphism data, complex coordinate windows, derivative readback, metric preservation, boundary transport, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}$ packet is generated from a PoincareDiskAutomorphism row, Complex coordinate windows, derivative-window readback, HyperbolicMetric preservation, PoincareDiskBoundaryTransport, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7499.1, Definition 7499.2, Definition 7499.3, Definition 7499.4, Definition 7499.5, and Definition 7499.6 seed the finite derivative-window route between disk automorphism, coordinate readback, metric preservation, boundary transport, and Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskAutomorphismDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host holomorphic equality, analytic continuation, a completed tangent bundle, detached boundary dynamics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked automorphism exposure, coordinate-window readback, derivative readback, metric preservation, boundary transport, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDiskAutomorphismDerivativeUp.

Chapter 7500

A Concrete Naming Certificate for MetaCICResidualJoinGauge$^{\uparrow}$

The MetaCICResidualJoinGauge$^{\uparrow}$ packet realizes a bounded residual-join gauge for the MetaCIC confluence frontier of section 9386.3. It sits beside the residual-substitution boundary of chapter 2181, the confluence critical-pair boundary of chapter 2212, the parallel-diamond frontier of chapter 4238, the closed type-checker seal of chapter 2182, and the closed-normal confluence fragment of chapter 737. The packet records a finite residual-pair and bounded local-join surface without claiming residual-substitution compatibility, full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 7500.1 (MetaCIC residual-join gauge carrier)**.** *A* MetaCICResidualJoinGauge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, R, K, L, B, S, F, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row exposing the finite MetaCIC source, target, and context window inspected by the gauge.*
2. *R is the residual-pair row, recording the two residual contraction paths whose local join is being tested.*
3. *K is the critical-pair boundary row, keeping the inspected peak inside the confluence critical-pair surface.*
4. *L is the bounded local-join row, listing the candidate common reducts and the finite search budget used to inspect them.*
5. *B is the bounded checker row for the local join.*
6. *S is the residual-substitution boundary row, retained as a premise-facing obstruction rather than discharged by the packet.*
7. *F is the closed type-checker seal and closed-normal fragment row used to keep the inspected terms inside the sealed fragment.*
8. *O is the obstruction-retention row for residual substitution, full parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, and kernel consistency.*
9. *H records componentwise* hsame *transport for T, R, K, L, B, S, F, O and for replay, provenance, and naming.*

10. *C records displayed* Cont *replay through the same residual-pair and bounded local-join route.*
11. *P is the* Pkg *provenance over* MetaCICResidualJoinGauge$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceCriticalPairBoundary$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{MetaCICResidualJoinGauge}^{\uparrow}}$ *row.*

The classifier compares accepted gauges only through $T, R, K, L, B, S, F, O, H, C, P, N$. It has no coordinate for a premise-free residual-substitution theorem, full closed confluence, evaluator equality, quotient syntax equality, subject reduction, or kernel consistency.

Theorem 7500.2 (MetaCIC residual-join gauge NameCert obligations)**.** *For every accepted* MetaCICResidualJoinG *carrier*

$$J = (T, R, K, L, B, S, F, O, H, C, P, N),$$

the local NameCert$_{\text{MetaCICResidualJoinGauge}^{\uparrow}}$ *surface consists exactly of typed-window admission through T, residual-pair exposure through R, critical-pair boundary retention through K, bounded local-join exposure through L, bounded checker routing through B, residual-substitution boundary retention through S, closed-checker and closed-normal fragment sealing through F, obstruction retention through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7500.1. The confluence-facing rows are T, R, K, L, B, S, F, O, and the structural certificate rows are H, C, P, N.

Read the residual rows first. The typed-window row T scopes the inspected source and target data, while R and K expose the residual pair and its critical-pair boundary before any local-join read is available.

Read the bounded join rows next. The local-join row L and checker row B provide only a finite inspection surface, and the row F keeps the route inside the closed type-checker seal and closed-normal fragment.

Finally S, O, H, C, P, N retain the residual-substitution premise, refused endpoints, transport, replay, provenance, and local naming. Since no carrier coordinate discharges residual substitution or proves full confluence, the listed rows exhaust the local NameCert obligations. □

Theorem 7500.3 (MetaCIC residual-join gauge diamond handoff)**.** *Every confluence consumer of an accepted* MetaCICResidualJoinGauge$^{\uparrow}$ *packet must read the residual pair R, bounded local-join row L, checker row B, residual-substitution boundary S, closed type-checker and closed-normal fragment row F, obstruction row O, and structural rows H, C, P, N before using the packet in a conditional diamond route. The handoff supplies a finite bounded local-join gauge; it does not claim residual-substitution compatibility, full parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Start from the obligation theorem Definition 7500.2. It forces every confluence-facing read through the typed-window, residual-pair, critical-pair, bounded local-join, checker, residual-substitution, sealed-fragment, and obstruction rows.

The residual pair and critical-pair rows scope the peak. A consumer cannot read a local join before R and K identify the finite residual pair under inspection.

The bounded local-join and checker rows then expose only a finite gauge. The closed type-checker seal and closed-normal fragment row F keep the inspected route inside the sealed fragment, while the retained boundary row S prevents the handoff from being retyped as residual-substitution compatibility.

Finally O, H, C, P, N preserve the refused endpoints and the structural certificate. Hence the packet may feed a later conditional diamond argument, but it does not itself close the full confluence or typing endpoints. □

Falsifiable prediction: A $\mathsf{MetaCICResidualJoinGauge}^{\uparrow}$ consumer that exports a diamond handoff without residual-pair, bounded local-join, bounded checker, residual-substitution boundary, closed type-checker seal, closed-normal fragment, obstruction, transport, replay, provenance, and local naming rows refutes the carrier of Definition 7500.1.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-critical-pair-boundary, metacic-parallel-diamond-frontier, closed-type-checker-seal, metacicconfluencenormal-fragment: the residual-substitution boundary retains the missing compatibility premise without the bounded local-join gauge; the critical-pair boundary records peaks without the residual-pair gauge; the parallel-diamond frontier records the broader conditional handoff without this bounded local-join packet; the closed type-checker seal records typing admission without residual joins; and the closed-normal fragment records normal-source joins without the residual-pair gauge. None is bijective to $\mathsf{MetaCICResidualJoinGauge}^{\uparrow}$.

Lean TasteGate.lean must later provide Nontrivial and FieldFaithful instances for $\mathsf{MetaCICResidualJoinGauge}^{\uparrow}$ so the typed-window, residual-pair, critical-pair, bounded local-join, checker, residual-substitution boundary, sealed-fragment, obstruction, transport, replay, provenance, and local naming fields remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualJoinGauge}^{\uparrow}$ packet is generated from typed-window, residual-pair, critical-pair boundary, bounded local-join, bounded checker, residual-substitution boundary, closed checker and closed-normal fragment, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7500.1, Definition 7500.2, and Definition 7500.3 seed the finite residual-pair and bounded local-join gauge for conditional MetaCIC diamond consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, full parallel diamond, full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window admission, residual-pair exposure, critical-pair boundary retention, bounded local-join exposure, bounded checker routing, residual-substitution boundary retention, sealed-fragment routing, obstruction retention, transport, replay, provenance, Nontrivial, FieldFaithful, and local naming for BEDC.Derived.MetaCICResidualJoinGaugeUp.

Chapter 7501

A Concrete Naming Certificate for $\mathsf{CantorScheme}^{\uparrow}$

Following Bishop and Bridges, a Cantor scheme is the finite binary tree surface used when compact metric and Cantor-space arguments must expose their branch choices without importing countable choice or a hidden limit selector. The $\mathsf{CantorScheme}^{\uparrow}$ packet sits between the Cantor-space cylinder route of chapter 1475, the finite observation rows of chapter 126, the nested interval discipline of chapter 320, and the compact support route of chapter 129. It also shares the regular rational readback surface of chapter 301 when a compact-metric consumer asks for radius or diameter data along a displayed branch.

Definition 7501.1 (Cantor scheme carrier)**.** *A* $\mathsf{CantorScheme}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, B, W, R, K, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite binary tree row, listing the nodes, parent links, left and right successor rows, and the level of each displayed node.*
2. *B is the branch-prefix row, recording the finite bit string or cylinder prefix currently read by the consumer.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that says which branch-prefix coordinates have been inspected.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the scheme carries dyadic radii, diameters, or compact-metric comparison data.*
5. *K is the compact support row, read through* $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, *or* $\mathsf{CompactMetric}^{\uparrow}$ *according to the consumer-facing route.*
6. *H records componentwise* hsame *transport for tree nodes, branch prefixes, finite windows, readback rows, compact support rows, provenance, replay, and local naming.*
7. *C records displayed* Cont *replay from tree-node requests to branch-prefix reads, from branch-prefix reads to stream windows, and from those windows to regular readback and compact support.*
8. *P is the* Pkg *provenance over* $\mathsf{CantorScheme}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CantorScheme}^\uparrow}$ *row.*

The classifier compares accepted schemes only through $T, B, W, R, K, H, C, P, N$. It has no coordinate for a selected infinite branch, quotient stream equality, detached path choice, open-cover compactness, countable choice, or ambient completion.

Theorem 7501.2 (Cantor scheme NameCert obligations)**.** *For every accepted* $\mathsf{CantorScheme}^\uparrow$ *carrier $S = (T, B, W, R, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorScheme}^\uparrow}$ *surface consists exactly of finite binary tree exposure, branch-prefix exposure, finite* $\mathsf{StreamName}^\uparrow$ *window inspection,* $\mathsf{RegSeqRat}^\uparrow$ *readback, compact support through* $\mathsf{CantorSpace}^\uparrow$*,* $\mathsf{NestedInterval}^\uparrow$*, or* $\mathsf{CompactMetric}^\uparrow$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read a compact cylinder, nested interval prefix, or compact-metric support row only after these displayed rows have been exposed.*

Proof. Project the carrier of Definition 7501.1. The finite tree row T and branch-prefix row B are the only source rows for the scheme.

The observation route is W followed by R. A consumer can inspect only the displayed branch-prefix coordinates and the corresponding regular rational readback data.

The compact support row K is downstream of the same prefix and window rows. It may route to Cantor-space cylinders, nested interval prefixes, or compact-metric comparison data, but it cannot add a selected infinite branch or quotient stream equality.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded coordinate appears in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 7501.3 (Cantor scheme branch nonescape)**.** *Every accepted branch read of a* $\mathsf{CantorScheme}^\uparrow$ *packet factors through the displayed route*

$$\mathsf{CantorSpace}^\uparrow \longmapsto \mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{NestedInterval}^\uparrow \longmapsto \mathsf{CompactMetric}^\uparrow.$$

The read may extend a finite prefix or refine a compact support row, but it must keep the finite tree row, branch-prefix row, inspected StreamName windows, regular readback, compact support, transport, replay, provenance, and local naming visible. It cannot escape to an unlogged infinite path, quotient stream equality, detached path choice, open-cover compactness, countable choice, or ambient completion.

Proof. Begin with the finite tree and branch-prefix rows. They expose a finite cylinder boundary, not a completed infinite path.

Read the finite observation rows next. The $\mathsf{StreamName}^\uparrow$ window row determines which prefix coordinates are inspected, and the $\mathsf{RegSeqRat}^\uparrow$ row records any diameter, radius, or comparison data attached to that inspection.

The compact support row then routes the same prefix through the relevant Cantor-space, nested-interval, or compact-metric sibling. This row refines displayed finite data; it does not introduce a hidden branch selector.

The structural rows H, C, P, N preserve the route under transport, replay, provenance, and local naming. Therefore every branch read remains inside the displayed scheme packet. □

Falsifiable prediction: Every accepted $\mathsf{CantorScheme}^\uparrow$ branch read exposes finite tree, branch-prefix, StreamName window, RegSeqRat readback, compact support, transport, replay, provenance, and NameCert rows before any compact-cylinder or nested-interval consumer reads it.

Independence witness: Nearest siblings: cantorspace, streamname, nestedinterval, compact-metric, and regseqrat. $\mathsf{CantorScheme}^\uparrow$ is not bijective to any one sibling because it jointly carries

finite binary tree structure, branch-prefix inspection, finite observation windows, regular readback, compact support, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorScheme}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorScheme}^{\uparrow}$ packet is generated from finite binary tree rows, branch-prefix rows, StreamName windows, RegSeqRat readback, compact support through CantorSpace, NestedInterval, or CompactMetric rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorScheme}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7501.1, Definition 7501.2, and Definition 7501.3 seed the finite branching-scheme carrier consumed by Cantor-space, nested-interval, and compact-metric reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorScheme}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected infinite branch, quotient stream equality, detached path choice, open-cover compactness, countable choice, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite-tree exposure, branch-prefix stability, StreamName window inspection, RegSeqRat readback, compact support nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CantorSchemeUp.

Chapter 7502

A Concrete Naming Certificate for $\mathsf{LipschitzSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LipschitzSpace}^{\uparrow}$ packet records the finite BEDC surface for a metric-domain real-valued map whose variation is controlled by a displayed rational Lipschitz constant. It sits over the metric source of chapter 57, the terminal real-name seal of chapter 38, the map graph carrier of chapter 130, the tolerance-only modulus consumer of chapter 369, and the Lipschitz-function packet of chapter 3762. The packet names a finite function-space row only; it does not add quotient equality of functions, selected representatives, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7502.1 (LipschitzSpace carrier)**.** *A* $\mathsf{LipschitzSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, K, I, T, C, P, N)$$

with the following displayed rows:

1. *M is the metric-domain row, exposing only finite* $\mathsf{Met}^{\uparrow}$ *distance inspections for the source points read by the packet.*
2. *F is the real-valued map row, routed through* $\mathsf{ContinuousMap}^{\uparrow}$ *graph data before any modulus or inequality ledger is exported.*
3. *K is the positive rational Lipschitz-constant row.*
4. *I is the metric inequality ledger, recording only displayed finite comparisons of the form $d_{\mathsf{Real}^{\uparrow}}(F(x), F(y)) \leq K d_M(x, y)$ at inspected source windows.*
5. *T records componentwise* hsame *transport for the metric row, map row, rational constant, inequality ledger, replay, provenance, and local naming row.*
6. *C records displayed* Cont *replay from metric inspection and graph readback through the inequality ledger.*
7. *P is the* Pkg *provenance over* $\mathsf{LipschitzSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{LipschitzFunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, F, K, I, T, C, P, N. It has no coordinate for quotient equality of functions, selected representatives, open-cover compactness, countable choice, measure-theoretic regularity, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7502.2 (LipschitzSpace NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzSpace}^{\uparrow}$ *carrier* $S = (M, F, K, I, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LipschitzSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric-domain row, real-valued continuous-map graph row, rational Lipschitz-constant row, finite metric inequality ledger, componentwise transport, displayed continuation replay, package provenance, and local naming. Every consumer must read the displayed metric and graph windows before the inequality ledger is available.*

Proof. Project the accepted packet. Its analytic rows are exactly M, F, K, I, followed by the structural rows T, C, P, N.

The metric-domain row supplies finite source-distance inspections, and the map row supplies only the displayed real-valued graph data. The rational row K is read before the inequality ledger I, so every displayed bound is tied to the same finite source and target windows.

Rows T, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for quotient function equality, selected representatives, open-cover compactness, countable choice, measure-theoretic regularity, or ambient Real completeness, none of those principles can be projected from the local NameCert surface. □

Lean4 (statement) `BEDC.Derived.LipschitzSpaceUp`

Theorem 7502.3 (LipschitzSpace uniform-modulus handoff)**.** *Every accepted* $\mathsf{LipschitzSpace}^{\uparrow}$ *carrier exposes a* $\mathsf{UniformModulus}^{\uparrow}$ *handoff only through the displayed route*

$$\mathsf{Met}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{LipschitzFunction}^{\uparrow}, \quad \mathsf{UniformModulus}^{\uparrow}.$$

The handoff may consume the rational constant row K *and the finite inequality ledger* I*, but it cannot export a host-selected modulus, quotient equality of functions, open-cover compactness, countable choice, measure-theoretic regularity, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with $S = (M, F, K, I, T, C, P, N)$. The only rows that can feed a modulus consumer are the metric-domain row M, the real-valued map row F, the rational constant row K, and the inequality ledger I.

The sibling $\mathsf{LipschitzFunction}^{\uparrow}$ surface reads those rows as finite Lipschitz data. The $\mathsf{UniformModulus}^{\uparrow}$ consumer receives only the tolerance-facing consequence recorded by that route.

Transport and replay through T and C preserve the same displayed rows, while P and N only record provenance and naming. Therefore the handoff is a finite BEDC route, not a selected external modulus or an ambient compactness or completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzSpace}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7502.1, Definition 7502.2, and Definition 7502.3 seed the finite Lipschitz function-space carrier over Metric, Real, ContinuousMap, UniformModulus, LipschitzFunction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of functions, selected representatives, open-cover compactness, countable choice, measure-theoretic regularity, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-domain readback, real-valued graph exposure, rational Lipschitz-constant exactness, inequality-ledger nonescape, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzSpaceUp.

Constructive story: A $\mathsf{LipschitzSpace}^{\uparrow}$ packet is generated from a metric-domain row, real-valued map row, rational Lipschitz constant row, finite metric inequality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7503

A Concrete Naming Certificate for $\mathsf{DyadicShadowCone}^{\uparrow}$

The $\mathsf{DyadicShadowCone}^{\uparrow}$ packet realizes the boundary-shadow and observer-expansion reading of chapter 9463 as finite dyadic radius windows. It sits after the boundary-shadow carrier of chapter 3813, the observer-expansion route of chapter 4167, the visual metric surface of chapter 3866, the finite observation rows of chapter 126, the regular rational readback rows of chapter 301, and the terminal Real seal of chapter 38. It names the dyadic cone of visible boundary shadows around an observer-side read; it does not complete the boundary, select a global observer horizon, or import host hyperbolic geometry.

Definition 7503.1 (Dyadic shadow cone carrier)**.** *A* $\mathsf{DyadicShadowCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, S, O, V, W, R, E, T, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the dyadic-radius row, listing the finite radius budget and the center of the observer-side window.*
2. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row exposing the boundary shadow read at that radius.*
3. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row recording the observer-expansion source ledger.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row comparing the boundary shadow through a finite visual metric read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which finite observer and boundary coordinates have been inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the dyadic radius and visual metric data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the finite radius or visual metric value.*
8. *T is the transport row keeping the dyadic radius, boundary shadow, observer-expansion, visual metric, stream-window, readback, and Real-seal rows in one displayed route.*
9. *L is the replay ledger that records the accepted read as a cone row rather than as an isolated shadow or isolated expansion row.*
10. *H records componentwise* hsame *transport for the radius, shadow, observer, visual metric, window, readback, seal, transport, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from dyadic-radius requests through boundary-shadow reads, observer-expansion rows, visual-metric comparison, finite windows, regular readback, Real sealing, and transport.*
12. *P is the* Pkg *provenance over* $\mathsf{DyadicShadowCone}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicShadowCone}^{\uparrow}}$ *row.*

The classifier compares accepted cones only through $Q, S, O, V, W, R, E, T, L, H, C, P, N$. It has no coordinate for a completed hyperbolic boundary, selected observer horizon, quotient boundary equality, detached visual metric scalar, global disk model, or host geometric compactness.

Theorem 7503.2 (Dyadic shadow cone NameCert obligations)**.** *For every accepted* $\mathsf{DyadicShadowCone}^{\uparrow}$ *carrier*

$$D = (Q, S, O, V, W, R, E, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicShadowCone}^{\uparrow}}$ *surface consists exactly of dyadic-radius exposure, boundary-shadow exposure, observer-expansion exposure, visual-metric comparison, finite* $\mathsf{StreamName}^{\uparrow}$ *window inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, route transport, cone replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may replace the dyadic radius window by a completed boundary point, detach the visual metric from the boundary-shadow route, or read observer expansion without the same finite cone packet.*

Proof. Project the carrier of Definition 7503.1. The dyadic radius row Q, boundary-shadow row S, observer-expansion row O, and visual metric row V are simultaneous source rows for the cone.

Read the finite observation route next. The stream window W fixes which observer and boundary coordinates are inspected, while R and E provide the regular rational and Real-facing values reached by that inspection.

The transport and replay rows T, L keep the read as one cone route. They prevent a consumer from taking an isolated shadow, an isolated expansion row, or a detached visual scalar as the whole carrier.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no completed boundary, selected horizon, quotient equality, detached visual metric scalar, global disk model, or host compactness coordinate appears in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 7503.3 (Dyadic shadow cone observer-window nonescape)**.** *Every accepted observer-expansion read of a* $\mathsf{DyadicShadowCone}^{\uparrow}$ *packet factors through*

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longmapsto \mathsf{HyperbolicObserverExpansion}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto$$

The read may narrow the dyadic radius or refine the finite boundary window, but it must keep the radius, boundary-shadow, observer-expansion, visual-metric, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and NameCert rows visible. It cannot escape to a completed boundary object, selected horizon, quotient boundary equality, detached visual scalar, global disk model, or host hyperbolic compactness.

Proof. Begin with the dyadic radius and boundary-shadow rows. They expose a finite cone window, not a completed boundary point.

Read the observer-expansion and visual-metric rows next. The observer row records the source ledger being expanded, and the visual metric row compares it only through the displayed boundary-shadow route.

The StreamName and RegSeqRat rows then expose the finite observation schedule and the regular rational readback. The Real seal is downstream of those rows and therefore cannot be consumed as an independent geometric scalar.

Transport, replay, provenance, and local naming preserve the same packet through T, L, H, C, P, N. Thus every observer-window read remains inside the displayed dyadic shadow cone. □

The Lean TasteGate file at `lean4/BEDC/Derived/DyadicShadowConeUp/TasteGate.lean` must include explicit `Nontrivial DyadicShadowConeUp` and `FieldFaithful DyadicShadowConeUp` instances preserving $Q, S, O, V, W, R, E, T, L, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can witness the gate.

Falsifiable prediction: Every accepted $\mathsf{DyadicShadowCone}^{\uparrow}$ read exposes dyadic-radius, boundary-shadow, observer-expansion, visual-metric, StreamName, RegSeqRat, Real-seal, transport, replay, provenance, and NameCert rows before any boundary-shadow or observer-expansion consumer reads it.

Independence witness: Nearest siblings: hyperbolic-boundary-shadow, hyperbolic-observer-expansion, hyperbolic-visual-metric, streamname, and regseqrat. $\mathsf{DyadicShadowCone}^{\uparrow}$ is not bijective to any one sibling because it jointly carries dyadic radius windows, boundary shadows, observer-expansion rows, visual-metric reads, finite observations, regular readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicShadowCone}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicShadowCone}^{\uparrow}$ packet is generated from dyadic-radius rows, boundary-shadow rows, observer-expansion rows, visual-metric comparison, StreamName windows, RegSeqRat readback, a Real seal, route transport, cone replay, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicShadowCone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7503.1, Definition 7503.2, and Definition 7503.3 seed the finite dyadic shadow-cone route for boundary-shadow and observer-expansion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicShadowCone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary compactification, selected observer horizons, quotient boundary equality, detached visual metric scalars, global disk models, host hyperbolic compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic-radius exposure, boundary-shadow exposure, observer-expansion exposure, visual-metric comparison, StreamName window inspection, RegSeqRat readback, Real sealing, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.DyadicShadowConeUp.

Chapter 7504

A Concrete Naming Certificate for $\mathsf{DyadicRealDensity}^{\uparrow}$

Following Bishop and Bridges-style constructive real analysis, the $\mathsf{DyadicRealDensity}^{\uparrow}$ packet records the finite route by which dyadic rational approximants become visible to a displayed $\mathsf{Real}^{\uparrow}$ name through regular rational readback, finite stream windows, dyadic tolerance data, transport, replay, provenance, and a local naming row. It sits after the dyadic arithmetic surface of chapter 291, the finite-window naming route of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names a density handoff for Real and Completion consumers; it does not choose a representative stream, quotient real names, invoke trichotomy, use countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7504.1 (DyadicRealDensity carrier)**.** *A* $\mathsf{DyadicRealDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (D, W, R, E, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row carrying the dyadic rational approximant and its arithmetic certificate.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule at which the Real name is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after the dyadic source, window, and readback rows have been displayed.*
5. *T is the dyadic tolerance row, read from the same dyadic ledger as D, that bounds the approximation request.*
6. *H records componentwise* hsame *transport for D, W, R, E, T and the structural rows.*
7. *C records displayed* Cont *replay from a Real approximation request through D, W, R, E, T, H.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and local* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRealDensity}^{\uparrow}}$ *row.*

The carrier stores only displayed finite rows. It has no coordinate for selected representatives, quotient equality of real names, trichotomy, countable choice, host least-upper-bound data, or ambient Real completeness.

Theorem 7504.2 (DyadicRealDensity NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRealDensity}^{\uparrow}$ *carrier*

$$Z = (D, W, R, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRealDensity}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the dyadic source, finite window, regular readback, Real seal, dyadic tolerance, transport, replay, provenance, and local naming rows;*
2. *tolerance compatibility, requiring the tolerance row* T *to be read from the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger as the source row* D*;*
3. *window-readback exactness, requiring every Real approximation request to inspect the finite* $\mathsf{StreamName}^{\uparrow}$ *windows* W *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R *before the Real seal* E *is consumed;*
4. *transport stability, requiring componentwise* hsame *transport and displayed* Cont *replay to preserve the route* D, W, R, E, T*;*
5. *ledger non-escape, stating that* P *and* N *export no selected representative stream, quotient real equality, trichotomy, countable-choice selector, host least-upper-bound object, or ambient Real completeness principle.*

Proof. Project the carrier of Definition 7504.1. The rows $D, W, R, E, T, H, C, P, N$ are exactly the available coordinates, so carrier admission is finite.

The tolerance clause reads D and T together. Since both rows come from the dyadic ledger, an approximation request cannot import a separate host radius or a selected rational outside the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ source.

The Real-facing clause then reads W, R, E. A consumer reaches the Real seal only after the finite windows and regular rational readback have been displayed, so the approximation route remains a finite read rather than a quotient stream judgement.

Finally H, C, P, N transport, replay, source, and name the same rows. None of the refused host-side objects is a coordinate of Z, and therefore the listed obligations exhaust the local NameCert surface. □

Theorem 7504.3 (DyadicRealDensity Real approximation)**.** *Every Real-facing approximation exported by an accepted* $\mathsf{DyadicRealDensity}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

with its dyadic tolerance, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The exported approximation cannot inspect selected limits, quotient equality of real names, countable choice, trichotomy, host least-upper-bound data, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $Z = (D, W, R, E, T, H, C, P, N)$. The dyadic source row D and tolerance row T provide the only approximation scale visible to the packet.

The finite observation then passes through W and R. The StreamName row opens only the displayed windows, and the RegSeqRat row supplies the regular rational readback attached to those windows.

The Real seal E is downstream of that finite route. Componentwise transport and replay preserve the same coordinates through H and C, while P and N record provenance and local naming.

Thus every Real-facing approximation is a read of $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ in the displayed order. Since no other coordinate exists in the carrier, the refused host-side principles are unavailable to the approximation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRealDensity}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRealDensity}^{\uparrow}$ packet is generated from a DyadicRatCore source row, finite StreamName windows, a RegSeqRat readback row, a RealUp seal row, a dyadic tolerance row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRealDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7504.1, Definition 7504.2, and Definition 7504.3 seed the finite density route from dyadic rational approximants to Real-facing reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRealDensity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected representatives, quotient equality of real names, trichotomy, countable choice, host least-upper-bound data, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance compatibility, window-readback exactness, transport stability, and ledger non-escape for BEDC.Derived.DyadicRealDensityUp.

Chapter 7505

A Concrete Naming Certificate for $\mathsf{SupportFunction}^{\uparrow}$

Following Schneider on convex bodies, the $\mathsf{SupportFunction}^{\uparrow}$ packet records the finite NameCert surface for support-function rows over $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, and $\mathsf{ConvexSet}^{\uparrow}$. It sits over the scalar seal of chapter 38, the vector carrier of chapter 47, and the convex membership boundary of chapter 208. The packet names support values only through displayed direction rows, convex witness rows, real comparison rows, and finite supremum budgets; it does not import host compactness, a selected maximizing point, quotient dual spaces, or ambient real completeness.

Definition 7505.1 (Support-function carrier)**.** *A* $\mathsf{SupportFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, V, D, E, B, H, C, P, N)$$

with the following displayed rows:

1. *K is the convex body row, read through* $\mathsf{ConvexSet}^{\uparrow}$*, carrying membership, convex-combination, and located boundary tests for the inspected points.*
2. *V is the ambient vector-space row, read through* $\mathsf{VecSpace}^{\uparrow}$*, carrying vector addition, scalar action, and finite pairing coordinates used by the packet.*
3. *D is the direction row, listing the finitely many inspected linear-functional or dual-direction reads.*
4. *E is the evaluation row, whose entries pair displayed directions from D with displayed convex witnesses from K and seal the values through* $\mathsf{Real}^{\uparrow}$*.*
5. *B is the support-budget row, listing finite upper-bound comparisons and the inspected witnesses that justify each support value read.*
6. *H records componentwise* hsame *transport for K, V, D, E, B and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from vector and convex-set reads to evaluations and from evaluations to budgeted real comparisons.*
8. *P is the* Pkg *provenance over* $\mathsf{SupportFunction}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SupportFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, D, E, B, H, C, P, N$. It has no coordinate for a host supremum operator, a chosen maximizer, quotient dual equality, compactness of K, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SupportFunctionUp.SupportFunctionTasteGate single carrier alignment`

Theorem 7505.2 (Support-function finite supremum budget)**.** *Every support value read from an accepted* $\mathsf{SupportFunction}^{\uparrow}$ *packet factors through the displayed route*

$$K, V, D, E \longmapsto B$$

before any downstream consumer may inspect a real bound. The row B contains the only supremum-facing data: finite inspected witnesses, upper-bound comparisons sealed through $\mathsf{Real}^{\uparrow}$*, and the replay route tying those comparisons to the convex and vector rows. No support read may be interpreted as a host supremum over all points of K, a selected exposed point, an ambient compactness theorem, or a quotient dual-space value.*

Proof. Project the carrier of Definition 7505.1. The only rows that can mention support values are the direction row D, the evaluation row E, and the support-budget row B, all attached to the convex and vector rows K, V.

The evaluation route is finite. Each inspected direction is paired with displayed convex witnesses, and every resulting comparison is sealed through the $\mathsf{Real}^{\uparrow}$ dependency rather than by an external supremum operation.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since the carrier contains no maximizer selector, host compactness row, quotient dual equality, or ambient completeness field, the finite budget B exhausts the support-function supremum surface. □

Theorem 7505.3 (Support-function NameCert obligations)**.** *For every accepted* $\mathsf{SupportFunction}^{\uparrow}$ *carrier*

$$S = (K, V, D, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SupportFunction}^{\uparrow}}$ *surface consists exactly of convex-set admission for K, vector-space admission for V, direction exposure for D, real evaluation sealing for E, finite support-budget exposure for B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. These obligations are sufficient to hand a finite support-bound surface to later convex-duality and compact-convex consumers, but they do not assert classical support-function reconstruction or compact-convex duality.*

Proof. Start from Definition 7505.1. The carrier lists exactly the convex row, vector row, direction row, evaluation row, support-budget row, transport row, replay row, provenance row, and local naming row.

Apply Definition 7505.2. It forces every support-facing read through K, V, D, E, B before a real bound can be consumed, so the local NameCert obligations include budget exposure and real sealing but no host supremum.

The structural rows H, C, P, N preserve the same displayed packet under transport, replay, provenance, and naming. Because no coordinate records a selected maximizer, quotient dual equality, compactness theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the accepted support-function surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SupportFunction}^{\uparrow}}$**.**

Constructive story: A SupportFunction$^{\uparrow}$ packet is generated from convex-set rows, vector-space rows, displayed direction rows, real evaluation rows, finite support-budget comparisons, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SupportFunction}^{\uparrow}}$, seed)

Scope closed: Definition 7505.1, Definition 7505.2, and Definition 7505.3 seed the finite support-function NameCert surface over RealUp, VecSpaceUp, and ConvexSetUp.

Formal verification: FormalStatus(NameCert$_{\mathsf{SupportFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host support-function theorem, compactness of convex bodies, selected maximizers, quotient dual spaces, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, direction exposure, finite evaluation sealing, support-budget nonescape, transport, replay, provenance, and local naming for $K, V, D, E, B, H, C, P, N$.

Chapter 7506

A Concrete Naming Certificate for $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$

Following Clarkson's uniformly convex space theory and the Bishop–Bridges practice of keeping metric and real-name evidence explicit, the $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ packet records a closed fiber inside a uniformly convex carrier as finite NameCert data. It sits over the modulus route of chapter 5831, the complete-metric boundary of chapter 128, and the terminal real-name discipline of chapter 38. The packet gives projection, fixed-point, and completion consumers a named closed-fiber convexity surface without importing quotient subspaces, selected nearest points, weak compactness, or choice.

Definition 7506.1 (Closed fiber uniform convexity carrier)**.** *A* $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, K, \Phi, \Gamma, \Delta, \Pi, E, H, T, P, N)$$

with the following displayed rows:

1. *U is the ambient* $\mathsf{UniformlyConvexSpace}^{\uparrow}$ *row, exposing the norm, metric, midpoint, and positive modulus routes only through its local certificate.*
2. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row used by Cauchy and fixed-point consumers of the fiber.*
3. *Φ is the fiber membership classifier, read as a displayed predicate on the ambient carrier rather than as a quotient subspace.*
4. *Γ is the closedness row: every finite Cauchy read in the fiber that lands through K must replay Φ at the displayed limit row.*
5. *Δ is the uniform-convexity restriction row, reusing the ambient Clarkson modulus from U for pairs whose membership reads pass through Φ.*
6. *Π is the projection-route row, recording how a consumer may ask for a fiber-facing projection bound through the displayed metric, real, midpoint, and closedness rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for norm gaps, radius comparisons, modulus margins, and projection-distance readback.*
8. *H records componentwise* hsame *transport for $U, K, \Phi, \Gamma, \Delta, \Pi, E$ and the local structural rows.*
9. *T records displayed* Cont *replay from a closed-fiber request through the ambient uniform-convexity, complete-metric, membership, closedness, projection, and real-seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$, $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedFiberUniformConvexity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for quotient fibers, selected nearest points, weak compactness, Hahn–Banach separation, or an ambient choice principle.

Theorem 7506.2 (Closed fiber uniform convexity NameCert obligations)**.** *For every accepted* $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ *packet* $F = (U, K, \Phi, \Gamma, \Delta, \Pi, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClosedFiberUniformConvexity}}$ *surface consists exactly of ambient uniformly convex admission, complete-metric boundary visibility, fiber-membership readback, closedness replay for finite Cauchy reads, restricted modulus admission, projection-route exposure, real-seal comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside* $U, K, \Phi, \Gamma, \Delta, \Pi, E, H, T, P, N$.

Proof. Carrier admission is projection from Definition 7506.1. The rows $U, K, \Phi, \Gamma, \Delta, \Pi, E, H, T, P, N$ are the whole accepted packet.

Read the ambient and closedness rows first. The row U supplies only the certified uniform-convexity route, while K, Φ, Γ bind completion-facing Cauchy reads to the displayed fiber predicate.

Read the convexity and projection rows next. The row Δ restricts the ambient modulus to pairs whose membership is displayed by Φ, and Π exposes only the metric, midpoint, closedness, and real-comparison route already present in U, K, Γ, E.

Finally H, T, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores quotient fibers, selected nearest points, weak compactness, Hahn–Banach separation, or choice, those objects cannot be obligations of the local certificate. □

Theorem 7506.3 (Closed fiber uniform convexity projection route)**.** *Every accepted* $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ *consumer that asks for a fiber-facing projection or distance estimate factors through*

$$\mathsf{UniformlyConvexSpace}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \Phi, \Gamma, \Delta, \Pi, H, T, P, N.$$

The route may read the restricted Clarkson modulus only after the ambient uniformly convex row, the fiber-membership row, the complete-metric closedness row, and the real-valued comparison seal have been displayed. It exports a finite closed-fiber NameCert surface, not a selected nearest point, quotient fiber equality, weak compactness, Hahn–Banach separation, or choice.

Proof. Begin with a projection or distance request. The ambient row U supplies the only norm, metric, midpoint, and modulus data, and the real seal E supplies the only visible comparison values.

Pass through the fiber rows before reading the modulus. The predicate row Φ displays membership, and the closedness row Γ ensures that completion-facing Cauchy reads landing through K replay the same predicate at the limit row.

Only then may Δ and Π answer the request. The restricted modulus is tied to pairs already admitted by Φ, and the projection route is tied to the displayed metric, midpoint, closedness, and real-comparison data.

Finally H, T, P, N keep the route invariant under transport, continuation replay, provenance, and local naming. The excluded selected nearest point, quotient-fiber equality, weak compactness, Hahn–Banach separation, and choice objects are absent from the carrier, so the finite route is the whole exported surface. □

Falsifiable prediction: An accepted $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ read is refuted if a consumer obtains a restricted uniform-convexity margin or fiber-facing projection bound without first displaying the ambient $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, fiber-membership, closedness, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: uniformly-convex-space, completemetric, real: no listed sibling is bijective to $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ because the packet jointly carries an ambient uniformly convex route, a complete-metric boundary, fiber membership, closedness replay, restricted modulus access, projection-route exposure, real comparisons, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedFiberUniformConvexity}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedFiberUniformConvexity}^{\uparrow}$ packet is generated from an ambient UniformlyConvexSpace row, a CompleteMetric boundary row, fiber membership, closedness replay, restricted modulus access, projection-route exposure, Real comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedFiberUniformConvexity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7506.1, Definition 7506.2, and Definition 7506.3 seed the finite closed-fiber route over uniformly convex, complete-metric, and real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedFiberUniformConvexity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient fiber equality, selected nearest points, weak compactness, Hahn–Banach separation, choice, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, closedness replay, restricted modulus exactness, projection-route nonescape, and local naming for BEDC.Derived.ClosedFiberUniformConvexityUp.

Chapter 7507

RegularCauchyDistributiveLaw NameCert Construction

From Bishop and Bridges constructive real arithmetic, the $\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}$ packet records the finite window calculation that lets multiplication distribute over addition for regular rational Cauchy names. It consumes the two-source surfaces of $\mathsf{RegularCauchySum}^{\uparrow}$ and $\mathsf{RegularCauchyProduct}^{\uparrow}$, the difference route of $\mathsf{RegularCauchyDifference}^{\uparrow}$, the algebraic operation inventory of $\mathsf{RegularCauchyRing}^{\uparrow}$, and the source and seal layers $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ from chapter 417, chapter 461, chapter 429, chapter 1470, chapter 301, chapter 291, and chapter 38. The packet names only the finite distributive-window proof surface; it does not import host real algebra or equality of completed real quotients.

Definition 7507.1 (Regular Cauchy distributive-law carrier)**.** *A* $\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, B, C, W_A, W_B, W_C, S_L, P_L, P_B, P_C, S_R, \Delta, E, R, H, T, Q, N)$$

with the following displayed coordinates:

1. *A, B, and C are three* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows for regular rational Cauchy real names.*
2. *W_A, W_B, and W_C are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows opened at the same requested precision scale.*
3. *S_L is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row for the source sum $B + C$.*
4. *P_L is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *row for the left route $A \cdot (B + C)$.*
5. *P_B and P_C are the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *rows for the two right-route products $A \cdot B$ and $A \cdot C$.*
6. *S_R is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row for the right route $(A \cdot B) + (A \cdot C)$.*
7. *Δ is the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *comparison row between the left-route readback and the right-route readback.*
8. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the source endpoint rows, product endpoint rows, sum endpoint rows, and the finite distributive error budget for the synchronized window.*
9. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the left route, right route, difference comparison, and tolerance ledger have been displayed.*

10. *H stores componentwise* hsame *transport for the three source rows, synchronized windows, sum rows, product rows, difference row, dyadic tolerance ledger, terminal seal, continuation, provenance, and local naming.*

11. *T stores displayed* Cont *replay from the three source windows to the left product route, the two right product routes, the right sum route, the comparison route, and the terminal real-facing route.*

12. *Q is the* Pkg *provenance over* $\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}$, $\mathsf{RegularCauchySum}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{RegularCauchyDifference}^{\uparrow}$, $\mathsf{RegularCauchyRing}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient streams, host real equality, trichotomy, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7507.2 (Regular Cauchy distributive-law NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDistributi}}$ *surface for Definition 7507.1 consists exactly of carrier admission, synchronized source-window admission, left-route product admission, right-route product-and-sum admission, difference-row comparison, dyadic tolerance-ledger exactness, terminal real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7507.1. The three source rows, synchronized windows, operation rows, difference row, tolerance ledger, transports, continuations, provenance, and local name are all visible coordinates of D.

The left route uses the sum row S_L and then the product row P_L. Apply Definition 417.2 to expose $B + C$, then apply Definition 461.2 to expose $A \cdot (B + C)$ through the same synchronized window scale.

The right route uses P_B, P_C, and S_R. Apply the product obligation surface twice to expose $A \cdot B$ and $A \cdot C$, and then apply the sum obligation surface to expose their displayed sum. The difference row Δ is then read through the comparison surface of Definition 429.2.

The tolerance and structural rows are packet coordinates. The ledger E records the dyadic endpoint and error-budget rows used by both routes, while H, T, Q, N transport, replay, source, and name the same finite calculation. Since no other coordinate is present, the obligation surface excludes host real algebra, quotient equality, trichotomy, selected limits, and ambient completeness. □

Theorem 7507.3 (Regular Cauchy distributive-window induction)**.** *For every accepted* RegularCauchyDistributiveL *carrier, the equality of the two distributive routes is witnessed by induction on the displayed synchronized window ledger. At each finite precision window, the endpoint calculation reads only the three* $\mathsf{RegSeqRat}^{\uparrow}$ *sources, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchySum}^{\uparrow}$ *rows, the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *rows, the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *comparison row, the* $\mathsf{RegularCauchyRing}^{\uparrow}$ *operation inventory, and the structural* hsame, Cont, Pkg, *and* NameCert *rows.*

Proof. Begin with the empty window ledger. No source endpoint has been read, so both routes expose only the trivial displayed tolerance row in E and no real-facing equality claim is available.

For the induction step, open the next synchronized windows W_A, W_B, W_C. The sum row S_L computes the endpoint for $B + C$, and the product row P_L computes the left-route endpoint from A and that displayed sum.

On the same window, the rows P_B and P_C compute the two product endpoints $A \cdot B$ and $A \cdot C$. The row S_R then sums those two displayed endpoints. The dyadic arithmetic entries in E record the finite distributive identity at this precision and the accumulated error budget for both routes.

The difference row Δ consumes the two route readbacks and records that their displayed tolerance gap is absorbed by the same ledger. Componentwise hsame transport and displayed Cont replay preserve the induction state, so the finite calculation remains inside the named BEDC packet at every step. □

Theorem 7507.4 (Regular Cauchy distributive-law Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}$ *packet reaches the terminal distributive handoff only after reading the three source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the left route* $A \cdot (B + C)$*, the right route* $(A \cdot B) + (A \cdot C)$*, the* $\mathsf{RegularCauchyDifference}^{\uparrow}$ *comparison row, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, componentwise* hsame *transports, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The handoff exports no host real equality, quotient stream, trichotomy, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Project the carrier of Definition 7507.1. The only real-facing route is the one assembled from the left product readback, the two right product readbacks, their sum, and the difference comparison row.

Apply Definition 7507.2. It forces every consumer to keep the source windows, operation rows, tolerance ledger, transport, replay, provenance, and local naming attached to the route.

Apply Definition 7507.3. The route comparison is established at finite synchronized windows and is carried by the displayed dyadic ledger before any $\mathsf{Real}^{\uparrow}$ seal is read.

Finally use the Real-seal boundaries of the sibling operation chapters and the operation inventory of Definition 1470.9. They expose only regular-Cauchy readbacks and terminal seals. Since the distributive-law carrier adds no further real-facing coordinate, the consumer cannot replace the packet by host equality, quotient streams, trichotomy, selected limits, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}$ packet is generated from three RegSeqRat source rows, synchronized StreamName windows, RegularCauchySum and RegularCauchyProduct routes for the left and right distributive expressions, a RegularCauchyDifference comparison row, a DyadicRatCore tolerance ledger, componentwise transport, continuation replay, package provenance, terminal RealUp seal access, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}}$, seed)

Scope closed: Definition 7507.1, Definition 7507.2, Definition 7507.3, and Definition 7507.4 seed the finite distributive-window surface consumed by regular-Cauchy real arithmetic.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyDistributiveLaw}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host real equality, quotient streams, trichotomy, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized window admission, dyadic tolerance-ledger exactness, distributive-window induction, and Real-seal nonescape for the same finite packet.

Chapter 7508

A Concrete Naming Certificate for $\mathsf{PixleyRoySpace}^{\uparrow}$

Following Pixley and Roy on finite-set hyperspaces, the $\mathsf{PixleyRoySpace}^{\uparrow}$ packet records the finite topology surface whose points are nonempty finite closed-subset rows and whose basic opens are hit windows of the form "the displayed finite row is kept inside a displayed open neighbourhood while meeting the named finite core." It sits next to the indexed-open carrier of chapter 88, the observable-open classifier of chapter 1860, the membership discipline of chapter 3668, the finite-set surface of chapter 112, and the lower-limit topology example chapter 3363. The packet names only the finite hit-and-containment interface; it does not import a host powerset hyperspace, selected compact subsets, Vietoris completeness, countable choice, or ambient separation theorems.

Definition 7508.1 (Pixley–Roy space carrier)**.** *A* $\mathsf{PixleyRoySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, S, F, O, W, H, C, Q, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *indexed-open row for the source space.*
2. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open truth row used to read membership in displayed opens.*
3. *F is the nonempty finite closed-subset row, exposed through* $\mathsf{FinSet}^{\uparrow}$ *and* $\mathsf{SetLike}^{\uparrow}$ *membership data rather than through a host powerset.*
4. *O is the finite basic-open hit window. It displays a finite core row and an ambient open row, and it records that the finite closed-subset row lies inside the open row while hitting every named core coordinate.*
5. *W is the finite observation schedule for the hit and containment reads.*
6. *H records componentwise* hsame *transport for the topology, observable-open, finite closed-subset, hit-window, schedule, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an observable-open request through T, S, F, O, W.*
8. *Q is the* Pkg *provenance over* $\mathsf{PixleyRoySpace}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{SierpinskiSpace}^{\uparrow}$*,* $\mathsf{FinSet}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* $\mathsf{SorgenfreyLine}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PixleyRoySpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary hyperspace powerset, a selected compact-subset representative, countable choice, host equality of closed sets, Vietoris completeness, or an ambient separation theorem.

Lean4 ✓ `BEDC.Derived.PixleyRoySpaceUp.PixleyRoySpaceTasteGate single carrier alignment`

Theorem 7508.2 (Pixley–Roy space NameCert obligations)**.** *For every accepted* $\mathsf{PixleyRoySpace}^{\uparrow}$ *carrier* $P = (T, S, F, O, W, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PixleyRoySpace}^{\uparrow}}$ *surface consists exactly of ambient topology admission, Sierpinski observable-open admission, finite nonempty closed-subset admission through* $\mathsf{FinSet}^{\uparrow}$ *and* $\mathsf{SetLike}^{\uparrow}$*, basic-open hit-window exactness, finite observation scheduling, componentwise transport, displayed replay, provenance, and local naming. Every public neighbourhood read must display* T, S, F, O, W *before the structural rows* H, C, Q, N *are consumed.*

Proof. Project the accepted carrier of Definition 7508.1. The mathematical rows are exactly the ambient topology row T, the observable-open truth row S, the finite closed-subset row F, the hit-window row O, and the finite observation schedule W.

The finite-subset admission is local. The row F is read through the displayed $\mathsf{FinSet}^{\uparrow}$ and $\mathsf{SetLike}^{\uparrow}$ membership surfaces, so nonemptiness, membership, and closed-subset evidence are visible finite data rather than a host powerset element.

The basic-open obligation is also local. The row O records the finite core and ambient open row, while S supplies observable-open truth for the containment and hit reads scheduled by W.

Finally H, C, Q, N transport, replay, source, and name the same rows. Since none of the excluded objects is a coordinate of the carrier, the local NameCert surface is exhausted by the listed finite obligations. □

Theorem 7508.3 (Pixley–Roy finite-open handoff)**.** *Every* $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$*, compactness-boundary, or lower-limit-topology consumer of an accepted* $\mathsf{PixleyRoySpace}^{\uparrow}$ *packet receives a neighbourhood only through the finite route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{SierpinskiSpace}^{\uparrow} \longrightarrow \mathsf{FinSet}^{\uparrow}, \mathsf{SetLike}^{\uparrow} \longrightarrow O \longrightarrow W.$$

The route exposes finite nonempty closed-subset rows and finite basic-open hit windows before any downstream read is public; it exports no host powerset of closed sets, selected compact-subset representative, countable choice, Vietoris completeness, or ambient separation theorem.

Proof. Start with the NameCert obligations of Definition 7508.2. Any neighbourhood read must first open the ambient indexed topology row and then read observable-open truth through the Sierpinski row.

The finite closed-subset row is then inspected through $\mathsf{FinSet}^{\uparrow}$ and $\mathsf{SetLike}^{\uparrow}$. Only after those membership rows are displayed can the hit-window row O record that the named finite core is hit and that the displayed finite row stays inside the ambient open.

The schedule W lists the finite observations used by the handoff, while H, C, Q, N preserve the same route under transport, replay, provenance, and local naming. Thus a consumer such as the lower-limit topology surface of chapter 3363 receives a finite-open Pixley–Roy packet, not a hidden hyperspace or an external compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{PixleyRoySpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PixleyRoySpace}^{\uparrow}$ packet is generated from a Topology indexed-open row, a SierpinskiSpace observable-open row, a finite nonempty closed-subset row, a finite basic-open hit window, a finite observation schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PixleyRoySpace}^{\uparrow}}$, seed)

Scope closed: Definition 7508.1, Definition 7508.2, and Definition 7508.3 seed the finite Pixley–Roy hyperspace interface over Topology, SierpinskiSpace, FinSet, SetLike, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PixleyRoySpace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host powerset hyperspace, selected compact-subset representatives, countable choice, host equality of closed sets, Vietoris completeness, ambient separation theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked ambient topology admission, observable-open admission, finite closed-subset admission, basic-open hit-window exactness, schedule exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.PixleyRoySpaceUp.

Chapter 7509

A Concrete Naming Certificate for RegulatedFunctionFiniteJump$^{\uparrow}$

Following Bishop and Bridges on regulated functions, the RegulatedFunctionFiniteJump$^{\uparrow}$ packet records the finite-jump subclass as a bounded local NameCert surface rather than as host-level function equality. It sits beside the regulated-function carrier of chapter 1906, the step-function endpoint rows of chapter 3780, the uniform-limit route of chapter 463, and the dyadic mesh-gauge schedule of chapter 7496. The packet names only finite source intervals, jump partitions, one-sided windows, step approximants, uniform-limit seals, transport, replay, provenance, and local naming rows.

Definition 7509.1 (Finite-jump regulated-function carrier)**.** *A* RegulatedFunctionFiniteJump$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, J, W, A, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the source interval row, naming the displayed closed interval, endpoint order, and observation windows read by the regulated-function consumer.*
2. *J is the finite jump partition row, listing the finitely many jump sites and the adjacent cells on which one-sided data is inspected.*
3. *W is the one-sided window ledger, recording the left and right window rows at each jump site together with ordinary interior windows away from J.*
4. *A is the step approximant ledger, read through the* StepFunction$^{\uparrow}$ *sibling surface and indexed by the finite partition and requested tolerance.*
5. *U is the* UniformLimit$^{\uparrow}$ *seal row, consuming the step approximant ledger and the dyadic mesh-gauge schedule before any regulated-function or integration-facing consumer reads the packet.*
6. *H records componentwise* hsame *transport for intervals, finite jump partitions, one-sided windows, step approximants, uniform-limit seals, replay, provenance, and naming.*
7. *C records displayed* Cont *replay from a source-window request through the partition, one-sided window, step approximant, mesh-gauge, and uniform-limit rows.*
8. *P is the* Pkg *provenance over* RegulatedFunctionFiniteJump$^{\uparrow}$, RegulatedFunction$^{\uparrow}$, StepFunction$^{\uparrow}$, UniformLimit$^{\uparrow}$, DyadicMeshGauge$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $I, J, W, A, U, H, C, P, N$. It has no coordinate for arbitrary discontinuity classification, Lebesgue differentiation, quotient equality of host functions, countable choice, selected point values, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegulatedFunctionFiniteJumpUp.RegulatedFunctionFiniteJumpTasteGate single carrier alignment`

Theorem 7509.2 (Finite-jump regulated-function NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}$ *carrier $F = (I, J, W, A, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}}$ *surface consists exactly of carrier admission, finite jump-row stability, the step approximation route through* $\mathsf{StepFunction}^{\uparrow}$*, the uniform-limit consumer route through* $\mathsf{UniformLimit}^{\uparrow}$ *and* $\mathsf{DyadicMeshGauge}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger non-escape from undisplayed analytic principles.*

Proof. Project the carrier of Definition 7509.1. The rows $I, J, W, A, U, H, C, P, N$ are the whole visible packet.

The finite jump-row stability clause is read from J and W. A consumer may inspect only the displayed finite partition, the adjacent one-sided windows at each listed jump, and the ordinary interior windows away from the listed jump sites.

The approximation route is read from A. Each approximation passes through the sibling $\mathsf{StepFunction}^{\uparrow}$ pattern, while C replays the same source-window request through the selected step row.

The limiting route is read from U. It consumes the displayed approximant ledger together with the dyadic mesh-gauge schedule before exposing a $\mathsf{RegulatedFunction}^{\uparrow}$ or integration-facing handoff.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier row stores arbitrary discontinuity classification, Lebesgue differentiation, host function equality, selected point values, countable choice, or ambient completeness, none of those endpoints belongs to the local obligation surface. □

Theorem 7509.3 (Finite-jump regulated-function UniformLimit consumer)**.** *An accepted* RegulatedFunctionFiniteJ *packet supplies a finite-window consumer route for* $\mathsf{UniformLimit}^{\uparrow}$ *and later regulated-integration chapters:*

$$I, J, W, A \longmapsto U$$

with transport, replay, provenance, and local naming carried by H, C, P, N. The route exposes finite jump partitions, one-sided windows, step approximant rows, and the dyadic mesh-gauge handoff, but it exports no host function equality, arbitrary discontinuity classifier, Lebesgue differentiation theorem, selected countable family, or quotient function-space endpoint.

Proof. Begin with the accepted carrier. A source request first reads the interval row I and the finite jump partition row J, so every later window is attached to a displayed cell or a displayed one-sided jump window.

Use the window ledger W and the step approximant ledger A. The one-sided windows and ordinary interior windows determine which step approximant rows may be inspected, and those rows use the finite-data pattern supplied by $\mathsf{StepFunction}^{\uparrow}$.

Next read the uniform-limit seal U. The seal consumes the step approximant ledger and the dyadic mesh-gauge schedule before a $\mathsf{UniformLimit}^{\uparrow}$ or regulated-integration consumer may use the packet.

Finally apply the structural rows H, C, P, N. They preserve the same finite-window route under transport, replay, provenance, and naming, so no host function equality, countable choice, arbitrary discontinuity classification, Lebesgue differentiation, or quotient function-space endpoint is exported. □

Falsifiable prediction: Every accepted $\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}$ consumer displays a source interval, finite jump partition, one-sided window ledger, step approximant ledger, $\mathsf{UniformLimit}^{\uparrow}$ seal, $\mathsf{DyadicMeshGauge}^{\uparrow}$ schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any regulated-function or integration-facing handoff is read.

Independence witness: regulated-function, step-function, uniformlimit, dyadic-mesh-gauge: $\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite jump partition, one-sided window ledger, step approximant route, uniform-limit seal, dyadic mesh-gauge schedule, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}$ packet is generated from a source interval, finite jump partition, one-sided window rows, step approximant rows, a UniformLimit seal, a DyadicMeshGauge schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7509.1, Definition 7509.2, and Definition 7509.3 seed the finite-jump regulated-function interface over $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, and $\mathsf{DyadicMeshGauge}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedFunctionFiniteJump}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary discontinuity classification, Lebesgue differentiation, host-level function extensionality, quotient function-space equality, countable choice, selected point values, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite jump-row stability, step approximation routing, UniformLimit consumer routing, DyadicMeshGauge scheduling, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.RegulatedFunctionFiniteJumpUp.

Chapter 7510

A Concrete Naming Certificate for $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ packet records the finite Archimedean completion route by which rational regular names are exposed as a located Real-facing completion object. It sits after the dyadic arithmetic ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located completion packet of chapter 2231. The packet names an Archimedean located-completion interface; it is not quotient stream equality, a selected limit representative, countable choice, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

It also consumes the effective completion route of chapter 5930 through visible $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows, and terminal $\mathsf{Real}^{\uparrow}$ seal data. The Archimedean row therefore attaches to the same L10 completion lattice before its located-completion tests are read.

Definition 7510.1 (BishopArchimedeanCompletion carrier)**.** *A* $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, S, R, L, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *Archimedean tolerance ledger, carrying dyadic scales, rational slack rows, and comparison budgets.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected rational-name windows at the dyadic scales displayed by D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row obtained from the inspected windows and the dyadic tolerance ledger.*
4. *L is the located-completion row, aligned with* $\mathsf{BishopLocatedCompletion}^{\uparrow}$ *and recording the displayed locatedness tests consumed before the terminal seal is visible.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R, L have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic, stream-window, regular-readback, located-completion, Real-seal, replay, provenance, and naming rows.*
7. *C records the displayed* Cont *replay from an Archimedean completion request through D, S, R, L, E, H, P, N.*

8. *P is the* Pkg *provenance over* $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopLocatedCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopArchimedeanCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, L, E, H, C, P, N$. It has no coordinate for quotient representatives, hidden limit selection, countable choice, trichotomy, host equality of reals, or an unmediated completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 7510.2 (BishopArchimedeanCompletion NameCert obligations)**.** *For every accepted* $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ *carrier $A = (D, S, R, L, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopArchimedeanCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic Archimedean tolerance exposure, finite stream-window exposure, regular rational readback, located-completion handoff, Real-seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier coordinates. The rows D, S, R, L, E display the finite dyadic tolerance data, the inspected name windows, the regular Cauchy readback, the located-completion tests, and the terminal Real-facing seal.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. They do not add a quotient representative, a selected limit, or an ambient completeness witness.

Since the carrier has no coordinate outside $D, S, R, L, E, H, C, P, N$, every accepted local NameCert obligation is one of the listed rows, and every listed row is explicitly present in the accepted packet. □

Theorem 7510.3 (BishopArchimedeanCompletion regular Cauchy handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{BishopLocatedCompletion}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the $\mathsf{Real}^{\uparrow}$ *seal is not public until the dyadic tolerance ledger, finite stream windows, regular rational readback, and located-completion row have all been displayed.*

Proof. Begin with a Real-facing consumer of A. Carrier admission gives access to the terminal seal only as the row E in the same finite packet as D, S, R, L.

Replay the continuation row C. The request first reads the Archimedean dyadic scales through D, opens the finite $\mathsf{StreamName}^{\uparrow}$ windows S, obtains the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback R, and then consumes the located-completion row L.

Only after that route is displayed can E be read. Componentwise transport and package provenance preserve the same order, so no host limit operation can bypass the regular Cauchy handoff. □

Theorem 7510.4 (BishopArchimedeanCompletion no quotient nonescape)**.** *No accepted* BishopArchimedeanCompl *packet exports quotient stream equality, a selected representative of a Cauchy class, countable choice, trichotomy, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any such datum is outside the local carrier unless it is re-expressed through the displayed dyadic, stream-window, regular-readback, located-completion, Real-seal, transport, replay, provenance, and naming rows.*

Proof. Inspect the classifier of Definition 7510.1. It compares accepted packets only through the nine displayed rows $D, S, R, L, E, H, C, P, N$.

The excluded data are not among those coordinates. The handoff theorem also forces every Real-facing read through the dyadic, finite-window, regular-readback, and located-completion route before the terminal seal is visible.

Therefore an export using quotient equality, selected representatives, countable choice, trichotomy, host equality, or ambient completeness has left the accepted $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ surface rather than escaping from it. □

Falsifiable prediction: Every accepted BishopArchimedeanCompletionUp Real-facing read factors through DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat regular readback, BishopLocatedCompletion locatedness tests, a RealUp seal, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, bishop-located-completion, real: $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic Archimedean tolerances, finite windows, regular readback, located-completion tests, Real sealing, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopArchimedeanCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopArchimedeanCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore Archimedean tolerance ledger, StreamName finite windows, RegSeqRat regular Cauchy readback, BishopLocatedCompletion locatedness tests, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopArchimedeanCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7510.1, Definition 7510.2, Definition 7510.3, and Definition 7510.4 seed the finite Archimedean located-completion route through dyadic tolerance, finite stream-window, regular-readback, located-completion, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopArchimedeanCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Archimedean dyadic tolerance exposure, finite-window readback, regular Cauchy handoff, located-completion tests, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopArchimedeanCompletionUp.

Chapter 7511

A Concrete Naming Certificate for $\mathsf{RegularCauchyInverseBoundary}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyInverseBoundary}^{\uparrow}$ packet records the constructive boundary at which a regular Cauchy real name may be read through a reciprocal row. It sits next to the algebra inventory of chapter 1470, the finite product readback of chapter 461, and the terminal real-name seal of chapter 38. The packet does not import host real inversion; it keeps the apartness precondition, reciprocal budget, product-unit check, and seal handoff as displayed NameCert rows.

Definition 7511.1 (Regular Cauchy inverse-boundary carrier)**.** *A* $\mathsf{RegularCauchyInverseBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, W, D, Q, R, M, U, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row for the denominator regular Cauchy name.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row on which the denominator is read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing the endpoint, lower-bound, reciprocal-budget, and product-tolerance entries for the same window.*
4. *Q is the apartness precondition row, read through the positive-gap surfaces used by* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$
5. *R is the* $\mathsf{RegularCauchyReciprocal}^{\uparrow}$ *readback row exposed only after Q, W, D have been displayed.*
6. *M is the* $\mathsf{RegularCauchyProduct}^{\uparrow}$ *handoff row for multiplying the source row by the reciprocal readback.*
7. *U is the product-unit ledger row saying that the M route reaches the displayed unit readback at the requested window and budget.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the reciprocal readback and product-unit handoff are public.*
9. *H records componentwise* hsame *transport for the source, window, dyadic ledger, apartness row, reciprocal row, product row, unit ledger, seal row, continuation, provenance, and local name.*
10. *C records displayed* Cont *replay for opening the source window, reading the apartness lower bound, invoking the reciprocal row, checking the product-unit ledger, and exposing the terminal seal.*

11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyInverseBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$, $\mathsf{RegularCauchyReciprocal}^{\uparrow}$, $\mathsf{RegularCauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseBoundary}^{\uparrow}}$ *row.*

The carrier is a reciprocal-boundary packet. It stores no total inverse on $\mathsf{Real}^{\uparrow}$*, no quotient real equality, no selected stream representative, no trichotomy, no countable-choice row, and no ambient completeness principle.*

Theorem 7511.2 (Regular Cauchy inverse-boundary NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInverse}}$ *surface for Definition 7511.1 consists exactly of the following finite obligation rows:*

1. *apartness precondition, requiring the positive-gap row Q to be displayed before the reciprocal branch is readable;*
2. *reciprocal readback, requiring R to consume only the source row A, window row W, dyadic ledger D, and apartness evidence Q;*
3. *product-unit handoff, requiring M and U to witness the finite route from A and R to the displayed unit readback through* $\mathsf{RegularCauchyProduct}^{\uparrow}$*;*
4. *componentwise* hsame *transport, requiring H to move $A, W, D, Q, R, M, U, E, C, P, N$ together;*
5. *Real-seal non-escape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer of E to read the apartness, reciprocal, product-unit, transport, replay, provenance, and naming rows first.*

These rows are the whole local inverse-boundary surface.

Proof. Carrier admission is projection from Definition 7511.1. The source, window, dyadic, apartness, reciprocal, product, unit, seal, transport, replay, provenance, and naming rows are explicit coordinates.

The apartness and reciprocal obligations are read in order. The positive-gap row Q is the only eligibility coordinate, and the reciprocal row R is listed as downstream of Q, W, D. Thus a consumer cannot read a reciprocal branch from the source row alone.

The product-unit handoff is the displayed algebra check. The row M routes the product through the existing $\mathsf{RegularCauchyProduct}^{\uparrow}$ surface, while U records the finite unit readback at the same window and budget. This is a packet-level check, not host real multiplication.

Finally the transport and seal obligations keep the route closed. The rows H, C, P, N preserve and replay the same displayed data, and E is reached only after the reciprocal and unit rows are public. Therefore the packet exports a partial inverse boundary without total real inversion, quotient equality, selected representatives, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7511.3 (Regular Cauchy inverse-boundary seal discipline)**.** *Every accepted* RegularCauchyInverseBoundar *carrier exposes its terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$A, W, D, Q \longmapsto R \longmapsto M, U \longmapsto E.$$

The route is stable under the stored componentwise hsame *and displayed* Cont *replay rows, and it exports no total inverse operation on all real names.*

Proof. Project an accepted carrier $I = (A, W, D, Q, R, M, U, E, H, C, P, N)$. The only real-facing coordinate is E, and its listed dependencies are the apartness row, reciprocal readback, product row, and product-unit ledger.

Use the NameCert obligations. Apartness precondition and reciprocal readback force the route through Q and R; product-unit handoff forces the route through M and U; componentwise transport and replay force later consumers to keep H and C attached.

Since the carrier has no coordinate for a total inverse, quotient representative, trichotomy decision, choice principle, or ambient completeness theorem, the terminal seal is exactly a partial inverse-boundary seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInverseBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyInverseBoundary}^{\uparrow}$ packet is generated from a RegSeqRat source row, a StreamName window, a DyadicRatCore reciprocal ledger, a positive apartness precondition, a RegularCauchyReciprocal readback, a RegularCauchyProduct product-unit handoff, a terminal RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInverseBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7511.1, Definition 7511.2, and Definition 7511.3 seed the finite reciprocal-boundary surface consumed before field-like Real handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInverseBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close total inversion on RealUp, quotient real equality, trichotomy, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness eligibility, reciprocal readback, product-unit exactness, transport stability, and Real-seal nonescape for BEDC.Derived.RegularCauchyInverseBoundaryUp.

Chapter 7512

A Concrete Naming Certificate for $\mathsf{DarbouxIntegrable}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxIntegrable}^{\uparrow}$ packet separates integrability evidence from the $\mathsf{DarbouxIntegral}^{\uparrow}$ value packet. It sits between the Darboux criterion of chapter 5712, the finite lower and upper sum rows of chapter 5858 and chapter 4083, the finite Riemann–Darboux criterion of chapter 7383, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the value-level Darboux integral route of chapter 1460. The chapter records a finite predicate-level carrier for integrability only; it does not select an integral value, quotient integrands by host equality, import measure completion, select a partition by choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7512.1 (Darboux integrable carrier)**.** *A* $\mathsf{DarbouxIntegrable}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, P, L, U, G, M, Q, R, H, C, V, N)$$

with the following rows:

1. *F is the bounded function row exposed only through finite interval and value observations.*
2. *P is the finite partition row used by the Darboux criterion.*
3. *L is the* $\mathsf{LowerDarbouxSum}^{\uparrow}$ *row over F and P.*
4. *U is the* ***??*** *row over the same F and P.*
5. *G is the oscillation-gap row comparing U and L at the displayed tolerance request.*
6. *M is the tolerance-modulus row that chooses later partition requests only through finite data.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the gap estimates.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row available after the regular rational readback.*
9. *H is componentwise* hsame *transport for F, P, L, U, G, M, Q, R.*
10. *C is displayed* Cont *replay for the same route.*
11. *V is the* Pkg *provenance over* $\mathsf{DarbouxIntegrable}^{\uparrow}$, $\mathsf{DarbouxCriterion}^{\uparrow}$, $\mathsf{LowerDarbouxSum}^{\uparrow}$, ***??***, $\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegrable}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for a selected integral value, host integrand equality, measure completion, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7512.2 (Darboux integrable NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxIntegrable}^{\uparrow}$ *carrier* $I = (F, P, L, U, G, M, Q, R, H, C, V, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DarbouxIntegrable}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet, common-partition compatibility for* L *and* U*, oscillation-gap exactness through* G*, tolerance-modulus coverage through* M*,* $\mathsf{DarbouxCriterion}^{\uparrow}$ *and* $\mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}$ *handoff,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* V*, and local naming through* N*.*

Proof. Project the carrier of Definition 7512.1. The rows $F, P, L, U, G, M, Q, R, H, C, V, N$ are the whole certificate surface, so every obligation must begin by reading one of those rows.

The common-partition obligation uses P before either sum row is consumed. The lower and upper sums therefore compare the same bounded function row F on the same finite partition, and the oscillation gap G is a row over that shared surface.

The tolerance-modulus row M supplies the finite requests used by the Darboux and Riemann–Darboux criterion packets. Once those requests are displayed, Q gives regular rational readback for the gap estimates and R supplies the terminal Real seal.

Finally, H, C, V, N transport, replay, source, and name the same finite packet. Because the carrier has no coordinate for a selected integral value, quotient function equality, measure completion, selected partitions by choice, or ambient completeness, those objects cannot be exported by the local NameCert surface. □

Theorem 7512.3 (Darboux integrable oscillation classifier)**.** *An accepted* $\mathsf{DarbouxIntegrable}^{\uparrow}$ *packet classifies integrability by the displayed oscillation-gap route*

$$\mathsf{DarbouxCriterion}^{\uparrow} \longmapsto \mathsf{LowerDarbouxSum}^{\uparrow} \longmapsto ?? \longmapsto \mathsf{RiemannDarbouxCriterionFinite}^{\uparrow}.$$

Every classifier read must use the bounded function row, partition row, lower and upper sum rows, oscillation gap, tolerance modulus, regular rational readback, and Real seal of Definition 7512.1. It cannot read integrability from the value-level $\mathsf{DarbouxIntegral}^{\uparrow}$ *packet alone.*

Proof. Start with the NameCert obligations of Definition 7512.2. They force the lower and upper Darboux rows to share the same bounded function and partition rows before the gap row is inspected.

The oscillation classifier is then the finite route through G and M. The row G records the upper-minus-lower comparison, while M records the tolerance requests under which the comparison is reusable by Darboux and Riemann–Darboux criteria.

The readback rows Q and R only seal this displayed classifier route. Since $\mathsf{DarbouxIntegral}^{\uparrow}$ is named only in provenance as a downstream value consumer, the predicate-level classifier is independent of any selected integral value. □

Theorem 7512.4 (Darboux integrable Real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{DarbouxIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{DarbouxIntegrable}^{\uparrow}$ *packet receives the integrability evidence only through the displayed finite route*

$$F \longmapsto P \longmapsto (L, U) \longmapsto G \longmapsto M \longmapsto Q \longmapsto R.$$

The handoff exports integrability-as-carrier data without exporting a chosen integral value, quotient integrand equality, measure completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the oscillation classifier theorem Definition 7512.3. It identifies the route that any integrability consumer must read before the predicate can be used.

Next use the NameCert obligations. The regular rational and Real rows are downstream of the same gap and modulus rows, so a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer cannot bypass F, P, L, U, G, M when reading Q or R.

For a $\mathsf{DarbouxIntegral}^{\uparrow}$ consumer, the packet supplies only the predicate-level evidence needed before a value packet may be read. It does not add a coordinate for the value itself, so the handoff remains a finite integrability carrier rather than a value certificate. □

Falsifiable prediction: Every $\mathsf{DarbouxIntegral}^{\uparrow}$ consumer that cites $\mathsf{DarbouxIntegrable}^{\uparrow}$ must first display the bounded function, partition, lower sum, upper sum, oscillation gap, tolerance modulus, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: darboux-criterion, lower-darboux-sum, upper-darboux-sum, riemann-darboux-criterion-finite, darboux-integral, regseqrat, real: $\mathsf{DarbouxIntegrable}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries predicate-level oscillation-gap evidence and a Real handoff without carrying the selected Darboux integral value.

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxIntegrable}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxIntegrable}^{\uparrow}$ packet is generated from a bounded function row, finite partition row, lower and upper Darboux sum rows, oscillation-gap row, tolerance-modulus row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxIntegrable}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7512.1, Definition 7512.2, Definition 7512.3, and Definition 7512.4 seed the finite predicate-level Darboux integrability carrier between criterion data and value-level integral packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxIntegrable}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a selected Darboux integral value, host integrand equality, measure completion, selected partitions by choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: The next closure step requires checked carrier admission, oscillation classifier, and Real handoff rows for the displayed finite packet.

Chapter 7513

A Concrete Naming Certificate for $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$

Following Bishop–Bridges constructive sequence bookkeeping, the $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ packet records the finite route by which a regular-Cauchy tail request is routed through stream windows, regular rational readback, dyadic tolerance arithmetic, and the terminal Real seal. It concretizes the regular-Cauchy diagonal-limit route of chapter 9238 and sits over the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the real-name seal of chapter 38. The router is a finite precision-and-tail packet; it does not choose a limit, quotient streams by host equality, supply countable choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7513.1 (StreamName tail-window router carrier)**.** *A* $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (r, W, Q, D, E, H, C, P, N)$$

with the following rows:

1. *r is the finite request row naming the precision budget, tail threshold, and diagonal-window demand.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by that request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback row for the displayed window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row comparing the requested precision with the inspected tail cells.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after W, Q, D are displayed.*
6. *H is componentwise* hsame *transport for r, W, Q, D, E.*
7. *C is displayed* Cont *replay for the same route.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamNameTailWindowRouter}^{\uparrow}}$ *row.*

The classifier compares accepted routers only through $r, W, Q, D, E, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, countable-choice schedule, hidden tail selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7513.2 (StreamName tail-window router NameCert obligations)**.** *For every accepted* $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ *carrier* $T = (r, W, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StreamNameTailWindowRouter}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed request, StreamName window coverage, RegSeqRat tail readback, DyadicRatCore tolerance exactness, Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every regular-Cauchy diagonal-limit consumer must read those rows in that order before it treats* E *as a Real-facing seal.*

Proof. Project the carrier of Definition 7513.1. The request row r names the only precision and tail data available to the router.

The stream-window row W is downstream of r, and the regular rational readback Q is downstream of that displayed window. Thus a tail read cannot reach $\mathsf{RegSeqRat}^{\uparrow}$ without first exposing the finite StreamName window it uses.

The dyadic row D supplies the tolerance arithmetic for the same request and window. Once W, Q, D are present, the Real seal E is available as a terminal handoff rather than as a selected limit or quotient-stream equality.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores a hidden tail selector, countable-choice schedule, host real equality, or ambient completeness, those objects cannot be exported by the local NameCert surface. □

Falsifiable prediction: Every regular-Cauchy diagonal-limit read through $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ must display the finite request, StreamName window, RegSeqRat tail readback, DyadicRatCore tolerance row, RealUp seal, transport, replay, provenance, and local NameCert rows before the Real-facing output is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite tail request, one StreamName window, RegSeqRat tail readback, DyadicRatCore tolerance arithmetic, and a terminal Real seal as one router packet.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamNameTailWindowRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamNameTailWindowRouter}^{\uparrow}$ packet is generated from a finite precision-and-tail request, a StreamName window row, RegSeqRat tail readback, DyadicRatCore tolerance arithmetic, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StreamNameTailWindowRouter}^{\uparrow}}$, seed)

Scope closed: Definition 7513.1 and Definition 7513.2 seed the regular-Cauchy diagonal-limit router as finite request, window, tail, tolerance, readback, and Real-seal data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StreamNameTailWindowRouter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, hidden tail selectors, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: The next closure step requires checked carrier admission, window coverage, tolerance exactness, regular readback, and Real-seal handoff for the displayed router packet.

Chapter 7514

Regular Real Located Modulus NameCert Construction

Following Bishop–Bridges constructive analysis, regular real names carry usable real information only through displayed rational windows, dyadic tolerances, and explicit tail moduli. The $\mathsf{RegularRealLocatedModulus}^{\uparrow}$ packet records that finite-means surface over the L10 Real and Completion substrate. It sits after the stream schedule of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal seal of chapter 38, the located real-name route of chapter 1933, and the regular Cauchy located-modulus sibling of chapter 3655.

Definition 7514.1 (Regular real located modulus carrier)**.** *A* $\mathsf{RegularRealLocatedModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, D, Q, E, M, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule for the regular real name.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger of positive tolerances, endpoints, and radius rows used by located brackets.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback visible on the windows named by S.*
4. *E is the located interval row displaying lower and upper dyadic bracket data over D, S, Q.*
5. *M is the modulus row assigning each displayed dyadic tolerance in D a tail depth after which the Q-readback remains inside the bracket row E.*
6. *W is the Real-facing seal window, recording the point at which the* $\mathsf{Real}^{\uparrow}$ *row may be read only after S, D, Q, E, M have been exposed.*
7. *H records componentwise* hsame *transport for S, D, Q, E, M, W and the structural rows.*
8. *C records displayed* Cont *replay of the same finite schedule, bracket, modulus, and seal-window reads.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularRealLocatedModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{RegularCauchyLocatedModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRealLocatedModulus}^{\uparrow}}$ *row binding these displayed rows as one certificate.*

The carrier contains no quotient equality of real names, no selected representative, no selected limit, no host real equality, no trichotomy oracle, and no ambient completeness principle.

Theorem 7514.2 (Regular real located modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealLocatedModulus}^{\uparrow}$ *carrier* $R = (S, D, Q, E, M, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularRealLocatedModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the stream schedule, dyadic ledger, regular readback, located bracket, modulus, Real-seal window, transport, replay, provenance, and local naming rows;*
2. *modulus admission, requiring each request in* M *to consume a positive tolerance row already displayed in* D*;*
3. *located bracket witness, requiring* E *to expose lower and upper dyadic bounds over the same* S, D, Q *rows;*
4. *tail localization, requiring the depth supplied by* M *to bind all later* Q*-reads to the bracket row* E *before* W *is available;*
5. *transport and replay stability for* S, D, Q, E, M, W *through* H *and* C*;*
6. *provenance, requiring* P *to name the StreamName, DyadicRatCore, RegSeqRat, LocatedReal, RegularCauchyLocatedModulus, and Real sibling surfaces used by the packet;*
7. *nonescape, excluding quotient completion equality, selected representatives, selected limits, host equality, trichotomy, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as local data.*

Proof. Project the carrier of Definition 7514.1. The projection exposes exactly the rows $S, D, Q, E, M, W, H, C, P, N$

The modulus and bracket obligations are row-local. The modulus row M has no tolerance coordinate other than the positive rows of D, and the located bracket row E reads the same stream schedule and regular rational source through S and Q.

Tail localization is the compatibility of M with E. Once a requested dyadic tolerance is fixed, the depth supplied by M determines which later Q-windows remain inside the displayed bracket before the Real seal window W can be read.

Transport, replay, provenance, and local naming are structural rows. Since the carrier has no coordinate for quotient equality, selected representatives, selected limits, host equality, trichotomy, choice, or ambient completeness, the listed obligations exhaust the local certificate surface. □

Theorem 7514.3 (Regular real located modulus tail localization)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularRealLocatedModulus}^{\uparrow}$ *packet must expose the modulus row* M *and the located tail window* (E, W) *before any Real seal is read. Thus a consumer receives the regular real name only through the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*, located bracket* E*, modulus* M*, Real-seal window* W*, transport* H*, replay* C*, provenance* P*, and local name* N*.*

Proof. Begin with an accepted carrier $R = (S, D, Q, E, M, W, H, C, P, N)$. The only Real-facing coordinate is W, and its row is placed after the stream, dyadic, regular readback, located bracket, and modulus rows.

Apply Definition 7514.2. Tail localization forces each requested tolerance to pass through M and the bracket row E before the seal window is exposed.

The transport and replay rows preserve the same order of reads. Therefore every Real-facing consumer must display the modulus and located tail window before reading the $\mathsf{Real}^{\uparrow}$ seal, and no quotient representative, selected limit, host equality, or ambient completeness route can bypass the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealLocatedModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRealLocatedModulus}^{\uparrow}$ packet is generated from a StreamName schedule, a DyadicRatCore tolerance ledger, a RegSeqRat readback, a located bracket row, an explicit tail modulus, a Real-seal window, componentwise transport, displayed replay, provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealLocatedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7514.1, Definition 7514.2, and Definition 7514.3 name the seed carrier, finite obligation surface, and tail-localized Real-facing route for regular real located modulus data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRealLocatedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real names, selected representatives, selected limits, host real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, modulus admission, located bracket witness, tail localization, transport, replay, provenance, and nonescape for BEDC.Derived.RegularRealLocatedModulusUp.

Chapter 7515

Hyperbolic Visual Metric Modulus NameCert Construction

Following Gromov boundary practice and the Poincare disk tradition, visual metrics expose boundary distance only after an observer base, a shadow comparison, and a tolerance modulus are fixed. The $\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}$ packet records this finite surface for the observer-expansion reading of chapter 9463. It sits after the visual metric route of chapter 3866, the boundary-shadow packet of chapter 3813, the observer-expansion packet of chapter 4167, the dyadic shadow cone of chapter 7503, and the Real-and-Completion substrate of chapter 291 and chapter 38.

Definition 7515.1 (Hyperbolic visual metric modulus carrier)**.** *A* $\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (G, B, S, D, M, R, O, W, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *source row supplying the visual metric read over the displayed hyperbolic boundary surface.*
2. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *boundary-shadow row that records which shadow comparison is being measured.*
3. *S is the finite shadow-window row, read through the observer-expansion surface of* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$*.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for visual-radius and shadow-depth requests.*
5. *M is the modulus row assigning each displayed dyadic tolerance in D a finite boundary-shadow depth for the rows G, B, S.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the visual-distance readback, available only after G, B, S, D, M are exposed.*
7. *O is the observer-expansion row tying the visual metric and shadow modulus to the finite observer surface named by chapter 4167.*
8. *W is the nonescape row refusing completed boundary quotients, selected geodesic representatives, global hyperbolic compactifications, and physical horizon semantics.*
9. *H records componentwise* hsame *transport for G, B, S, D, M, R, O, W and the structural rows.*

10. *C records displayed* Cont *replay from a boundary-shadow request through the visual metric, dyadic tolerance, modulus, Real seal, observer-expansion, and nonescape rows.*

11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShad}$ $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{DyadicShadowCone}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}}$ *row.*

The carrier is modulus data for a displayed visual metric route. It is not a completed Gromov boundary, not a quotient boundary equality, not a selected geodesic, not a physical horizon, and not an ambient compactness theorem.

Theorem 7515.2 (Hyperbolic visual metric modulus NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}$ *carrier* $V = (G, B, S, D, M, R, O, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualM}}$ *surface consists exactly of the following finite obligations:*

1. *visual metric admission for the row G and its displayed boundary surface;*
2. *boundary-shadow admission for the row B and its finite shadow comparison;*
3. *shadow-window admission for S through the observer-expansion route;*
4. *dyadic tolerance admission for D and modulus admission for M;*
5. *Real-seal discipline, requiring R to be read only after G, B, S, D, M have been displayed;*
6. *observer-expansion compatibility for O;*
7. *transport, replay, provenance, and local naming through H, C, P, N;*
8. *nonescape through W, excluding completed boundary quotients, selected geodesic representatives, global hyperbolic compactifications, physical horizon semantics, and ambient compactness.*

Proof. Project the carrier of Definition 7515.1. The geometric rows are G, B, S, the tolerance and modulus rows are D, M, and the Real-facing row is R.

The modulus is finite because every request in M is indexed by a displayed dyadic tolerance in D and by the already visible shadow rows G, B, S. No boundary quotient or selected geodesic coordinate is available to answer a request.

The Real-seal and observer-expansion obligations are then forced by the row order. The seal R is downstream of G, B, S, D, M, while O records the observer-expansion route that receives the same finite shadow-depth data.

Finally W, H, C, P, N record refusal, transport, replay, source, and local naming. These rows preserve the same packet and refuse every global or physical endpoint listed in the statement, so the obligations exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}$ packet is generated from visual metric rows, boundary-shadow rows, observer-expansion shadow windows, dyadic tolerance rows, an explicit modulus row, a Real-seal row, nonescape data, componentwise transport, displayed replay, provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7515.1 and Definition 7515.2 name the seed carrier and finite obligation surface for visual-metric modulus data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicVisualMetricModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed Gromov boundaries, quotient boundary equality, selected geodesic representatives, global hyperbolic compactification, physical horizon semantics, ambient compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked visual metric admission, boundary-shadow admission, shadow-window admission, dyadic tolerance admission, modulus admission, Real-seal discipline, observer-expansion compatibility, transport, replay, provenance, and nonescape for BEDC.Derived.HyperbolicVisualMetricModulusUp.

Chapter 7516

A Concrete Naming Certificate for $\mathsf{TropicalSemiring}^{\uparrow}$

Following Speyer–Sturmfels and standard idempotent algebra, the $\mathsf{TropicalSemiring}^{\uparrow}$ packet records the finite BEDC surface for the max-plus tropical semiring. It sits over the algebraic inventory of chapter 43, the order-facing comparison rows of chapter 1378, and the scalar readback boundary of chapter 38. The packet names tropical addition and multiplication only through displayed carrier, endpoint, order, transport, replay, provenance, and local NameCert rows; it does not import host real completeness, quotient scalar equality, a selected limit, or an unledgered convention for infinity.

Definition 7516.1 (Tropical semiring carrier)**.** *A* $\mathsf{TropicalSemiring}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, A, M, E, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the carrier-source row, read through the* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *scalar boundary together with a displayed endpoint symbol for the tropical additive zero.*
2. *A is the idempotent tropical-addition row. On visible scalar entries it records the chosen max-plus operation, so the displayed addition satisfies $x \oplus x = x$ by comparison with the same inspected value.*
3. *M is the tropical-multiplication row. On finite scalar entries it records ordinary scalar addition, with the endpoint row acting as the absorbing boundary for products involving the tropical additive zero.*
4. *E is the endpoint-convention ledger. It records whether the packet is read in the bottom-adjoined max-plus presentation or the dual top-adjoined min-plus presentation, and it binds the additive identity, absorbing multiplication boundary, and excluded unledgered endpoint cases.*
5. *O is the order-compatibility row. It reads the order surface of chapter 1378 and records monotonicity of A and M on the displayed finite comparisons.*
6. *H records componentwise* hsame *transport for S, A, M, E, O and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from scalar and endpoint rows to tropical sums, tropical products, and order-compatible comparisons.*

8. *P is the* Pkg *provenance over* $\mathsf{TropicalSemiring}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{TropicalSemiring}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, M, E, O, H, C, P, N$. It has no coordinate for host-level real completeness, quotient scalar equality, selected extrema, unbounded optimization data, or an endpoint convention not written in E.

Theorem 7516.2 (Tropical semiring NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{TropicalSemiring}^{\uparrow}}$ *surface for Definition 7516.1 consists exactly of carrier-source admission, idempotent tropical-addition exposure, tropical-multiplication exposure, endpoint-convention accounting, order compatibility, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier $T = (S, A, M, E, O, H, C, P, N)$. The first five rows expose the scalar source, the two tropical operations, the endpoint convention, and the order comparisons available to consumers.

The endpoint row is part of the packet rather than ambient notation. Hence the additive zero, the absorbing multiplication boundary, and the max-plus or dual min-plus orientation are checked before any operation row is consumed.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since no further coordinate is present, the displayed rows exhaust the local NameCert obligations and exclude host completeness, quotient scalar equality, selected extrema, and unrecorded endpoint choices. □

Theorem 7516.3 (Tropical idempotent order route)**.** *Every order-facing consumer of an accepted* $\mathsf{TropicalSemiring}^{\uparrow}$ *packet reads tropical idempotence and operation monotonicity through the same finite route*

$$S, E \longmapsto A, M \longmapsto O$$

before it may use the packet for path-weight, optimization, or idempotent-algebra arguments. The route exports no total comparison beyond the displayed order rows and no completed-real supremum principle.

Proof. Begin with the carrier-source and endpoint rows S, E. They determine which scalar entries and which additive boundary are visible to the packet.

Next read A and M. Idempotence of tropical addition is the diagonal projection of the displayed max-plus comparison in A, while multiplication is ordinary scalar addition only on entries admitted by S and the boundary convention recorded by E.

Finally read O. The order-compatibility row is the only place where monotonicity is exported to a consumer, and it is transported and replayed only through H and C. Therefore downstream path-weight or optimization packets receive a finite idempotent order route, not a host supremum theorem, trichotomy principle, selected extremum, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{TropicalSemiring}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TropicalSemiring}^{\uparrow}$ packet is generated from a scalar carrier source, idempotent tropical addition, tropical multiplication, endpoint-convention ledger, order-compatibility rows, componentwise transports, displayed continuations, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TropicalSemiring}^{\uparrow}}$, seed)

Scope closed: Definition 7516.1, Definition 7516.2, and Definition 7516.3 seed the finite max-plus tropical semiring surface over scalar, endpoint, order, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TropicalSemiring}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host tropical algebra, completed-real suprema, quotient scalar equality, selected extrema, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, idempotent-addition exposure, multiplication exposure, endpoint accounting, order compatibility, transport, replay, provenance, and local naming for the same finite packet.

Chapter 7517

A Concrete Naming Certificate for $\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley metric completion, the TotallyBoundedCompletionCri packet records the finite-metric criterion that a displayed metric source reaches its completion-facing compact metric form by combining finite ε-net data with complete-metric limit data. It consumes the total-boundedness surface of chapter 127, the complete-metric limit surface of chapter 128, the metric-completion handoff of chapter 1506, and the compact-metric certificate surface of chapter 129. The packet is a BEDC criterion row, not an open-cover compactness theorem, a selected-limit principle, a quotient-completion equality, or a host compactness claim.

Definition 7517.1 (Totally bounded completion criterion carrier)**.** *A* $\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, E, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Met}^{\uparrow}$ *source row, including its point classifier and* MetricDistanceWitness *surface.*
2. *E is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger, recording for each visible positive* $\mathsf{Rat}^{\uparrow}$ *tolerance a closed* ProbeBundle *of centers, membership rows, coverage rows, and rational bound comparisons.*
3. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit ledger, recording regular* $\mathsf{StreamName}^{\uparrow}$ *Cauchy names, explicit moduli, displayed limit histories, and convergence-distance rows.*
4. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row, recording whether a completion-facing consumer reads the source through the Cauchy-filter branch or the Cauchy-net branch before any separated-limit comparison.*
5. *H records componentwise* hsame *transport for X, E, L, Q, the replay row, the provenance row, and the local naming row.*
6. *C records displayed* Cont *replay for finite-net coverage, complete-limit witnesses, completion handoff, separated comparison, and compact-metric consumption.*
7. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

8. N is the local $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}}$ *row.*
The carrier has no coordinate for open-cover compactness, selected limits, countable choice, quotient completion equality, host compactness, or a detached ambient complete metric space.

Theorem 7517.2 (Totally bounded completion criterion NameCert obligations)**.** *For an accepted* $\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}$ *packet* $T = (X, E, L, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletionCrit}}$ *surface consists exactly of carrier admission for the displayed metric source X, finite-net coverage through E, complete-limit witnesses through L, completion handoff through Q, componentwise transport through H, replay through C, package provenance through P, and local naming through N.*

Every compact-metric consumer of this criterion must read the finite-net row before invoking total boundedness, read the limit row before invoking completeness, and pass through the completion handoff row before comparing displayed completion endpoints. No consumer can project open-cover compactness, selected representatives, countable-choice schedules, quotient equality of completion names, or host compactness from the packet.

Proof. Project the accepted packet through Definition 7517.1. The source metric row is X, and every finite-net request is forced through E because no other row carries a $\mathsf{ProbeBundle}$ center ledger or rational coverage comparison.

The complete-metric part is forced through L. It carries the regular stream name, modulus, displayed limit, and convergence-distance rows, while the completion-facing branch is forced through Q before separated comparison can be replayed.

The structural rows H, C, P, N transport, replay, package, and name exactly the same finite tuple. Since the tuple has no coordinate for open covers, selected limits, countable choice, quotient completion equality, or host compactness, the listed obligations exhaust the local NameCert surface. □

Theorem 7517.3 (Totally bounded completion finite-net route)**.** *Let $T = (X, E, L, Q, H, C, P, N)$ be an accepted* $\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}$ *packet. Every finite-net compactness use of T factors first through the* $\mathsf{TotallyBounded}^{\uparrow}$ *row E, then through the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit row L, and then through the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row Q when the consumer asks how a Cauchy-filter or Cauchy-net reading reaches a displayed completion endpoint.*

The resulting route is the finite BEDC chain

$$X \longmapsto E \longmapsto L \longmapsto Q \longmapsto H, C, P, N,$$

not an open-cover compactness proof, not a selected-limit principle, not a quotient of completion names, and not a host compact metric object.

Proof. Start with a compact-metric consumer. The metric carrier and distance rows are projected from X, while total boundedness is available only through the finite $\mathsf{ProbeBundle}$ data in E.

Completeness is read next through L. This row supplies the displayed regular Cauchy stream, modulus, limit, and convergence-distance witnesses; it does not select a host representative or assert ambient completeness outside the packet.

When the consumer asks for the completion-facing route, Q records whether the visible evidence is filter-based or net-based before any separated-limit comparison is used. The transport, replay, provenance, and local naming rows then keep the same finite chain stable, so no open-cover, choice, quotient-equality, or host-compactness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}$ packet is generated from a metric source row, a finite-net ledger, a complete-limit ledger, a metric-completion handoff row, componentwise transport, replay, provenance, and a local naming row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7517.1, Definition 7517.2, and Definition 7517.3 bind the finite NameCert criterion joining total boundedness, complete metrics, and metric completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedCompletionCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected limits, countable choice, quotient completion equality, or host compactness.

Upgrade path: The next paper-side grade requires a scoped dependency theorem over the displayed metric source, finite-net ledger, complete-limit ledger, completion handoff, transport, replay, provenance, and local naming rows.

Chapter 7518

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$ packet records the filter presentation of regular Cauchy completion as finite BEDC data. It sits between the Cauchy-filter basis route of chapter 1501, the sequence-indexed filter route of chapter 6712, finite stream windows from chapter 126, regular rational readback from chapter 301, dyadic tolerance ledgers from chapter 291, and the terminal real-name seal of chapter 38. The packet names the L10 filter route for completion without quotienting filters, selecting limits, importing countable choice, using trichotomy, or appealing to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7518.1 (Bishop regular Cauchy filter carrier)**.** *A* $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, S, W, R, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row generated by regular tail requests and common-refinement witnesses.*
2. *S is the* $\mathsf{SequentialCauchyFilter}^{\uparrow}$ *row tying the basis to a sequence-indexed Cauchy-filter read.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by the inspected tail requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row exposed from those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window and readback route.*
6. *Q is the Cauchy-filter saturation row, recording that every completion-facing filter request factors through the displayed basis route.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, S, W, R, D, Q have been displayed.*
8. *H is the componentwise* hsame *transport row for the basis, sequential filter, windows, readback, dyadic ledger, saturation row, real seal, replay, provenance, and local naming.*
9. *C is the displayed* Cont *replay row for the same finite filter route.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{SequentialCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, W, R, D, Q, E, H, C, P, N$. It has no coordinate for quotient filters, selected limit points, host equality of filters, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7518.2 (Bishop regular Cauchy filter NameCert obligations)**.** *For every accepted* BishopRegularCauchyFil *carrier $F = (B, S, W, R, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; Cauchy-filter basis generation through B; sequence-indexed filter routing through S; finite stream-window exposure through W; regular rational readback through R; dyadic tolerance accounting through D; filter saturation through Q; terminal real-seal boundary through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Carrier admission is tuple projection from Definition 7518.1. The displayed filter data are exactly B, S, Q, the completion-facing readback data are W, R, D, E, and the structural certificate rows are H, C, P, N.

The basis and sequence rows are read first. The row B records the finite common-refinement surface for regular Cauchy tails, while S keeps that basis tied to the sequence-indexed Cauchy-filter route before saturation is consumed.

The completion-facing rows are downstream. Rows W, R, D expose finite observations, regular rational readback, and dyadic tolerance accounting before the real seal E is available, and Q records that the filter request remains attached to the displayed basis.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no remaining coordinate stores quotient filters, selected limits, host filter equality, trichotomy, countable choice, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 7518.3 (Bishop regular Cauchy filter Real seal non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$ *carrier reaches the terminal seal only through*

$$\mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{SequentialCauchyFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the saturation row Q, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}$ *row. The packet exports no quotient filter, selected limit, host filter equality, trichotomy, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Start with the obligation surface of Definition 7518.2. It forces every accepted read to expose the finite Cauchy-filter basis, the sequence-indexed route, the stream windows, the regular rational readback, and the dyadic tolerance ledger before the terminal seal appears.

The saturation row Q keeps the filter request attached to the displayed basis route. A completion-facing consumer therefore receives the Cauchy-filter presentation as finite refinement data, not as a quotient filter or selected limit object.

Transport, replay, provenance, and local naming preserve only that route. Because the carrier has no coordinate for quotient filters, selected limits, host filter equality, trichotomy, countable choice, or ambient completeness, none of those endpoints can be exported by a $\mathsf{Real}^{\uparrow}$ seal consumer. □

Falsifiable prediction: A $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$ completion read that exports a terminal $\mathsf{Real}^{\uparrow}$ seal without displaying CauchyFilterBasis, SequentialCauchyFilter, StreamName, RegSeqRat, DyadicRatCore, saturation, transport, replay, provenance, and local NameCert rows refutes the carrier of Definition 7518.1.

Independence witness: cauchy-filter-basis, sequential-cauchy-filter, streamname, regseqrat, dyadicratcore, real: no listed sibling carries the whole Bishop regular Cauchy filter packet because each supplies only a basis generator, sequence-indexed filter route, finite window row, regular readback, dyadic tolerance ledger, or terminal seal while this chapter binds them into one L10 completion-facing filter certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyFilter}^{\uparrow}$ packet is generated from CauchyFilterBasis rows, SequentialCauchyFilter routing, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance rows, a Cauchy-filter saturation row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7518.1, Definition 7518.2, and Definition 7518.3 seed the finite L10 filter presentation of regular Cauchy completion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, host filter equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cauchy-filter basis generation, sequence-indexed filter routing, finite window exposure, regular rational readback, dyadic tolerance exactness, saturation, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyFilterUp.

Chapter 7519

A Concrete Naming Certificate for MetaCICTypedSubstitutionWindow$^{\uparrow}$

The MetaCICTypedSubstitutionWindow$^{\uparrow}$ packet realizes the MetaCIC substitution audit boundary of chapter 9380 as a finite typed-window certificate. It sits beside the substitution spine of chapter 6103, the audit packet of **??**, the closed audit map of chapter 779, the route window of chapter 824, the context audit of chapter 840, the generator audit of chapter 910, the boundary audit of chapter 1102, the substitution spine realizer of chapter 6990, and the closed type-checker seal of chapter 2182. The packet records typed context, closedness, substitution, obstruction, transport, replay, provenance, and NameCert rows without claiming subject reduction, definitional equality, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 7519.1 (MetaCIC typed substitution window carrier)**.** *A* MetaCICTypedSubstitutionWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (\Gamma, A, U, V, C, S, O, B, H, R, P, N)$$

with the following displayed rows:

1. Γ *is the finite typed-context window, listing the context entries inspected by the substitution request.*
2. A *is the typed source-term row and target-type row inside that context window.*
3. U *is the substitute-in term row, carrying its typed boundary and the binder depth at which it is inserted.*
4. V *is the closedness row, recording the relevant* `ClosedAt` *boundaries for the source, inserted term, and substituted output.*
5. C *is the closed type-checker seal row consumed by the typed window.*
6. S *is the substitution audit route, recording shift, substitution, closed-composition, and generator-closure reads.*
7. O *is the obstruction row for missing subject reduction, beta preservation beyond the sealed window, evaluator equality, quotient syntax equality, and kernel consistency.*
8. B *is the binder-transport row that records how the typed context window advances across binders.*
9. H *is the componentwise* hsame *transport row for* $\Gamma, A, U, V, C, S, O, B$ *and for replay, provenance, and local naming.*

10. *R is the displayed* Cont *replay row for the same typed substitution route.*

11. *P is the* Pkg *provenance over* $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$, $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$, $\mathsf{MetaCICSubstitutionAuditPacket}^{\uparrow}$, $\mathsf{SubstitutionAuditMap}^{\uparrow}$, $\mathsf{SubstitutionAuditWindowRoute}^{\uparrow}$, $\mathsf{SubstitutionContext}^{\uparrow}$ $\mathsf{SubstitutionGeneratorAudit}^{\uparrow}$, $\mathsf{SubstitutionBoundaryAudit}^{\uparrow}$, $\mathsf{ClosedTypeCheckerSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for an unrestricted subject-reduction theorem, definitional equality oracle, evaluator equality, quotient syntax equality, or kernel consistency theorem.

Theorem 7519.2 (MetaCIC typed substitution window NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$ *carrier* $T = (\Gamma, A, U, V, C, S, O, B, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}}$ *surface consists exactly of typed-context admission through* Γ*; source and inserted-term typing through* A *and* U*; closedness boundary exposure through* V*; closed type-checker sealing through* C*; shift, substitution, closed-composition, and generator-closure routing through* S*; obstruction retention through* O*; binder-window transport through* B*; componentwise* hsame *transport through* H*; displayed replay through* R*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 7519.1. The typed-window rows are $\Gamma, A, U, V, C, S, O, B$, and the structural certificate rows are H, R, P, N.

Read the context rows first. The finite context window Γ, typed source data A, inserted-term data U, and closedness row V determine the boundary at which substitution is inspected.

Read the audit rows next. The closed type-checker seal C scopes the window, while S records the shift, substitution, closed-composition, and generator-closure route. The binder row B is the only row that advances the typed window across binders.

Finally O, H, R, P, N retain refused endpoints and structural certificate data. Since the carrier has no row for full subject reduction, definitional equality, evaluator equality, quotient syntax equality, or kernel consistency, the listed rows exhaust the local NameCert surface. □

Theorem 7519.3 (MetaCIC typed substitution window subject-reduction handoff)**.** *Every subject-reduction consumer of an accepted* $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$ *packet must first read the typed context window, typed source and inserted-term rows, closedness row, closed type-checker seal, substitution audit route, binder-window transport, obstruction row, componentwise transport, replay, provenance, and local naming. The handoff exposes only a finite typed substitution window; it does not prove unrestricted subject reduction, beta preservation beyond the displayed window, definitional equality, evaluator equality, quotient syntax equality, or kernel consistency.*

Proof. Start with the obligation theorem Definition 7519.2. It orders every accepted read through the typed context, source typing, inserted-term typing, closedness, closed checker, substitution audit, binder transport, and obstruction rows.

The typed rows scope the handoff. A consumer cannot read the substitution route before the context window, term rows, and closedness boundary are visible, because those rows determine which substitution instance is under inspection.

The audit and obstruction rows then delimit the result. The substitution route gives finite shift, substitution, closed-composition, and generator-closure evidence, while the obstruction row records the endpoints not discharged by the packet.

The structural rows transport, replay, source, and name only that displayed route. Therefore the packet may feed a later subject-reduction proof, but it cannot itself be read as unrestricted subject reduction or as a kernel-consistency theorem. □

Falsifiable prediction: A $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$ consumer that exports a subject-reduction handoff without typed-context, source typing, inserted-term typing, closedness, closed checker, substitution audit, binder transport, obstruction, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 7519.1.

Independence witness: metacic-substitution-spine, metacic-substitution-audit-packet, substitutionauditmap, substitutionauditwindowroute, substitutioncontextaudit, substitutiongeneratoraudit, substitutionboundaryaudit, closed-type-checker-seal: the typed substitution window is not bijective to any listed sibling because it jointly carries typed context rows, typed source and inserted-term rows, ClosedAt boundaries, closed checker sealing, substitution audit routing, binder-window transport, obstruction retention, replay, provenance, and local naming.

Lean TasteGate.lean must later provide Nontrivial and FieldFaithful instances for MetaCICTypedSubstitutionWind so the typed-context, closedness, substitution, obstruction, transport, replay, provenance, and local naming fields remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$ packet is generated from typed-context rows, typed source and inserted-term rows, ClosedAt boundaries, a closed checker seal, substitution audit rows, binder-window transport, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7519.1, Definition 7519.2, and Definition 7519.3 seed the finite typed substitution window for MetaCIC subject-reduction consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted subject reduction, beta preservation beyond the displayed window, definitional equality, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-context admission, source and inserted-term typing, closedness exposure, closed checker sealing, substitution audit routing, binder transport, obstruction retention, transport, replay, provenance, Nontrivial, FieldFaithful, and local naming for BEDC.Derived.MetaCICTypedSubstitutionWindowUp.

Chapter 7520

WeylEquidistribution NameCert Construction

Following Weyl, the $\mathsf{WeylEquidistribution}^{\uparrow}$ packet reads equidistribution through finite rational interval tests over $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, not through measure or choice. It sits after the rational interval surface of chapter 354, the finite stream-name surface of chapter 126, the regular rational sequence surface of chapter 301, and the real-name seal of chapter 38. The packet names only the finite test ledger, discrepancy budget, transport, replay, provenance, and local NameCert rows needed before a constructive distribution statement can be consumed.

Definition 7520.1 (Weyl equidistribution finite carrier)**.** *A* $\mathsf{WeylEquidistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, I, K, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the sequence-source row, reading a* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *name indexed by* $\mathsf{Nat}^{\uparrow}$ *and sealed only through the displayed* $\mathsf{Real}^{\uparrow}$ *readback.*
2. *I is the finite rational interval-test ledger. Each entry names rational endpoints from* $\mathsf{Rat}^{\uparrow}$*, a half-open interval in the unit window, and the finite prefix length over which the test is inspected.*
3. *K is the counting row, recording for each entry of I the finite set of indices whose displayed real readback falls in that rational interval.*
4. *D is the discrepancy row, comparing the counted frequency with the rational interval length by a displayed* $\mathsf{Rat}^{\uparrow}$ *tolerance.*
5. *E is the exhaustion row, recording the finite list of interval tests currently exposed to a consumer and the remaining tests not claimed by the packet.*
6. *H records componentwise* hsame *transport for the sequence source, interval ledger, counting row, discrepancy row, exhaustion row, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite interval-test request through S, I, K, D, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{WeylEquidistribution}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WeylEquidistribution}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, I, K, D, E, H, C, P, N$. It has no coordinate for a measure space, an infinite choice of test intervals, a selected subsequence, host real equality, or an unbounded limiting frequency claim.

Lean4 ✓ `BEDC.Derived.WeylEquidistributionUp.WeylEquidistributionTasteGate single carrier alignment`

Theorem 7520.2 (WeylEquidistribution NameCert obligations)**.** *For every accepted* $\mathsf{WeylEquidistribution}^{\uparrow}$ *carrier* $W = (S, I, K, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WeylEquidistribution}^{\uparrow}}$ *surface consists exactly of sequence-source admission, finite rational interval-test exposure, finite counting exposure, discrepancy-budget exposure, test-exhaustion accounting, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier coordinates. The rows S, I, K, D, E expose the inspected sequence name, the finite interval ledger, the counted index set for each ledger entry, the rational discrepancy comparison, and the finite-test exhaustion boundary.

The structural rows H, C, P, N then transport, replay, source, and name the same finite packet. They do not add a measure object, an infinite interval family, or a selected representative outside the displayed sequence row.

Since the carrier has no coordinate outside $S, I, K, D, E, H, C, P, N$, every accepted local NameCert obligation is one of the listed rows, and each listed row is present before the packet is public to a downstream distribution consumer. □

Theorem 7520.3 (WeylEquidistribution interval-test coverage)**.** *Every constructive distribution statement consumed from an accepted* $\mathsf{WeylEquidistribution}^{\uparrow}$ *packet first factors through the finite route*

$$\mathsf{Nat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow}\text{-}\textit{interval tests} \longmapsto \mathsf{Rat}^{\uparrow}\text{-}\textit{discrepancy budgets}.$$

The route covers exactly the rational interval tests displayed in I and recorded by E; it does not assert measure-theoretic equidistribution, an unrestricted limiting frequency, countable choice, or host equality of real representatives.

Proof. Start with an accepted packet W. Carrier admission exposes the sequence source only through the displayed natural-indexed stream or regular rational name and the terminal real readback named in S.

Next read the interval ledger I and the counting row K. Each test is finite: it names rational endpoints, a prefix length, and the counted indices visible inside that prefix.

Finally read the discrepancy and exhaustion rows D, E. They record the rational tolerance currently certified and the finite test list currently covered. Thus any downstream constructive distribution statement receives finite interval-test coverage and no hidden measure, choice principle, or unbounded limit assertion. □

Falsifiable prediction: Every accepted WeylEquidistributionUp consumer that exports distribution evidence must expose a finite rational interval-test ledger, finite counts, rational discrepancy budgets, exhaustion accounting, transport, replay, provenance, and local naming before export.

Independence witness: real, rat, streamname, regseqrat, rationalinterval: $\mathsf{WeylEquidistribution}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the natural-indexed sequence source, rational interval ledger, finite counting row, discrepancy budget, exhaustion row, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WeylEquidistribution}^{\uparrow}}$.

Constructive story: A $\mathsf{WeylEquidistribution}^{\uparrow}$ packet is generated from a natural-indexed sequence source, rational interval-test ledger, finite counting rows, rational discrepancy budgets, test-exhaustion accounting, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeylEquidistribution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7520.1, Definition 7520.2, and Definition 7520.3 seed the finite rational interval-test surface for constructive equidistribution reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeylEquidistribution}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic equidistribution, unrestricted limiting frequencies, countable choice, selected subsequences, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite interval-test exposure, counting exposure, rational discrepancy accounting, exhaustion accounting, transport, replay, provenance, and local naming for BEDC.Derived.WeylEquidistributionUp.

Chapter 7521

A Concrete Naming Certificate for TotalBoundedCompletionCompactness$^{\uparrow}$

Following Bishop and Bridges on compact metric completions, the TotalBoundedCompletionCompactness$^{\uparrow}$ packet records the finite handoff by which a totally bounded completion route may be read by compact-metric consumers while retaining explicit net and Cauchy rows. It sits after the total-bounded completion route of chapter 1573, the precompact completion route of chapter 1842, and the constructive metric completion route of chapter 1556, and it supplies a compactness-facing boundary for chapter 129. The packet is a finite NameCert surface; it is not an open-cover compactness theorem, a countable-choice principle, a quotient completion, or an ambient Real$^{\uparrow}$ completeness theorem.

Definition 7521.1 (TotalBoundedCompletionCompactness carrier)**.** *A* TotalBoundedCompletionCompactness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, F, C, Q, S, H, R, P, N)$$

with the following displayed rows:

1. *M is the source metric carrier row, including the point histories, metric-distance witnesses, and classifier transport data used by the completion route.*
2. *T is the total-bounded finite-net ledger inherited from* TotallyBoundedCompletion$^{\uparrow}$ *and* PrecompactCompletion$^{\uparrow}$*, naming centers, membership rows, rational radius bounds, and refinement reads for each displayed tolerance request.*
3. *F is the* CauchyFilterBasis$^{\uparrow}$ *or regular Cauchy basis row generated from the same finite-net data.*
4. *C is the* ConstructiveMetricCompletion$^{\uparrow}$ *route through dense embedding, regular Cauchy readback, dyadic tolerance control, and the terminal* Real$^{\uparrow}$ *naming boundary.*
5. *Q is the compact-metric reading row, allowing a downstream* CompactMetric$^{\uparrow}$ *consumer to inspect only the displayed total-bounded completion route.*
6. *S is the seal row recording that every compactness-facing read factors through T, F, C, Q before any completion point, net refinement, or real-name boundary is consumed.*
7. *H records componentwise* hsame *transport for the metric, net ledger, basis row, constructive completion route, compact-metric reading row, seal row, provenance, and local naming rows.*
8. *R records displayed* Cont *replay for the same row order.*

9. *P is the* Pkg *provenance over* TotalBoundedCompletionCompactness$^{\uparrow}$, TotallyBoundedCompletion$^{\uparrow}$, PrecompactCompletion$^{\uparrow}$, ConstructiveMetricCompletion$^{\uparrow}$, CompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{TotalBoundedCompletionCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, T, F, C, Q, S, H, R, P, N$. No coordinate stores open-cover compactness, a countable-choice selector, a quotient completion, selected completion representatives, detached host equality, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7521.2 (TotalBoundedCompletionCompactness NameCert obligations)**.** *For every accepted* TotalBoundedCompletionCompactness$^{\uparrow}$ *carrier*

$$K = (M, T, F, C, Q, S, H, R, P, N),$$

the local NameCert$_{\text{TotalBoundedCompletionCompactness}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed metric row, finite-net ledger, Cauchy basis row, constructive completion route, compact-metric reading row, seal row, transport, replay, provenance, and local naming row;*

2. *finite-net persistence, requiring every compactness-facing tolerance request to expose the centers, membership constructors, rational radius bounds, and refinement reads stored in T;*

3. *completion-route admission, requiring the basis row F and constructive route C to be displayed before the compact-metric reader reaches Q;*

4. *compactness-facing seal discipline, requiring S to record the same T, F, C, Q order for every downstream compact-metric or uniform-continuity consumer;*

5. *nonescape from open-cover compactness, countable choice, quotient completion, selected representatives, host equality, and ambient* Real$^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside these displayed rows.

Proof. Carrier admission is projection from Definition 7521.1. The accepted packet displays exactly the metric row, total-bounded finite-net ledger, Cauchy basis row, constructive completion route, compact-metric reading row, seal row, and structural rows.

Finite-net persistence is read from T. A compactness-facing tolerance request first opens the same finite centers, membership rows, radius bounds, and refinement data already named by TotallyBoundedCompletion$^{\uparrow}$ and PrecompactCompletion$^{\uparrow}$; it cannot replace them by an open cover or by a selected convergent subnet.

The completion route is then forced through F and C. The basis row is generated from the displayed finite-net ledger, and the constructive completion row exposes only dense embedding, regular Cauchy readback, dyadic tolerance, and terminal real-name data before Q is visible.

Finally S, H, R, P, N seal, transport, replay, source, and name the same finite route. Since the excluded principles have no carrier coordinate and no replay edge, the five rows exhaust the local NameCert surface. □

Theorem 7521.3 (TotalBoundedCompletionCompactness compact handoff)**.** *Every accepted* TotalBoundedComple *carrier $K = (M, T, F, C, Q, S, H, R, P, N)$ hands a compact-metric or uniform-continuity consumer only the displayed finite route*

$$M, T \longmapsto F \longmapsto C \longmapsto Q \longmapsto S, H, R, P, N.$$

The route reads $\mathsf{TotallyBoundedCompletion}^{\uparrow}$ *or* $\mathsf{PrecompactCompletion}^{\uparrow}$ *net data before it reads* $\mathsf{ConstructiveMetricCompletion}^{\uparrow}$ *completion data, and it reads the* $\mathsf{CompactMetric}^{\uparrow}$ *boundary only as a consumer of that route.*

Proof. Begin with the finite-net ledger T over the source metric row M. These rows provide the only tolerance and center data available to the packet.

The basis and completion rows F and C are downstream of that ledger. They expose the constructive completion route without adding quotient representatives, selected limits, countable choice, or an ambient completeness theorem.

The compact-metric row Q is then a reader of the displayed route, not an independent compactness proof. The seal and structural rows S, H, R, P, N preserve the same order, so every downstream consumer receives the finite handoff stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotalBoundedCompletionCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{TotalBoundedCompletionCompactness}^{\uparrow}$ packet is generated from a source metric row, total-bounded finite-net ledger, Cauchy basis row, constructive completion route, compact-metric reading row, seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotalBoundedCompletionCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7521.1, Definition 7521.2, and Definition 7521.3 seed the finite completion-to-compactness route over TotallyBoundedCompletionUp, PrecompactCompletionUp, ConstructiveMetricCompletionUp, CompactMetricUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotalBoundedCompletionCompactness}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, quotient completion, selected representatives, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove finite-net persistence, completion-route admission, compactness-facing seal discipline, transport, replay, provenance, and nonescape for the same packet.

Chapter 7522

A Concrete Naming Certificate for $\mathsf{SchwartzDistribution}^{\uparrow}$

Following Schwartz, the $\mathsf{SchwartzDistribution}^{\uparrow}$ packet records a finite distribution-action surface over displayed test windows. It sits beside the rapidly decreasing carrier of chapter 3399, the compact-support test probe of chapter 6945, the tempered-distribution handoff of chapter 2310, the weak-action route of chapter 3751, and the terminal scalar seal of chapter 38. The chapter names a finite BEDC carrier for distribution reads on Schwartz-style test windows; it does not import the full locally convex dual, measure-theoretic distribution theory, Fourier transform completeness, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7522.1 (Schwartz distribution carrier)**.** *A* $\mathsf{SchwartzDistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, T, A, W, Q, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *test-window row. It records the rapidly decreasing smooth windows, derivative orders, polynomial-weight labels, and finite observation domains visible to the packet.*
2. *T is the* $\mathsf{TestFunction}^{\uparrow}$ *compact-support row. It records the compact test windows through which local reads may be compared with the Schwartz-function row.*
3. *A is the response-ledger row. It lists the finite action values assigned to the displayed test windows and records which response belongs to which test-window request.*
4. *W is the test-window coverage row. It records that every public action read names a test window in S or T before any scalar response in A is exposed.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational approximations to the finite response ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row reached only after the corresponding rational readback in Q has been displayed.*
7. *L is the local classifier row. It admits two packets together exactly when their Schwartz windows, compact-support windows, response ledger, coverage row, rational readback, and Real seal match componentwise.*
8. *H records componentwise* hsame *transport for S, T, A, W, Q, E, L.*
9. *C records displayed* Cont *replay from a distribution-action request through S, T, W, A, Q, E, L, H in that order.*

10. *P is the* Pkg *provenance over* $\mathsf{SchwartzDistribution}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TestFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{DistributionDerivative}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchwartzDistribution}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for the full locally convex dual, measure completion, quotient distribution equality, Fourier transform completeness, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SchwartzDistributionUp.SchwartzDistributionTasteGate single carrier alignment`

Theorem 7522.2 (Schwartz distribution NameCert obligations)**.** *For every accepted* $\mathsf{SchwartzDistribution}^{\uparrow}$ *carrier* $D = (S, T, A, W, Q, E, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SchwartzDistribution}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed test-window rows, response-ledger rows, test-window coverage, rational readback, Real scalar sealing, local classification, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 7522.1. The rows $S, T, A, W, Q, E, L, H, C, P, N$ are the whole visible packet, so every local obligation starts from one of those displayed rows.

The test-window obligations are the rows S, T, W. The row S exposes Schwartz-function windows, T exposes compact-support test windows, and W records that a public action read first names one of those windows.

The response obligations are the rows A, Q, E. The response ledger A stores only finite action values for displayed windows, Q gives their regular-rational readback, and E supplies the terminal Real scalar seal after the readback has been opened.

Finally, L, H, C, P, N compare, transport, replay, source, and name the same finite distribution-action surface. Since the carrier has no row for a full locally convex dual, measure completion, Fourier transform completeness, quotient distribution equality, selected representatives, or countable choice, none of those objects belongs to the local NameCert surface. □

Theorem 7522.3 (Schwartz distribution test-window nonescape)**.** *Every* $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{DistributionDerivative}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{SchwartzDistribution}^{\uparrow}$ *packet receives a scalar action only through the finite route*

$$S, T \longmapsto W \longmapsto A \longmapsto Q \longmapsto E \longmapsto L, H, C, P, N.$$

Thus no consumer can extract a response without first displaying a Schwartz or compact-support test window, and no consumer can extract the full locally convex dual, measure-theoretic distribution data, Fourier transform completeness, quotient distribution equality, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Start with an accepted carrier and apply Definition 7522.2. The theorem identifies the visible rows and in particular forces every response read to pass through the coverage row W.

The route to a scalar response is then fixed. A consumer reads either the Schwartz-function window S or the compact-support test row T, checks the coverage row W, and only then reads the response ledger A.

The numeric endpoint remains downstream of A. The regular-rational readback Q and Real seal E expose scalar names for the displayed response, while L, H, C, P, N only compare, transport, replay, source, and name the same route.

Because the carrier inventory contains no dual-space coordinate, no measure-completion coordinate, no Fourier-completeness coordinate, no quotient-distribution equality, and no selected representative, the finite route cannot export those principles to tempered-distribution, derivative, or Real-facing consumers. □

Falsifiable prediction: Every accepted $\mathsf{SchwartzDistribution}^{\uparrow}$ read that reaches a scalar response must first expose a SchwartzFunctionUp or TestFunctionUp window, a coverage row, a response-ledger entry, RegSeqRat readback, RealUp sealing, classifier, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: schwartzfunction, testfunction, tempereddistribution, distributionderivative, real: $\mathsf{SchwartzDistribution}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries test-window rows, response-ledger rows, coverage, readback, scalar seals, transport, replay, provenance, and local naming while refusing full dual-space and measure-theoretic distribution data.

Closure status for $\mathsf{NameCert}_{\mathsf{SchwartzDistribution}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchwartzDistribution}^{\uparrow}$ packet is generated from SchwartzFunction and TestFunction window rows, a response ledger, a test-window coverage row, RegSeqRat readback, RealUp scalar sealing, local classification, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchwartzDistribution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7522.1, Definition 7522.2, and Definition 7522.3 seed the finite distribution-action surface over Schwartz and compact-support test windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchwartzDistribution}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full locally convex dual, measure-theoretic distribution theory, Fourier transform completeness, quotient distribution equality, selected representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: The next closure step requires checked carrier admission, test-window coverage, response-ledger stability, scalar readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SchwartzDistributionUp.

Chapter 7523

A Concrete Naming Certificate for $\mathsf{JungTheorem}^{\uparrow}$

Following Jung's theorem and compact metric radius bounds, the $\mathsf{JungTheorem}^{\uparrow}$ packet records the finite BEDC surface by which a displayed compact metric source exports a radius-bound handoff through Chebyshev-center and finite-projection rows. It sits after the compact-metric source of chapter 129, the metric carrier of chapter 57, the Chebyshev-center certificate of chapter 6623, the finite metric projection boundary of chapter 7348, and the terminal real-radius seal of chapter 38. The packet names one constructive radius-bound route; it is not a host inner-product theorem, selected center principle, quotient compactum, ambient completeness claim, or choice-based extremal argument.

Definition 7523.1 (Jung theorem carrier)**.** *A* $\mathsf{JungTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (K, M, C, F, R, B, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including its finite-net and compactness-facing observation schedule.*
2. *M is the underlying* $\mathsf{Met}^{\uparrow}$ *distance row read by every radius comparison.*
3. *C is the* $\mathsf{ChebyshevCenter}^{\uparrow}$ *center-candidate row, exposing the finite center ledger before any radius claim is read.*
4. *F is the* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *projection row, recording the finite subconfiguration on which the radius comparison is witnessed.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *radius-seal row carrying the displayed bound as real-name data.*
6. *B is the Jung-bound handoff row, recording that K, M, C, F are consumed before R is exported.*
7. *H records componentwise* hsame *transport for the compact source, metric distance row, center row, projection row, radius seal, bound handoff, replay row, provenance row, and local naming row.*
8. *T records displayed* Cont *replay for the same row order.*
9. *P is the* Pkg *provenance over* $\mathsf{JungTheorem}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ChebyshevCenter}^{\uparrow}$, $\mathsf{FiniteMetricProjection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{JungTheorem}^\uparrow}$ *row.*
The classifier compares accepted packets only through $K, M, C, F, R, B, H, T, P, N$. It has no coordinate for host Euclidean structure, selected centers, quotient compacta, ambient completeness, or choice.

Theorem 7523.2 (Jung theorem NameCert obligations)**.** *For every accepted* $\mathsf{JungTheorem}^\uparrow$ *carrier*

$$J = (K, M, C, F, R, B, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{JungTheorem}^\uparrow}$ *surface consists exactly of carrier admission for the displayed compact metric source, metric distance row, Chebyshev-center row, finite-projection row, radius seal, bound handoff, transport, replay, provenance, and local naming row; compact-metric dependency exposure through K; distance comparison exposure through M; center-candidate exposure through C; finite witness exposure through F; real-radius sealing through R; and nonescape from host geometry, selected centers, quotient compacta, ambient completeness, and choice.*

Every downstream consumer of this packet must read the compact metric source before reading the metric distance row, read the Chebyshev-center and finite-projection rows before reading the Jung-bound handoff, and read the $\mathsf{Real}^\uparrow$ *radius row only after that finite route is displayed.*

Proof. Project the accepted carrier through Definition 7523.1. The compact source row K and metric row M are the only places where compactness-facing and distance-facing data occur, so every radius request begins with those rows.

The center and witness data are then forced through C and F. The row C exposes the Chebyshev-center candidate ledger, while F records the finite metric projection that witnesses the displayed radius comparison. No other carrier coordinate can supply a center or finite subconfiguration.

Finally B, R, H, T, P, N hand off, seal, transport, replay, source, and name the same finite route. Since the carrier has no row for host Euclidean structure, selected centers, quotient compacta, ambient completeness, or choice, the listed clauses exhaust the local NameCert surface. □

Theorem 7523.3 (Jung theorem radius-bound handoff)**.** *Every accepted* $\mathsf{JungTheorem}^\uparrow$ *carrier hands a compact-metric consumer only the displayed finite route*

$$K, M \longmapsto C, F \longmapsto B \longmapsto R \longmapsto H, T, P, N.$$

The handoff records a radius-bound interface over $\mathsf{CompactMetric}^\uparrow$, $\mathsf{Met}^\uparrow$, $\mathsf{ChebyshevCenter}^\uparrow$, $\mathsf{FiniteMetricProjection}^\uparrow$ *and* $\mathsf{Real}^\uparrow$ *rows. It does not export a host geometric proof, a selected minimizing center, a quotient compact object, an ambient completeness theorem, or a choice principle.*

Proof. Start with the compact-metric and metric rows K, M. They provide the displayed source and distance data that a radius-bound consumer is allowed to inspect.

Next read the center and projection rows C, F. These rows make the finite Chebyshev-center candidate and finite metric witness visible before the bound handoff is consumed.

The handoff and real-radius rows B, R then expose the stated bound as $\mathsf{Real}^\uparrow$ data. The structural rows H, T, P, N preserve the same finite route under transport, replay, provenance, and local naming, so no host geometry, selected center, quotient compactum, ambient completeness, or choice-based extremal principle is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{JungTheorem}^\uparrow}$.

Constructive story: A JungTheorem$^{\uparrow}$ packet is generated from a compact metric source row, metric distance row, Chebyshev-center row, finite-projection row, real-radius seal, bound handoff, componentwise transport, displayed replay, package provenance, and local naming row.

Theory closure: TheoryGate(NameCert$_{\mathsf{JungTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 7523.1, Definition 7523.2, and Definition 7523.3 seed the finite compact-metric radius-bound route through CompactMetricUp, MetricUp, ChebyshevCenterUp, FiniteMetricProjectionUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{JungTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host Euclidean geometry, selected centers, quotient compacta, ambient completeness, Lean theorem verification, or bridge checking.

Upgrade path: The next paper-side grade requires a full obligation package over carrier admission, compact-metric dependency exposure, distance comparison exposure, center and projection rows, radius sealing, transport, replay, provenance, and nonescape.

Chapter 7524

A Concrete Naming Certificate for $\mathsf{MetricDenseEmbedding}^{\uparrow}$

Following Bourbaki and Kelley on dense embeddings in metric and uniform spaces, the $\mathsf{MetricDenseEmbedding}^{\uparrow}$ packet records the metric-specific interface by which a source metric carrier enters a target metric carrier as a dense displayed subobject. It sits between the metric embedding surface of chapter 3339, the uniform dense embedding route of chapter 1651, the completion handoff of chapter 1512, the metric source of chapter 57, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet is a finite NameCert interface for metric density plus graph control; it is not a quotient completion, a selected representative, a host equality of functions, countable choice, or an ambient completeness principle.

Definition 7524.1 (MetricDenseEmbedding carrier)**.** *A* $\mathsf{MetricDenseEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, F, D, I, M, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, including its metric-distance readback and classifier transport surface.*
2. *Y is the target* $\mathsf{Met}^{\uparrow}$ *row in which the dense image is inspected.*
3. *F is the graph row naming the embedding route from displayed source observations to displayed target observations.*
4. *D is the graph-distance control row, recording the metric comparison budget attached to F without asserting host equality of all distances.*
5. *I is the dense-image witness: every displayed target ball request is met by a source observation routed through F within the named metric tolerance.*
6. *M is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *handoff row used by completion-facing consumers after the dense-image witness has been read.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *tolerance readback row attached to the metric budget named by D and I.*
8. *H records componentwise* hsame *transport for the metric rows, graph row, distance-control row, dense-image witness, completion handoff, tolerance readback, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay for the same row order.*
10. *P is the* Pkg *provenance over* $\mathsf{MetricDenseEmbedding}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricEmbedding}^{\uparrow}$, $\mathsf{DenseUniformEmbedding}^{\uparrow}$, $\mathsf{CompletionEmbedding}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricDenseEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $X, Y, F, D, I, M, R, H, C, P, N$. No coordinate stores quotient completion classes, selected representatives, selected dense points, host function equality, countable choice, or ambient completeness.

Theorem 7524.2 (MetricDenseEmbedding NameCert obligations)**.** *For every accepted* $\mathsf{MetricDenseEmbedding}^{\uparrow}$ *carrier $E = (X, Y, F, D, I, M, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricDenseEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the two metric rows, graph route, graph-distance control, dense-image witness, completion-embedding handoff, tolerance readback, componentwise transport, displayed replay, provenance, and local naming. Every dense-image read must first inspect X, Y, F, D, I before it can pass to M, R, H, C, P, N, and every completion-facing read must preserve that same order.*

Proof. Project the accepted carrier of Definition 7524.1. The packet exposes the source and target metric rows, graph row, graph-distance control, dense-image witness, completion handoff, tolerance readback, and the structural rows, with no further coordinate available.

The dense-image coverage clause is the row I. A target ball request is opened inside Y, routed back through a source observation in X, and then returned along F with the metric budget named by D and read back by R.

Transport and replay are structural. The row H moves each displayed coordinate componentwise, and C repeats the same graph-control and dense-image route for later consumers. Since the excluded objects have no carrier coordinate and no replay edge, the listed rows exhaust the local NameCert surface. □

Theorem 7524.3 (MetricDenseEmbedding completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{MetricDenseEmbedding}^{\uparrow}$ *packet $E = (X, Y, F, D, I, M, R, H, C, P, N)$ receives the finite route*

$$X, Y \longrightarrow F \longrightarrow D \longrightarrow I \longrightarrow M \longrightarrow R, H, C, P, N.$$

The handoff is therefore a metric dense embedding route through graph control, dense-image coverage, and completion embedding data. It never replaces those rows by quotient completion classes, selected representatives, selected limits, host equality, countable choice, or ambient completeness.

Proof. Start from carrier projection. The only completion-facing row is M, and it is stored after the source and target metric rows, the graph row, the graph-distance control row, and the dense-image witness.

Use the NameCert obligations of Definition 7524.2. They require any dense-image read to consume X, Y, F, D, I before M or the tolerance readback row R can be used by a downstream completion route.

Finally replay the route through H, C, P, N. These rows transport, replay, source, and name the same finite carrier coordinates, so the completion handoff cannot escape into quotient completion equality, selected representatives, host equality of functions, countable-choice selection, or an ambient completeness assumption. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetricDenseEmbedding}^{\uparrow}}$.

Constructive story: A MetricDenseEmbedding$^{\uparrow}$ packet is generated from source and target MetricSpace rows, a graph row, graph-distance control, a dense-image witness, a CompletionEmbedding handoff, RegSeqRat and Real tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetricDenseEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 7524.1, Definition 7524.2, and Definition 7524.3 seed the metric dense embedding interface over MetricSpaceUp, MetricEmbeddingUp, DenseUniformEmbeddingUp, CompletionEmbeddingUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{MetricDenseEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected representatives, selected dense points, host function equality, countable choice, ambient completeness, Lean theorem verification, or bridge checking.

Upgrade path: The next grade requires Lean encoding of carrier admission, graph-distance control, dense-image coverage, completion handoff, tolerance readback, transport, replay, provenance, local naming, and nonescape for the displayed packet.

Chapter 7525

A Concrete Naming Certificate for $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$

Following Doob and Meyer, the $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$ packet records the finite predictable-bracket data attached to an inspected martingale prefix. It sits over the adapted martingale surface of chapter 190, the random-variable endpoint rows of chapter 185, the probability source of chapter 184, the conditional-expectation route of chapter 188, and the terminal real-name seal of chapter 38. The packet names the bracket as displayed finite BEDC rows; it does not identify quotient stochastic processes, complete a measure space, select limiting variation, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7525.1 (Martingale quadratic-variation carrier)**.** *A* $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, F, X, D, B, A, E, H, C, P, N)$$

with the following displayed coordinates:

1. *M is the consumed* $\mathsf{Martingale}^{\uparrow}$ *adapted-sequence packet over a displayed* $\mathsf{ProbSpace}^{\uparrow}$ *source.*
2. *F is the finite filtration and visibility row inherited from the martingale packet.*
3. *X is the finite endpoint family $X_0, \ldots, X_n$ of* $\mathsf{RandomVar}^{\uparrow}$ *rows read through M.*
4. *D is the finite difference family $\Delta X_k = X_k - X_{k-1}$ recorded as displayed random-variable endpoint rows for $1 \leq k \leq n$.*
5. *B is the predictable-bracket row whose kth face is read through the conditional-expectation packet as the displayed previous-time expectation of the squared difference row.*
6. *A is the accumulated bracket ledger, built by finite prefix summation of the displayed faces of B.*
7. *E stores the* $\mathsf{CondExp}^{\uparrow}$ *rows used to read each previous-time predictable face.*
8. *H stores componentwise* hsame *transport for the martingale row, filtration row, endpoint family, difference rows, bracket faces, accumulated ledger, conditional-expectation rows, replay, provenance, and local naming data.*
9. *C stores displayed* Cont *replay for opening the martingale prefix, reading a difference row, reading the predictable face, and appending it to the accumulated ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{Martingale}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MartingaleQuadraticVariation}^{\uparrow}}$ *row.*

The carrier is a finite predictable-bracket packet over the inspected martingale prefix. It stores no almost-sure quotient equality of processes, no completed-measure representative, no selected infinite bracket limit, and no $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 7525.2 (Martingale quadratic-variation predictable bracket)**.** *For every accepted* MartingaleQuadraticVar *carrier Q, each bracket face in B is admitted only through the displayed predecessor filtration row, the adjacent martingale endpoints in X, the difference row in D, and the corresponding* $\mathsf{CondExp}^{\uparrow}$ *row in E. The accumulated row A may append only those admitted predictable faces, so a bracket consumer cannot replace the finite route by an almost-sure process equality, a completed-measure argument, a selected limiting variation, or ambient real completeness.*

Proof. Project the carrier of Definition 7525.1. The rows M, F, X, D, B, A, E are explicit coordinates of the accepted packet, and the predictable face is listed only beside the previous-time filtration data and the corresponding conditional-expectation row.

Use the martingale finite-prefix and finite-suffix restrictions from Definition 190.17 and Definition 190.20. They ensure the bracket read is made on an inspected finite time spine, with the same consumed $\mathsf{NameCert}_{\mathsf{RandomVar}^{\uparrow}}$ and $\mathsf{NameCert}_{\mathsf{CondExp}^{\uparrow}}$ rows as the parent martingale packet.

Finally apply componentwise transport through H and replay through C. These rows preserve the displayed difference and predictable-face coordinates while adding no carrier slot for quotient process equality, completed measures, selected limits, or $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7525.3 (Martingale quadratic-variation ledger)**.** *The local* $\mathsf{NameCert}_{\mathsf{MartingaleQuadraticVariation}^{\uparrow}}$ *surface for the carrier of Definition 7525.1 consists exactly of carrier admission for Q, predictable-face admission through* $\mathsf{CondExp}^{\uparrow}$*, finite accumulation of the bracket faces, componentwise classifier transport through H, displayed replay through C, package provenance through P, and local naming through N. No obligation row outside $M, F, X, D, B, A, E, H, C, P, N$ is part of the packet.*

Proof. Carrier admission is projection from Definition 7525.1. The martingale row, filtration row, endpoint family, difference family, bracket faces, accumulated ledger, conditional-expectation rows, transport, replay, provenance, and local name are the whole displayed tuple.

Predictable-face admission is supplied by Definition 7525.2. The same theorem fixes the finite accumulation boundary for A: every appended face first passes through the martingale prefix and the conditional-expectation route.

The structural rows H, C, P, N then name the packet without adding semantic coordinates. Therefore the NameCert ledger has no hidden almost-sure quotient equality row, no measure-completion row, no selected-limit row, and no ambient completeness row. □

Falsifiable prediction: Every $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$ bracket-facing read factors through a displayed finite martingale prefix, adjacent random-variable endpoint rows, finite difference rows, predictable $\mathsf{CondExp}^{\uparrow}$ faces, accumulated bracket ledger, componentwise transport, replay, provenance, and local naming.

Independence witness: martingale, randomvar, condexp, probspace, real: $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores martingale prefix data, difference rows, predictable conditional-expectation faces, an accumulated bracket ledger, structural transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleQuadraticVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{MartingaleQuadraticVariation}^{\uparrow}$ packet is generated from a finite Martingale row, filtration row, random-variable endpoints, difference rows, predictable bracket faces, accumulated bracket ledger, conditional-expectation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleQuadraticVariation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7525.1, Definition 7525.2, and Definition 7525.3 seed the finite predictable-bracket packet over martingale prefixes and conditional-expectation faces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MartingaleQuadraticVariation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure quotient equality, measure completion, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, predictable-face admission, finite accumulation, componentwise transport, replay, provenance, and local naming for BEDC.Derived.MartingaleQuadraticVariationUp.

Chapter 7526

A Concrete Naming Certificate for $\mathsf{PseudocompactSpace}^{\uparrow}$

Following Kelley and Engelking, the $\mathsf{PseudocompactSpace}^{\uparrow}$ packet records the finite BEDC surface for spaces whose displayed real-valued continuous reads carry boundedness ledgers. It sits between the topological source of chapter 88, the compactness comparison boundary of chapter 60, the real-valued map route of chapter 130, and the terminal real seal of chapter 38. The chapter names boundedness of displayed continuous real reads; it does not claim open-cover compactness, countable subcover extraction, or a host function-space theorem.

7526.1 Pseudocompact Carrier

Definition 7526.1 (Pseudocompact space finite packet)**.** *A* $\mathsf{PseudocompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, F, B, R, H, C, Q, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row naming the underlying open-set interface.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed real-valued continuous read.*
3. *B is the boundedness ledger for the read carried by F.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the lower and upper real bounds used by B.*
5. *H records componentwise* hsame *transport for the topological, continuous-map, boundedness, real-bound, provenance, and naming rows.*
6. *C records the displayed* Cont *replay from the topology row through the continuous real-valued read to the boundedness ledger.*
7. *Q is the* Pkg *provenance over* $\mathsf{PseudocompactSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PseudocompactSpace}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these displayed rows. In particular, it has no coordinate for finite subcover choice, countable compactness, uniform continuity, a compact-open function space, quotient equality of maps, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

7526.2 Certificate Obligations

Theorem 7526.2 (Pseudocompact space NameCert obligations)**.** *For the carrier of Definition 7526.1, the local* $\mathsf{NameCert}_{\mathsf{PseudocompactSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the rows*

$$T, F, B, R, H, C, Q, N,$$

topology exposure through T*, continuous real-valued read exposure through* F*, boundedness-ledger exactness through* B*, real-bound sealing through* R*, componentwise transport through* H*, displayed replay through* C*, provenance through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 7526.1. The packet lists exactly the topology, continuous-map, boundedness, real-bound, transport, replay, provenance, and naming rows.

The topology-facing coordinate is T, and the real-valued continuous read is exposed only through F. Thus a certificate reader cannot replace the displayed read by an arbitrary host function or by a compact-open function-space object.

The boundedness obligation is the row B sealed by the $\mathsf{Real}^{\uparrow}$ row R. Transport and replay through H and C preserve this route rowwise, while Q and N only record provenance and local naming.

Since the carrier contains no finite-subcover, countable-compactness, uniform-continuity, quotient-map, or ambient real-completeness coordinate, those objects are outside the local certificate surface. □

Theorem 7526.3 (Pseudocompact bounded continuous handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or boundedness-facing consumer of an accepted* $\mathsf{PseudocompactSpace}^{\uparrow}$ *carrier*

$$P = (T, F, B, R, H, C, Q, N)$$

must first expose the $\mathsf{Topology}^{\uparrow}$ *source row* T*, the* $\mathsf{ContinuousMap}^{\uparrow}$ *real-valued read row* F*, and the boundedness ledger* B *before it may consume the real-bound seal* R*. The exported handoff is a finite bounded-continuous-read route over the same topology, continuous-map, boundedness, transport, replay, provenance, and local naming rows; it does not export open-cover compactness, a finite subcover selector, countable compactness, quotient equality of maps, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a boundedness-facing consumer of the accepted carrier. The only real-bound coordinate available to that consumer is the row R, and R is displayed as the seal for the boundedness ledger B.

Apply Definition 7526.2. It forces the topology source to be read through T, the real-valued continuous map through F, and the boundedness ledger through B before the real-bound seal can be consumed.

The replay and transport rows C and H keep this route inside the same finite packet, and the rows Q and N only source and name the route. Hence the handoff cannot introduce open-cover compactness, a finite subcover selector, countable compactness, quotient equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{PseudocompactSpace}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PseudocompactSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7526.1, Definition 7526.2, and Definition 7526.3 seed the finite bounded-continuous-read packet over topology, continuous-map, boundedness, Real-bound, transport, replay, provenance, and local NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PseudocompactSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, finite subcover extraction, countable compactness, compact-open function spaces, quotient equality of maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous real-valued read exposure, boundedness-ledger exactness, Real-bound sealing, transport stability, replay accountability, and non-escape for BEDC.Derived.PseudocompactSpaceUp.

Constructive story: A PseudocompactSpace$^{\uparrow}$ packet is generated from a topology source row, a continuous real-valued read row, a boundedness ledger, a RealUp bound seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7527

A Concrete Naming Certificate for $\mathsf{CauchyCompletionIntersection}^{\uparrow}$

Following Bishop and Bridges and Kelley-style completion theory, the $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ packet records the finite BEDC route by which two completion-facing Cauchy reads are compared through a shared window before any terminal real seal is consumed. It sits after the regular Cauchy completion route of chapter 1639, the completion monad law surface of chapter 3834, and the L10 readback spine through chapter 126, chapter 291, chapter 301, and chapter 38. The packet names finite intersection stability for completion routes; it is not a quotient completion equality, not a selected representative, not a countable-choice schedule, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7527.1 (CauchyCompletionIntersection carrier)**.** *A* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the first completion-facing Cauchy route, including its source name, regularity request, and completion consumer boundary.*
2. *B is the second completion-facing Cauchy route, with the same kind of source, regularity, and consumer data.*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row through which both routes must expose finite observations before either route reaches a completion seal.*
4. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radius, slack, comparison budget, and refinement data used by both window reads.*
5. *R is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after A and B have both passed through W and D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the two displayed routes have reached the same finite window, tolerance, and regular-rational readback surface.*
7. *H records componentwise* hsame *transport for $A, B, W, D, R, E, C, P, N$.*
8. *C records displayed* Cont *replay for the route order $A, B, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$, $\mathsf{BishopRegularCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionIntersection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, B, W, D, R, E, H, C, P, N$. No coordinate stores quotient completion classes, selected stream representatives, a countable-choice selector, detached host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7527.2 (CauchyCompletionIntersection NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ *carrier $I = (A, B, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionIntersection}}$ *surface consists exactly of carrier admission for the two completion-facing Cauchy routes, shared* $\mathsf{StreamName}^{\uparrow}$ *window exposure, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure, shared* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every consumer of the packet must read A and B before opening the shared window row W, must read D before comparing regular-rational readbacks through R, and must reach the terminal seal E only after the same finite rows have been displayed for both routes.

Proof. Project the accepted carrier of Definition 7527.1. The two completion-facing Cauchy routes are exactly A and B, and the shared analytic readback surface is exactly W, D, R, E.

The window and tolerance obligations are forced by the carrier order. A consumer must first display both Cauchy routes, then open the common $\mathsf{StreamName}^{\uparrow}$ window and the shared $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before any $\mathsf{RegSeqRat}^{\uparrow}$ readback can be compared.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since there is no coordinate for quotient classes, selected representatives, countable choice, host equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7527.3 (CauchyCompletionIntersection shared-window route)**.** *Let $I = (A, B, W, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ *packet. Any completion-facing read that claims the two Cauchy routes meet must factor through the finite route*

$$A, B \longmapsto W \longmapsto D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the intersection is witnessed by shared StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, and the Real seal, not by quotienting the two routes or selecting a representative completion point.

Proof. Start with the two route rows A and B. They are separate coordinates of the carrier, so neither one can be erased or replaced by the other before the shared readback surface is opened.

The common window row W and tolerance ledger D provide the finite comparison surface. The regular-rational row R is read only after both routes have passed through those shared rows, and the real seal E is downstream of that readback.

Finally the transport, replay, provenance, and naming rows preserve the displayed order. The carrier therefore supplies a finite shared-window route and no quotient, selected representative, choice schedule, host equality, or ambient-completeness route. □

Theorem 7527.4 (CauchyCompletionIntersection nonescape)**.** *Every accepted* $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ *consumer that reaches the* $\mathsf{Real}^{\uparrow}$ *seal has already consumed the finite packet rows*

$$A, B, W, D, R, E, H, C, P, N.$$

The resulting read cannot export quotient completion equality, a selected completion representative, countable choice, detached host equality of completed points, a closed-subspace theorem, a metric-intersection theorem, Lean verification, or bridge checking.

Proof. Apply the NameCert obligations of Definition 7527.2. They force every accepted consumer through the two Cauchy routes, shared window, tolerance ledger, regular-rational readback, real seal, and structural rows.

Use the shared-window route of Definition 7527.3. It identifies the only path to the terminal $\mathsf{Real}^{\uparrow}$ seal as the finite route through $A, B, W, D, R, E, H, C, P, N$.

The excluded conclusions require coordinates not present in the carrier. Since the packet stores no quotient class, selected representative, choice schedule, host equality, closed-subspace certificate, metric-intersection certificate, verification credential, or bridge-checked row, none of those conclusions can escape from the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionIntersection}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionIntersection}^{\uparrow}$ packet is generated from two completion-facing Cauchy routes, shared StreamName windows, a shared DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionIntersection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7527.1, Definition 7527.2, Definition 7527.3, and Definition 7527.4 seed the finite intersection route for two completion-facing Cauchy reads over shared StreamName, DyadicRatCore, RegSeqRat, Real, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionIntersection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected representatives, countable choice, host equality of completed points, closed-subspace closure, metric-intersection closure, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exposure, shared-tolerance exposure, regular-rational readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionInters

Chapter 7528

A Concrete Naming Certificate for $\mathsf{CauchyBornologicalUniformity}^{\uparrow}$

Following Bourbaki on uniform structures and bornologies, and Bishop–Bridges on constructive Cauchy data, the $\mathsf{CauchyBornologicalUniformity}^{\uparrow}$ packet records the finite interface where Cauchy filters, bounded sets, metric-bornological control, and uniform entourages are read as one NameCert surface. It sits after the Cauchy-filter carrier of chapter 333, the bornology carrier of chapter 3370, the metric-bornology comparison of chapter 4091, the uniform-space entourage discipline of chapter 339, and the complete-metric handoff of chapter 128. The packet gives Real and Completion consumers a bounded-uniform Cauchy interface without quotient completions, selected limits, countable choice, trichotomy, or ambient completeness outside the displayed rows.

Definition 7528.1 (Cauchy bornological uniformity carrier)**.** *A* $\mathsf{CauchyBornologicalUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, B, M, U, C, H, R, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{CauchyFilter}^{\uparrow}$ *request row, including the finite filter-base and Cauchy-eventuality data consumed from chapter 333;*
2. *B is the* $\mathsf{Bornology}^{\uparrow}$ *bounded-family row, recording the bounded subsets or bounded events that may be inspected by the filter;*
3. *M is the* ***??*** *comparison row, tying metric balls and boundedness requests to the same displayed source;*
4. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, carrying the finite entourage requests through which Cauchy behavior is read;*
5. *C is the compatibility row asserting that every bounded Cauchy-filter read requested by F remains contained in the bornological row B, is measured by M, and is stable under the entourage route U;*
6. *H stores componentwise* hsame *transport for F, B, M, U, C, replay, provenance, and local naming rows;*
7. *R records the displayed* Cont *replay routes used by bounded-filter, bornological-containment, metric-bornology, and entourage-stability consumers;*

8. *P is the* Pkg *provenance over* CauchyFilter$^{\uparrow}$, Bornology$^{\uparrow}$, *??*, UniformSpace$^{\uparrow}$, CompleteMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

9. *N is the local* NameCert$_{\text{CauchyBornologicalUniformity}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient completion, selected Cauchy limit, countable-choice schedule, trichotomy over distances, host equality of filters, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyBornologicalUniformityUp.TasteGate.CauchyBornologicalUniformityTasteGate single carrier alignment`

Theorem 7528.2 (Cauchy bornological uniformity NameCert obligations)**.** *For every accepted* CauchyBornologicalUniformity$^{\uparrow}$ *carrier*

$$Q = (F, B, M, U, C, H, R, P, N),$$

the local NameCert$_{\text{CauchyBornologicalUniformity}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded Cauchy-filter compatibility, bornological containment, metric-bornology comparison, uniform entourage stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer that asks for a bounded-uniform Cauchy handoff must read these rows before it can consume a completion-facing seal.*

Proof. Carrier admission is projection from Definition 7528.1. The accepted packet exposes exactly $F, B, M, U, C, H, R, P, N$, so the Cauchy-filter, bornology, metric-bornology, uniform-space, compatibility, transport, replay, provenance, and naming rows are all finite BEDC data.

Bounded Cauchy-filter compatibility is read from F together with C. The Cauchy-filter row supplies the finite eventuality requests, while the compatibility row records that these requests remain bounded by B and measurable through M before any completion consumer can read them.

Bornological containment and uniform entourage stability are read from B, U, C, and R. The bornology row supplies the bounded family, the uniform row supplies entourage requests, and the replay row preserves the displayed route through bounded-filter and entourage consumers.

Finally inspect H, P, N. Componentwise transport, provenance, and local naming preserve the same finite packet. Since no coordinate stores a quotient completion, selected limit, countable-choice schedule, trichotomy row, host filter equality, or ambient completeness theorem, the NameCert obligations are exhausted by the displayed bounded-uniform Cauchy ledger. □

Falsifiable prediction: Every accepted CauchyBornologicalUniformity$^{\uparrow}$ consumer displays a CauchyFilter$^{\uparrow}$ row, a Bornology$^{\uparrow}$ row, a **??** row, a UniformSpace$^{\uparrow}$ row, a bounded-compatibility row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any completion-facing seal is consumed.

Independence witness: cauchyfilter, bornology, metric-bornology, uniformspace, completemetric: CauchyBornologicalUniformity$^{\uparrow}$ is not bijective to any listed sibling because it packages bounded Cauchy-filter compatibility, bornological containment, metric-bornology comparison, and uniform entourage stability as one finite NameCert surface.

Closure status for NameCert$_{\text{CauchyBornologicalUniformity}^{\uparrow}}$.
Theory closure: TheoryGate(NameCert$_{\text{CauchyBornologicalUniformity}^{\uparrow}}$, seed)
Scope closed: Definition 7528.1 and Definition 7528.2 seed the bounded-uniform Cauchy interface over CauchyFilter$^{\uparrow}$, Bornology$^{\uparrow}$, **??**, UniformSpace$^{\uparrow}$, CompleteMetric$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.
Formal verification: FormalStatus(NameCert$_{\text{CauchyBornologicalUniformity}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human

Not claimed: This chapter does not close Lean verification, quotient completion, selected limits, countable choice, trichotomy, host equality of filters, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded Cauchy-filter compatibility, bornological containment, metric-bornology comparison, uniform entourage stability, transport replay, and ledger non-escape for BEDC.Derived.CauchyBornologicalUniformityUp.

Constructive story: A CauchyBornologicalUniformity$^{\uparrow}$ packet is generated from Cauchy-filter requests, bornological bounded-family rows, metric-bornology comparisons, uniform entourage rows, bounded compatibility, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Chapter 7529

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ packet records the finite handoff by which apartness data already exposed over regular Cauchy names are transported into later real-name and completion-facing consumers. It sits over the regular rational source of chapter 301, the finite stream windows of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38; it also consumes the order boundary of chapter 1710, the reflector of chapter 6139, the located-apartness route of chapter 6730, and the finite budget row of chapter 991. The packet is a constructive transfer surface for apartness reads, not a trichotomy principle, quotient-real equality test, selected-limit operation, countable-choice schedule, or ambient completeness assertion.

Definition 7529.1 (Regular Cauchy apartness transfer carrier)**.** *A* $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, O, B, F, L, R, W, D, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose apartness relation is being transferred.*
2. *O is the* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *comparison row that supplies the order-facing apartness read.*
3. *B is the* $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$ *positive lower-bound budget required before any strict or apartness-facing read is public.*
4. *F is the* $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$ *row that reflects the order read into an inspected apartness surface.*
5. *L is the* $\mathsf{RegularCauchyLocatedApartness}^{\uparrow}$ *row that keeps the apartness read located over displayed regular Cauchy data.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational and apartness rows have been displayed.*
7. *W records the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the transfer.*
8. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and lower-bound ledgers attached to those windows.*

9. *H stores componentwise* hsame *transport for the source, order, budget, reflector, located-apartness, seal, window, and dyadic rows.*
10. *C stores displayed* Cont *replay for the same transfer route.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$, $\mathsf{RegularCauchyApartnessReflector}^{\uparrow}$, RegularCauchyLocated $\mathsf{RegularCauchyApartnessBudget}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy, quotient real equality, selected limits, countable choice, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7529.2 (Regular Cauchy apartness transfer NameCert obligations)**.** *For the carrier of Definition 7529.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}}$ *surface consists exactly of carrier admission for T, source admission for X, Y, apartness-order admission through O, positive-budget admission through B, reflector admission through F, located-apartness admission through L, terminal real-seal handoff through R, finite window and dyadic ledger admission through W, D, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 7529.1. The listed rows are exactly the available coordinates of T.

The apartness-facing obligations are inherited from the sibling packets. The order row O supplies the comparison surface, the budget row B supplies the positive lower-bound evidence, the reflector row F exposes the inspected apartness read, and the located row L keeps the read attached to displayed regular Cauchy data.

The structural rows W, D, H, C, P, N keep the same finite route under window inspection, dyadic readback, transport, replay, provenance, and local naming. Since no further coordinate is present, the NameCert surface is exactly the displayed transfer packet. □

Theorem 7529.3 (Regular Cauchy apartness transfer real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ *packet reaches the terminal seal R only after the regular rational sources X, Y, the apartness-order row O, the budget row B, the reflector row F, the located-apartness row L, the finite stream windows W, and the dyadic ledger D have been displayed. The handoff exports a real-facing apartness read, but no quotient equality, selected representative, trichotomy decision, countable-choice schedule, or ambient completeness row.*

Proof. Start from the NameCert obligations of Definition 7529.2. They place R downstream of the source, apartness, budget, reflector, located, window, and dyadic rows.

Use the sibling order and budget boundaries. The $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ and RegularCauchyApartnessBu rows force the positive apartness read through displayed finite lower-bound data before any real-facing seal is public.

Finally use the reflector and located-apartness rows. They preserve the inspected apartness route into the real-facing handoff, while the absent objects are not coordinates of T. □

Theorem 7529.4 (Regular Cauchy apartness transfer transport)**.** *Componentwise* hsame *transport of an accepted* $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ *carrier preserves the source rows, apartness-order row, budget row, reflector row, located-apartness row, terminal seal, finite windows, dyadic ledger, replay, provenance, and local naming together. A transported packet therefore carries the same apartness-transfer route and cannot detach the reflected apartness read from its displayed budget, window, dyadic, or real-seal boundary.*

Proof. Project the transport row H from the carrier. It is componentwise over every displayed coordinate used by the transfer.

Apply the NameCert obligation theorem. The order, budget, reflector, located-apartness, window, dyadic, and seal rows are admitted as one packet surface, so a transport of the packet transports those rows together.

The replay and provenance rows preserve the same route for downstream consumers. Thus transport may rename the finite packet but cannot split the apartness read from its displayed constructive witnesses. □

Theorem 7529.5 (Regular Cauchy apartness transfer non-escape)**.** *Every downstream read of an accepted* $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ *packet factors through*

$$X, Y, O, B, F, L, R, W, D, H, C, P, N.$$

It may inspect regular rational sources, stream windows, dyadic lower-bound data, apartness-order evidence, the apartness budget, reflector and located-apartness rows, the terminal real seal, transport, replay, provenance, and the local NameCert *row. It cannot inspect trichotomy, quotient real equality, selected limits, countable choice, host real equality, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier definition and the NameCert obligations. They enumerate all rows available to a consumer of the accepted packet.

Apply the real-seal handoff and transport theorems. The handoff keeps the real-facing read after the displayed apartness route, while transport preserves the same finite route component by component.

The excluded principles are absent from the carrier inventory and from the sibling apartness rows used by the transfer. Therefore no downstream consumer can extract them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}$ packet is generated from regular rational sources, apartness-order evidence, a positive apartness budget, reflector and located-apartness rows, a terminal RealUp seal, finite StreamName windows, DyadicRatCore ledgers, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7529.1, Definition 7529.2, Definition 7529.3, Definition 7529.4, and Definition 7529.5 describe the finite apartness-transfer carrier and its real-seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessTransfer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-order admission, budget admission, reflector and located-apartness handoff, transport, nonescape, and real-seal handoff for the displayed transfer packet.

Chapter 7530

A Concrete Naming Certificate for $\mathsf{ShadowingLemma}^{\uparrow}$

Following Bowen's hyperbolic dynamics and Walters' formulation of shadowing for expansive systems, the $\mathsf{ShadowingLemma}^{\uparrow}$ packet isolates the finite pseudo-orbit data needed to read a shadowing orbit inside BEDC. It sits downstream of chapter 6707, chapter 195, chapter 57, chapter 38, chapter 126, and chapter 301. The packet records a local certificate route; it does not assert a global hyperbolic decomposition, expansivity theorem, invariant measure, selected orbit, or host-level completeness principle.

Definition 7530.1 (ShadowingLemma carrier)**.** *A* $\mathsf{ShadowingLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, T, W, E, Q, M, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{DynSystem}^{\uparrow}$ *row naming the finite system interface and the branch of the orbit map used by the certificate.*
2. *T is the* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *dependency row that names the hyperbolic-shadowing sibling packet consumed by the local route.*
3. *W is the pseudo-orbit window schedule, read as finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *E is the error-modulus row assigning the displayed tolerance budget to each pseudo-orbit window.*
5. *Q is the pseudo-orbit row whose adjacent iterates are compared only through W and E.*
6. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row measuring the pseudo-orbit errors and the shadowing errors in the same displayed metric interface.*
7. *S is the shadowing-orbit row, storing the orbit read that shadows Q over the windows W under the modulus E.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row converting the window and error data into regular rational approximants.*
9. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the metric-error bounds read from M and R.*
10. *H records componentwise* hsame *transport for the system, dependency, window, modulus, pseudo-orbit, metric comparison, shadowing orbit, readback, and Real-seal rows.*

11. *C records displayed* Cont *replay from a shadowing query through $X, T, W, E, Q, M, S, R, A, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{ShadowingLemma}^{\uparrow}$, $\mathsf{HyperbolicShadowing}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ShadowingLemma}^{\uparrow}}$ *row.*

The carrier stores no selected host orbit, no ambient compactness theorem, no global stability theorem, no real-number trichotomy, and no quotient equality of orbit names.

Theorem 7530.2 (ShadowingLemma NameCert obligations)**.** *For every accepted* $\mathsf{ShadowingLemma}^{\uparrow}$ *carrier*

$$L = (X, T, W, E, Q, M, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ShadowingLemma}^{\uparrow}}$ *surface consists exactly of system admission through X, hyperbolic-shadowing dependency through T, pseudo-orbit windows through W, error-modulus exposure through E, pseudo-orbit readback through Q, metric comparison through M, shadowing-orbit exposure through S, regular-rational readback through R, terminal Real seal through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7530.1. Its dynamical rows are exactly $X, T, W, E, Q, M, S, R, A$, and its structural rows are exactly H, C, P, N.

The pseudo-orbit part is finite. The window row W determines which adjacent iterates can be inspected, and the modulus row E determines which error budget is visible on each window.

The shadowing part is then read through M, S, R, A. The metric row compares pseudo-orbit and shadowing-orbit errors, the regular-rational row gives the finite readback, and the Real row seals the resulting bounds.

Finally H, C, P, N transport, replay, source, and name the same finite data. Since no omitted global theorem is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7530.3 (ShadowingLemma pseudo-orbit handoff)**.** *Every consumer of an accepted* $\mathsf{ShadowingLemma}^{\uparrow}$ *packet must expose the* $\mathsf{DynSystem}^{\uparrow}$ *row X, the* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *sibling row T, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, the error-modulus row E, the pseudo-orbit row Q, and the* $\mathsf{Met}^{\uparrow}$ *comparison row M before reading the shadowing orbit row S. The resulting readback must pass through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and the* $\mathsf{Real}^{\uparrow}$ *seal A, with* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows preserving the same route.*

Proof. Begin with the obligation surface of Definition 7530.2. It makes X, T, W, E, Q, M visible before the shadowing row can be consumed.

The sibling dependencies keep the route local. The $\mathsf{DynSystem}^{\uparrow}$ row supplies the finite system interface, the $\mathsf{HyperbolicShadowing}^{\uparrow}$ row supplies the traditional shadowing dependency, and the $\mathsf{Met}^{\uparrow}$ row supplies the only comparison surface for the pseudo-orbit and shadowing-orbit errors.

The readback is then forced through R, A, H, C, P, N. The regular-rational row records the finite approximants, the Real row seals the displayed bounds, and the transport, replay, provenance, and naming rows preserve the same packet. Thus the handoff is a finite BEDC route rather than a selected-orbit or ambient-completeness claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{ShadowingLemma}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ShadowingLemma}^{\uparrow}}$, seed)

Scope closed: Definition 7530.1, Definition 7530.2, and Definition 7530.3 seed the finite pseudo-orbit, error-modulus, metric comparison, shadowing-orbit, regular-rational readback, Real-seal, transport, replay, provenance, and local naming route.

Formal verification: FormalStatus(NameCert$_{\text{ShadowingLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global hyperbolic decomposition, expansivity, invariant measures, selected host orbits, quotient equality of orbit names, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked system admission, hyperbolic-shadowing dependency, pseudo-orbit window exactness, error-modulus exactness, Metric comparison, StreamName and RegSeqRat readback, Real seal, transport, replay, provenance, and local naming for BEDC.Derived.ShadowingLemmaUp.

Constructive story: A ShadowingLemma$^{\uparrow}$ packet is generated from a DynSystem row, HyperbolicShadowing dependency row, StreamName pseudo-orbit windows, an error-modulus row, a pseudo-orbit row, a Metric comparison row, a shadowing-orbit row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7531

A Concrete Naming Certificate for $\mathsf{KatetovExtension}^{\uparrow}$

Following Katetov and Urysohn on finite metric one-point extensions, the $\mathsf{KatetovExtension}^{\uparrow}$ packet records the standalone finite extension certificate that L10 metric and completion consumers can read before any host Urysohn space is named. It sits over the metric carrier of chapter 57, the separable-metric support schedule of chapter 1458, the isometric handoff surface of chapter 439, the completion-facing route of chapter 1506, the terminal real-distance seal of chapter 38, and the Urysohn finite-extension consumer of chapter 6554. The packet exposes a finite support, Real-valued triangle and reverse-triangle budgets, an isometric handoff, and completion-order obligations without claiming a host Urysohn-space existence theorem or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7531.1 (Katetov extension carrier)**.** *A* $\mathsf{KatetovExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, S, R, F, A, I, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose finite support distances are inspected.*
2. *S is the* $\mathsf{SeparableMetric}^{\uparrow}$ *or finite support schedule row naming exactly the support points used by the one-point request.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row for the support distances and the proposed distances from the new point to each support point.*
4. *F is the finite Katetov budget row. It lists, for every displayed support pair, the triangle and reverse-triangle inequalities that the proposed distances must satisfy.*
5. *A is the admission ledger row recording that the inequalities in F have been checked against the same M, S, R surface.*
6. *I is the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *handoff row. It exports the old support points with their displayed distances unchanged before a consumer reads the new-point distances.*
7. *L is the* $\mathsf{MetricCompletion}^{\uparrow}$ *order row. It permits completion-facing consumers to read the extension request only after M, S, R, F, A, I have been exposed.*
8. *H records componentwise* hsame *transport for the metric source, support schedule, real-distance seal, Katetov budget, admission ledger, isometric handoff, completion order, replay, provenance, and local name.*

9. *C records displayed* Cont *replay for the same finite one-point extension route.*

10. *P is the* Pkg *provenance over* $\mathsf{KatetovExtension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparableMetric}^{\uparrow}$, $\mathsf{IsometricEmbedding}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *finite Katetov requests,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{KatetovExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, R, F, A, I, L, H, C, P, N$. It has no coordinate for a host Urysohn space, an infinite extension chain, quotient completion equality, a selected completion point, countable choice, Lean verification, a standard bridge, or ambient real completeness.

Theorem 7531.2 (Katetov extension NameCert obligations)**.** *For every accepted* $\mathsf{KatetovExtension}^{\uparrow}$ *carrier*

$$K = (M, S, R, F, A, I, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KatetovExtension}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the metric source, support schedule, real-distance seal, finite Katetov budget, admission ledger, isometric handoff, completion order, transport, replay, provenance, and local name;*

2. *common-source discipline, requiring S, R, F, A, I, L to be read over the same metric source row M;*

3. *finite support visibility, requiring every requested new distance to attach to a support point named by S;*

4. *Real-valued Katetov exposure, requiring F and A to display each triangle and reverse-triangle budget through the same* $\mathsf{Real}^{\uparrow}$ *seal row R;*

5. *isometric and completion order, requiring I to preserve the old support distances before L may be read by a completion-facing consumer;*

6. *nonescape, excluding host Urysohn spaces, infinite extension chains, quotient completion equality, selected completion points, countable choice, Lean verification, bridge credentials, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Katetov extension obligation is stored outside these rows.

Proof. Project the carrier of Definition 7531.1. The tuple $M, S, R, F, A, I, L, H, C, P, N$ is the whole public surface, so carrier admission is exactly admission of those rows.

The common-source and finite-support obligations follow from M and S. Every proposed new distance is read through a support name displayed by S and through the same metric source row M.

The Katetov inequalities are recorded by F and A. The budget row lists the triangle and reverse-triangle comparisons, while the admission ledger records that each comparison is checked through the displayed real-distance seal R.

Finally I, L, H, C, P, N preserve only that displayed finite route. The old support distances are exported through the isometric handoff before the completion-order row is available, and no carrier coordinate stores a host Urysohn space, quotient completion equality, selected completion point, infinite extension chain, choice functional, Lean credential, bridge credential, or ambient completeness theorem. □

Theorem 7531.3 (Katetov extension isometric handoff)**.** *Every completion-facing or Urysohn-facing consumer of an accepted* $\mathsf{KatetovExtension}^{\uparrow}$ *carrier factors through*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{SeparableMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto F, A \longmapsto \mathsf{IsometricEmbedding}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}.$$

Thus the packet exports a displayed finite one-point metric-extension certificate: the old support is handed off isometrically, the new distances satisfy the displayed Real-valued Katetov budgets, and completion-facing reads occur only after those rows have been exposed.

Proof. Begin with the metric source row M and the support schedule S. These rows expose the only old points and support distances available to the extension request.

Read the real-distance row R, then the finite Katetov rows F and A. They display the proposed new distances and the triangle and reverse-triangle budgets over the same finite support.

The isometric row I then exports the old support without changing its displayed distances. Only after this handoff may the completion-order row L be read.

Consequently any $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ or $\mathsf{MetricCompletion}^{\uparrow}$ consumer receives a finite one-point extension route, not a host universal space, quotient completion construction, selected limit point, choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{KatetovExtension}^{\uparrow}$ read exposes the $\mathsf{Met}^{\uparrow}$ source row, finite $\mathsf{SeparableMetric}^{\uparrow}$ support schedule, $\mathsf{Real}^{\uparrow}$ distance seal, Katetov budget, admission ledger, and $\mathsf{IsometricEmbedding}^{\uparrow}$ handoff before any $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{UrysohnUniversalMetric}^{\uparrow}$ consumer may inspect the completion-order row.

Independence witness: metric, separablemetric, isometric-embedding, metriccompletion, real, urysohnuniversalmetric: $\mathsf{KatetovExtension}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite support schedules, Real-valued one-point distance requests, triangle and reverse-triangle budgets, admission ledgers, isometric handoffs, completion-order rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows while refusing host Urysohn spaces and completion quotients.

Closure status for $\mathsf{NameCert}_{\mathsf{KatetovExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{KatetovExtension}^{\uparrow}$ packet is generated from a displayed metric source, finite support schedule, Real-valued distance seal, finite Katetov budget, admission ledger, isometric handoff, completion-order row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KatetovExtension}^{\uparrow}}$, seed)

Scope closed: Definition 7531.1, Definition 7531.2, and Definition 7531.3 seed the finite one-point metric-extension certificate for L10 metric and completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KatetovExtension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host Urysohn-space existence, quotient completion equality, countable choice, infinite extension chains, selected completion points, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-source discipline, finite support visibility, Real-valued Katetov exposure, isometric handoff order, completion order, and nonescape for BEDC.Derived.KatetovExtensionUp.

Chapter 7532

A Concrete Naming Certificate for $\mathsf{CofinalTailMesh}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion, the $\mathsf{CofinalTailMesh}^{\uparrow}$ packet records the shared tail-window mesh used when several regular rational names are read before a Real or Completion consumer may inspect a terminal seal. It sits over the finite stream schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the regular Cauchy tail-meet route of chapter 560, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and completion-facing Cauchy routes. The packet names a common cofinal window surface; it does not quotient streams, select limits, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7532.1 (CofinalTailMesh carrier)**.** *A* $\mathsf{CofinalTailMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, M_0, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule family naming the finite windows inspected for every participating regular Cauchy name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every mesh comparison.*
4. *M_0 is the regular Cauchy tail-meet row, recording the common cofinal tail at which the named reads are compared.*
5. *W is the shared cofinal window row consumed before any* $\mathsf{Real}^{\uparrow}$ *or completion-facing seal is read.*
6. *H records componentwise* hsame *transport for S, R, D, M_0, W and for the structural rows.*
7. *C records displayed* Cont *replay for opening the stream windows, reading regular rational tails, checking dyadic tolerances, and handing the shared window to downstream consumers.*
8. *P is the* Pkg *provenance over* $\mathsf{CofinalTailMesh}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *regular Cauchy completion routes,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofinalTailMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, R, D, M_0, W, H, C, P, N$. No coordinate stores quotient stream equality, a selected limit, a host cofinal subsequence, countable choice, or ambient completeness.

Theorem 7532.2 (CofinalTailMesh NameCert obligations)**.** *For every accepted* $\mathsf{CofinalTailMesh}^{\uparrow}$ *carrier* $M = (S, R, D, M_0, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofinalTailMesh}^{\uparrow}}$ *surface consists exactly of carrier admission, StreamName window scheduling, RegSeqRat readback, DyadicRatCore tolerance comparison, regular Cauchy tail-meet admission, shared cofinal window handoff, componentwise transport, displayed replay, provenance, and local naming. Every consumer must read the stream schedules and dyadic ledger before it can consume the shared window row.*

Proof. Project the carrier of Definition 7532.1. The visible inventory is $S, R, D, M_0, W, H, C, P, N$, and each row has a fixed role in the mesh.

The stream and rational rows are read first. The schedule row S opens the finite windows, while R supplies regular rational readback for those same windows.

The dyadic and tail-meet rows then bind the comparison. The row D supplies the tolerance ledger, and M_0 records the common regular Cauchy tail at which the participating reads are compared before W exposes the shared cofinal window.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since quotient streams, selected limits, host cofinal subsequences, countable choice, and ambient completeness have no carrier coordinate, they are not NameCert obligations of the packet. □

Theorem 7532.3 (CofinalTailMesh Real-completion route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CofinalTailMesh}^{\uparrow}$ *carrier receives the finite route*

$$S \longrightarrow R \longrightarrow D \longrightarrow M_0 \longrightarrow W \longrightarrow H, C, P, N.$$

Thus the consumer reads finite StreamName windows, RegSeqRat tails, a DyadicRatCore tolerance ledger, a regular Cauchy tail meet, and one shared cofinal window before any terminal $\mathsf{Real}^{\uparrow}$ *or completion seal can be consumed.*

Proof. Start from carrier admission in Definition 7532.1. The only completion-facing row is the shared window W, and it is stored after the stream schedule, regular rational readback, dyadic ledger, and tail-meet rows.

Apply Definition 7532.2. It requires the stream schedules and dyadic ledger to be read before the shared window handoff, so a Real-facing read cannot bypass S, R, D, M_0.

The replay row C and transport row H preserve the same route for downstream consumers, while P and N name the provenance and local certificate. Therefore the route exports a finite mesh and not a quotient completion, selected representative, countable-choice tail, or ambient complete-space witness. □

Theorem 7532.4 (CofinalTailMesh nonescape)**.** *Any accepted* $\mathsf{CofinalTailMesh}^{\uparrow}$ *read is exhausted by* $S, R, D, M_0, W, H, C, P, N$*. It cannot produce quotient equality of streams, a selected regular Cauchy representative, a global cofinal subsequence, countable choice, a completed host limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The carrier definition gives the complete coordinate list. A consumer may inspect the finite stream schedule, regular rational readback, dyadic tolerance ledger, regular Cauchy tail meet, shared cofinal window, transport, replay, provenance, and local naming rows.

The Real-completion route of Definition 7532.3 keeps every value-facing handoff inside that list. Its only terminal-facing row is W, and W is reached through S, R, D, M_0.

The excluded objects would require additional carrier coordinates or an external selection principle. Since neither appears in $M = (S, R, D, M_0, W, H, C, P, N)$, the accepted read remains within the finite NameCert packet. □

Falsifiable prediction: Every accepted $\mathsf{CofinalTailMesh}^{\uparrow}$ read factors through displayed StreamName schedules, RegSeqRat readback, a DyadicRatCore tolerance ledger, a regular Cauchy tail meet, a shared cofinal window, componentwise transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-tail-meet: $\mathsf{CofinalTailMesh}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the common cofinal tail-window mesh consumed before Real and Completion routes inspect a seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CofinalTailMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{CofinalTailMesh}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readback, a DyadicRatCore tolerance ledger, a regular Cauchy tail meet, a shared cofinal window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofinalTailMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7532.1, Definition 7532.2, Definition 7532.3, and Definition 7532.4 seed the finite shared-tail mesh for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofinalTailMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, global cofinal subsequences, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window admission, dyadic tolerance comparison, Real-completion routing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.CofinalTailMeshUp.

Chapter 7533

A Concrete Naming Certificate for $\mathsf{BlackBoxFiberWitness}^{\uparrow}$

The $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ packet realizes the black-box decomposition surface of section 9462.18 as finite NameCert data that keeps visible behavior separate from hidden-fiber opacity. It sits beside classifier-forming learning in chapter 6097, the hard-certificate layer of section 9462.5, the interpretability classifier-novelty route of section 9462.11, formal-verification certified interpretability in section 9462.17, and the certificate-preserving discipline of chapter 481. The packet names a finite witness for behavior support, missing certificate rows, hidden-fiber refusal, and ledger provenance; it is not a semantic oracle for the model internals.

Falsifiable prediction: Deleting the missing-certificate row or identifying the hidden fiber with the visible behavior refutes the $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ carrier.

Independence witness: classifier-forming-learning, hard-certificate-layer, interpretability-classifier-novelty, formal-verification-certified-interpretability, namecert: none is bijective to $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ because this packet simultaneously carries visible behavior, support-candidate, missing-certificate, hidden-fiber, ledger, transport, replay, provenance, and local NameCert rows.

Definition 7533.1 (BlackBoxFiberWitness carrier)**.** *A* $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, S, M, K, L, H, C, P, N)$$

with the following displayed rows:

1. *B is the visible behavior row read from samples, outputs, traces, failure cases, or an observation protocol.*
2. *S is the support-candidate row naming the classifier candidate that supports the behavior.*
3. *M is the missing-certificate row, recording which source, pattern, classifier, stability, or ledger-policy fields are absent or incomplete.*
4. *K is the hidden-fiber row, kept distinct from the visible behavior row and used only as an opacity boundary.*
5. *L is the ledger row recording present evidence, missing fields, and debt for the target (B, S).*
6. *H records componentwise* hsame *transport for the visible behavior, support candidate, missing-certificate, hidden-fiber, ledger, replay, provenance, and local naming rows.*

7. *C records displayed* Cont *replay for opening behavior evidence, checking support, preserving missing-field data, and refusing hidden-fiber identification.*
8. *P is the* Pkg *provenance over* $\mathsf{BlackBoxFiberWitness}^{\uparrow}$*, classifier-forming learning, hard-certificate layers, interpretability classifier novelty, formal-verification certified interpretability,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BlackBoxFiberWitness}^{\uparrow}}$ *row.*

The classifier compares packets only through $B, S, M, K, L, H, C, P, N$. No coordinate identifies the hidden fiber with visible behavior, supplies a complete explanation, or imports model-internal semantic truth.

Theorem 7533.2 (BlackBoxFiberWitness NameCert obligations)**.** *For every accepted* $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ *carrier $F = (B, S, M, K, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BlackBoxFiberWitness}^{\uparrow}}$ *surface consists exactly of visible behavior admission, support-candidate admission, missing-certificate preservation, hidden-fiber separation, ledger accounting, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7533.1. The displayed rows are $B, S, M, K, L, H, C, P, N$, with B and K occupying separate coordinates.

The support and certificate rows are read next. The row S records the classifier candidate supporting B, while M records the certificate fields that remain absent or incomplete.

The ledger row L binds present evidence, missing fields, and debt for the same target. Transport through H and replay through C preserve those distinctions, and P, N only source and name the finite packet. □

Theorem 7533.3 (BlackBoxFiberWitness visible-hidden route)**.** *Every accepted* $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ *read reaches the hidden-fiber boundary only through the finite route*

$$B \longrightarrow S \longrightarrow M \longrightarrow K \longrightarrow L \longrightarrow H, C, P, N.$$

The visible behavior row B and the hidden-fiber row K remain distinct throughout the route, and the support candidate may be consumed only together with the missing-certificate row and ledger row.

Proof. Start with carrier projection. The visible behavior B, support candidate S, missing-certificate row M, hidden-fiber row K, and ledger row L are separate fields.

Use Definition 7533.2. It preserves missing-certificate data and hidden-fiber separation as explicit NameCert obligations, so a consumer cannot turn support evidence into a closed explanation.

Finally replay the route through H, C, P, N. These rows transport and name the same finite fields, not a semantic identification between visible behavior and hidden model fiber. □

Theorem 7533.4 (BlackBoxFiberWitness nonescape)**.** *No accepted* $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ *packet exports a hidden model-internal truth, a complete interpretability certificate, an identification of hidden fiber with visible behavior, or a verification-hardening proof. It exports only the finite rows $B, S, M, K, L, H, C, P, N$ and the visible-hidden route stated above.*

Proof. The carrier of Definition 7533.1 lists the entire accepted inventory. Hidden-fiber opacity is represented by the row K, while certificate debt is represented by M and L.

Apply the visible-hidden route of Definition 7533.3. Every consumer reaches K only after B, S, M and before the structural rows, so the packet cannot bypass missing-certificate data.

The hard-certificate and verification siblings may later harden a certificate, and classifier-novelty siblings may compare explanation states. This packet itself supplies neither a complete certificate nor hidden semantic truth, because those objects are absent from $F = (B, S, M, K, L, H, C, P, N)$. □

Closure status for $\mathsf{NameCert}_{\mathsf{BlackBoxFiberWitness}\uparrow}$.

Constructive story: A $\mathsf{BlackBoxFiberWitness}^{\uparrow}$ packet is generated from visible behavior, support-candidate, missing-certificate, hidden-fiber, ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BlackBoxFiberWitness}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7533.1, Definition 7533.2, Definition 7533.3, and Definition 7533.4 seed the finite visible-hidden black-box witness packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BlackBoxFiberWitness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close hidden model semantics, complete interpretability, verification hardening, classifier novelty, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, missing-certificate preservation, hidden-fiber separation, visible-hidden routing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BlackBoxFiberWitnessUp.

Chapter 7534

A Concrete Naming Certificate for $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$

Following Busemann and Bridson–Haefliger on boundary functions in hyperbolic geometry, the $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ packet realizes the scalar readback surface requested by chapter 9463. It sits after the hyperbolic metric carrier of chapter 3474, the boundary-point packet of chapter 3732, the additive cocycle packet of chapter 4134, the horocycle packet of chapter 3534, and the terminal real seal of chapter 38. The packet names a finite boundary-point, geodesic-ray, metric-difference, Real-seal, and horosphere-readback route; it does not complete the ideal boundary, quotient geodesic rays, choose a global ray representative, or import an ambient curvature model.

Definition 7534.1 (Hyperbolic Busemann function carrier)**.** *A* $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, \Xi, G, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row for the visible disk, geodesic, or metric source.*
2. *Ξ is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-point row toward which the function is read.*
3. *G is the geodesic-ray row. It records the displayed ray window used to compare the point of evaluation with the boundary point Ξ.*
4. *D is the metric-difference row. It stores the finite difference of metric reads that defines the Busemann-function value over the displayed ray window.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the scalar value read from D.*
6. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *readback row. It records the level-set or horosphere-facing surface determined by the same scalar value.*
7. *H records componentwise* hsame *transport for metric, boundary, geodesic-ray, metric-difference, Real-seal, horocycle readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the same function-read route.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{HyperbolicHorocycle}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, \Xi, G, D, E, Q, H, C, P, N$. It has no coordinate for completed ideal-boundary quotients, selected infinite rays, global horosphere foliations, host curvature analysis, physical observer trajectories, Lean verification, or bridge credentials.

Theorem 7534.2 (Hyperbolic Busemann function NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ *carrier*

$$B = (M, \Xi, G, D, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannFunction}^{\uparrow}}$ *surface consists exactly of six finite obligation rows:*

1. *carrier admission for the hyperbolic metric row, boundary-point row, geodesic-ray window, metric-difference row, Real seal, horocycle readback, transport, replay, provenance, and local name;*
2. *common-boundary discipline, requiring G, D, E, Q to be read toward the same boundary row Ξ;*
3. *metric-difference exposure, requiring D to display the distance comparisons through M before any scalar seal is consumed;*
4. *Real-seal order, requiring E to be downstream of M, Ξ, G, D and to expose only the scalar value named by the function row;*
5. *horosphere readback, requiring Q to be determined by the same Ξ and the same sealed scalar value E;*
6. *nonescape, excluding completed ideal-boundary quotients, selected infinite rays, global horosphere foliations, host curvature analysis, physical observer trajectories, Lean verification, and bridge credentials.*

No Hyperbolic Busemann function obligation is stored outside these rows.

Proof. Project the carrier of Definition 7534.1. The tuple $M, \Xi, G, D, E, Q, H, C, P, N$ is the whole public surface, so carrier admission is exactly admission of those rows.

The common-boundary obligation follows from Ξ and G. The geodesic-ray window is read toward the same boundary point that the function names, so a consumer cannot detach the scalar read from its boundary source.

The metric-difference and Real-seal obligations are recorded by D and E. The row D displays the metric comparisons through M, and E seals only the scalar value supplied by that displayed difference.

Finally Q, H, C, P, N preserve the same finite function read. The horocycle row is downstream of the boundary point and scalar seal, while transport, replay, provenance, and naming add no coordinate for quotient boundaries, selected rays, global horosphere foliations, host curvature theorems, physical observer trajectories, Lean credentials, or bridge credentials. □

Theorem 7534.3 (Hyperbolic Busemann function boundary handoff)**.** *Every boundary-facing or horosphere-facing consumer of an accepted* $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ *carrier factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto G, D \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{HyperbolicHorocycle}^{\uparrow}.$$

The handoff is therefore a displayed scalar readback between Busemann-boundary data, Busemann-cocycle consumers, and horosphere-level consumers, not a replacement for the boundary packet or the additive cocycle packet.

Proof. Begin with the metric row M and boundary row Ξ. They determine the visible source and the boundary point toward which the function is evaluated.

Read the geodesic-ray row G and metric-difference row D next. These rows supply the finite comparison window and the distance difference before any scalar value is public.

The Real seal E exports that scalar value, and the horocycle row Q reads its level surface through the same boundary point. The cocycle packet may consume the scalar read as one boundary comparison, and horosphere-facing consumers may consume the level-set row, but neither route obtains a completed ideal-boundary quotient, selected ray representative, global foliation, host curvature theorem, or physical observer trajectory. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ scalar read exposes the $\mathsf{HyperbolicMetric}^{\uparrow}$ metric row, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ boundary row, geodesic-ray window, metric-difference row, $\mathsf{Real}^{\uparrow}$ seal, and $\mathsf{HyperbolicHorocycle}^{\uparrow}$ readback before any cocycle-facing or horosphere-facing consumer may inspect the handoff.

Independence witness: hyperbolic-metric, hyperbolic-busemann-boundary, hyperbolic-busemann-cocycle, hyperbolic-horocycle, real: $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a boundary point, a geodesic-ray window, metric-difference rows, a Real scalar seal, horocycle readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows while refusing quotient boundaries, selected rays, and global horosphere foliations.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBusemannFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBusemannFunction}^{\uparrow}$ packet is generated from HyperbolicMetric rows, HyperbolicBusemannBoundary rows, geodesic-ray windows, metric-difference rows, RealUp scalar seals, HyperbolicHorocycle readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7534.1, Definition 7534.2, and Definition 7534.3 seed the finite scalar readback route from boundary-point and geodesic-ray data to Real-sealed horosphere consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBusemannFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed ideal-boundary quotients, selected infinite rays, global horosphere foliations, host curvature analysis, or physical observer dynamics.

Upgrade path: Obligation closure requires checked carrier admission, common-boundary discipline, metric-difference exposure, Real-seal order, horosphere readback, and nonescape for BEDC.Derived.HyperbolicBusemannFunctionUp.

Chapter 7535

A Concrete Naming Certificate for $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and Cauchy filters, the $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ packet records the finite uniform-filter diagonal by which Cauchy-filter rows are read through StreamName windows, regular rational readback, dyadic tolerance ledgers, and the Real seal. It sits next to the finite diagonal interface of chapter 6873, the window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the completed real-name seal of chapter 38. The chapter names a non-quotient uniform-filter diagonal interface only; it does not choose a filter representative, select a limit, quotient streams, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7535.1 (Uniform Cauchy-filter diagonal carrier)**.** *A* $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, W, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the uniform Cauchy-filter row, recording finite entourage requests and the corresponding Cauchy-filter response rows before any diagonal consumer reads the packet;*
2. *W is the finite diagonal-window row, selecting the bounded family of window indices inspected by the uniform route;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger that exposes the named stream windows used by W;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic error bounds used to compare the uniform-filter rows with the regular rational readback;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational readback and dyadic tolerance ledger are present;*
7. *H records componentwise* hsame *transport for $F, W, S, Q, D, R, C, P, N$;*
8. *C records displayed* Cont *replay from a finite uniform Cauchy-filter request through the diagonal window, StreamName window ledger, RegSeqRat readback, DyadicRatCore tolerance ledger, and Real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$, $\mathsf{CauchyFilterDiagonal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, W, S, Q, D, R, H, C, P, N$. The carrier has no coordinate for quotient filters, selected representatives, chosen limits, countable-choice schedules, quotient stream equality, host real equality, or ambient Real completeness.

Theorem 7535.2 (Uniform Cauchy-filter diagonal NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ *carrier $U = (F, W, S, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}}$ *surface consists exactly of carrier admission, uniform Cauchy-filter exposure, finite diagonal-window routing, StreamName window access, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may read a Real-facing completion seal before these displayed rows are present.*

Proof. Carrier admission is projection from Definition 7535.1. The accepted packet exposes exactly the rows $F, W, S, Q, D, R, H, C, P, N$, so every local obligation must be read from those finite rows.

The uniform-filter and diagonal-window obligations are read from F and W. The row F exposes only displayed uniform Cauchy-filter requests, while W fixes the finite window family through which the diagonal observation is allowed to pass.

The readback route is then forced by S, Q, D, R. StreamName windows are exposed by S, regular rational data are read by Q, dyadic tolerances are accounted for by D, and the Real-facing seal appears only at R after those ledgers are present.

Transport, replay, provenance, and local naming are structural. Componentwise hsame in H preserves the displayed rows, Cont replay in C repeats the same route, and P, N add provenance and local naming without adding a quotient, selector, choice schedule, stream equality, host equality, or ambient completeness row. □

Theorem 7535.3 (Uniform diagonal-window subsequence route)**.** *Every* $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ *or Real-facing completion consumer that reads an accepted* $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ *packet receives the same finite diagonal-window subsequence*

$$F, W, S, Q, D, R$$

before it can consume the displayed $\mathsf{Real}^{\uparrow}$ *seal. The route factors through chapter 126, chapter 301, and chapter 291; it exports no quotient filter, selected representative, selected limit, countable-choice schedule, quotient stream equality, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $U = (F, W, S, Q, D, R, H, C, P, N)$. The only rows available to a downstream consumer are the displayed carrier rows and their transport, replay, provenance, and local naming data.

The diagonal-window subsequence is therefore fixed by W after the uniform Cauchy-filter row F is exposed. A consumer cannot bypass W, because the StreamName row S and the regular rational row Q are attached to the windows selected by W.

The tolerance and seal part is read next. The dyadic ledger D records the tolerance bounds used by the regular rational readback, and the Real seal R is consumed only after Q and D are present.

Finally, H, C, P, N preserve this same route under transport, replay, provenance, and local naming. Since no other coordinate exists, the handoff to $\mathsf{CauchyFilterDiagonal}^{\uparrow}$ and to Real-facing completion consumers remains the finite route F, W, S, Q, D, R and cannot export the excluded quotient, choice, equality, or completeness data. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ consumer displays a uniform Cauchy-filter row, a finite diagonal-window row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any completion-facing seal is consumed.

Independence witness: cauchy-filter-diagonal, streamname, regseqrat, dyadicratcore, real: UniformCauchyFilterD is not bijective to any listed sibling because it packages uniform Cauchy-filter exposure and a finite diagonal-window subsequence together with dyadic tolerance accounting before the Real seal is public.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7535.1, Definition 7535.2, and Definition 7535.3 seed the uniform Cauchy-filter diagonal route through finite windows, regular rational readback, dyadic tolerance ledgers, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient filters, selected representatives, selected limits, countable choice, quotient stream equality, host real equality, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier exposure, uniform Cauchy-filter routing, diagonal-window subsequence routing, StreamName access, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal admission, transport replay, provenance, and local naming for BEDC.Derived.UniformCauchyFilterDiagonalUp.

Constructive story: A $\mathsf{UniformCauchyFilterDiagonal}^{\uparrow}$ packet is generated from uniform Cauchy-filter rows, a finite diagonal-window row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed continuation replay, package provenance, and local naming evidence.

Chapter 7536

A Concrete Naming Certificate for CauchyBornologyDuality$^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion, and Bourbaki and Hogbe-Nlend on bornological control, the CauchyBornologyDuality$^{\uparrow}$ packet records the finite interface where boundedness tests and Cauchy-completion reads determine one another without passing to quotient completions or selected limits. It sits after the bounded-uniform Cauchy surface of chapter 7528, the Cauchy-filter carrier of chapter 333, the metric-completion surface of chapter 1506, the uniform-space entourage discipline of chapter 339, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the dual passage between bounded Cauchy data and completion-facing reads as finite NameCert evidence, not as ambient Real completeness.

Definition 7536.1 (Cauchy bornology duality carrier)**.** *A* CauchyBornologyDuality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, F, U, M, W, R, A, C, H, P, N)$$

with the following displayed rows:

1. *B is the bornological boundedness row read from bounded subsets or bounded events;*
2. *F is the* CauchyFilter$^{\uparrow}$ *row that turns bounded Cauchy tests into finite eventuality requests;*
3. *U is the* UniformSpace$^{\uparrow}$ *entourage row that supplies the uniform reading of the same Cauchy data;*
4. *M is the* MetricCompletion$^{\uparrow}$ *row through which completion-facing consumers inspect the resulting route;*
5. *W is the* StreamName$^{\uparrow}$ *finite-window row used to read Cauchy observations;*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the window schedule;*
7. *A is the terminal* Real$^{\uparrow}$ *seal for the displayed tolerance and distance reads;*
8. *C is the compatibility row asserting that the bornological boundedness tests and completion-facing Cauchy reads replay through the same bounded-uniform route of chapter 7528;*
9. *H stores componentwise* hsame *transport for the boundedness, Cauchy-filter, uniform, completion, window, readback, Real-seal, and compatibility rows;*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyBornologyDuality}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBornologyDuality}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected limit, countable choice, host equality of filters, trichotomy over distances, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7536.2 (Cauchy bornology duality NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBornologyDuality}^{\uparrow}$ *carrier*

$$D = (B, F, U, M, W, R, A, C, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyBornologyDuality}^{\uparrow}}$ *surface consists exactly of carrier admission, bornological boundedness, Cauchy-filter eventuality, uniform entourage stability, metric-completion routing, finite StreamName windows, RegSeqRat readback, Real-seal tolerance, bounded-completion compatibility, componentwise* hsame *transport,* Pkg *provenance, and local naming. A consumer may pass from boundedness tests to completion reads, or from completion reads back to bounded Cauchy tests, only through these rows.*

Proof. Project the carrier of Definition 7536.1. The packet exposes $B, F, U, M, W, R, A, C, H, P, N$ as the whole local surface, so the boundedness, Cauchy-filter, uniform, completion, finite-window, readback, Real-seal, compatibility, transport, provenance, and naming rows are all displayed finite BEDC data.

The forward direction reads bounded Cauchy tests through B, F, U before any completion-facing row is available. The compatibility row C ties that route to the bounded-uniform Cauchy packet of chapter 7528, so the metric-completion row M can only consume the same displayed bounded-uniform route.

The reverse direction starts from a completion-facing read through M, W, R, A. The finite StreamName windows, RegSeqRat readback, and Real seal recover only the bounded Cauchy observations stored in B, F, U, C, not a chosen limit point or quotient representative.

Finally inspect H, P, N. Componentwise transport, provenance, and local naming preserve the same finite packet. Since the carrier has no quotient-completion, selected-limit, countable-choice, host-filter-equality, trichotomy, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7536.3 (Cauchy bornology duality completion route)**.** *Every completion-facing* $\mathsf{CauchyBornologyDuality}^{\uparrow}$ *consumer factors through*

$\mathsf{CauchyBornologicalUniformity}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, Rea

before it exports a completion seal. The route is dual in the finite BEDC sense: boundedness tests determine exactly the Cauchy-completion reads carried by the packet, and completion reads reflect back only to those bounded Cauchy tests. It does not export quotient completions, selected representatives, countable choice, or ambient Real completeness.

Proof. Use the NameCert obligations of Definition 7536.2. They force every accepted consumer to expose boundedness, Cauchy-filter, uniform, completion, finite-window, readback, Real-seal, compatibility, transport, provenance, and local naming rows.

The bounded-uniform route of chapter 7528 supplies the common interface. Thus a boundedness-to-completion read and a completion-to-boundedness read share the same B, F, U, C spine before the metric-completion row M reaches the stream, regular rational, and Real-seal rows.

The excluded endpoints are absent by carrier inspection. No row stores a quotient completion, selected representative, countable-choice schedule, or ambient completeness theorem, so the completion seal is only the displayed bounded Cauchy route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyBornologyDuality}^{\uparrow}$ completion consumer displays the boundedness row, $\mathsf{CauchyFilter}^{\uparrow}$ row, $\mathsf{UniformSpace}^{\uparrow}$ row, $\mathsf{MetricCompletion}^{\uparrow}$ row, $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{Real}^{\uparrow}$ seal, compatibility row, transport, provenance, and local NameCert before a completion seal is exported.

Independence witness: cauchy-bornological-uniformity, cauchyfilter, metriccompletion, uniformspace, streamname, regseqrat, real: $\mathsf{CauchyBornologyDuality}^{\uparrow}$ is not bijective to any listed sibling because it packages the two-way boundedness and completion readback route as one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBornologyDuality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBornologyDuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7536.1, Definition 7536.2, and Definition 7536.3 seed the boundedness and completion readback interface over $\mathsf{CauchyBornologicalUniformity}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBornologyDuality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient completion, selected limits, countable choice, host filter equality, trichotomy, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, boundedness-to-completion routing, completion-to-boundedness readback, compatibility, transport, provenance, local naming, and ledger non-escape for BEDC.Derived.CauchyBornologyDualit

Constructive story: A $\mathsf{CauchyBornologyDuality}^{\uparrow}$ packet is generated from bornological boundedness rows, Cauchy-filter eventuality rows, uniform entourage rows, metric-completion routing, finite stream windows, regular rational readback, Real-seal tolerance, bounded-completion compatibility, componentwise transport, package provenance, and local naming evidence.

Chapter 7537

Birkhoff Distributive Lattice NameCert Construction

Following Birkhoff and Davey–Priestley, the $\mathsf{BirkhoffDistributiveLattice}^{\uparrow}$ packet records the finite representation surface for distributive lattices before any Stone-style, Boolean, or order-facing consumer may read the object as a represented lattice. The packet sits after the order carrier of chapter 53, the meet-join surface of chapter 55, the bounded endpoint rows of chapter 6501, the Boolean comparison envelope of chapter 3733, and the prime-filter dual route of chapter 261. It is a finite NameCert reconstruction of the Birkhoff distributive-lattice handoff, not an import of host algebraic representation theorems, choice-selected prime filters, quotient lattice equality, or classical completeness.

Definition 7537.1 (Birkhoff distributive lattice carrier)**.** *A* $\mathsf{BirkhoffDistributiveLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (P, L, E, J, M, D, F, S, H, C, Q, N)$$

with the following visible rows:

1. *P is the* $\mathsf{Poset}^{\uparrow}$ *order row naming the displayed carrier order.*
2. *L is the* $\mathsf{Lattice}^{\uparrow}$ *meet-join row over the same carrier.*
3. *E is the* $\mathsf{BoundedLattice}^{\uparrow}$ *endpoint row exposing the displayed bottom and top entries.*
4. *J is the finite join-irreducible ledger used by the representation read.*
5. *M is the finite meet-irreducible ledger used for the dual read.*
6. *D is the distributivity witness row, read only through the displayed meet and join coordinates.*
7. *F is the finite down-set representation row attached to J and the order row P.*
8. *S is the* $\mathsf{StoneDuality}^{\uparrow}$ *and* $\mathsf{BooleanAlgebra}^{\uparrow}$ *sibling handoff row for Boolean comparison and prime-filter inspection.*
9. *H records componentwise* hsame *transport for P, L, E, J, M, D, F, S and the structural rows.*
10. *C records displayed* Cont *replay for opening the order, lattice, endpoint, irreducible, representation, and sibling handoff rows.*
11. *Q is the* Pkg *provenance over* $\mathsf{BirkhoffDistributiveLattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{BoundedLattice}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{StoneDuality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. N is the local $\mathsf{NameCert}_{\mathsf{BirkhoffDistributiveLattice}^{\uparrow}}$ *row.*
The carrier stores no host lattice quotient, no choice-selected prime ideal, no ambient powerset equality, no classical completeness theorem, and no Boolean algebra replacement for the displayed distributive-lattice rows.

Theorem 7537.2 (Birkhoff distributive lattice NameCert obligations)**.** *For every accepted* BirkhoffDistributiveLatti *carrier $B = (P, L, E, J, M, D, F, S, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{BirkhoffDistributiveLattice}^{\uparrow}}$ *surface consists exactly of carrier admission, order exposure through P, meet-join exposure through L, bounded endpoint exposure through E, finite irreducible ledgers J and M, distributivity inspection through D, finite down-set representation through F, Boolean and Stone sibling handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through Q, and local naming through N.*

No accepted read may replace these rows by host distributive-lattice equality, a selected prime-filter family, classical Stone representation, unbounded ideal completion, or an ambient Boolean algebra quotient.

Proof. Project the carrier of Definition 7537.1. Its algebraic rows are the order row P, the lattice row L, the endpoint row E, the irreducible ledgers J, M, the distributivity row D, the representation row F, and the sibling route S; its structural rows are H, C, Q, N.

The order-facing obligations are supplied by the $\mathsf{Poset}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, and $\mathsf{BoundedLattice}^{\uparrow}$ sibling chapters. They make the carrier order, meet-join operations, and endpoints visible before any representation read is consumed.

The representation-facing obligations then read J, M, D, F as finite ledgers. Distributivity is inspected through the displayed meet and join rows, while the down-set row remains attached to the finite irreducible ledger rather than becoming an ambient powerset quotient.

Finally the Boolean and Stone sibling handoff S is only a route through chapter 3733 and chapter 261. Transport, replay, provenance, and local naming preserve that finite route, so the packet exports the listed NameCert surface and no host representation theorem. □

Theorem 7537.3 (Birkhoff distributive lattice sibling handoff)**.** *Every order-facing, Boolean-facing, or Stone-facing consumer of an accepted* $\mathsf{BirkhoffDistributiveLattice}^{\uparrow}$ *carrier must first factor through*

$$\mathsf{Poset}^{\uparrow} \longrightarrow \mathsf{Lattice}^{\uparrow} \longrightarrow \mathsf{BoundedLattice}^{\uparrow} \longrightarrow \mathsf{BooleanAlgebra}^{\uparrow} \longrightarrow \mathsf{StoneDuality}^{\uparrow}$$

as displayed sibling rows attached to P, L, E, S. The finite irreducible ledgers J, M, distributivity row D, down-set representation row F, componentwise transport H, replay C, provenance Q, and local name N remain visible throughout the handoff.

The route does not claim a general representation theorem for all host lattices, a choice-selected spectrum, quotient equality of down-sets, classical prime-filter separation, or Boolean replacement of the original carrier.

Proof. Start with the NameCert obligations of Definition 7537.2. They require the order, lattice, bounded endpoint, irreducible, distributivity, representation, sibling handoff, transport, replay, provenance, and local naming rows to be visible together.

For order-facing consumers, project P, L, E and use the sibling chapters chapter 53, chapter 55, and chapter 6501. These rows expose order, meet, join, bottom, and top data before a representation row can be read.

For Boolean-facing and Stone-facing consumers, project S together with J, M, D, F. The Boolean and Stone sibling chapters provide comparison and duality routes, but the irreducible ledgers and down-set row remain part of the carrier and are not discharged by those routes.

Thus every consumer sees the displayed sibling chain and the local representation data before using the Birkhoff packet. Since no coordinate stores a host quotient, selected spectrum, prime-filter choice, or classical completeness theorem, no such endpoint is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffDistributiveLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffDistributiveLattice}^{\uparrow}$ packet is generated from Poset, Lattice, BoundedLattice, BooleanAlgebra, and StoneDuality sibling rows, finite irreducible ledgers, a distributivity row, a down-set representation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffDistributiveLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7537.1, Definition 7537.2, and Definition 7537.3 seed the finite distributive-lattice representation packet and its order, Boolean, and Stone sibling route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffDistributiveLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distributive-lattice representation, choice-selected spectra, quotient equality of down-sets, classical Stone separation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, irreducible-ledger exactness, distributivity-row preservation, down-set representation routing, sibling handoff, transport, replay, provenance, and local naming for BEDC.Derived.BirkhoffDistributiveLatticeUp.

Chapter 7538

A Concrete Naming Certificate for $\mathsf{RoundedRealDomain}^{\uparrow}$

Following Bishop–Bridges constructive analysis and domain-theoretic real approximation, the $\mathsf{RoundedRealDomain}^{\uparrow}$ packet records rounded real approximants as finite NameCert data before any Real or Completion consumer may treat them as completed reals. It sits between the formal-ball surface of chapter 1510, the interval-domain carrier of chapter 1543, the way-below refinement of chapter 1545, the lower-upper located-cut boundary of chapter 2087, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a rounded approximation surface; it is not a quotient real, not a host supremum, not a selected representative, and not an ambient completeness principle.

Definition 7538.1 (Rounded real domain carrier)**.** *A* $\mathsf{RoundedRealDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, I, W, K, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FormalBall}^{\uparrow}$ *row, recording the center-radius request and the rounded inclusion budget inspected by the approximant.*
2. *I is the* $\mathsf{IntervalDomain}^{\uparrow}$ *row, displaying the current interval-domain cell to which the formal ball is attached.*
3. *W is the* $\mathsf{IntervalDomainWayBelow}^{\uparrow}$ *row, recording the strict containment margin by which the rounded cell refines a coarser interval-domain observation.*
4. *K is the* $\mathsf{LowerUpperRealCut}^{\uparrow}$ *row, keeping the rounded interval adjacent to the lower-upper cut boundary used by Real-facing consumers.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, storing the dyadic center, radius, slack, endpoint, and comparison data used by F, I, W, K.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which endpoint and radius observations are inspected.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the same windows and dyadic budgets.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after the formal ball, interval-domain, way-below, cut-boundary, dyadic, stream, and regular readback rows have been displayed.*

9. *H records componentwise* hsame *transport for F, I, W, K, Q, S, R, E and the structural rows.*
10. *C records displayed* Cont *replay for the same rounded approximation route.*
11. *P is the* Pkg *provenance over* $\mathsf{RoundedRealDomain}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{LowerUpperRealCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RoundedRealDomain}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $F, I, W, K, Q, S, R, E, H, C, P, N$. It contains no coordinate for quotient real equality, host supremum, trichotomy, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7538.2 (Rounded real domain NameCert obligations)**.** *For an accepted* $\mathsf{RoundedRealDomain}^{\uparrow}$ *carrier*

$$D = (F, I, W, K, Q, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RoundedRealDomain}^{\uparrow}}$ *surface consists exactly of carrier admission, formal-ball rounding visibility, interval-domain attachment, way-below margin stability, lower-upper cut boundary visibility, dyadic exactness, finite-window scheduling, regular rational readback, terminal real-seal non-escape, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7538.1. The accepted packet exposes exactly the formal-ball row, interval-domain row, way-below row, lower-upper cut row, dyadic ledger, stream window, regular readback, real seal, and structural rows.

The rounded approximation rows are read in order. The formal-ball row F supplies the radius request, I attaches it to the interval-domain carrier, and W records the strict way-below refinement that keeps the rounded cell inside the displayed approximation route.

The cut and readback rows then prevent escape. The lower-upper cut row K keeps the approximant adjacent to the two-sided located boundary, while Q, S, R provide the dyadic, finite-window, and regular rational reads consumed before the seal row E.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient, host-supremum, trichotomy, choice, selected-representative, or completeness coordinate, the local certificate cannot export those principles. □

Theorem 7538.3 (Rounded real domain cut handoff)**.** *Let*

$$D = (F, I, W, K, Q, S, R, E, H, C, P, N)$$

be an accepted $\mathsf{RoundedRealDomain}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$*-facing or Completion-facing read of D factors through the displayed route*

$\mathsf{FormalBall}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, $\mathsf{IntervalDomainWayBelow}^{\uparrow}$, $\mathsf{LowerUpperRealCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Re

Thus a rounded real-domain approximant reaches the real seal only by passing through formal-ball rounding data, interval-domain containment, way-below margin evidence, the lower-upper cut boundary, dyadic tolerance rows, finite windows, regular rational readback, and the structural naming rows. It does not import quotient reals, host suprema, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the formal-ball and interval-domain rows. The row F records the rounded center-radius request, and the row I supplies the displayed interval-domain cell that the request is allowed to refine.

Next read the way-below and lower-upper cut rows. The row W supplies strict containment for the rounded cell, and the row K keeps the same approximation adjacent to the lower-upper cut boundary before any Real-facing seal is consumed.

Then read the arithmetic and observation rows. The dyadic ledger Q records the endpoint and radius budgets, S schedules the finite observations, and R provides the regular rational readback for the same windows.

The seal row E is downstream of those rows, and H, C, P, N only transport, replay, source, and name the displayed route. Therefore every real or completion handoff factors through the stated finite tuple and cannot project a quotient real, host supremum, selected representative, choice principle, trichotomy decision, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RoundedRealDomain}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoundedRealDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7538.1, Definition 7538.2, and Definition 7538.3 seed the finite rounded real-domain approximation surface over formal balls, interval-domain cells, way-below refinements, lower-upper cuts, dyadic ledgers, finite windows, regular readbacks, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoundedRealDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, host suprema, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{RoundedRealDomain}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, formal-ball rounding visibility, interval-domain attachment, way-below margin stability, lower-upper cut boundary visibility, dyadic exactness, finite-window scheduling, regular readback, real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RoundedRealDomainUp.

Constructive story: A $\mathsf{RoundedRealDomain}^{\uparrow}$ packet is generated from FormalBall, IntervalDomain, IntervalDomainWayBelow, LowerUpperRealCut, DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Chapter 7539

A Concrete Naming Certificate for $\mathsf{MenelausTheorem}^{\uparrow}$

Following Menelaus and Coxeter-style projective geometry, the $\mathsf{MenelausTheorem}^{\uparrow}$ packet records the finite collinearity and directed-ratio certificate dual to the concurrency certificate of chapter 3509. It sits over the affine coordinate carrier of chapter 206, the projective incidence boundary of chapter 207, the rational ratio ledger of chapter 37, and the terminal real comparison surface of chapter 38. The packet names one displayed triangle, one transversal line, and three side-intersection witnesses as finite BEDC data; it is not a host projective theorem, a selected coordinate chart, an unrestricted orientation principle, or an ambient completeness claim for $\mathsf{Real}^{\uparrow}$.

Definition 7539.1 (MenelausTheorem carrier)**.** *A* $\mathsf{MenelausTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, P, L, I, R, Q, H, C, G, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AffineSpace}^{\uparrow}$ *triangle row, including three displayed vertices and the affine side carriers on which ratios are read.*
2. *P is the* $\mathsf{ProjectiveSpace}^{\uparrow}$ *incidence row carrying the projective line and side-completion data needed to treat parallel affine cases uniformly.*
3. *L is the transversal-line row, displayed as a finite incidence object rather than as a host subset of points.*
4. *I records the three side-intersection witnesses, including the permitted at-infinity branch supplied by P.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *directed-ratio ledger for the three side cuts, with numerator, denominator, sign, and nonzero-side rows visible.*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *readback row used only to compare the terminal product relation after the rational ledger has been displayed.*
7. *H records componentwise* hsame *transport for the affine triangle, projective incidence, transversal, intersections, directed ratios, and real readback.*
8. *C is the displayed* Cont *replay of the route from affine incidence through projective completion and rational ratio multiplication to the real-facing comparison.*

9. *G is the* Pkg *provenance over* MenelausTheorem$^{\uparrow}$, Ceva$^{\uparrow}$, AffineSpace$^{\uparrow}$, ProjectiveSpace$^{\uparrow}$, Rat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MenelausTheorem}^{\uparrow}}$ *row.*

The classifier accepts only packets exposing all ten rows. It has no coordinate for a hidden projective model, selected affine chart, untracked signed length, quotient real equality, or detached Real$^{\uparrow}$ *completeness theorem.*

Theorem 7539.2 (MenelausTheorem NameCert obligations)**.** *For every accepted* MenelausTheorem$^{\uparrow}$ *carrier $M = (A, P, L, I, R, Q, H, C, G, N)$, the local* NameCert$_{\text{MenelausTheorem}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the displayed affine triangle, projective incidence boundary, transversal line, side-intersection witnesses, directed-ratio ledger, real readback, transport, replay, provenance, and local name;*
2. *incidence exactness, requiring the three side intersections in I to be read through A, P, L before any ratio row is consumed;*
3. *ratio exactness, requiring every directed ratio in R to expose its* Rat$^{\uparrow}$ *numerator, denominator, sign, and nonzero-side rows before the product comparison is read;*
4. *real-seal handoff, requiring the* Real$^{\uparrow}$ *row Q to be downstream of R and never a replacement for the rational ratio ledger;*
5. *Ceva companion separation, recording that chapter 3509 supplies a concurrency route while this packet supplies the transversal-collinearity route;*
6. *ledger non-escape, excluding hidden projective models, selected charts, host orientation, quotient real equality, countable choice, and detached ambient completeness.*

No Menelaus obligation is stored outside $A, P, L, I, R, Q, H, C, G, N$.

Proof. Carrier admission is projection from Definition 7539.1. The ten rows list the triangle, projective boundary, transversal, intersections, directed ratios, real readback, transport, replay, provenance, and local naming data available to the certificate.

Incidence exactness is forced before ratio formation. The transversal row L and side-intersection row I can be read only against the affine triangle A and the projective incidence boundary P, so no ratio row is formed from an untracked host line.

The ratio ledger is then local to R. Each directed ratio exposes rational numerator, denominator, sign, and nonzero-side rows before the terminal product comparison reaches Q.

Finally compare with the Ceva companion. The provenance row G points to the concurrency certificate of chapter 3509, while the present packet keeps the transversal-collinearity route separate. Since Q, H, C, G, N only read, transport, replay, source, and name the displayed route, the certificate exports none of the refused hidden projective, chart-selection, quotient-real, choice, or ambient-completeness data. □

Closure status for NameCert$_{\text{MenelausTheorem}^{\uparrow}}$**.**

Constructive story: A MenelausTheorem$^{\uparrow}$ packet is generated from an affine triangle, projective incidence boundary, transversal line, side-intersection witnesses, directed rational ratios, real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MenelausTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 7539.1 and Definition 7539.2 seed the finite transversal-collinearity certificate over Ceva$^{\uparrow}$, AffineSpace$^{\uparrow}$, ProjectiveSpace$^{\uparrow}$, Rat$^{\uparrow}$, and Real$^{\uparrow}$ rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MenelausTheorem}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close Lean verification, bridge checking, full projective incidence geometry, selected affine charts, quotient real equality, countable choice, or ambient Real$^{\uparrow}$ completeness.
Upgrade path: Scoped closure requires checked incidence exactness, directed-ratio exactness, real-seal handoff, Ceva companion separation, transport, replay, provenance, and local naming for BEDC.Derived.MenelausTheoremUp.

Chapter 7540

A Concrete Naming Certificate for $\mathsf{MetricMidpointConvexity}^{\uparrow}$

Following Menger and Busemann, the $\mathsf{MetricMidpointConvexity}^{\uparrow}$ packet records the finite midpoint-convexity surface for a displayed metric carrier before any ambient geodesic or convexity theorem is read. It sits over the metric carrier of chapter 57, the real-valued distance comparison row used by $\mathsf{RealMetric}^{\uparrow}$, the geodesic segment route of chapter 2213, the convex-set membership boundary of chapter 208, and the regular-Cauchy midpoint packet of chapter 1670. The packet names midpoint witnesses and distance ledgers as finite BEDC rows; it does not assert host midpoint uniqueness, open-cover compactness, selected geodesics, quotient point equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7540.1 (Metric midpoint convexity carrier)**.** *A* $\mathsf{MetricMidpointConvexity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, R, G, V, W, D, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *carrier row, including the point classifier, distance request surface, and metric-law ledger used by all midpoint reads.*
2. *R is the* $\mathsf{RealMetric}^{\uparrow}$ *distance row, recording the real-valued distance comparison only through finite rational or dyadic observations.*
3. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *segment row that displays the two endpoints and the inspected midpoint witness as geodesic data, not as a host path choice.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *membership row for the inspected subset, including endpoint admission and midpoint admission as visible convexity-ledger entries.*
5. *W is the* $\mathsf{RegularCauchyMidpoint}^{\uparrow}$ *row that supplies the finite regular-Cauchy midpoint window read by Real-facing consumers.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the two endpoint distances, the midpoint distance comparison, and the convexity admission budget.*
7. *H records componentwise* hsame *transport for metric, distance, geodesic, convex-membership, midpoint-window, dyadic-ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a midpoint-convexity request through X, R, G, V, W, D and then to H, P, N.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricMidpointConvexity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RegularCauchyMidpoint}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricMidpointConvexity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, R, G, V, W, D, H, C, P, N$. It has no coordinate for a selected global geodesic, a quotient point equality, a host convexity principle, an open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7540.2 (Metric midpoint convexity NameCert obligations)**.** *For every accepted* MetricMidpointConvexity *carrier $M = (X, R, G, V, W, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricMidpointConvexity}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric row, real-distance row, geodesic midpoint row, convex-set membership row, regular-Cauchy midpoint window, dyadic tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It also requires endpoint exposure through X, distance exactness through R, D, midpoint witness exposure through G, W, convex-membership exactness through V, and non-escape for selected geodesics, quotient point equality, host convexity, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7540.1. The rows $X, R, G, V, W, D, H, C, P, N$ are the complete accepted inventory, so every local naming obligation must be read from those rows.

The midpoint witness is finite. The metric row X exposes the endpoints and point classifier, the geodesic row G exposes the inspected midpoint witness, and the regular-Cauchy midpoint row W gives the Real-facing finite window for the same midpoint read.

The convexity and distance ledgers are then local. The row V records endpoint and midpoint membership, while R and D record the real-valued distance comparisons and dyadic tolerance budget before any consumer can inspect a terminal real-distance value.

Finally H, C, P, N transport, replay, source, and name the displayed route. Since the packet contains no row for a selected global geodesic, quotient point equality, host convexity theorem, open-cover compactness, or ambient completeness, none of those claims can be exported by the local certificate. □

Falsifiable prediction: Every accepted $\mathsf{MetricMidpointConvexity}^{\uparrow}$ read exposes MetricSpace, RealMetric, GeodesicMetric, ConvexSet, RegularCauchyMidpoint, DyadicRatCore, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a midpoint-convexity consumer can inspect the packet.

Independence witness: metricspace, realmetric, geodesicmetric, convexset, regular-cauchy-midpoint: $\mathsf{MetricMidpointConvexity}^{\uparrow}$ is not bijective to any listed sibling because it binds metric endpoints, real-distance comparisons, a geodesic midpoint witness, convex-set membership, regular-Cauchy midpoint windows, dyadic tolerances, transport, replay, provenance, and local naming as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricMidpointConvexity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricMidpointConvexity}^{\uparrow}$ packet is generated from a MetricSpace carrier row, a RealMetric distance row, a GeodesicMetric midpoint witness, ConvexSet membership rows, a RegularCauchyMidpoint window, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricMidpointConvexity}^{\uparrow}}$, seed)

Scope closed: Definition 7540.1 and Definition 7540.2 seed the finite midpoint-convexity certificate over MetricSpace, RealMetric, GeodesicMetric, ConvexSet, RegularCauchyMidpoint, and DyadicRatCore rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricMidpointConvexity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Real completeness, open-cover compactness, selected geodesics, host midpoint uniqueness, quotient point equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, midpoint witness exactness, distance-ledger exactness, convex-membership exactness, transport, replay, provenance, and local naming for BEDC.Derived.MetricMidpointConvexityUp.

Chapter 7541

A Concrete Naming Certificate for $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$

Following Heine–Cantor finite-cover arguments in constructive analysis, the $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ packet records the finite fold that turns a compact finite cover and pointwise modulus rows into one tolerance-only uniform-modulus ledger. It realizes the finite ProbeBundle lower-bound fold of Definition 9237.5 in chapter 9237. The packet sits after the compact finite-net surface of chapter 60, the continuous-map route of chapter 130, the finite Lebesgue-number ledger of chapter 452, the rational lower-bound route of chapter 37, and the uniform-modulus consumer of chapter 369. It is a finite cover-fold certificate, not a selected global modulus functional, open-cover compactness theorem, quotient function equality, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 7541.1 (Compact uniform finite-cover fold carrier)**.** *A* $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, L, B, R, U, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-cover source row, exposing one finite* ProbeBundle*, its centers, coverage witnesses, and nonempty spine.*
2. *F is the continuous-map pointwise-modulus row over the same source carrier, with local precision histories attached to the bundled centers.*
3. *L is the finite Lebesgue-number or subordinate-radius row tying each bundled center to a positive cover radius.*
4. *B is the finite lower-bound fold row over the bundled positive radius histories.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row used by the fold comparisons.*
6. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *row receiving the tolerance-only precision history produced by B.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for center observations, local-modulus reads, radius comparisons, and uniform-modulus output.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to Real-facing tolerance and output estimates.*

9. *H records componentwise* hsame *transport for the compact cover, continuous-map row, Lebesgue-number row, lower-bound fold, rational readback, uniform-modulus output, finite windows, regular readbacks, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay through $K, F, L, B, R, U, W, Q, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, B, R, U, W, Q, H, C, P, N$. It has no coordinate for an external global-modulus selector, arbitrary open-cover compactness, selected cover refinements, quotient function equality, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Theorem 7541.2 (Compact uniform finite-cover fold NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ *carrier*

$$G = (K, F, L, B, R, U, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact finite cover, pointwise-modulus rows, subordinate positive-radius ledger, lower-bound fold, rational readbacks, uniform-modulus output, finite windows, regular readbacks, transport, replay, provenance, and local naming;*

2. *cover exactness, requiring every center, coverage, and nonempty-spine read to pass through the displayed compact finite-cover row K;*

3. *local-modulus exactness, requiring every pointwise precision row to pass through F over the centers supplied by K;*

4. *radius-fold exactness, requiring every positive-radius comparison to pass through L, R before the finite lower-bound fold B is read;*

5. *uniform-output ordering, requiring the* $\mathsf{UniformModulus}^{\uparrow}$ *row U to be downstream of B and not an independent modulus selector;*

6. *readback ordering, requiring W and Q to expose finite windows and regular rational readbacks before any Real-facing uniform estimate is consumed;*

7. *nonescape, excluding open-cover compactness, selected global moduli, quotient function equality, countable choice, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No compact uniform finite-cover fold obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7541.1. The accepted packet displays exactly one compact finite-cover row, one continuous pointwise-modulus row, one subordinate-radius ledger, one lower-bound fold, one rational readback route, one uniform-modulus output, finite windows, regular readbacks, and structural rows.

Cover exactness is supplied by K. The bundle centers, coverage witnesses, and nonempty spine have no second cover coordinate, so every cover read enters the packet through the displayed compact finite-cover source.

Local-modulus exactness is supplied by F over the centers from K. Pointwise precision rows are therefore tied to the finite cover and cannot be replaced by an external continuity theorem.

The fold route is supplied by L, R, B. The positive-radius ledger and rational readback rows expose the finite comparisons before primitive recursion over the bundle records the lower-bound fold.

Finally U, W, Q, H, C, P, N impose output order and local naming. The uniform-modulus row is downstream of the fold, finite windows and regular readbacks precede Real-facing estimates, and the structural rows contain none of the refused compactness, selection, quotient, choice, completeness, verification, or bridge data. □

Theorem 7541.3 (Compact uniform finite-cover fold route)**.** *Every tolerance-only uniform-modulus read exported by an accepted* $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ *packet factors through*

$$K, F, L \longmapsto R, B \longmapsto U, W, Q, H, C, P, N.$$

The read first receives the finite compact cover, pointwise-modulus rows, and subordinate positive-radius ledger; only then may it inspect the rational comparison readback, finite lower-bound fold, uniform-modulus output, finite windows, regular readbacks, and structural NameCert rows. It exports no selected global modulus functional or open-cover compactness theorem.

Proof. Start with an accepted packet $G = (K, F, L, B, R, U, W, Q, H, C, P, N)$. The compact cover row K supplies the finite $\mathsf{ProbeBundle}$, centers, coverage rows, and nonempty spine, while F supplies the local pointwise-modulus rows over those centers.

The subordinate-radius row L records the positive radius attached to each bundled center. The rational readback R exposes the comparison data needed by the finite fold, and B records the lower-bound fold over the displayed finite spine.

The uniform output is then read through U. The finite-window and regular-readback rows W, Q supply the observation and Real-facing estimate boundary, while H, C, P, N transport, replay, source, and name the same route.

Because no row stores a global modulus selector, arbitrary open-cover compactness proof, selected refinement, quotient function equality, countable choice, host real equality, or ambient completeness witness, the displayed factorization is the whole public route. □

Theorem 7541.4 (Compact uniform finite-cover fold vision realization)**.** *The finite lower-bound fold of Definition 9237.5 is realized by an accepted* $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ *carrier exactly at the boundary where compact finite-cover data and continuous pointwise-modulus rows become a* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row. The realization is a concrete NameCert packet over* $K, F, L, B, R, U, W, Q, H, C, P, N$*, not a separate analytic compactness principle.*

Proof. Read the capstone theorem through chapter 9237. Its finite $\mathsf{ProbeBundle}$, center rows, pointwise-modulus rows, subordinate radius rows, and rational lower-bound fold are precisely the rows displayed as K, F, L, R, B.

The theorem's output uniform-modulus ledger is the row U. The remaining rows W, Q, H, C, P, N provide finite windows, regular readbacks, transport, replay, provenance, and local naming for that output.

Thus the vision-side fold lands as one concrete NameCert packet. Since the packet contains no additional compactness, selection, quotient, choice, host equality, or completeness coordinate, the realization does not enlarge the theorem beyond the displayed finite cover-fold boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7541.1, Definition 7541.2, Definition 7541.3, and Definition 7541.4 seed the finite cover-fold route from compact finite covers and pointwise-modulus rows through positive-radius ledgers, rational lower-bound folds, uniform-modulus output, finite windows, readbacks, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, selected global moduli, selected cover refinements, quotient function equality, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, cover exactness, local-modulus exactness, radius-fold exactness, uniform-output ordering, readback ordering, and nonescape proofs for BEDC.Derived.CompactUniformFiniteCoverFoldUp

Constructive story: A $\mathsf{CompactUniformFiniteCoverFold}^{\uparrow}$ packet is generated from a compact finite-cover row, continuous pointwise-modulus row, subordinate positive-radius ledger, rational readback row, finite lower-bound fold, UniformModulus output, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7542

A Concrete Naming Certificate for $\mathsf{IntervalImageConnected}^{\uparrow}$

Following Bishop and Bridges on constructive interval arguments, the $\mathsf{IntervalImageConnected}^{\uparrow}$ packet records the finite route by which a continuous image of a displayed interval remains connected at the Real-facing certificate boundary. It sits after the continuous image packet of chapter 1897, the located intermediate-value rows of chapter 1402, the located interval boundary of chapter 56, the Darboux-property surface carried by $\mathsf{DarbouxProperty}^{\uparrow}$, and the terminal real-name seal of chapter 38. The packet names a constructive interval-image connectedness carrier; it does not assert open-cover compactness, host image-set connectedness, quotient equality of real names, selected preimages, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7542.1 (Interval image connected carrier)**.** *An* $\mathsf{IntervalImageConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, V, D, L, R, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, including the displayed endpoints, membership ledger, and located interval-window reads.*
2. *F is the* $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *row carrying the continuous map, source interval boundary, image-output seal, and finite image-window route.*
3. *V is the* $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ *or* $\mathsf{DyadicIntermediateValue}^{\uparrow}$ *route used when an image-connectedness request must pass between two displayed Real-facing image values.*
4. *D is the* $\mathsf{DarbouxProperty}^{\uparrow}$ *sibling row, read only as the interval-value handoff induced by the same continuous image route.*
5. *L records the finite lower and upper image brackets whose endpoints are read through I, F, V, D before a connectedness request is answered.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for image values, reached only after the interval, continuity, intermediate-value, Darboux, and bracket rows are displayed.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for interval endpoints, source probes, image observations, and intermediate-value bisection reads.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows and image-value comparisons.*

9. *H records componentwise* hsame *transport for the interval, continuous-image, intermediate-value, Darboux, bracket, Real seal, finite-window, readback, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through $I, F, V, D, L, R, W, Q, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{IntervalImageConnected}^{\uparrow}$, $\mathsf{ContinuousIntervalImage}^{\uparrow}$, $\mathsf{LocatedRealIntermediateValue}^{\uparrow}$ $\mathsf{DyadicIntermediateValue}^{\uparrow}$, $\mathsf{DarbouxProperty}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalImageConnected}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, V, D, L, R, W, Q, H, C, P, N$. It has no coordinate for host image subsets, selected preimages, endpoint-choice functionals, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.IntervalImageConnectedUp.IntervalImageConnectedTasteGate single carrier alignment`

Theorem 7542.2 (Interval image connected NameCert obligations)**.** *For every accepted* $\mathsf{IntervalImageConnected}^{\uparrow}$ *carrier*

$$K = (I, F, V, D, L, R, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalImageConnected}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval row, continuous interval-image row, intermediate-value route, Darboux handoff, bracket row, Real seal, finite windows, regular readbacks, transport, replay, provenance, and local naming;*

2. *interval-source exactness, requiring endpoint, membership, and source-window reads to pass through the displayed* $\mathsf{LocatedInterval}^{\uparrow}$ *row I;*

3. *image-route exactness, requiring image-value reads to pass through the* $\mathsf{ContinuousIntervalImage}^{\uparrow}$ *row F before the connectedness row is inspected;*

4. *intermediate-value exactness, requiring every between-value request to pass through V and the same displayed image route rather than through host order completeness;*

5. *Darboux compatibility, requiring D to be read as a sibling route over the same interval and continuous-image rows;*

6. *Real-seal ordering, requiring W and Q to expose finite StreamName windows and RegSeqRat readbacks before the terminal* $\mathsf{Real}^{\uparrow}$ *seal R is available;*

7. *nonescape, excluding host image subsets, selected preimages, endpoint selectors, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No interval-image connectedness obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7542.1. The accepted packet displays exactly one located interval source, one continuous image row, one intermediate-value route, one Darboux handoff, one bracket row, one Real seal, finite windows, readbacks, and structural rows.

Interval-source exactness is supplied by I. Endpoint, membership, and source-window requests have no second source interval coordinate, so each enters the packet through the displayed $\mathsf{LocatedInterval}^{\uparrow}$ row.

Image-route exactness is supplied by F. The continuous interval-image row carries the map, image-output route, and finite image windows before any connectedness request can read an image value.

The between-value route is supplied by V and checked against D. These rows expose the located or dyadic intermediate-value handoff and the Darboux sibling surface over the same interval data, so no host order-completeness theorem is substituted.

Finally L, R, W, Q, H, C, P, N impose readback order and local naming. The bracket row is read before the Real seal, StreamName windows and RegSeqRat readbacks precede terminal image-value comparison, and the structural rows contain none of the refused host image, selection, quotient, choice, compactness, completeness, verification, or bridge data. □

Theorem 7542.3 (Interval image connected intermediate-value route)**.** *Every connectedness read exported by an accepted* $\mathsf{IntervalImageConnected}^{\uparrow}$ *carrier factors through*

$$I, F \longmapsto V, D, L \longmapsto W, Q, R, H, C, P, N.$$

The read uses the located interval source, continuous interval-image route, located or dyadic intermediate-value row, Darboux handoff, bracket row, finite windows, regular readbacks, Real seal, and structural NameCert rows. It does not introduce host image connectedness, selected preimages, open-cover compactness, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted packet $K = (I, F, V, D, L, R, W, Q, H, C, P, N)$. The source and image sides are fixed by I and F: the located interval row supplies the endpoint and membership boundary, and the continuous interval-image row supplies the image-value route over that same source.

A connectedness request between two displayed image values must then read V and D. The intermediate-value row supplies the finite bisection or located crossing route, while the Darboux row records the same interval-value handoff as a sibling route.

The bracket, window, and readback rows are downstream. The row L identifies the displayed image brackets, W and Q expose finite observations and rational readbacks, and R seals the image values as $\mathsf{Real}^{\uparrow}$ names.

The structural rows H, C, P, N transport, replay, source, and name only this route. Since no row stores a host image set, selected preimage, open-cover compactness theorem, quotient real equality, trichotomy, choice, or ambient completeness witness, every connectedness read remains inside the displayed factorization. □

Theorem 7542.4 (Interval image connected Real seal)**.** *Every Real-facing seal read of an accepted* $\mathsf{IntervalImageConnected}^{\uparrow}$ *packet is downstream of the interval-image connectedness route. A consumer may inspect the terminal* $\mathsf{Real}^{\uparrow}$ *row only after it has read the located interval source* I*, the continuous image row* F*, the intermediate-value row* V*, the Darboux handoff* D*, the bracket row* L*, the finite windows* W*, and the RegSeqRat readback row* Q*. The seal exports no ambient Real completeness theorem.*

Proof. The carrier definition places the terminal Real seal at R and places R after I, F, V, D, L, W, Q in the displayed reading order. Thus a Real-facing consumer must first inspect the source interval, continuous image route, intermediate-value route, Darboux handoff, bracket row, finite windows, and rational readbacks.

The structural rows do not change that order. They transport, replay, source, and name the same packet, but they contain no coordinate for host real equality, quotient representatives, selected preimages, open-cover compactness, countable choice, or ambient completeness.

Therefore the Real seal is exactly a downstream image-value seal for the displayed finite route, not an independent completeness or host-connectedness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalImageConnected}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalImageConnected}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7542.1, Definition 7542.2, Definition 7542.3, and Definition 7542.4 seed the finite interval-image connectedness route from a located interval through continuous interval-image, intermediate-value, Darboux, bracket, finite-window, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalImageConnected}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.IntervalImageConnectedUp.IntervalImageConnectedTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host image-set connectedness, selected preimages, endpoint selection, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, interval-source exactness, image-route exactness, intermediate-value exactness, Darboux compatibility, Real-seal ordering, and nonescape proofs for BEDC.Derived.IntervalImageConnected

Constructive story: An $\mathsf{IntervalImageConnected}^{\uparrow}$ packet is generated from a located interval row, continuous interval-image row, located or dyadic intermediate-value route, Darboux handoff, bracket row, Real seal, StreamName windows, RegSeqRat readbacks, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7543

A Concrete Naming Certificate for $\mathsf{BeurlingLax}^{\uparrow}$

Following Beurling and Lax, the $\mathsf{BeurlingLax}^{\uparrow}$ packet records the finite invariant-subspace rows by which a Hardy-space subspace is read through shift-stability data. It sits beside the Hardy-space boundary carrier of chapter 5108, the bounded-operator surface of chapter 1644, and the operator-neighbour route of chapter 7271. The packet names the displayed Beurling–Lax dependency pattern over finite NameCert rows; it does not import a host Hilbert quotient, a selected inner function, a spectral theorem, orthogonal projection choice, or ambient closed-subspace completeness.

Definition 7543.1 (Beurling–Lax carrier)**.** *A* $\mathsf{BeurlingLax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (H, O, S, I, W, R, E, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{HardySpace}^{\uparrow}$ *source row, exposing the finite coefficient prefix, boundary window, Hardy-control, summation, readback, tolerance, and real-seal rows used by the invariant-subspace read.*
2. *O is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the displayed shift or multiplication action as bounded operator data.*
3. *S is the shift-stability row, recording the finite witnesses that the inspected subspace rows are stable under the displayed operator action.*
4. *I is the inner-divider ledger row. It names a finite divisor or multiplier certificate when such a row is displayed, but it is not a selected inner function.*
5. *W is the finite window row for inspected basis, boundary, or coefficient probes.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the coefficient, boundary, operator, and stability probes.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the Hardy-space, operator, shift-stability, window, and readback rows are visible.*
8. *T records componentwise* hsame *transport for H, O, S, I, W, R, E.*
9. *C records displayed* Cont *replay from Hardy boundary data through bounded shift action, stability, optional divider ledger, readback, and real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{BeurlingLax}^{\uparrow}$, $\mathsf{HardySpace}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{KoopmanOperator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BeurlingLax}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host Hilbert quotient, a chosen orthogonal projection, a selected inner function, full spectral resolution, quotient equality of boundary functions, or ambient Hilbert-space completeness.

Theorem 7543.2 (Beurling–Lax NameCert obligations)**.** *For every accepted* $\mathsf{BeurlingLax}^{\uparrow}$ *carrier* $B = (H, O, S, I, W, R, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BeurlingLax}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the displayed Hardy-space source, bounded-operator action, shift-stability ledger, optional divider ledger, finite windows, readback, real seal, transport, replay, provenance, and local name;*
2. *Hardy boundary exposure, requiring every invariant-subspace read to consume the* $\mathsf{HardySpace}^{\uparrow}$ *coefficient, boundary-window, Hardy-control, summation, tolerance, and seal rows before it can inspect S;*
3. *bounded shift exposure, requiring the operator row O and the finite stability row S to be read before any invariant-subspace claim is exported;*
4. *readback and seal nonescape, requiring W, R, E to supply the visible coefficient and boundary reads without host quotient equality or selected representatives;*
5. *structural transport, replay, provenance, and naming nonescape through T, C, P, N.*

No obligation is discharged by a host Hilbert-space quotient, a selected inner function, a spectral theorem, orthogonal projection choice, or ambient closed-subspace completeness.

Proof. Project the carrier of Definition 7543.1. The displayed analytic rows are H, O, S, I, W, R, E, and the structural rows are T, C, P, N.

The Hardy-space source H is read first, so the coefficient and boundary data remain those of the finite $\mathsf{HardySpace}^{\uparrow}$ packet. The bounded operator row O and shift-stability row S then record the displayed invariant-subspace action.

The divider ledger I is only a finite certificate row. It cannot choose an inner function because the carrier contains no selector for one. The window, readback, and real-seal rows W, R, E keep the boundary reads inside the L10 surface.

Finally T, C, P, N transport, replay, source, and name the same route. Since no excluded host object appears among the carrier coordinates, the five rows exhaust the local NameCert obligations. □

Theorem 7543.3 (Beurling–Lax Hardy shift route)**.** *Let $B = (H, O, S, I, W, R, E, T, C, P, N)$ be an accepted* $\mathsf{BeurlingLax}^{\uparrow}$ *carrier. Every Hardy-space shift consumer of B first reads the* $\mathsf{HardySpace}^{\uparrow}$ *row H, then reads the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *action row O, then reads the shift-stability row S, and only then may consume the finite divider ledger I, the window and readback rows W, R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E.*

Thus the route

$$\mathsf{HardySpace}^{\uparrow} \longmapsto \mathsf{BoundedLinearOperator}^{\uparrow} \longmapsto \mathsf{KoopmanOperator}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRa}$$

is a displayed dependency route for the packet. It is not a claim of host Hilbert quotient reconstruction, selected inner-function factorization, orthogonal projection choice, full spectral theorem, or ambient closed-subspace completeness.

Proof. Start with a shift-facing read of the accepted carrier. The only Hardy-space source is the row H, so the read begins with the finite boundary and coefficient data already exposed by $\mathsf{HardySpace}^{\uparrow}$.

The operator action is then forced through O and its stability evidence through S. The operator-neighbour row is used only as a comparison surface for shift-style reads and does not replace the bounded action row.

Rows I, W, R, E provide the finite divider ledger, inspected windows, regular rational readback, and terminal real seal. Structural rows T, C, P, N preserve this ordering under transport, replay, provenance, and local naming.

Therefore every Hardy-space shift consumer factors through the listed sibling rows, while the excluded Hilbert quotient, selected inner function, projection choice, spectral theorem, and ambient completeness data remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{BeurlingLax}^{\uparrow}$ invariant-subspace read exposes HardySpaceUp source rows, a BoundedLinearOperatorUp action row, shift-stability data, finite windows, RegSeqRatUp readback, DyadicRatCoreUp tolerance, RealUp sealing, transport, replay, provenance, and local NameCert before any shift-stability claim is exported.

Independence witness: hardyspace, boundedlinearoperator, koopmanoperator, streamname, regseqrat, dyadicratcore, real: $\mathsf{BeurlingLax}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Hardy boundary data, bounded shift action, stability, optional divider ledger, finite windows, readback, sealing, transport, replay, provenance, and local naming for an invariant-subspace route.

Closure status for $\mathsf{NameCert}_{\mathsf{BeurlingLax}^{\uparrow}}$.

Constructive story: A $\mathsf{BeurlingLax}^{\uparrow}$ packet is generated from HardySpace rows, a BoundedLinearOperator shift-action row, shift-stability data, an optional divider ledger, finite windows, RegSeqRat readback, DyadicRatCore tolerance, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BeurlingLax}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7543.1, Definition 7543.2, and Definition 7543.3 seed the finite Beurling–Lax invariant-subspace route over Hardy-space, bounded-operator, shift-stability, readback, tolerance, real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BeurlingLax}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host Hilbert quotients, selected inner functions, orthogonal projection choice, quotient boundary equality, full spectral theorems, or ambient closed-subspace completeness.

Upgrade path: Obligation closure requires checked carrier admission, Hardy boundary exposure, bounded shift exposure, readback and seal nonescape, structural transport, replay, provenance, and local naming for BEDC.Derived.BeurlingLaxUp.

Chapter 7544

A Concrete Naming Certificate for $\mathsf{CauchyTailStability}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{CauchyTailStability}^{\uparrow}$ packet records the finite-tail stability surface needed before a regular rational stream is admitted to the $\mathsf{Real}^{\uparrow}$ seal. It sits over the regular rational classifier of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the regular Cauchy shift route of chapter 1578. The packet names only finite prefix erasure, tail-window replay, tolerance preservation, and seal handoff; it does not introduce quotient streams, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7544.1 (Cauchy tail stability carrier)**.** *A* $\mathsf{CauchyTailStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (Q, k, W, R, D, E, H, C, P, N)$$

with the following visible rows:

1. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, read as a regular rational Cauchy name before any finite prefix is ignored.*
2. *k is the displayed finite prefix length whose removal is being certified.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row, sending each later window request to the source window beginning after k.*
4. *R is the replayed regular-rational classifier for the tail stream.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger witnessing that the tail replay preserves the same dyadic error budgets.*
6. *E is the exclusion ledger for quotient streams, selected limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*
7. *H records componentwise* hsame *transport for source, prefix length, tail window, classifier, dyadic ledger, exclusion ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tail-stability request through Q, k, W, R, D, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailStability}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, k, W, R, D, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, countable-choice tail selectors, trichotomy, host real equality, or an ambient completeness proof for $\mathsf{Real}^{\uparrow}$.

Theorem 7544.2 (Cauchy tail stability NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailStability}^{\uparrow}$ *carrier $T = (Q, k, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailStability}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-prefix exposure, tail-window replay, regular-rational classifier retention, dyadic tolerance preservation, exclusion-ledger nonescape, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the carrier. The source regular rational row, finite prefix length, tail-window row, replayed classifier, dyadic ledger, exclusion ledger, and structural rows are all displayed coordinates.

The finite-prefix exposure and tail-window replay are read through k and W. A consumer cannot inspect the tail before the prefix length is visible, and it cannot detach the replayed window from the source row Q.

The regular-rational classifier and dyadic tolerance obligations are read through R and D. They keep the tail stream attached to the same regular Cauchy route and the same dyadic budget surface.

Finally, E, H, C, P, N record nonescape, transport, replay, provenance, and naming. Since no row stores quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7544.3 (Cauchy tail stability Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyTailStability}^{\uparrow}$ *carrier receives the tail-stable regular Cauchy name only through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegularCauchyShift}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

as displayed by $Q, k, W, R, D, E, H, C, P, N$. Finite prefixes therefore cannot affect the admitted Real seal, and the handoff exports no quotient stream, selected representative, selected limit, countable-choice schedule, trichotomy principle, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the source row Q and prefix length k. The packet exposes the regular rational Cauchy name before it exposes the tail, so the removed prefix is finite and named.

Read the tail-window row W and the replayed classifier row R. Each requested tail window is a displayed source window after k, and the classifier remains the regular-rational classifier attached to that replay.

Read the dyadic ledger D before the real seal. It records the same tolerance budgets for the tail route, so the $\mathsf{Real}^{\uparrow}$ consumer sees a regular Cauchy readback with preserved dyadic control.

The remaining rows transport, replay, source, and name the route, while the exclusion ledger blocks every non-displayed exit. Thus finite prefixes cannot change the admitted Real seal inside this packet. □

Falsifiable prediction: Any consumer that deletes k or W can no longer distinguish a finite-prefix read from an unrecorded quotient-stream identification.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-shift: $\mathsf{CauchyTailStability}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source regular rational row, displayed prefix length, tail-window replay, dyadic tolerance ledger, exclusion ledger, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailStability}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailStability}^{\uparrow}$ packet is generated from a source regular rational Cauchy row, a finite prefix length, StreamName tail windows, a replayed RegSeqRat classifier, a DyadicRatCore tolerance ledger, an exclusion ledger, componentwise transport, displayed replay, package provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7544.1, Definition 7544.2, and Definition 7544.3 seed the finite-tail stability route from regular rational names to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix exposure, tail-window replay, dyadic tolerance preservation, Real-seal handoff, and exclusion-ledger nonescape for BEDC.Derived.CauchyTailStabilityUp.

Chapter 7545

A Concrete Naming Certificate for $\mathsf{CriticalStripOscillation}^{\uparrow}$

Following Riemann, Hadamard, de la Vallee Poussin, and the constructive contour discipline used in the RH route, the $\mathsf{CriticalStripOscillation}^{\uparrow}$ packet records a finite zero-window boundary inside the critical strip. It sits beside the RH boundary of chapter 9239, the route-halting boundary of chapter 9336, the zeta-continuation application of chapter 9342, and the critical-strip dependency named in chapter 72. The packet is a local oscillation-window certificate only; it does not prove RH, refute RH, move a zero to the critical line, assert zero-free regions beyond the displayed window, or decide any global zeta-zero statement.

Definition 7545.1 (Critical-strip oscillation carrier)**.** *A* $\mathsf{CriticalStripOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, Z, W, B, A, E, H, C, P, N)$$

with the following visible rows:

1. *S is the displayed critical-strip window row, naming a bounded rational rectangle inside $0 < \Re(s) < 1$ and excluding the pole at $s = 1$.*
2. *Z is the zeta-continuation source row, read only through the finite continuation and factor ledgers already exposed by the RH route.*
3. *W is the finite zero-window row listing inspected subwindows, sample histories, and local sign or argument-variation observations.*
4. *B is the boundary ledger requiring every inspected zero claim to remain inside the displayed window S.*
5. *A is the oscillation ledger recording finite argument-variation or sign-change budget data available on the inspected boundary.*
6. *E is the exclusion ledger refusing RH, $\neg\mathsf{RH}$, global zero-free regions, unrestricted analytic continuation, hidden contour integrals, selected zeros, and oracle decisions.*
7. *H records componentwise* hsame *transport for strip window, zeta source, zero window, boundary, oscillation, exclusion, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a zero-window request through S, Z, W, B, A, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CriticalStripOscillation}^{\uparrow}$, $\mathsf{ZetaCont}^{\uparrow}$, $\mathsf{CritStrip}^{\uparrow}$, $\mathsf{ZetaZeros}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CriticalStripOscillation}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, Z, W, B, A, E, H, C, P, N$. It has no coordinate for a proof of RH, a disproof of RH, a global zero classifier, selected zeros, unrestricted contour evaluation, or a decision oracle.

Theorem 7545.2 (Critical-strip oscillation NameCert obligations)**.** *For every accepted* $\mathsf{CriticalStripOscillation}^{\uparrow}$ *carrier $O = (S, Z, W, B, A, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CriticalStripOscillation}^{\uparrow}}$ *surface consists exactly of carrier admission, critical-strip window exposure, zeta-source retention, finite zero-window coverage, boundary nonescape, oscillation-budget replay, exclusion-ledger refusal, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Project the carrier. The strip window, zeta source, zero-window ledger, boundary ledger, oscillation ledger, exclusion ledger, and structural rows are all displayed coordinates.

The zero-window obligations are local. A consumer first reads the bounded strip window S, then the zeta source Z, and only then the inspected subwindows and observations in W.

Boundary nonescape and oscillation replay are read through B and A. They keep every inspected zero or variation claim attached to the same finite window and prevent it from being promoted to a global zero theorem.

The exclusion and structural rows then close the local NameCert surface. Since no row stores RH, $\neg\mathsf{RH}$, a selected zero, unrestricted contour evaluation, or a decision oracle, the listed obligations exhaust the packet. □

Theorem 7545.3 (Critical-strip zero-window nonescape)**.** *Every zero-window read exported by an accepted* $\mathsf{CriticalStripOscillation}^{\uparrow}$ *carrier remains inside the displayed critical-strip window S and the finite observation ledger W. The packet may report local oscillation, boundary variation, and inspected zero-window data, but it does not prove RH, refute RH, assert that all critical-strip zeros lie on the critical line, claim a global zero-free region, select a zero outside the window, or decide any RH condition chain.*

Proof. Start with the strip row S. It is the only domain row exposed by the carrier, so every zero-window read is bounded by the displayed rational rectangle.

Read the zeta source and zero-window rows next. The route through Z and W supplies only the finite continuation source and inspected subwindows available in the packet.

The boundary and oscillation ledgers B and A keep the read local. They record window containment and finite variation data, not a global classification of zeros.

Finally apply the exclusion ledger E. It refuses RH decisions, selected off-window zeros, global zero-free regions, unrestricted contour evaluation, and oracle routes, so the zero-window read cannot escape the finite oscillation packet. □

Falsifiable prediction: A consumer that removes the boundary ledger B can turn a finite inspected window into an unbounded zero claim, which is rejected by the $\mathsf{CriticalStripOscillation}^{\uparrow}$ carrier.

Independence witness: critical-strip, zeta-continuation, rh-route-halting-boundary, rh-zero-window: $\mathsf{CriticalStripOscillation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded strip window, zeta source, inspected zero-window ledger, oscillation budget, boundary nonescape ledger, exclusion ledger, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CriticalStripOscillation}^{\uparrow}}$.

Constructive story: A CriticalStripOscillation$^{\uparrow}$ packet is generated from a bounded critical-strip window, zeta-continuation source row, finite zero-window ledger, boundary ledger, oscillation budget, exclusion ledger, componentwise transport, displayed replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{CriticalStripOscillation}\uparrow}$, seed)

Scope closed: Definition 7545.1, Definition 7545.2, and Definition 7545.3 seed the finite zero-window boundary used by the RH route.

Formal verification: FormalStatus(NameCert$_{\text{CriticalStripOscillation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RH, ¬RH, global zero-free regions, unrestricted analytic continuation, selected zeros, oracle decisions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, strip-window exposure, zeta-source retention, finite zero-window coverage, oscillation-budget replay, and exclusion-ledger refusal for BEDC.Derived.CriticalStripOscillationUp.

Chapter 7546

A Concrete Naming Certificate for ClassifierFormationTrace$^{\uparrow}$

The ClassifierFormationTrace$^{\uparrow}$ packet realizes the learning classifier shift of Definition 9462.356 as finite before-and-after classifier data. It refines the broader ClassifierFormingLearning$^{\uparrow}$ route of chapter 6097 by naming the trace row where a learning transition exposes source scope, before classifier, after classifier, ledger residue, audit export, and local NameCert obligations. The packet records classifier formation as a finite trace; it does not claim model-family correctness, benchmark validity, causal explanation, positive net information, or metric improvement as learning by itself.

Definition 7546.1 (Classifier-formation trace carrier)**.** *A* ClassifierFormationTrace$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, B, A, L, R, G, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-scope row naming the task, observations, training protocol, and common comparison domain for the before and after classifiers.*
2. *B is the before-classifier row read from the pre-transition learning classifier state.*
3. *A is the after-classifier row read from the post-transition learning classifier state.*
4. *L is the classifier-shift ledger row, recording that B and A do not agree on the displayed common source scope.*
5. *R is the learning-residue row for parameter motion, loss movement, benchmark evidence, memorization, shortcut behavior, and distribution-boundary residue.*
6. *G is the registry and audit export row inherited from* RegistryExportSurface$^{\uparrow}$, MachineReadableAuditInterface$^{\uparrow}$, *and* GroundCompilerAuditMap$^{\uparrow}$.
7. *Q is the TasteGate commitment row requiring later Lean work to provide* Nontrivial ClassifierFormationTrace$^{\uparrow}$ *and* FieldFaithful ClassifierFormationTrace$^{\uparrow}$ *instances for this trace carrier.*
8. *H records componentwise* hsame *transport for S, B, A, L, R, G, Q.*
9. *C records displayed* Cont *replay from source scope through before classifier, after classifier, shift ledger, residue, audit export, TasteGate commitments, provenance, and local naming.*
10. *P is the* Pkg *provenance over* ClassifierFormationTrace$^{\uparrow}$, ClassifierFormingLearning$^{\uparrow}$, RegistryExportSurface$^{\uparrow}$, MachineReadableAuditInterface$^{\uparrow}$, GroundCompilerAuditMap$^{\uparrow}$, BHist, hsame, Cont, Pkg, TasteGate, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierFormationTrace}^{\uparrow}}$ *row.*

The carrier compares accepted traces only by $S, B, A, L, R, G, Q, H, C, P, N$. Parameter motion, loss reduction, and benchmark movement remain residue rows unless L displays classifier shift between the before and after rows on the same source scope.

Theorem 7546.2 (Classifier-formation trace NameCert obligations)**.** *For every accepted* $\mathsf{ClassifierFormationTrace}^{\uparrow}$ *carrier $T = (S, B, A, L, R, G, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClassifierFormationTrace}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for source scope, before classifier, after classifier, shift ledger, residue ledger, audit export, TasteGate commitments, transport, replay, provenance, and local naming;*
2. *before/after classifier exposure, requiring B and A to be read on the same displayed source scope S;*
3. *ledger-residue separation, requiring classifier shift through L and keeping parameter motion, loss movement, benchmark evidence, memorization, shortcuts, and distribution residue in R;*
4. *audit and TasteGate handoff through G, Q, with nontriviality and field-faithfulness instances left as explicit Lean obligations for the trace carrier;*
5. *structural transport, replay, provenance, and naming nonescape through H, C, P, N.*

No obligation is discharged by parameter motion alone, lower loss alone, benchmark improvement alone, memorized examples, shortcut performance, or unregistered interpretability prose.

Proof. Project the carrier of Definition 7546.1. The source and classifier rows are S, B, A, while L records the displayed classifier shift on the same scope.

The residue row R is read separately. It may record parameter, loss, benchmark, memorization, shortcut, or distribution-boundary evidence, but none of those rows is the classifier-shift row.

The audit row G and TasteGate row Q make the trace exportable and record the later Lean obligations for nontriviality and field faithfulness. These commitments attach to the same finite carrier rather than to a private training narrative.

Finally H, C, P, N transport, replay, source, and name the same route. Since the excluded metric and prose substitutes have no carrier coordinate that can replace L, the listed rows exhaust the local NameCert surface. □

Theorem 7546.3 (Classifier-formation trace shift witness)**.** *Let $T = (S, B, A, L, R, G, Q, H, C, P, N)$ be an accepted* $\mathsf{ClassifierFormationTrace}^{\uparrow}$ *carrier. A learning transition exports classifier formation through T only when the before classifier B and after classifier A are compared on the source row S, the shift ledger L records nonagreement on that scope, the residue row R keeps training side effects separate, and the audit and TasteGate rows G, Q are displayed before local naming through N.*

Thus the trace realizes the route from Definition 9462.356 as finite NameCert data. It does not assert positive net explanation information, benchmark validity, causal explanation, field faithfulness before the later Lean instance, or nontriviality before the later Lean instance.

Proof. Begin with the accepted trace carrier. The source row S fixes the common domain on which the before and after classifier rows can be compared.

The rows B, A, L then form the classifier-shift witness. Without L, the transition remains a pair of classifier rows and does not export certified classifier formation.

The residue row R keeps parameter motion, loss movement, benchmark evidence, memorization, shortcut behavior, and distribution residue outside the classifier-shift claim. The audit row G and TasteGate row Q preserve the public-checking and later-instance boundary.

Transport and replay through H, C preserve the row order, and P, N source and name the trace. Therefore the accepted packet realizes classifier shift as finite NameCert data without claiming the excluded metric, causal, positive-information, or completed TasteGate facts. □

Falsifiable prediction: A $\mathsf{ClassifierFormationTrace}^{\uparrow}$ packet with before and after classifier rows but no same-scope shift ledger is rejected, even if it records parameter motion, lower loss, benchmark movement, memorization evidence, or audit prose.

Independence witness: classifier-forming-learning, classifier-shift-ledger-residue, namecert, pkg, bhist: $\mathsf{ClassifierFormationTrace}^{\uparrow}$ is not bijective to its listed neighbors because it jointly carries source scope, before classifier, after classifier, classifier-shift ledger, residue separation, audit export, TasteGate commitments, transport, replay, provenance, and local naming as one finite trace.

Later Lean TasteGate work must provide $\mathsf{Nontrivial\ ClassifierFormationTrace}^{\uparrow}$ and $\mathsf{FieldFaithful\ ClassifierFormatio}$ instances for the carrier of Definition 7546.1. Those instances must preserve the rows $S, B, A, L, R, G, Q, H, C, P, N$ so classifier formation remains separated from training residue.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierFormationTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierFormationTrace}^{\uparrow}$ packet is generated from source scope, before classifier, after classifier, classifier-shift ledger, learning-residue rows, registry and audit export, TasteGate commitments, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierFormationTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7546.1, Definition 7546.2, and Definition 7546.3 seed the finite trace route for learning classifier shift over before/after classifier rows, ledger residue, audit export, TasteGate commitments, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierFormationTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, model-family correctness, benchmark validity, causal explanation, positive net information, Nontrivial instances, FieldFaithful instances, or metric improvement as learning by itself.

Upgrade path: Obligation closure requires checked carrier admission, before/after classifier exposure, ledger-residue separation, audit export, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.ClassifierFormationTraceUp.

Chapter 7547

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ packet records the finite cotransitivity route for apartness between regular Cauchy real names before any trichotomy or quotient-real equality is exposed. It sits over the positive apartness boundary of chapter 1710, the located comparison route of chapter 1681, the dyadic rational core of chapter 291, the finite stream windows of chapter 126, the regular rational sequence readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a finite cotransitivity surface for displayed regular Cauchy names; it is not a trichotomy principle, not quotient real equality, not a selected limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7547.1 (Regular Cauchy apartness cotransitivity carrier)**.** *A* $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, Z, A, O, L, R, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose apartness is already displayed by regular Cauchy data.*
2. *Z is the third* $\mathsf{RegSeqRat}^{\uparrow}$ *row through which cotransitivity is read.*
3. *A is the* $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$ *source-apartness row for X and Y.*
4. *O is the* $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$ *comparison row that keeps the branch read located over the same regular Cauchy windows.*
5. *L is the left branch row, witnessing apartness from X to Z when that branch is displayed.*
6. *R is the right branch row, witnessing apartness from Z to Y when that branch is displayed.*
7. *W records the common* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule inspected by the source apartness row and by the active branch.*
8. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-gap ledger, tolerance budget, and slack consumed by the source apartness and branch rows.*
9. *Q records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback handoff for the three regular rational names.*

10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after A, O, L, R, W, D, Q have been displayed.*
11. *H stores componentwise* hsame *transport for the source, third-name, apartness, located-order, branch, window, dyadic, readback, seal, provenance, and local naming rows.*
12. *C stores displayed* Cont *replay for the same cotransitivity route.*
13. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$, $\mathsf{RegularCauchyApartnessOrder}^{\uparrow}$, $\mathsf{RegularCauchyLocatedOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, Z, A, O, L, R, W, D, Q, E, H, C, P, N$. It has no coordinate for trichotomy, quotient real equality, selected limit representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ BEDC.Derived.RegularCauchyApartnessCotransitivityUp.RegularCauchyApartnessCotransitivityTasteGa
single carrier alignment

Theorem 7547.2 (Regular Cauchy apartness cotransitivity NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ *carrier $K = (X, Y, Z, A, O, L, R, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}}$ *surface consists exactly of carrier admission for K, source apartness admission through A, located-order admission through O, one displayed cotransitivity branch through L or R, common window admission through W, dyadic positive-gap admission through D, regular rational readback through Q, terminal Real seal handoff through E, componentwise transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 7547.1. The displayed tuple lists every row available to a consumer of the accepted packet.

The apartness and located-order rows supply the constructive middle of the route. The source apartness row A fixes the positive comparison of X and Y, while O keeps the branch comparison located over the same finite regular Cauchy windows.

The branch rows are exclusive as displayed data. A consumer may read the left branch L or the right branch R, but the packet does not export a separate trichotomy branch or a choice function selecting among all future comparisons.

The window, dyadic, readback, and Real-seal rows keep the branch finite. The common schedule W, positive-gap ledger D, regular rational handoff Q, and seal E must be read in the same carrier route before the result is offered to Real or Completion consumers.

Finally, H, C, P, N transport, replay, source, and name the same rows. Since the excluded principles are absent from the carrier inventory, the listed obligations exhaust the local NameCert surface. □

Theorem 7547.3 (Regular Cauchy apartness cotransitivity route)**.** *Every accepted* RegularCauchyApartnessCotrans
read with source apartness between X and Y and third regular Cauchy name Z reaches a Real-facing consumer only through the finite route

$$\mathsf{RegularCauchyApartnessOrder}^{\uparrow} \longmapsto \mathsf{RegularCauchyLocatedOrder}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSe}$$

The consumer receives exactly one displayed branch: either the left branch witnessing X apart from Z, or the right branch witnessing Z apart from Y. The route exports no trichotomy of X, Z, Y, no quotient real equality, no selected limit, no countable-choice branch selector, no host real equality, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the accepted carrier $K = (X, Y, Z, A, O, L, R, W, D, Q, E, H, C, P, N)$. The source apartness is exposed through A, and the third regular Cauchy name is exposed through Z and the readback row Q.

Use the located-order row O to keep the branch read attached to the same regular Cauchy windows. If L is the displayed branch, the route witnesses apartness from X to Z; if R is the displayed branch, the route witnesses apartness from Z to Y.

The finite evidence is then read through W, D, Q. The stream schedule fixes the inspected windows, the dyadic ledger supplies the positive-gap and slack data, and the regular rational readback keeps all three names inside displayed regular Cauchy data.

Only after those rows are displayed may the terminal Real seal E be consumed. The structural rows H, C, P, N preserve and name the same finite route, so the Real-facing consumer receives a cotransitivity handoff rather than trichotomy, quotient equality, selected limits, countable choice, host equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ read factors through source RegSeqRat rows, one third RegSeqRat row, a RegularCauchyApartnessOrder row, a RegularCauchyLocatedOrder row, one displayed cotransitivity branch, StreamName windows, a DyadicRatCore positive-gap ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regular-cauchy-apartness-order, regular-cauchy-located-order, dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source apartness row, a third regular Cauchy name, one displayed cotransitivity branch, the common window and dyadic positive-gap ledgers, regular rational readback, and the Real seal exclusions that keep cotransitivity separate from trichotomy and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}$ packet is generated from source RegSeqRat rows, one third RegSeqRat row, a RegularCauchyApartnessOrder source-apartness row, a RegularCauchyLocatedOrder comparison row, one displayed left-or-right branch, StreamName windows, a DyadicRatCore positive-gap ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7547.1, Definition 7547.2, and Definition 7547.3 seed the finite cotransitivity route for regular Cauchy apartness through displayed branch, located-order, window, dyadic, readback, Real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessCotransitivity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source apartness admission, located-order admission, branch stability, dyadic positive-gap preservation, RegSeqRat readback, Real-seal non-escape, and ledger exclusion for BEDC.Derived.RegularCauchyApartnessCotransitivityUp.

Chapter 7548

A Concrete Naming Certificate for $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$ packet records the finite grid on which bounded variation, Riemann-sum, and compact-interval oscillation consumers inspect an interval function before any ambient real-completeness principle is available. It sits over the compact interval source of chapter 3986, the closed endpoint boundary of chapter 1591, the dyadic tolerance arithmetic of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite variation grid only; it does not choose an optimal partition, quotient real values, or appeal to open-cover compactness.

Definition 7548.1 (Compact interval variation grid carrier)**.** *A* $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, K, M, D, V, W, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval-source row, exposing the closed bounded endpoint data through chapter 1591.*
2. *K is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *row, recording the compact-interval finite inspection surface attached to I.*
3. *M is the finite mesh-grid row, listing ordered cells and adjacent endpoints over the displayed interval source.*
4. *D is the dyadic tolerance row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, for mesh width, local oscillation budgets, and variation comparison budgets.*
5. *V is the finite variation ledger, recording the displayed adjacent changes and the finite sum row that a variation consumer may inspect.*
6. *W is the window-read row, carrying the* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used at the mesh endpoints and at any displayed refinement cell.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the terminal scalar comparisons exported by the packet.*
8. *H is the componentwise* hsame *transport row for interval source, compact row, mesh, dyadic tolerances, variation ledger, window reads, real seal, replay, provenance, and local naming.*
9. *C is the displayed* Cont *replay from an interval-grid request through $I, K, M, D, V, W, R, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalVariationGrid}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, a selected partition outside the displayed grid, quotient equality of real values, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7548.2 (Compact interval variation grid NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$ *carrier*

$$G = (I, K, M, D, V, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalVariationGrid}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *interval and compact-source admission through I, K;*
2. *finite mesh-grid exposure through M, with every endpoint and adjacent cell read over the same displayed interval source;*
3. *dyadic tolerance and variation-ledger exactness through D, V;*
4. *regular readback and real-seal handoff through W, R; and*
5. *componentwise transport, replay, provenance, and local naming through H, C, P, N.*

No variation-grid obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 7548.1. The interval source and Bishop compact interval row are the first displayed coordinates, so every consumer reads I, K before it can inspect the grid.

The finite mesh obligation is projection to M. Because the mesh row is attached to the same interval source, endpoint and adjacent-cell reads cannot be detached from the closed bounded interval boundary.

The numerical ledger is read from D, V. The dyadic row records the tolerances and comparison budgets, while the variation row records the finite adjacent changes and their finite sum.

The readback and scalar handoff are read from W, R. Regular rational windows supply the finite endpoint observations, and the Real row seals only the terminal scalar comparisons already exposed by those windows.

Finally, H, C, P, N exhaust transport, replay, provenance, and local naming. With no further coordinate, the certificate cannot export open-cover compactness, a selected partition outside the grid, quotient equality of real values, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalVariationGrid}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactIntervalVariationGrid}^{\uparrow}}$, seed)

Scope closed: Definition 7548.1 and Definition 7548.2 seed the finite compact-interval variation grid surface over interval source, compact row, mesh, dyadic tolerances, variation ledger, regular readbacks, real seal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactIntervalVariationGrid}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected partitions outside the displayed mesh, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked interval-source admission, compact-row attachment, mesh-grid exactness, dyadic tolerance exactness, variation-ledger exactness, regular readback, real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalVariationGridUp.

Constructive story: A $\mathsf{CompactIntervalVariationGrid}^{\uparrow}$ packet is generated from interval source, BishopCompactInterval, mesh-grid, DyadicRatCore, finite variation ledger, RegSeqRat, Real, hsame, Cont, Pkg, and NameCert rows.

Chapter 7549

A Concrete Naming Certificate for $\mathsf{EuclideanAlgorithm}^{\uparrow}$

Following Euclid and Knuth, the $\mathsf{EuclideanAlgorithm}^{\uparrow}$ packet records the finite descent trace behind a greatest-common-divisor computation as displayed BEDC data. It consumes the unary natural-number surface of chapter 28, the signed coefficient rows of chapter 31, the multiplication-witness divisibility boundary of chapter 331, the backtracking route of chapter 6993, and the division-with-remainder interface of chapter 7053. The chapter names the algorithm only as a finite history packet: input rows, quotient and remainder rows, a strict natural-valued descent budget, terminal divisor data, Bezout backtracking, transport, replay, provenance, and local naming all remain visible.

Definition 7549.1 (Euclidean algorithm carrier)**.** *A* $\mathsf{EuclideanAlgorithm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, S, B, T, Z, H, C, P, N)$$

with the following displayed rows:

1. *I is the input row, naming the two displayed arithmetic inputs through* $\mathsf{Nat}^{\uparrow}$ *rows, with signed readback through* $\mathsf{Int}^{\uparrow}$ *only when coefficient consumers ask for it.*
2. *S is the finite step ledger. Each row of S records one quotient-and-remainder step, its dividend and divisor rows, the quotient row, the remainder row, and the local division-with-remainder evidence read through* $\mathsf{EuclideanDomain}^{\uparrow}$*.*
3. *B is the strict* $\mathsf{Nat}^{\uparrow}$*-valued descent budget. It assigns a displayed natural value to every non-terminal divisor row and records that each nonzero remainder row in S has strictly smaller budget.*
4. *T is the terminal divisor row. It records the first step whose remainder row is the displayed zero row and stores the terminal divisor as the candidate gcd row.*
5. *Z is the Bezout backtracking route. It reads the terminal divisor and the reversed finite step ledger through* $\mathsf{BezoutIdentity}^{\uparrow}$ *and the* $\mathsf{Divisibility}^{\uparrow}$ *boundary.*
6. *H records componentwise* hsame *transport for input rows, step rows, budget rows, terminal divisor rows, Bezout backtracking, continuation replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from the input row through the step ledger, descent budget, terminal divisor, and Bezout backtracking route.*

8. *P is the* Pkg *provenance over* $\mathsf{EuclideanAlgorithm}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Divisibility}^{\uparrow}$, $\mathsf{BezoutIdentity}^{\uparrow}$, $\mathsf{EuclideanDomain}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{EuclideanAlgorithm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by replaying these displayed coordinates. It has no coordinate for a hidden host gcd routine, a selected quotient stream, quotient equality of ideals, a normalized gcd convention, global well-ordering, or an off-packet Euclidean-domain theorem.

Lean4 (definition) `BEDC.Derived.EuclideanAlgorithmUp.EuclideanAlgorithmUp`
Lean4 ✓ `BEDC.Derived.EuclideanAlgorithmUp.EuclideanAlgorithmTasteGate single carrier alignment`

Theorem 7549.2 (Euclidean algorithm NameCert obligations)**.** *For every accepted* $\mathsf{EuclideanAlgorithm}^{\uparrow}$ *carrier*

$$A = (I, S, B, T, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EuclideanAlgorithm}^{\uparrow}}$ *surface consists exactly of input-row admission, quotient-and-remainder step admission through S, strict* $\mathsf{Nat}^{\uparrow}$*-budget admission through B, terminal divisor admission through T, Bezout and divisibility backtracking through Z, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Lean4 ✓ `BEDC.Derived.EuclideanAlgorithmUp.EuclideanAlgorithmCarrier namecert obligations`

Proof. Project the carrier of Definition 7549.1. The input row I supplies the two displayed arithmetic inputs, while the step ledger S supplies every quotient-and-remainder row consumed by the computation.

Read the budget and terminal rows next. The row B is the only coordinate that records strict descent, and the row T is the only coordinate that records the terminal zero-remainder step and its divisor output.

Finally read the backtracking and structural rows. The row Z routes the reversed finite trace through $\mathsf{BezoutIdentity}^{\uparrow}$ and $\mathsf{Divisibility}^{\uparrow}$, while H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate stores a host gcd routine, quotient stream, ideal quotient equality, normalized-gcd convention, global well-ordering, or detached Euclidean-domain theorem, none of those objects belongs to the local NameCert surface. □

Theorem 7549.3 (Euclidean algorithm descent budget)**.** *Every accepted* $\mathsf{EuclideanAlgorithm}^{\uparrow}$ *carrier exposes termination only through the finite budget row B. If a nonterminal step of S has divisor row d and nonzero remainder row r, then the budget ledger records a strict* $\mathsf{Nat}^{\uparrow}$ *comparison from the value attached to r below the value attached to d. The terminal row T may be read only after this finite descent ledger reaches a displayed zero-remainder step.*

Proof. Induct over the finite step ledger S. In the base case, the first displayed step is read with its divisor, quotient, remainder, and local division evidence, and the budget row B supplies the comparison attached to that step.

For the induction step, assume the current nonterminal row exposes a nonzero remainder. The next row of S uses that remainder as the new divisor row, and B records the strict $\mathsf{Nat}^{\uparrow}$ descent from the old divisor budget to the new divisor budget.

Because the induction ranges only over the displayed finite ledger, it cannot appeal to a host well-ordering or to an unlisted search procedure. The terminal divisor row T is available exactly when the next inspected remainder is the displayed zero row, and the Bezout row Z can then replay the reversed finite ledger without adding another termination principle. □

Falsifiable prediction: Every accepted $\mathsf{EuclideanAlgorithm}^{\uparrow}$ read must expose the input row, every quotient-and-remainder step row, the strict $\mathsf{Nat}^{\uparrow}$ descent budget, the terminal divisor row, the Bezout backtracking row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before it may be consumed as a gcd or Bezout computation.

Independence witness: nat, int, divisibility, bezout-identity, euclidean-domain: $\mathsf{EuclideanAlgorithm}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the input rows, the whole finite quotient-and-remainder trace, a strict natural-valued descent budget, the terminal divisor row, and the Bezout backtracking route as one algorithm packet.

Closure status for $\mathsf{NameCert}_{\mathsf{EuclideanAlgorithm}^{\uparrow}}$.

Constructive story: A $\mathsf{EuclideanAlgorithm}^{\uparrow}$ packet is generated from input rows, finite quotient-and-remainder step rows, a strict NatUp-valued descent budget, a terminal divisor row, Bezout backtracking, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EuclideanAlgorithm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7549.1, Definition 7549.2, and Definition 7549.3 seed the finite Euclidean descent trace over NatUp, IntUp, DivisibilityUp, BezoutIdentityUp, and EuclideanDomainUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EuclideanAlgorithm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unique gcd normalization, ideal quotient equality, a selected host algorithm, global well-ordering, or a Euclidean-domain theorem beyond the displayed finite trace.

Upgrade path: Obligation closure requires checked input admission, step-ledger exactness, strict descent, terminal divisor exposure, Bezout backtracking, transport, replay, provenance, and local naming for BEDC.Derived.EuclideanAlgorithmUp.

Chapter 7550

A Concrete Naming Certificate for $\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}$ packet records the finite surface by which located interval data yield an explicit dyadic modulus row for later real-name and regular-Cauchy consumers. It sits after the dyadic endpoint ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, the located completion boundary of chapter 6253, the compact interval modulus surface of chapter 5937, and the choice-free completion route of chapter 4237. The packet extracts finite modulus rows from displayed located endpoint and tolerance data; it does not assert Heine–Borel compactness, open-cover compactness, selected representatives, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7550.1 (Located interval modulus extraction carrier)**.** *A* $\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, G, W, T, M, H, C, P, N)$$

with the following displayed rows:

1. *E is the located interval endpoint row, listing lower and upper dyadic endpoint reads together with the finite locatedness witnesses that separate an external rational probe from the interval boundary.*
2. *G is the dyadic grid-window row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh levels and endpoint refinements through which the interval is inspected.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to request only finitely many endpoint and regular-name observations.*
4. *T is the regular-Cauchy tolerance row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and carrying the requested precision scale for each displayed window.*
5. *M is the extracted modulus row, assigning to each displayed tolerance request a dyadic grid window sufficient for the located interval read.*
6. *H records componentwise* hsame *transport for endpoint rows, dyadic grid windows, StreamName windows, regular-Cauchy tolerance rows, extracted modulus rows, replay, provenance, and local naming.*

7. *C records displayed* Cont *replay from a modulus request through E, G, W, T, M, H, P, N.*

8. *P is the* Pkg *provenance over* LocatedIntervalModulusExtraction$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, LocatedIntervalCompletion$^{\uparrow}$, CompactIntervalModulus$^{\uparrow}$, RegularCauchyChoiceFreeCompletion$^{\uparrow}$ BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{LocatedIntervalModulusExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $E, G, W, T, M, H, C, P, N$. It has no coordinate for open covers, selected real representatives, quotient equality of real names, trichotomy, countable choice, or a completeness principle for Real$^{\uparrow}$.

Theorem 7550.2 (Located interval modulus extraction obligations)**.** *For every accepted* LocatedIntervalModulusEx *carrier*

$$K = (E, G, W, T, M, H, C, P, N),$$

the local NameCert$_{\text{LocatedIntervalModulusExtraction}^{\uparrow}}$ *surface consists exactly of finite located endpoint exposure through E, dyadic grid-window exposure through G, finite observation scheduling through W, regular-Cauchy tolerance exposure through T, extracted modulus rows through M, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Every consumer of the extracted modulus first reads the sibling route

DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, LocatedIntervalCompletion$^{\uparrow}$, CompactIntervalModulus$^{\uparrow}$, Regula

and receives only the displayed finite rows of that route. The packet does not export Heine–Borel compactness, open-cover compactness, selected representatives, countable choice, quotient real equality, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7550.1. Rows E, G, W, T, M are the endpoint, dyadic-window, finite-observation, tolerance, and modulus coordinates, while H, C, P, N transport, replay, source, and name the same finite packet.

Read the endpoint and grid rows first. The dyadic endpoint ledger is supplied by chapter 291, and the finite observation schedule is supplied by chapter 126; hence a modulus request can inspect only displayed dyadic windows and listed observations.

Next read the regular-Cauchy and real-name rows. The tolerance row T is the RegSeqRat$^{\uparrow}$ source route of chapter 301, and its terminal real-facing seal is the Real$^{\uparrow}$ row of chapter 38. The located interval completion route of chapter 6253 keeps the endpoint data attached to that same finite read.

Finally use the modulus and completion siblings. The finite modulus surface is the one exposed by chapter 5937, and the source-side completion route is the choice-free packet of chapter 4237. Since none of the excluded principles appears as a carrier coordinate, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: Every accepted LocatedIntervalModulusExtraction$^{\uparrow}$ read exposes located endpoint rows, dyadic grid windows, StreamName observations, RegSeqRat tolerance rows, extracted modulus rows, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing real seal consumes the extracted modulus.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-interval-completion, compact-interval-modulus, regular-cauchy-choice-free-completion: none is bijective with LocatedIntervalModulusExt because this packet alone binds finite located endpoint rows, dyadic grid windows, regular-Cauchy

tolerance requests, extracted modulus rows, and structural transport into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}$ packet is generated from located interval endpoint rows, dyadic grid-window rows, StreamName finite observations, RegSeqRat tolerance rows, extracted modulus rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7550.1 and Definition 7550.2 seed the finite located interval modulus extraction surface over dyadic, stream, regular-Cauchy, real, located-completion, compact-modulus, and choice-free completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedIntervalModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, open-cover compactness, selected representatives, countable choice, quotient real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-row exposure, dyadic grid-window coverage, regular-Cauchy tolerance extraction, modulus-row exactness, transport, replay, provenance, and local naming for BEDC.Derived.LocatedIntervalModulusExtractionUp.

Chapter 7551

A Concrete Naming Certificate for $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$

Following Hardy's summability theory, the $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$ packet records the finite Cauchy–Stolz transform route by which a regular rational sequence is inspected through displayed numerator differences, denominator growth rows, and Stolz–Cesaro comparison windows before a real-facing consumer reads the transformed endpoint. It sits after the regular rational readback of chapter 301, the finite observation discipline of chapter 126, the rational arithmetic carrier of chapter 37, the terminal real-name seal of chapter 38, and the Stolz–Cesaro sibling of chapter 6137. The packet names a finite L10 summability transform; it does not claim host quotient equality of real names, selected limits, trichotomy, countable choice, or classical completeness.

Definition 7551.1 (Regular Cauchy–Stolz transform carrier)**.** *A* $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, Q, D, A, Z, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational windows supply the inspected sequence values.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the source indices, successor indices, and transform windows used by the comparison.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *arithmetic row for numerator differences, denominator differences, and quotient comparisons.*
4. *D is the positive denominator-growth row, recording that the inspected denominator windows are ordered and never read through an invisible zero divisor.*
5. *A is the finite difference-ratio row comparing $(a_{n+1} - a_n)$ with $(b_{n+1} - b_n)$ over the displayed windows.*
6. *Z is the* $\mathsf{StolzCesaroTheorem}^{\uparrow}$ *handoff row, used only after R, W, Q, D, A have been exposed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available to downstream summability consumers after the regular source, window, arithmetic, growth, and Stolz rows are visible.*
8. *H records componentwise* hsame *transport for the source, window, rational arithmetic, denominator-growth, difference-ratio, Stolz handoff, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through the same finite transform route.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StolzCesaroTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyStolzTransform}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, Q, D, A, Z, E, H, C, P, N$. It has no coordinate for host quotient equality of real names, an unlogged infinite matrix transform, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7551.2 (Regular Cauchy–Stolz transform NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$ *carrier $S = (R, W, Q, D, A, Z, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyStolzTransf}}$ *surface consists exactly of carrier admission for the displayed regular rational source, finite windows, rational arithmetic, denominator-growth row, difference-ratio row, Stolz handoff, real seal, componentwise transport, displayed replay, provenance, and local naming. Every transform read must expose R, W, Q, D, A before the Stolz–Cesaro handoff Z and the real seal E are available.*

Proof. Project the carrier of Definition 7551.1. The analytic rows are R, W, Q, D, A, Z, E, and the structural rows are H, C, P, N.

The source and windows are read first. The $\mathsf{RegSeqRat}^{\uparrow}$ row supplies regular rational values, while the $\mathsf{StreamName}^{\uparrow}$ row fixes the finite source and successor windows used by the transform.

The rational arithmetic route is then forced through Q, D, A. Numerator differences, denominator differences, denominator-growth witnesses, and quotient comparisons are displayed before any Stolz-facing handoff is read.

Finally Z, E, H, C, P, N preserve and name the same route. Since no carrier coordinate stores a selected limit, quotient equality, countable-choice schedule, trichotomy witness, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 7551.3 (Regular Cauchy–Stolz squeeze handoff)**.** *Every completion-facing squeeze read exported by an accepted* $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{StolzCesaroTheorem}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In carrier coordinates, the read exposes R, W, Q, D, A before Z and exposes Z before E. Thus the consumer sees a finite regular-source and difference-ratio certificate, not a host quotient equality, selected endpoint, or classical completeness theorem.

Proof. Start with an accepted carrier $S = (R, W, Q, D, A, Z, E, H, C, P, N)$. The finite source values and observation windows are exactly the rows R, W.

The arithmetic comparison is displayed by Q, D, A. These rows supply the rational differences, denominator-growth evidence, and quotient comparison windows needed for a Stolz–Cesaro squeeze read.

Only then can the handoff row Z be consumed. The terminal row E is reached through the $\mathsf{Real}^{\uparrow}$ seal after the Stolz route is visible, while H, C, P, N preserve transport, replay, provenance, and local naming. The refused host principles are absent from the carrier coordinates. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyStolzTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyStolzTransform}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName finite windows, Rat arithmetic rows, denominator-growth data, finite difference-ratio comparisons, a StolzCesaroTheorem handoff, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchyStolzTransform}^{\uparrow}}$, seed)

Scope closed: Definition 7551.1, Definition 7551.2, and Definition 7551.3 seed the finite Cauchy–Stolz transform route over regular rational source windows, rational difference rows, Stolz handoff, real sealing, transport, replay, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyStolzTransform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host quotient equality, selected limits, trichotomy, countable choice, classical completeness, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, rational difference-ratio exactness, denominator-growth compatibility, Stolz handoff ordering, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyStolzTransformUp.

Chapter 7552

A Concrete Naming Certificate for $\mathsf{BusemannProjection}^{\uparrow}$

The $\mathsf{BusemannProjection}^{\uparrow}$ packet realizes the hyperbolic observer-expansion route of chapter 9463 as a finite boundary projection surface. It sits after the Busemann-boundary rows of chapter 3732, the visual-boundary rows of chapter 4181, the observer-expansion rows of chapter 4167, the hyperbolic metric rows of chapter 3474, and the disk-metric rows of chapter 6209. The packet records a finite projection from observer windows to Busemann boundary coordinates; it is not a completed ideal boundary, a quotient ray space, a selected geodesic representative, or a host compactification theorem.

Definition 7552.1 (Busemann projection carrier)**.** *A* $\mathsf{BusemannProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, D, \Xi, V, O, W, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row for the inspected disk or boundary-facing source.*
2. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric row supplying the local disk coordinate and distance comparison windows.*
3. *Ξ is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary row that receives the projected direction.*
4. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *visual-boundary row used to compare the projected direction with observer-visible boundary data.*
5. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *observer-window row that supplies finite expansion and phase-readout windows.*
6. *W is the projection-window row, listing the finite metric, boundary, visual, and observer windows consumed by the projection.*
7. *R is the refusal row excluding host compactifications, quotient ray spaces, selected geodesic representatives, and unlogged global boundary models.*
8. *H records componentwise* hsame *transport for the metric, disk, Busemann, visual, observer, projection-window, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through $M, D, \Xi, V, O, W, R, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BusemannProjection}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BusemannProjection}^{\uparrow}}$ *row.*

The later Lean TasteGate file for $\mathsf{BusemannProjection}^{\uparrow}$ *must provide Nontrivial and FieldFaithful instances before the packet can be treated as a positive discovery gate rather than a finite carrier row.*

Theorem 7552.2 (Busemann projection NameCert obligations)**.** *For every accepted* $\mathsf{BusemannProjection}^{\uparrow}$ *carrier* $B = (M, D, \Xi, V, O, W, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BusemannProjection}^{\uparrow}}$ *surface consists exactly of metric admission, disk-metric admission, Busemann-boundary admission, visual-boundary comparison, observer-window admission, projection-window exactness, refusal exactness, componentwise transport, displayed replay, provenance, and local naming. Every projection read must expose the finite boundary, Busemann, visual-metric, observer-window, provenance, and NameCert rows before it is consumed as a boundary projection.*

Proof. Project the carrier of Definition 7552.1. The metric and disk rows are M, D, the boundary-facing rows are Ξ, V, O, W, R, and the structural rows are H, C, P, N.

The projection begins with displayed metric data. The hyperbolic metric and disk-metric rows provide the distance windows and disk coordinate comparisons used by the boundary-facing read.

The Busemann, visual, and observer rows are then read together. The boundary target Ξ, the visual comparison V, and the observer-expansion window O determine the finite projection route, while W records which windows are consumed.

Finally the refusal and structural rows prevent escape to host geometry. Since R, H, C, P, N contain no completed ideal boundary, quotient ray space, selected geodesic representative, or global compactification theorem, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{BusemannProjection}^{\uparrow}$ read exposes HyperbolicMetric, PoincareDiskMetric, HyperbolicBusemannBoundary, HyperbolicVisualBoundary, HyperbolicObserverExpansion, projection-window, refusal, transport, replay, provenance, and local NameCert rows before any boundary projection is consumed.

Independence witness: hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-observer-expansion, hyperbolic-metric, poincare-disk-metric: $\mathsf{BusemannProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric admission, disk-metric comparison, Busemann boundary target, visual-boundary comparison, observer-window projection, host-geometry refusal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BusemannProjection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BusemannProjection}^{\uparrow}$ packet is generated from HyperbolicMetric rows, PoincareDiskMetric rows, HyperbolicBusemannBoundary rows, HyperbolicVisualBoundary rows, HyperbolicObserverExpansion windows, finite projection-window data, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BusemannProjection}^{\uparrow}}$, seed)

Scope closed: Definition 7552.1 and Definition 7552.2 seed the finite boundary projection route over hyperbolic metric, disk metric, Busemann boundary, visual boundary, observer-window, refusal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BusemannProjection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, completed ideal boundaries, quotient ray spaces, selected geodesic representatives, host compactification theorems, or global hyperbolic models.

Upgrade path: Obligation closure requires checked metric admission, disk-metric admission, Busemann-boundary admission, visual-boundary comparison, observer-window admission, projection-window exactness, refusal exactness, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BusemannProjectionUp.

Chapter 7553

A Concrete Naming Certificate for CompactModulusMonotoneConvergence$^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the CompactModulusMonotoneConvergence$^{\uparrow}$ packet records the finite-modulus surface by which a monotone sequence of continuous maps on a compact metric source is read as a uniform convergence candidate. It sits over the compact metric carrier of chapter 129, the continuous-map rows of chapter 130, the uniform-limit consumer of chapter 463, the uniform-modulus route of chapter 369, the stream naming surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a displayed finite-modulus convergence interface only; it does not import open-cover compactness, quotient function equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ completeness.

Falsifiable prediction: Every accepted CompactModulusMonotoneConvergence$^{\uparrow}$ read exposes compact source probes, continuous-map rows, a monotone comparison ledger, a finite modulus row, StreamName windows, RegSeqRat readbacks, and the Real seal before any uniform-limit consumer may inspect the convergence handoff.

Independence witness: compactmetric, continuousmap, uniformlimit, uniformmodulus, regseqrat: the compact metric source lacks monotone comparison and finite-modulus rows; the continuous-map route lacks a convergence handoff; the uniform-limit consumer lacks the compact source provenance; the uniform-modulus packet lacks monotone sequence data; and the regular rational readback lacks the NameCert rows that bind the whole interface. None is bijective to CompactModulusMonotoneConvergence$^{\uparrow}$.

Definition 7553.1 (Compact modulus monotone convergence carrier)**.** *A* CompactModulusMonotoneConvergence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, M, U, L, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* CompactMetric$^{\uparrow}$ *source row, exposing the compact metric probes and finite inspection windows used by the convergence read.*
2. *F is the* ContinuousMap$^{\uparrow}$ *family row, carrying the displayed continuous-map data for the monotone sequence.*
3. *M is the monotone comparison ledger, recording the finite order checks between adjacent displayed maps at inspected source probes.*

4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, supplying the finite tolerance-to-window modulus consumed by the convergence handoff.*
5. *L is the* $\mathsf{UniformLimit}^{\uparrow}$ *row receiving only the convergence candidate produced by K, F, M, U, S, Q, R.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row for sequence indices, source probes, and finite comparison reads.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerances and Real-facing estimates.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for terminal scalar comparisons already exposed by Q.*
9. *H records componentwise* hsame *transport for compact source, map family, monotone ledger, modulus, limit handoff, stream windows, regular readbacks, Real seal, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a convergence request through $K, F, M, U, L, S, Q, R, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, M, U, L, S, Q, R, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, quotient equality of functions, selected limit objects, countable-choice schedules, host supremum principles, ambient Real completeness, Lean verification, or bridge checking.

Theorem 7553.2 (Compact modulus monotone convergence NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}$ *carrier*

$$G = (K, F, M, U, L, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact-source admission through K;*
2. *continuous-family admission through F over the same source row;*
3. *monotone comparison exactness through M, with each displayed adjacent comparison attached to the same finite source and stream windows;*
4. *finite-modulus exactness through U, requiring the tolerance-to-window ledger to be read before the convergence handoff;*
5. *uniform-limit handoff through L, downstream of K, F, M, U, S, Q, R and not an independent selected limit;*
6. *stream, regular readback, and Real-seal ordering through S, Q, R; and*
7. *componentwise transport, replay, provenance, local naming, and nonescape through H, C, P, N.*

No compact modulus monotone convergence obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7553.1. The compact source, continuous family, monotone ledger, finite modulus, uniform-limit handoff, stream windows, regular readbacks, Real seal, and structural rows are all displayed coordinates of the packet.

The compact and continuous-map obligations are read first through K and F. Because the map-family row is attached to the same compact source row, a consumer cannot replace the finite source probes by an ambient open-cover compactness theorem or a quotient function-space equality.

The monotone and modulus obligations are read through M and U. The comparison ledger keeps adjacent-map order checks visible at inspected source probes, while the modulus row supplies only a finite tolerance-to-window route.

Finally L, S, Q, R, H, C, P, N impose output order and local naming. The uniform-limit row receives the candidate after the displayed rows have been exposed, stream and rational readbacks precede the Real seal, and the structural rows contain none of the refused selected-limit, choice, quotient, completeness, verification, or bridge data. □

Theorem 7553.3 (Compact modulus monotone convergence handoff)**.** *Every uniform-limit consumer of an accepted* $\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}$ *carrier must read the route*

$$K, F \longmapsto M, U \longmapsto L, S, Q, R, H, C, P, N.$$

The handoff exposes compact source probes, continuous-map rows, monotone comparisons, a finite modulus, stream windows, regular rational readbacks, and the Real seal before the convergence candidate is consumed. It exports no open-cover compactness theorem, quotient function equality, selected limit, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with an accepted packet $G = (K, F, M, U, L, S, Q, R, H, C, P, N)$. The source and map-family rows K, F provide the displayed compact metric and continuous-map data.

Next read M, U. The monotone comparison ledger and finite modulus row are the only coordinates through which adjacent-map order and tolerance-to-window information enter the packet.

The convergence handoff is then read through L, with S, Q, R supplying stream windows, regular rational estimates, and the Real seal. The rows H, C, P, N transport, replay, source, and name the same finite route.

Since no coordinate stores open-cover compactness, quotient function equality, selected limits, countable choice, or ambient Real completeness, the displayed handoff is the whole public convergence interface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7553.1, Definition 7553.2, and Definition 7553.3 seed the finite-modulus convergence surface over compact source probes, continuous-map rows, monotone comparisons, uniform modulus, uniform-limit handoff, stream windows, regular readbacks, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient function equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, continuous-family admission, monotone comparison exactness, finite-modulus exactness, uniform-limit handoff ordering, readback ordering, and nonescape proofs for BEDC.Derived.CompactModulusMonotoneConvergenceUp.

Constructive story: A $\mathsf{CompactModulusMonotoneConvergence}^{\uparrow}$ packet is generated from CompactMetric, ContinuousMap, monotone comparison, UniformModulus, UniformLimit, StreamName, RegSeqRat, Real, hsame, Cont, Pkg, and NameCert rows.

Chapter 7554

A Concrete Naming Certificate for $\mathsf{CauchyCompletionCategory}^{\uparrow}$

Following Mac Lane and Bishop–Bridges on Kleisli composition and constructive completion, the $\mathsf{CauchyCompletionCategory}^{\uparrow}$ packet records the finite category surface whose objects are displayed completion packets and whose morphisms are completion-valued BEDC routes. It sits after the completion monad of chapter 378, the unit row of chapter 1527, the bind row of chapter 3777, the metric-completion boundary of chapter 1506, and the finite real-name route through chapter 126, chapter 301, chapter 291, and chapter 38. The chapter names a completion-category interface as BEDC rows; it is not quotient completion equality, not a selected limit principle, not host equality of completed objects, and not countable choice.

Definition 7554.1 (CauchyCompletionCategory carrier)**.** *A* $\mathsf{CauchyCompletionCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (O, A, U, B, T, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the completion-object row. Each object is read through* $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *A is the completion-morphism row. Each morphism is a completion-valued BEDC route whose source and target are displayed by O.*
3. *U is the identity row, routing object identities through* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *and the same source-completion data.*
4. *B is the bind and Kleisli-composition row, exposing composition only through* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *and* $\mathsf{CauchyCompletionBind}^{\uparrow}$.
5. *T is the classifier-transport row, recording componentwise transport for object, morphism, unit, bind, metric-completion, stream, regular-rational, dyadic, and Real-seal reads.*
6. *R is the replay row, forcing each category-facing consumer to replay the displayed completion route before reading identity or composition data.*
7. *H records componentwise* hsame *transport for completion objects, completion morphisms, identities, compositions, classifier transport, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for object reads, morphism reads, identity reads, Kleisli-composition reads, and terminal* $\mathsf{Real}^{\uparrow}$ *seal requests.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionCategory}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCategory}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected limits, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7554.2 (CauchyCompletionCategory NameCert obligations)**.** *For every accepted* CauchyCompletionCate *carrier $G = (O, A, U, B, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCategory}^{\uparrow}}$ *surface consists exactly of carrier admission, object exposure, morphism exposure, identity exposure, composition exposure, classifier transport, replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape of quotient completion equality, selected limits, host equality, countable choice, hidden representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7554.1. The object, morphism, identity, composition, transport, replay, structural transport, displayed replay, provenance, and naming rows are precisely $O, A, U, B, T, R, H, C, P, N$.

The object and morphism clauses come from O and A. The identity clause is read through U, while the composition clause is read through B and therefore through the displayed monad and bind rows rather than through host equality of functions.

Classifier transport and replay are local to T and R. The rows H and C preserve and replay the same carrier coordinates componentwise, and P, N source and name the packet.

Since no carrier coordinate stores quotient completion equality, selected limits, host equality, countable choice, hidden representatives, or ambient completeness, the non-escape obligation follows by exhaustion. □

Theorem 7554.3 (CauchyCompletionCategory Kleisli factorization)**.** *Every morphism read and every composition read of an accepted* $\mathsf{CauchyCompletionCategory}^{\uparrow}$ *packet factors through*

$\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Re

The factorization may inspect $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows along the regular-rational route, but it exports no quotient completion equality, selected limits, host equality of completed objects, countable choice, hidden stream representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a morphism or composition request. By Definition 7554.2, the request first projects the accepted carrier and reads only the displayed object and morphism rows.

For identities, the row U routes the request through $\mathsf{CauchyCompletionUnit}^{\uparrow}$. For composites, the row B routes the request through $\mathsf{CauchyCompletionMonad}^{\uparrow}$ and $\mathsf{CauchyCompletionBind}^{\uparrow}$, so categorical composition is a finite Kleisli-composition read.

The completion-facing part then passes through $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with $\mathsf{DyadicRatCore}^{\uparrow}$ supplying the tolerance observations used by the regular-rational readback. These rows are named in the provenance row P and replayed by R and C.

The transport rows T and H preserve the same route componentwise. Because the carrier has no row for quotient completion equality, selected limits, host equality, countable choice, hidden representatives, or ambient completeness, no second route can supply categorical composition data. □

Falsifiable prediction: A $\mathsf{CauchyCompletionCategory}^{\uparrow}$ consumer that reads composition without first exposing the monad, unit, bind, metric-completion, stream-window, regular-rational, Real-seal, transport, replay, provenance, and local NameCert rows refutes the packet.

Independence witness: cauchycompletionmonad, cauchycompletionunit, cauchycompletionbind, metriccompletion, streamname, regseqrat, real: none is bijective to $\mathsf{CauchyCompletionCategory}^{\uparrow}$ because the category packet jointly carries completion objects, completion morphisms, identity rows, bind-composition rows, classifier transport, replay, provenance, and local naming in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionCategory}^{\uparrow}$ packet is generated from completion-object rows, completion-morphism rows, identity rows, bind-composition rows, classifier-transport rows, replay rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7554.1, Definition 7554.2, and Definition 7554.3 seed the finite completion-category packet for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, hidden stream representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, object exposure, morphism exposure, identity exposure, composition exposure, classifier transport, replay stability, provenance exhaustion, and non-escape for BEDC.Derived.CauchyCompletionCategoryUp.

Chapter 7555

A Concrete Naming Certificate for $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$ packet records the finite modulus data needed to read a nested interval construction as Real-facing and Completion-facing evidence. It sits after the dyadic interval rows of chapter 7491, the subdivision ledger of chapter 7480, the regular rational route of chapter 301, and the terminal real-name boundary of chapter 38. The packet names a finite nested-interval schedule and does not claim open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, a selected limit, countable choice, trichotomy, or host equality of real numbers.

Definition 7555.1 (Bishop interval nesting modulus carrier)**.** *A* $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (D, L, U, M, S, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and radius ledger for the displayed nested intervals.*
2. *L is the lower-endpoint row, read as a finite dyadic list over D.*
3. *U is the upper-endpoint row, read as a finite dyadic list over D.*
4. *M is the modulus row assigning each requested precision a finite depth after which the interval width is inside the requested dyadic tolerance.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule for the interval endpoints and widths.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed on the windows named by S.*
7. *H records componentwise* hsame *transport for D, L, U, M, S, R and the structural rows.*
8. *C records displayed* Cont *replay of the same endpoint, width, modulus, stream, and regular-rational reads.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingModulus}^{\uparrow}}$ *row binding the displayed interval-nesting surface.*

The carrier has no coordinate for open-cover compactness, ambient real completeness, selected limits, countable choice, trichotomy, or host real equality.

Theorem 7555.2 (BishopIntervalNestingModulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$ *carrier* $J = (D, L, U, M, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingModulus}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the dyadic endpoint ledger, lower endpoint row, upper endpoint row, modulus row, stream schedule, regular rational readback, transport, replay, provenance, and local naming rows;*
2. *nestedness admission, requiring each displayed interval row to read the same dyadic ledger* D *and to place the next lower and upper endpoints inside the previous endpoints;*
3. *width-modulus admission, requiring every request in* M *to consume a positive tolerance row already displayed in* D*;*
4. *finite-window admission, requiring the stream schedule* S *to expose the endpoint and width windows before the regular rational row* R *is read;*
5. *Real-facing replay stability, requiring* H *and* C *to preserve the same endpoint, modulus, stream, and readback rows componentwise;*
6. *provenance and local naming through* P *and* N*;*
7. *nonescape from open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, countable choice, trichotomy, and host real equality.*

Proof. Project the carrier of Definition 7555.1. The only available rows are $D, L, U, M, S, R, H, C, P, N$.

Nestedness, width-modulus admission, and finite-window admission are row-local. The lower and upper endpoint rows are read over the same dyadic ledger D, the modulus row M consumes tolerances from D, and the stream row S exposes the finite windows before R is available.

Transport, replay, provenance, and naming are exactly the structural rows H, C, P, N. Since the carrier has no coordinate for open-cover compactness, selected limits, countable choice, trichotomy, host equality, or ambient completeness, the listed obligations exhaust the local certificate surface. □

Theorem 7555.3 (BishopIntervalNestingModulus Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$ *packet must first read the finite route*

$$D,\ L,\ U,\ M,\ S,\ R$$

and then the structural rows H, C, P, N*. The handoff exposes a nested dyadic interval schedule together with a width modulus and regular-rational readback, but it does not expose open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, a selected limit, countable choice, trichotomy, or host real equality.*

Proof. Start from an accepted carrier $J = (D, L, U, M, S, R, H, C, P, N)$. The endpoint and width information is displayed only through the dyadic ledger D and the lower and upper endpoint rows L, U.

Apply Definition 7555.2. The width-modulus row M and stream row S must be read before the regular rational row R, so the Real-facing consumer receives the nested interval data as a finite schedule.

Finally use the structural rows H, C, P, N. They transport, replay, source, and locally name the same route, leaving no coordinate through which a consumer could import open-cover compactness, ambient completeness, a selected limit, countable choice, trichotomy, or host real equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalNestingModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopIntervalNestingModulus}^{\uparrow}$ packet is generated from a dyadic endpoint ledger, lower and upper endpoint rows, a width modulus, a finite stream schedule, a regular rational readback, componentwise transport, displayed replay, provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestingModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7555.1, Definition 7555.2, and Definition 7555.3 name the seed carrier, finite obligation surface, and Real-facing nested-interval handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopIntervalNestingModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, ambient Real completeness, selected limits, countable choice, trichotomy, host real equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, nestedness admission, width-modulus admission, finite-window admission, Real-facing replay stability, provenance, local naming, and nonescape for BEDC.Derived.BishopIntervalNestingModulu

Chapter 7556

A Concrete Naming Certificate for $\mathsf{ChoiceFreeRealSeal}^{\uparrow}$

Following Bishop and Bridges on constructive real names, the $\mathsf{ChoiceFreeRealSeal}^{\uparrow}$ packet records the terminal finite seal for a real-name route that stays inside displayed name data. It reads stream windows from chapter 126, regular rational readback from chapter 301, dyadic tolerances from chapter 291, and the terminal real-name surface of chapter 38. The packet is a finite NameCert seal for accepted real-name consumers, not a completeness theorem for $\mathsf{Real}^{\uparrow}$ and not a quotient stream presentation.

Definition 7556.1 (Choice-free real seal carrier)**.** *A* $\mathsf{ChoiceFreeRealSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *window used by the consumer read.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to that window.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling the inspected precision.*
4. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after* W, R, D *have been read.*
5. L *is the nonescape ledger refusing countable-choice, quotient-stream, trichotomy, host-real-equality, and completeness routes.*
6. H *records componentwise* hsame *transport for* W, R, D, E, L, P, N*.*
7. C *records the displayed* Cont *replay from stream window to rational readback, dyadic tolerance, and terminal real seal.*
8. P *is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and the local naming row.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{ChoiceFreeRealSeal}^{\uparrow}}$ *row.*

The carrier has no coordinate for a countable-choice selector, quotient stream equality, trichotomy on real names, host real equality, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7556.2 (Choice-free real seal NameCert obligations)**.** *For the carrier of Definition 7556.1, the local* $\mathsf{NameCert}_{\mathsf{ChoiceFreeRealSeal}^{\uparrow}}$ *surface consists of five finite rows: carrier admission for* S*;*

stream-window, regular-rational, and dyadic-tolerance visibility before the terminal real seal; componentwise hsame *transport for the displayed rows;* Cont *replay and* Pkg *provenance for the same route; and nonescape from countable-choice, quotient-stream, trichotomy, host-real-equality, and completeness routes.*

Proof. Carrier admission is the displayed packet $S = (W, R, D, E, L, H, C, P, N)$. The first read exposes the stream window, regular rational readback, and dyadic tolerance rows before the terminal $\mathsf{Real}^{\uparrow}$ seal can be used.

The transport, replay, and provenance rows are H, C, P. They keep every accepted read on the same finite packet and attach the local naming row N to that route.

The ledger row L supplies the refusal boundary. Since the carrier lists no selector, quotient equality, trichotomy, host equality, or completeness coordinate, those principles cannot be exported by the local NameCert surface. □

Lean4 (definition) `BEDC.Derived.ChoiceFreeRealSealUp`

Theorem 7556.3 (Choice-free real seal no-choice route)**.** *An accepted* $\mathsf{ChoiceFreeRealSeal}^{\uparrow}$ *packet exports no countable-choice selector, no quotient stream equality, no trichotomy row for real names, no host real equality, and no* $\mathsf{Real}^{\uparrow}$ *completeness row. Every real-facing consumer must read the finite stream window W, regular rational row R, dyadic tolerance row D, terminal real seal E, nonescape ledger L, transport H, replay C, provenance P, and local name N as its complete surface.*

Proof. Inspect the carrier rows in Definition 7556.1. The only real-facing rows are W, R, D, E together with the ledger, transport, replay, provenance, and naming rows.

Apply Definition 7556.2. It forces every local naming read to keep the same five-row obligation surface and the same nonescape ledger.

The excluded principles have no row in S. A consumer asking for countable choice, quotient stream equality, trichotomy, host real equality, or $\mathsf{Real}^{\uparrow}$ completeness therefore leaves the accepted packet rather than reading an exported coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceFreeRealSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{ChoiceFreeRealSeal}^{\uparrow}$ packet is generated from a finite StreamNameUp window, RegSeqRatUp readback, DyadicRatCoreUp tolerance, terminal RealUp seal, nonescape ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChoiceFreeRealSeal}^{\uparrow}}$, seed)

Scope closed: Definition 7556.1, Definition 7556.2, and Definition 7556.3 seed the finite choice-free real-name seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChoiceFreeRealSeal}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.ChoiceFreeRealSealUp`

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient stream equality, trichotomy, host real equality, Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and nonescape exactness for the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert route.

Chapter 7557

A Concrete Naming Certificate for $\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}$

Following Bishop-style finite-cover proofs of uniform continuity on compact metric data, the $\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}$ packet records the finite envelope needed by constructive compact-continuous consumers. It reads compact metric finite-net data from chapter 129, total-bounded schedules from chapter 127, continuous-map pointwise rows from chapter 130, and formal-ball tolerances from chapter 1510. The envelope is a displayed finite cover and modulus route, not an open-cover compactness theorem and not a host continuity principle.

Definition 7557.1 (Finite-cover uniform modulus envelope carrier)**.** *A* $\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, T, F, B, M, W, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite compact source row.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite schedule row selecting the inspected cover cells.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise continuity row read at the selected cells.*
4. *B is the* $\mathsf{FormalBall}^{\uparrow}$ *tolerance and containment row for the cover cells.*
5. *M is the displayed uniform modulus envelope extracted from K, T, F, B.*
6. *W is the finite window ledger tying the cover cells, pointwise moduli, and output modulus to one read.*
7. *H records componentwise* hsame *transport for the displayed rows.*
8. *C records the* Cont *replay from compact source to finite cover, pointwise continuity, formal-ball tolerance, and modulus envelope.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, BHist, hsame, Cont, *and the local naming row.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for open-cover compactness, countable choice, selected subsequences, host semantic continuity, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7557.2 (Finite-cover uniform modulus envelope NameCert obligations)**.** *For the carrier of Definition 7557.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}}$ *surface consists of carrier admission for* U*; finite cover visibility through* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{TotallyBounded}^{\uparrow}$ *rows; pointwise continuity and formal-ball tolerance visibility through* $\mathsf{ContinuousMap}^{\uparrow}$ *and* $\mathsf{FormalBall}^{\uparrow}$ *rows; componentwise transport and replay stability through* H, C, P*; and nonescape from open-cover compactness, countable choice, selected-subsequence, host-continuity, and completeness routes.*

Proof. Carrier admission exposes the finite packet $U = (K, T, F, B, M, W, H, C, P, N)$. The compact and total-bounded rows supply only displayed finite cover data, and the continuous-map and formal-ball rows supply only pointwise and tolerance reads.

The modulus envelope M is read through the window ledger W and replay row C. Transport in H and provenance in P keep that read attached to the same finite packet and local name.

No excluded principle has a carrier coordinate. Thus open-cover compactness, countable choice, selected subsequences, host semantic continuity, and $\mathsf{Real}^{\uparrow}$ completeness are outside the exported NameCert surface. □

Lean4 (definition) `BEDC.Derived.FiniteCoverUniformModulusEnvelopeUp`

Theorem 7557.3 (Finite-cover uniform modulus consumer route)**.** *Every constructive compact-continuous consumer of an accepted* $\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}$ *packet must read the compact source row* K*, total-bounded schedule* T*, continuous-map row* F*, formal-ball tolerance* B*, modulus envelope* M*, finite window ledger* W*, transport* H*, replay* C*, provenance* P*, and local name* N *before treating the packet as a uniform-modulus source.*

Proof. Read the carrier rows of Definition 7557.1. The compact source, total-bounded schedule, continuous-map row, and formal-ball tolerance are the only inputs to the displayed envelope.

Apply Definition 7557.2. It binds those rows to M, W, H, C, P, N as one local NameCert route.

Therefore a consumer can use the packet as a uniform-modulus source only by following the displayed route. Any appeal to open-cover compactness, countable choice, selected subsequences, host semantic continuity, or completeness has no exported row. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}$ packet is generated from CompactMetricUp finite cover data, TotallyBoundedUp schedules, ContinuousMapUp pointwise rows, FormalBallUp tolerances, a displayed modulus envelope, finite window ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 7557.1, Definition 7557.2, and Definition 7557.3 seed the finite cover uniform modulus envelope.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCoverUniformModulusEnvelope}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.FiniteCoverUniformModulusEnvelopeUp`

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, selected subsequences, host semantic continuity, Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and consumer-route exactness for the displayed $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FormalBall}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert route.

Chapter 7558

A Concrete Naming Certificate for $\mathsf{DarbouxStieltjesSum}^{\uparrow}$

Following Riemann, Stieltjes, and Bishop–Bridges, the $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ packet records the finite upper-lower Stieltjes sum boundary for a regulated integrand read against a bounded-variation integrator. It sits beside the Riemann–Stieltjes packet of chapter 1637, the bounded-variation ledger of chapter 398, the regulated-function surface of chapter 1906, the tagged finite-sum row of chapter 1615, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite partition cells, local oscillation rows, bounded-variation cell contributions, dyadic comparison budgets, rational readback, and the Real-facing seal handoff; it does not import measure integration, quotient functions, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7558.1 (Darboux–Stieltjes sum carrier)**.** *A* $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, A, T, U, L, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *integrand row, exposing only the finite value windows and one-sided oscillation reads requested by the displayed partition.*
2. *A is the* $\mathsf{BoundedVariation}^{\uparrow}$ *integrator row, carrying the finite partition-variation ledger and transported endpoint changes of the integrator.*
3. *T is the tagged partition row, read through the* $\mathsf{RiemannSum}^{\uparrow}$ *mesh and tag-containment surface.*
4. *U is the upper Darboux–Stieltjes cell row, recording for each carried cell a displayed upper oscillation bound for F multiplied by the corresponding positive variation contribution of A.*
5. *L is the lower Darboux–Stieltjes cell row, recording for each carried cell a displayed lower oscillation bound for F multiplied by the corresponding signed variation contribution of A when that row is licensed by A.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *oscillation budget, fixing the dyadic tolerances used to compare upper and lower cell ledgers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite upper sum, lower sum, and gap comparison ledgers.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after F, A, T, U, L, Q, R have all been displayed.*

9. *H records componentwise* hsame *transport for the integrand, integrator, tagged partition, upper and lower cell rows, dyadic budget, rational readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a partition request through the regulated-function windows, bounded-variation cell contributions, upper and lower cell ledgers, dyadic budget, rational readback, and Real seal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{DarbouxStieltjesSum}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxStieltjesSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $F, A, T, U, L, Q, R, E, H, C, P, N$. It has no coordinate for measure integration, a quotient of functions, a selected refinement limit, countable choice, or an ambient Real-completeness theorem.

Theorem 7558.2 (Darboux–Stieltjes NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ *carrier $D = (F, A, T, U, L, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxStieltjesSum}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated integrand, bounded-variation integrator, tagged partition, upper and lower Darboux cell rows, dyadic oscillation budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every accepted read follows the finite route*

$$F, A, T \longrightarrow U, L \longrightarrow Q \longrightarrow R \longrightarrow E$$

together with H, C, P, N.

Proof. Project the carrier of Definition 7558.1. The displayed rows list the regulated integrand windows, bounded-variation cell contributions, tagged partition, upper and lower cell ledgers, dyadic budget, rational readback, Real seal, and structural provenance.

For each carried cell, the upper and lower rows are formed from the same partition row T. The integrand contribution is read through F, while the Stieltjes cell contribution is read through A, so both Darboux rows are finite cellwise records rather than host-level extrema or a measure integral.

The dyadic budget Q and readback row R compare the two finite ledgers before the seal row E is visible. Transport through H and replay through C preserve the same route, and P, N only source and name it.

Since no carrier coordinate names measure integration, quotient functions, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligation surface. □

Theorem 7558.3 (Darboux–Stieltjes RegSeqRat handoff)**.** *Every* $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ *read that is consumed by a* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *route factors through a finite partition refinement before the numerical seal is inspected. For an accepted carrier $D = (F, A, T, U, L, Q, R, E, H, C, P, N)$, the consumer must first read the common refinement of the tagged partition, the regulated integrand windows, the bounded-variation cell contributions, the upper and lower Darboux cell rows, and the dyadic oscillation budget; only then may it read R and the terminal seal row E.*

Proof. Start with the finite tagged partition row T and refine it inside the displayed partition surface. The refinement changes only carried cells and their tag-containment data, so it remains a finite BHist calculation.

Read F and A on that refinement. The regulated integrand supplies the local value windows and oscillation bounds, while the bounded-variation integrator supplies the endpoint changes and variation ledger needed by each Stieltjes cell.

Rebuild the upper and lower ledgers U, L on the refined cells and compare them through the dyadic budget Q. The $\mathsf{RegSeqRat}^{\uparrow}$ row R reads back exactly those finite sums and their gap, after which the $\mathsf{Real}^{\uparrow}$ seal E may be consumed.

The structural rows H, C, P, N transport, replay, source, and name the same refinement route. Therefore the handoff never uses measure integration, quotient functions, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxStieltjesSum}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ packet is generated from a regulated integrand row, a bounded-variation integrator row, a tagged partition, upper and lower Darboux–Stieltjes cell ledgers, a dyadic oscillation budget, a regular rational readback row, a Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxStieltjesSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7558.1, Definition 7558.2, and Definition 7558.3 specify the finite Darboux–Stieltjes sum carrier, its NameCert obligation rows, and its RegSeqRat-to-Real handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxStieltjesSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure integration, quotient functions, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: The next grade requires Lean encoding of the carrier and checked theorems for finite partition refinement, upper and lower cell comparison, dyadic oscillation budgeting, RegSeqRat readback, and Real seal nonescape.

Chapter 7559

A Concrete Naming Certificate for $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$

Following Mac Lane's monad multiplication and Bishop–Bridges constructive completion, the $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ packet records the finite join surface that flattens a completion-of-completion name into the displayed Cauchy-completion boundary. It sits beside the law ledger of chapter 3834, the multiplication packet of chapter 1829, the unit route of chapter 1527, the bind route of chapter 3777, the idempotence packet of chapter 2381, and the finite readback layers chapter 126, chapter 291, chapter 301, and chapter 38. The chapter names join as a local BEDC carrier for constructive completion; it is not quotient completion equality, not a selected limit, not host equality of completed objects, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7559.1 (Cauchy completion monad join carrier)**.** *A* $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (O, U, B, I, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the completion-of-completion input row. It displays the outer completion name before any flattening data are public.*
2. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row, recording how source and already completed inputs enter the join surface.*
3. *B is the* $\mathsf{CauchyCompletionBind}^{\uparrow}$ *row, recording the finite bind schedule used to flatten the outer name.*
4. *I is the* $\mathsf{CompletionIdempotence}^{\uparrow}$ *row, requiring an already completed inner name to reuse the displayed completion boundary rather than produce a second quotient object.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposed after O, U, B, I have been read.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to the same flattened windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the flattened name.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after the stream, tolerance, and regular-rational rows have been fixed.*
9. *H records componentwise* hsame *transport for outer completion, unit, bind, idempotence, stream, dyadic, regular-rational, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the outer completion request through the join route and then through S, D, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, CauchyCompletionM $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadJoin}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve displayed rows. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, hidden stream witnesses, or an ambient completeness theorem.

Theorem 7559.2 (Cauchy completion monad join NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ *carrier $J = (O, U, B, I, S, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionMona}}$ *surface consists exactly of carrier admission, outer-completion exposure, unit exposure, bind-schedule exposure, idempotence reuse, flattened StreamName window exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, terminal Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape of quotient completion equality, selected representatives, countable choice, host equality, hidden stream witnesses, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7559.1. The rows $O, U, B, I, S, D, R, E, H, C, P, N$ are the whole public surface, so carrier admission and row exposure are exactly these projections.

The join-specific obligations come from O, U, B, I. The outer completion row must be displayed first, the unit row records admission into the completion surface, the bind row records the finite flattening schedule, and the idempotence row forces already completed inner data back to the same displayed boundary.

The readback obligations come from S, D, R, E. These rows are downstream of the join route, so a consumer cannot inspect a stream window, dyadic tolerance, regular-rational readback, or Real seal detached from O, U, B, I.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since the carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality, hidden stream witnesses, or ambient completeness, the nonescape clause follows by exhaustion. □

Theorem 7559.3 (Cauchy completion monad join flattening route)**.** *Every completion-of-completion consumer of an accepted* $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ *packet must read*

$$O \longmapsto \mathsf{CauchyCompletionUnit}^{\uparrow} \longmapsto \mathsf{CauchyCompletionBind}^{\uparrow} \longmapsto \mathsf{CompletionIdempotence}^{\uparrow}$$

before it can consume the finite readback route

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route is the local join/multiplication face consumed by $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *and by the existing* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *packet; it exports no quotient completion, selected representative, countable-choice schedule, host equality, hidden stream witness, or ambient completeness principle.*

Proof. Begin with an accepted carrier $J = (O, U, B, I, S, D, R, E, H, C, P, N)$. Projection exposes the outer completion row O before any readback row is available.

The row U supplies the completion-unit admission used by constant or already displayed inputs. The row B supplies the bind schedule that flattens the outer completion. The row I records that already completed inner data are reused through the same completion boundary.

Only after those rows have been read does the packet expose S, D, R, E. Componentwise transport through H and replay through C preserve this order for every transported packet.

The provenance row P ties the route to the monad-law and multiplication siblings. Because no excluded object is stored in the carrier, the consumer receives only the displayed join route and the finite readback rows named in the statement. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ read exposes completion-of-completion input, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionBind}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any flattened completion seal can be consumed.

Independence witness: cauchy-completion-monad-law, cauchycompletionmultiplication, cauchy-completionunit, cauchy-completion-bind, completion-idempotence, streamname, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ because this packet jointly binds the outer completion input, unit admission, bind schedule, idempotence reuse, finite readback rows, transport, replay, provenance, and local naming as one join carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadJoin}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ packet is generated from a completion-of-completion input row, CauchyCompletionUnit admission, CauchyCompletionBind scheduling, CompletionIdempotence reuse, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, terminal RealUp seal access, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadJoin}^{\uparrow}}$, seed)

Scope closed: Definition 7559.1, Definition 7559.2, and Definition 7559.3 seed the finite join packet for constructive completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionMonadJoin}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality, hidden stream witnesses, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, outer-completion exposure, unit exposure, bind-schedule exposure, idempotence reuse, readback exactness, transport, replay, provenance, and nonescape for BEDC.Derived.CauchyCompletion

Chapter 7560

A Concrete Naming Certificate for $\mathsf{BoundaryPairing}^{\uparrow}$

The $\mathsf{BoundaryPairing}^{\uparrow}$ packet realizes the paired-boundary handoff surface of chapter 9463 as finite BEDC data. It sits after the Gromov-boundary carrier of chapter 6470, the cross-ratio packet of chapter 3948, the geodesic-flow route of chapter 3856, the Busemann-cocycle row of chapter 4134, and the Poincare-disk boundary transport route of chapter 6267. The packet records a displayed ordered pair of boundary rows before cross-ratio or geodesic-flow consumers may inspect a handoff; it is not quotient ideal-boundary equality, not a selected geodesic, not a completed hyperbolic disk, and not a host compactification theorem.

Definition 7560.1 (Boundary pairing carrier)**.** *A* $\mathsf{BoundaryPairing}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, R, G, X, F, B, T, H, C, P, N)$$

with the following displayed rows:

1. *L is the left* $\mathsf{GromovBoundary}^{\uparrow}$ *boundary row.*
2. *R is the right* $\mathsf{GromovBoundary}^{\uparrow}$ *boundary row.*
3. *G is the pair-guard row, recording that L and R are exposed as two boundary rows before any downstream consumer reads a cross-ratio or flow handoff.*
4. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *handoff row, available only after the ordered pair L, R and the guard G have been displayed.*
5. *F is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *handoff row, recording the boundary-paired flow route consumed by geodesic-facing readers.*
6. *B is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *comparison row tying the same pair to Busemann-level boundary transport.*
7. *T is the* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *row, recording disk-boundary movement that preserves the displayed pair.*
8. *H records componentwise* hsame *transport for the two boundary rows, pair guard, cross-ratio handoff, geodesic-flow handoff, Busemann comparison, disk-boundary transport, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a paired-boundary request through $L, R, G, X, F, B, T, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BoundaryPairing}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlo}$ $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryPairing}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, G, X, F, B, T, H, C, P, N$. It has no coordinate for quotient ideal-boundary equality, selected geodesic representatives, completed disks, unlogged cross-ratio shortcuts, physical observer laws, or host compactification data.

Theorem 7560.2 (Boundary pairing NameCert obligations)**.** *For every accepted* $\mathsf{BoundaryPairing}^{\uparrow}$ *carrier $Q = (L, R, G, X, F, B, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundaryPairing}^{\uparrow}}$ *surface consists exactly of carrier admission, left-boundary exposure, right-boundary exposure, pair-guard exactness, cross-ratio handoff exposure, geodesic-flow handoff exposure, Busemann-cocycle comparison, Poincare-disk boundary-transport exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape of quotient ideal-boundary equality, selected geodesics, completed disks, unlogged cross-ratio shortcuts, physical observer laws, and host compactification data.*

Proof. Project the carrier of Definition 7560.1. The rows $L, R, G, X, F, B, T, H, C, P, N$ are the whole accepted packet, so carrier admission and the two boundary exposures are direct projections.

The guard row G supplies pair exactness. It records that both boundary rows are visible as a pair before any cross-ratio, geodesic-flow, Busemann, or disk-transport row can be consumed.

The downstream handoffs are the rows X, F, B, T. Each handoff is attached to the same displayed pair, so no consumer can replace the pair by a hidden boundary quotient or by a selected geodesic representative.

The structural rows H, C, P, N transport, replay, source, and name the same finite surface. Since the carrier has no coordinate for quotient ideal-boundary equality, selected geodesics, completed disks, unlogged shortcuts, physical observer laws, or host compactification data, the nonescape clause follows by exhaustion. □

Theorem 7560.3 (Boundary pairing cross-ratio handoff)**.** *Every cross-ratio, geodesic-flow, or Busemann-facing consumer of an accepted* $\mathsf{BoundaryPairing}^{\uparrow}$ *packet first reads the ordered boundary pair*

$$L \longmapsto R \longmapsto G$$

and only then reads the handoff route

$\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$.

The handoff exports paired boundary rows and their finite transport provenance; it exports no quotient ideal-boundary equality, selected global geodesic, completed hyperbolic disk, unlogged cross-ratio shortcut, physical observer law, or host compactification theorem.

Proof. Start with an accepted carrier $Q = (L, R, G, X, F, B, T, H, C, P, N)$. Projection exposes the two boundary rows and the pair guard before any handoff row is available.

The cross-ratio handoff X reads the pair only after G has certified that both boundary rows are visible. The geodesic-flow row F and Busemann row B consume the same pair, while T records the disk-boundary transport route that preserves it.

Componentwise transport through H and displayed replay through C keep the order fixed for transported packets. Provenance P names the sibling boundary, cross-ratio, flow, Busemann, and Poincare-disk routes, and N names the local certificate.

Because none of the excluded objects appears as a carrier coordinate, every listed consumer receives only the displayed ordered pair and its finite handoff rows. □

Falsifiable prediction: Every accepted $\mathsf{BoundaryPairing}^{\uparrow}$ read exposes two boundary rows before any cross-ratio handoff can be consumed.

Independence witness: gromov-boundary, hyperbolic-cross-ratio, hyperbolic-geodesic-flow, hyperbolic-busemann-cocycle, poincare-disk-boundary-transport: none is bijective to $\mathsf{BoundaryPairing}^{\uparrow}$ because this packet alone binds two displayed $\mathsf{GromovBoundary}^{\uparrow}$ rows, a pair guard, cross-ratio handoff, geodesic-flow handoff, Busemann-cocycle comparison, disk-boundary transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

The Lean TasteGate surface for this packet must keep the two boundary rows and the pair guard as separate fields before Nontrivial and FieldFaithful instances for $\mathsf{BoundaryPairing}^{\uparrow}$ can serve downstream cross-ratio or geodesic-flow consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryPairing}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryPairing}^{\uparrow}$ packet is generated from two GromovBoundary rows, a pair-guard row, HyperbolicCrossRatio handoff, HyperbolicGeodesicFlow handoff, HyperbolicBusemannCocycle comparison, PoincareDiskBoundaryTransport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryPairing}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7560.1, Definition 7560.2, and Definition 7560.3 seed the finite paired-boundary route consumed before cross-ratio and geodesic-flow handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryPairing}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ideal-boundary equality, selected geodesics, completed disks, physical observer laws, host compactification data, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked boundary exposure, pair-guard exactness, cross-ratio handoff exposure, geodesic-flow handoff exposure, Busemann comparison, disk-boundary transport, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.BoundaryPairingUp.

Chapter 7561

A Concrete Naming Certificate for $\mathsf{AlexiewiczNorm}^{\uparrow}$

Following Alexiewicz and the Henstock–Kurzweil integral literature, the $\mathsf{AlexiewiczNorm}^{\uparrow}$ packet records the finite BEDC surface by which a displayed primitive-window norm is read from gauge-integral data before any real-valued bound is exported. It sits beside the Henstock–Kurzweil route of chapter 4180, the gauge-integral packet of chapter 1999, the regular rational readback of chapter 301, the dyadic endpoint ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names a norm carrier for one displayed integration window; it does not import measure completion, quotient function equality, selected suprema, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7561.1 (AlexiewiczNorm carrier)**.** *An* $\mathsf{AlexiewiczNorm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, G, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{HenstockKurzweil}^{\uparrow}$ *integrability row that supplies the accepted gauge-integral source.*
2. *G is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *row recording the finite tagged-window integral route used by the primitive read.*
3. *W is the primitive-window row, carrying the displayed interval endpoints and the finite list of subinterval reads on which the norm request is evaluated.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger for those windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembling the visible rational bounds for the primitive-window values.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after K, G, W, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the Henstock–Kurzweil, gauge-integral, primitive-window, dyadic, readback, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from an Alexiewicz-norm request through $K, G, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{AlexiewiczNorm}^{\uparrow}$, $\mathsf{HenstockKurzweil}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexiewiczNorm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, W, D, R, E, H, C, P, N$. There is no coordinate for a measure space, quotient equality of functions, selected primitive, selected supremum, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7561.2 (AlexiewiczNorm NameCert obligations)**.** *For every accepted* $\mathsf{AlexiewiczNorm}^{\uparrow}$ *carrier $A = (K, G, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexiewiczNorm}^{\uparrow}}$ *surface consists exactly of carrier admission, Henstock–Kurzweil exposure through K, gauge-integral exposure through G, primitive-window exactness through W, DyadicRatCore endpoint and tolerance exposure through D, RegSeqRat readback through R, Real seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No obligation may be discharged by measure completion, quotient function equality, selected primitives, selected suprema, countable choice, host almost-everywhere equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7561.1. The displayed rows are exactly $K, G, W, D, R, E, H, C, P, N$, so carrier admission exposes only Henstock–Kurzweil, gauge-integral, primitive-window, dyadic, readback, seal, transport, replay, provenance, and naming data.

The integration side starts with K and G. The Henstock–Kurzweil row supplies the accepted integral source, while the gauge-integral row supplies the finite tagged-window route through which primitive-window values are read.

The numerical side then reads W, D, R, E in order. The primitive-window row fixes the displayed interval reads, the dyadic row supplies endpoint and tolerance data, the regular rational row records the visible bounds, and the real seal is available only after those rows have been replayed.

Finally the structural rows H, C, P, N preserve the same route. Since the excluded measure, quotient, selection, choice, host-equality, and completeness principles have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7561.3 (AlexiewiczNorm Henstock handoff)**.** *Every completion-facing or Real-facing read of an accepted* $\mathsf{AlexiewiczNorm}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{HenstockKurzweil}^{\uparrow} \longmapsto \mathsf{GaugeIntegral}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The primitive-window row W is read before the dyadic tolerance ledger and the real seal, and the route cannot bypass $K, G, W, D, R, E, H, C, P, N$.

Proof. Begin with an accepted carrier read. The carrier exposes the Henstock–Kurzweil source K and the gauge-integral row G before any norm-facing numerical read can be inspected.

Replay the continuation row C. The read moves from the integration rows through the primitive-window row W, then through the dyadic ledger D and regular rational readback R before it reaches the seal E.

The structural rows H, P, N do not add another norm object. They preserve the same finite handoff, and no excluded measure, quotient, selection, choice, host-equality, or completeness coordinate is available in the packet. □

Falsifiable prediction: Every accepted $\mathsf{AlexiewiczNorm}^{\uparrow}$ read factors through $\mathsf{HenstockKurzweil}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexiewiczNorm}^{\uparrow}}$.

Constructive story: An AlexiewiczNorm$^{\uparrow}$ packet is generated from a HenstockKurzweil row, GaugeIntegral row, primitive-window row, DyadicRatCore endpoint and tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{AlexiewiczNorm}^{\uparrow}}$, seed)

Scope closed: Definition 7561.1, Definition 7561.2, and Definition 7561.3 seed the finite primitive-window norm route over HenstockKurzweilUp, GaugeIntegralUp, DyadicRatCoreUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{AlexiewiczNorm}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, measure completion, quotient function equality, selected primitives, selected suprema, countable choice, host almost-everywhere equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, primitive-window exactness, HenstockKurzweil exposure, GaugeIntegral exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, Real seal nonescape, and TasteGate field faithfulness for BEDC.Derived.AlexiewiczNormUp.

Chapter 7562

A Concrete Naming Certificate for $\mathsf{RealCauchyWindow}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealCauchyWindow}^{\uparrow}$ packet records the finite tail-window certificate by which a real-facing or completion-facing read must pass from displayed Cauchy criterion data to a terminal Real seal. It sits under the Real and Completion route of chapter 9238, refines the real-name discipline of chapter 38, and threads together the window, regular-rational, and dyadic surfaces of chapter 126, chapter 301, and chapter 291. It also specializes the finite convergence surfaces of chapter 1509 and chapter 6459. The packet is a tail-window handoff certificate; it is not Real completeness, quotient-stream equality, a selected limit, countable choice, trichotomy, or host equality.

Definition 7562.1 (Real Cauchy window carrier)**.** *A* $\mathsf{RealCauchyWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, Q, D, M, T, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, carrying the finite observation windows and the order in which tail requests are inspected.*
2. *Q is the criterion request row, naming the displayed Cauchy or Bishop-Cauchy criterion to be discharged before any Real seal is read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying requested radii, split tolerances, comparison budgets, and endpoint observations.*
4. *M is the modulus row, recording the finite index bound that answers the criterion request over the schedule S at tolerance D.*
5. *T is the finite tail-window row, listing the inspected tail segment downstream of M and upstream of the Real seal.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after S, Q, D, M, T have been displayed.*
7. *H records componentwise* hsame *transport for the schedule, criterion request, tolerance, modulus, finite tail window, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S \longmapsto Q \longmapsto D \longmapsto M \longmapsto T \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealCauchyWindow}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{BishopCauchyConvergenceCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, M, T, R, H, C, P, N$. It has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host equality, ambient Real completeness, Lean verification, or bridge checking.

Theorem 7562.2 (Real Cauchy window NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyWindow}^{\uparrow}$ *carrier*

$$W = (S, Q, D, M, T, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCauchyWindow}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the StreamName schedule, criterion request, DyadicRatCore tolerance, modulus row, finite tail window, Real seal, transport, replay, provenance, and local naming;*
2. *criterion-to-tail scheduling, requiring the request Q to be read over the finite schedule S before M and T are consumed;*
3. *dyadic tolerance readback, requiring D to display the requested radii, split tolerances, comparison budgets, and endpoint observations before the modulus row answers the request;*
4. *Real seal handoff, requiring R to be downstream of S, Q, D, M, T and never upstream of the finite tail window;*
5. hsame *transport and* Cont *replay, requiring H and C to preserve exactly the displayed route;*
6. Pkg *provenance and local naming, requiring P and N to name the same finite packet and no hidden host construction;*
7. *nonescape from quotient streams, selected limits, countable choice, trichotomy, host equality, and ambient Real completeness.*

No Real Cauchy window obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7562.1. The accepted tuple displays exactly the schedule, criterion request, dyadic tolerance, modulus, finite tail window, Real seal, transport, replay, provenance, and local naming rows.

The criterion-to-tail schedule is read from S, Q, M, T. A consumer first exposes the finite observation schedule and the criterion request, then reads the modulus row, and only then inspects the tail-window row that answers the request.

Dyadic tolerance readback is the role of D. The row displays the requested radii, split tolerances, comparison budgets, and endpoint observations used by the modulus and tail-window rows, so no external real-order or trichotomy principle is introduced.

The Real seal handoff is the projection to R together with the structural rows H, C, P, N. These rows transport, replay, source, and name the same finite route, and the carrier has no coordinate for quotient streams, selected limits, countable choice, host equality, or ambient Real completeness. □

Theorem 7562.3 (Real Cauchy window finite tail handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RealCauchyWindow}^{\uparrow}$ *packet must pass through the finite tail route*

$$S \longmapsto Q \longmapsto D \longmapsto M \longmapsto T \longmapsto R \longmapsto H, C, P, N$$

before reading the Real seal. The handoff exports a StreamName schedule, criterion request, DyadicRatCore tolerance readback, modulus row, finite tail window, terminal Real seal, componentwise transport, replay, provenance, and local naming; it exports no Real completeness, quotient streams, selected limits, trichotomy, countable choice, host equality, Lean verification, or bridge checking.

Proof. Begin with a Real-facing or completion-facing read of the packet. Projection from Definition 7562.1 exposes the ordered rows $S, Q, D, M, T, R, H, C, P, N$.

Apply Definition 7562.2. The criterion request is tied to the finite StreamName schedule, the dyadic tolerance row is read before the modulus answers the request, and the finite tail window is downstream of that answer.

The terminal Real seal is the row R. Since the carrier admits no other seal coordinate and the transport, replay, provenance, and naming rows preserve only the displayed route, every consumer reaches R only after the finite tail window has been displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyWindow}\uparrow}$.

Constructive story: A $\mathsf{RealCauchyWindow}^{\uparrow}$ packet is generated from StreamName schedules, criterion requests, DyadicRatCore tolerance rows, modulus rows, finite tail windows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyWindow}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7562.1, Definition 7562.2, and Definition 7562.3 seed the finite route from displayed Cauchy criterion data through tail-window inspection into a terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyWindow}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient streams, selected limits, trichotomy, countable choice, host equality, Lean verification, or bridge checking.

Upgrade path: Formalization requires carrier admission, criterion-to-tail scheduling, dyadic tolerance readback, Real seal handoff, transport and replay, provenance, naming, and non-escape proofs for BEDC.Derived.RealCauchyWindowUp.

Chapter 7563

A Concrete Naming Certificate for $\mathsf{CauchyConvergenceRate}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyConvergenceRate}^{\uparrow}$ packet records a tolerance-to-index rate ledger for regular Cauchy names. It sits between the finite stream surface of chapter 126, the dyadic tolerance carrier of chapter 291, the regular-rational readback surface of chapter 301, and the terminal Real seal of chapter 38. The chapter names the finite rate object used by Real-and-Completion consumers; it is not a chosen limit, not a quotient of Cauchy names, and not an ambient completeness theorem.

Definition 7563.1 (Cauchy convergence rate carrier)**.** *A* $\mathsf{CauchyConvergenceRate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (E, I, R, D, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the tolerance request row. It displays the dyadic error level to be met before any index is exposed.*
2. *I is the unary index row assigned to the tolerance in E.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular Cauchy name at the displayed index.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound row comparing the requested tolerance with the finite tail bound.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after E, I, R, D have been fixed.*
6. *H records componentwise* hsame *transport for tolerance, index, RegSeqRat readback, dyadic bound, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tolerance request through the unary index, regular-rational readback, dyadic bound, and Real seal rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyConvergenceRate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceRate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for a selected Cauchy limit, quotient equality of names, countable choice, hidden tail witnesses, host equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7563.2 (Cauchy convergence rate NameCert obligations)**.** *For every accepted* $\mathsf{CauchyConvergenceRate}^{\uparrow}$ *carrier* $Q = (E, I, R, D, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceRate}^{\uparrow}}$ *surface consists exactly of carrier admission, tolerance request exposure, total unary-index assignment for displayed tolerances, monotone tolerance refinement, RegSeqRat handoff,* $\mathsf{Real}^{\uparrow}$ *nonescape, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7563.1. Carrier admission and tolerance exposure are the projections of Q and E.

The rate obligations are carried by I, D. Totality means that every displayed tolerance row has a displayed unary index row, and monotone refinement means that a sharper displayed tolerance is routed through the same finite ledger before its index can be consumed.

The readback and seal obligations are carried by R, S. The row R is the regular-rational handoff, while S is downstream of E, I, R, D and therefore cannot export a Real-facing use without the rate rows.

Transport, replay, provenance, and local naming are exhausted by H, C, P, N. Since the carrier has no coordinate for selected limits, quotient equality, countable choice, hidden tail witnesses, host equality, or ambient completeness, the nonescape clause follows by exhaustion. □

Theorem 7563.3 (Cauchy convergence rate RegSeqRat handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing use of an accepted* $\mathsf{CauchyConvergenceRate}^{\uparrow}$ *packet first reads the* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows that expose the stream window, the displayed dyadic tolerance, and the regular-rational readback. No Real-facing consumer receives the seal row* S *from* $Q = (E, I, R, D, S, H, C, P, N)$ *without those finite rows and their transport, replay, provenance, and local naming data.*

Proof. Begin with the accepted carrier $Q = (E, I, R, D, S, H, C, P, N)$. The provenance row P names the stream, dyadic, regular-rational, and Real surfaces that the packet is allowed to consume.

The tolerance row E and index row I expose the rate request. The dyadic row D fixes the finite tolerance comparison, and the regular-rational row R fixes the readback point for the displayed Cauchy name.

The Real seal row S is downstream of those rows by the carrier definition. Componentwise transport through H and replay through C preserve the same order under every accepted presentation, and N names only this local packet. □

Falsifiable prediction: Every accepted $\mathsf{CauchyConvergenceRate}^{\uparrow}$ read exposes tolerance, unary index, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any Real-facing convergence-rate use can be consumed.

Independence witness: streamname, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{CauchyConvergenceRate}^{\uparrow}$ because this packet jointly binds a tolerance request, unary index, regular-rational readback, dyadic bound, Real seal, transport, replay, provenance, and local naming as one finite rate ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyConvergenceRate}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyConvergenceRate}^{\uparrow}$ packet is generated from a displayed tolerance row, a unary index row, RegSeqRat readback, DyadicRatCore bounds, Real seal access, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyConvergenceRate}^{\uparrow}}$, seed)

Scope closed: Definition 7563.1, Definition 7563.2, and Definition 7563.3 seed the finite rate packet for Real-and-Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyConvergenceRate}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected Cauchy limits, quotient equality of names, countable choice, hidden tail witnesses, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rate totality, monotone tolerance refinement, RegSeqRat handoff, RealUp nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyConvergenceRateUp.

Chapter 7564

A Concrete Naming Certificate for $\mathsf{TailWindowFilterRefinement}^{\uparrow}$

Following Bishop and Bridges / Kelley filter terminology, the $\mathsf{TailWindowFilterRefinement}^{\uparrow}$ packet records the finite common-filter refinement by which two displayed Cauchy tail-window schedules can be read through one downstream Real-facing route. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the dyadic tail envelope of chapter 1659, and the terminal real-name seal of chapter 38. The packet names a finite refinement carrier for completion consumers; it is not a quotient stream, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7564.1 (TailWindowFilterRefinement carrier)**.** *A* $\mathsf{TailWindowFilterRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S_0, S_1, R_0, R_1, D, E, W, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are* $\mathsf{StreamName}^{\uparrow}$ *tail-window rows naming the two schedules being compared.*
2. R_0 *and* R_1 *are* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row requested by the downstream comparison.*
4. E *is a* $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ *row witnessing that both readbacks enter the same finite tail-envelope route.*
5. W *is the common refinement row, displaying a tail window through which both* S_0, R_0 *and* S_1, R_1 *factor before any* $\mathsf{Real}^{\uparrow}$ *seal is read.*
6. H *records componentwise* hsame *transport for the two schedules, two readbacks, dyadic tolerance, envelope, common refinement, replay, provenance, and naming rows.*
7. C *records displayed* Cont *replay from a refinement request through* $S_0, S_1, R_0, R_1, D, E, W, H, P, N$.
8. P *is the* Pkg *provenance over* $\mathsf{TailWindowFilterRefinement}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{TailWindowFilterRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, R_0, R_1, D, E, W, H, C, P, N$. *There is no coordinate for quotient equality of streams, a selected limit representative, countable choice, trichotomy, host real equality, or an ambient Real completeness principle.*

Theorem 7564.2 (TailWindowFilterRefinement NameCert obligations)**.** *For every accepted* TailWindowFilterRefin *carrier* $F = (S_0, S_1, R_0, R_1, D, E, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TailWindowFilterRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission, two StreamName tail-window exposures, two RegSeqRat readback exposures, shared DyadicRatCore tolerance exposure, DyadicCauchyTailEnvelope exposure, common-refinement window exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No obligation may be discharged by quotient stream equality, selected limits, countable-choice selectors, trichotomy, host real equality, detached completion objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7564.1. The displayed rows are exactly $S_0, S_1, R_0, R_1, D, E, W, H, C, P, N$, so carrier admission exposes only the two schedules, two readbacks, shared dyadic tolerance, tail envelope, common refinement, transport, replay, provenance, and local naming data.

The two schedule branches are then read through the same tolerance request. Rows S_0, R_0 and S_1, R_1 provide the two finite tail-window presentations, while D fixes the dyadic scale at which the comparison is made.

The envelope and refinement rows are the only meeting point. Row E certifies that both branches enter a displayed $\mathsf{DyadicCauchyTailEnvelope}^{\uparrow}$ route, and W records the common tail window consumed before any $\mathsf{Real}^{\uparrow}$ seal-facing read.

Finally the structural rows preserve that route. Since the excluded quotient, selection, choice, trichotomy, host-equality, detached-completion, and ambient-completeness principles have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7564.3 (TailWindowFilterRefinement Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of an accepted* $\mathsf{TailWindowFilterRefinement}^{\uparrow}$ *carrier factors through the ordered finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{DyadicCauchyTailEnvelope}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The common refinement row W *is read before the Real seal, and no downstream consumer can bypass* $S_0, S_1, R_0, R_1, D, E, W, H, C, P, N$*.*

Proof. Begin with an accepted carrier read. The two StreamName windows and two RegSeqRat readbacks are exposed as displayed rows before a downstream consumer can inspect the shared dyadic tolerance.

Read the dyadic and envelope rows next. The tolerance row D fixes the comparison scale, and the envelope row E places both branches inside the same finite dyadic tail-envelope surface.

The common window row W supplies the refinement consumed by the Real-facing route. Transport, replay, provenance, and naming preserve that route, and the carrier has no coordinate from which a quotient stream, selected limit, countable-choice schedule, trichotomy datum, host equality, detached completion object, or ambient completeness theorem could be read. □

Falsifiable prediction: Every accepted $\mathsf{TailWindowFilterRefinement}^{\uparrow}$ read factors two StreamName tail windows and two RegSeqRat readbacks through one DyadicRatCore tolerance, one DyadicCauchyTailEnvelope row, one common refinement window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any RealUp seal-facing consumer reads the route.

Closure status for $\mathsf{NameCert}_{\mathsf{TailWindowFilterRefinement}^{\uparrow}}$**.**

Constructive story: A TailWindowFilterRefinement$^{\uparrow}$ packet is generated from two StreamName tail-window rows, two RegSeqRat readback rows, a shared DyadicRatCore tolerance row, a DyadicCauchyTailEnvelope route, a common refinement window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{TailWindowFilterRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 7564.1, Definition 7564.2, and Definition 7564.3 seed the finite common-filter refinement surface over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, DyadicCauchyTailEnvelopeUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{TailWindowFilterRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, detached completion objects, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, paired StreamName exposure, RegSeqRat readback, DyadicRatCore tolerance exactness, DyadicCauchyTailEnvelope exposure, common-refinement exactness, and TasteGate field faithfulness for BEDC.Derived.TailWindowFilterRefinementUp.

Chapter 7565

A Concrete Naming Certificate for $\mathsf{LindebergCondition}^{\uparrow}$

Following Lindeberg and Feller, the $\mathsf{LindebergCondition}^{\uparrow}$ packet records the finite replacement-condition surface used by central-limit windows before any asymptotic theorem is visible. It sits after the probability source of chapter 184, the random-variable window of chapter 185, the distribution readback of chapter 186, the regular rational comparison route of chapter 301, the terminal real-name seal of chapter 38, and the finite central-limit window of chapter 5800. The packet names only displayed truncation windows, variance-budget comparisons, distribution and Real seal handoffs, transport, replay, provenance, and local naming; it does not import the asymptotic central limit theorem, characteristic-function convergence, countable choice, quotient distribution equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7565.1 (Lindeberg-condition carrier)**.** *A* $\mathsf{LindebergCondition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, X, V, T, D, R, E, H, C, Q, N).$$

Here P is the source $\mathsf{ProbSpace}^{\uparrow}$ *row carrying the event classifier and total-mass normalization. The row X is the triangular-window* $\mathsf{RandomVar}^{\uparrow}$ *display, including the finite row index, the visible summand range, and the local law token read by each displayed summand. The row V is the variance-budget ledger naming the finite total variance request, the component variance rows, and the positive scale comparison used by the window. The row T is the truncation-threshold row, recording the displayed cutoff, the truncated summand window, and the finite exceptional-event ledger. The row D is the* $\mathsf{Distribution}^{\uparrow}$ *readback for the truncated and untruncated finite sums. The row R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison row used to compare the displayed variance and tail budgets. The row E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after P, X, V, T, D, R have all been exposed. The row H records componentwise* hsame *transport for the probability source, triangular window, variance budget, threshold, distribution readback, RegSeqRat comparison, Real seal, replay, provenance, and local name. The row C records displayed* Cont *replay from a truncation request through P, X, V, T, D, R, E and then through the structural rows. The row Q is the* Pkg *provenance over* $\mathsf{LindebergCondition}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$. *The row N is the local* $\mathsf{NameCert}_{\mathsf{LindebergCondition}^{\uparrow}}$ *row. The classifier compares accepted packets only through these eleven rows.*

Theorem 7565.2 (Lindeberg-condition NameCert obligations)**.** *For every accepted* $\mathsf{LindebergCondition}^{\uparrow}$ *carrier $L = (P, X, V, T, D, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{LindebergCondition}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the probability source, triangular random-variable window, variance budget, truncation threshold, distribution readback, RegSeqRat comparison, Real seal, transport, replay, provenance, and local naming rows;*
2. *truncation-window exactness, requiring every tail event and truncated summand read to pass through the displayed threshold row T over the same finite window X;*
3. *variance-budget compatibility, requiring the scale and component variance reads to pass through V before any RegSeqRat comparison row R is exposed;*
4. *distribution and Real-seal handoff, requiring D and R to precede the terminal seal row E;*
5. *nonescape from the asymptotic central limit theorem, characteristic-function limits, countable choice, quotient distribution equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier rows of Definition 7565.1. The probability source P and triangular window X provide the only random-variable data, while V and T provide the only variance and truncation coordinates.

The comparison route is then forced through D, R, E. The distribution row D reads the displayed finite sums, the RegSeqRat row R compares the finite variance and tail budgets, and the Real seal row E is visible only after those rows are already present.

Finally H, C, Q, N transport, replay, source, and name the same finite route. Since no coordinate names an asymptotic theorem, characteristic-function convergence, quotient-law equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7565.3 (Lindeberg-condition central-limit handoff)**.** *Every* $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ *consumer that uses Lindeberg data must first read an accepted* $\mathsf{LindebergCondition}^{\uparrow}$ *packet* $L = (P, X, V, T, D, R, E, H, C, Q, N)$*. The consumer receives only the finite replacement-condition surface consisting of the probability source, triangular random-variable window, variance budget, truncation threshold, distribution readback, RegSeqRat comparison, Real seal, transport, replay, provenance, and local naming rows; it receives no asymptotic central limit theorem, characteristic-function limit, countable-choice schedule, quotient distribution equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a central-limit finite-window consumer that asks for Lindeberg data. The consumer can inspect the probability source and triangular window only through P and X, and it can inspect tail removal only through the displayed threshold row T.

The variance and comparison data are then read through V, D, R, E. These rows provide a finite budget, finite distribution readback, rational comparison, and Real-facing seal, not an asymptotic convergence theorem.

The structural rows H, C, Q, N preserve this same finite packet for the $\mathsf{CentralLimitFiniteWindow}^{\uparrow}$ route. Therefore the handoff supplies exactly the finite replacement-condition surface and none of the excluded analytic or choice principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{LindebergCondition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LindebergCondition}^{\uparrow}$ packet is generated from a probability source row, triangular random-variable window, variance-budget ledger, truncation-threshold row, distribution readback, RegSeqRat comparison row, Real seal handoff, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LindebergCondition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7565.1, Definition 7565.2, and Definition 7565.3 seed the finite Lindeberg replacement-condition surface for central-limit windows.

Formal verification: FormalStatus(NameCert$_{\text{LindebergCondition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the asymptotic central limit theorem, characteristic-function convergence, countable-choice schedules, quotient distribution equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: The next grade requires Lean encoding of the carrier and checked theorems for carrier admission, truncation-window exactness, variance-budget compatibility, distribution-to-RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 7566

A Concrete Naming Certificate for $\mathsf{SeparatedUniformCompletion}^{\uparrow}$

Following Kelley and Bourbaki, the $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ packet records the finite separated-reflection route by which Cauchy-filter data over a uniform source reaches a completion seal without carrying indistinguishable representatives into the public object. It sits after the uniform completion surface of chapter 3560, the Cauchy-filter interface of chapter 333, the uniform entourage source of chapter 339, the regular-rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The separated completion route also consumes the Real-induced entourage basis of chapter 1624 and the generated finite subbasis route of chapter 4232 before the separated reflection row can be read. The packet names the L10 separated completion handoff as displayed NameCert data; it is not a quotient-completion construction, selected-limit operator, countable-choice principle, host equality test, trichotomy claim, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7566.1 (Separated uniform completion carrier)**.** *A* $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, F, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage-source row, exposing the finite entourage tests used by the completion consumer.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, recording the Cauchy-filter demands accepted over the displayed uniform source.*
3. *R is the separated-reflection row, identifying only those Cauchy-filter readings that the displayed uniform tests cannot distinguish.*
4. *Q is the* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *handoff row, read only after U, F, R have been displayed.*
5. *E is the completion seal row, with the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback anchors named in the provenance surface.*
6. *H records componentwise* hsame *transport for the uniform source, Cauchy-filter row, separated-reflection row, completion handoff, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Cauchy-filter demand through the separated reflection and into the completion seal.*

8. *P is the* Pkg *provenance over* $\mathsf{SeparatedUniformCompletion}^{\uparrow}$, $\mathsf{UniformSpaceCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedUniformCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, R, Q, E, H, C, P, N$ and their displayed replay paths. It has no coordinate for quotient representatives, hidden filter equality, selected limits, countable choice, host equality, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7566.2 (Separated uniform completion NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ *carrier $S = (U, F, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SeparatedUniformCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, uniform-source exposure through U, Cauchy-filter exactness through F, separated-reflection non-escape through R, completion handoff through Q, completion-seal stability through E, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 7566.1. The only source and Cauchy rows are U and F, so every completion-facing demand is tested against displayed uniform entourages and displayed Cauchy-filter data.

The separated-reflection row is then read before the completion handoff. The row R is the only place where indistinguishable Cauchy-filter readings are compared, and the row Q can be consumed only after that comparison has been displayed.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier has no row for quotient representatives, hidden filter equality, selected limits, countable choice, host equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those principles can serve as a NameCert obligation. □

Theorem 7566.3 (Separated uniform completion Cauchy-filter route)**.** *Every accepted Cauchy-filter read of a* $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{SeparatedUniformCompletion}^{\uparrow} \longmapsto \mathsf{UniformSpaceCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In the notation of Definition 7566.1, a consumer reads F against U, then the separated-reflection row R, then the completion handoff Q, and only then the completion seal E with its structural rows.

Proof. Begin with a Cauchy-filter read of the separated completion packet. The row F supplies the only Cauchy-filter data, and U supplies the only uniform entourage source available to test it.

The route then passes through separation. The row R records the displayed indistinguishability boundary before any completion handoff can be read, so no consumer can skip directly from a filter row to a completion seal.

The completion-facing rows are downstream from that boundary. The handoff Q reads the $\mathsf{UniformSpaceCompletion}^{\uparrow}$ surface, while E, H, C, P, N keep the Real-facing seal, transport, replay, provenance, and local naming attached to the same finite packet. □

Falsifiable prediction: Every accepted $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ completion read exposes a UniformSpace source row, a CauchyFilter row, a separated-reflection row, a UniformSpaceCompletion handoff, a completion seal, transport, replay, provenance, and local naming.

Independence witness: uniform-space-completion, cauchyfilter, uniformspace, regseqrat, real: $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a uniform

source, Cauchy-filter exactness, separated reflection, completion handoff, terminal seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedUniformCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedUniformCompletion}^{\uparrow}$ packet is generated from a uniform entourage source row, a Cauchy-filter row, a separated-reflection row, a UniformSpaceCompletion handoff, a completion seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedUniformCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7566.1, Definition 7566.2, and Definition 7566.3 seed the finite L10 separated completion route from Cauchy-filter data through uniform-source tests, separated reflection, completion handoff, seal stability, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedUniformCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion classes, selected limits, countable choice, hidden filter equality, host equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of BEDC.Derived.SeparatedUniformCompletionUp with checked carrier admission, uniform-source exposure, Cauchy-filter exactness, separated-reflection non-escape, completion handoff, seal stability, transport replay, provenance non-escape, and classifier faithfulness.

Chapter 7567

A Concrete Naming Certificate for $\mathsf{ClosedMetricSubspace}^{\uparrow}$

Following Kelley and Bishop–Bridges metric-space practice, the $\mathsf{ClosedMetricSubspace}^{\uparrow}$ packet records the finite closed-subspace route by which a displayed subspace admission row inherits convergence from a parent metric carrier. It refines the subspace surface of chapter 1519, reads the parent metric packet of chapter 57, consumes the complete-metric limit boundary of chapter 128, and keeps its convergence data visible through chapter 126, chapter 301, and chapter 38. The resulting carrier is a closed-subspace certificate, not a host-subset quotient, selected-representative principle, arbitrary completeness theorem, or compactness assertion.

Definition 7567.1 (ClosedMetricSubspace carrier)**.** *A* $\mathsf{ClosedMetricSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (M, A, D, L, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *M is the parent* $\mathsf{Met}^{\uparrow}$ *row, including its point classifier, distance witness, metric-law ledger, and finite observation histories.*
2. *A is the displayed subspace admission row. A point is readable by the closed-subspace packet only after the parent point classifier of M and the admission row A both accept it.*
3. *D is the inherited-distance row. It exports no independent distance; each closed-subspace distance read is the parent distance row of M applied to two admitted points.*
4. *L is the closed-under-limit witness. It states that a parent limit witness for an admitted Cauchy stream is admitted again by A.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *Cauchy witness row naming the finite observation windows used by the convergence consumer.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row recording the regular rational comparison data attached to the stream.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after the stream, regular-rational, inherited-distance, and closed-limit rows have been displayed.*
8. *H records componentwise* hsame *transport for the parent metric row, admission row, inherited distance, closed-limit witness, stream witness, regular-rational readback, Real seal, replay row, provenance row, and local naming row.*

9. *K records the displayed* Cont *route replaying point admission, subspace distance restriction, Cauchy-window admission, parent limit handoff, closedness admission, and Real-seal handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{ClosedMetricSubspace}^{\uparrow}$, $\mathsf{MetricSubspace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedMetricSubspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $M, A, D, L, S, R, E, H, K, P, N$ and their replay paths. It has no coordinate for host subset equality, quotient membership, selected representatives, arbitrary completeness, open-cover compactness, countable choice, or ambient Real completeness.

Theorem 7567.2 (ClosedMetricSubspace NameCert obligations)**.** *For every accepted* $\mathsf{ClosedMetricSubspace}^{\uparrow}$ *carrier $C = (M, A, D, L, S, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedMetricSubspace}^{\uparrow}}$ *surface consists exactly of carrier admission, inherited metric restriction, closure under parent limit witnesses, convergence handoff through StreamName windows and RegSeqRat readback, transport, replay, provenance, and local naming.*

Equivalently, every completion-facing or Real-facing consumer must read

$$M, \quad A, \quad D, \quad L, \quad S, \quad R, \quad E, \quad H, \quad K, \quad P, \quad N$$

before it can use a closed-subspace conclusion, and no consumer can import host subsets, quotient equality, selected representatives, arbitrary completeness, open-cover compactness, or bridge data.

Proof. Carrier admission is projection from Definition 7567.1. The tuple lists the parent metric, displayed admission, inherited distance, closed-limit witness, StreamName Cauchy witness, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

The inherited metric restriction is forced by D and K. A distance read first admits both endpoints through M and A, then reads the parent distance row of M; the carrier contains no second metric coordinate.

Closure under parent limits is the role of L. A convergence consumer opens the finite StreamName row S, reads the RegSeqRat comparisons in R, uses the parent metric and complete-metric boundary named by M, and then applies L to admit the parent limit back into A.

Finally E, H, K, P, N seal, transport, replay, source, and name the same route. Since the carrier has no row outside $M, A, D, L, S, R, E, H, K, P, N$, host subset equality, quotient equality, selected representatives, arbitrary completeness, open-cover compactness, and bridge checking cannot be exported by the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{ClosedMetricSubspace}^{\uparrow}$ convergence read exposes a parent Metric row, displayed admission row, inherited-distance row, closed-under-limit witness, StreamName Cauchy witness, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming before any closed-subspace conclusion is consumed.

Independence witness: metric-subspace, metric, complete-metric, streamname, regseqrat, real: $\mathsf{ClosedMetricSubspace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries displayed subspace admission, inherited distance, closed-limit admission, Cauchy-window data, regular-rational readback, terminal Real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedMetricSubspace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedMetricSubspace}^{\uparrow}$ packet is generated from a parent Metric row, displayed subspace admission row, inherited distance row, closed-under-limit witness, StreamName Cauchy witness, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{ClosedMetricSubspace}\uparrow}$, seed)

Scope closed: Definition 7567.1 and Definition 7567.2 seed the finite L10 closed-subspace route from admitted Cauchy-window data through inherited distance, parent limit witnessing, closedness admission, Real seal handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ClosedMetricSubspace}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host subsets, quotient equality, selected representatives, arbitrary completeness, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inherited metric restriction, closure under parent limit witnesses, convergence handoff, transport replay, provenance non-escape, and classifier faithfulness for BEDC.Derived.ClosedMetricSubspaceUp.

Chapter 7568

A Concrete Naming Certificate for $\mathsf{DirichletUniformModulus}^{\uparrow}$

Following Dirichlet and Abel summation-by-parts, the $\mathsf{DirichletUniformModulus}^{\uparrow}$ packet records the finite uniform-tail budget obtained from bounded partial sums and monotone coefficient windows before any Real-or-Completion consumer reads a series endpoint. It sits beside the summation-by-parts certificate of chapter 1763, the Dirichlet convergence-test certificate of chapter 1497, the shared uniform-tail route of chapter 1736, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a constructive modulus object for displayed tails; it is not a host convergence theorem, a selected infinite sum, quotient series equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7568.1 (Dirichlet uniform modulus carrier)**.** *A* $\mathsf{DirichletUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, A, M, D, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded-partial-sum row, exposing the inspected partial sums and one displayed uniform bound for the relevant source windows.*
2. *A is the Abel summation-by-parts row, carrying the finite boundary and difference-window data used to rewrite the inspected tail.*
3. *M is the monotone coefficient-window row, naming the finite comparisons and endpoint coefficient values visible on each requested tail.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget row, recording the dyadic radius, comparison slack, and arithmetic loss used by the displayed estimate.*
5. *T is the exported uniform-tail modulus row, assigning to each displayed dyadic request a named tail window whose later reads must pass through S, A, M, D.*
6. *H records componentwise* hsame *transport for the bounded-sum, summation-by-parts, monotone-window, dyadic-budget, modulus, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of a precision request through*

$$S \longmapsto A \longmapsto M \longmapsto D \longmapsto T.$$

8. *P is the* Pkg *provenance over* DirichletUniformModulus$^{\uparrow}$, AbelSummation$^{\uparrow}$, DirichletTest$^{\uparrow}$, UniformCauchySeries$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{DirichletUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for a selected limit, quotient series, countable-choice threshold, host series equality, or ambient real-completeness witness.

Lean4 (definition) `BEDC.Derived.DirichletUniformModulusUp.DirichletUniformModulusCarrier`

Theorem 7568.2 (Dirichlet uniform modulus tail budget)**.** *For every accepted* DirichletUniformModulus$^{\uparrow}$ *carrier $K = (S, A, M, D, T, H, C, P, N)$, the exported row T is a uniform tail modulus only through the displayed summation-by-parts route*

$$\sum_{k=m}^{n} a_k b_k = A_m B_m - A_n B_{n+1} + \sum_{k=m}^{n-1} A_k (b_k - b_{k+1})$$

and the dyadic-budget rows S, M, D. Thus any Real-or-Completion consumer reading the modulus must first display the bounded partial-sum bound, the monotone coefficient window, and the dyadic loss ledger.

Proof. Project the carrier of Definition 7568.1. The only analytic rows upstream of T are S, A, M, D, so every tail request reaches the modulus through those displayed coordinates.

The row A supplies the summation-by-parts identity on the inspected finite window. The row S bounds the partial sums that occur in the boundary and difference terms, while M names the monotone coefficient comparisons that make the boundary and variation terms readable on the same window.

The dyadic budget row D records the requested radius and the arithmetic slack assigned to the boundary and difference contributions. Reading T therefore amounts to reading the same finite estimate after the dyadic losses have been allocated.

The structural rows H, C, P, N transport, replay, source, and name this route. Since the carrier contains no selected-limit, quotient-series, choice, host-equality, or ambient-completeness coordinate, no consumer can export a uniform tail modulus except through the displayed rows. □

Lean4 ✓ `BEDC.Derived.DirichletUniformModulusUp.DirichletUniformModulusTailBudget`

Theorem 7568.3 (Dirichlet uniform modulus NameCert obligations)**.** *For every accepted* DirichletUniformModulus$^{\uparrow}$ *carrier $K = (S, A, M, D, T, H, C, P, N)$, the local* NameCert$_{\text{DirichletUniformModulus}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the finite packet K and its displayed* BHist *rows;*
2. *bounded-partial-sum and Abel summation-by-parts exposure through S and A;*
3. *monotone coefficient-window and dyadic tail-budget exactness through M and D;*
4. *uniform-tail modulus export through T, with every readback to* UniformCauchySeries$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *or* Real$^{\uparrow}$ *downstream of S, A, M, D;*
5. *componentwise transport, displayed replay, provenance, and local naming through exactly H, C, P, N.*

No NameCert obligation is stored outside those five groups.

Lean4 ✓ `BEDC.Derived.DirichletUniformModulusUp.DirichletUniformModulusNameCertObligations`

Proof. Carrier admission is the direct read of the tuple K. The accepted packet exposes exactly the nine rows listed in Definition 7568.1.

The analytic evidence is split into two displayed groups. Rows S and A provide the bounded partial-sum data and finite summation-by-parts rewrite, while rows M and D provide the monotone coefficient window and dyadic loss accounting.

The public modulus obligation is row T. By Definition 7568.2, a read of T factors through S, A, M, D before any uniform Cauchy, regular readback, or Real-facing consumer can inspect the tail bound.

Finally read H, C, P, N. These rows transport, replay, source, and name the same finite route, and the carrier supplies no further coordinate. The five listed groups therefore exhaust the local certificate surface. □

Falsifiable prediction: An accepted $\mathsf{DirichletUniformModulus}^{\uparrow}$ read is refuted if a uniform Cauchy, regular readback, Real, or Completion consumer reaches the exported modulus row without first displaying the bounded partial-sum row, summation-by-parts row, monotone coefficient window, dyadic budget, transport, replay, provenance, and local NameCert rows.

Independence witness: abel-summation, dirichlet-test, uniform-cauchy-series, dyadicratcore, regseqrat, real: $\mathsf{DirichletUniformModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded partial sums, summation-by-parts data, monotone coefficient windows, dyadic tail budgets, a named uniform-tail modulus, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{DirichletUniformModulus}^{\uparrow}$ packet is generated from bounded partial-sum rows, Abel summation-by-parts windows, monotone coefficient windows, dyadic tail budgets, an exported uniform-tail modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DirichletUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7568.1, Definition 7568.2, and Definition 7568.3 seed the finite constructive uniform-tail budget route over bounded partial sums, summation-by-parts rows, monotone coefficient windows, dyadic budgets, uniform Cauchy series readback, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DirichletUniformModulus}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.DirichletUniformModulusUp.DirichletUniformModulusCarrier`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient series, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, host series equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded partial-sum exposure, summation-by-parts exposure, monotone coefficient-window exactness, dyadic tail-budget exactness, uniform-tail modulus export, transport, replay, provenance, and local naming for BEDC.Derived.DirichletUniformModulusUp.

Chapter 7569

A Concrete Naming Certificate for $\mathsf{KuratowskiEmbedding}^{\uparrow}$

Following Bourbaki's and Kelley's metric-space treatment of distance functions, the $\mathsf{KuratowskiEmbedding}^{\uparrow}$ packet records the classical embedding of a metric space into a space of distance-to-point functions as finite BEDC data. It sits over the metric source of chapter 57, the real-distance rows of chapter 38, and the distance-preserving interface of chapter 439. The packet exposes a selected basepoint or displayed family row, distance-function target rows, and the isometric route; it does not import quotient completion, host function extensionality, or a detached real-valued function space.

Definition 7569.1 (Kuratowski embedding carrier)**.** *A* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, B, D, T, I, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row whose point and distance-witness data supply the domain of the embedding.*
2. *B is the selected basepoint or displayed point-family row used to normalize and compare distance functions.*
3. *D is the* $\mathsf{Real}^{\uparrow}$ *distance-witness row recording the finite reads $d(x, b)$ and $d(y, b)$ against the selected basepoint or family.*
4. *T is the distance-function target row naming the displayed family of* $\mathsf{Real}^{\uparrow}$ *distance observations rather than a host function space.*
5. *I is the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *route row witnessing that source distances are preserved by the displayed distance-function target.*
6. *H records componentwise* hsame *transport for M, B, D, T, I.*
7. *C records displayed* Cont *replay from metric-distance reads to target distance-function reads and then to the isometric route.*
8. *P is the* Pkg *provenance over* $\mathsf{KuratowskiEmbedding}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{IsometricEmbedding}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, host function extensionality, ambient Banach-space structure, or a selected completion representative.

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingTasteGate single carrier alignment`

Theorem 7569.2 (Kuratowski embedding NameCert obligations)**.** *For the carrier of Definition 7569.1, the local* $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$ *surface consists of six finite rows:*

1. *carrier admission: every accepted packet exposes* $K = (M, B, D, T, I, H, C, P, N)$ *and no hidden function-space coordinate;*
2. *metric-source exposure: every source point and source-distance read enters through the* $\mathsf{Met}^{\uparrow}$ *row* M*;*
3. *basepoint or family selection: the row* B *is the only displayed source for the normalizing point or comparison family;*
4. *real-distance target exposure: the rows* D *and* T *turn source-distance reads into* $\mathsf{Real}^{\uparrow}$ *distance-function observations before any target comparison is made;*
5. *isometric route: the row* I *is the only distance-preserving handoff, and it is read after* M, B, D, T*;*
6. *structural replay: the rows* H, C, P, N *preserve, replay, source, and name the same route without exporting quotient completion or host function extensionality.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 7569.1. The accepted packet displays the metric source, basepoint or family row, real-distance witness row, target row, isometric route, transport, continuation, provenance, and local naming row.

Read the dependency rows in order. The metric source row M supplies point and distance-witness data; the row B supplies the selected basepoint or displayed family; and the real-distance row D records the corresponding $\mathsf{Real}^{\uparrow}$ observations.

The target row T is therefore a displayed distance-function surface, not a host function space. The isometric row I can only be read after those source and target observations are visible, and H, C, P, N preserve that same finite route. □

The route consumes the metric source of chapter 57, the real-distance rows of chapter 38, and the distance-preserving handoff of chapter 439.

Theorem 7569.3 (Kuratowski embedding distance route)**.** *Every accepted* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *packet routes source-distance comparison through*

$$M \to B \to D \to T \to I \to H \to C \to P \to N.$$

Thus a consumer reaches the $\mathsf{IsometricEmbedding}^{\uparrow}$ *handoff only after reading the* $\mathsf{Met}^{\uparrow}$ *source, the selected basepoint or family row, and the* $\mathsf{Real}^{\uparrow}$ *distance-function target rows. No consumer receives quotient completion, host function extensionality, ambient Banach-space structure, or a selected completion representative from the packet.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbeddingCarrier distance route`

Proof. Start with an accepted carrier $K = (M, B, D, T, I, H, C, P, N)$. A source-distance query must read M, and a distance-function query must next read the basepoint or family row B.

The real-valued observations are then stored in D and organized by T. Because T is part of the finite carrier, it supplies only displayed $\mathsf{Real}^{\uparrow}$ distance observations and not host-level function extensionality.

Finally apply the isometric route row I. The structural rows H, C, P, N keep the same route under transport and replay, so the only exported embedding data are the displayed metric, basepoint or family, real-distance, target, and isometric rows. □

Theorem 7569.4 (Kuratowski embedding distance readback exactness)**.** *Every accepted* $\mathsf{KuratowskiEmbedding}^{\uparrow}$ *packet reads source metric distance exactly through the displayed route*

$$M \to D \to T \to I.$$

The $\mathsf{Met}^{\uparrow}$ *row* M *supplies the source distance query, the* $\mathsf{Real}^{\uparrow}$ *row* D *supplies the distance witnesses used by the distance-function target* T*, and the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *row* I *is the first row from which a completion, hyperspace, or distance-function consumer may inspect the resulting target comparison. No consumer may read a distance-function target as exact before the metric source, real-distance witnesses, and isometric handoff have all been displayed.*

Lean4 ✓ `BEDC.Derived.KuratowskiEmbeddingUp.KuratowskiEmbedding distance readback exactness`

Proof. Project the accepted carrier $K = (M, B, D, T, I, H, C, P, N)$ from Definition 7569.1. The source-distance query starts in M, while the basepoint or displayed family row B fixes the finite comparison context.

Apply the NameCert obligations of Definition 7569.2. They force every source-distance read through M and every real-valued distance observation through D before the target row T can be inspected.

Finally use the source-distance route of Definition 7569.3. The isometric handoff I is downstream of M, B, D, T, and the structural rows H, C, P, N only preserve that route. Thus completion, hyperspace, and distance-function consumers receive exactness through the displayed isometric readback rather than from an ambient function space. □

Closure status for $\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KuratowskiEmbedding}^{\uparrow}$ packet is generated from a MetricUp source row, a selected basepoint or displayed family row, RealUp distance-witness rows, a distance-function target row, an IsometricEmbeddingUp route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7569.1, Definition 7569.2, and Definition 7569.3 seed the finite distance-function embedding surface over MetricUp, RealUp, and IsometricEmbeddingUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KuratowskiEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient completion, host function extensionality, ambient Banach-space structure, selected completion representatives, or bridge checking.

Upgrade path: Lean closure requires checked carrier admission, basepoint or family exposure, RealUp distance target exposure, isometric-route preservation, and structural replay proofs for BEDC.Derived.KuratowskiEmbeddingUp.

Chapter 7570

A Concrete Naming Certificate for KuratowskiEmbeddingDistanceProfile$^{\uparrow}$

Following Kuratowski's metric embedding of a metric space into distance functions, the KuratowskiEmbeddingDistan packet records the finite BEDC row that turns a source point or compact-source query into a displayed distance-profile classifier. It sits between the embedding carrier of chapter 7569, the finite compact-subset comparison of chapter 2086, the compact-metric source of chapter 129, and the metric-distance surface of chapter 57. The packet names the distance-profile classifier consumed by hyperspace and Hausdorff-facing chapters; it is not a host function space, quotient subset equality, selected completion representative, ambient supremum construction, or open-cover compactness theorem.

Definition 7570.1 (Kuratowski embedding distance-profile packet)**.** *A* KuratowskiEmbeddingDistanceProfile$^{\uparrow}$ *packet is a finite* BHist *carrier*

$$P = (M, K, E, H, D, R, S, C, Q, N)$$

with the following displayed rows:

1. *M is the source* Met$^{\uparrow}$ *row carrying the visible point names, source-distance witnesses, and tolerance requests for the profile read.*
2. *K is the optional* CompactMetric$^{\uparrow}$ *support row used when the profile is read against compact finite-net data.*
3. *E is the accepted* KuratowskiEmbedding$^{\uparrow}$ *row that converts the metric source into displayed distance-function observations.*
4. *H is the* HausdorffMetric$^{\uparrow}$ *comparison row available only when two compact-supported profile reads are compared.*
5. *D is the distance-profile classifier row, listing the finite family of displayed distance observations and the tolerance window used by the consumer.*
6. *R is the readback row that routes each displayed distance observation to the same metric and compact-support data named by M, K, E, H.*
7. *S records componentwise* hsame *transport for the metric, compact-support, embedding, Hausdorff, profile, readback, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay along the route*

$$M, K, E, H \longmapsto D \longmapsto R.$$

9. *Q is the* Pkg *provenance over* KuratowskiEmbeddingDistanceProfile$^{\uparrow}$, KuratowskiEmbedding$^{\uparrow}$, HausdorffMetric$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{KuratowskiEmbeddingDistanceProfile}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host real-valued function extensionality, quotient compact-set equality, selected completion representatives, ambient suprema, open-cover compactness, or a detached hyperspace object.

Theorem 7570.2 (Kuratowski embedding distance-profile NameCert obligations)**.** *For every accepted* KuratowskiEmbeddingDistanceProfile$^{\uparrow}$ *packet $P = (M, K, E, H, D, R, S, C, Q, N)$, the local* NameCert$_{\text{KuratowskiEmbeddingDistanceProfile}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric, compact-support, Kuratowski embedding, Hausdorff comparison, distance-profile, readback, transport, replay, provenance, and local naming rows;*
2. *source exposure, requiring every distance-profile observation in D to be read through the same* Met$^{\uparrow}$ *row M and, when compact support is present, through the same* CompactMetric$^{\uparrow}$ *row K;*
3. *embedding-profile coherence, requiring the profile row D to be downstream of the* KuratowskiEmbedding$^{\uparrow}$ *row E rather than a detached host function;*
4. *Hausdorff compatibility, requiring any compact-supported comparison to read the* HausdorffMetric$^{\uparrow}$ *row H before comparing two profile windows;*
5. *readback and transport, requiring R, S, C to replay and transport only the displayed finite route;*
6. *provenance exhaustion, requiring Q, N to name only the cited BEDC rows and to export no host function extensionality, quotient compact-set equality, selected completion representative, ambient supremum, open-cover compactness, or detached hyperspace object.*

No distance-profile obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7570.1. The accepted packet displays exactly the metric source, compact support, Kuratowski embedding row, Hausdorff comparison row, profile row, readback row, and structural rows.

Source exposure follows by reading M first and K when the profile is compact-supported. The profile row D has no independent source coordinate, so every visible distance observation is tied to the same metric and compact-support data.

Embedding-profile coherence is the projection to E, D. The row E is the only embedding row in the carrier, and D is read after it, so the profile is a displayed Kuratowski distance-function read rather than a host function-space object.

For compact-supported comparison, the row H supplies the Hausdorff finite-net comparison before any two profile windows are compared. The readback and transport rows R, S, C preserve and replay that same finite route.

Finally, Q, N exhaust provenance and local naming. Since the carrier has no coordinate for host function extensionality, quotient compact-set equality, selected completion representatives, ambient suprema, open-cover compactness, or detached hyperspace objects, none of these can be exported by the NameCert surface. □

Theorem 7570.3 (Kuratowski embedding distance-profile handoff)**.** *Every hyperspace-facing, Hausdorff-facing, or compact-metric-facing consumer of an accepted* KuratowskiEmbeddingDistanceProfile$^{\uparrow}$ *packet factors through*

$$M, K, E, H \longmapsto D \longmapsto R \longmapsto S, C, Q, N.$$

Consequently the consumer receives only the displayed metric source, compact-support row, Kuratowski embedding row, Hausdorff comparison row, finite distance-profile classifier, readback, componentwise transport, replay, provenance, and local name. It cannot claim host real-valued function extensionality, quotient compact-set equality, a selected completion representative, an ambient supremum, open-cover compactness, or a detached hyperspace object from the packet.

Proof. Start with an accepted packet $P = (M, K, E, H, D, R, S, C, Q, N)$. A profile read must first expose the metric source M and the compact-support row K when the read is compact-supported.

The Kuratowski embedding row E then supplies the displayed distance-function observations. If the consumer compares compact-supported profiles, it must also read the Hausdorff comparison row H before the profile classifier D is public.

The readback row R ties each displayed profile coordinate to the same source route. Componentwise transport, replay, provenance, and local naming are then supplied by S, C, Q, N without adding any new object coordinate.

Thus the consumer receives exactly the finite rows listed in the statement and none of the excluded host-level function, quotient, representative, supremum, compactness, or hyperspace data. □

Closure status for NameCert$_{\text{KuratowskiEmbeddingDistanceProfile}^{\uparrow}}$.

Constructive story: A KuratowskiEmbeddingDistanceProfile$^{\uparrow}$ packet is generated from MetricUp source rows, optional CompactMetricUp support, KuratowskiEmbeddingUp distance-function observations, HausdorffMetricUp compact-supported comparisons, a finite distance-profile classifier, readback rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KuratowskiEmbeddingDistanceProfile}^{\uparrow}}$, seed)

Scope closed: Definition 7570.1, Definition 7570.2, and Definition 7570.3 seed the finite distance-profile classifier route between Kuratowski embedding, Hausdorff metric comparison, compact-metric support, and metric source data.

Formal verification: FormalStatus(NameCert$_{\text{KuratowskiEmbeddingDistanceProfile}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host function extensionality, quotient compact-set equality, selected completion representatives, ambient suprema, open-cover compactness, detached hyperspace objects, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, Kuratowski profile coherence, Hausdorff compatibility, readback, transport, replay, provenance, and local NameCert exhaustion for BEDC.Derived.KuratowskiEmbeddingDista

Chapter 7571

A Concrete Naming Certificate for $\mathsf{SequentialCompactnessModulus}^{\uparrow}$

Following Bishop–Bridges compact metric arguments, the $\mathsf{SequentialCompactnessModulus}^{\uparrow}$ packet records the finite modulus data by which a compact metric source exposes bounded sequence windows, nested finite covers, dyadic tolerance requests, regular rational readback, and a terminal Real seal before any cluster-facing consumer may proceed. It sits after the compact metric source of chapter 129, total boundedness data from chapter 127, the completion boundary of chapter 128, finite stream windows from chapter 126, regular rational readback from chapter 301, and the Real naming seal of chapter 38. The packet supplies explicit finite modulus data for sequential compactness evidence consumed by Bolzano–Weierstrass and compact-metric sequence arguments; it is not a proof of general sequential compactness.

Definition 7571.1 (SequentialCompactnessModulus carrier)**.** *A* $\mathsf{SequentialCompactnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, T, C, S, D, R, E, Q, H, U, P, N)$$

with the following rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact metric carrier used by the sequence argument.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-cover row, listing the cover cells inspected at the displayed tolerances.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row, recording that Cauchy-style readback may be sealed only through the displayed completion boundary.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the sequence being inspected.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the precision requests and dyadic margins used by the finite cover refinement.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected finite windows and dyadic tolerances.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after K, T, C, S, D, R have been displayed.*
8. *Q is the cluster handoff row, giving the downstream Bolzano–Weierstrass or compact-metric sequence consumer the displayed finite modulus route.*

9. *H records componentwise* hsame *transport for the source, cover, completion-boundary, stream-window, tolerance, readback, seal, and handoff rows.*
10. *U records displayed* Cont *replay for refinements of the finite tolerance and window budget.*
11. *P is the* Pkg *provenance over* $\mathsf{SequentialCompactnessModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompactnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, T, C, S, D, R, E, Q, H, U, P, N$. It has no coordinate for a general sequential compactness theorem, a selected infinite subsequence, countable choice, open-cover compactness, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7571.2 (SequentialCompactnessModulus NameCert obligations)**.** *For every accepted* $\mathsf{SequentialCompactnessModulus}^{\uparrow}$ *carrier*

$$M = (K, T, C, S, D, R, E, Q, H, U, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialCompactnessModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source K, total-bounded finite-cover row T, completion-boundary row C, stream-window row S, dyadic tolerance row D, regular readback row R, Real seal E, cluster handoff Q, and structural rows H, U, P, N;*
2. *finite-modulus exposure, requiring every tolerance request in D to be matched with a displayed finite cover cell in T and a finite stream window in S;*
3. *completion-boundary discipline, requiring every Cauchy-style readback to pass through C before reaching R and E;*
4. *cluster handoff nonescape, requiring any Bolzano–Weierstrass or compact-metric sequence consumer to read Q only after the route*

$$K, T, C, S, D \longmapsto R \longmapsto E$$

   has been displayed;
5. *provenance and local naming, requiring H, U, P, N to transport, replay, source, and name only the displayed finite rows.*

No obligation row contains general sequential compactness, selected subsequences, countable choice, open-cover compactness, quotient stream equality, or ambient Real completeness.

Proof. Project the carrier of Definition 7571.1. The rows $K, T, C, S, D, R, E, Q, H, U, P, N$ are the whole accepted packet.

For finite-modulus exposure, read D together with T and S. Each precision request is paired with a displayed finite cover cell and a finite stream window before any readback row is visible.

For the completion-boundary discipline, route the selected window and tolerance data through C before R and E. The packet therefore uses completion only as the displayed boundary row named by chapter 128.

The cluster handoff Q is downstream of the same finite route. Since H, U, P, N only transport, replay, source, and name the displayed rows, the packet exports finite modulus data and no host sequential compactness, selected subsequence, countable-choice schedule, open-cover theorem, quotient stream equality, or ambient Real completeness. □

Lean4 (statement) `BEDC.Derived.SequentialCompactnessModulusUp`

Theorem 7571.3 (SequentialCompactnessModulus compact-metric sequential-net route)**.** *Every accepted* SequentialCompactnessModulus$^{\uparrow}$ *consumer that supplies a compact-metric sequence argument through a sequential-net packet must read the compact metric source row K, total-bounded finite-cover row T, complete-metric boundary row C,* StreamName$^{\uparrow}$ *finite-window row S,* DyadicRatCore$^{\uparrow}$ *tolerance row D,* RegSeqRat$^{\uparrow}$ *readback row R, terminal* Real$^{\uparrow}$ *seal E, and cluster handoff row Q before consuming* CompactMetricSequentialNet$^{\uparrow}$ *through chapter 4019. The route exports finite modulus data only; it does not supply general sequential compactness, selected subsequences, countable choice, open-cover compactness, quotient stream equality, or ambient Real completeness.*

Proof. Project the carrier of Definition 7571.1. The accepted packet exposes exactly the compact metric source, total-bounded cover, complete-metric boundary, stream-window, dyadic tolerance, readback, Real seal, cluster handoff, and structural rows.

Apply Definition 7571.2. Its finite-modulus exposure reads D together with T and S, while its completion-boundary discipline routes Cauchy-style readback through C before R and E.

Now read the compact-metric sequential-net sibling of chapter 4019. The cluster handoff row Q can feed CompactMetricSequentialNet$^{\uparrow}$ only after the source, finite-cover, boundary, window, tolerance, readback, and seal rows have been displayed.

The structural rows H, U, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores a general sequential-compactness theorem, a selected subsequence, a countable-choice schedule, open-cover compactness, quotient stream equality, or ambient Real completeness, the sibling route remains a finite modulus handoff. □

Falsifiable prediction: A SequentialCompactnessModulus$^{\uparrow}$ consumer that obtains a cluster handoff without reading compact metric source data, total-bounded finite covers, completion-boundary data, finite StreamName windows, dyadic tolerances, RegSeqRat readback, and the Real seal refutes the carrier surface.

Independence witness: compactmetric, totallybounded, completemetric, streamname, regseqrat, real: no listed sibling supplies the whole finite modulus packet because each sibling contributes compact source data, cover finiteness, completion-boundary discipline, observation windows, regular readback, or sealing, while SequentialCompactnessModulus$^{\uparrow}$ binds the cluster-facing route with transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{SequentialCompactnessModulus}^{\uparrow}}$**.**

Constructive story: A SequentialCompactnessModulus$^{\uparrow}$ packet is generated from CompactMetric source data, TotallyBounded finite covers, CompleteMetric boundary rows, StreamName finite windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, cluster handoff data, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SequentialCompactnessModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7571.1 and Definition 7571.2 seed the finite modulus surface for sequential compactness evidence over compact-metric sequence consumers.

Formal verification: FormalStatus(NameCert$_{\text{SequentialCompactnessModulus}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.SequentialCompactnessModulusUp`

Bridge status: none

Not claimed: This chapter does not close general sequential compactness, selected infinite subsequences, countable choice, open-cover compactness, quotient stream equality, ambient RealUp completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-modulus exposure, completion-boundary discipline, cluster handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SequentialCompactnessModulusUp.

Chapter 7572

A Concrete Naming Certificate for HausdorffLocatedUniformReflection$^{\uparrow}$

Following Kelley and Bourbaki, the HausdorffLocatedUniformReflection$^{\uparrow}$ packet records the finite located separated-reflection boundary for uniform data whose completion-facing consumers must keep Real-induced tests visible. It sits after the Real uniformity surface of chapter 1624, the separated completion packet of chapter 7566, the generated Cauchy-filter interface of chapter 4232, the uniform entourage source of chapter 339, and the terminal Real-name seal of chapter 38. The packet names a finite reflection route only; it is not a quotient-completion construction, selected-limit operator, countable-choice principle, trichotomy claim, host equality test, or ambient Real$^{\uparrow}$ completeness theorem.

Definition 7572.1 (Hausdorff located uniform reflection carrier)**.** *A* HausdorffLocatedUniformReflection$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (R, U, S, B, F, L, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *R is the* RealUniformStructure$^{\uparrow}$ *row exposing Real endpoints, metric distances, positive dyadic radii, and generated entourages.*
2. *U is the* UniformSpace$^{\uparrow}$ *entourage-source row read by the reflection consumer.*
3. *S is the* CauchyFilterSubbasis$^{\uparrow}$ *row displaying primitive subbasis tokens, finite intersections, generated events, and the generation ledger.*
4. *B is the generated* FilterBase$^{\uparrow}$ *row obtained from S.*
5. *F is the* CauchyFilter$^{\uparrow}$ *row read through B and U.*
6. *L is the locatedness row, recording the finite apartness and neighbourhood tests used before separation is public.*
7. *Q is the separated-reflection row consumed by* SeparatedUniformCompletion$^{\uparrow}$ *readers.*
8. *E is the completion-facing seal row, naming the retained* RegSeqRat$^{\uparrow}$ *readback and terminal* Real$^{\uparrow}$ *seal.*
9. *T records componentwise* hsame *transport for Real-uniform data, uniform entourages, subbasis generation, generated bases, Cauchy filters, located tests, separated reflection, seal rows, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay from Real-uniform entourage requests through generated subbasis bases, Cauchy-filter rows, located tests, separated reflection, and the seal.*
11. *P is the* Pkg *provenance over* HausdorffLocatedUniformReflection$^{\uparrow}$, RealUniformStructure$^{\uparrow}$, SeparatedUniformComp CauchyFilterSubbasis$^{\uparrow}$, FilterBase$^{\uparrow}$, CauchyFilter$^{\uparrow}$, UniformSpace$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{HausdorffLocatedUniformReflection}^{\uparrow}}$ *row.*

The classifier reads only $R, U, S, B, F, L, Q, E, T, C, P, N$ and their displayed replay paths. It has no coordinate for quotient completion, selected limits, countable choice, hidden filter equality, host real equality, trichotomy, or ambient completeness of Real$^{\uparrow}$.

Theorem 7572.2 (Hausdorff located uniform reflection NameCert obligations)**.** *For every accepted* HausdorffLocatedUniformReflection$^{\uparrow}$ *carrier $H = (R, U, S, B, F, L, Q, E, T, C, P, N)$, the local* NameCert$_{\text{HausdorffLocatedUniformReflection}^{\uparrow}}$ *surface consists exactly of carrier admission, Real-induced uniformity exposure through R, uniform entourage exposure through U, finite subbasis generation through S, B, Cauchy-filter exactness through F, locatedness testing through L, separated-reflection non-escape through Q, completion-facing seal stability through E, and structural transport, replay, provenance, and local naming through T, C, P, N.*

Proof. Project the carrier of Definition 7572.1. The Real-induced uniformity, uniform entourage, subbasis, generated-base, Cauchy-filter, locatedness, separated-reflection, seal, transport, replay, provenance, and local naming rows are exactly $R, U, S, B, F, L, Q, E, T, C, P, N$.

Read the generation route first. The rows S and B expose the finite subbasis and generated base before the Cauchy-filter row F is available, while R and U keep the Real-induced entourage source visible to the same consumer.

The located and separated rows are downstream from those data. The row L supplies the finite located tests, and Q records the separated reflection consumed by the completion-facing seal E.

Finally T, C, P, N preserve and name the same finite route. Since the carrier has no row for quotient completion, selected limits, countable choice, hidden filter equality, host real equality, trichotomy, or ambient Real$^{\uparrow}$ completeness, none of those principles is a NameCert obligation. □

Theorem 7572.3 (Hausdorff located uniform reflection completion route)**.** *Every completion-facing read of an accepted* HausdorffLocatedUniformReflection$^{\uparrow}$ *carrier factors through*

$$\text{RealUniformStructure}^{\uparrow} \longmapsto \text{CauchyFilterSubbasis}^{\uparrow} \longmapsto \text{FilterBase}^{\uparrow} \longmapsto \text{CauchyFilter}^{\uparrow} \longmapsto \text{SeparatedUniformCompletio}$$

In the notation of Definition 7572.1, a consumer reads Real-uniform and uniform-source rows R, U, finite subbasis and generated-base rows S, B, the Cauchy-filter row F, located and separated rows L, Q, and only then the completion-facing seal E with its structural rows.

Proof. Start with the Real-uniform and generated-base inputs. The rows R, U, S, B are the only displayed sources for entourage and subbasis generation, so a completion-facing read cannot begin from an ambient uniform completion object.

Apply the generated-base discipline of the CauchyFilterSubbasis$^{\uparrow}$ route. It keeps the Cauchy-filter row F downstream from the finite subbasis tokens, finite intersections, generated events, and generated FilterBase$^{\uparrow}$ row.

Now read the separated reflection. The located row L supplies the finite tests used before Q is public, and the seal row E is downstream from that separated-reflection boundary.

The structural rows T, C, P, N transport, replay, source, and name the same path. Because no quotient, selected-limit, choice, trichotomy, host-equality, or ambient-completeness coordinate occurs in the carrier, the displayed route is the complete completion-facing surface. □

Theorem 7572.4 (Hausdorff located uniform reflection Real-uniform handoff)**.** *Every accepted* $\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}$ *consumer that asks for a Real-induced uniformity read must inspect the* $\mathsf{RealUniformStructure}^{\uparrow}$ *row* R*, the* $\mathsf{UniformSpace}^{\uparrow}$ *row* U*, the generated subbasis rows* S, B*, and the* $\mathsf{CauchyFilter}^{\uparrow}$ *row* F *before the located row* L *or separated-reflection row* Q *can be used. The handoff exports no quotient completion, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Inspect the carrier rows in Definition 7572.1. The only Real-uniform input is R, the only independent uniform source is U, and the only generated-base path is S, B.

The Cauchy-filter row is downstream of those rows. A consumer reaches F only after the Real-induced entourage and subbasis-generated base have been displayed.

The located and separated rows are later in the same packet. Rows L and Q therefore refine the displayed uniform data rather than replacing it with an external quotient or selected completion.

The excluded principles have no carrier coordinate. Thus the Real-uniform handoff remains a finite NameCert route through $R, U, S, B, F, L, Q, E, T, C, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}$ completion read exposes RealUniformStructureUp, UniformSpaceUp, CauchyFilterSubbasisUp, generated FilterBaseUp, CauchyFilterUp, locatedness, separated reflection, completion seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: real-uniform-structure, separated-uniform-completion, cauchy-filter-subbasis, uniformspace, real: $\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Real-induced uniformity, uniform-source exposure, finite generated subbasis data, Cauchy-filter exactness, located tests, separated reflection, seal stability, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}$ packet is generated from RealUniformStructureUp data, UniformSpaceUp entourages, CauchyFilterSubbasisUp finite-generation rows, a generated FilterBaseUp row, a CauchyFilterUp row, locatedness tests, separated-reflection data, a completion-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7572.1, Definition 7572.2, Definition 7572.3, and Definition 7572.4 seed the finite located separated-reflection route for Real-uniform completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffLocatedUniformReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, hidden filter equality, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of BEDC.Derived.HausdorffLocatedUniformReflectionUp with checked carrier admission, Real-uniform exposure, subbasis generation, Cauchy-filter exactness, locatedness, separated-reflection non-escape, seal stability, transport, replay, provenance, and classifier faithfulness.

Chapter 7573

A Concrete Naming Certificate for $\mathsf{AffineFilterHull}^{\uparrow}$

Following Kelley on finite filter bases and the standard affine-hull closure discipline for generated neighbourhood systems, the $\mathsf{AffineFilterHull}^{\uparrow}$ packet records a finite hull route from displayed affine generators to a filter-base handoff. It concretizes the vision-routing surface of chapter 9236 through a traditional filter-hull object grounded in the coverage index of chapter 7381, the coverage ledger of chapter 7484, and the filter-base interface of chapter 1601. The packet names the generated affine-filter boundary only; it does not assert convex completeness, select limits, quotient filters, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7573.1 (Affine filter hull carrier)**.** *An* $\mathsf{AffineFilterHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (V, G, M, I, B, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite affine-generator row, listing the displayed generator tokens available to the hull.*
2. *G is the finite generator-family row, recording which finite affine combinations are admitted as local hull requests.*
3. *M is the membership-event row, exposing the* BHist *surface attached to each admitted hull request.*
4. *I is the inclusion ledger from generator tokens and finite affine combinations into generated filter requests.*
5. *B is the generated* $\mathsf{FilterBase}^{\uparrow}$ *row exposed to downstream consumers.*
6. *R is the routing row linking this concrete object back to the vision coverage index and ledger surfaces.*
7. *H records componentwise* hsame *transport for generators, finite affine combinations, membership events, inclusion ledgers, filter-base rows, routing rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from affine-generator requests through finite hull membership and into the generated filter-base handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{AffineFilterHull}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{VisionCoverageIndex}^{\uparrow}$, $\mathsf{VisionCoverageLedger}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{AffineFilterHull}^{\uparrow}}$ *row.*
The classifier reads only $V, G, M, I, B, R, H, C, P, N$. It has no coordinate for an infinite affine span, quotient filters, selected limits, countable choice, host equality of hulls, or ambient completeness.

Theorem 7573.2 (Affine filter hull NameCert obligations)**.** *For every accepted* $\mathsf{AffineFilterHull}^{\uparrow}$ *carrier $A = (V, G, M, I, B, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AffineFilterHull}^{\uparrow}}$ *surface consists exactly of carrier admission, finite affine-generator exposure through V, finite affine-combination admission through G, membership-event exposure through M, inclusion-ledger coverage through I, generated* $\mathsf{FilterBase}^{\uparrow}$ *handoff through B, vision-routing compatibility through R, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 7573.1. The rows V, G, M, I are the complete finite affine-hull generation surface, and B is the only generated filter-base row.

The routing row is separate from the generated base. It records that the hull object realizes a vision coverage route, but it does not create a second carrier or a hidden completion object.

Transport, replay, provenance, and local naming are exactly H, C, P, N. Since the carrier has no row for an infinite affine span, quotient filters, selected limits, countable choice, host equality of hulls, or ambient completeness, those principles cannot appear as local NameCert obligations. □

Theorem 7573.3 (Affine filter hull generated-base route)**.** *Every downstream read of an accepted* $\mathsf{AffineFilterHull}^{\uparrow}$ *carrier reaches the generated* $\mathsf{FilterBase}^{\uparrow}$ *row B only after finite affine generators V, admitted finite combinations G, membership events M, and the inclusion ledger I have been displayed. The route exports no quotient filters, selected limits, countable choice, host equality of generated hulls, infinite affine span, or ambient completeness.*

Proof. Begin with the carrier rows. The only source data for the hull are the finite generator row V and finite-combination row G.

The membership-event and inclusion-ledger rows M, I mediate all access from those generators to the generated base. Thus B is available only through the displayed finite hull route.

Apply the NameCert obligations of Definition 7573.2. They force the generated $\mathsf{FilterBase}^{\uparrow}$ handoff and the routing row to remain inside the same finite packet.

The excluded coordinates are absent from A. Hence a downstream consumer cannot read quotient filters, selected limits, countable choice, host equality, infinite spans, or ambient completeness from this packet. □

Theorem 7573.4 (Affine filter hull vision routing)**.** *The* $\mathsf{AffineFilterHull}^{\uparrow}$ *packet realizes a concrete routing object for the vision coverage surface: a read through R must point to the existing vision coverage index and coverage ledger while the generated* $\mathsf{FilterBase}^{\uparrow}$ *handoff remains the row B of the same carrier. No vision-side marker supplies an independent theorem, hidden carrier, quotient filter, selected limit, or countable-choice schedule.*

Proof. Inspect the routing row R in Definition 7573.1. It names the already displayed coverage index and ledger surfaces as provenance for the concrete hull route.

The generated filter-base handoff is still B. Rows V, G, M, I produce it, and rows H, C, P, N transport, replay, source, and name the same object.

Therefore the vision marker is a pointer to this concrete carrier rather than a separate mathematical payload. Since the carrier has no quotient, selected-limit, choice, hidden-carrier, or ambient-completeness coordinate, the routing read cannot export any of those objects. □

Falsifiable prediction: Every accepted $\mathsf{AffineFilterHull}^{\uparrow}$ read exposes finite affine generators, finite affine-combination rows, membership events, an inclusion ledger, a generated FilterBaseUp row, a vision-routing row, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: filterbase, vision-coverage-index, vision-coverage-ledger: $\mathsf{AffineFilterHull}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite affine generators, generated membership events, inclusion-ledger coverage, a generated filter-base handoff, vision-routing compatibility, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AffineFilterHull}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AffineFilterHull}^{\uparrow}$ packet is generated from finite affine-generator rows, finite affine-combination rows, membership-event rows, an inclusion ledger, a generated FilterBaseUp row, a vision-routing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AffineFilterHull}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7573.1, Definition 7573.2, Definition 7573.3, and Definition 7573.4 seed the finite affine-filter hull route from displayed generators to generated filter-base handoff and vision routing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AffineFilterHull}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite affine spans, quotient filters, selected limits, countable choice, host equality of hulls, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires Lean encoding of BEDC.Derived.AffineFilterHullUp with checked carrier admission, finite affine generation, membership-event exposure, inclusion-ledger coverage, FilterBaseUp handoff, vision-routing compatibility, transport, replay, provenance, and classifier faithfulness.

Chapter 7574

A Concrete Naming Certificate for $\mathsf{CauchyApproximationSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyApproximationSpace}^{\uparrow}$ packet records the finite approximation interface by which a regular rational source answers completion-facing Real reads through named finite windows. It sits after the StreamName finite observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the located metric comparison surface of chapter 3685. The chapter packages the four-face route as BEDC-native finite data rather than as informal Cauchy approximation prose.

Definition 7574.1 (Cauchy approximation space carrier)**.** *A* $\mathsf{CauchyApproximationSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger for the observed unary request spine.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row family attached to those windows, including common-scale comparison and radius rows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that identifies the regular rational source consumed by the window and tolerance data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the finite window, dyadic tolerance, and regular readback rows have been displayed.*
5. *H stores componentwise* hsame *transport for W, D, R, E, C, P, N and for every local comparison row opened by the packet.*
6. *C stores displayed* Cont *replay from StreamName requests through dyadic tolerance checks and RegSeqRat readback into the Real seal row.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedMetricSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected real representative, countable choice, trichotomy, host metric completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7574.2 (Cauchy approximation space NameCert obligations)**.** *For an accepted* CauchyApproximationSpac *carrier* $A = (W, D, R, E, H, C, P, N)$*, the local* NameCert *surface consists exactly of finite* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-row exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. Every completion-facing consumer of the carrier must read these rows before it can use a Real-facing approximation result.*

Proof. Project the accepted carrier through Definition 7574.1. The rows W, D, R, E are the only analytic coordinates, while H, C, P, N supply transport, replay, provenance, and local naming.

The finite window obligation is read from the StreamName chapter chapter 126. The dyadic tolerance obligation is read from chapter 291, and the regular rational readback is read from chapter 301.

The Real-facing endpoint is sealed only after those rows are present. The local NameCert therefore names the displayed four-face route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, with the located metric surface of chapter 3685 available only as a dependency of the displayed comparison rows. □

Theorem 7574.3 (Cauchy approximation space window stability)**.** *Let two accepted* $\mathsf{CauchyApproximationSpace}^{\uparrow}$ *carriers agree under componentwise* hsame *transport on their finite* $\mathsf{StreamName}^{\uparrow}$ *window rows and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows. Then every retained request reads the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, the same* $\mathsf{Real}^{\uparrow}$ *seal handoff, the same* Cont *replay, the same* Pkg *provenance, and the same local* NameCert *row. The comparison remains a finite BEDC window comparison rather than quotient stream equality or host real equality.*

Proof. Start with the common transported window and tolerance rows. The StreamName finite observation surface keeps every retained request inside the same displayed finite section, and the DyadicRatCore tolerance ledger keeps the comparison rows on the same finite scale.

Read the RegSeqRat row through that shared window. Since R is a carrier coordinate and not a hidden tail selector, the readback available to a retained request is the same regular rational source row on both carriers.

Finally replay the support rows. The hsame row identifies the displayed coordinates, Cont repeats the same route, and P, N package and name that route without adding quotient stream equality, a selected limit, host real equality, or an ambient completeness principle. □

Theorem 7574.4 (Cauchy approximation space Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CauchyApproximationSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

carried by W, D, R, E, H, C, P, N*. The consumer may use the located metric dependency of chapter 3685 only through the displayed dyadic comparison rows, and it cannot introduce a selected completion point, quotient Cauchy equality, host metric completeness, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7574.2 to expose the carrier rows. A Real-facing consumer sees the finite StreamName window, dyadic tolerance ledger, and regular rational readback before it reaches the seal row E.

Apply Definition 7574.3 to retained requests. Enlarging or replaying a request preserves the old window, tolerance ledger, readback, support rows, provenance, and local name.

The located metric dependency is therefore already internal to the displayed dyadic comparison rows. The final handoff exports only the finite approximation route into $\mathsf{Real}^{\uparrow}$, so no selected completion point, quotient equality, host metric completeness, countable choice, trichotomy, or ambient Real completeness can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyApproximationSpace}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7574.1, Definition 7574.2, Definition 7574.3, and Definition 7574.4 seed the finite L10 approximation route from StreamName windows and dyadic tolerance rows to RegSeqRat readback and RealUp seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completion points, host metric completeness, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window stability, dyadic tolerance exactness, RegSeqRat readback, RealUp seal nonescape, and located metric dependency coverage for BEDC.Derived.CauchyApproximationSpaceUp.

Chapter 7575

A Concrete Naming Certificate for $\mathsf{FreeTopologicalGroup}^{\uparrow}$

Following Markov and Graev on free topological groups, the $\mathsf{FreeTopologicalGroup}^{\uparrow}$ packet records the finite BEDC surface by which a displayed topological source generates reduced-word group rows equipped with Graev uniformity data. It sits over the open-row discipline of chapter 88, the entourage discipline of chapter 339, the continuous operation ledger of chapter 204, the metric witness route of chapter 57, and the algebraic operation surface of chapter 41. The certificate names finite reduced-word rows, Graev entourage rows, continuity rows for multiplication and inverse, componentwise transport, replay, provenance, and local naming; it does not import a host quotient, a universal-property oracle, or an ambient free-object primitive.

Definition 7575.1 (Free topological group carrier)**.** *A* $\mathsf{FreeTopologicalGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, T, U, G, W, E, M, I, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-object row whose points are read only through the displayed* $\mathsf{Topology}^{\uparrow}$ *surface.*
2. *T is the topology row from chapter 88, exposing the open-neighbourhood requests used by the source.*
3. *U is the uniformity row from chapter 339, exposing entourage requests used to compare reduced words.*
4. *G is the algebraic group row from chapter 41, naming multiplication, unit, inverse, and reduced-word comparison rows.*
5. *W is the reduced-word ledger, listing finite alternating source letters and formal inverse tags together with the local cancellation record.*
6. *E is the Graev entourage ledger, recording the finite word-level entourages generated from source entourages and their compatibility with reduction.*
7. *M is the optional* $\mathsf{Met}^{\uparrow}$ *handoff row, read through chapter 57 when the source uniformity is supplied by a displayed metric.*
8. *I is the* $\mathsf{TopGroup}^{\uparrow}$ *continuity row from chapter 204, requiring multiplication and inverse to be continuous for the topology generated by E.*

9. *H stores componentwise* hsame *transport for $X, T, U, G, W, E, M, I, C, P, N$.*
10. *C stores displayed* Cont *replay from source rows through reduced words, Graev uniformity, group operations, metric handoff, and topological-group continuity.*
11. *P is the* Pkg *provenance over* $\mathsf{FreeTopologicalGroup}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FreeTopologicalGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, U, G, W, E, M, I, H, C, P, N$. It has no coordinate for host quotient equality of words, selected representatives, ambient universal arrows, untracked topologies, external completion, Lean verification, or bridge checking.

Theorem 7575.2 (Free topological group NameCert obligations)**.** *For every accepted* $\mathsf{FreeTopologicalGroup}^{\uparrow}$ *carrier*

$$F = (X, T, U, G, W, E, M, I, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FreeTopologicalGroup}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source topology, source uniformity, algebraic group row, reduced-word ledger, Graev entourage ledger, optional metric handoff, topological-group continuity row, componentwise transport, replay, provenance, and local naming. A consumer may read a free topological group only after these rows have been displayed together.*

Proof. Project the accepted carrier through Definition 7575.1. The source data are X, T, U, the algebraic data are G, W, and the Graev uniform route is stored in E with optional metric support in M.

The topological-group obligation is read through I. This forces the multiplication and inverse rows named by G to be consumed together with the topology generated by the Graev entourage ledger, using the sibling topological-group surface rather than an ambient operation theorem.

Finally H, C, P, N exhaust transport, replay, provenance, and local naming. Since the classifier has no further coordinate, the packet cannot export host quotient equality of words, selected representatives, ambient universal arrows, untracked topologies, external completion, Lean verification, or bridge checking. □

Theorem 7575.3 (Free topological group Graev uniform route)**.** *Every Graev-uniform read exported by an accepted* $\mathsf{FreeTopologicalGroup}^{\uparrow}$ *packet factors through the displayed source route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{UniformSpace}^{\uparrow},\ \mathsf{Group}^{\uparrow} \longrightarrow \mathsf{TopGroup}^{\uparrow}$$

and, when metric data are present, through the optional $\mathsf{Met}^{\uparrow}$ *row before the word-level entourage is consumed. The reduced-word ledger W and the Graev entourage ledger E remain visible at the point of use, so no consumer can replace the packet by a host quotient group, an external free topological group, or an untracked universal map.*

Proof. Begin with $F = (X, T, U, G, W, E, M, I, H, C, P, N)$. The topology row T and uniformity row U expose the source neighbourhood and entourage requests before any generated word can be compared.

The reduced-word and group rows are W and G. They provide the finite word ledger, cancellation record, unit, multiplication, and inverse rows that the Graev route may inspect.

The Graev-uniform route is E together with the continuity row I. If a metric source is available, M records the displayed metric handoff before the word-level entourage is used; otherwise no metric coordinate is exported. Transport and replay through H, C, P, N preserve exactly these rows, so the consumer receives only the finite NameCert route. □

Lean4 (statement) `BEDC.Derived.FreeTopologicalGroupUp`

Closure status for $\mathsf{NameCert}_{\mathsf{FreeTopologicalGroup}^{\uparrow}}$.

Constructive story: A $\mathsf{FreeTopologicalGroup}^{\uparrow}$ packet is generated from a displayed topological source row, uniformity row, algebraic group row, reduced-word ledger, Graev entourage ledger, optional metric handoff, topological-group continuity row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FreeTopologicalGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7575.1, Definition 7575.2, and Definition 7575.3 seed the finite route from displayed topology and uniformity rows through reduced-word group rows into topological-group continuity.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FreeTopologicalGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host quotient group, an ambient universal property, selected word representatives, external completion, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reduced-word exactness, Graev entourage compatibility, multiplication and inverse continuity, metric handoff, transport, provenance, and local naming obligations for BEDC.Derived.FreeTopologicalGroupUp.

Chapter 7576

A Concrete Naming Certificate for $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$

Following Arzela and Ascoli, the $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ packet records the finite-net extraction surface for an equicontinuous family on a compact metric source as BEDC NameCert data. It sits after the compact and metric source rows of chapter 60, chapter 57, and chapter 129, the pointwise continuous-map rows of chapter 59 and chapter 130, the finite-net ledger of chapter 127, the real-name boundary of chapter 38, and the shared family-modulus route of chapter 4076. The packet names the finite extraction boundary only; it is not an open-cover compactness theorem, a selected subsequence, a quotient function-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7576.1 (Arzela–Ascoli finite-net carrier)**.** *An* $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, M, C, T, E, R, W, H, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read through the* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *certificates.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used by finite-net comparisons on the source.*
3. *C is the finite* $\mathsf{Continuous}^{\uparrow}$ *or* $\mathsf{ContinuousMap}^{\uparrow}$ *family row whose values are inspected only through displayed pointwise windows.*
4. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net ledger of centers, membership rows, distance witnesses, and refinement data.*
5. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *shared tolerance-radius row for the same family and source.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *value-readback row used for displayed pointwise distances and oscillation bounds.*
7. *W is the finite extraction window row, recording which center values and tolerance budgets are exposed to a completion or compactness-facing consumer.*
8. *H records componentwise* hsame *transport for the compact, metric, continuity, total-bounded, equicontinuity, Real, window, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, C, T, E, R, W, H, P, N$. It has no coordinate for open-cover compactness, host function-space topology, quotient equality of maps, selected subsequences, countable choice, or ambient Real completeness.

Theorem 7576.2 (Arzela–Ascoli finite-net NameCert obligations)**.** *For every accepted* $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ *carrier* $A = (K, M, C, T, E, R, W, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact source, metric row, continuous-family row, total-bounded finite-net ledger, equicontinuity modulus row, Real value-readback row, extraction window, componentwise transport, provenance, and local naming; finite-net compatibility requiring T to be read before W; equicontinuity compatibility requiring E to be read before the extracted window is consumed; Real readback exactness requiring R to remain attached to the displayed pointwise values; and nonescape excluding open-cover compactness, selected subsequences, quotient function equality, countable choice, and ambient completeness.*

Proof. Carrier admission is projection from Definition 7576.1. The accepted packet displays exactly $K, M, C, T, E, R, W, H, P, N$, so every local obligation must be read from those rows.

The finite-net compatibility row is T. It supplies centers, membership rows, distance witnesses, and refinement data before the extraction window W can expose any finite sample of the family.

The equicontinuity compatibility row is E. Its shared tolerance-radius handoff is read after the continuous-family row C and before W, so the extracted window is controlled by the same family modulus rather than by memberwise radius choices.

Real readback exactness is the role of R. The value comparisons consumed by W remain terminal real-name reads for displayed pointwise data, not quotient equality of functions or a host supremum.

Finally H, P, N transport, source, and name only the displayed rows. Since no row stores open-cover compactness, selected subsequences, quotient function equality, countable choice, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7576.3 (Arzela–Ascoli finite-net extraction)**.** *Every completion-facing or compactness-facing read exported by an accepted* $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ *carrier*

$$A = (K, M, C, T, E, R, W, H, P, N)$$

factors through the finite route

$$K, M, C, T, E, R \longmapsto W \longmapsto H, P, N.$$

Thus the exported object is a finite-net extraction window over compact, metric, continuous, totally bounded, Real, and equicontinuity rows. It does not export a selected subsequence, a function-space compactness theorem, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7576.2. They force any accepted read to display the compact source, metric row, continuous-family row, finite-net ledger, shared equicontinuity row, and Real value-readback row before the extraction window is consumed.

Use the cited sibling chapters for the route data. The compact and metric rows supply the source boundary, the continuity rows supply displayed value reads, the total-bounded row supplies finite centers, the Real row supplies terminal value seals, and the equicontinuity row supplies the shared tolerance-radius handoff.

The extraction window W can therefore expose only finite center values and displayed tolerance budgets inherited from K, M, C, T, E, R. The structural rows H, P, N then transport, source, and name that same window without adding another analytic coordinate.

The exclusions follow from the carrier inventory. Since selected subsequences, function-space compactness, quotient equality of maps, countable choice, and ambient Real completeness do not occur in $K, M, C, T, E, R, W, H, P, N$, no completion-facing or compactness-facing read can export them from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7576.1, Definition 7576.2, and Definition 7576.3 seed the finite-net extraction surface for equicontinuous families over compact metric source, total-bounded net, Real readback, transport, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequences, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net compatibility, equicontinuity compatibility, Real readback exactness, extraction-window routing, transport, provenance, and local naming for BEDC.Derived.ArzelaAscoliFiniteNetUp

Constructive story: An $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ packet is generated from compact and metric source rows, continuous-family rows, a total-bounded finite-net ledger, an Equicontinuity shared modulus row, Real value readback, an extraction window, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Chapter 7577

A Concrete Naming Certificate for $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ packet records the finite calibration row that ties a displayed precision request to the dyadic tolerance, stream window, regular-rational readback, and terminal Real seal used by a Bishop-style Cauchy name. It sits after the dyadic core of chapter 291, the finite stream-name surface of chapter 126, the regular rational sequence route of chapter 301, and the real-name seal of chapter 38. It also sits beside the finite tail-window handoff of chapter 7562. The packet is calibration data for inspected regular Cauchy names; it is not $\mathsf{Real}^{\uparrow}$ completeness, quotient equality of real names, trichotomy, selected representatives, or countable choice.

Definition 7577.1 (Bishop Cauchy modulus calibration carrier)**.** *A* $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying the requested precision, its dyadic radius, and the finite comparison budget used by the name.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row inspected at that requested precision.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the inspected window into regular rational observations.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after D, S, R have been displayed.*
5. *M is the calibration row tying the precision request, tolerance row, window row, readback row, and Real seal into one Bishop Cauchy modulus route.*
6. *H records componentwise* hsame *transport for D, S, R, E, M, C, P, N.*
7. *C records displayed* Cont *replay of the route*

$$D \longmapsto S \longmapsto R \longmapsto M \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalibration}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, E, M, H, C, P, N$. It has no coordinate for quotient real equality, trichotomy, countable choice, selected representatives, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7577.2 (Bishop Cauchy modulus calibration NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ *carrier*

$$K = (D, S, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalibration}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D,* $\mathsf{StreamName}^{\uparrow}$ *window row S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R,* $\mathsf{Real}^{\uparrow}$ *seal row E, calibration row M, transport row H, replay row C, provenance row P, and local naming row N;*
2. *dyadic-window calibration, requiring D to determine the precision budget under which S is inspected;*
3. *regular readback calibration, requiring R to consume the same S and D before the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is visible;*
4. hsame *transport and* Cont *replay, requiring H and C to preserve the displayed route D, S, R, M, E without inserting any hidden selector;*
5. Pkg *provenance and local* $\mathsf{NameCert}$ *naming, requiring P and N to name the same finite packet and to refuse quotient equality, trichotomy, countable choice, selected representatives, host real equality, and ambient Real completeness.*

No calibration obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7577.1. The packet displays exactly the dyadic tolerance, stream window, regular rational readback, terminal Real seal, calibration, transport, replay, provenance, and local naming rows.

The calibration rows are D, S, R, M, E. A precision request first exposes the dyadic budget D, reads the finite window S, and then checks the regular rational observations through R before the calibration row M can hand the request to the terminal $\mathsf{Real}^{\uparrow}$ seal E.

The structural rows are H, C, P, N. They transport, replay, source, and name the same finite route, so a consumer cannot introduce a quotient equality row, trichotomy row, countable-choice schedule, selected representative, host equality, or ambient completeness coordinate through the local certificate. □

Theorem 7577.3 (Bishop Cauchy modulus calibration seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ *carrier reaches the seal row only through the finite chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

as calibrated by M and preserved by H, C, P, N. The route exports a calibrated regular-Cauchy observation packet; it exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient equality of real names, trichotomy, selected representative, host real equality, or countable-choice schedule.*

Proof. Apply Definition 7577.2. The obligation rows force a real-facing read to expose the dyadic tolerance row, the stream window, and the regular rational readback before the calibration row can present the terminal seal.

The terminal seal row is E. Since E is downstream of the same D, S, R, M route and the transport, replay, provenance, and local naming rows preserve only that route, every accepted consumer reaches $\mathsf{Real}^{\uparrow}$ through the displayed finite packet. □

Falsifiable prediction: A $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the DyadicRatCore tolerance row, StreamName window row, RegSeqRat readback row, calibration row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier.

Independence witness: dyadicratcore, streamname, regseqrat, real, realcauchywindow: no listed sibling is bijective to $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ because this packet binds the precision tolerance, inspected stream window, regular rational readback, terminal Real seal, calibration row, transport, replay, provenance, and local NameCert row into one finite Bishop Cauchy route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalibration}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyModulusCalibration}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName window row, RegSeqRat readback row, RealUp seal row, calibration row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalibration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7577.1, Definition 7577.2, and Definition 7577.3 seed the finite Bishop Cauchy modulus calibration route from dyadic precision requests to the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalibration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient equality of real names, trichotomy, selected representatives, host real equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-window calibration, regular readback calibration, RealUp seal nonescape, hsame transport, Cont replay, Pkg provenance, and local naming for BEDC.Derived.BishopCauchyModulusCali

Chapter 7578

A Concrete Naming Certificate for $\mathsf{HilbertCubeCompactness}^{\uparrow}$

Following Kelley and Engelking on the Hilbert cube and compact metric products, the $\mathsf{HilbertCubeCompactness}^{\uparrow}$ packet records compactness through finite coordinate-window nets over $\mathsf{HilbertCube}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CompactMetric}^{\uparrow}$. It consumes the finite Hilbert-cube carrier of chapter 1995, the stream and regular-rational readback routes of chapter 126 and chapter 301, the dyadic tolerance core of chapter 291, the terminal real seal of chapter 38, and the compact-metric row of chapter 129. The packet names finite coordinate-window net data; it does not claim open-cover compactness, a choice-selected subnet, host product completeness, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7578.1 (Hilbert cube compactness carrier)**.** *A* $\mathsf{HilbertCubeCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (H, W, R, D, E, K, B, T, P, N)$$

with the following displayed rows:

1. *H is the accepted* $\mathsf{HilbertCube}^{\uparrow}$ *source row, read through the finite coordinate-window carrier of chapter 1995.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *coordinate-window schedule naming exactly the coordinates inspected by the current net request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those inspected coordinate windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic mesh radii and comparison cells used by the finite net.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, attaching each displayed coordinate readback to a real interval boundary.*
6. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-metric support row for the inspected product window.*
7. *B is the finite coordinate-window net ledger, listing the displayed centers, mesh radii, and containment rows for the inspected window.*
8. *T records componentwise* hsame *transport and displayed* Cont *replay for H, W, R, D, E, K, B.*
9. *P is the* Pkg *provenance over* $\mathsf{HilbertCubeCompactness}^{\uparrow}$, $\mathsf{HilbertCube}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, W, R, D, E, K, B, T, P, N$. It has no coordinate for open-cover compactness, host product completeness, a selected subnet, quotient stream equality, countable choice, Lean verification, or bridge checking.

Theorem 7578.2 (Hilbert cube compactness NameCert obligations)**.** *For every accepted* $\mathsf{HilbertCubeCompactness}^{\uparrow}$ *carrier*

$$C = (H, W, R, D, E, K, B, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}$ *surface consists exactly of carrier admission, Hilbert-cube source exposure, finite coordinate-window scheduling, regular-rational readback, dyadic mesh tolerance exposure, real interval sealing, compact-metric finite-window support, finite net containment, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7578.1. The accepted tuple exposes the Hilbert-cube source row, stream schedule, regular-rational readback, dyadic tolerance ledger, real seal row, compact-metric support row, finite net ledger, transport and replay row, provenance row, and local name.

The finite coordinate-window obligations are read from H, W, R, D, E. The source row H supplies only the displayed Hilbert-cube carrier, W names the inspected coordinates, R reads their rational data, D fixes the dyadic mesh, and E seals the inspected coordinates as real interval data.

The compact-metric support and net obligations are read from K and B. The row K records the finite metric support for the inspected product window, while B lists the centers, radii, and containment checks used by the net consumer.

Finally, T, P, N exhaust transport, replay, provenance, and local naming. Since the carrier has no additional coordinate, the certificate cannot store open-cover compactness, host product completeness, a selected subnet, quotient stream equality, countable choice, Lean verification, or bridge checking. □

Theorem 7578.3 (Hilbert cube compactness finite coordinate net)**.** *Every accepted* $\mathsf{HilbertCubeCompactness}^{\uparrow}$ *consumer read factors through the finite coordinate-window net route*

$$\mathsf{HilbertCube}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompactMetric}^{\uparrow}.$$

The exported net is therefore a finite ledger over inspected coordinates, dyadic mesh radii, sealed real intervals, compact-metric support, and displayed containment rows, not an open-cover compactness proof or a choice-selected countable product argument.

Proof. Start with an accepted carrier $C = (H, W, R, D, E, K, B, T, P, N)$. The Hilbert-cube source row H can be read only through the finite coordinate-window surface already displayed by chapter 1995.

The consumer then reads W, R, D, E in order. These rows name the inspected coordinates, recover regular rational data, choose the dyadic mesh budget, and seal the inspected coordinates into real interval rows.

The net itself is exported only after K and B are visible. The compact-metric support row fixes the finite metric window, and the net ledger lists the displayed centers, radii, and containment checks for that same window.

Transport, replay, provenance, and local naming preserve this route componentwise through T, P, N. No row remains from which the consumer could obtain an arbitrary open-cover argument, a selected subnet, host product completeness, quotient stream equality, or countable choice. □

Theorem 7578.4 (Hilbert cube compactness real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{HilbertCubeCompactness}^{\uparrow}$ *packet is bounded by the displayed finite route through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh tolerances,* $\mathsf{Real}^{\uparrow}$ *interval seals,* $\mathsf{CompactMetric}^{\uparrow}$ *finite support, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}$ *row. The packet exports no ambient real completeness principle and no equality of host streams.*

Proof. Project the carrier. A real-facing consumer reaches the terminal real rows only after the finite stream schedule, regular rational readback, and dyadic tolerance ledger have all been displayed.

The compactness read does not alter that boundary. The compact-metric support row and finite net ledger consume the sealed interval data already present in E and do not add a separate real-completion or host-product coordinate.

The structural rows T, P, N preserve the same finite route. Therefore every real-facing read remains inside the displayed coordinate-window seal and cannot be reread as ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, host product completeness, open-cover compactness, or a selected subnet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7578.1, Definition 7578.2, Definition 7578.3, and Definition 7578.4 seed the finite coordinate-window net route from $\mathsf{HilbertCube}^{\uparrow}$ through stream windows, regular-rational readback, dyadic mesh tolerances, real interval seals, compact-metric support, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertCubeCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host product completeness, quotient stream equality, selected subnets, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite coordinate-window scheduling, dyadic mesh exposure, real interval sealing, compact-metric support, finite net containment, transport, replay, provenance, and local naming for BEDC.Derived.HilbertCubeCompactnessUp.

Constructive story: A $\mathsf{HilbertCubeCompactness}^{\uparrow}$ packet is generated from a $\mathsf{HilbertCube}^{\uparrow}$ source row, finite $\mathsf{StreamName}^{\uparrow}$ coordinate windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback rows, $\mathsf{DyadicRatCore}^{\uparrow}$ mesh ledgers, $\mathsf{Real}^{\uparrow}$ interval seals, $\mathsf{CompactMetric}^{\uparrow}$ finite support rows, a finite net containment ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7579

A Concrete Naming Certificate for $\mathsf{CompletionModulusLifting}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completions and Kelley on completion and uniform structures, the $\mathsf{CompletionModulusLifting}^{\uparrow}$ packet records the finite route by which a displayed completion modulus is lifted into StreamName, RegSeqRat, DyadicRatCore, and Real seal rows before any Real or Completion consumer reads it. It sits after the modulus surface of chapter 292, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, the Bishop completion-modulus carrier of chapter 1469, and the threshold-selection surface of chapter 7210. The packet names only displayed finite lifting data; it does not select limits, quotient streams, countable-choice schedules, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7579.1 (Completion modulus lifting carrier)**.** *A* $\mathsf{CompletionModulusLifting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the completion modulus row, read through* $\mathsf{BishopCompletionModulus}^{\uparrow}$ *and* $\mathsf{CauchyModulus}^{\uparrow}$*, assigning a finite threshold to each displayed precision request.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family opened at the thresholds named by M.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic request, threshold comparison, and radius accounting used by M and R.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, S, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the modulus, window, readback, tolerance, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through completion-modulus thresholding, finite windows, rational readback, dyadic tolerance accounting, and the terminal Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CompletionModulusLifting}^{\uparrow}$, $\mathsf{BishopCompletionModulus}^{\uparrow}$, BishopCompletionModulus $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CompletionModulusLifting}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, S, R, D, E, H, C, P, N$. The carrier has no coordinate for a selected completion point, quotient stream representative, countable-choice schedule, trichotomy, host real equality, or ambient Real completeness.

Theorem 7579.2 (Completion modulus lifting NameCert obligations)**.** *For every accepted* CompletionModulusLiftin *carrier $L = (M, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusLifting}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed completion modulus, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows; threshold coverage requiring every precision request to be discharged by M before S is opened; tolerance exactness requiring D before R is read; Real seal ordering requiring E to be downstream of M, S, R, D; and nonescape for quotient streams, selected limits, countable choice, trichotomy, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7579.1. The only available rows are $M, S, R, D, E, H, C, P, N$, so carrier admission exposes exactly the completion modulus, finite windows, rational readback, dyadic tolerance ledger, Real seal, and structural data.

Threshold coverage is the first lifting step. A precision request is read by the completion-modulus row M, and the finite StreamName windows S are opened only at the threshold displayed by that row.

Tolerance exactness and readback are the next step. The DyadicRatCore ledger D records the requested dyadic radius and the threshold comparison before the RegSeqRat row R is read from the opened windows.

Finally the Real seal E is downstream of M, S, R, D. The structural rows H, C, P, N transport, replay, source, and name the same route, and no carrier coordinate stores quotient streams, selected limits, countable-choice schedules, trichotomy, host equality, or ambient completeness. □

Theorem 7579.3 (Completion modulus lifting Real seal handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{CompletionModulusLifting}^{\uparrow}$ *carrier must factor through the displayed route*

$$\mathsf{BishopCompletionModulus}^{\uparrow},\ \mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{C}$$

In particular, the terminal $\mathsf{Real}^{\uparrow}$ *seal is available only after the completion modulus row, finite windows, regular rational readback, dyadic tolerance ledger, componentwise transport, replay, provenance, and local naming rows have been displayed.*

Proof. Start with the NameCert obligations of Definition 7579.2. They force the consumer to read M before S, to read D before R, and to read M, S, R, D before the terminal seal E.

Use the neighbouring Bishop completion-modulus route of chapter 1469 and the threshold-selection surface of chapter 7210. Those routes supply the finite threshold discipline used by M without turning it into a host-selected limit.

The remaining rows are structural. Componentwise hsame transport and displayed Cont replay preserve the same lifting path, while Pkg provenance and the local NameCert row name it for downstream Real and Completion consumers. Since no listed row contains quotient streams, selected limits, countable choice, trichotomy, host equality, or ambient completeness, the Real seal handoff exports none of those objects. □

Falsifiable prediction: An accepted $\mathsf{CompletionModulusLifting}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the completion modulus row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet.

Independence witness: cauchymodulus, streamname, regseqrat, dyadicratcore, real, bishopcompletionmodulus, bishop-completion-modulus-selection: no listed sibling is bijective to $\mathsf{CompletionModulusLifting}^{\uparrow}$ because this packet jointly carries a completion modulus row, finite windows, regular rational readback, dyadic tolerance accounting, terminal Real seal, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusLifting}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionModulusLifting}^{\uparrow}$ packet is generated from a completion modulus row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusLifting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7579.1, Definition 7579.2, and Definition 7579.3 seed the finite completion-modulus lifting route over completion modulus, stream-window, regular-rational, dyadic tolerance, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusLifting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient streams, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, threshold coverage, tolerance exactness, RegSeqRat readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusLiftingUp.

Chapter 7580

A Concrete Naming Certificate for $\mathsf{CauchyRealsCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealsCompletion}^{\uparrow}$ packet records the traditional Cauchy-real completion interface as finite BEDC rows rather than as a quotient carrier or a selected representative. It reads the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the displayed monad-multiplication boundary of chapter 1829. The packet is a finite completion-facing interface for the open Real and Completion phase; it does not assert quotient classes, selected representatives, countable choice, ambient completeness, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7580.1 (Cauchy reals completion carrier)**.** *A* $\mathsf{CauchyRealsCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, Q, D, M, E, J, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the regular Cauchy input.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same scheduled windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by every admitted precision request.*
4. *M is the modulus-readback row that sends each unary precision request to a displayed finite window and dyadic tolerance entry.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after S, Q, D, M have been displayed.*
6. *J is the* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *handoff row used when a completion-of-completion consumer asks to flatten its request before reading the Real-facing seal.*
7. *H records componentwise* hsame *transport for the schedule, readback, tolerance, modulus, seal, join, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

   $$S \longmapsto Q \longmapsto D \longmapsto M \longmapsto E$$

   and of the join route through J when a nested completion request is present.
9. *P is the* Pkg *provenance over* $\mathsf{CauchyRealsCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyRealsCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, Q, D, M, E, J, H, C, P, N$. It has no coordinate for quotient classes, selected representatives, countable choice, host equality, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$*, Lean verification, or bridge checking.*

Theorem 7580.2 (Cauchy reals completion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealsCompletion}^{\uparrow}$ *carrier*

$$R = (S, Q, D, M, E, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyRealsCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, finite-window scheduling through S, regular-rational readback through Q, dyadic tolerance accounting through D, modulus readback through M, Real-seal handoff through E, nested completion flattening through J, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No local obligation is stored in quotient classes, selected representatives, countable-choice schedules, host equality, ambient completeness, or a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 7580.1. The tuple displays exactly the StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, modulus row, Real seal, completion-multiplication handoff, transport, replay, provenance, and local name.

The scheduling, readback, tolerance, and modulus obligations are read from S, Q, D, M. The Real-facing obligation is read from E only after those rows have been displayed.

The nested completion obligation is read through J, so a completion-of-completion consumer must use the same finite route already named by chapter 1829. Transport, replay, provenance, and local naming are exhausted by H, C, P, N.

Since the carrier has no further coordinate, the excluded quotient, representative, choice, host-equality, and completeness objects cannot store a local obligation. □

Theorem 7580.3 (Cauchy reals completion modulus readback)**.** *Let $R = (S, Q, D, M, E, J, H, C, P, N)$ be an accepted* $\mathsf{CauchyRealsCompletion}^{\uparrow}$ *carrier. Every unary precision request is answered by the modulus row M as one displayed finite route through a* $\mathsf{StreamName}^{\uparrow}$ *window in S, a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback in Q, and a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance entry in D before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E is read.*

The readback exports no quotient class, selected representative, countable-choice selector, host equality, ambient completeness datum, or completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start with a precision request at the accepted carrier. The only public request-answering row is M, and it is tied in the carrier to the finite schedule S.

Read the regular rational observation through Q and the corresponding dyadic tolerance entry through D. These rows are the only displayed data that can justify the requested accuracy before the seal row is reached.

The terminal Real-facing read is E. The structural rows H, C, P, N transport, replay, source, and name the same route, while J is used only when a nested completion request must first be flattened.

Thus the precision request is answered by the stated finite route. The excluded quotient, representative, choice, host-equality, and completeness data have no row from which they could be read. □

Theorem 7580.4 (Cauchy reals completion classifier stability)**.** *If two accepted* $\mathsf{CauchyRealsCompletion}^{\uparrow}$ *carriers agree componentwise under displayed* hsame *transport on their* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, modulus-readback row,* $\mathsf{Real}^{\uparrow}$ *seal,* CauchyCompletionMultipli

handoff, replay, provenance, and local naming rows, then they have the same public completion classifier read.

The classifier is stable only over those finite rows and cannot be altered by quotient classes, selected representatives, countable choice, host equality, ambient completeness, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the componentwise transport row H for the two accepted packets. It compares exactly the rows named in Definition 7580.1.

Replay the transported rows through C. The finite schedule, regular readback, dyadic tolerance ledger, modulus answer, Real seal, and nested completion handoff remain on the same displayed route.

The provenance row P and local name N do not add classifier data; they only source and name the accepted route. Since the carrier exposes no quotient, representative, choice, host-equality, or completeness coordinate, no such object can change the classifier read. □

Theorem 7580.5 (Cauchy reals completion Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyRealsCompletion}^{\uparrow}$ *carrier reaches the seal row* E *only after reading the displayed* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, modulus row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. If the consumer begins with a nested completion request, it must first pass through the* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *handoff row* J*.*

The seal is a terminal BEDC row for the displayed route; it is not a proof of ambient completeness and it is not a completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the accepted carrier. The Real-facing seal coordinate is E, and the rows upstream of it are the schedule S, readback Q, tolerance ledger D, and modulus row M.

If the request is nested, the handoff row J supplies the completion-multiplication route before the same Real-facing rows are consumed. This keeps the completion-of-completion case inside the displayed BEDC packet.

Transport, replay, provenance, and local naming are carried by H, C, P, N. These rows preserve and source the same route without adding a host Real-completeness premise.

Therefore every Real-facing consumer reaches E only through the finite surface listed in the statement, and the terminal seal cannot be read as ambient completeness or as completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealsCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRealsCompletion}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a modulus-readback row, a terminal RealUp seal, a CauchyCompletionMultiplication handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRealsCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7580.1, Definition 7580.2, Definition 7580.3, Definition 7580.4, and Definition 7580.5 seed the finite completion-facing interface for regular Cauchy names through StreamName, RegSeqRat, DyadicRatCore, RealUp, CauchyCompletionMultiplication, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRealsCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient classes, selected representatives, countable choice, ambient completeness, completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus readback, classifier stability, Real-seal nonescape, nested completion handoff, and local NameCert registration for BEDC.Derived.CauchyRealsCompletionUp.

Chapter 7581

A Concrete Naming Certificate for $\mathsf{DependentChoiceBoundary}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DependentChoiceBoundary}^{\uparrow}$ packet records the constructive boundary between finite-prefix diagonal selection and dependent-choice assumptions in the Real and Completion corridor. It sits after the countable-choice refusal packet of chapter 1872, the LLPO boundary of chapter 1978, the diagonal regular-Cauchy route of chapter 3782, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite prefix dependency rows; it is not a dependent-choice functional, not a branch selector through all stages, not quotient stream equality, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7581.1 (Dependent-choice boundary carrier)**.** *A* $\mathsf{DependentChoiceBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, L, G, W, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *Q is the inherited* $\mathsf{CountableChoiceBoundary}^{\uparrow}$ *refusal row, keeping countable witness selection outside the carrier.*
2. *L is the* $\mathsf{LLPOBoundary}^{\uparrow}$ *row, recording that binary separation principles are not supplied by the packet.*
3. *G is the* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ *source row for the inspected diagonal family.*
4. *W is the finite prefix-dependency window, listing the already inspected source indices and their dependency edges.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite regular-rational data exposed by W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite prefix window and regular-rational readback are displayed.*
7. *F is the nonescape ledger refusing a dependent-choice chain, a hidden global selector, quotient stream equality, selected limits, and ambient completion.*
8. *H records componentwise* hsame *transport for the displayed rows.*
9. *C records displayed* Cont *replay of the same finite prefix route.*
10. *P is the* Pkg *provenance over* $\mathsf{DependentChoiceBoundary}^{\uparrow}$, $\mathsf{CountableChoiceBoundary}^{\uparrow}$, $\mathsf{LLPOBoundary}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{DependentChoiceBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, L, G, W, R, E, F, H, C, P, N$. It has no coordinate for dependent choice, a global branch selector, quotient stream equality, selected limits, trichotomy, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7581.2 (Dependent-choice boundary finite-prefix nonescape)**.** *Every accepted* DependentChoiceBoundary *carrier exposes its diagonal data through the finite route*

$$\mathsf{CountableChoiceBoundary}^{\uparrow},\quad \mathsf{LLPOBoundary}^{\uparrow},\quad \mathsf{RegularCauchyDiagonalization}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}.$$

Any consumer that asks for an infinite dependent-choice chain, a hidden global selector, quotient stream equality, a selected real limit, or ambient completion must stop at the nonescape ledger F.

Proof. Project the carrier $D = (Q, L, G, W, R, E, F, H, C, P, N)$. The rows Q and L place the request behind the countable-choice and LLPO refusal boundaries before the diagonal source row is read.

Read the finite prefix data next. The diagonal source G supplies only the inspected regular-Cauchy family, while W records the finite dependency window and R reads back the regular rational data visible in that window.

The terminal real-name row E is therefore downstream of finite prefix evidence. The nonescape row F has no field for a dependent-choice chain, a global branch selector, quotient stream equality, selected limits, or ambient completion, and the structural rows H, C, P, N preserve this same finite route. □

Theorem 7581.3 (Dependent-choice boundary Real-completion refusal)**.** *Every Real or Completion consumer reading an accepted* $\mathsf{DependentChoiceBoundary}^{\uparrow}$ *packet must first display the countable-choice boundary row, the LLPO boundary row, the diagonal regular-Cauchy source, the finite prefix-dependency window, the regular rational readback, the terminal real-name seal, and the structural rows H, C, P, N. The consumer may use those rows as a finite diagonal selection certificate, but it receives no dependent-choice assumption and no completed Real object beyond the displayed* $\mathsf{Real}^{\uparrow}$ *seal route.*

Proof. Start from the displayed carrier. The Real-facing consumer reaches $\mathsf{Real}^{\uparrow}$ only through G, W, R, E: the diagonal row gives the source family, the prefix window lists the finite dependencies, the regular-rational row reads the inspected data, and the real seal records the terminal boundary.

Now apply the refusal rows. The inherited $\mathsf{CountableChoiceBoundary}^{\uparrow}$ row blocks countable selection, while the $\mathsf{LLPOBoundary}^{\uparrow}$ row prevents binary separation from being supplied as a hidden principle.

Finally read F, H, C, P, N. These rows refuse dependent choice and replay the same finite packet under transport, continuation, provenance, and local naming. Thus the Real-completion handoff is a finite-prefix route through the cited sibling chapters, not a dependent-choice construction or an ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{DependentChoiceBoundary}^{\uparrow}}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DependentChoiceBoundary}^{\uparrow}}, \mathsf{seed})$
Scope closed: Definition 7581.1, Definition 7581.2, and Definition 7581.3 seed the finite-prefix diagonal boundary over countable-choice refusal, LLPO refusal, regular-Cauchy diagonalization, regular-rational readback, Real sealing, transport, replay, provenance, and local naming.
Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DependentChoiceBoundary}^{\uparrow}}, \mathsf{unformalized})$
Bridge status: none

Not claimed: This chapter does not close dependent choice, countable choice, LLPO, selected limits, quotient stream equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix nonescape, Real-completion refusal, transport, replay, provenance, and local naming for BEDC.Derived.DependentChoiceBoundaryUp.

Constructive story: A DependentChoiceBoundary$^{\uparrow}$ packet is generated from countable-choice and LLPO refusal rows, a regular-Cauchy diagonal source, a finite prefix-dependency window, regular-rational readback, a Real seal row, nonescape ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7582

A Concrete Naming Certificate for RealityConstrainedSelectorBoundary$^{\uparrow}$

The RealityConstrainedSelectorBoundary$^{\uparrow}$ packet realizes the selector-facing boundary of Definition 9413.89 as finite NameCert data. It sits after the finite observation interface of chapter 1007, the model-audit classifier of chapter 1124, the open-fit carrier of chapter 1132, the certified physical truth surface of chapter 1130, the failure-surface packet of chapter 1163, and the final-synthesis ledger of chapter 1178. The packet names a selector boundary only through finite source records, classifiers, physical-fit rows, failure surfaces, and gap ledgers; it is not a final model, a truth oracle, an unbounded observation selector, or a host reality predicate.

Definition 7582.1 (Reality-constrained selector boundary carrier)**.** *A* RealityConstrainedSelectorBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, K, F, O, G, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the source-record row, read through finite observation records and certified trace fragments.*
2. *K is the classifier row, exposing the reality-facing audit classifier and its admissible comparison surface.*
3. *F is the physical-fit row, recording finite agreement with the displayed open-fit and certified-truth surfaces.*
4. *O is the failure-surface row, listing defeats, domain exits, classifier mismatches, and continuation limits.*
5. *G is the gap-ledger row, recording omitted selector supply, hidden-source pressure, failed fit claims, and cannot-claim residues.*
6. *B is the boundary-decision row, admitting a selector read only when A, K, F, O, G are all present in the same packet.*
7. *H records componentwise* hsame *transport for the displayed source, classifier, fit, failure, gap, and boundary rows.*
8. *C records displayed* Cont *replay of the same selector-boundary route.*
9. *P is the* Pkg *provenance over* RealityConstrainedSelectorBoundary$^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert, *and the cited sibling chapters.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $A, K, F, O, G, B, H, C, P, N$. It has no coordinate for final truth, unbounded observation, model–reality identity, a hidden selector, private source access, Lean verification, or bridge checking.

Theorem 7582.2 (Reality-constrained selector boundary NameCert obligations)**.** *For every accepted* $\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ *carrier*

$$S = (A, K, F, O, G, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}}$ *surface consists exactly of source-record admission, classifier exposure, physical-fit exposure, failure-surface exposure, gap-ledger exposure, boundary-decision admission, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the displayed carrier. The source row A, classifier row K, physical-fit row F, failure row O, gap ledger G, and boundary-decision row B are the complete selector-facing data.

Read the structural rows next. Transport through H preserves each displayed component, replay through C keeps the consumer inside the same finite route, provenance through P records the cited sibling surfaces, and N locally names the packet.

No additional coordinate is available. Therefore a selector read that omits a source record, classifier, fit row, failure surface, gap ledger, or boundary decision is a projection of the packet rather than an accepted $\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ carrier. □

Theorem 7582.3 (Reality-constrained selector boundary failure-surface nonescape)**.** *Every accepted selector read through* $\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ *must expose the failure-surface row O and the gap-ledger row G before the boundary-decision row B is consumed. If a consumer reaches a selector conclusion while hiding a defeat, domain exit, classifier mismatch, omitted selector supply, or cannot-claim residue, the read is rejected by the local classifier.*

Proof. Start from $S = (A, K, F, O, G, B, H, C, P, N)$. The boundary-decision row B is defined only over the five displayed source, classifier, fit, failure, and gap rows.

The failure-surface row O records defeats, exits, mismatches, and continuation limits. The gap-ledger row G records omitted supply and cannot-claim residue. Hiding either row changes the displayed selector boundary before B is read.

Finally read H, C, P, N. These rows transport, replay, source, and name the same packet; they do not add hidden evidence or erase listed failures. Hence a selector conclusion is accepted only while O and G remain visible. □

Theorem 7582.4 (Reality-constrained selector boundary sibling separation)**.** *The* $\mathsf{RealityConstrainedSelectorBound}$ *carrier is not bijective to the finite observation interface, reality-constrained model audit, open-fit packet, certified physical truth packet, failure-surface packet, final-synthesis ledger, or model-selection boundary named above. Each sibling supplies one surface, but none alone carries the joint source-record, classifier, physical-fit, failure-surface, gap-ledger, boundary-decision, transport, replay, provenance, and local naming rows of S.*

Proof. Compare the row roles. The finite observation interface supplies source windows, the model audit supplies classifier comparison, the open-fit and certified-truth chapters supply fit and truth-facing rows, the failure-surface chapter supplies defeats, the final-synthesis ledger supplies synthesis accounting, and the model-selection boundary supplies comparative selection discipline.

The selector boundary requires all of these roles at once, together with G and B. The gap-ledger row records selector pressure that none of the sibling packets alone carries, and the boundary-decision row admits or refuses the selector read only after the other rows are jointly displayed.

Thus no listed sibling is bijective to $\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$. Replacing the packet by any one sibling loses at least one of the source, classifier, fit, failure, gap, decision, transport, replay, provenance, or local naming rows. □

Falsifiable prediction: Any accepted selector-boundary read that omits either the failure-surface row O or the gap-ledger row G is rejected before the boundary-decision row B is consumed.

Independence witness: finite-observation-interface, reality-constrained-model-audit, reality-constrained-open-fit, realityconstrainedfailuresurface, model-selection-boundary: none is bijective because RealityConstrainedSel jointly carries source-record, classifier, physical-fit, failure-surface, gap-ledger, boundary-decision, transport, replay, provenance, and local naming rows.

The Lean follow-up must provide explicit $\mathsf{Nontrivial}\ \mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ TasteGate instances in `lean4/BEDC/Derived/RealityConstrain` The nontriviality instance must separate an accepted selector-boundary packet from a packet missing O or G, and the field-faithful instance must preserve $A, K, F, O, G, B, H, C, P, N$ as distinct rows before any checked carrier-alignment theorem can serve as a TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7582.1, Definition 7582.2, Definition 7582.3, Definition 7582.4, the falsifiable prediction, and the independence witness seed the finite selector boundary over source records, classifiers, physical-fit rows, failure surfaces, gap ledgers, boundary decisions, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close final truth, model–reality identity, unbounded observation, hidden selectors, private source access, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-record exposure, classifier exposure, physical-fit exposure, failure-surface nonescape, gap-ledger exactness, boundary-decision admission, transport, replay, provenance, and local naming for BEDC.Derived.RealityConstrainedSelectorBoundaryUp.

Constructive story: A $\mathsf{RealityConstrainedSelectorBoundary}^{\uparrow}$ packet is generated from source-record, classifier, physical-fit, failure-surface, gap-ledger, boundary-decision, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 7583

A Concrete Naming Certificate for $\mathsf{KolmogorovWidth}^{\uparrow}$

Following Kolmogorov and Tikhomirov on n-widths, the $\mathsf{KolmogorovWidth}^{\uparrow}$ packet records finite-dimensional approximation width as displayed NameCert data. It sits after the norm and normed-space rows of chapter 89 and chapter 1950, the compact metric source of chapter 129, the metric comparison row of chapter 57, the vector-space and linear-map rows of chapter 47 and chapter 48, and the terminal real-name boundary of chapter 38. The packet names a finite approximation ledger; it does not import a host infimum, choose an optimal subspace, quotient a normed space, invoke compactness by open covers, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7583.1 (Kolmogorov width carrier)**.** *A* $\mathsf{KolmogorovWidth}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (K, A, E, M, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the source compact family row, read through* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*, and the surrounding* $\mathsf{VecSpace}^{\uparrow}$ *source.*
2. *A is the finite-dimensional approximant packet, displaying the chosen dimension bound, basis-window ledger,* $\mathsf{LinMap}^{\uparrow}$ *projection or inclusion row, and admissible finite subspace data.*
3. *E is the* $\mathsf{Real}^{\uparrow}$ *error-bound row recording the displayed radius by which A approximates every inspected member of K.*
4. *M is the norm or metric comparison row, naming the* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *faces used to read distances from source elements to the finite-dimensional approximant.*
5. *Q is the classifier row, comparing accepted width packets only through $K, A, E, M, L, H, C, P, N$.*
6. *L is the width ledger, recording inspected precision requests, candidate subspace witnesses, failure rows for too-large errors, and the refusal of a host infimum or selected best subspace.*
7. *H stores componentwise* hsame *transport for the compact source, approximant, error-bound, norm or metric, classifier, ledger, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from compact-family inspection through finite-dimensional approximation rows, norm or metric comparison,* $\mathsf{Real}^{\uparrow}$ *error readback, and refusal boundaries.*
9. *P is the* Pkg *provenance over* $\mathsf{KolmogorovWidth}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{KolmogorovWidth}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host-level infimum over all subspaces, an optimal-subspace selector, quotient norm equality, open-cover compactness, countable choice, or ambient Real completeness.

Theorem 7583.2 (Kolmogorov width NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovWidth}^{\uparrow}$ *carrier* $W = (K, A, E, M, Q, L, H, C, P, N)$*, the local NameCert surface consists exactly of compact-family admission, finite-dimensional approximant admission,* $\mathsf{Real}^{\uparrow}$ *error-bound readback, norm or metric comparison, classifier exactness, width-ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every approximation-width consumer must read these rows before treating the packet as a finite-dimensional approximation certificate.*

Proof. Project the carrier of Definition 7583.1. The analytic rows are K, A, E, M, Q, L, while H, C, P, N provide transport, replay, provenance, and local naming.

Read the sibling sources. The compact metric, metric, norm, vector-space, linear-map, and real-name chapters supply the rows named by K, A, E, M; none supplies a hidden optimal subspace or host infimum.

The classifier and ledger rows then bind the approximation claim to the displayed finite data. Since Q compares only the listed coordinates and L records both candidate witnesses and failure boundaries, every accepted consumer remains inside the stated NameCert surface. □

Theorem 7583.3 (Kolmogorov width finite approximation route)**.** *Every finite approximation, compactness, or completion-facing read exported by an accepted* $\mathsf{KolmogorovWidth}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{LinMap}^{\uparrow},\ \mathsf{Norm}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

carried by $K, A, E, M, Q, L, H, C, P, N$*. The read may expose a displayed finite-dimensional approximant and a displayed error ledger, but it cannot export a host infimum, selected optimal subspace, quotient norm equality, open-cover compactness, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the NameCert obligations of Definition 7583.2. They force a consumer to display the compact source, finite-dimensional approximant, norm or metric comparison, real error bound, classifier, ledger, transport, replay, provenance, and local name.

The finite-dimensional row A is the only approximant coordinate. It may name a basis-window ledger and linear-map row, but it is not an optimizer over all subspaces.

The width ledger L records requested precision, candidate witnesses, and failure boundaries. Thus the exported read is a finite approximation route over displayed data, with the excluded host infimum, selected optimum, quotient equality, open-cover compactness, countable choice, and ambient completeness objects absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovWidth}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KolmogorovWidth}^{\uparrow}$ packet is generated from a compact metric source family, finite-dimensional approximant data, a RealUp error bound, norm or metric comparison, classifier, width ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovWidth}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7583.1, Definition 7583.2, and Definition 7583.3 seed the finite-dimensional approximation-width route without a host infimum or selected optimal subspace.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovWidth}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host infimum, optimal-subspace selector, quotient norm equality, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximant admission, error-bound readback, classifier exactness, width-ledger exposure, finite approximation routing, and non-escape for BEDC.Derived.KolmogorovWidthUp.

Chapter 7584

A Concrete Naming Certificate for $\mathsf{FiniteApproximationKernel}^{\uparrow}$

Following standard finite approximation theory and the finite relation-certificate discipline of chapter 9416, the $\mathsf{FiniteApproximationKernel}^{\uparrow}$ packet records source, approximant, classifier, error-ledger, failure-boundary, transport, replay, provenance, and local naming rows as a concrete NameCert surface. It sits beside the Cauchy approximation space of chapter 7574, the Arzela–Ascoli finite-net surface of chapter 7576, the compact metric source of chapter 129, the metric and real readback rows of chapter 57 and chapter 38, and the finite-dimensional width packet of chapter 7583. The packet is a finite relation-certificate kernel for approximation reads; it is not a selected limit, universal approximation theorem, host infimum, quotient equality, open-cover compactness, countable choice, or ambient completeness principle.

Definition 7584.1 (Finite approximation kernel carrier)**.** *A* $\mathsf{FiniteApproximationKernel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, A, K, E, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source row naming the observed domain, admissible requests, compact or Cauchy windows, and relation-certificate source boundary.*
2. *A is the finite approximant row naming candidate approximants, finite-net centers, finite-dimensional windows, or Cauchy approximation rows available to the read.*
3. *K is the classifier row, comparing accepted kernels only through S, A, E, B, H, C, P, N.*
4. *E is the error-ledger row recording displayed* $\mathsf{Real}^{\uparrow}$ *bounds, tolerance budgets, residual rows, and inspected failure thresholds.*
5. *B is the failure-boundary row, naming requests that exceed the displayed approximant, hidden-source attempts, classifier mismatches, missing error ledgers, and over-reads into host completeness.*
6. *H records componentwise* hsame *transport for source, approximant, classifier, error-ledger, failure-boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from source inspection through approximant selection, classifier comparison, error-ledger readback, and failure-boundary refusal.*

8. *P is the* Pkg *provenance over* FiniteApproximationKernel$^{\uparrow}$, CauchyApproximationSpace$^{\uparrow}$, ArzelaAscoliFiniteNet$^{\uparrow}$, KolmogorovWidth$^{\uparrow}$, CompactMetric$^{\uparrow}$, Met$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteApproximationKernel}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected limits, unrestricted approximation theorems, host infima, quotient equality, open-cover compactness, countable choice, or ambient completion.

Theorem 7584.2 (Finite approximation kernel NameCert obligations)**.** *For every accepted* FiniteApproximationKer *carrier $F = (S, A, K, E, B, H, C, P, N)$, the local NameCert surface consists exactly of finite source admission, finite approximant admission, classifier exactness, error-ledger exposure, failure-boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any finite approximation consumer must display these rows before reading the packet as approximation data.*

Proof. Project the carrier of Definition 7584.1. The source and approximant rows are S, A, the comparison and audit rows are K, E, B, and the structural rows are H, C, P, N.

Read the sibling approximation surfaces. The Cauchy approximation, Arzela–Ascoli finite-net, compact metric, metric, real, and Kolmogorov width chapters provide the finite rows that may populate S, A, E.

The classifier and failure boundary prevent relation-certificate language from becoming object identity or host completeness. Hence a consumer receives exactly the finite approximation kernel rows and none of the excluded selected, quotient, compactness, choice, or completeness endpoints. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteApproximationKernel}^{\uparrow}}$.

Constructive story: A FiniteApproximationKernel$^{\uparrow}$ packet is generated from finite source rows, finite approximant rows, classifier exactness, error-ledger rows, failure-boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteApproximationKernel}^{\uparrow}}$, seed)

Scope closed: Definition 7584.1 and Definition 7584.2 seed the finite relation-certificate approximation kernel over source, approximant, classifier, error-ledger, failure-boundary, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteApproximationKernel}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected limits, unrestricted approximation theorems, host infima, quotient equality, open-cover compactness, countable choice, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, error-ledger exposure, failure-boundary exposure, finite approximation consumer routing, and non-escape for BEDC.Derived.FiniteApproximationKernelUp.

Chapter 7585

A Concrete Naming Certificate for $\mathsf{DecidableBar}^{\uparrow}$

Following Brouwer on bars over spreads and Bishop–Bridges on finite binary inspection in constructive analysis, the $\mathsf{DecidableBar}^{\uparrow}$ packet names the finite decidable-bar row used by fan arguments before any real-completion consumer reads it. It sits beside the finite fan surface of chapter 400, the binary prefix carrier of chapter 1475, and the finite observation gateway of chapter 126. The packet records finite prefix windows, decidable bar hits, unary depth ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row. It does not select an infinite branch, assert countable choice, supply open-cover compactness, or close ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7585.1 (Decidable bar carrier)**.** *A* $\mathsf{DecidableBar}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, S, W, R, D, H, T, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *finite binary-prefix row inspected by the bar.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row naming the finite prefix window read by the current consumer.*
3. *W is the finite prefix-window ledger, listing the inspected binary prefixes and their parent-prefix inclusions.*
4. *R is the decidable bar-hit row, recording for each displayed prefix whether the bar predicate has fired inside the finite window.*
5. *D is the unary depth ledger bounding all inspected prefixes and bar-hit checks.*
6. *H records componentwise* hsame *transport for C, S, W, R, D, T, P, N.*
7. *T records displayed* Cont *replay of the finite route*

$$C \longmapsto S \longmapsto W \longmapsto R \longmapsto D.$$

8. *P is the* Pkg *provenance over* $\mathsf{DecidableBar}^{\uparrow}$*,* $\mathsf{CantorSpace}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, S, W, R, D, H, T, P, N$. It has no coordinate for selected infinite branches, countable choice, open-cover compactness, host Cantor-space compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DecidableBarUp.DecidableBarTasteGate single carrier alignment`

Theorem 7585.2 (Decidable bar NameCert obligations)**.** *For every accepted* $\mathsf{DecidableBar}^{\uparrow}$ *carrier*

$$B = (C, S, W, R, D, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed Cantor prefix row, StreamName window row, finite prefix-window ledger, decidable bar-hit row, unary depth ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read these rows as finite bar data, but no obligation is stored outside the displayed packet.*

Lean4 ✓ `BEDC.Derived.DecidableBarUp.DecidableBarCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 7585.1. The accepted tuple exposes exactly the Cantor prefix row, stream observation row, prefix-window ledger, bar-hit row, unary depth ledger, transport row, replay row, provenance row, and local name.

The bar obligations are finite because W, R, D are displayed rows. The window row lists the prefixes under inspection, the hit row gives a decidable answer on that displayed list, and the depth ledger bounds the readback.

The structural rows H, T, P, N preserve that same finite packet. Since the carrier has no further coordinate, the local certificate cannot store a selected infinite branch, a countable-choice schedule, an open-cover compactness witness, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Theorem 7585.3 (Decidable bar stream-window route)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *consumer reading an accepted* $\mathsf{DecidableBar}^{\uparrow}$ *packet must first expose the finite route*

$$\mathsf{CantorSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto W \longmapsto R \longmapsto D.$$

Thus the public bar read is a finite prefix-window computation preserved by BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows, not an infinite branch selection or a host-level choice principle.*

Lean4 ✓ `BEDC.Derived.DecidableBarUp.DecidableBarCarrier stream window route`

Proof. Start with the carrier projection. The stream observation row S is downstream of the Cantor prefix row C, and the prefix-window ledger W is downstream of that displayed stream observation.

The decidable bar-hit row R is read only over the prefixes listed by W. The unary depth ledger D records the bound under which those hits are available, so the route remains finite.

Finally, transport, replay, provenance, and local naming through H, T, P, N preserve the same finite route. They do not add a selector for an infinite binary branch or a countable family of choices. □

Theorem 7585.4 (Decidable bar real-completion boundary)**.** *If a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer cites an accepted* $\mathsf{DecidableBar}^{\uparrow}$ *packet, the citation can use only the finite Cantor prefix row, StreamName window, prefix-window ledger, decidable hit row, unary depth ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}$ *row. The citation cannot be read as selected branch data, countable choice, open-cover compactness, quotient equality of real names, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DecidableBarUp.DecidableBarRealCompletionBoundary`

Proof. Apply Definition 7585.2. It identifies the full public surface of the packet with the finite rows $C, S, W, R, D, H, T, P, N$.

Apply Definition 7585.3. Any real-facing or completion-facing read must pass through the finite StreamName window and the decidable bar-hit ledger before it can cite the packet.

Coordinate exhaustion gives the boundary. No row records a chosen infinite branch, a countable-choice selector, an open-cover compactness proof, quotient equality of real names, or a completeness witness for $\mathsf{Real}^{\uparrow}$. □

Theorem 7585.5 (Decidable bar finite-branch induction)**.** *Every induction over an accepted* $\mathsf{DecidableBar}^{\uparrow}$ *packet is induction over the displayed finite prefix-window ledger* W *and its unary depth ledger* D*. At each stage the consumer exposes only the current Cantor prefix row, StreamName observation row, decidable bar-hit row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row.*

Lean4 ✓ `BEDC.Derived.DecidableBarUp.DecidableBarFiniteBranchInduction`

Proof. Induct on the displayed ledger W. The empty window exposes no hidden branch data; it carries only the structural rows already present in the accepted packet.

For a nonempty window, read the head prefix through C and S, inspect its decidable hit row in R, and retain the unary depth bound in D. The induction hypothesis applies to the remaining displayed prefixes because the carrier stores them in the same finite ledger.

Transport and replay through H and T preserve the component currently under inspection, while P and N preserve provenance and local naming. The induction therefore never leaves the finite BEDC packet and cannot produce a selected infinite branch, countable choice, open-cover compactness, or real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7585.1, Definition 7585.2, Definition 7585.3, Definition 7585.4, and Definition 7585.5 seed the finite decidable-bar carrier, NameCert obligations, StreamName window route, real-completion boundary, and finite-branch induction surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecidableBar}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite branches, countable choice, Brouwer bar induction, open-cover compactness, quotient equality of real names, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix-window coverage, decidable bar-hit readback, unary depth ledger exposure, stream-window routing, finite-branch induction, transport, replay, provenance, and local naming for BEDC.Derived.DecidableBarUp.

Constructive story: A $\mathsf{DecidableBar}^{\uparrow}$ packet is generated from a finite $\mathsf{CantorSpace}^{\uparrow}$ prefix row, a $\mathsf{StreamName}^{\uparrow}$ observation row, a finite prefix-window ledger, a decidable bar-hit row, a unary depth ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7586

A Concrete Naming Certificate for $\mathsf{CauchyPairLocator}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy data, the $\mathsf{CauchyPairLocator}^{\uparrow}$ packet records the finite locator surface for a paired regular Cauchy read before any Real or Completion consumer may treat the pair as separated, equal, or ready for a downstream handoff. It sits after the dyadic core of chapter 291, the finite stream-name surface of chapter 126, the regular rational sequence route of chapter 301, the terminal real-name seal of chapter 38, and the paired-modulus surface of chapter 7130. The packet is a located pair witness over displayed finite rows; it is not quotient equality, a selected representative pair, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7586.1 (Cauchy pair locator carrier)**.** *A* $\mathsf{CauchyPairLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, B, S, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *A is the first* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying the regular rational observations read from the first name.*
2. *B is the second* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying the regular rational observations read from the second name.*
3. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite windows inspected from both names before a locator request is answered.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, displaying the dyadic radius, split tolerance, comparison budget, and endpoint accounting used by the pair read.*
5. *R is the* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ *row, recording the finite pair-modulus budget that synchronizes A and B at the tolerance named by D.*
6. *Q is the locator decision and witness row, storing the displayed comparison branch, its finite witness data, and the exact tolerance at which the branch is read.*
7. *H records componentwise* hsame *transport for $A, B, S, D, R, Q, C, P, N$.*
8. *C records displayed* Cont *replay of the route*

$$S, D \longmapsto A, B \longmapsto R \longmapsto Q.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyPairLocator}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyPairModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyPairLocator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, S, D, R, Q, H, C, P, N$. It has no coordinate for quotient real equality, selected representatives, countable choice, trichotomy, host equality, or ambient Real completeness.

Theorem 7586.2 (Cauchy pair locator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyPairLocator}^{\uparrow}$ *carrier*

$$L = (A, B, S, D, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyPairLocator}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *carrier admission for the two regular readback rows, shared stream windows, dyadic tolerance ledger, pair-modulus row, locator row, transport row, replay row, provenance row, and local naming row;*
2. *two-sided regular readback, requiring A and B to be read from the same displayed windows S and the same dyadic budget D before the pair modulus is consumed;*
3. *dyadic locator exactness, requiring Q to name its comparison branch and witness at the exact tolerance displayed by D and synchronized by R;*
4. *Real seal nonescape, requiring every Real-facing or Completion-facing handoff to keep the two readback rows, window row, tolerance ledger, pair modulus, and locator row visible before any seal is read;*
5. *structural stability through H, C, P, N, requiring componentwise transport, displayed replay, provenance, and local naming to preserve the same finite packet.*

No locator obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7586.1. The accepted packet displays exactly the two regular readback rows, shared StreamName windows, DyadicRatCore tolerance ledger, pair-modulus row, locator row, transport, replay, provenance, and local naming.

The two-sided regular readback is read from A, B, S, D, R. Both regular sequences are inspected through the same finite window and tolerance ledger before the pair modulus row synchronizes them for a locator request.

Dyadic locator exactness is the role of Q. Its branch and witness are tied to the tolerance ledger D and to the synchronized pair-modulus row R, so the locator cannot appeal to an external trichotomy, quotient equality, selected representative, or hidden host comparison.

The Real seal nonescape and structural clauses are carried by H, C, P, N. These rows transport, replay, source, and name the same packet for Real and Completion consumers without adding quotient equality, countable choice, host equality, or ambient completeness. □

Theorem 7586.3 (Cauchy pair locator L10 handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CauchyPairLocator}^{\uparrow}$ *carrier must read the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchyPairModulus}^{\uparrow}$ *row, and the locator row before any equality or separation handoff. The handoff exports only the displayed finite locator packet and its structural rows H, C, P, N; it does not claim quotient equality, selected representatives, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 7586.2. The obligation rows force a consumer to expose A and B as regular readbacks over the shared windows S and dyadic ledger D before the pair-modulus row R and locator row Q can be consumed.

The equality or separation handoff is downstream of Q. Since the locator row records only the displayed comparison branch and finite witness at the named tolerance, it cannot supply quotient equality, a selected representative pair, countable choice, trichotomy, or ambient Real completeness.

The rows H, C, P, N preserve the same route. Componentwise transport, displayed replay, provenance, and local naming do not add a second access path to Real or Completion consumers, so every handoff remains confined to the finite locator packet. □

Falsifiable prediction: An accepted $\mathsf{CauchyPairLocator}^{\uparrow}$ consumer that reaches an equality or separation handoff without displaying both RegSeqRat readback rows, the StreamName windows, the DyadicRatCore tolerance ledger, the RegularCauchyPairModulus row, the locator row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-pair-modulus: no listed sibling is bijective to $\mathsf{CauchyPairLocator}^{\uparrow}$ because this packet jointly carries two regular readbacks, shared finite windows, dyadic tolerance accounting, a pair-modulus synchronizer, a locator decision and witness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyPairLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyPairLocator}^{\uparrow}$ packet is generated from two RegSeqRat readback rows, shared StreamName windows, a DyadicRatCore tolerance ledger, a RegularCauchyPairModulus row, a locator decision and witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyPairLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7586.1, Definition 7586.2, and Definition 7586.3 seed the finite paired regular Cauchy locator route over readback, window, tolerance, pair-modulus, locator, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyPairLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality, selected representatives, countable choice, trichotomy, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-sided regular readback, dyadic locator exactness, Real seal nonescape, structural stability, provenance, and local naming for BEDC.Derived.CauchyPairLocatorUp.

Chapter 7587

A Concrete Naming Certificate for $\mathsf{ConstructiveRealModulus}^{\uparrow}$

Following Bishop and Bridges on constructive real moduli, the $\mathsf{ConstructiveRealModulus}^{\uparrow}$ packet records the finite modulus surface that a Real and Completion consumer reads before treating a regular rational stream as a completed real name. It sits over the dyadic tolerance rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed modulus schedule only; it does not assert quotient stream equality, select a limit, import countable choice, or close ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7587.1 (Constructive real modulus carrier)**.** *A* $\mathsf{ConstructiveRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the inspected source positions.*
2. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic radii requested by the consumer.*
3. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name inside the displayed window.*
4. R *is the modulus-response row, assigning each requested dyadic radius a displayed tail threshold inside* S*.*
5. A *is the visible* $\mathsf{Real}^{\uparrow}$ *seal available only after* S, D, Q, R *have been displayed.*
6. H *records componentwise* hsame *transport for* S, D, Q, R, A, C, P, N*.*
7. C *records displayed* Cont *replay of the route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto R \longmapsto \mathsf{Real}^{\uparrow}.$$

8. P *is the* Pkg *provenance over* $\mathsf{ConstructiveRealModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, D, Q, R, A, H, C, P, N$*. It has no coordinate for quotient equality of real names, a selected limit, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ConstructiveRealModulusUp`

Theorem 7587.2 (Constructive real modulus NameCert obligations)**.** *For every accepted* ConstructiveRealModulus *carrier*

$$M = (S, D, Q, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveRealModulus}^{\uparrow}}$ *surface consists exactly of finite StreamName window exposure, DyadicRatCore tolerance readback, RegSeqRat regular-rational readback, modulus-response threshold exposure, visible Real seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside these displayed rows.*

Proof. Project the carrier of Definition 7587.1. The packet exposes exactly the window, tolerance, readback, response, seal, transport, replay, provenance, and naming rows.

The modulus obligations are finite because S, D, Q, R are displayed rows. The window row lists the inspected positions, the dyadic ledger lists the requested tolerances, the regular-rational readback row supplies the inspected values, and the response row records the threshold used by the consumer.

The structural rows H, C, P, N preserve the same packet. Since the carrier has no further coordinate, the local certificate cannot store quotient equality of real names, a selected limit, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7587.3 (Constructive real modulus Real-completion route)**.** *Every Real and Completion consumer reading an accepted* $\mathsf{ConstructiveRealModulus}^{\uparrow}$ *packet must first expose the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto R \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the packet supplies a displayed modulus window for the completion exit route through chapter 126, chapter 291, chapter 301, and chapter 38; it does not supply Real completeness, quotient equality, selected limits, or countable choice.

Proof. Start with the carrier projection. The consumer first reads the finite source window S, then the dyadic tolerance ledger D, and then the regular rational readback row Q.

The modulus-response row R is available only over the displayed S, D, Q surface. The Real seal A is therefore downstream of a finite modulus response, not a host completion principle.

Finally H, C, P, N transport, replay, source, and name the same finite route. Because the route is exhausted by $S, D, Q, R, A, H, C, P, N$, it cannot export quotient equality of real names, selected limits, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRealModulus}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConstructiveRealModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7587.1, Definition 7587.2, and Definition 7587.3 seed the finite modulus carrier, NameCert obligations, and Real-completion route over StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConstructiveRealModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real names, selected limits, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic tolerance readback, regular-rational readback, modulus-response threshold exposure, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveRealModulusUp.

Constructive story: A $\mathsf{ConstructiveRealModulus}^{\uparrow}$ packet is generated from finite StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, modulus-response thresholds, a visible Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7588

A Concrete Naming Certificate for $\mathsf{BishopIntervalCantor}^{\uparrow}$

Following Bishop and Bridges on nested interval arguments, the $\mathsf{BishopIntervalCantor}^{\uparrow}$ packet records the finite extraction route by which a shrinking nested interval family yields a regular rational name and then a Real-facing seal. It sits beside the dyadic endpoint rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the interval-domain surface of chapter 1543. The packet names the nested-window extraction surface only; it does not assert Heine–Borel compactness, selected limits, quotient Real equality, countable choice, ambient Real completeness, or a host interval theorem.

Definition 7588.1 (Bishop interval Cantor carrier)**.** *A* $\mathsf{BishopIntervalCantor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, N, D, M, R, E, H, C, P, A)$$

with the following displayed rows:

1. *L, U are the lower and upper dyadic endpoint rows, each read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *N is the nested-inclusion ledger, recording that every inspected later window is contained in every earlier displayed interval window.*
3. *D is the diameter-shrink row, giving a dyadic tolerance bound for every inspected precision request.*
4. *M is the located midpoint and refinement ledger, naming the finite midpoint checks and interval-refinement choices already displayed by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *extraction row obtained from the endpoint and midpoint schedules.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after R has displayed the regular rational name.*
7. *H stores componentwise* hsame *transport for endpoint rows, nested inclusion, shrink rows, located midpoint refinements, extraction, Real sealing, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from a precision request through finite endpoint windows, midpoint refinement, regular rational extraction, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalCantor}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{IntervalDomain}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

10. A is the local $\mathsf{NameCert}_{\mathsf{BishopIntervalCantor}^{\uparrow}}$ *row.*
The carrier has no coordinate for Heine–Borel compactness, an arbitrary interval intersection theorem, a selected limit, quotient Real equality, countable choice, or ambient Real completeness.

Theorem 7588.2 (Bishop interval Cantor nested window)**.** *For every accepted* $\mathsf{BishopIntervalCantor}^{\uparrow}$ *carrier* $I = (L, U, N, D, M, R, E, H, C, P, A)$*, every nested-window read factors through the dyadic endpoint rows* L, U*, the nested-inclusion ledger* N*, the diameter-shrink row* D*, the located midpoint and refinement ledger* M*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*,* Pkg *provenance* P*, and local naming* A *before any regular rational extraction can be consumed. The read exports no host interval intersection, selected limit, countable-choice schedule, quotient Real equality, or ambient completeness row.*

Proof. Project the carrier of Definition 7588.1. The endpoint rows are L, U, the nesting and shrink data are N, D, and the located refinement ledger is M.

Read the route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{IntervalDomain}^{\uparrow}$. These rows expose finite endpoint windows and containment evidence, so the consumer receives displayed interval data rather than a host compactness theorem.

The structural rows H, C, P, A keep the read inside the same packet. Since the tuple contains no selected limit, quotient equality, choice schedule, or ambient completeness coordinate, the nested-window read has exactly the displayed finite surface. □

Theorem 7588.3 (Bishop interval Cantor completion handoff)**.** *Every completion-facing read of an accepted* $\mathsf{BishopIntervalCantor}^{\uparrow}$ *carrier reaches* $\mathsf{Real}^{\uparrow}$ *only through the route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

displayed by $L, U, N, D, M, R, E, H, C, P, A$*. The handoff may expose dyadic endpoints, finite windows, midpoint refinement, a regular rational extraction row, Real sealing, transport, replay, provenance, and local naming; it cannot export Heine–Borel compactness, an arbitrary interval-intersection principle, selected limits, quotient Real equality, countable choice, or ambient Real completeness.*

Proof. Use Definition 7588.2. It forces the completion-facing consumer to display endpoint, nesting, shrink, refinement, transport, replay, provenance, and local naming rows before the extraction row is available.

The extraction row R is the only route to a regular rational name. It is read from the same finite StreamName and dyadic endpoint windows, so the Real-facing row E can only seal that regular rational extraction.

Thus the completion handoff is the finite route through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. No excluded compactness, selected-limit, quotient, choice, or ambient-completeness endpoint has a coordinate in the accepted carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalCantor}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopIntervalCantor}^{\uparrow}$ packet is generated from dyadic endpoint rows, nested-inclusion rows, diameter-shrink rows, located midpoint and refinement rows, RegSeqRat extraction, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopIntervalCantor}^{\uparrow}}$, seed)

Scope closed: Definition 7588.1, Definition 7588.2, and Definition 7588.3 seed the nested-interval extraction route for Real-facing completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopIntervalCantor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, arbitrary interval intersection, selected limits, quotient Real equality, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-inclusion stability, shrink-ledger exactness, midpoint-refinement compatibility, RegSeqRat extraction, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalCantorUp.

Chapter 7589

A Concrete Naming Certificate for $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$

The $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$ packet realizes the Mobius-invariant disk branch of chapter 9463 as finite NameCert data. It sits after the disk-coordinate surface of chapter 377, the Poincare disk metric of chapter 6209, the Schwarz–Pick disk-contraction packet of chapter 3682, the hyperbolic cross-ratio packet of chapter 3948, the hyperbolic metric packet of chapter 3474, and the Poincare disk automorphism packet of chapter 6776. The packet records boundary quadruples, disk transport, cross-ratio readback, metric provenance, refusal rows, and local naming; it does not add a completed boundary quotient, an analytic Mobius group action, a selected geodesic representative, global curvature, or ambient complex-field completeness.

Definition 7589.1 (Mobius disk cross-ratio carrier)**.** *A* $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (B, D, T, Q, M, S, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the ordered boundary-quadruple row, naming four inspected boundary slots and their admissibility evidence.*
2. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *disk-coordinate row through which the boundary data is read inside a finite Poincare disk window.*
3. *T is the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *transport row, recording the displayed Mobius disk transport and its inverse-facing ledger.*
4. *Q is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *readback row for the transported quadruple.*
5. *M is the* $\mathsf{PoincareDiskMetric}^{\uparrow}/\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-provenance row.*
6. *S is the* $\mathsf{SchwarzPickDiskContraction}^{\uparrow}$ *nonexpansion guard used by downstream disk maps.*
7. *O is the boundary-refusal row, recording over-reads into completed boundary quotients, selected ideal points, host analytic group actions, and global curvature claims.*
8. *H stores componentwise* hsame *transport for boundary, disk, transport, cross-ratio, metric, contraction, refusal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from boundary quadruple inspection through disk transport, metric provenance, cross-ratio readback, and refusal.*

10. *P is the* Pkg *provenance over* MobiusDiskCrossRatio$^{\uparrow}$, UnitDisk$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, SchwarzPickDiskContractio HyperbolicCrossRatio$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskAutomorphism$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{MobiusDiskCrossRatio}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed boundary quotient, selected ideal representative, ambient analytic Mobius group, global curvature theorem, unrestricted Schwarz–Pick theorem, or complex-field completion.

Theorem 7589.2 (Mobius disk cross-ratio invariance)**.** *For every accepted* MobiusDiskCrossRatio$^{\uparrow}$ *carrier $X = (B, D, T, Q, M, S, O, H, C, P, N)$, an invariance read must display the same boundary quadruple row B, disk-coordinate row D, Poincare automorphism transport row T, cross-ratio readback row Q, metric provenance M, Schwarz–Pick guard S, transport H, replay C, provenance P, and local name N. The read is invariant only as this finite transported packet; it exports no host Mobius group action, quotient boundary equality, selected geodesic representative, global curvature theorem, or ambient analytic completion.*

Proof. Project the carrier of Definition 7589.1. The boundary, disk, transport, readback, metric, and contraction rows are B, D, T, Q, M, S.

Read the Poincare disk automorphism row T through the same displayed disk data D. The cross-ratio row Q is then read after transport, with metric provenance supplied by M and nonexpansion compatibility guarded by S.

The structural rows H, C, P, N preserve the displayed route. Since the carrier contains no host group action, quotient boundary equality, selected geodesic representative, global curvature theorem, or analytic completion coordinate, the invariance claim is exactly the finite transported NameCert surface. □

Theorem 7589.3 (Mobius disk cross-ratio boundary refusal)**.** *Every boundary-facing read of an accepted* MobiusDiskCrossRatio$^{\uparrow}$ *carrier must pass through $B, D, T, Q, M, S, O, H, C, P, N$ before exporting cross-ratio data. The refusal row O blocks completed boundary quotients, selected ideal points, unrestricted analytic Mobius actions, global hyperbolic geometry, and ambient complex-field completeness from being read as rows of the packet.*

Proof. Use Definition 7589.2. It already forces the read through the boundary quadruple, disk-coordinate, transport, cross-ratio, metric, contraction, transport, replay, provenance, and local naming rows.

Now inspect the refusal row O. It is attached to the same packet and names exactly the boundary over-reads that are not represented by $B, D, T, Q, M, S, H, C, P, N$.

Therefore a boundary consumer receives only the finite cross-ratio packet. Completed boundary quotients, selected ideal points, unrestricted analytic actions, global geometry, and ambient complex-field completeness remain outside the accepted NameCert surface. □

Falsifiable prediction: Every accepted MobiusDiskCrossRatio$^{\uparrow}$ read factors through boundary quadruple rows, UnitDisk disk-coordinate rows, PoincareDiskAutomorphism transport, HyperbolicCrossRatio readback, PoincareDiskMetric and HyperbolicMetric provenance, SchwarzPick-DiskContraction guards, boundary refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: poincare-disk-metric, schwarz-pick-disk-contraction, hyperbolic-cross-ratio, hyperbolic-metric, poincare-disk-automorphism: MobiusDiskCrossRatio$^{\uparrow}$ is not bijective to

any listed sibling because it jointly carries boundary quadruple rows, disk transport, cross-ratio readback, metric provenance, contraction guard, boundary refusal, transport, replay, provenance, and local NameCert data.

Future Lean TasteGate obligations for $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$ must certify Nontrivial and FieldFaithful instances at `lean4/BEDC/Derived/MobiusDiskCrossRatioUp/TasteGate.lean`.

Closure status for $\mathsf{NameCert}_{\mathsf{MobiusDiskCrossRatio}^{\uparrow}}$.

Constructive story: A $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$ packet is generated from boundary quadruple rows, UnitDisk disk-coordinate rows, PoincareDiskAutomorphism transport, HyperbolicCrossRatio readback, PoincareDiskMetric and HyperbolicMetric provenance, SchwarzPickDiskContraction guards, boundary refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MobiusDiskCrossRatio}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7589.1, Definition 7589.2, and Definition 7589.3 seed the finite Mobius disk cross-ratio route for the hyperbolic phase geometry vision.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MobiusDiskCrossRatio}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed boundary quotients, selected ideal representatives, unrestricted analytic Mobius actions, global curvature, ambient complex-field completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-quadruple admission, disk transport, cross-ratio readback, metric provenance, contraction guarding, boundary refusal, Nontrivial and FieldFaithful TasteGate obligations, transport, replay, provenance, and local naming for BEDC.Derived.MobiusDiskCrossRatioUp.

Chapter 7590

A Concrete Naming Certificate for $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$

Following Frostman and Falconer's finite-cover formulation, the $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ packet records the finite growth-measure witness that links Hausdorff cover budgets to measure-facing readback without assuming an ambient regular Borel measure. It sits after the finite content row of chapter 3765, the measure-facing ledger of chapter 5808, the gauge corridor of chapter 4119, and the metric and dyadic substrate of chapter 57 and chapter 291. The packet names a displayed finite support, ball-growth budget, cover compatibility row, and terminal finite-measure seal; it is not a completed Hausdorff measure construction, a choice-selected mass distribution, countable regularity theorem, quotient measure equality, or ambient compactness principle.

Definition 7590.1 (Frostman finite-measure carrier)**.** *A* $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, A, S, R, G, U, L, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance observations are sealed through finite* $\mathsf{Real}^{\uparrow}$ *readback.*
2. *A is the inspected source or subset row, exposed only by finite membership probes.*
3. *S is the finite support row listing the displayed support probes on which the witness measure is read.*
4. *R is the rational radius and dyadic tolerance row inherited from* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
5. *G is the Frostman growth-budget row, recording the displayed exponent and coefficient used in each ball estimate.*
6. *U is the finite ball-cover row, pairing each listed ball with the support probes it meets.*
7. *L is the finite-measure ledger row, sealing the displayed masses and total mass through the measure-facing* $\mathsf{Real}^{\uparrow}$ *route.*
8. *E is the cover-growth exactness row, asserting that every admitted ball read uses the same support, radius, growth, and finite-measure ledgers.*
9. *H records componentwise* hsame *transport for source, support, radius, growth, cover, measure, exactness, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a cover request through radius selection, growth comparison, finite-measure readback, exactness, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$, $\mathsf{HausdorffContent}^{\uparrow}$, $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{HausdorffDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FrostmanFiniteMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, S, R, G, U, L, E, H, C, P, N$. It has no coordinate for an ambient regular Borel measure, countable cover schedule, selected minimizing cover, quotient measure equality, host compactness, or completed Hausdorff measure existence theorem.

Theorem 7590.2 (Frostman finite-measure NameCert obligations)**.** *For every accepted* $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ *carrier*

$$F = (M, A, S, R, G, U, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrostmanFiniteMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, inspected subset, finite support probes, radius and dyadic tolerance row, growth-budget row, finite ball-cover row, finite-measure ledger, cover-growth exactness row, componentwise transport, displayed replay, provenance, and local naming. No obligation is stored outside $M, A, S, R, G, U, L, E, H, C, P, N$.*

Proof. Project the carrier of Definition 7590.1. Rows M and A give the metric source and inspected subset, while S lists the only support probes available to the witness.

The cover-growth data are displayed before any measure-facing read. The radius row R, growth row G, and ball-cover row U determine which finite balls are being tested, and L records the finite mass and total-mass readback for the same support probes.

Exactness, transport, and replay add no hidden analytic object. Row E binds the cover and growth comparison to the measure ledger, while H, C, P, N preserve, replay, source, and name that same finite packet.

Because the carrier has no ambient regular Borel measure, countable cover schedule, selected minimizing cover, quotient measure equality, host compactness, or completed Hausdorff measure theorem, those objects cannot become local NameCert obligations. □

Theorem 7590.3 (Frostman finite-measure cover-growth route)**.** *Every Hausdorff-cover consumer of an accepted* $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{HausdorffContent}^{\uparrow}, \mathsf{HausdorffMeasure}^{\uparrow}, \mathsf{HausdorffDimension}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto S, R, G, U, L, E$$

together with H, C, P, N. The route exports a finite growth-measure witness for displayed balls and covers. It does not export a completed Hausdorff measure, exact Hausdorff dimension value, countable regularity theorem, selected mass distribution, quotient measure equality, or ambient compactness principle.

Proof. Read the Hausdorff corridor through the sibling rows first. The content, measure-facing, and dimension packets supply only finite cover budgets, finite measure ledgers, and gauge data, and the metric and dyadic rows determine the displayed balls.

The Frostman witness then lives in S, R, G, U, L, E. The support row S, radius row R, growth row G, ball-cover row U, finite-measure ledger L, and exactness row E jointly state how each displayed ball receives a growth-bounded finite mass read.

Finally H, C, P, N transport, replay, source, and name the same route for downstream consumers. A consumer that asks for completed measure existence, selected mass distributions,

countable regularity, quotient measure equality, or ambient compactness is outside the accepted packet. □

Falsifiable prediction: Every accepted $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ read is refuted if it exports a growth-measure witness without displaying $\mathsf{HausdorffContent}^{\uparrow}$, $\mathsf{HausdorffMeasure}^{\uparrow}$, $\mathsf{HausdorffDimension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, finite support probes, radius and growth budgets, finite ball-cover rows, finite-measure ledger, exactness, componentwise hsame transport, Cont replay, provenance, and local NameCert rows.

Independence witness: hausdorff-content, hausdorff-measure, hausdorff-dimension, metric, dyadicratcore: none is bijective to $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ because this packet alone binds finite support probes, radius budgets, growth estimates, ball-cover rows, finite-measure readback, and exactness into one finite witness surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FrostmanFiniteMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{FrostmanFiniteMeasure}^{\uparrow}$ packet is generated from HausdorffContent, HausdorffMeasure, HausdorffDimension, Metric, DyadicRatCore, finite support probes, radius and growth budgets, finite ball-cover rows, finite-measure ledger, exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrostmanFiniteMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7590.1, Definition 7590.2, and Definition 7590.3 seed the finite growth-measure witness corridor for Hausdorff cover consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrostmanFiniteMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed Hausdorff measure existence, exact Hausdorff dimension values, countable cover schedules, selected mass distributions, quotient measure equality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support admission, radius and growth budget readback, finite ball-cover exposure, finite-measure sealing, exactness, transport, replay, provenance, and local naming for BEDC.Derived.FrostmanFiniteMeasureUp.

Chapter 7591

A Concrete Naming Certificate for $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$ packet records the finite criterion by which displayed Cauchy data becomes completion-facing $\mathsf{Real}^{\uparrow}$ data only after windows, dyadic tolerances, regular rational readback, and an explicit modulus row have all been exposed. It sits after the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a Bishop-style completeness criterion for the L10 Real and Completion route; it is not quotient stream equality, a selected limit, countable choice over tail indices, trichotomy, host real equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7591.1 (Bishop Cauchy completeness criterion carrier)**.** *A* $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, naming every observation window and precision request used by the Cauchy criterion.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording requested dyadic radii, split tolerances, slack cells, and comparison budgets for those windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row obtained from the displayed windows and dyadic tolerances.*
4. *M is the explicit Cauchy modulus row, recording a finite threshold schedule for the criterion before any completion-facing consumer reads R as convergent data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, D, R, M have been displayed.*
6. *H records componentwise* hsame *transport for the window, tolerance, readback, modulus, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S \longmapsto D \longmapsto R \longmapsto M \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $S, D, R, M, E, H, C, P, N$. It has no coordinate for quotienting Cauchy streams, choosing a limiting representative, invoking countable choice, importing trichotomy, using host real equality, or asserting ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7591.2 (Bishop Cauchy completeness criterion obligations)**.** *For every accepted* BishopCauchyCompleten *carrier $K = (S, D, R, M, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission, exposing the StreamName finite windows, DyadicRatCore tolerances, RegSeqRat regular readback, explicit Cauchy modulus, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *criterion-to-modulus exposure, requiring the Cauchy criterion to display M before any downstream consumer treats R as completion-facing data;*
3. *modulus-to-RegSeqRat readback, requiring each read of M to be tied back to the regular rational observations in R and to the finite windows and dyadic tolerances in S, D;*
4. *terminal Real seal nonescape, requiring E to be downstream of S, D, R, M and to export no quotient stream equality, selected limit, countable choice, trichotomy, host equality, or ambient completeness;*
5. *transport, replay, and provenance stability, requiring H, C, P, N to preserve only the displayed criterion route and the local naming row.*

No Bishop Cauchy completeness criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7591.1. The accepted packet displays exactly the window row, dyadic tolerance row, regular readback row, explicit modulus row, terminal seal, and the structural rows.

Criterion-to-modulus exposure is the role of M. A completion-facing read cannot treat the regular rational row as complete before the threshold schedule has been displayed as finite data.

The modulus-to-readback clause ties M back to R and then to S, D. Thus the criterion is read through finite StreamName windows and DyadicRatCore tolerances rather than through an unbounded host sequence predicate.

The terminal seal row E is downstream of the four analytic rows. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, trichotomy, host equality, or ambient completeness, none of those objects can be exported by consuming the seal.

Finally H, C, P, N transport, replay, source, and name the same route. They add no independent completion principle, so the listed rows exhaust the local NameCert surface. □

Theorem 7591.3 (Bishop Cauchy completeness Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto M \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N.$$

The handoff exposes only finite windows, dyadic tolerances, regular rational readback, an explicit Cauchy modulus, componentwise transport, displayed replay, package provenance, and local naming.

Proof. Start with an accepted carrier $K = (S, D, R, M, E, H, C, P, N)$. The only observation rows available to a completion-facing consumer are the StreamName windows S and the DyadicRatCore tolerance ledger D.

The regular readback row R is attached to those rows, and the explicit modulus row M is displayed before the terminal seal can be read. This orders the criterion as finite Cauchy data rather than as quotient equality or a selected limit.

The $\mathsf{Real}^{\uparrow}$ seal row E is reached only after S, D, R, M. The structural rows preserve that route, so every Real or Completion consumer factors through the displayed handoff and receives no ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7591.1, Definition 7591.2, and Definition 7591.3 seed the finite Bishop Cauchy completeness criterion through StreamName windows, DyadicRatCore tolerances, RegSeqRat regular readback, an explicit Cauchy modulus, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-to-modulus exposure, modulus-to-RegSeqRat readback, Real seal nonescape, transport stability, replay stability, and provenance stability for BEDC.Derived.BishopCauchyComple

Constructive story: A $\mathsf{BishopCauchyCompletenessCriterion}^{\uparrow}$ packet is generated from StreamName finite windows, DyadicRatCore tolerances, RegSeqRat regular readback, an explicit Cauchy modulus, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Chapter 7592

A Concrete Naming Certificate for $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$

The $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ packet realizes the fixed-boundary shadow branch of chapter 9463 as finite NameCert data. It sits after the boundary-fixed transport route of chapter 6267, the boundary-shadow carrier of chapter 3813, the metric readback of chapter 3474, the Busemann boundary row of chapter 3732, and the observer-expansion packet of chapter 4167. The packet names a finite shadow window whose boundary far-end is held fixed by displayed transport; it is not an interior-center fixed point, selected ideal endpoint, quotient boundary equality, physical observer motion, or completed hyperbolic compactification.

Definition 7592.1 (Fixed-boundary hyperbolic shadow carrier)**.** *A* $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, B, M, U, V, W, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$ *row preserving the selected boundary commitment along the displayed disk route.*
2. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row naming the finite shadow window attached to that boundary commitment.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row used for disk and shadow distance readback.*
4. *U is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row recording the Busemann-facing far-end comparison.*
5. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *or* $\mathsf{GromovBoundary}^{\uparrow}$ *readback row that exposes the public boundary token.*
6. *W is the fixed-boundary witness row, asserting that the boundary token read by V is preserved by T while the shadow window B is transported.*
7. *E is the refusal and exactness row excluding interior-center fixed points, selected ideal endpoints, quotient boundary equality, physical observer motion, and global compactification.*
8. *H records componentwise* hsame *transport for transport, shadow, metric, Busemann, visual-boundary, witness, refusal, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from boundary transport through shadow readback, metric comparison, Busemann comparison, fixed-boundary witness, refusal, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$, $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, M, U, V, W, E, H, C, P, N$. It has no coordinate for a fixed interior disk center, selected ideal endpoint, quotient boundary equality, physical observer trajectory, completed compactification, or unlogged global hyperbolic model.

Theorem 7592.2 (Fixed-boundary hyperbolic shadow NameCert obligations)**.** *For every accepted* $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ *carrier*

$$S = (T, B, M, U, V, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}}$ *surface consists exactly of boundary-transport admission, boundary-shadow admission, hyperbolic metric readback, Busemann-boundary comparison, public boundary-token readback, fixed-boundary witness, refusal exactness, componentwise transport, displayed replay, provenance, and local naming. No obligation is stored outside $T, B, M, U, V, W, E, H, C, P, N$.*

Proof. Project the carrier of Definition 7592.1. The transport row T and shadow row B give the finite route whose boundary commitment is being tested.

The metric and boundary readback rows are downstream. Rows M, U, V expose the hyperbolic metric comparison, the Busemann-facing far-end comparison, and the public boundary token before any fixedness claim is read.

The fixed-boundary content is exactly row W. It states preservation of the displayed boundary token along the transported shadow window, while E records the refusals needed to keep the reading from becoming an interior-center or quotient-boundary claim.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no fixed interior center, selected ideal endpoint, quotient boundary equality, physical observer trajectory, completed compactification, or unlogged global model, none can become a local NameCert obligation. □

Theorem 7592.3 (Fixed-boundary hyperbolic shadow boundary route)**.** *Every boundary-shadow consumer of an accepted* $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ *carrier factors through*

$$\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}, \mathsf{HyperbolicBoundaryShadow}^{\uparrow}, \mathsf{HyperbolicMetric}^{\uparrow}, \mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto$$

together with H, C, P, N. The route exports only a finite transported shadow whose public boundary token is preserved. It does not export an interior fixed point, selected ideal endpoint, quotient boundary equality, physical observer motion, completed compactification, or host-level boundary object.

Proof. Begin with the boundary-transport and shadow rows. The transport row T records the fixed boundary commitment, and the shadow row B records which finite shadow window is being moved.

Read the metric and Busemann comparisons next. Rows M and U expose the hyperbolic readbacks needed to interpret the shadow as a boundary-facing packet, and V supplies the public boundary token.

The preservation claim is then exactly W, constrained by the refusal row E. The structural rows H, C, P, N keep the exported route attached to the same finite transport, shadow, metric, Busemann, boundary-token, and witness rows.

Thus any consumer bypassing $T, B, M, U, V, W, E, H, C, P, N$ is not reading the accepted fixed-boundary shadow packet. □

Falsifiable prediction: Every accepted $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ read is refuted if it exports fixed-boundary shadow data without displaying $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ or $\mathsf{GromovBoundary}^{\uparrow}$, the fixed-boundary witness, refusal exactness, componentwise hsame transport, Cont replay, provenance, and local NameCert rows.

Independence witness: poincare-disk-boundary-transport, hyperbolic-boundary-shadow, hyperbolic-metric, hyperbolic-busemann-boundary, hyperbolic-observer-expansion: none is bijective to FixedBoundaryHyperbol because this packet alone binds boundary-fixed transport, finite shadow windows, metric comparison, Busemann readback, public boundary-token preservation, refusal exactness, and observer-expansion provenance into one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}}$.

Constructive story: A $\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}$ packet is generated from PoincareDiskBoundaryTransport, HyperbolicBoundaryShadow, HyperbolicMetric, HyperbolicBusemannBoundary, HyperbolicVisualBoundary or GromovBoundary, HyperbolicObserverExpansion, a fixed-boundary witness, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7592.1, Definition 7592.2, and Definition 7592.3 seed the finite fixed-boundary shadow route for hyperbolic observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FixedBoundaryHyperbolicShadow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close interior fixed points, selected ideal endpoints, quotient boundary equality, physical observer motion, completed compactification, host-level boundary objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary transport preservation, shadow admission, metric readback, Busemann comparison, public boundary-token readback, fixed-boundary witness exactness, refusal coverage, transport, replay, provenance, and local naming for BEDC.Derived.FixedBoundaryHyperbolicShadowUp.

Chapter 7593

A Concrete Naming Certificate for $\mathsf{CauchyTailExtraction}^{\uparrow}$

Following the Bishop–Bridges tail-extraction step for regular Cauchy data, the $\mathsf{CauchyTailExtraction}^{\uparrow}$ packet records the displayed witness carrier that turns a tail threshold into the finite windows, dyadic tolerances, and readback rows consumed by Real and Completion-facing routes. It sits after the tail-budget service of chapter 906, the finite stream interface of chapter 126, the regular rational readback route of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the observation cap of chapter 903. The packet is a finite extracted-tail witness surface; it is not quotient stream equality, a selected limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7593.1 (Cauchy tail extraction carrier)**.** *A* $\mathsf{CauchyTailExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, T, O, W, D, Q, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular Cauchy tail is being extracted.*
2. *T is the* $\mathsf{RegularCauchyTailBudget}^{\uparrow}$ *row naming the finite tail threshold and its served request.*
3. *O is the* $\mathsf{ObservationBudgetLimiter}^{\uparrow}$ *row bounding the number of observations used after T is displayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the limiter for the extracted tail.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same window service.*
6. *Q is the extracted-tail witness row, recording the finite tail segment, its endpoint accounting, and the exact tolerance at which it is read back.*
7. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R, T, O, W, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for $R, T, O, W, D, Q, S, C, P, N$.*
9. *C records displayed* Cont *replay of the route*

$$R \longmapsto T \longmapsto O \longmapsto W \longmapsto D \longmapsto Q \longmapsto S.$$

10. *P is the* Pkg *provenance over* $\mathsf{CauchyTailExtraction}^{\uparrow}$, $\mathsf{RegularCauchyTailBudget}^{\uparrow}$, $\mathsf{ObservationBudgetLimiter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailExtraction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, T, O, W, D, Q, S, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected host limits, countable choice, trichotomy, host equality, or ambient Real completeness.

Theorem 7593.2 (Cauchy tail extraction NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailExtraction}^{\uparrow}$ *carrier*

$$E = (R, T, O, W, D, Q, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular source, tail-budget row, observation limiter, finite stream windows, dyadic tolerance ledger, extracted-tail witness, Real seal handoff, componentwise transport, displayed replay, provenance, and local naming.*

Every Real-facing or Completion-facing consumer of the extracted tail must therefore read the finite route

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailBudget}^{\uparrow} \longmapsto \mathsf{ObservationBudgetLimiter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \mapsto$$

through $R, T, O, W, D, Q, S, H, C, P, N$ before treating the tail as sealed. The route exports no quotient stream equality, selected representative, selected host limit, countable choice, trichotomy, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7593.1. The accepted packet displays exactly the regular source row, tail-budget row, observation limiter, finite windows, dyadic ledger, extracted-tail witness, terminal seal, transport, replay, provenance, and local naming.

The extraction part is finite. The row T names the threshold supplied by the regular Cauchy tail budget, O bounds the observations after that threshold is displayed, and W, D, Q record the inspected windows, tolerance ledger, and extracted witness for the same request.

The seal row S is downstream of those fields, while H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for quotient stream equality, selected representatives, selected limits, choice, trichotomy, host equality, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: An accepted $\mathsf{CauchyTailExtraction}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the RegSeqRat source, RegularCauchyTailBudget threshold, ObservationBudgetLimiter cap, StreamName windows, DyadicRatCore tolerance ledger, extracted-tail witness, transport, replay, provenance, and local NameCert rows refutes the packet.

Independence witness: regular-cauchy-tail-budget, streamname, regseqrat, dyadicratcore, real, observationbudgetlimiter: no listed sibling is bijective to $\mathsf{CauchyTailExtraction}^{\uparrow}$ because this packet jointly stores the extracted-tail witness row Q together with the source, threshold, limiter, window, dyadic, seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailExtraction}^{\uparrow}$ packet is generated from a RegSeqRat source row, RegularCauchyTailBudget threshold row, ObservationBudgetLimiter cap, StreamName window service, DyadicRatCore tolerance ledger, extracted-tail witness, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7593.1 and Definition 7593.2 seed the finite Bishop tail-extraction route from regular Cauchy tail budgets to Real-facing seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-budget threshold exposure, observation-limiter exposure, stream-window service, dyadic tolerance readback, extracted-tail witness coverage, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailExtractionUp.

Chapter 7594

A Concrete Naming Certificate for $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$ packet records located nested closed-set completeness over $\mathsf{Real}^{\uparrow}$ as finite BEDC NameCert data. It sits after the located-real comparison surface of **??**, the nested-interval route of chapter 320, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the interval nesting route of chapter 7588, and the metric-completion handoff of chapter 1506. The packet names a shrinking inhabited located closed family and its completion-facing handoff; it is not open-cover compactness, sequential compactness, a selected point principle, quotient real equality, countable choice, or a host closed-set intersection theorem.

Definition 7594.1 (Bishop nested closed-set carrier)**.** *A* $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, I, D, Q, R, A, H, C, P, N)$$

with the following displayed rows:

1. *F is the located closed-set row, listing the inspected* $\mathsf{Real}^{\uparrow}$ *predicates together with located distance or apartness witnesses read through* $\mathsf{LocatedReal}^{\uparrow}$*.*
2. *I is the inhabited witness row, giving for each inspected depth a displayed finite witness row rather than a chosen global point.*
3. *D is the diameter-modulus row, assigning every requested dyadic radius a displayed depth after which the inspected closed-set row has that diameter bound.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the diameter and locatedness reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the nested witness windows and the dyadic diameter schedule.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after F, I, D, Q, R have been displayed.*
7. *H records componentwise* hsame *transport for located closed-set rows, inhabited witnesses, diameter moduli, dyadic tolerances, regular rational readback, Real sealing, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from nested located closed-set inspection through witness windows, diameter-modulus comparison, regular rational readback, and Real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{BishopIntervalCantor}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, I, D, Q, R, A, H, C, P, N$. It has no coordinate for open-cover compactness, sequential compactness, an unbounded choice schedule, quotient equality of real names, a host closed-set intersection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopNestedClosedSetPrincipleUp`

Theorem 7594.2 (Bishop nested closed-set NameCert obligations)**.** *For every accepted* BishopNestedClosedSetPrin *carrier*

$$K = (F, I, D, Q, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}}$ *surface consists exactly of located closed-set admission, inhabited finite witness exposure, diameter-modulus admission, dyadic tolerance readback, regular rational readback, terminal Real seal admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside these displayed rows.*

Proof. Project the carrier of Definition 7594.1. The located closed-set row F, witness row I, diameter-modulus row D, dyadic row Q, readback row R, and seal row A are the only mathematical coordinates.

The locatedness and inhabitedness obligations are finite because the packet records inspected rows rather than a host family of all closed subsets. The witness row gives depthwise evidence, and the diameter row supplies a displayed modulus for the requested precision.

The structural rows H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Since the carrier contains no open-cover compactness, sequential compactness, global choice schedule, quotient equality, host intersection, or ambient completeness coordinate, none can become a local NameCert obligation. □

Theorem 7594.3 (Bishop nested closed-set diameter handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$ *carrier must expose*

$$\mathsf{LocatedReal}^{\uparrow}, \quad \mathsf{NestedInterval}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows $F, I, D, Q, R, A, H, C, P, N$ before it reads diameter-modulus data as a completed Real-facing witness. The handoff may cite chapter 7588 and chapter 1506; it does not claim open-cover compactness, sequential compactness, countable choice, quotient real equality, or host closed-set completeness.

Proof. Start with the located closed-set and witness rows. The consumer reads F and I as finite displayed rows, so the nested family is available only through inspected located data and depthwise inhabitants.

Next read the diameter modulus. The row D is measured by the dyadic tolerance row Q, and therefore any precision request reaches the nested family through $\mathsf{DyadicRatCore}^{\uparrow}$ rather than through a host compactness argument.

The regular rational readback row R is the only route into the terminal $\mathsf{Real}^{\uparrow}$ seal A. The same route is preserved by H, C, P, N, so completion consumers receive a finite diameter handoff compatible with the interval nesting and metric-completion siblings.

No additional coordinate remains from which a selected point, open-cover compactness theorem, sequential compactness theorem, countable-choice schedule, quotient equality, or ambient completeness claim could be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}$ packet is generated from nested located closed Real rows, inhabited witness rows, diameter-modulus rows, DyadicRatCore tolerance rows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7594.1, Definition 7594.2, and Definition 7594.3 seed the finite located nested closed-set route over Real, LocatedReal, NestedInterval, DyadicRatCore, RegSeqRat, MetricCompletion, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopNestedClosedSetPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, selected intersection points, countable choice, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located closed-set exposure, inhabited witness exposure, diameter-modulus exactness, DyadicRatCore tolerance readback, RegSeqRat extraction, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopNestedClosedSetPrincipleUp.

Chapter 7595

A Concrete Naming Certificate for $\mathsf{CartanAngularBoundaryInvariant}^{\uparrow}$

The $\mathsf{CartanAngularBoundaryInvariant}^{\uparrow}$ packet realizes the ordered-boundary-triple branch of chapter 9463 as finite hyperbolic phase data. It sits after the boundary-shadow packet of chapter 3813, the hyperbolic cross-ratio packet of chapter 3948, the Mobius disk cross-ratio packet of chapter 7589, and the complex phase-surface fiber of chapter 6044. The packet records an ordered boundary triple, cross-ratio phase readback, Mobius stability, refusal rows, and provenance; it is not a completed boundary quotient, a selected ideal-triangle object, a host Lie-group invariant, or a global hyperbolic compactification.

Definition 7595.1 (Cartan angular boundary invariant carrier)**.** *A* $\mathsf{CartanAngularBoundaryInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, Q, M, S, \Phi, O, H, C, P, N)$$

with the following displayed rows:

1. *B is the ordered boundary-triple row, naming three oriented boundary slots and their admissibility witnesses.*
2. *Q is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *phase-readback row obtained by inserting the triple into the displayed boundary comparison window.*
3. *M is the* $\mathsf{MobiusDiskCrossRatio}^{\uparrow}$ *transport row, recording the disk-map comparison under which the phase read remains stable.*
4. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row that anchors the triple to visible boundary-shadow data.*
5. *Φ is the* $\mathsf{ComplexPhaseSurfaceFiber}^{\uparrow}$ *readback row through which the angular phase is exposed as a finite surface value.*
6. *O is the refusal row excluding completed boundary quotients, selected ideal triangles, hidden host Mobius actions, global curvature, and unlogged complex-field completion.*
7. *H records componentwise* hsame *transport for boundary triples, cross-ratio phase readback, Mobius transport, boundary shadows, phase-surface fibers, refusal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from ordered boundary triple inspection through cross-ratio readback, Mobius transport, boundary-shadow anchoring, phase readback, refusal, provenance, and local naming.*
9. *P is the* Pkg *provenance over* CartanAngularBoundaryInvariant$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, MobiusDiskCrossRatio$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, ComplexPhaseSurfaceFiber$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{CartanAngularBoundaryInvariant}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, Q, M, S, \Phi, O, H, C, P, N$. It has no coordinate for completed boundary quotients, selected ideal-triangle representatives, a host Mobius group action, global curvature, or ambient complex-field completion.

Lean4 (statement) `BEDC.Derived.CartanAngularBoundaryInvariantUp`

Theorem 7595.2 (Cartan angular boundary invariant NameCert obligations)**.** *For every accepted* CartanAngularBoundaryInvariant$^{\uparrow}$ *carrier*

$$J = (B, Q, M, S, \Phi, O, H, C, P, N),$$

the local NameCert$_{\text{CartanAngularBoundaryInvariant}^{\uparrow}}$ *surface consists exactly of ordered boundary-triple admission, cross-ratio phase readback, Mobius disk cross-ratio transport, boundary-shadow anchoring, complex phase-surface fiber readback, refusal exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside these displayed rows.*

Proof. Project the carrier of Definition 7595.1. The boundary triple, cross-ratio readback, Mobius transport, boundary shadow, phase fiber, and refusal rows are exactly B, Q, M, S, Φ, O.

The invariant is boundary-facing because B is ordered and S anchors it to visible boundary-shadow data. The phase value is not a host angle: it is the finite readback Φ supplied after Q and M are displayed.

The structural rows H, C, P, N preserve the same packet under componentwise transport, replay, provenance, and naming. Since no other coordinate is present, the local certificate cannot store a completed boundary quotient, selected ideal triangle, host Mobius action, global curvature theorem, or ambient complex-field completion. □

Theorem 7595.3 (Cartan angular boundary invariant Mobius stability)**.** *Every Mobius-stability read of an accepted* CartanAngularBoundaryInvariant$^{\uparrow}$ *carrier factors through the displayed route*

$$B \longmapsto Q \longmapsto M \longmapsto S \longmapsto \Phi$$

together with O, H, C, P, N. The future Lean TasteGate *for this packet must include* Nontrivial CartanAngularBoundar *and* FieldFaithful CartanAngularBoundaryInvariant$^{\uparrow}$ *instances preserving the ordered triple, phase readback, Mobius transport, boundary-shadow, and provenance rows.*

Proof. Start from the ordered boundary-triple row B. The cross-ratio row Q reads its phase only after the boundary slots have been displayed.

The Mobius disk cross-ratio row M is then the stability witness. It compares the transported triple without replacing the displayed route by a host Mobius group action or quotient boundary equality.

The boundary-shadow row S and phase-surface row Φ expose the visible boundary and angular readback surfaces. The refusal and structural rows O, H, C, P, N keep this route finite and record the excluded over-reads.

Thus a stable invariant read is exactly the displayed packet. The named TasteGate obligations demand Nontrivial and FieldFaithful evidence for the same finite row separation. □

Falsifiable prediction: Every accepted CartanAngularBoundaryInvariant$^{\uparrow}$ read is refuted if it exports angular boundary-invariant data without displaying ordered boundary triples, HyperbolicCrossRatio$^{\uparrow}$ phase readback, MobiusDiskCrossRatio$^{\uparrow}$ transport, HyperbolicBoundaryShadow$^{\uparrow}$ anchoring, ComplexPhaseSurfaceFibe readback, refusal exactness, componentwise hsame transport, Cont replay, provenance, and local NameCert rows.

Independence witness: hyperbolic-cross-ratio, mobius-disk-cross-ratio, hyperbolic-boundary-shadow, complex-phase-surface-fiber: HyperbolicCrossRatio$^{\uparrow}$ compares boundary data without owning the ordered triple and phase-fiber provenance; MobiusDiskCrossRatio$^{\uparrow}$ supplies transport without the Cartan triple row; HyperbolicBoundaryShadow$^{\uparrow}$ anchors boundary visibility without angular phase readback; ComplexPhaseSurfaceFiber$^{\uparrow}$ reads phase fibers without boundary-triple stability. None is bijective to CartanAngularBoundaryInvariant$^{\uparrow}$.

Closure status for NameCert$_{\text{CartanAngularBoundaryInvariant}^{\uparrow}}$.

Constructive story: A CartanAngularBoundaryInvariant$^{\uparrow}$ packet is generated from ordered boundary-triple rows, HyperbolicCrossRatio phase readback, MobiusDiskCrossRatio transport, HyperbolicBoundaryShadow anchoring, ComplexPhaseSurfaceFiber readback, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CartanAngularBoundaryInvariant}^{\uparrow}}$, seed)

Scope closed: Definition 7595.1, Definition 7595.2, and Definition 7595.3 seed the finite boundary-triple angular invariant route for the hyperbolic phase geometry vision.

Formal verification: FormalStatus(NameCert$_{\text{CartanAngularBoundaryInvariant}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed boundary quotients, selected ideal triangles, host Mobius group actions, global curvature, ambient complex-field completion, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ordered boundary-triple exposure, cross-ratio phase readback, Mobius stability, boundary-shadow anchoring, phase-fiber readback, Nontrivial and FieldFaithful TasteGate instances, refusal coverage, transport, replay, provenance, and local naming for BEDC.Derived.CartanAngularBoundaryInvariantUp.

Chapter 7596

A Concrete Naming Certificate for $\mathsf{FiniteProductCompletion}^{\uparrow}$

Following Bourbaki and Kelley on finite products and completions, the $\mathsf{FiniteProductCompletion}^{\uparrow}$ packet records the finite route by which a displayed finite family of metric or uniform sources is completed componentwise and read back as one product-completion object. It sits after the product naming surface of chapter 34, the metric source of chapter 57, the completeness boundary of chapter 128, the product-uniform route of chapter 4040, the Cauchy product-completion carrier of chapter 3797, and the completion universal property of chapter 397. The packet names only the finite componentwise completion surface; it does not import quotient completion equality, selected representatives, countable products, arbitrary limits, choice, or ambient real completeness.

Definition 7596.1 (Finite product completion carrier)**.** *A* $\mathsf{FiniteProductCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, X, M, U, Q, \Pi, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index packet. It records the finite list of component names and the admissible projection indices, with no coordinate for countable or dependent products.*
2. *X is the product carrier row. It reads the* ***??*** *surface componentwise and exposes only tuples whose entries are named by I.*
3. *M and U are the product metric and product uniformity rows. They record the finite maximum, finite sum, or finite entourage route chosen for the displayed sources, as mediated by* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{ProductUniformSpace}^{\uparrow}$*.*
4. *Q is the component completion row. For each index in I, it records the completion-facing packet, the local completeness certificate, and the componentwise terminal seal.*
5. *Π is the projection readback row. Every component projection out of the completed product first reads I, then X, then the corresponding component of Q.*
6. *L is the universal route row. A map into the completed finite product is accepted only by giving all component maps and their completion-compatible routes before the terminal product read.*
7. *H records componentwise* hsame *transport for the index packet, product carrier, metric or uniformity rows, component completions, projections, and universal route.*

8. *C records displayed* Cont *replay from finite source data through product formation, component completion, projection readback, and universal routing.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteProductCompletion}^{\uparrow}$, *??*, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ProductUniformSpace}^{\uparrow}$, $\mathsf{CauchyProductCompletion}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteProductCompletion}^{\uparrow}}$ *row.*

The accepted carrier contains no coordinate for countable products, quotient completions, selected limits, choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7596.2 (Finite product completion NameCert obligations)**.** *For every accepted* $\mathsf{FiniteProductCompletion}^{\uparrow}$ *carrier $F = (I, X, M, U, Q, \Pi, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteProductCompletion}^{\uparrow}}$ *surface consists exactly of the finite index admission, product carrier admission, product metric or uniformity admission, component completion admission, projection readback coverage, universal route coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows displayed in Definition 7596.1.*

Proof. Project the carrier. The rows $I, X, M, U, Q, \Pi, L, H, C, P, N$ are the only rows available to the local naming surface, so every accepted obligation must be read through this finite inventory.

The index row I and product carrier row X force product formation to be finite and componentwise. The product metric or uniformity rows M, U then supply the only admissible product structure before completion data can be read.

Component completion is confined to Q. Projection reads use Π, and maps into the product use L; both rows refer back to the same finite index packet and component completion rows.

Finally H, C, P, N transport, replay, source, and name exactly this route. Since the carrier has no coordinate for countable products, quotient completions, selected limits, choice, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7596.3 (Finite product completion projection and universal route)**.** *Every projection read or completion-universal-property read exported by an accepted* $\mathsf{FiniteProductCompletion}^{\uparrow}$ *packet factors through the displayed product, completion, and projection rows before the terminal completion seal. More explicitly, the read first consumes the finite index packet I, the product carrier X, the product metric or uniformity rows M, U, and the component completion row Q; it then reaches the projection row Π or universal route row L, and only afterward uses H, C, P, N for transport, replay, provenance, and local naming.*

Proof. Begin with an accepted carrier $F = (I, X, M, U, Q, \Pi, L, H, C, P, N)$. The carrier definition makes I and X prior to every product-facing read, so a consumer cannot inspect a projection or universal route before the finite product data are displayed.

The metric or uniformity rows M, U and the component completion row Q provide the completion-facing surface. Thus a projection read reaches Π only after the component completion row has named the relevant coordinate, and a universal-property read reaches L only after all component routes have been displayed.

The remaining rows preserve the same route. Componentwise hsame transport is recorded in H, replay in C, provenance in P, and local naming in N.

No row supplies countable product formation, quotient completion equality, selected limits or representatives, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence every accepted projection or universal-property read factors through the displayed finite product-completion route before the terminal seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteProductCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteProductCompletion}^{\uparrow}$ packet is generated from a finite index packet, product carrier row, product metric or uniformity rows, component completion rows, projection readback rows, a universal route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteProductCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7596.1, Definition 7596.2, and Definition 7596.3 seed the finite product-completion route used by completion-product consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteProductCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable products, quotient completions, selected limits or representatives, choice, ambient completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode finite index admission, product carrier admission, component completion admission, projection readback coverage, universal route coverage, componentwise transport, replay, provenance, and local naming for BEDC.Derived.FiniteProductCompletionUp.

Chapter 7597

A Concrete Naming Certificate for $\mathsf{FiniteCoverNerve}^{\uparrow}$

Following the classical nerve construction for finite covers, and the Bishop–Bridges finite-net reading of compact metric continuity, the $\mathsf{FiniteCoverNerve}^{\uparrow}$ packet records cover membership, overlap incidence, nerve faces, rational radius folds, and the uniform-modulus handoff as displayed BEDC rows. It realizes the finite cover branch of Definition 9237.5 in chapter 9237 without invoking open-cover compactness or a selected subcover theorem. The packet sits after $\mathsf{CompactMetric}^{\uparrow}$ finite-cover data, $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-modulus rows, $\mathsf{Rat}^{\uparrow}$ radius comparisons, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer.

Definition 7597.1 (Finite cover nerve carrier)**.** *A* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (K, V, O, F, R, B, U, H, C, P, Q)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite cover source row, displaying a finite* $\mathsf{ProbeBundle}$ *of centers and cover-radius histories.*
2. *V is the cover-member row, recording which displayed probe covers which inspected source point.*
3. *O is the overlap-incidence row, recording finite pairwise and higher overlap reads among displayed probes.*
4. *F is the nerve-face row, accepting exactly the finite probe lists whose overlap rows are displayed by O.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *radius and lower-bound comparison row attached to the displayed cover radii.*
6. *B is the rational-fold row that computes a finite positive lower-bound ledger from the accepted face and radius rows.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed after the rational fold.*
8. *H records componentwise* hsame *transport for K, V, O, F, R, B, U and the structural rows.*
9. *C records displayed* Cont *replay through cover membership, overlap incidence, nerve faces, rational folding, and uniform-modulus handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverNerve}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, V, O, F, R, B, U, H, C, P, Q$. It has no coordinate for arbitrary open covers, selected subcovers, quotient equality of covers, trichotomy, countable choice, host set equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteCoverNerveUp.FiniteCoverNerveTasteGate single carrier alignment`

Theorem 7597.2 (Finite cover nerve NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *carrier*

$$N = (K, V, O, F, R, B, U, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverNerve}^{\uparrow}}$ *surface consists exactly of carrier admission, cover-member exposure through K, V, overlap-incidence readback through O, nerve-face admission through F, rational radius comparison through R, finite rational folding through B, uniform-modulus handoff through U, and structural transport, replay, provenance, and local naming through H, C, P, Q.*

Lean4 ✓ `BEDC.Derived.FiniteCoverNerveUp.FiniteCoverNerveCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 7597.1. The accepted packet displays the finite cover source, cover-member row, overlap-incidence row, nerve-face row, rational comparison row, finite fold, uniform-modulus handoff, and structural rows.

Cover membership is exposed through K, V. Every membership read is tied to a displayed probe from the finite $\mathsf{ProbeBundle}$, so the packet has no route to an arbitrary open cover.

Overlap and face obligations are exposed through O, F. A nerve face is admitted only when its finite overlap rows are already displayed, and the carrier has no separate coordinate for host-set intersection equality.

The radius and output obligations are exposed through R, B, U. The rational fold reads only the displayed radius comparisons before the uniform-modulus handoff is consumed. □

Theorem 7597.3 (Finite cover nerve compact-uniform handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *row exported by an accepted* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *packet factors through the finite route*

$$K, V, O, F \longmapsto R, B \longmapsto U, H, C, P, Q.$$

The route first reads compact-metric cover membership and overlap incidence, then accepts finite nerve faces, then folds rational radius data, and only then exposes the uniform-modulus handoff. It exports no open-cover compactness theorem, selected subcover, quotient cover equality, trichotomy, countable choice, host set equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.FiniteCoverNerveUp.FiniteCoverNerveCompactUniformHandoff`

Proof. Start with the carrier rows K, V, O, F. The compact metric source supplies the finite probe list, the member row records coverage reads, the incidence row records finite overlaps, and the face row records exactly the accepted finite nerve faces.

Next read R, B. The rational comparison row exposes radius histories, and the finite fold row records the lower-bound ledger used by the compact-uniform construction.

Finally read U, H, C, P, Q. The uniform-modulus row is downstream of the fold, while transport, replay, provenance, and local naming repack only the same finite cover-nerve data. □

Theorem 7597.4 (Finite cover nerve vision realization)**.** *The finite cover and rational lower-bound construction used in Definition 9237.5 is realized by an accepted* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *carrier as CompactMetric cover-member rows, overlap-incidence rows, nerve-face rows, rational-fold rows, and a UniformModulus handoff. The realization is a concrete finite NameCert packet, not a separate compactness or selection principle.*

Lean4 ✓ `BEDC.Derived.FiniteCoverNerveUp.FiniteCoverNerveVisionRealization`

Proof. Read the vision theorem through chapter 9237. Its finite ProbeBundle and center-radius coverage data are the rows K, V, while the finite overlap checks and accepted faces are the rows O, F.

The rational lower-bound construction is recorded by R, B. The output tolerance-only uniform-modulus ledger is recorded by U, with H, C, P, Q supplying transport, replay, provenance, and local naming.

Thus the vision-side finite cover branch lands as one concrete NameCert carrier. Since the carrier contains no arbitrary open-cover, selected subcover, quotient-cover, choice, trichotomy, host-equality, or completeness coordinate, the realization remains finite. □

Theorem 7597.5 (Finite cover nerve sibling route)**.** *Let*

$$N = (K, V, O, F, R, B, U, H, C, P, Q)$$

be an accepted $\mathsf{FiniteCoverNerve}^{\uparrow}$ *carrier. Any consumer that reads* N *as a compact-uniform or finite-cover dependency must first expose the compact and metric source rows through chapter 60, chapter 129, and chapter 57; the finite cover-radius and lower-bound rows through chapter 452; and the downstream uniform-modulus rows through chapter 369. The route is substantive:* K, V, O, F *supply the compact finite cover and overlap data,* R, B *supply the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold, and* U, H, C, P, Q *supply the uniform-modulus handoff, transport, replay, provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.FiniteCoverNerveUp.FiniteCoverNerveOrphanSiblingRoute`

Proof. Project the carrier rows $K, V, O, F, R, B, U, H, C, P, Q$. The compact and metric source dependency is read from K together with the cover-member and overlap rows V, O, F, so the finite nerve cannot be inspected before the displayed compact finite-cover surface is present.

The rational dependency is read from R, B. These rows record radius comparisons and the finite lower-bound ledger, using the same finite cover rows rather than a separate host Lebesgue-number theorem.

Finally the compact-uniform dependency is read from U, H, C, P, Q. The uniform-modulus handoff is downstream of the cover and rational-fold rows, while transport, replay, provenance, and local naming keep the consumer attached to the same packet. Thus the cited sibling chapters are load-bearing sources of rows, not decorative references. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverNerve}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7597.1, Definition 7597.2, Definition 7597.3, and Definition 7597.4 seed the finite cover-member, overlap-incidence, nerve-face, rational-fold, uniform-modulus, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverNerve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient equality of covers, trichotomy, countable choice, host set equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-member exactness, overlap-incidence exactness, nerve-face admission, rational-fold stability, uniform-modulus handoff, and nonescape proofs for BEDC.Derived.FiniteCoverNerveUp.

Constructive story: A FiniteCoverNerve$^{\uparrow}$ packet is generated from CompactMetric finite-cover rows, cover-member rows, overlap-incidence rows, nerve-face rows, Rat radius comparisons, rational-fold rows, UniformModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7598

A Concrete Naming Certificate for $\mathsf{ContinuityModulusLattice}^{\uparrow}$

Following Bishop and Bridges on compact metric continuity and constructive moduli, the $\mathsf{ContinuityModulusLattice}^{\uparrow}$ packet records the finite order surface on which displayed local moduli can be compared, combined by finite meet, and handed to a uniform-modulus consumer. It sits after the continuous-map rows of chapter 130, the uniform-modulus consumer of chapter 369, the compact metric finite-net source of chapter 129, the metric source rows of chapter 57, and rational tolerance data from chapter 37. The packet names a finite lattice of modulus rows; it is not open-cover compactness, a selected modulus functional, quotient equality of functions, trichotomy, countable choice, or ambient completeness.

Definition 7598.1 (Continuity modulus lattice carrier)**.** *A* $\mathsf{ContinuityModulusLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, D, F, U, R, O, M, J, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *over the same* $\mathsf{Met}^{\uparrow}$ *carrier.*
2. *D is the metric-distance comparison row used to compare source balls and target tolerances.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise modulus histories are being ordered.*
4. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *row that consumes a tolerance-only modulus history.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *tolerance and lower-bound comparison row.*
6. *O is the finite preorder row on displayed modulus histories.*
7. *M is the finite meet row, recording the common lower precision history for finitely many comparable modulus rows.*
8. *J is the join-readback row used only to report compatibility of already displayed modulus histories.*
9. *H records componentwise* hsame *transport for X, D, F, U, R, O, M, J and the structural rows.*
10. *C records displayed* Cont *replay through compact-source, metric, continuous-map, rational, order, meet, and uniform-modulus reads.*
11. *P is the* Pkg *provenance over* $\mathsf{ContinuityModulusLattice}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{ContinuityModulusLattice}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, D, F, U, R, O, M, J, H, C, P, N$. It has no coordinate for open-cover compactness, selected moduli, quotient equality, trichotomy, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7598.2 (Continuity modulus lattice NameCert obligations)**.** *For every accepted* ContinuityModulusLattice *carrier*

$$L = (X, D, F, U, R, O, M, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuityModulusLattice}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-metric source exposure through X, D, continuous-map modulus exposure through F, rational tolerance comparison through R, finite preorder readback through O, finite meet readback through M, compatibility readback through J, uniform-modulus handoff through U, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Carrier admission is projection from Definition 7598.1. The accepted packet displays the compact metric source, metric comparison row, continuous-map row, uniform-modulus consumer row, rational tolerance row, finite order rows, and structural rows.

The order obligations are read through O and R. A comparison between two modulus histories must expose the rational tolerance comparisons used by the preorder row, so the packet cannot replace finite order by an ambient order theorem.

The meet obligations are read through M. The meet row records only a finite common lower precision history for already displayed modulus histories, and J reports compatibility without adding an independent selector.

Finally U, H, C, P, N keep the handoff local. The uniform-modulus consumer receives only the displayed finite meet route, while the structural rows transport, replay, source, and name the same finite data. □

Theorem 7598.3 (Continuity modulus lattice finite-meet stability)**.** *Every finite meet read exported by an accepted* $\mathsf{ContinuityModulusLattice}^{\uparrow}$ *packet remains stable under* hsame *transport of the displayed rows $X, D, F, U, R, O, M, J, H, C, P, N$. A downstream compact-uniform or completion-modulus consumer may cite the meet as a finite order object over continuous-map and rational tolerance rows, but it may not read the meet as open-cover compactness, a selected global modulus, quotient equality, trichotomy, countable choice, host function equality, or ambient completeness.*

Proof. Project the carrier rows. The finite meet row M is stored together with the rational comparison row R, the preorder row O, the compatibility row J, and the structural transport row H.

Transport first acts componentwise on X, D, F, U, R, O, M, J. Since M is not a detached selector, a transported meet read must carry along the same compact-source, metric, continuous-map, rational, order, and compatibility rows.

The replay and provenance rows C, P, N then repack the transported data as the same local NameCert surface. No refused object is introduced by this repacking, so finite-meet stability is exactly stability of the displayed carrier rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuityModulusLattice}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuityModulusLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7598.1, Definition 7598.2, and Definition 7598.3 seed the finite order surface on compact metric, metric, continuous-map, rational tolerance, finite preorder, finite meet, compatibility, uniform-modulus, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{ContinuityModulusLattice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected moduli, quotient equality, trichotomy, countable choice, host function equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite preorder exactness, finite meet stability, compatibility readback, uniform-modulus handoff, and nonescape proofs for BEDC.Derived.ContinuityModulusLatticeUp.

Constructive story: A ContinuityModulusLattice$^{\uparrow}$ packet is generated from compact metric source rows, metric comparison rows, continuous-map modulus rows, uniform-modulus handoff rows, rational tolerance comparisons, finite preorder and meet rows, compatibility readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7599

A Concrete Naming Certificate for $\mathsf{PointedSet}^{\uparrow}$

Following Bourbaki and standard category-theoretic usage of pointed sets, the $\mathsf{PointedSet}^{\uparrow}$ packet names a finite carrier together with a displayed basepoint row. It sits after the finite Boolean tag discipline of chapter 32, the nullable constructor route of chapter 33, the coproduct sibling surface of chapter 35, the product sibling surface of chapter 34, and the finite list observation route of chapter 36. The packet records basepoint admission, option-style absence routing, product and wedge handoff rows, transport, replay, provenance, and local naming; it is not a host pointed type, a selected global element oracle, a quotient of carriers, or a completed algebraic structure.

Definition 7599.1 (Pointed set carrier)**.** *A* $\mathsf{PointedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, b, O, P, W, H, C, Q, N)$$

with the following displayed rows:

1. *X is the finite carrier row, read as BEDC data rather than as a host set.*
2. *b is the distinguished basepoint row, displayed before any pointed consumer may read a map, product, or wedge route.*
3. *O is the* $\mathsf{Option}^{\uparrow}$ *basepoint route, recording whether a consumer reads the distinguished point directly or reads an optional payload after the basepoint boundary is fixed.*
4. *P is the* $\mathsf{Prod}^{\uparrow}$ *handoff row, recording the ordered pair of carrier and basepoint data consumed by product-facing routes.*
5. *W is the wedge handoff row, built from* $\mathsf{Sum}^{\uparrow}$ *and* $\mathsf{Bool}^{\uparrow}$ *branch marks together with the common basepoint row.*
6. *H records componentwise* hsame *transport for carrier, basepoint, option, product, wedge, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each pointed consumer through b, O, P, W, H.*
8. *Q is the* Pkg *provenance over* $\mathsf{PointedSet}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{Option}^{\uparrow}$, $\mathsf{Sum}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PointedSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, b, O, P, W, H, C, Q, N$. It has no coordinate for a host pointed type, global element choice, quotient carrier equality, selected coproduct representative, or ambient algebraic structure.

Theorem 7599.2 (Pointed set NameCert obligations)**.** *For every accepted* $\mathsf{PointedSet}^{\uparrow}$ *carrier* $S = (X, b, O, P, W, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PointedSet}^{\uparrow}}$ *surface consists exactly of carrier admission, basepoint admission, option-basepoint routing, product handoff, wedge handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows of* S*.*

Proof. Project the carrier of Definition 7599.1. The rows X and b expose the finite carrier and distinguished point before any consumer can read pointed structure.

The option, product, and wedge obligations are the rows O, P, W. The option row uses the nullable sibling only after the basepoint row is visible; the product row packages carrier and basepoint data together; the wedge row uses sum and Boolean branch marks while retaining the common basepoint.

The structural rows add no hidden object. Componentwise hsame transport in H, displayed Cont replay in C, provenance in Q, and the local naming row N carry the same finite packet. Since the excluded host pointed type, choice, quotient, selected representative, and ambient algebraic coordinates are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7599.3 (Pointed set option basepoint route)**.** *Every* $\mathsf{Option}^{\uparrow}$ *consumer of an accepted* $\mathsf{PointedSet}^{\uparrow}$ *packet must read the displayed basepoint row* b *before it may distinguish an absent optional value from a present payload. The route passes through* X, b, O, H, C, Q, N *and exports no host default element, selected payload representative, quotient carrier equality, or global choice of basepoint.*

Proof. Start with the carrier projection. The optional route is not a detached nullable object; it is the row O of the displayed packet $S = (X, b, O, P, W, H, C, Q, N)$.

Read the basepoint first. The row b supplies the distinguished point against which the absent optional case is interpreted, while the finite carrier row X supplies the payload boundary for present cases.

Transport and replay preserve that order. The rows H, C, Q, N carry the basepointed option route without adding a host default element, selected representative, quotient equality, or global choice coordinate. □

Theorem 7599.4 (Pointed set product and wedge handoff)**.** *Every product-facing or wedge-facing consumer of an accepted* $\mathsf{PointedSet}^{\uparrow}$ *carrier reads the finite route*

$$X, b \longmapsto P, W \longmapsto H, C, Q, N.$$

The $\mathsf{Prod}^{\uparrow}$ *handoff may package the carrier and basepoint rows together, and the wedge handoff may read* $\mathsf{Sum}^{\uparrow}$ *and* $\mathsf{Bool}^{\uparrow}$ *branch marks, but neither route identifies carriers by quotient equality, chooses a coproduct representative, imports a host pointed type, or exports an ambient algebraic structure.*

Proof. Project S through Definition 7599.1. The product route is the row P, and the wedge route is the row W; both rows are downstream of the carrier row X and the distinguished basepoint row b.

For product consumers, P packages the finite carrier and basepoint data without introducing a new equality principle. For wedge consumers, W uses the $\mathsf{Sum}^{\uparrow}$ branch surface and $\mathsf{Bool}^{\uparrow}$ marks while keeping the same basepoint row visible across the branches.

The rows H, C, Q, N transport, replay, source, and name the same finite handoff. Since no quotient carrier equality, selected coproduct representative, host pointed type, or ambient algebraic structure appears in the packet, neither product nor wedge consumption can export one. □

Closure status for $\mathsf{NameCert}_{\mathsf{PointedSet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PointedSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7599.1, Definition 7599.2, Definition 7599.3, and Definition 7599.4 seed the finite basepoint certificate over Bool, Option, Sum, Prod, List, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PointedSet}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.PointedSetUp`

Bridge status: none

Not claimed: This chapter does not close host pointed types, selected global elements, quotient carrier equality, selected coproduct representatives, ambient algebraic structure, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basepoint admission, option-basepoint routing, product and wedge handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.PointedSetUp.

Constructive story: A $\mathsf{PointedSet}^{\uparrow}$ packet is generated from a finite carrier row, a displayed basepoint row, Option, Prod, Sum, and Bool handoff rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7600

A Concrete Naming Certificate for $\mathsf{FrontdoorCriterion}^{\uparrow}$

Following Pearl's front-door criterion, the $\mathsf{FrontdoorCriterion}^{\uparrow}$ packet records the finite mediation certificate used to identify an intervention-facing query through observed mediator rows. It sits after the intervention-row packet of chapter 1290, the normalized probability surface of chapter 184, and the carried random-variable rows of chapter 185. The packet names the front-door surface as BEDC data; it does not claim full do-calculus, back-door completeness, counterfactual semantics, or probability-space completion.

Definition 7600.1 (Front-door criterion carrier)**.** *A* $\mathsf{FrontdoorCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, M, Y, I, B, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the treatment* $\mathsf{RandomVar}^{\uparrow}$ *row whose intervention-facing value is read by the query.*
2. *M is the mediator* $\mathsf{RandomVar}^{\uparrow}$ *row through which the treatment effect must pass.*
3. *Y is the outcome* $\mathsf{RandomVar}^{\uparrow}$ *row whose response is queried.*
4. *I is the* $\mathsf{CausalIntervention}^{\uparrow}$ *row that names the finite intervention on T.*
5. *B is the observed-blocking ledger, recording that the mediator row blocks every displayed directed treatment-to-outcome path admitted by the packet.*
6. *A is the adjustment ledger, recording the observed rows used to read the treatment-to-mediator and mediator-to-outcome probability factors.*
7. *H records componentwise* hsame *transport for the treatment, mediator, outcome, intervention, blocking, adjustment, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

   $$T, I \longmapsto M \longmapsto Y$$

   together with the blocking and adjustment ledgers.
9. *P is the* Pkg *provenance over* $\mathsf{FrontdoorCriterion}^{\uparrow}$*,* $\mathsf{CausalIntervention}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{RandomVar}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FrontdoorCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host structural causal model, selected counterfactual universe, unbounded graph search, hidden back-door completeness proof, or completed probability space.

Lean4 ✓ `BEDC.Derived.FrontdoorCriterionUp.FrontdoorCriterionTasteGate single carrier alignment`

Theorem 7600.2 (Front-door criterion NameCert obligations)**.** *For every accepted* $\mathsf{FrontdoorCriterion}^{\uparrow}$ *carrier* $F = (T, M, Y, I, B, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrontdoorCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed treatment, mediator, outcome, intervention, observed-blocking, adjustment, transport, replay, provenance, and local naming rows. Any consumer that reads a front-door claim must display the treatment-to-mediator route, the mediator-to-outcome route, the observed blocking ledger, the adjustment ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local name before the claim is public.*

Proof. Project the carrier of Definition 7600.1. Its rows expose $T, M, Y, I, B, A, H, C, P, N$ and no other coordinate.

Read the causal route first. The intervention row I is attached to the treatment row T, the mediator row M is the only displayed handoff between treatment and outcome, and the outcome row Y is consumed only after that handoff is visible.

Read the two ledgers next. The blocking row B records the displayed path-blocking surface, while the adjustment row A records the observed probability-facing rows used by the two front-door factors. These rows are supported by the $\mathsf{ProbSpace}^{\uparrow}$ and $\mathsf{RandomVar}^{\uparrow}$ siblings rather than by a host model.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for full do-calculus, back-door completeness, counterfactual semantics, or probability-space completion, those objects are not local NameCert obligations. □

Theorem 7600.3 (Front-door criterion causal handoff)**.** *Every intervention-facing consumer of an accepted* $\mathsf{FrontdoorCriterion}^{\uparrow}$ *packet reaches its causal query only after reading the finite route*

$$T, I, B, A, H, C, P, N \longmapsto M \longmapsto Y.$$

The handoff is a displayed mediator route from $\mathsf{CausalIntervention}^{\uparrow}$ *through* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{RandomVar}^{\uparrow}$ *rows. It exports no host causal graph, full do-calculus derivation, back-door completeness theorem, selected counterfactual, or completed probability space.*

Proof. Start with the intervention row I and treatment row T. The carrier supplies no intervention-facing conclusion until the blocking ledger B and adjustment ledger A have been inspected with the same transport, replay, provenance, and naming rows.

The mediator row M is then the only displayed bridge to the outcome row Y. Thus the consumer can reach the outcome-facing query only through the finite mediator handoff and not by projecting a hidden causal graph or back-door theorem.

Because the probability-facing rows are cited through $\mathsf{ProbSpace}^{\uparrow}$ and $\mathsf{RandomVar}^{\uparrow}$, the route stays inside existing NameCert siblings. The absence of any counterfactual or probability-completion coordinate gives the claimed nonescape boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrontdoorCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrontdoorCriterion}^{\uparrow}$ packet is generated from treatment, mediator, and outcome random-variable rows; a finite intervention row; observed blocking and adjustment ledgers; componentwise hsame transport; displayed Cont replay; Pkg provenance; and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{FrontdoorCriterion}\uparrow}$, seed)

Scope closed: Definition 7600.1, Definition 7600.2, and Definition 7600.3 seed the finite front-door mediation packet over CausalIntervention, ProbSpace, RandomVar, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{FrontdoorCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full do-calculus, back-door completeness, counterfactual semantics, probability-space completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mediator blocking, adjustment route, causal handoff, transport, replay, provenance, and local naming for BEDC.Derived.FrontdoorCriterionUp.

Chapter 7601

A Concrete Naming Certificate for $\mathsf{BishopRealEqualityModulus}^{\uparrow}$

Following Bishop and Bridges constructive real equality, the $\mathsf{BishopRealEqualityModulus}^{\uparrow}$ packet records the finite equality-modulus route by which two regular real names are compared before a terminal $\mathsf{Real}^{\uparrow}$ consumer reads an equality boundary. It sits between the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It refines the criterion surface of chapter 6461 and the equality packet of chapter 2180 by naming the displayed modulus row that every equality read must traverse.

Definition 7601.1 (Bishop real equality-modulus carrier)**.** *A* $\mathsf{BishopRealEqualityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S_0, S_1, R_0, R_1, D, \mu, E, H, C, P, N)$$

with the following displayed rows:

1. S_0, S_1 *are paired finite* $\mathsf{StreamName}^{\uparrow}$ *windows for the two regular real names being compared.*
2. R_0, R_1 *are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the requested radii, split dyadic budgets, endpoint observations, and comparison cells used by the equality read.*
4. μ *is the displayed equality-modulus row. For every admitted tolerance request* ε *in* D*, the row supplies a finite bound after which the paired readbacks* R_0, R_1 *are compared only inside the displayed dyadic budget.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal handoff, exposed only after* $S_0, S_1, R_0, R_1, D, \mu$ *have been displayed.*
6. H *records componentwise* hsame *transport for the paired windows, readbacks, tolerance ledger, equality modulus, Real seal handoff, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto \mu \longmapsto E.$$

8. P *is the* Pkg *provenance over* $\mathsf{BishopRealEqualityModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyEqualityCriterion}^{\uparrow}$, $\mathsf{CauchyRealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealEqualityModulus}^{\uparrow}}$ *row naming exactly this finite equality-modulus packet.*

The classifier compares accepted packets only through $S_0, S_1, R_0, R_1, D, \mu, E, H, C, P, N$. It has no coordinate for quotient real equality, trichotomy, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7601.2 (Bishop real equality-modulus NameCert obligations)**.** *For every accepted* BishopRealEqualityMo *carrier*

$$M = (S_0, S_1, R_0, R_1, D, \mu, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealEqualityModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the paired StreamName windows, paired RegSeqRat readbacks, DyadicRatCore tolerance ledger, equality-modulus row, Real seal handoff, transport, replay, provenance, and local naming;*
2. *paired finite-window exposure, requiring both names to display the inspected windows before any equality-modulus answer is consumed;*
3. *regular readback exactness, requiring R_0, R_1 to be the only regular rational rows read from the paired windows;*
4. *dyadic tolerance visibility, requiring D to display the requested radii and split budgets before μ answers a comparison request;*
5. *equality-modulus exactness, requiring every admitted equality read to pass through μ before the terminal Real seal handoff E is exposed;*
6. *componentwise* hsame *transport and displayed* Cont *replay through H and C;*
7. Pkg *provenance and local naming through P and N;*
8. *nonescape from quotient real equality, trichotomy, selected limits, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No Bishop real equality-modulus obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7601.1. The accepted tuple displays exactly the paired stream windows, paired regular readbacks, dyadic tolerance ledger, equality modulus, Real seal handoff, transport, replay, provenance, and local naming rows.

The finite-window and readback obligations are read from S_0, S_1, R_0, R_1. A consumer first exposes the inspected coordinates of both names and then reads the regular rational rows obtained from those windows.

The tolerance and equality-modulus obligations are read from D and μ. The dyadic ledger displays the requested radii and split comparison budgets; the equality-modulus row supplies the finite bound that makes the paired readbacks comparable inside that displayed budget.

Finally the structural rows E, H, C, P, N seal, transport, replay, source, and name exactly the same finite route. Since the carrier contains no coordinate for quotient equality, trichotomy, selected limits, countable choice, host equality, or ambient completeness, those principles cannot enter the local NameCert surface. □

Theorem 7601.3 (Bishop real equality-modulus L10 handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing equality read exported by an accepted* $\mathsf{BishopRealEqualityModulus}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{BishopRealEqualityModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

implemented by $S_0, S_1, R_0, R_1, D, \mu, E, H, C, P, N$. The route exports a finite equality-modulus certificate for later Real and Completion consumers; it exports no quotient real equality, trichotomy, selected limit, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real-facing equality read of the packet. Projection exposes the paired finite windows S_0, S_1 and their regular rational readbacks R_0, R_1.

Next read the dyadic tolerance ledger D. It fixes the requested radii, split budgets, and comparison cells before the equality-modulus row can answer the read.

Now consume μ and then E. The modulus row is downstream of the displayed windows, readbacks, and tolerance ledger; the terminal Real seal handoff is downstream of the modulus row. Transport, replay, provenance, and local naming preserve this order through H, C, P, N.

Thus every L10 equality-facing consumer sees the displayed modulus route before any Real seal is available. Because no quotient, trichotomy, selected-limit, choice, host-equality, or ambient-completeness coordinate is present in the carrier, none is exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealEqualityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealEqualityModulus}^{\uparrow}$ packet is generated from paired finite StreamName windows, paired RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a displayed equality-modulus row, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealEqualityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7601.1, Definition 7601.2, and Definition 7601.3 seed the finite equality-modulus route over paired stream windows, regular rational readbacks, dyadic tolerance ledgers, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealEqualityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, trichotomy, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formalization requires carrier admission, paired finite-window exposure, regular readback exactness, dyadic tolerance visibility, equality-modulus exactness, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealEqualityModulusUp.

Chapter 7602

A Concrete Naming Certificate for $\mathsf{RieszBasis}^{\uparrow}$

Following Young, Christensen, and constructive Hilbert-space analysis, the $\mathsf{RieszBasis}^{\uparrow}$ packet records the finite BEDC naming surface for a sequence that is read as stable Hilbert coordinates through displayed lower and upper frame bounds. It sits beside the Hilbert carrier of chapter 91, the vector and norm rows of chapter 47 and **??**, the finite orthonormal comparison row of chapter 4758, and the Cauchy-name surface of chapter 406. The packet names only the displayed coordinate reconstruction route; it does not import host Hilbert equality, a selected infinite series, ambient completeness, countable choice, or an external basis theorem.

Definition 7602.1 (RieszBasis carrier)**.** *A* $\mathsf{RieszBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (H, V, N, I, L, U, Q, \Gamma, T, C, P, Z)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, exposing only the inner-product and Hilbert-facing carrier reads used by the coordinate packet.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row over the same endpoint, recording vector addition, zero, inverse, scalar action, and finite linear-combination windows.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row induced from the Hilbert source, naming norm evaluations and norm-comparison ledgers used by the bound checks.*
4. *I is the sequence-index carrier, a finite visible row for requested index windows, coefficient locations, and truncation schedules.*
5. *L is the lower frame-bound row, carrying a displayed positive rational or real bound and the finite inequality ledgers that witness lower stability on inspected coefficient windows.*
6. *U is the upper frame-bound row, carrying a displayed finite upper bound and the finite inequality ledgers that witness bounded synthesis on the same windows.*
7. *Q is the coordinate reconstruction ledger, recording the inspected partial sums, coefficient reads, residual windows, and Cauchy-name handoff used before a reconstruction consumer may read the vector endpoint.*
8. *Γ is the local classifier, comparing accepted packets only by the shared Hilbert, vector, norm, index, frame-bound, and reconstruction rows.*

9. *T records componentwise* hsame *transport for $H, V, N, I, L, U, Q, \Gamma, C, P, Z$.*
10. *C records displayed* Cont *replay from a coordinate request through the same source, bound, classifier, and reconstruction rows.*
11. *P is the* Pkg *provenance over* $\mathsf{RieszBasis}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *Z is the local* $\mathsf{NameCert}_{\mathsf{RieszBasis}^{\uparrow}}$ *row binding the packet.*

The carrier has no coordinate for a host basis equality, a chosen infinite synthesis series, a quotient of Hilbert vectors, or an ambient completeness proof.

Theorem 7602.2 (RieszBasis NameCert obligations)**.** *For every accepted* $\mathsf{RieszBasis}^{\uparrow}$ *carrier* $R = (H, V, N, I, L, U, Q, \Gamma, T, C, P, Z)$*, the local* $\mathsf{NameCert}_{\mathsf{RieszBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, Hilbert and norm source compatibility, sequence-index exposure, lower frame-bound display, upper frame-bound display, coordinate reconstruction ledger display, classifier stability, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A coordinate consumer may inspect reconstruction only along the displayed route*

$$H, V, N, I, L, U \longrightarrow Q, \Gamma \longrightarrow T, C, P, Z.$$

It receives no host Hilbert equality, no selected infinite series, no quotient vector equality, no countable-choice selector, and no ambient completeness coordinate.

Proof. Carrier admission is projection from Definition 7602.1. The rows H, V, N expose the Hilbert, vector, and norm sources, while I exposes the only index windows on which coefficient reads may be requested.

The frame-bound rows L and U are displayed beside the same index windows. The lower row records finite stability ledgers, and the upper row records finite bounded-synthesis ledgers, so neither bound can be read as an external Hilbert-space theorem.

The reconstruction row Q is accepted only after those source and bound rows are visible. The classifier Γ compares packets by the same displayed rows, and the structural rows T, C, P, Z preserve that route under transport, replay, provenance, and local naming.

Since the carrier contains no host basis equality, selected infinite synthesis series, quotient vector equality, countable-choice selector, or ambient completeness coordinate, the listed rows exhaust the local naming surface. □
