Theorem 7602.3 (RieszBasis frame-coordinate handoff)**.** *Every Hilbert-facing consumer read exported by an accepted* $\mathsf{RieszBasis}^{\uparrow}$ *carrier factors through the displayed* $\mathsf{Hilbert}^{\uparrow}$ *row H, the* $\mathsf{VecSpace}^{\uparrow}$ *row V, the* $\mathsf{Norm}^{\uparrow}$ *row N, the sequence-index carrier I, the lower and upper frame-bound rows L, U, the coordinate reconstruction ledger Q, the local classifier Γ, componentwise* hsame *transport T, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row Z. Thus a coordinate reconstruction reaches the Hilbert source only through finite frame and coefficient ledgers, not through host Hilbert equality, a selected infinite series, quotient vector equality, countable choice, or ambient completeness.*

Proof. Begin with an accepted packet $R = (H, V, N, I, L, U, Q, \Gamma, T, C, P, Z)$. Projection by Definition 7602.1 identifies the Hilbert, vector, norm, sequence-index, frame-bound, reconstruction, classifier, transport, replay, provenance, and naming rows as the whole carrier inventory.

Use Definition 7602.2. It forces every coordinate request to pass first through the displayed source and index rows, then through the lower and upper frame-bound ledgers, and only then through the reconstruction ledger and classifier.

The structural rows keep the same finite route under hsame transport and Cont replay. Because the packet has no coordinate for host Hilbert equality, chosen infinite synthesis, quotient equality, countable choice, or ambient completeness, the Hilbert-facing read cannot leave the displayed frame-coordinate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RieszBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszBasis}^{\uparrow}$ packet is generated from a Hilbert source row, vector and norm source rows, sequence-index windows, lower and upper frame-bound ledgers, a coordinate reconstruction ledger, classifier data, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7602.1, Definition 7602.2, and Definition 7602.3 seed the finite Riesz-basis certificate over $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows for later coordinate reconstruction consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert equality, selected infinite synthesis, quotient vector equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Hilbert and norm source compatibility, sequence-index exposure, lower and upper frame-bound display, coordinate reconstruction, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.RieszBasisUp.

Chapter 7603

A Concrete Naming Certificate for $\mathsf{CousinGaugeCover}^{\uparrow}$

Following Bishop–Bridges constructive integration and the Henstock gauge-cover route, the $\mathsf{CousinGaugeCover}^{\uparrow}$ packet records the finite gauge-cover data that sits between the local gauge rows of chapter 3426, the finite gauge cells of chapter 6708, and the tagged partition handoff of chapter 7044. It keeps the traditional Cousin argument as displayed NameCert data: a gauge assignment is inspected through finitely many tagged cells, each cell has a finite refinement witness, the Cousin cover selection is replayed by Cont, and every exported row remains attached to its Pkg provenance and local naming row. The packet is not an open-cover compactness principle, a hidden subcover selector, a quotient equality of covers, or an ambient real-completeness assertion.

$\mathsf{CousinGaugeCover}^{\uparrow}$ hands its finite gauge-cover rows to the theorem-level subdivision route of chapter 1861 before $\mathsf{GaugeIntegral}^{\uparrow}$ or $\mathsf{FiniteGaugeCover}^{\uparrow}$ consumers inspect tagged subdivisions.

Definition 7603.1 (Cousin gauge-cover carrier)**.** *A* $\mathsf{CousinGaugeCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, T, F, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the gauge-assignment row over the displayed interval or compact interval source.*
2. *T is the finite tagged-cell row; each entry records its tag, cell boundary, and local gauge-admission witness.*
3. *F is the finite-refinement row, recording subdivisions or shrinkages used to make each tagged cell subordinate to D.*
4. *S is the Cousin cover-selection row, read through the finite cover surfaces of* $\mathsf{CousinCover}^{\uparrow}$*,* $\mathsf{CousinFiniteCover}^{\uparrow}$*, and* $\mathsf{FiniteGaugeCover}^{\uparrow}$*.*
5. *H records componentwise* hsame *transport for D, T, F, S and the structural rows.*
6. *C records displayed* Cont *replay from a gauge-cover request through D, T, F, S, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{CousinGaugeCover}^{\uparrow}$*,* $\mathsf{CousinCover}^{\uparrow}$*,* $\mathsf{CousinFiniteCover}^{\uparrow}$*,* $\mathsf{FiniteGaugeCover}^{\uparrow}$*,* $\mathsf{CousinLemma}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CousinGaugeCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through D, T, F, S, H, C, P, N. It contains no coordinate for arbitrary open covers, selected subcovers outside the displayed finite cells, quotient cover equality, countable choice, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CousinGaugeCoverUp.CousinGaugeCoverTasteGate single carrier alignment`

Theorem 7603.2 (Cousin gauge-cover finite refinement)**.** *Let $G = (D, T, F, S, H, C, P, N)$ be an accepted* $\mathsf{CousinGaugeCover}^{\uparrow}$ *carrier. Every finite cover row exported by G factors through the displayed refinement route*

$$D, T \longmapsto F \longmapsto S, H, C, P, N.$$

Thus the cover is assembled from gauge-assigned tagged cells and finite refinement rows before the Cousin selection row is consumed. It exports no open-cover compactness theorem, no selected subcover outside T, F, no quotient equality of covers, no countable choice, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier rows D, T, F, S, H, C, P, N. The gauge row and tagged-cell row expose the only local cover data available to a consumer.

The refinement row F records the finite step that makes the tagged cells subordinate to the gauge assignment. Since F is a displayed row of the same packet, the consumer cannot replace it by an external compactness or subcover principle.

Finally the Cousin selection row S is replayed through H, C, P, N. Transport, replay, provenance, and local naming keep the exported cover attached to the same finite tagged cells, so every accepted cover read follows the displayed route. □

Theorem 7603.3 (Cousin gauge-cover NameCert obligations)**.** *For every accepted* $\mathsf{CousinGaugeCover}^{\uparrow}$ *carrier*

$$G = (D, T, F, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CousinGaugeCover}^{\uparrow}}$ *surface consists exactly of gauge-assignment admission through D, tagged-cell exposure through T, finite-refinement exactness through F, Cousin cover-selection exposure through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No local obligation is discharged by open-cover compactness, hidden subcover choice, quotient cover equality, host interval equality, countable choice, or ambient real completeness.*

Proof. Carrier admission is projection from Definition 7603.1. The accepted packet displays the gauge assignment, tagged cells, finite refinement, Cousin selection, and structural rows.

The cover-facing obligations are exhausted by D, T, F, S. Gauge admission is read from D, the finite cell witnesses are read from T, refinement is read from F, and the Cousin-facing finite cover is read from S.

The structural obligations are exhausted by H, C, P, N. Componentwise transport preserves the displayed rows, replay follows the finite route, provenance names the source packets, and the local NameCert row admits only the listed data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CousinGaugeCover}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CousinGaugeCover}^{\uparrow}$ packet is generated from gauge-assignment rows, finite tagged-cell rows, finite-refinement rows, Cousin cover-selection rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CousinGaugeCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7603.1, Definition 7603.2, and Definition 7603.3 seed the finite Bishop–Bridges and Henstock gauge-cover route over CousinCoverUp, CousinFiniteCoverUp, FiniteGaugeCoverUp, CousinLemmaUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CousinGaugeCover}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers outside the displayed finite cells, quotient cover equality, host interval equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, gauge-assignment exposure, tagged-cell exactness, finite-refinement exactness, Cousin cover-selection exposure, structural replay, provenance exhaustion, and local naming for BEDC.Derived.CousinGaugeCoverUp.

Chapter 7604

A Concrete Naming Certificate for $\mathsf{CompactOscillationModulus}^{\uparrow}$

Following Bishop–Bridges compact metric analysis and the finite-net proof of uniform continuity in chapter 9237, the $\mathsf{CompactOscillationModulus}^{\uparrow}$ packet records compact oscillation control as finite NameCert data. It sits over the compact source of chapter 60, the metric inspection rows of chapter 57, the compact-metric finite-net surface of chapter 129, the finite cover nerve of chapter 7597, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer. The packet names finite compact-net oscillation bounds and the handoff from local oscillation ledgers to a tolerance-only uniform modulus; it is not an external modulus selector, an arbitrary open-cover argument, a host minimum over all points, or an ambient completeness theorem.

Definition 7604.1 (Compact oscillation-modulus carrier)**.** *A* $\mathsf{CompactOscillationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, M, V, L, F, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, carrying finite compact-net coverage data.*
2. *M is the metric observation row used to read source distances and finite ball membership.*
3. *V is the finite cover-nerve row recording the displayed compact-net cover and overlap incidence.*
4. *L is the local oscillation row, assigning to each displayed center a target oscillation bound.*
5. *F is the finite oscillation fold row, computing a compact-net-wide bound from the listed local rows.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *comparison row for the finite radii, tolerances, and oscillation bounds.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exposed only after K, M, V, L, F, R have been displayed.*
8. *H records componentwise* hsame *transport for the compact, metric, cover-nerve, oscillation, fold, rational, handoff, and structural rows.*
9. *C records displayed* Cont *replay from compact-net oscillation requests through $K, M, V, L, F, R, U, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationModulus}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, V, L, F, R, U, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, a host supremum of oscillations, quotient equality of covers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7604.2 (Compact oscillation-modulus NameCert obligations)**.** *For every accepted* CompactOscillationMo *carrier*

$$O = (K, M, V, L, F, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationModulus}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, metric readback through M, finite cover-nerve exposure through V, local oscillation-bound exposure through L, finite oscillation folding through F, rational comparison through R, uniform-modulus handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 7604.1. The accepted packet displays the compact source, metric observations, finite cover nerve, local oscillation rows, finite fold, rational comparisons, uniform-modulus handoff, and structural rows.

The compact and cover obligations are read through K, M, V. These rows expose finite compact-net coverage and overlap incidence, not an arbitrary open-cover compactness theorem.

The oscillation obligations are read through L, F, R. Local oscillation bounds are folded over the displayed finite net and compared by the rational row, so no host supremum or selected global minimum is available.

Finally U, H, C, P, N expose only the downstream handoff and structural replay of the same packet. This exhausts the local NameCert surface. □

Theorem 7604.3 (Compact oscillation-modulus uniform handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationModulus}^{\uparrow}$ *carrier factors through the finite route*

$$K, M, V \longmapsto L, F, R \longmapsto U, H, C, P, N.$$

The route first exposes compact-net and metric cover data, then folds local oscillation bounds over the finite cover-nerve rows, and only then exports the tolerance-only uniform-modulus handoff. It exports no arbitrary open-cover compactness theorem, selected subcover, host oscillation supremum, quotient cover equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with K, M, V. The compact source and metric rows identify the finite compact-net observations, and the finite cover nerve records the cover and overlap rows that control which local oscillation bounds can be compared.

Next read L, F, R. The local oscillation row supplies the displayed bounds, the fold row combines only the finite list, and the rational row records the tolerance and radius comparisons used by the fold.

The handoff row U is downstream of those finite rows. Componentwise transport, replay, provenance, and local naming through H, C, P, N therefore keep every accepted uniform-modulus read inside the same compact oscillation packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationModulus}^{\uparrow}$ packet is generated from compact finite-net rows, metric observation rows, finite cover-nerve rows, local oscillation-bound rows, finite oscillation folds, RatUp comparisons, UniformModulus handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactOscillationModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7604.1, Definition 7604.2, and Definition 7604.3 seed the finite compact-net oscillation route through CompactUp, CompactMetricUp, MetricUp, FiniteCoverNerveUp, OscillationModulusUp, UniformModulusUp, RatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CompactOscillationModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host oscillation suprema, quotient cover equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, cover-nerve exactness, local oscillation-bound exposure, finite fold stability, uniform-modulus handoff, structural replay, provenance exhaustion, and local naming for BEDC.Derived.CompactOscillationModulusUp.

Chapter 7605

A Concrete Naming Certificate for $\mathsf{PietschDomination}^{\uparrow}$

Following Pietsch, the $\mathsf{PietschDomination}^{\uparrow}$ packet records the finite domination surface through which an absolutely summing operator request may be read inside BEDC. It sits over displayed Banach rows of chapter 90, bounded operator and norm rows of chapter 1644 and chapter 3603, finite measure rows of chapter 92, normalized probability rows of chapter 184, and terminal scalar rows of chapter 38. The packet names only the BEDC carrier rows and their NameCert obligation surface; it does not assert Hahn–Banach separation, choice of a representing probability measure, or the full Pietsch domination theorem.

Definition 7605.1 (PietschDomination carrier)**.** *A* $\mathsf{PietschDomination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$(X, Y, T, N, A, M, P, R, H, C, Q, L)$$

with the following displayed rows:

1. *X and Y are source and target* $\mathsf{Banach}^{\uparrow}$ *rows;*
2. *T is a* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row from X to Y;*
3. *N is the associated* $\mathsf{OperatorNorm}^{\uparrow}$ *bound row for T;*
4. *A is a finite absolutely-summing test ledger, listing only displayed finite families of carried source endpoints and their target norm reads;*
5. *M is a* $\mathsf{Measure}^{\uparrow}$ *row exposing the finite event and value windows used by the domination read;*
6. *P is a* $\mathsf{ProbSpace}^{\uparrow}$ *normalization row over the same measure surface;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-bound row through which the domination constant and all endpoint comparisons are read;*
8. *H records componentwise* hsame *transport for the Banach, operator, norm, measure, probability, and Real rows;*
9. *C records displayed* Cont *replay of the finite domination request;*
10. *Q is the* Pkg *provenance over* $\mathsf{PietschDomination}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{PietschDomination}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed coordinates. It has no coordinate for a selected Hahn–Banach functional, an external probability measure chosen by choice, quotient equality of operators, a host domination theorem, or bridge checking.

Theorem 7605.2 (PietschDomination NameCert obligations)**.** *For every accepted* $\mathsf{PietschDomination}^{\uparrow}$ *carrier* $(X, Y, T, N, A, M, P, R, H, C, Q, L)$*, the local* $\mathsf{NameCert}_{\mathsf{PietschDomination}^{\uparrow}}$ *surface consists exactly of carrier admission, Banach endpoint exposure, bounded-operator exposure, operator-norm bound exposure, finite absolutely-summing test-window coverage, measure-window coverage, probability-normalization coverage, Real scalar-bound readback, componentwise transport, displayed replay, provenance, and local naming.*

Every domination read by a consumer must factor through

$$\mathsf{Banach}^{\uparrow},\ \mathsf{BoundedLinearOperator}^{\uparrow},\ \mathsf{OperatorNorm}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \mathsf{ProbSpace}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

The certificate does not export Hahn–Banach separation, countable or dependent choice, a full domination theorem, selected representing measures, quotient operator equality, ambient Banach-space completeness beyond the displayed input rows, or bridge checking data.

Proof. Project the carrier coordinates. The source, target, operator, and norm data are the rows X, Y, T, N, so any operator-facing read is already routed through the existing Banach and bounded-operator packets.

The finite absolutely-summing tests are the entries of A. The measure and probability rows M, P expose only their displayed event, value, and normalization windows, while the scalar endpoint R supplies the Real-facing comparison data.

Transport, replay, provenance, and local naming are exactly H, C, Q, L. Since the carrier has no further field, a consumer cannot recover a selected Hahn–Banach witness, a choice-selected probability measure, a quotient operator equality, or a completed domination theorem from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{PietschDomination}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PietschDomination}^{\uparrow}$ packet is generated from displayed Banach source and target rows, a bounded-operator row, an operator-norm row, finite absolutely-summing test windows, measure and probability rows, a Real scalar-bound row, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PietschDomination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7605.1 and Definition 7605.2 seed the finite domination packet through Banach, bounded-operator, operator-norm, MeasureUp, ProbSpaceUp, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PietschDomination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach separation, choice of a representing probability measure, the full Pietsch domination theorem, quotient operator equality, Lean verification, or bridge checking.

Upgrade path: A stronger grade requires Lean definitions and checked obligations for the displayed finite domination carrier and its NameCert surface.

Chapter 7606

A Concrete Naming Certificate for $\mathsf{RegularRectangularModulus}^{\uparrow}$

Following Pringsheim, Moore–Osgood, and Bishop–Bridges, the $\mathsf{RegularRectangularModulus}^{\uparrow}$ packet records the finite rectangular modulus surface that sits between regular double Cauchy data and the $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ completion handoff. It isolates the window-and-tolerance budget used by chapter 4155 before the diagonal consumer reads a seal. The packet is anchored in the uniform-modulus discipline of chapter 4158, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the completion-facing route of chapter 360, and the terminal real-name surface of chapter 38. It names the rectangular budget as finite BEDC data; it does not assert a host double limit, quotient arrays, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7606.1 (Regular rectangular modulus carrier)**.** *A* $\mathsf{RegularRectangularModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, R, Q, T, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *rectangular-window family, giving the finite row and column windows inspected for each rectangular request.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for those windows, including the dyadic budget assigned to each row-column face.*
3. *R is the row-column* $\mathsf{RegSeqRat}^{\uparrow}$ *modulus row, recording the regular rational bounds obtained from the displayed windows and tolerances.*
4. *Q is the uniform rectangular comparison row inherited from the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *discipline, restricted to the finite rectangle visible in S, D, R.*
5. *T is the diagonal handoff row, available only after the rectangular surface S, D, R, Q has been displayed.*
6. *W is the* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal route, read after the diagonal handoff or by a completion consumer that factors through the same rectangular surface.*
7. *H records componentwise* hsame *transport for the window family, tolerance ledger, row-column modulus, diagonal handoff, seal route, provenance, and local name.*

8. *C records displayed* Cont *replay from a consumer request through S, D, R, Q, T, W and then to the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularRectangularModulus}^{\uparrow}$, $\mathsf{RegularDoubleCauchy}^{\uparrow}$, $\mathsf{RegularCauchyUniformModulu}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRectangularModulus}^{\uparrow}}$ *row.*

No carrier coordinate stores a host double limit, quotient array, selected limiting value, countable-choice schedule, or ambient real-completeness theorem.

Theorem 7606.2 (Regular rectangular modulus obligation surface)**.** *For every accepted* RegularRectangularModulu *carrier $M = (S, D, R, Q, T, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularRectangularModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, rectangular window display, dyadic tolerance accounting, row-column* $\mathsf{RegSeqRat}^{\uparrow}$ *modulus readback, uniform rectangular comparison, diagonal handoff discipline,* $\mathsf{RealCauchyCompletion}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must consume the rectangular surface S, D, R, Q, H, C, P, N before it may read either T or W.*

Proof. Project the accepted carrier. The rows S, D, R, Q display the finite rectangular surface: windows, tolerances, regular rational row-column bounds, and uniform comparison over the inspected rectangle.

The diagonal row T and the completion-facing row W appear after that surface in the packet inventory. Transport through H and replay through C preserve the same displayed rows for any accepted consumer request, while P and N keep the route local to the named packet.

Since the carrier has no coordinate for a host double limit, quotient array, selected limit, countable-choice schedule, or ambient completeness theorem, the listed rows exhaust the local obligation surface. □

Theorem 7606.3 (Regular rectangular modulus handoff factorization)**.** *Every* $\mathsf{RegularDoubleCauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{RegularRectangularModulus}^{\uparrow}$ *carrier factors through the finite route*

$$S, D \longmapsto R, Q \longmapsto T \longmapsto W.$$

The diagonal handoff may refine a request to a cofinal line, but it cannot replace the displayed StreamName windows, DyadicRatCore tolerance ledger, or row-column RegSeqRat modulus surface.

Proof. Begin with the consumer request and read the rectangular rows S and D. These rows fix the inspected StreamName windows and dyadic tolerance entries before any regular rational or real-facing seal is visible.

Apply the row-column modulus row R and the uniform comparison row Q. Together they supply the finite regular rational surface that a regular double Cauchy packet or a RegSeqRat consumer may inspect.

Only then may the route read the diagonal handoff T and the completion seal W. The structural rows H, C, P, N replay and name the same path, so no consumer obtains a bypass through a selected double limit, quotient array, choice schedule, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularRectangularModulus}^{\uparrow}$ read displays StreamName rectangular windows, a DyadicRatCore tolerance ledger, row-column RegSeqRat modulus data,

a uniform comparison row, a diagonal handoff, a RealCauchyCompletion and Real seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any completion-facing consumer reads a terminal seal.

Independence witness: regular-double-cauchy, regular-cauchy-uniform-modulus, streamname, regseqrat, dyadicratcore, realcauchycompletion, real: $\mathsf{RegularRectangularModulus}^{\uparrow}$ is not bijective to any listed sibling because it names the finite rectangular modulus surface itself, separating the row-column budget from both the source double Cauchy carrier and the downstream completion seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRectangularModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularRectangularModulus}^{\uparrow}$ packet is generated from finite StreamName rectangular windows, a DyadicRatCore tolerance ledger, row-column RegSeqRat modulus data, a uniform comparison row, a diagonal handoff, a RealCauchyCompletion and Real seal route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRectangularModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7606.1, Definition 7606.2, and Definition 7606.3 seed the finite rectangular modulus surface between regular double Cauchy data and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularRectangularModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host double limits, quotient arrays, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, rectangular window display, dyadic tolerance accounting, row-column modulus readback, uniform comparison, diagonal handoff, seal routing, and local NameCert surface proofs for BEDC.Derived.RegularRectangularModulusUp.

Chapter 7607

A Concrete Naming Certificate for $\mathsf{EquivalenceRelation}^{\uparrow}$

Following Bourbaki and standard set-theoretic algebra, the $\mathsf{EquivalenceRelation}^{\uparrow}$ packet records the reusable finite classifier-law surface for reflexive, symmetric, and transitive binary rows. It sits beside the membership discipline of chapter 3668, the order-law contrast of chapter 52, the regular Cauchy comparison packet of chapter 1412, the equality-facing setoid boundary of chapter 1820, and the rational source of chapter 37. The packet gives L10 comparison chapters one named BEDC object for classifier laws; it is not a quotient carrier, a representative selector, or a host equality principle.

Definition 7607.1 (Equivalence relation carrier)**.** *An* $\mathsf{EquivalenceRelation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the carried source data on which the classifier row is displayed; it may be a set-like row, a rational-history row, or an L10 comparison source, but it is read only through its own NameCert surface;*
2. *R is the displayed binary classifier row on accepted source observations;*
3. *L stores the reflexive, symmetric, and transitive law witnesses for R on the accepted displayed rows;*
4. *H transports the source, classifier, law, replay, provenance, and local name rows componentwise by* hsame*;*
5. *C replays the same finite classifier-law packet by displayed* Cont *routes;*
6. *P is the* Pkg *provenance over* $\mathsf{EquivalenceRelation}^{\uparrow}$*, the source packet named by S,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*
7. *N is the local* $\mathsf{NameCert}_{\mathsf{EquivalenceRelation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotienting S, selecting canonical representatives, choosing class witnesses, or importing host equality of source objects.

Theorem 7607.2 (Equivalence relation NameCert obligations)**.** *For an accepted* $\mathsf{EquivalenceRelation}^{\uparrow}$ *carrier $E = (S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EquivalenceRelation}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the source, binary classifier, law witnesses, transport, replay, provenance, and local naming rows;*
2. *law-row exactness, requiring L to expose precisely reflexivity, symmetry, and transitivity for R on accepted displayed rows;*
3. *classifier transport, requiring H and C to move the same source, classifier, and law rows without changing their public read;*
4. *non-quotient boundary, excluding quotient carriers, representative selectors, host equality, and selected equivalence classes;*
5. *downstream classifier handoff, allowing comparison packets such as regular Cauchy and rational-history readers to cite S, R, L, H, C, P, N as one finite classifier-law substrate.*

No equivalence-relation NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. The analytic data are exactly the source row S, the displayed binary classifier R, and the law row L.

The law row is read without leaving the carrier. Its three fields state reflexivity, symmetry, and transitivity only for displayed accepted rows, so the public classifier law is not a host relation on an ambient set.

The structural rows H, C, P, N transport, replay, source, and locally name the same classifier-law packet. Since no quotient, selector, class representative, or host equality row occurs in E, the listed five obligations exhaust the local NameCert surface. □

Theorem 7607.3 (Equivalence relation classifier laws)**.** *Every public classifier read of an accepted* $\mathsf{EquivalenceRelation}^{\uparrow}$ *packet exposes exactly the reflexive, symmetric, and transitive laws stored in L for the displayed classifier row R on accepted source rows from S. The exported read may be handed to downstream comparison packets through H, C, P, N, but it exports no quotient carrier, representative selector, selected equivalence class, host equality of source objects, or ambient extensionality principle.*

Proof. Begin with a public classifier read. Carrier admission forces the read to pass through S and then through the displayed binary classifier row R.

Next read the law row L. The only laws available there are reflexivity on each accepted displayed row, symmetry for accepted displayed pairs, and transitivity for accepted displayed triples.

Finally transport the read through H and replay it through C, with provenance and local naming supplied by P and N. These rows preserve the displayed classifier-law packet but do not add a quotient carrier or a representative-selection coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{EquivalenceRelation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquivalenceRelation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7607.1, Definition 7607.2, and Definition 7607.3 seed the finite classifier-law substrate for displayed equivalence rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquivalenceRelation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient carriers, representative selectors, selected equivalence classes, host equality, ambient extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, law-row exactness, classifier transport, non-quotient boundary, and downstream classifier handoff for BEDC.Derived.EquivalenceRelationUp.

Constructive story: An $\mathsf{EquivalenceRelation}^{\uparrow}$ packet is generated from carried source data, a displayed binary classifier row, reflexive/symmetric/transitive law witnesses, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7608

A Concrete Naming Certificate for $\mathsf{CriticalPairResidualStream}^{\uparrow}$

The $\mathsf{CriticalPairResidualStream}^{\uparrow}$ packet realizes the residual-join edge of chapter 9463 as finite MetaCIC-facing NameCert data. It sits beside the parallel-diamond frontier of chapter 4238, the normalization frontier of chapter 892, the same-schema certificate of chapter 1093, and the inter-Hist invariant surface of chapter 656. These siblings supply conditional local-diamond rows, candidate-normalization rows, relation-certificate scope, and history-invariance rows; this packet records a displayed stream of residual critical-pair windows without turning the stream into a global confluence theorem.

Definition 7608.1 (Critical-pair residual stream carrier)**.** *A* $\mathsf{CriticalPairResidualStream}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, N, L, I, R, J, W, E, H, C, P, T)$$

with the following displayed rows:

1. *D is the* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *row supplying the conditional local-diamond frontier.*
2. *N is the* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ *row supplying candidate-normalization and endpoint-readback evidence.*
3. *L is the* $\mathsf{LayeredRelationCert}^{\uparrow}$ *row naming the same-schema comparison used to keep residual windows in one displayed schema.*
4. *I is the* $\mathsf{InterHistInvariant}^{\uparrow}$ *row preserving the residual stream across the inspected Hist boundaries.*
5. *R is the finite residual-window ledger, listing the critical-pair residuals under inspection.*
6. *J is the candidate-join ledger attached to the residual windows of R.*
7. *W is the stream-order row, recording the displayed predecessor relation among residual windows.*
8. *E is the failure row for windows that cannot be routed through the diamond and normalization frontiers.*
9. *H stores componentwise* hsame *transport for $D, N, L, I, R, J, W, E, C, P, T$.*
10. *C stores displayed* Cont *replay of the route from diamond-frontier evidence through normalization, relation scope, inter-Hist invariance, residual windows, and candidate joins.*

11. *P is the* Pkg *provenance over* $\mathsf{CriticalPairResidualStream}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{LayeredRelationCert}^{\uparrow}$, $\mathsf{InterHistInvariant}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *T is the local* $\mathsf{NameCert}_{\mathsf{CriticalPairResidualStream}^{\uparrow}}$ *row.*

The carrier has no coordinate for residual-substitution discharge, subject reduction, premise-free parallel diamond, unrestricted Church–Rosser, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 7608.2 (Critical-pair residual stream NameCert obligations)**.** *For every accepted* CriticalPairResidualStre *carrier*

$$S = (D, N, L, I, R, J, W, E, H, C, P, T),$$

the local $\mathsf{NameCert}_{\mathsf{CriticalPairResidualStream}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed diamond-frontier row, normalization-frontier row, same-schema relation row, inter-Hist invariant row, residual-window ledger, candidate-join ledger, stream-order row, failure row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7608.1. The accepted tuple displays every row used by the residual-stream read: diamond frontier, normalization frontier, relation scope, inter-Hist invariance, residual windows, joins, order, failure, transport, replay, provenance, and name.

The positive residual read is routed through D, N, L, I, R, J, W. A consumer first exposes the conditional diamond frontier and candidate-normalization rows, then reads the same-schema and inter-Hist rows, and only then inspects the finite residual-window and candidate-join ledgers.

The failure row E remains in the same packet. Thus a window that lacks the displayed frontier, normalization, relation, or invariant support is not retyped as a successful residual join.

Finally H, C, P, T only preserve, replay, package, and name the displayed rows. Since the carrier contains no further coordinate, the NameCert surface exports no hidden confluence theorem or quotient-level equality. □

Theorem 7608.3 (Critical-pair residual stream route)**.** *Every public residual-stream read of an accepted* $\mathsf{CriticalPairResidualStream}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow} \longmapsto \mathsf{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto \mathsf{LayeredRelationCert}^{\uparrow} \longmapsto \mathsf{InterHistInvariar}$$

The route may feed a MetaCIC parallel-diamond consumer as displayed candidate-mediated residual data, but it cannot discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient equality of terms, or kernel consistency.

Proof. Start with the carrier projection. The residual-window ledger R is not public until the frontier row D, normalization row N, relation row L, and inter-Hist row I have all been exposed.

The candidate joins in J are read only over the displayed windows of R, and the stream-order row W records only the finite predecessor relation among those windows. Hence the route is a finite stream of inspected residual windows rather than an ambient reduction relation.

Transport and replay through H and C preserve the same displayed route, while P and T preserve provenance and naming. No structural row adds a residual-substitution proof, subject-reduction proof, global confluence theorem, evaluator equality, quotient equality, or kernel endpoint. □

Theorem 7608.4 (Critical-pair residual stream frontier handoff)**.** *Every* MetaCICParallelDiamondFrontier$^{\uparrow}$ *consumer of an accepted* CriticalPairResidualStream$^{\uparrow}$ *packet must first read the rows* D, N, L, I, R, J, W*. The consumer may export only the displayed candidate-mediated residual data carried by the frontier row, normalization row, same-schema relation row, inter-Hist invariant row, residual-window ledger, candidate-join ledger, and stream-order row.*

It cannot discharge residual substitution, subject reduction, unrestricted confluence, evaluator equality, quotient equality, or kernel consistency.

Proof. Project the carrier of Definition 7608.1. The rows D, N, L, I, R, J, W are the only rows that expose a parallel-diamond frontier, normalization frontier, same-schema relation, inter-Hist invariant, residual-window ledger, candidate-join ledger, and stream order.

Apply Definition 7608.2. The local certificate admits exactly those displayed rows together with the failure, transport, replay, provenance, and naming rows, so a frontier consumer cannot read a residual window before the frontier and normalization rows are exposed.

Now use Definition 7608.3. The route factors any public residual-stream read through D, N, L, I, R, J, W and exports only candidate-mediated residual data along that route.

The refusal boundary is preserved because none of the carrier coordinates stores substitution discharge, subject reduction, unrestricted confluence, evaluator equality, quotient equality, or kernel consistency. Thus the AI chapter remains a residual-frontier handoff rather than a hidden MetaCIC metatheorem. □

Falsifiable prediction: If the residual-window ledger R is read without the displayed MetaCICParallelDiamondFron MetaCICNormalizationFrontier$^{\uparrow}$, LayeredRelationCert$^{\uparrow}$, and InterHistInvariant$^{\uparrow}$ rows, the packet must route the request to the failure row E rather than to a residual-stream certificate.

Independence witness: metacicparallel, metacicnormalization, layeredrelationcert, interhistinvariant: MetaCICParallelDiamondFrontier$^{\uparrow}$ supplies conditional local-diamond rows without the residual stream ledger; MetaCICNormalizationFrontier$^{\uparrow}$ supplies candidate-normalization rows without the critical-pair stream order; LayeredRelationCert$^{\uparrow}$ supplies same-schema relation scope without residual joins; InterHistInvariant$^{\uparrow}$ supplies history-invariance rows without the diamond and normalization handoff. None is bijective to CriticalPairResidualStream$^{\uparrow}$ under NameCert-row preservation.

Lean follow-up requires Nontrivial CriticalPairResidualStream$^{\uparrow}$ and FieldFaithful CriticalPairResidualStream$^{\uparrow}$ TasteGate instances before the packet can be checked as a single-carrier handoff. Those instances must preserve exactly the rows $D, N, L, I, R, J, W, E, H, C, P, T$.

Closure status for NameCert$_{\text{CriticalPairResidualStream}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{CriticalPairResidualStream}^{\uparrow}}$, seed)

Scope closed: Definition 7608.1, Definition 7608.2, Definition 7608.3, the falsifiable prediction, and the independence witness seed the finite residual-stream route over MetaCIC parallel-diamond, normalization-frontier, same-schema relation, inter-Hist invariant, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CriticalPairResidualStream}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim residual-substitution discharge, subject reduction, premise-free parallel diamond, unrestricted Church–Rosser, evaluator equality, quotient equality of terms, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-window coverage, candidate-join readback, stream-order visibility, frontier and normalization routing, relation and inter-Hist preservation, transport, replay, provenance, and local naming for BEDC.Derived.CriticalPairResidualStreamUp.

Constructive story: A CriticalPairResidualStream$^{\uparrow}$ packet is generated from MetaCICParallelDiamondFrontierUp and MetaCICNormalizationFrontierUp rows, a LayeredRelationCertUp same-schema row, an InterHistInvariantUp row, residual-window and candidate-join ledgers, a stream-order row, failure row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7609

A Concrete Naming Certificate for $\mathsf{NonArchimedeanMetric}^{\uparrow}$

Following Bourbaki and standard ultrametric geometry, the $\mathsf{NonArchimedeanMetric}^{\uparrow}$ packet records the finite strong-triangle metric surface used by constructive ultrametric consumers. It sits over the metric carrier of chapter 57, the finite dyadic tolerance ledger of chapter 291, the terminal real-name boundary of chapter 38, and the observation schedule of chapter 126. The packet names the non-Archimedean comparison route as displayed BEDC data; it is not a quotient metric construction, a selected representative discipline, or a Real completeness theorem.

Definition 7609.1 (Non-Archimedean metric carrier)**.** *A* $\mathsf{NonArchimedeanMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, D, R, S, V, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row containing the admitted carrier, distance classifier, and metric local* $\mathsf{NameCert}$*.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare distances by finite dyadic bounds.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *distance-seal row reached only after the metric and dyadic rows have been displayed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the point and distance observations read by a consumer.*
5. *V is the strong-triangle ledger, recording that every inspected triple is routed through the displayed maximum-of-two-distance comparison before the third distance is public.*
6. *H records componentwise* hsame *transport for the metric, dyadic, Real-seal, stream-window, strong-triangle, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite triple request through S, M, D, V and then to R.*
8. *P is the* Pkg *provenance over* $\mathsf{NonArchimedeanMetric}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{NonArchimedeanMetric}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient metric points, selected representatives, trichotomy of distances, countable choice, host equality of reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7609.2 (Non-Archimedean metric NameCert obligations)**.** *For every accepted* $\mathsf{NonArchimedeanMetric}^{\uparrow}$ *carrier*

$$U = (M, D, R, S, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NonArchimedeanMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; metric admission through the common* $\mathsf{Met}^{\uparrow}$ *row* M*; dyadic tolerance admission through* D*; finite observation scheduling through* S*; Real-distance sealing through* R*; strong-triangle comparison through* V*; componentwise transport and replay through* H, C*; and provenance with local naming through* P, N*. No additional obligation stores a quotient metric construction, selected representatives, host real equality, countable choice, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 7609.1. The accepted packet displays exactly the metric row, dyadic tolerance ledger, Real-distance seal, stream-window schedule, strong-triangle ledger, and the structural rows.

Metric and dyadic admission are read before any strong-triangle comparison. A finite triple request first opens the observation window S, then reads the common metric row M and dyadic tolerance ledger D used to compare the three displayed distances.

The strong-triangle row is V. It records only the finite maximum comparison between the two displayed legs and the third distance, and it reaches the Real-distance seal R only after those rows are public.

Finally inspect H, C, P, N. They transport, replay, source, and name the same displayed route, while the excluded quotient, representative, trichotomy, choice, host-equality, and completeness data have no projection from the packet. □

Theorem 7609.3 (Non-Archimedean ultrametric triangle route)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{NonArchimedeanMetric}^{\uparrow}$ *carrier reads the strong triangle route through*

$$S \longmapsto M \longmapsto D \longmapsto V \longmapsto R.$$

The route exposes the finite observation window, the common metric row, the dyadic tolerance comparison, the ultrametric strong-triangle ledger, and the terminal Real-distance seal before any consumer treats the distance comparison as public. It exposes no quotient metric, selected representative, trichotomy branch, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start from the accepted carrier $U = (M, D, R, S, V, H, C, P, N)$. The only consumer-facing observation row is S, and the only metric source is M.

Use Definition 7609.2. It forces each finite triple request to read the dyadic tolerance ledger D before the strong-triangle ledger V can compare the displayed distances.

The terminal Real-facing boundary is R. Since R is reached only after S, M, D, V, a consumer cannot bypass the displayed rows by appealing to a quotient metric, a selected representative, trichotomy, choice, host equality of reals, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{NonArchimedeanMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{NonArchimedeanMetric}^{\uparrow}$ packet is generated from a MetricSpace row, a DyadicRatCore tolerance ledger, a RealUp distance seal, a StreamName observation schedule, a strong-triangle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NonArchimedeanMetric}^{\uparrow}}$, seed)

Scope closed: Definition 7609.1, Definition 7609.2, and Definition 7609.3 seed the finite non-Archimedean metric carrier, NameCert obligations, and strong-triangle route over MetricSpace, DyadicRatCore, Real, StreamName, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{NonArchimedeanMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, quotient metric construction, selected representatives, trichotomy, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance routing, strong-triangle comparison, Real-distance sealing, transport, replay, provenance, and local naming for BEDC.Derived.NonArchimedeanMetricUp.

Chapter 7610

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy real name carries usable information only when its modulus data can be transferred along the displayed stream, rational-readback, and real-seal route. The $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ packet records that transfer as finite BEDC data from the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, through the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows of chapter 291 and the $\mathsf{RegSeqRat}^{\uparrow}$ readback route of chapter 301, to the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. It consumes the sibling uniform-tail budget of $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ from chapter 4158 and names the non-quotient handoff that later completion consumers may inspect.

Definition 7610.1 (RegularCauchyModulusTransfer carrier)**.** *A* $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, D, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the source name windows to which the modulus data applies;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic comparison budget for those windows;*
3. *U is the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *uniform-tail row that supplies one visible regular Cauchy modulus schedule;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that consumes the displayed windows and dyadic tolerances as a regular rational schedule;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by the same readback route, with no selected limit or quotient representative;*
6. *H records componentwise* hsame *transport for S, D, U, R, E, P, N;*
7. *C records displayed* Cont *replay of the stream-window, dyadic-tolerance, modulus, readback, and real-seal rows;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusTransfer}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through the displayed rows $S, D, U, R, E, H, C, P, N$. It therefore records transfer of modulus data across the StreamName-RegSeqRat-Real route, not equality of quotient completions, choice of a representative, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7610.2 (RegularCauchyModulusTransfer NameCert obligations)**.** *For the carrier of Definition 7610.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusTransfer}^{\uparrow}}$ *surface consists of carrier admission for*

$$Q = (S, D, U, R, E, H, C, P, N),$$

source-window exposure through S, dyadic-tolerance exposure through D, uniform-modulus exposure through U, regular-rational readback through R, terminal real-seal exposure through E, componentwise hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 7610.1. The tuple displays the stream windows, dyadic tolerance ledger, uniform-tail modulus, regular rational readback, terminal real seal, transport data, replay data, provenance, and local naming row.

The transfer route is ordered. Row S supplies the finite source windows, row D supplies the dyadic precision ledger for those windows, row U supplies the regular Cauchy tail budget, and row R consumes that visible data as regular rational readback before row E can be used as a real-seal endpoint.

The structural rows H, C, P, N preserve exactly that route. Since the carrier has no coordinate for a quotient stream, selected representative, countable-choice schedule, host equality of completions, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle, the listed rows are precisely the local NameCert obligations. □

Theorem 7610.3 (RegularCauchyModulusTransfer StreamName-RegSeqRat handoff)**.** *Let $Q = (S, D, U, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ *carrier. Any consumer that reads the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R must first expose the* $\mathsf{StreamName}^{\uparrow}$ *source windows S, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the* $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ *budget U; only then may it pass the readback to the* $\mathsf{Real}^{\uparrow}$ *seal row E through H, C, P, N.*

Proof. Project the accepted carrier. The readback coordinate R is part of the same finite packet as S, D, U, E, H, C, P, N, and the classifier compares packets only through those displayed rows.

Before R can be consumed, the source windows and tolerance data must be visible. The rows S and D provide that finite input, while U supplies the uniform regular Cauchy modulus that makes the readback route a transfer of displayed data rather than a hidden completion argument.

The real-seal row E is reached only through the structural rows H, C, P, N. These rows transport, replay, source, and name the same packet, so the StreamName-RegSeqRat handoff cannot be replaced by a quotient stream, selected limit, host equality of completions, or ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ consumer displays the $\mathsf{StreamName}^{\uparrow}$ source windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegularCauchyUniformModulus}^{\uparrow}$ budget, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before it claims a modulus-transfer handoff.

Independence witness: StreamName, DyadicRatCore, RegSeqRat, RegularCauchyUniformModulus, Real: $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ is not bijective to any listed sibling because it

packages the displayed transfer route between stream windows, dyadic tolerances, uniform modulus data, regular rational readback, and terminal real seal as one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusTransfer}^{\uparrow}$ packet is generated from stream windows, dyadic tolerance rows, a regular Cauchy uniform-modulus row, regular rational readback, terminal real-seal data, componentwise transport, displayed continuation replay, package provenance, and local naming evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Only the seed carrier, local NameCert obligations, and StreamName-RegSeqRat handoff route in Definition 7610.1, Definition 7610.2, and Definition 7610.3 are recorded.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusTransfer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality of completions, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean verification.

Upgrade path: Formal closure requires a Lean carrier and obligation theorem for the displayed rows $S, D, U, R, E, H, C, P, N$.

Chapter 7611

A Concrete Naming Certificate for $\mathsf{LocatedSequenceInfimum}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ packet records the lower-envelope certificate for a bounded displayed sequence of real names. It sits beside the upper-envelope route of chapter 6098, the bounded-sequence carrier of chapter 1415, the located-supremum boundary of chapter 1427, the finite window service of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite lower-bound and upper-approximation route; it is not Dedekind completeness, an arbitrary subset infimum, trichotomy, quotient streams, a selected extremum, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7611.1 (Located sequence infimum carrier)**.** *A* $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, L, U, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *row naming the bounded displayed* $\mathsf{Real}^{\uparrow}$ *sequence.*
2. *L is the lower-bound ledger, recording the finite lower rows against which every inspected sequence value is compared.*
3. *U is the upper-approximation and cut-response ledger, recording the finite request that produces an inspected sequence value within the requested dyadic tolerance above the lower envelope.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window service used by the lower and upper ledgers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected real-name windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including the precision split used by the lower-bound and upper-approximation ledgers.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row for the named lower-envelope output, reached only after B, L, U, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the sequence, lower ledger, upper-response ledger, window, readback, dyadic, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$B \longmapsto L \longmapsto U \longmapsto W \longmapsto R \longmapsto D \longmapsto A.$$

10. *P is the* Pkg *provenance over* $\mathsf{LocatedSequenceInfimum}^{\uparrow}$, $\mathsf{LocatedSequenceSupremum}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceInfimum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, U, W, R, D, A, H, C, P, N$. It has no coordinate for Dedekind completeness, arbitrary subset infima, trichotomy, quotient streams, selected extrema, host order equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7611.2 (Located sequence infimum NameCert obligations)**.** *For an accepted* $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ *carrier $I = (B, L, U, W, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceInfimum}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded sequence row, lower-bound ledger, upper-approximation response ledger, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Every lower-envelope consumer must read the displayed route

$$\mathsf{BoundedRealSequence}^{\uparrow} \longmapsto L, U \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $B, L, U, W, R, D, A, H, C, P, N$. The route exports a located lower-envelope certificate for the sequence only, with no arbitrary subset infimum, trichotomy, quotient-stream equality, selected extremum, or ambient completeness principle.

Proof. Project the carrier of Definition 7611.1. The accepted packet displays exactly the bounded sequence row, lower-bound ledger, upper-approximation ledger, finite windows, readback, dyadic tolerance, Real seal, and structural rows.

The lower-bound and upper-response ledgers are the analytic core. The row L records the finite lower comparisons for inspected values, while U records the finite response to a requested cut above the lower envelope. Both rows are read through the same W, R, D window, readback, and tolerance service.

The sibling routes supply only their displayed interfaces. $\mathsf{LocatedSequenceSupremum}^{\uparrow}$ and $\mathsf{LocatedSupremum}^{\uparrow}$ provide the dual located-envelope discipline, $\mathsf{BoundedRealSequence}^{\uparrow}$ supplies the sequence boundary, and $\mathsf{Real}^{\uparrow}$ is reached only as the seal row A.

Since the carrier contains no coordinate for arbitrary subset infima, trichotomy, quotient streams, selected extrema, host order equality, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7611.3 (Located sequence infimum Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ *packet receives the lower-envelope result only after the rows*

$$B, L, U, W, R, D, A, H, C, P, N$$

have been displayed. The handoff preserves the bounded sequence source, lower-bound ledger, upper-approximation response, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert row.*

Proof. Start with the NameCert obligations of Definition 7611.2. They identify $B, L, U, W, R, D, A, H, C, P, N$ as the full route available to a lower-envelope consumer.

The Real handoff is downstream of the finite numerical rows. A consumer reaches the seal A only after the bounded sequence row, the two located ledgers, the StreamName windows, the RegSeqRat readback, and the dyadic tolerance row have already been displayed.

The structural rows preserve the same packet. Componentwise transport, displayed replay, provenance, and local naming cannot add selected extrema, quotient streams, trichotomy, arbitrary infima, or ambient completeness, because none of those objects is a carrier coordinate. □

Falsifiable prediction: If an accepted $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ consumer obtains a lower-envelope $\mathsf{Real}^{\uparrow}$ seal without displaying the bounded sequence row, lower-bound ledger, upper-approximation response, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, transport, replay, provenance, and local NameCert rows, the packet is refuted.

Independence witness: located-sequence-supremum, bounded-real-sequence, located-supremum, streamname, regseqrat, dyadicratcore, real: the packet is not bijective to any listed sibling because it jointly stores the lower-bound ledger and upper-approximation response for one bounded sequence lower envelope.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequenceInfimum}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSequenceInfimum}^{\uparrow}$ packet is generated from a BoundedRealSequence row, a lower-bound ledger, an upper-approximation response ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSequenceInfimum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7611.1, Definition 7611.2, and Definition 7611.3 seed the finite lower-envelope route for bounded RealUp sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSequenceInfimum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, arbitrary subset infima, trichotomy, quotient streams, selected extrema, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-bound ledger exposure, upper-approximation response exposure, StreamName window service, RegSeqRat readback, DyadicRatCore tolerance, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSequenceInfimumUp.

Chapter 7612

A Concrete Naming Certificate for $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy representatives, the $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ packet records the finite comparison witness that two diagonal-limit representatives determine the same named real up to the displayed psame route. It concretizes the uniqueness clause of chapter 9238 through the compatibility surface of chapter 646, the observer surface of chapter 961, the Cauchy limit seal of chapter 386, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet compares paired representatives; it does not quotient streams, select a completed limit, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7612.1 (Diagonal limit uniqueness witness carrier)**.** *A* $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, Y, K, O, S, W, R, D, A, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the paired diagonal representative rows being compared.*
2. *K is the* $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$ *row, recording the finite compatibility comparison between the paired diagonal routes.*
3. *O is the* $\mathsf{DiagonalLimitObserver}^{\uparrow}$ *row, recording the observer budget and inspected diagonal windows used by the comparison.*
4. *S is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row that seals both representatives through the same displayed limit route.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the paired representative reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the synchronized windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the split precision used to compare the two representatives.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after X, Y, K, O, S, W, R, D have been displayed.*
9. *H records componentwise* hsame *transport for the paired representatives, compatibility, observer, seal, window, readback, dyadic, Real, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$X, Y \longmapsto K \longmapsto O \longmapsto S \longmapsto W \longmapsto R \longmapsto D \longmapsto A.$$

11. *P is the* Pkg *provenance over* $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$, $\mathsf{DiagonalLimitCompatibility}^{\uparrow}$, $\mathsf{DiagonalLimitObserver}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, K, O, S, W, R, D, A, H, C, P, N$. It has no coordinate for quotient stream equality, a selected completed limit, host equality of representatives, countable choice, or ambient Real completeness.

Theorem 7612.2 (Diagonal limit uniqueness witness NameCert obligations)**.** *For an accepted* $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ *carrier $U = (X, Y, K, O, S, W, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitU}}$ *surface consists exactly of carrier admission for the paired representatives, compatibility row, observer row, CauchyLimitSeal row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, componentwise transport, displayed replay, provenance, and local naming.*

Every uniqueness read must route the paired representatives through

$$\mathsf{DiagonalLimitCompatibility}^{\uparrow} \longmapsto \mathsf{DiagonalLimitObserver}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \mapsto$$

before it exposes a psame *comparison. The route is a finite witness packet and exports no quotient stream equality, selected completed limit, host representative equality, countable choice, or ambient completion principle.*

Proof. Project the carrier of Definition 7612.1. The accepted packet displays exactly the paired representatives, compatibility row, observer row, Cauchy limit seal, finite windows, readback, dyadic tolerance, Real seal, and structural rows.

The compatibility and observer rows are read before the seal. The row K records the finite comparison route for the two diagonal representatives, while O records the observer windows and budgets used by that comparison.

The seal and numerical rows are downstream. The $\mathsf{CauchyLimitSeal}^{\uparrow}$ row S binds the representatives to one displayed limit route, and W, R, D, A provide the finite window, regular readback, dyadic tolerance, and Real seal evidence for the psame comparison.

The carrier has no coordinate for quotient streams, selected completed limits, host representative equality, countable choice, or ambient Real completeness. Therefore the displayed rows exhaust the local NameCert obligation surface. □

Theorem 7612.3 (Diagonal limit uniqueness Real seal)**.** *Every Real-facing comparison exported by an accepted* $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ *packet reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed rows*

$$X, Y, K, O, S, W, R, D, A, H, C, P, N.$$

The resulting comparison is the finite paired diagonal-representative route through compatibility, observer, CauchyLimitSeal, StreamName, RegSeqRat, DyadicRatCore, hsame, Cont, Pkg, *and local NameCert data.*

Proof. Begin with the NameCert obligations of Definition 7612.2. They identify the full route that any uniqueness read may consume.

The Real seal A is reached after the paired representative comparison has passed through K, O, S, W, R, D. Thus the comparison is a sealed finite route rather than equality of host streams or selected completed limits.

Transport, replay, provenance, and local naming preserve the same displayed rows. Since the carrier lacks quotient-stream equality, selected limits, countable choice, host equality, and ambient completeness coordinates, the Real seal cannot export those objects. □

Falsifiable prediction: If a diagonal-limit uniqueness consumer compares two representatives without displaying the compatibility row, observer row, CauchyLimitSeal row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, replay, provenance, and local NameCert rows, it is not a $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ packet.

Independence witness: diagonal-limit-compatibility, diagonal-limit-observer, cauchy-limit-seal, streamname, regseqrat, dyadicratcore, real: the packet is not bijective to any listed sibling because it jointly stores the paired representatives and their finite uniqueness witness route.

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}$ packet is generated from paired diagonal representatives, a DiagonalLimitCompatibility row, a DiagonalLimitObserver row, a CauchyLimitSeal row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7612.1, Definition 7612.2, and Definition 7612.3 seed the finite uniqueness-witness route for paired diagonal-limit representatives.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalLimitUniquenessWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected completed limits, countable choice, host representative equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compatibility exposure, observer exposure, CauchyLimitSeal exposure, StreamName window service, RegSeqRat readback, DyadicRatCore tolerance, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DiagonalLimitUniquenessWitnessUp.

Chapter 7613

A Concrete Naming Certificate for $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$ packet records the finite certificate surface for the classical theorem that a displayed derivative has the Darboux property. It sits over the difference-quotient discipline of chapter 122, the target-value handoff of chapter 3348, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real seal of chapter 38. The packet names the derivative-Darboux route as finite NameCert data rather than as host differentiability semantics, quotient equality of functions, a selected intermediate point, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7613.1 (Darboux derivative property carrier)**.** *A* $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, Q, L, U, Y, S, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval source row, exposing the lower and upper endpoint reads and the finite orientation data used by derivative requests.*
2. *F is the function-source row whose local difference-quotient reads are inspected only through the derivative packet.*
3. *Q is the* $\mathsf{Derivative}^{\uparrow}$ *quotient row, carrying the displayed nonzero-step quotient and metric-distance ledger for derivative observations.*
4. *L and U are the two derivative-value rows read at the endpoint-side observations of I.*
5. *Y is the target derivative value displayed between the endpoint-side derivative rows.*
6. *S records the finite endpoint-side comparison data that place Y between L and U.*
7. *R is the* $\mathsf{DarbouxProperty}^{\uparrow}$ *handoff row reached after the derivative quotient route has exposed the target-value bracket.*
8. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the derivative quotient windows and requested dyadic tolerances.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *seal exposed only after Q, R, T have been displayed.*

10. *H stores componentwise* hsame *transport for the interval source, function source, derivative quotient, endpoint derivative values, target value, comparison data, Darboux handoff, readback, real seal, replay, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from a derivative-Darboux request through $I, F, Q, L, U, Y, S, R, T, E$.*
12. *P is the* Pkg *provenance over* $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DarbouxProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DarbouxDerivativeProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, Q, L, U, Y, S, R, T, E, H, C, P, N$. It has no coordinate for host differentiability semantics, quotient equality of functions, selected intermediate points, real trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7613.2 (Darboux derivative property NameCert obligations)**.** *For every accepted* DarbouxDerivativeProp *carrier $D = (I, F, Q, L, U, Y, S, R, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DarbouxDerivativeProperty}^{\uparrow}}$ *surface consists exactly of carrier admission through the displayed packet of Definition 7613.1; interval-source exposure through I; derivative quotient exposure through F, Q; endpoint-side derivative value and target-value exposure through L, U, Y, S; DarbouxProperty handoff through R; regular rational and dyadic readback through T and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance surface named by P; Real-seal exposure through E; componentwise transport through H; displayed continuation replay through C; provenance through P; local naming through N; and non-escape from host differentiability semantics, quotient equality of functions, selected intermediate points, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7613.1. The interval row I, function row F, and derivative quotient row Q expose the only derivative-source data, while L, U, Y, S expose the finite endpoint-side bracket for the requested target derivative value.

The Darboux handoff is the row R. It can be read only after the displayed quotient route and the target-value comparison data have been exposed, so the packet separates the derivative route from the continuous-image Darboux route of chapter 3702.

The readback rows are then T and E. The row T supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback against the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data named by provenance, and E is the terminal $\mathsf{Real}^{\uparrow}$ seal for derivative-Darboux consumers.

Finally H, C, P, N transport, replay, source, and name exactly those rows. Since the carrier has no coordinate for host differentiability semantics, quotient equality of functions, selected intermediate points, trichotomy, open-cover compactness, or ambient Real completeness, none of those objects can enter the local NameCert surface. □

Theorem 7613.3 (Darboux derivative property Darboux handoff)**.** *Every accepted* $\mathsf{DarbouxProperty}^{\uparrow}$ *consumer reading a* $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$ *carrier factors through the finite derivative route*

$$\mathsf{Derivative}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{DarbouxProperty}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

In particular, the consumer first reads the interval source, function source, derivative quotient row, endpoint-side derivative values, target value, and comparison data; then the regular rational and dyadic tolerance readback; and only then the $\mathsf{DarbouxProperty}^{\uparrow}$ *handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

Proof. Start from an accepted carrier $D = (I, F, Q, L, U, Y, S, R, T, E, H, C, P, N)$. The continuation row C exposes derivative-Darboux reads only through the interval source, function source,

quotient row, endpoint-side values, target value, and finite comparison data before any Darboux-facing handoff is available.

The derivative route is forced by Q, T, E. The carrier contains no alternate route from the function source to the target-value handoff, so a consumer cannot replace the displayed quotient windows by host differentiability semantics or quotient equality of functions.

After the derivative quotient and readback rows are visible, the consumer reaches R as the $\mathsf{DarbouxProperty}^{\uparrow}$ handoff. Transport through H and replay through C preserve the same route, while P, N only package and name it.

Thus every accepted Darboux-property read factors through the derivative quotient, regular readback, dyadic tolerance, and real-seal rows, with selected intermediate points, trichotomy, open-cover compactness, and ambient Real completeness remaining outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxDerivativeProperty}^{\uparrow}}$.

Constructive story: A $\mathsf{DarbouxDerivativeProperty}^{\uparrow}$ packet is generated from an interval source, a function source, a Derivative quotient row, endpoint-side derivative values, target-value comparison data, a DarbouxProperty handoff, RegSeqRat readback, DyadicRatCore tolerance data, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxDerivativeProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7613.1, Definition 7613.2, and Definition 7613.3 seed the derivative-Darboux property as a finite quotient-readback route from displayed derivative observations to DarbouxProperty handoff and Real-seal exposure.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxDerivativeProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host differentiability semantics, quotient equality of functions, selected intermediate points, trichotomy, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative quotient exposure, endpoint-side comparison, DarbouxProperty handoff, RegSeqRat and DyadicRatCore readback, Real-seal exposure, transport and replay stability, provenance exhaustion, and non-escape for BEDC.Derived.DarbouxDerivativePropertyUp.

Chapter 7614

A Concrete Naming Certificate for $\mathsf{LipschitzFreeSpace}^{\uparrow}$

Following Weaver and Arens–Eells, the $\mathsf{LipschitzFreeSpace}^{\uparrow}$ packet records the finite molecule-and-norm surface used when pointed metric data is linearized into a normed space. It reads the metric carrier of chapter 57, the Lipschitz seminorm surface of chapter 7502, the function-action route of chapter 3762, and the Arens–Eells norm carrier of chapter 5855. The packet names only the displayed finite molecule ledger and its universal linearization route; it does not assert Banach completion, dual-space representation, quotient completion equality, selected representatives, or a host free Banach space.

Definition 7614.1 (Lipschitz free space carrier)**.** *A* $\mathsf{LipschitzFreeSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, B, U, D, Z, L, A, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the pointed* $\mathsf{Met}^{\uparrow}$ *row, including the finite point list and the distinguished basepoint row.*
2. *B records the basepoint anchor used to interpret molecule sums as pointed metric data.*
3. *U is the finitely supported molecule row, listing formal point generators and their support.*
4. *D is the signed dyadic coefficient row for the finite molecule support.*
5. *Z is the zero-sum ledger, recording that the signed dyadic coefficients sum to zero before the molecule is admitted.*
6. *L is the* $\mathsf{LipschitzSpace}^{\uparrow}$ *seminorm-budget row for scalar Lipschitz tests on the pointed metric rows.*
7. *A is the* $\mathsf{ArensEellsSpace}^{\uparrow}$ *norm-witness row, exposing the finite decomposition budget used to read the Arens–Eells norm.*
8. *E is the evaluation row through* $\mathsf{LipschitzFunction}^{\uparrow}$*, recording how a Lipschitz function reads a molecule by the displayed finite coefficient ledger.*
9. *H records componentwise* hsame *transport for $M, B, U, D, Z, L, A, E, C, P, N$.*
10. *C records displayed* Cont *replay from pointed metric rows through molecules, zero-sum admission, Lipschitz seminorm budgets, Arens–Eells norm witnesses, and evaluation by Lipschitz functions.*

11. *P is the* Pkg *provenance over* $\mathsf{LipschitzFreeSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzSpace}^{\uparrow}$, $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{ArensEellsSpace}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzFreeSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for Banach completion, a selected completion representative, a dual-space equality theorem, an ambient quotient of measures, or an unrestricted extension principle.

Theorem 7614.2 (Lipschitz free space NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzFreeSpace}^{\uparrow}$ *carrier*

$$F = (M, B, U, D, Z, L, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzFreeSpace}^{\uparrow}}$ *surface consists exactly of pointed metric exposure through M, B; finitely supported molecule exposure through U; signed dyadic coefficient exposure through D; zero-sum admission through Z; Lipschitz seminorm budgeting through L; Arens–Eells norm witnessing through A; Lipschitz-function evaluation through E; componentwise transport and replay through H, C; and provenance with local naming through P, N.*

Proof. Project the carrier of Definition 7614.1. The visible mathematical rows are the pointed metric rows, the molecule support rows, the signed dyadic coefficient row, the zero-sum ledger, the seminorm budget, the Arens–Eells norm witness, and the Lipschitz-function evaluation row.

The molecule side is read first. A consumer opens M, B, U, D and may admit a molecule only after the zero-sum ledger Z has displayed the signed dyadic coefficient balance.

The norm and evaluation reads are then forced through L, A, E. The Lipschitz seminorm budget supplies the scalar test boundary, the Arens–Eells row supplies the finite norm witness, and the Lipschitz-function row records the evaluation of the same molecule support.

Finally H, C, P, N only transport, replay, source, and name this displayed route. Since the carrier contains no completion, quotient-measure, dual-space, or representative-selection coordinate, those objects are not local NameCert obligations. □

Theorem 7614.3 (Lipschitz free space universal linearization)**.** *Every accepted* $\mathsf{LipschitzFreeSpace}^{\uparrow}$ *packet exports a universal linearization route only through the finite spine*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{LipschitzSpace}^{\uparrow} \longmapsto \mathsf{LipschitzFunction}^{\uparrow} \longmapsto \mathsf{ArensEellsSpace}^{\uparrow} \longmapsto \mathsf{NormedSpace}^{\uparrow}.$$

For a carrier $F = (M, B, U, D, Z, L, A, E, H, C, P, N)$, any linear read must preserve the pointed metric rows, the finitely supported molecule row, the signed dyadic coefficient row, the zero-sum ledger, the Lipschitz seminorm budget, the Arens–Eells norm witness, and componentwise hsame *transport. It may treat the resulting packet as a normed-space-facing molecule certificate, but it may not claim Banach completion, dual identification, quotient-measure equality, or a selected free-space representative.*

Proof. Begin with the sibling dependency rows named in the chapter introduction. The metric chapter supplies pointed distance data, the Lipschitz space and Lipschitz function chapters supply seminorm and evaluation reads, and the Arens–Eells chapter supplies the finite molecule norm witness.

Next read the carrier rows M, B, U, D, Z, L, A, E. The zero-sum ledger turns signed dyadic coefficients into admitted molecules, while the seminorm and Arens–Eells rows keep the norm read tied to finite tests and finite decompositions.

The structural rows H, C, P, N preserve that same route under componentwise transport, displayed replay, provenance, and local naming. Therefore the exported universal property is only the finite BEDC linearization spine shown above, not a completed Banach-space or dual-space theorem. □

Falsifiable prediction: If an accepted $\mathsf{LipschitzFreeSpace}^{\uparrow}$ packet changes its pointed metric row, signed dyadic coefficient row, zero-sum ledger, Lipschitz seminorm budget, or Arens–Eells norm witness while retaining the same local name, then it is not the same finite NameCert packet.

Independence witness: metric, lipschitz-space, lipschitz-function, arens-eells-space, normed-space: the metric packet supplies pointed distance rows without molecules; the Lipschitz-space packet supplies seminorm budgets without zero-sum molecules; the Lipschitz-function packet supplies evaluation rows without the free carrier; the Arens–Eells packet supplies norm witnesses without this universal linearization route; and the normed-space packet supplies linear norm rows without pointed metric provenance. None is bijective to $\mathsf{LipschitzFreeSpace}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzFreeSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzFreeSpace}^{\uparrow}$ packet is generated from pointed Metric rows, basepoint rows, finitely supported molecule rows, signed dyadic coefficient rows, a zero-sum ledger, Lipschitz seminorm budgets, Arens–Eells norm witnesses, Lipschitz-function evaluation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzFreeSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7614.1, Definition 7614.2, Definition 7614.3, the falsifiable prediction, and the independence witness seed the finite pointed-molecule carrier and universal linearization route over Metric, LipschitzSpace, LipschitzFunction, ArensEellsSpace, NormedSpace, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzFreeSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Banach completion, dual-space representation, quotient-measure equality, selected free-space representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, zero-sum molecule admission, signed dyadic coefficient routing, Lipschitz seminorm budgeting, Arens–Eells norm witnessing, evaluation readback, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzFreeSpaceUp.

Chapter 7615

A Concrete Naming Certificate for $\mathsf{ContractionRealModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Banach's contraction principle, the $\mathsf{ContractionRealModulus}^{\uparrow}$ packet records the finite modulus data by which a displayed contraction on a located interval or complete metric row yields a Cauchy route toward a real-name seal. It sits between the interval contraction surface of chapter 5867, the fixed-point modulus surface of chapter 4188, the theorem-level contraction route of chapter 3931, and the real-completion rows of chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a finite contraction-modulus carrier; it is not an ambient completeness theorem, a selected fixed point, quotient equality of real names, countable choice, or trichotomy.

Definition 7615.1 (Contraction real modulus carrier)**.** *A* $\mathsf{ContractionRealModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, X, F, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the source located interval, located metric interval, or complete metric row. It gives the domain on which the contraction is read, using only the displayed* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{CompleteMetric}^{\uparrow}$ *surface supplied by the surrounding chapter.*

2. *X is the initial point or initial interval row. It names the finite source datum from which the contraction iteration is inspected.*

3. *F is the contraction self-map row. It records the displayed action of the map on the source row and the finite Lipschitz witness λ with the contraction comparison $\lambda < 1$ available only as a row of the packet.*

4. *Q is the dyadic shrinkage ledger. It records the finite sequence of dyadic radii, slack inequalities, and comparison budgets used to read the contraction decrease.*

5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected iterates.*

6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic budgets.*

7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is available only after the source row, self-map row, dyadic shrinkage ledger, finite windows, and regular rational readback have been displayed.*

8. *H records componentwise* hsame *transport for the source row, initial row, self-map, shrinkage ledger, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a contraction-modulus request through $L, X, F, Q, W, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* ContractionRealModulus$^{\uparrow}$, BishopIntervalContraction$^{\uparrow}$, BanachFixedPointModulus$^{\uparrow}$, ContractionMappingTheorem$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ContractionRealModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, X, F, Q, W, R, E, H, C, P, N$. It has no coordinate for a chosen fixed point, quotient equality of streams or real names, countable choice, trichotomy, or ambient completeness outside the displayed source row.

Theorem 7615.2 (Contraction real modulus NameCert obligations)**.** *For every accepted* ContractionRealModulus$^{\uparrow}$ *carrier $M = (L, X, F, Q, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{ContractionRealModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the source located or complete metric row, the initial datum, the contraction self-map, the dyadic shrinkage ledger, finite* StreamName$^{\uparrow}$ *windows,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The obligation surface may cite the interval-contraction source of chapter 5867, the fixed-point modulus row of chapter 4188, the contraction theorem route of chapter 3931, and the real-name dependencies of chapter 291, chapter 126, chapter 301, and chapter 38. It cannot add a selected fixed point, quotient stream equality, countable choice, trichotomy, host real equality, or a detached completeness principle.*

Proof. Project the accepted carrier. The analytic coordinates are exactly the source row L, initial row X, contraction self-map F, dyadic shrinkage ledger Q, finite stream windows W, regular rational readback R, and terminal Real seal E.

The NameCert obligations follow the displayed order. The self-map row cannot be read without L and X, the shrinkage ledger cannot be consumed without F, and the real-name handoff cannot inspect E before Q, W, R have all been displayed.

Transport and replay are structural. The row H moves every listed coordinate componentwise, while C repeats the same finite route for later contraction or fixed-point consumers.

Finally P and N source and name only that finite packet. Since the excluded objects are not carrier coordinates and are not produced by componentwise transport or replay, no local NameCert obligation exports them. □

Theorem 7615.3 (Contraction real modulus Cauchy Real handoff)**.** *Every accepted* ContractionRealModulus$^{\uparrow}$ *carrier $M = (L, X, F, Q, W, R, E, H, C, P, N)$ gives any Cauchy or Real-facing consumer the finite route*

$$L, X \longrightarrow F \longrightarrow Q \longrightarrow W \longrightarrow R \longrightarrow E$$

with structural rows H, C, P, N attached. Thus the consumer receives a contraction-modulus route through DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *before it can invoke the Banach fixed-point or contraction-mapping surface; it receives no selected fixed point, quotient stream, countable-choice schedule, trichotomy row, host real equality, or ambient completeness row outside the displayed carrier.*

Proof. Start with the carrier projection of Definition 7615.1. The only route from the source row to a Real-facing read is through the contraction self-map, dyadic shrinkage ledger, finite stream windows, regular rational readback, and Real seal.

The dyadic ledger Q controls the decrease row before the windows are opened. Once W is fixed, the regular rational row R reads the inspected iterates with the same budgets, and E seals only that displayed route.

Use the structural rows H, C, P, N to transport, replay, source, and locally name the same path. Therefore downstream uses by $\mathsf{BanachFixedPointModulus}^{\uparrow}$, $\mathsf{BanachFixedPointConstructive}^{\uparrow}$, or $\mathsf{ContractionMappingTheorem}^{\uparrow}$ can cite only the finite contraction-modulus handoff and not any excluded ambient principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContractionRealModulus}\uparrow}$.

Constructive story: A $\mathsf{ContractionRealModulus}^{\uparrow}$ packet is generated from a displayed source row, initial datum, contraction self-map, dyadic shrinkage ledger, finite StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContractionRealModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7615.1, Definition 7615.2, and Definition 7615.3 seed the finite contraction-modulus carrier over displayed source, self-map, dyadic shrinkage, StreamName, RegSeqRat, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContractionRealModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected fixed points, quotient stream equality, countable choice, trichotomy, host real equality, ambient completeness beyond the displayed source row, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction self-map exactness, dyadic shrinkage accounting, StreamName window readback, RegSeqRat handoff, Real-seal routing, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.ContractionRealModulusUp.

Chapter 7616

A Concrete Naming Certificate for $\mathsf{LocatedMetricBall}^{\uparrow}$

Following Bishop and Bridges on constructive metric spaces and located subsets, the $\mathsf{LocatedMetricBall}^{\uparrow}$ packet records the finite ball window that a metric consumer may inspect before any total-boundedness, compact-net, or uniform-continuity argument reads open-ball data. It sits over the metric carrier of chapter 57, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, and the regular Cauchy ball-basis sibling of chapter 6762. The packet names a located center-radius-radius-transport surface; it does not assert open-cover compactness, selected centers outside the displayed packet, quotient metric equality, trichotomy of distances, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7616.1 (LocatedMetricBall carrier)**.** *A* $\mathsf{LocatedMetricBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, X, C, R, Q, L, T, H, K, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, recording the displayed metric relation and the finite distance windows available to the packet.*
2. *X is the inspected point row, naming the point or finite point-window whose membership in the ball is being read.*
3. *C is the center row, naming the displayed center and its transport data inside the same metric source.*
4. *R is the positive radius row, read through* $\mathsf{Real}^{\uparrow}$ *and carried only as a displayed real-name seal.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that supplies rational tolerance windows for the radius and distance comparison.*
6. *L is the located comparison row, recording the finite alternatives $d_M(X, C) < R$ and $R < d_M(X, C)$ at the requested precision.*
7. *T is the radius-transport row, recording how the same center and radius are preserved when the metric source is transported by* hsame.
8. *H records componentwise* hsame *transport for $M, X, C, R, Q, L, T, P, N$.*
9. *K records displayed* Cont *replay of the metric, point, center, radius, rational-readback, located-comparison, and radius-transport rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedMetricBall}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyBallBasis}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMetricBall}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, X, C, R, Q, L, T, H, K, P, N$. It therefore records one located metric-ball packet, not a host open set, a completed metric space, a quotient distance equality, a selected finite cover, or an ambient compactness theorem.

Theorem 7616.2 (LocatedMetricBall NameCert obligations)**.** *For every accepted* $\mathsf{LocatedMetricBall}^{\uparrow}$ *carrier*

$$B = (M, X, C, R, Q, L, T, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedMetricBall}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, inspected point row, center row, real-radius row, regular rational readback row, located comparison row, radius-transport row, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7616.1. The tuple exposes the metric source M, inspected point X, center C, radius seal R, rational readback Q, located comparison L, radius transport T, structural transport H, replay K, provenance P, and local naming N.

The metric ball is read only after the distance and radius data are visible. Row M supplies the distance windows, C and X supply the two endpoints of the comparison, R supplies the real radius, and Q supplies the rational tolerance windows used to inspect that comparison.

The locatedness row L is the only public membership boundary. It records the displayed comparison alternatives at the requested precision and does not create a host open set or a quotient-level distance judgment.

The rows T, H, K, P, N preserve, replay, source, and name the same finite packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7616.3 (LocatedMetricBall radius transport)**.** *Let $B = (M, X, C, R, Q, L, T, H, K, P, N)$ be an accepted* $\mathsf{LocatedMetricBall}^{\uparrow}$ *carrier. Any consumer that transports the ball along an* hsame *comparison must preserve the metric source row M, center row C, real-radius row R, regular rational readback row Q, and located comparison row L before it may read the transported radius row T as the same located ball.*

Proof. Project the accepted carrier. The radius-transport row T is part of the same packet as the metric, center, radius, rational-readback, and located-comparison rows.

Transport first preserves the metric source and center. Without the displayed M and C rows, the expression $d_M(X, C)$ has no public metric-ball source inside the packet.

The radius and comparison must also be preserved. The row R supplies the real-name radius, Q supplies the rational readback used to compare it with the distance window, and L records the located comparison boundary.

Only after those rows are visible can T be consumed as radius transport for the same ball. The structural rows H, K, P, N do not add a selected center, quotient metric equality, compact cover, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{LocatedMetricBall}^{\uparrow}$ consumer displays the $\mathsf{Met}^{\uparrow}$ metric source, inspected point, center, $\mathsf{Real}^{\uparrow}$ radius seal, $\mathsf{RegSeqRat}^{\uparrow}$ rational readback, located comparison row, radius-transport row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before it claims a located metric-ball read.

Independence witness: metric, real, regseqrat, regular-cauchy-ball-basis: $\mathsf{Met}^{\uparrow}$ supplies the distance source without a located center-radius packet; $\mathsf{Real}^{\uparrow}$ supplies terminal real seals without metric membership; $\mathsf{RegSeqRat}^{\uparrow}$ supplies rational readback without a ball classifier; $\mathsf{RegularCauchyBallBasis}^{\uparrow}$ supplies a ball-basis route without this single located point-center-radius transport surface. None is bijective to $\mathsf{LocatedMetricBall}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMetricBall}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedMetricBall}^{\uparrow}$ packet is generated from a metric source row, inspected point row, center row, real-radius seal, regular rational readback, located comparison, radius transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMetricBall}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7616.1, Definition 7616.2, and Definition 7616.3 seed the finite located ball surface over Metric, Real, RegSeqRat, regular Cauchy ball-basis, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMetricBall}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected finite covers, quotient metric equality, trichotomy of distances, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located comparison exactness, radius transport, metric-source preservation, rational-readback preservation, transport, replay, provenance, and local naming for BEDC.Derived.LocatedMetricBallUp.

Chapter 7617

A Concrete Naming Certificate for $\mathsf{CandidateFrontierQueue}^{\uparrow}$

The $\mathsf{CandidateFrontierQueue}^{\uparrow}$ packet realizes the automated theory-discovery calculus of chapter 9410 as finite source-state, classifier-shift, score-budget, queue, ledger, replay, provenance, and NameCert rows. It sits beside the candidate frontier of chapter 5994, the before-and-after classifier residue of chapter 6985, the vision-coverage ledger of chapter 7484, and the critical-path source of chapter 765. The packet names an admission queue for candidate theory work; it does not by itself certify positive discovery, semantic novelty, theorem soundness, or bridge checking.

Definition 7617.1 (CandidateFrontierQueue carrier)**.** *A* $\mathsf{CandidateFrontierQueue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, A, F, D, B, U, L, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the certified source-state row, recording the current theory state, accepted theorem rows, and active boundary conditions read from the discovery calculus.*
2. *A is the automation-record row, naming the generator, admissible moves, replay seed, and bounded search surface used to propose candidates.*
3. *F is the* $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ *row, supplying candidate-frontier evidence rather than an evidence-free theorem.*
4. *D is the* $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ *row, exposing the before-and-after classifier comparison used to decide whether the queue entry can leave record growth.*
5. *B is the score-budget row, recording public cost, score, and resource bounds for the queued candidate.*
6. *U is the queue-order row, recording the displayed priority, dependency predecessor, and admission status of each candidate.*
7. *L is the ledger row, recording vision coverage, classifier-shift status, score account, replay obligations, and candidate rejection reasons.*
8. *R is the replay row, recording the deterministic route by which the source state, automation record, frontier row, classifier-shift row, budget, and queue order are rechecked.*
9. *H stores componentwise* hsame *transport for $S, A, F, D, B, U, L, R, C, P, N$.*

10. *C records displayed* Cont *replay from the source state through automation, frontier, classifier-shift, score, queue, ledger, and replay rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CandidateFrontierQueue}^{\uparrow}$, $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$, ClassifierShiftLedgerRes VisionCoverageLedger$^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CandidateFrontierQueue}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, A, F, D, B, U, L, R, H, C, P, N$. It therefore records finite queue admission for candidate-frontier work, not a host search process, an unledgered discovery verdict, a hidden semantic novelty score, or unchecked theorem soundness.

Theorem 7617.2 (CandidateFrontierQueue NameCert obligations)**.** *For every accepted* $\mathsf{CandidateFrontierQueue}^{\uparrow}$ *carrier*

$$Q = (S, A, F, D, B, U, L, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CandidateFrontierQueue}^{\uparrow}}$ *surface consists exactly of source-state admission, automation-record admission, candidate-frontier exposure, classifier-shift ledger exposure, score-budget exposure, queue-order exposure, ledger exposure, replay exposure, componentwise transport, displayed continuation replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7617.1. The accepted tuple displays the source state S, automation record A, candidate frontier F, classifier-shift ledger D, score budget B, queue order U, ledger L, replay row R, transport H, continuation replay C, provenance P, and local naming N.

The queue read starts from the source state and automation record. These rows fix which candidate was proposed and which bounded search surface produced it.

The frontier and classifier rows then decide admissibility. Row F keeps the candidate attached to a displayed frontier, while row D records the before-and-after classifier evidence required by the discovery calculus.

The budget, queue, ledger, and replay rows make the admission auditable. Since the carrier contains no further coordinate for semantic novelty, theorem soundness, or positive-discovery certification, the listed rows exhaust the local NameCert obligations. □

Theorem 7617.3 (CandidateFrontierQueue classifier-shift nonescape)**.** *Let $Q = (S, A, F, D, B, U, L, R, H, C, P, N)$ be an accepted* $\mathsf{CandidateFrontierQueue}^{\uparrow}$ *carrier. A queued candidate cannot be read as discovery-class work unless the same packet exposes the* $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ *row D, the score-budget row B, the ledger row L, and the replay row R over the source-state and automation rows S, A.*

Proof. Project the accepted carrier. The queue-order row U only records priority and dependency placement; it does not decide claim strength.

The source-state and automation rows S, A fix the candidate's origin. The candidate-frontier row F supplies admissible frontier evidence, but it still does not show classifier change.

Classifier-shift evidence must therefore be read through D. The score-budget row B records the public cost account, the ledger row L records the coverage and rejection boundary, and the replay row R records the deterministic recheck route over the same source and automation surface.

If any of D, B, L, R is absent, the queue entry remains record growth or candidate work inside this packet. The structural rows H, C, P, N preserve that boundary and do not create a hidden discovery verdict. □

Falsifiable prediction: A $\mathsf{CandidateFrontierQueue}^{\uparrow}$ packet that admits a candidate as discovery-class work while omitting the displayed $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ row, score-budget row, ledger

row, or replay row over the same source-state and automation rows fails the carrier of Definition 7617.1.

Independence witness: normalization-candidate-frontier, classifier-shift-ledger-residue, vision-coverage-ledger, metaciccriticalpath: $\mathsf{NormalizationCandidateFrontier}^{\uparrow}$ supplies candidate evidence without queue order; $\mathsf{ClassifierShiftLedgerResidue}^{\uparrow}$ supplies before-and-after classifier residue without score-budgeted queue admission; $\mathsf{VisionCoverageLedger}^{\uparrow}$ supplies coverage accounting without replay ordering; $\mathsf{MetaCICCriticalPath}^{\uparrow}$ supplies dependency pressure without classifier-shift queue discharge. None is bijective to $\mathsf{CandidateFrontierQueue}^{\uparrow}$ under NameCert-row preservation.

The Lean-side draft for $\mathsf{CandidateFrontierQueue}^{\uparrow}$ must include $\mathsf{Nontrivial\ CandidateFrontierQueue}^{\uparrow}$ and $\mathsf{FieldFaithful\ CandidateFrontierQueue}^{\uparrow}$ instances for the displayed carrier, with the field-faithful instance preserving exactly the rows $S, A, F, D, B, U, L, R, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{CandidateFrontierQueue}^{\uparrow}}$.

Constructive story: A $\mathsf{CandidateFrontierQueue}^{\uparrow}$ packet is generated from source-state rows, automation-record rows, candidate-frontier evidence, classifier-shift residue, score budgets, queue order, ledger rows, replay rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CandidateFrontierQueue}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7617.1, Definition 7617.2, and Definition 7617.3 seed the finite candidate-frontier queue over discovery-calculus, normalization-frontier, classifier-shift, vision-coverage, critical-path, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CandidateFrontierQueue}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim positive-discovery certification, theorem soundness, semantic novelty scoring, host search completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-frontier exposure, classifier-shift nonescape, score-budget preservation, queue-order preservation, ledger replay, transport, provenance, local naming, Nontrivial, and FieldFaithful rows for BEDC.Derived.CandidateFrontierQueueUp.

Chapter 7618

A Concrete Naming Certificate for $\mathsf{BishopRealSequence}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopRealSequence}^{\uparrow}$ packet records the finite surface of a sequence of real names whose inspected entries are given by stream windows, regular rational readback rows, dyadic tolerances, and terminal real seals. The packet sits after the finite-window discipline of chapter 126, the regular rational schedule of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name surface of chapter 38. It names a sequence object only through displayed finite BEDC rows; it does not choose a limit, quotient sequence representative, countable-choice schedule, host real equality, or ambient completeness theorem.

Definition 7618.1 (Bishop real sequence carrier)**.** *A* $\mathsf{BishopRealSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family indexed by the visible* $\mathsf{UnaryHistory}$ *entries requested by the consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those windows, recording the regular rational approximants exposed at each inspected index.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same finite window request.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after W, R, D have been displayed.*
5. *H records componentwise* hsame *transport for the window family, readback row, tolerance ledger, terminal seal, provenance, and local name.*
6. *C records displayed* Cont *replay from a sequence-entry request through W, R, D, E and then to the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealSequence}^{\uparrow}}$ *row.*

No carrier coordinate stores a selected limit, quotient sequence equality, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 7618.2 (Bishop real sequence pointwise stability)**.** *Let $S = (W, R, D, E, H, C, P, N)$ and $S' = (W', R', D', E', H', C', P', N')$ be accepted* $\mathsf{BishopRealSequence}^{\uparrow}$ *carriers. If the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows agree componentwise under the visible* hsame *transports, then every inspected* $\mathsf{UnaryHistory}$ *entry has the same exported real-name row in S and S'.*

Proof. Project both carriers through Definition 7618.1. The only entry-facing coordinates are W, R, D, E, and each is transported by the displayed rows H, H'.

For a fixed inspected $\mathsf{UnaryHistory}$ entry, read the stream window first. The readback row R is attached to that same finite window, and the tolerance row D records the dyadic budget used by the readback.

The terminal seal E is available only after those rows have been displayed. Since the corresponding rows agree componentwise under hsame, the replay routes C, C' export the same real-name row for the inspected entry. □

Theorem 7618.3 (Bishop real sequence tail window)**.** *Every accepted* $\mathsf{BishopRealSequence}^{\uparrow}$ *consumer that asks for a finite tail window must first display the* $\mathsf{StreamName}^{\uparrow}$ *windows indexed by the requested* $\mathsf{UnaryHistory}$ *tail, then the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, before any terminal* $\mathsf{Real}^{\uparrow}$ *seal can be read.*

Proof. Begin with the consumer request and project the carrier inventory. The request can reach only the displayed rows W, R, D, E, H, C, P, N.

The window row W fixes the finite tail segment being inspected. The readback row R is tied to this window, and the tolerance row D supplies the dyadic budget for the same indices.

Only after this finite surface is visible may the route read E. The structural rows H, C, P, N preserve and name the route without adding a selected tail limit, quotient sequence representative, or choice schedule. □

Theorem 7618.4 (Bishop real sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealSequence}^{\uparrow}$ *carrier $S = (W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealSequence}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{StreamName}^{\uparrow}$ *finite-window display,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7618.1. The tuple displays the finite windows, regular rational readback, dyadic tolerances, terminal real seal, transport data, continuation data, provenance, and local naming row.

The rows W, R, D, E are the complete pointwise read surface. A consumer may ask for more indices only by presenting another finite $\mathsf{UnaryHistory}$ window, not by extracting an infinite sequence object or a selected limit.

The remaining rows H, C, P, N transport, replay, source, and name the same finite surface. Since the carrier has no coordinate for quotient sequence equality, countable choice, host real equality, or completeness, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealSequence}^{\uparrow}$ read displays StreamName windows, RegSeqRat readback rows, DyadicRatCore tolerances, terminal Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a sequence-entry consumer obtains a real-name row.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopRealSequence}^{\uparrow}$ is not bijective to any listed sibling because it packages a finite family of pointwise real-name reads indexed by visible unary history windows, while each listed sibling supplies only one row type or terminal seal surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealSequence}^{\uparrow}$ packet is generated from finite StreamName windows indexed by visible unary-history entries, RegSeqRat readback rows, DyadicRatCore tolerance ledgers, terminal Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7618.1, Definition 7618.2, Definition 7618.3, and Definition 7618.4 seed the finite pointwise sequence surface between certified stream windows and terminal Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient sequence equality, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, bridge checking, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, pointwise stability, finite tail-window routing, and local NameCert surface proofs for BEDC.Derived.BishopRealSequenceUp.

Chapter 7619

A Concrete Naming Certificate for $\mathsf{JamesCompactnessCriterion}^{\uparrow}$

Following James's weak compactness criterion for bounded closed convex sets in Banach spaces, the $\mathsf{JamesCompactnessCriterion}^{\uparrow}$ packet records the finite BEDC surface by which a displayed weak compactness claim is tested through norm-attaining dual rows. It sits over the Banach carrier of chapter 90, the weak topology surface of chapter 3597, the weak compactness packet of chapter 6851, and the scalar comparison rows of chapter 38. The packet names only the finite criterion ledger and its local NameCert obligations; it does not assert a host dual ball, quotient weak topology, selected maximizing functional, or an ambient compactness theorem outside the displayed rows.

Definition 7619.1 (JamesCompactnessCriterion carrier)**.** *A* $\mathsf{JamesCompactnessCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (B, W, K, D, A, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the ambient* $\mathsf{Banach}^{\uparrow}$ *row, including the finite normed carrier data inspected by the criterion.*
2. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *row on the displayed Banach data.*
3. *K is the candidate* $\mathsf{WeakCompactness}^{\uparrow}$ *row whose acceptance is being routed through the James criterion ledger.*
4. *D is the finite dual-test ledger, listing only the displayed continuous linear functional names and their inspected bounded-set windows.*
5. *A is the norm-attainment row, recording the finite witnesses that each displayed dual test attains its supremum on the candidate set.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-comparison row for the displayed supremum and norm-attainment values.*
7. *H records componentwise* hsame *transport for $B, W, K, D, A, R, C, P, N$.*
8. *C records displayed* Cont *replay from Banach data through weak-topology exposure, finite dual tests, norm-attainment rows, scalar comparisons, and the weak-compactness handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{JamesCompactnessCriterion}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{JamesCompactnessCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected dual-ball point, quotient weak closure, countable choice, a host weak compactness theorem, or bridge checking data.

Theorem 7619.2 (JamesCompactnessCriterion NameCert obligations)**.** *For every accepted* JamesCompactnessCrit *carrier*

$$J = (B, W, K, D, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{JamesCompactnessCriterion}^{\uparrow}}$ *surface consists exactly of Banach carrier exposure through* B*; weak-topology exposure through* W*; candidate weak-compactness exposure through* K*; finite dual-test coverage through* D*; norm-attainment witnesses through* A*; scalar comparison through* R*; componentwise transport and displayed replay through* H, C*; and provenance with local naming through* P, N*.*

Proof. Project the carrier of Definition 7619.1. The analytic rows are precisely B, W, K, D, A, R, so a consumer first sees the Banach carrier, the weak topology, and the candidate weak compactness row.

The criterion-specific read is forced through D, A, R. The dual-test ledger D records the displayed functional names, the attainment row A records the finite witnesses for those tests, and the Real row R supplies the scalar comparison boundary.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no further field, no consumer can extract a selected dual-ball element, quotient weak closure, countable-choice schedule, host compactness theorem, or bridge data from this packet. □

Theorem 7619.3 (JamesCompactnessCriterion weak-compactness route)**.** *Every accepted* JamesCompactnessCrite *packet exports a weak-compactness-facing conclusion only through the finite spine*

$$\mathsf{Banach}^{\uparrow} \longmapsto \mathsf{WeakTopology}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{WeakCompactness}^{\uparrow}.$$

For a carrier $J = (B, W, K, D, A, R, H, C, P, N)$*, any downstream weak-compactness consumer must inspect the Banach row, weak-topology row, finite dual-test ledger, norm-attainment row, scalar comparison row, and componentwise* hsame *transport before it may read* K *as weak-compactness evidence. The route is a BEDC NameCert handoff, not an ambient theorem about all bounded closed convex subsets.*

Proof. Start with the sibling rows named in the chapter introduction. The $\mathsf{Banach}^{\uparrow}$ row supplies the normed carrier, the $\mathsf{WeakTopology}^{\uparrow}$ row supplies the topology-facing exposure, the $\mathsf{Real}^{\uparrow}$ row supplies scalar comparison data, and the $\mathsf{WeakCompactness}^{\uparrow}$ row is the only output coordinate.

Next read the James ledger rows D, A. They ensure that every displayed dual test and every displayed norm-attainment witness is consumed before the weak-compactness row K is exported.

Finally H, C, P, N preserve the same route under componentwise transport, displayed replay, provenance, and local naming. Thus the route reaches weak compactness only through the displayed finite certificate rows and not through a host duality or compactness oracle. □

Falsifiable prediction: An accepted $\mathsf{JamesCompactnessCriterion}^{\uparrow}$ consumer is refuted if it claims weak compactness without displaying the $\mathsf{Banach}^{\uparrow}$ carrier row, $\mathsf{WeakTopology}^{\uparrow}$ exposure row, finite dual-test ledger, norm-attainment row, $\mathsf{Real}^{\uparrow}$ scalar comparison, $\mathsf{WeakCompactness}^{\uparrow}$ handoff, transport, replay, provenance, and local NameCert row.

Independence witness: banach, weak-topology, weak-compactness, real: $\mathsf{Banach}^{\uparrow}$ supplies normed carrier data without the James dual-test ledger; $\mathsf{WeakTopology}^{\uparrow}$ supplies weak-open exposure without norm-attainment witnesses; $\mathsf{WeakCompactness}^{\uparrow}$ supplies a compactness-facing row without the

criterion route; and $\mathsf{Real}^{\uparrow}$ supplies scalar comparisons without Banach or weak-topology provenance. None is bijective to $\mathsf{JamesCompactnessCriterion}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{JamesCompactnessCriterion}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{JamesCompactnessCriterion}^{\uparrow}$ packet is generated from Banach carrier rows, weak-topology rows, weak-compactness candidate rows, finite dual-test ledgers, norm-attainment witnesses, Real scalar comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JamesCompactnessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7619.1, Definition 7619.2, Definition 7619.3, the falsifiable prediction, and the independence witness seed the finite James compactness criterion carrier and weak-compactness route over Banach, WeakTopology, WeakCompactness, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JamesCompactnessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host dual ball, quotient weak closure, selected norm-attaining functionals beyond displayed rows, the full ambient James theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite dual-test coverage, norm-attainment routing, scalar comparison, weak-compactness handoff, transport, replay, provenance, and local naming for BEDC.Derived.JamesCompactnessCrite

Chapter 7620

A Concrete Naming Certificate for $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ packet records a located closed real interval by endpoint order, finite window reads, and dyadic net data rather than by an ambient set of completed real points. It consumes the real-name surface of chapter 38, the regular rational readback of chapter 301, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the located endpoint discipline of chapter 394, and the finite-net interval route of chapter 6500. The packet is a closed-interval carrier for L10 Real and Completion consumers; it does not assert open-cover compactness, choose endpoints as host reals, quotient interval representatives, or import ambient completeness.

Definition 7620.1 (Constructive real closed interval carrier)**.** *A* $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, O, S, R, D, F, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are the lower and upper endpoint rows, each read through* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *name windows.*
2. *O is the endpoint-order row, recording that the lower endpoint is admitted before the upper endpoint as a located interval boundary.*
3. *S is the shared* $\mathsf{StreamName}^{\uparrow}$ *window ledger used by endpoint, membership, and net-cell reads.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row attached to those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for mesh budgets and endpoint comparisons.*
6. *F is the finite interval-net row, read through the closed-interval finite-net sibling before any completion-facing consumer inspects the interval.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint and cell readbacks.*
8. *H records componentwise* hsame *transport for endpoint, order, window, readback, dyadic, finite-net, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a precision request through the same endpoint and finite-net route.*

10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealClosedInterval}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, U, O, S, R, D, F, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected endpoint representatives, quotient interval equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7620.2 (ConstructiveRealClosedInterval NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ *carrier $I = (L, U, O, S, R, D, F, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealClosed}}$ *surface consists exactly of endpoint admission through L, U; endpoint-order admission through O; finite window and rational readback admission through S, R; dyadic tolerance admission through D; closed-interval finite-net admission through F; terminal real-name sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7620.1. The only endpoint rows are L, U, and the only order row is O.

The numerical reads are then forced through S, R, D. A precision request opens a finite stream window, reads regular rational endpoint data in that window, and consumes the dyadic tolerance ledger before reaching the finite-net row.

The finite-net and seal rows are downstream. The row F is the displayed closed-interval net surface, while E is the terminal Real seal reached only after the endpoint, order, window, readback, and dyadic rows have been displayed.

Finally H, C, P, N preserve, replay, source, and locally name that same route. Since the carrier has no coordinate for open covers, selected endpoint representatives, quotient interval equality, countable choice, trichotomy, or ambient completeness, no local NameCert obligation can be stored outside the displayed rows. □

Theorem 7620.3 (ConstructiveRealClosedInterval dyadic net route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ *carrier must read the finite dyadic net route*

$$L, U, O \longmapsto S, R, D \longmapsto F, E \longmapsto H, C, P, N$$

before it can inspect the interval as a closed real interval. The route consumes $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *as displayed packet rows, not as an open-cover compactness theorem, a selected subcover, quotient real equality, or a completed host interval.*

Proof. Begin with endpoint admission. The lower and upper endpoint rows, together with the endpoint-order row, are the only source rows for interval membership.

Next read the finite numerical route. The shared $\mathsf{StreamName}^{\uparrow}$ window row S and $\mathsf{RegSeqRat}^{\uparrow}$ readback row R supply endpoint approximations, while the $\mathsf{DyadicRatCore}^{\uparrow}$ row D supplies the mesh tolerance used by the finite net.

The row F is then the only closed-interval finite-net surface visible to the consumer, and the row E is the only Real-facing terminal seal. The structural rows H, C, P, N keep this route invariant under transport, replay, provenance, and local naming.

Therefore a consumer that reaches a closed real interval through the packet receives exactly the displayed dyadic finite-net data and no open-cover compactness proof, selected endpoint representative, selected subcover, quotient interval equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle. □

Falsifiable prediction: An accepted $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ consumer is refuted if it reads a closed real interval without first displaying endpoint rows, the endpoint-order row, StreamName and RegSeqRat windows, a DyadicRatCore tolerance row, and the finite closed-interval net row.

Independence witness: real, regseqrat, streamname, dyadicratcore, locatedinterval, and closed-interval-finite-net: none is bijective to the constructive real closed interval packet because only $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ records endpoint order and dyadic finite-net evidence as one local NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRealClosedInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ packet is generated from lower and upper Real endpoint rows, endpoint order, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a closed-interval finite-net row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveRealClosedInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7620.1, Definition 7620.2, and Definition 7620.3 seed the endpoint-order and dyadic finite-net carrier surface over $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ClosedIntervalFiniteNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveRealClosedInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected endpoint representatives, quotient interval equality, selected subcovers, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order admission, finite-window readback, dyadic mesh admission, finite-net exactness, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveRealClosedIn

Chapter 7621

A Concrete Naming Certificate for $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$

Following Hadamard and later constructive analysis, the $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ packet records the directional derivative surface in which the direction itself may be approached through a finite perturbation window. It sits between the point-direction interface of chapter 6344 and the full linear approximation interface of chapter 3634. Its displayed route consumes the map surface of chapter 130, the linear direction and response rows of chapter 48, and the terminal real-name seal of chapter 38. The packet names a stable directional read along finite approach windows; it is not a host function-space derivative, a quotient germ equality, a selected limit, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7621.1 (Hadamard directional derivative carrier)**.** *A* $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, A, V, Q, L, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the accepted source map row read through* $\mathsf{ContinuousMap}^{\uparrow}$ *and the surrounding local domain data;*
2. *A is the base-point and neighbourhood window over which the directional approach is inspected;*
3. *V is the displayed direction row, including the finite perturbation window through which nearby directions are compared;*
4. *Q is the finite difference-quotient schedule, listing the inspected step sizes and perturbed directions;*
5. *L is the* $\mathsf{LinMap}^{\uparrow}$ *response row that records the candidate directional linear value on the displayed direction surface;*
6. *S is the stability row requiring the quotient reads along perturbed directions to agree with the same response row over the finite schedule;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance seal through which the quotient comparison is read;*
8. *H records componentwise* hsame *transport for the source, base window, direction window, quotient schedule, linear response, stability row, Real seal, provenance, and local name;*

9. *C records the displayed* Cont *replay routes for source inspection, direction exposure, quotient readback, stability comparison, linear-response handoff, and Real-seal consumption;*
10. *P is the* Pkg *provenance over* $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$, $\mathsf{GateauxDerivative}^{\uparrow}$, $\mathsf{FrechetDerivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HadamardDirectionalDerivative}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through the displayed rows $X, A, V, Q, L, S, R, H, C, P, N$.

Theorem 7621.2 (Hadamard directional derivative NameCert obligations)**.** *For the carrier of Definition 7621.1, the local* $\mathsf{NameCert}_{\mathsf{HadamardDirectionalDerivative}^{\uparrow}}$ *surface consists of carrier admission, direction-window exposure, finite quotient scheduling, perturbation stability, linear-response handoff, classifier stability, and non-escape for the same finite packet $D = (X, A, V, Q, L, S, R, H, C, P, N)$. Direction-window exposure requires V before any quotient read. Finite quotient scheduling requires every inspected step and perturbed direction to be listed in Q. Perturbation stability requires the comparison row S to keep the quotient reads attached to L and R. The non-escape clause excludes host function equality, quotient germs, selected limits, unrestricted Frechet differentiability, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the displayed packet. Carrier admission exposes exactly the rows $X, A, V, Q, L, S, R, H, C, P, N$, so there is no hidden coordinate for a host derivative or a selected limiting value.

The direction-window and quotient clauses follow from the order of the carrier. The direction row V is displayed before Q, and Q is the only finite schedule from which quotient reads may be taken.

The stability and handoff clauses use S, L, R. The row S compares all listed perturbation reads against the same $\mathsf{LinMap}^{\uparrow}$ response L through the $\mathsf{Real}^{\uparrow}$ tolerance seal R.

Finally, H and C transport and replay only those rows. Thus a consumer asking for host function equality, quotient-germ equality, an unrestricted Frechet derivative, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness leaves the accepted packet. □

Theorem 7621.3 (Hadamard directional derivative finite-step stability)**.** *For every accepted* HadamardDirectionalD *carrier*

$$D = (X, A, V, Q, L, S, R, H, C, P, N),$$

each finite quotient read selected by Q is stable only along the displayed direction-window route

$$A, V, Q, L, S, R, H, C, P, N.$$

A $\mathsf{GateauxDerivative}^{\uparrow}$*-facing consumer may read the displayed directional value through V, Q, L, S, R, while a* $\mathsf{FrechetDerivative}^{\uparrow}$*-facing consumer must still supply a separate full linear-approximation packet. The Hadamard carrier itself exports no host derivative operator, no quotient germ, no selected limit, and no ambient completeness theorem.*

Proof. Begin with the finite quotient schedule Q. Its entries are admitted only after the base window A and the direction window V have been displayed.

Apply the NameCert obligations. They attach every quotient read to the stability row S, the linear response L, and the Real tolerance seal R.

The transport and replay rows H and C preserve that same finite route under accepted consumer motion. Provenance and local naming, P and N, record the route without adding derivative data.

Therefore the packet supplies a stable Hadamard directional read for $\mathsf{GateauxDerivative}^{\uparrow}$-style consumers, but it does not by itself provide the global linear approximation required by $\mathsf{FrechetDerivative}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ packet must expose a direction window, a finite quotient schedule, a perturbation-stability row, and a $\mathsf{Real}^{\uparrow}$ tolerance seal before any directional derivative read is public.

Independence witness: Nearest siblings: gateaux-derivative, frechet-derivative, continuousmap, linearmap, real. The carrier is not bijective to GateauxDerivativeUp because it carries a perturbation-stability window; not to FrechetDerivativeUp because it does not require a full norm-linear approximation over all directions; not to ContinuousMapUp because it adds quotient and derivative rows; not to LinearMapUp because it is a directional derivative certificate; not to RealUp because it keeps the source, direction, quotient, transport, replay, provenance, and naming rows visible.

Closure status for $\mathsf{NameCert}_{\mathsf{HadamardDirectionalDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{HadamardDirectionalDerivative}^{\uparrow}$ packet is generated from a continuous-map source row, a base-point window, a displayed direction window, finite quotient schedules, a LinearMap response row, a perturbation-stability row, a RealUp tolerance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HadamardDirectionalDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7621.1, Definition 7621.2, Definition 7621.3, the falsifiable prediction, and the independence witness bind the seed surface for Hadamard directional derivative reads between Gateaux and Frechet derivative packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HadamardDirectionalDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, host function equality, quotient germs, selected limits, unrestricted Frechet differentiability, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, direction-window exposure, finite quotient scheduling, perturbation stability, linear-response handoff, classifier stability, non-escape, provenance, and TasteGate alignment for the same finite packet.

Chapter 7622

A Concrete Naming Certificate for $\mathsf{MoreauEnvelope}^{\uparrow}$

Following Moreau's envelope construction, Rockafellar's convex-analysis account of infimal convolution, and Boyd–Vandenberghe's proximal-operator presentation, the $\mathsf{MoreauEnvelope}^{\uparrow}$ packet records the finite lower-envelope surface for a convex functional after a quadratic penalty has been displayed. It sits beside the conjugacy route of chapter 3563, the subgradient support ledger of chapter 3712, the proximal candidate route of chapter 3713, the real seal of chapter 38, and the norm source of chapter 89. The packet lets proximal and Fenchel consumers cite one finite envelope certificate without asserting selected minimizers, host suprema, quotient function equality, Hilbert projection theorems, or ambient completeness.

7622.1 Moreau Envelope Carrier

Definition 7622.1 (Moreau envelope carrier)**.** *A* $\mathsf{MoreauEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, \lambda, x, Y, Q, V, L, A, G, H, C, P, N)$$

with the following visible rows:

1. *X is the normed source row, read through* $\mathsf{Norm}^{\uparrow}$ *and the scalar seal of* $\mathsf{Real}^{\uparrow}$*.*
2. *F is the convex functional row, including the displayed convex-domain, epigraph, and conjugacy surfaces used by the request.*
3. *λ is the positive regularization-scale row carried as displayed real data.*
4. *x is the input point row in the source carrier.*
5. *Y is the finite comparison-window row listing the displayed candidate points inspected by the envelope request.*
6. *Q is the quadratic-penalty ledger recording the visible values $\frac{1}{2\lambda}\|y - x\|^2$ for y in Y.*
7. *V is the value ledger recording the displayed sums $F(y) + \frac{1}{2\lambda}\|y - x\|^2$ after both the functional and penalty rows have been read.*
8. *L is the lower-envelope budget row recording the finite lower comparison available to the packet; it is a BEDC ledger row, not a host infimum operator.*

9. *A is the proximal-candidate handoff row, read only when a displayed* $\mathsf{ProximalMap}^{\uparrow}$ *packet supplies a candidate compatible with the same $X, F, \lambda, x, Q, V, L$ rows.*

10. *G is the convex-conjugate and subdifferential handoff row, read through* $\mathsf{ConvexConjugate}^{\uparrow}$ *and* $\mathsf{Subdifferential}^{\uparrow}$ *after the envelope comparison rows have been displayed.*

11. *H records componentwise* hsame *transport for the source, functional, scale, input, comparison window, penalty, value, lower-envelope budget, proximal handoff, conjugacy handoff, replay, provenance, and local naming rows.*

12. *C records displayed* Cont *replay from an envelope request through norm evaluation, real penalty readback, convex-functional comparison, proximal handoff, and conjugacy or subgradient consumers.*

13. *P is the* Pkg *provenance over* $\mathsf{MoreauEnvelope}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{Subdifferential}^{\uparrow}$, $\mathsf{ProximalMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{MoreauEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, \lambda, x, Y, Q, V, L, A, G, H, C, P, N$. It has no coordinate for selected minimizers, host suprema, quotient function equality, Hilbert projection theorems, lower-semicontinuity existence theorems, or ambient completeness.

7622.2 Moreau Envelope Certificate

Theorem 7622.2 (Moreau envelope NameCert obligations)**.** *For every accepted* $\mathsf{MoreauEnvelope}^{\uparrow}$ *carrier $M = (X, F, \lambda, x, Y, Q, V, L, A, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MoreauEnvelope}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the normed source, convex functional, positive scale, input point, comparison window, quadratic penalty, value ledger, lower-envelope budget, proximal handoff, conjugacy handoff, transport, replay, provenance, and local naming rows;*

2. *penalty exactness, requiring every envelope comparison to read the same* $\mathsf{Norm}^{\uparrow}$ *source row,* $\mathsf{Real}^{\uparrow}$ *scalar row, scale row λ, and input row x before the penalty row Q is public;*

3. *value-ledger exactness, requiring each displayed value in V to be formed from the same functional row F and penalty row Q for a comparison point listed in Y;*

4. *lower-envelope nonescape, requiring the budget row L to remain a displayed finite ledger rather than a host infimum or host supremum;*

5. *proximal handoff compatibility, requiring any* $\mathsf{ProximalMap}^{\uparrow}$ *consumer to read the same $X, F, \lambda, x, Q, V, L$ rows before it treats a displayed candidate as an envelope witness;*

6. *conjugacy and subgradient compatibility, requiring Fenchel or subdifferential consumers to pass through* $\mathsf{ConvexConjugate}^{\uparrow}$ *and* $\mathsf{Subdifferential}^{\uparrow}$ *only after the envelope comparison rows have been displayed.*

Proof. Project the accepted carrier. The rows $X, F, \lambda, x, Y, Q, V, L, A, G$ are the entire envelope surface, and the rows H, C, P, N are the entire structural route that transports, replays, sources, and names that same packet.

Penalty exactness is read first. A comparison point in Y contributes to the envelope request only after the normed source, scalar seal, scale, input, and quadratic penalty value have all been displayed in X, λ, x, Q.

The value ledger is then forced by F, Q, V. Because V records only the displayed sums for listed comparison points, a consumer cannot replace the finite comparison window by a host function space or a quotient-function equality claim.

Finally read L, A, G, H, C, P, N. The row L is a finite lower-envelope budget, A is downstream of the proximal packet, and G is downstream of conjugacy and subgradient packets. Since no carrier coordinate stores a selected minimizer, host supremum, Hilbert projection theorem, or ambient completeness principle, none of those objects can be exported by the local certificate. □

Theorem 7622.3 (Moreau envelope proximal-real route)**.** *Every proximal, Fenchel, or real-valued optimization consumer of an accepted* $\mathsf{MoreauEnvelope}^{\uparrow}$ *packet must factor through the finite route*

$$X, F, \lambda, x, Y, Q, V, L, A, G \longmapsto H, C, P, N.$$

The consumer may read an envelope value only after the norm row, real scalar seal, convex-functional row, finite comparison window, quadratic-penalty ledger, value ledger, lower-envelope budget, and proximal or conjugacy handoff have all been displayed. It receives no selected minimizer, host supremum, quotient function equality, Hilbert projection theorem, or ambient completeness principle.

Proof. Begin with the real-valued read. The row Q supplies the only quadratic penalty values, and those values are available only through the $\mathsf{Norm}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ rows named by X and λ.

Next inspect the envelope comparison. The row V combines the displayed convex-functional values with the displayed penalty values for the finite window Y, while L records the lower-envelope budget available to the packet.

Now route downstream consumers. A proximal read must pass through A and the $\mathsf{ProximalMap}^{\uparrow}$ packet before a candidate can be treated as compatible with the envelope rows. A Fenchel or subgradient read must pass through G and the $\mathsf{ConvexConjugate}^{\uparrow}$ or $\mathsf{Subdifferential}^{\uparrow}$ rows after the same comparison data have been exposed.

The structural rows H, C, P, N preserve exactly this route. They add no selected minimizer, host supremum, quotient equality of functions, Hilbert projection semantics, or ambient completeness, so the handoff stops at the displayed proximal-real envelope boundary. □

Falsifiable prediction: Every accepted $\mathsf{MoreauEnvelope}^{\uparrow}$ consumer read factors through a NormUp source, RealUp scale and value rows, ConvexConjugateUp and SubdifferentialUp handoff rows when dual data are requested, a ProximalMapUp candidate route when a proximal witness is requested, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: convex-conjugate, subdifferential, proximal-map, real, norm: $\mathsf{MoreauEnvelope}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source row, functional row, positive scale, input, comparison window, quadratic penalty ledger, value ledger, lower-envelope budget, proximal handoff, conjugacy handoff, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MoreauEnvelope}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MoreauEnvelope}^{\uparrow}$ packet is generated from a normed source row, convex functional row, positive real scale, input point, finite comparison window, quadratic penalty values, displayed value ledger, lower-envelope budget, proximal handoff, convex-conjugate and subdifferential handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MoreauEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7622.1, Definition 7622.2, and Definition 7622.3 seed the finite Moreau-envelope certificate surface over proximal, convex-conjugate, subdifferential, real, and norm rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{MoreauEnvelope}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected minimizers, host suprema, quotient function equality, Hilbert projection theorems, lower-semicontinuity existence theorems, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, penalty exactness, value-ledger exactness, lower-envelope nonescape, proximal handoff compatibility, conjugacy and subgradient compatibility, transport, replay, provenance, and local naming for BEDC.Derived.MoreauEnvelopeUp.

Chapter 7623

A Concrete Naming Certificate for $\mathsf{MirrorDescent}^{\uparrow}$

Following Nemirovski and Yudin, Beck and Teboulle, and Bubeck, the $\mathsf{MirrorDescent}^{\uparrow}$ packet records mirror descent as finite convex-dual NameCert data. It sits after the feasible convex source of chapter 208, the convex-conjugate ledger of chapter 3563, the Fenchel-duality route of chapter 321, the proximal-map handoff of chapter 3713, and the linear-programming duality certificate of chapter 235. The chapter names the mirror update as displayed convex optimization data; it does not import Hilbert projection, quotient equality of iterates, a host minimizer choice, or a selected limiting point.

Definition 7623.1 (MirrorDescent carrier)**.** *A* $\mathsf{MirrorDescent}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, D, B, G, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the feasible convex row read through the* $\mathsf{ConvexSet}^{\uparrow}$ *surface.*
2. *F is the mirror potential row whose conjugate and subgradient-facing data are read through* $\mathsf{ConvexConjugate}^{\uparrow}$*.*
3. *D is the dual-gradient row carrying the finite dual read used by the update.*
4. *B is the Bregman transport row comparing the old primal row, the dual-gradient row, and the transported next-row candidate.*
5. *G is the step ledger, listing the displayed step size, tolerance, and update cell consumed by the route.*
6. *S is the descent certificate row produced only after X, F, D, B, G have been displayed.*
7. *H records componentwise* hsame *transport for the feasible row, mirror potential, dual-gradient data, Bregman transport, step ledger, descent certificate, provenance, and local naming row.*
8. *C records the displayed* Cont *replay from the feasible row to the mirror potential, from the mirror potential to the dual-gradient row, from the Bregman row to the step ledger, and from the step ledger to the descent certificate.*
9. *P is the* Pkg *provenance over* $\mathsf{MirrorDescent}^{\uparrow}$*,* $\mathsf{ConvexSet}^{\uparrow}$*,* $\mathsf{ConvexConjugate}^{\uparrow}$*,* $\mathsf{FenchelDuality}^{\uparrow}$*,* $\mathsf{ProximalMap}^{\uparrow}$*,* $\mathsf{LPDuality}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MirrorDescent}^\uparrow}$ *row.*
The carrier has no coordinate for Hilbert projection, a host-selected minimizer, quotient equality of iterates, countable choice, selected limits, global optimizer existence, or an ambient convergence theorem.

Theorem 7623.2 (MirrorDescent NameCert obligations)**.** *For every accepted* $\mathsf{MirrorDescent}^\uparrow$ *carrier* $M = (X, F, D, B, G, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MirrorDescent}^\uparrow}$ *surface consists exactly of carrier admission for the displayed tuple, classifier transport over* $X, F, D, B, G, S, H, C, P, N$*, Bregman transport stability through* B *and* H*, Fenchel-dual compatibility through* F, D *and the* $\mathsf{FenchelDuality}^\uparrow$ *provenance row, step-ledger nonescape through* G*, descent-certificate handoff through* S*, displayed replay through* C*, dependency provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The feasible convex row, mirror potential, dual-gradient data, Bregman transport row, step ledger, and descent certificate are the only analytic coordinates.

Classifier transport is componentwise through H. Bregman stability can compare only the displayed rows X, F, D, B, G, S, and the replay row C fixes the order in which these rows are consumed.

Fenchel-dual compatibility is read from the same provenance route. The $\mathsf{ConvexConjugate}^\uparrow$, $\mathsf{FenchelDuality}^\uparrow$, $\mathsf{ProximalMap}^\uparrow$, and $\mathsf{LPDuality}^\uparrow$ rows named by P supply the finite convex-dual ledgers, while G and S keep the step and descent handoff inside the packet.

Since no carrier coordinate stores Hilbert projection, a host minimizer, quotient equality, selected limits, global optimizer existence, or an ambient convergence theorem, none of those objects can be exported by the local NameCert surface. □

Theorem 7623.3 (MirrorDescent Bregman transport certificate)**.** *Every mirror update read from an accepted* $\mathsf{MirrorDescent}^\uparrow$ *packet consumes the* $\mathsf{ConvexSet}^\uparrow$ *feasible row,* $\mathsf{ConvexConjugate}^\uparrow$ *mirror-potential row,* $\mathsf{FenchelDuality}^\uparrow$ *dual-compatibility row,* $\mathsf{ProximalMap}^\uparrow$ *update handoff, and* $\mathsf{LPDuality}^\uparrow$ *dual ledger through the displayed packet*

$$X \longrightarrow F \longrightarrow D \longrightarrow B \longrightarrow G \longrightarrow S.$$

The route is a Bregman transport certificate over finite BEDC rows, not a Hilbert projection, host minimizer choice, quotient equality of iterates, or selected limiting argument.

Proof. Start from Definition 7623.1. The feasible row X is the only source row, and the mirror potential and dual-gradient rows F, D are displayed before the Bregman row B can be read.

Apply Definition 7623.2. Bregman transport stability and Fenchel-dual compatibility are obligations of the same carrier, with the replay row C ordering the read through X, F, D, B, G, S.

The proximal and linear-dual surfaces enter only as provenance rows. They certify that the update handoff and dual ledger have been read as finite dependency data, while the step ledger G and descent row S remain inside the displayed packet.

Thus the mirror update route consumes the convex, conjugate, Fenchel-dual, proximal, and linear-dual rows without adding Hilbert projection, host minimizer choice, quotient equality, or a selected limit. □

Closure status for $\mathsf{NameCert}_{\mathsf{MirrorDescent}^\uparrow}$**.**

Constructive story: A $\mathsf{MirrorDescent}^\uparrow$ packet is generated from feasible convex data, a mirror-potential row, dual-gradient data, Bregman transport, a step ledger, a descent certificate, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MirrorDescent}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 7623.1, Definition 7623.2, and Definition 7623.3 seed the finite convex-dual mirror update route.

Formal verification: FormalStatus(NameCert$_{\mathsf{MirrorDescent}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim convergence rates, global optimizer existence, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, Bregman transport stability, Fenchel-dual compatibility, step-ledger nonescape, descent-certificate handoff, replay, provenance, and local naming for BEDC.Derived.MirrorDescentUp.

Chapter 7624

A Concrete Naming Certificate for $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$

The $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ packet realizes the observer-expansion branch of chapter 9463 as a finite ledger that places Busemann, visual-shadow, boundary, metric, observer-window, transport, provenance, and local naming rows on one route. It sits after the cross-ratio boundary comparison of chapter 3948, the geodesic-lamination surface of chapter 4203, the Patterson–Sullivan shadow packet of chapter 6070, the visual-metric certificate of chapter 3866, and the Busemann-boundary certificate of chapter 3732. The packet names a finite horoball-shadow ledger; it is not a quotient ideal boundary, a selected geodesic ray, a completed conformal density, an ambient hyperbolic group action, a physical observer trajectory, or a global measure construction.

Definition 7624.1 (Hyperbolic horoball-shadow ledger carrier)**.** *A* $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (B, V, W, M, O, X, L, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row recording the horoball threshold and boundary-level Busemann read.*
2. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row recording the visible shadow metric used by the boundary read.*
3. *W is the visual-shadow window row, tying the Busemann threshold and visual metric to a finite aperture.*
4. *M is the metric comparison row that keeps the horoball threshold attached to displayed hyperbolic distance data.*
5. *O is the observer-window row recording the finite observer-expansion read that consumes the shadow.*
6. *X is the cross-ratio and lamination sibling row, recording the boundary comparison route through* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *and* $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ *when those rows are present.*
7. *L is the Patterson–Sullivan shadow sibling row, recording the counting and boundary-weight ledger consumed by the same shadow aperture when present.*

8. *T is the refusal row excluding quotient ideal-boundary equality, selected rays, completed conformal densities, host group actions, physical observer trajectories, and unlogged global measures.*
9. *H records componentwise* hsame *transport for $B, V, W, M, O, X, L, T, C, P, N$.*
10. *C records displayed* Cont *replay through Busemann readback, visual-shadow exposure, metric comparison, observer-window routing, sibling ledger rows, refusal, transport, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$, HyperbolicPattersonSullivanShad BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, V, W, M, O, X, L, T, H, C, P, N$.

Theorem 7624.2 (Hyperbolic horoball-shadow ledger NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ *carrier $Z = (B, V, W, M, O, X, L, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}}$ *surface consists exactly of Busemann-boundary admission through B; visual-shadow metric exposure through V, W; metric comparison through M; observer-window exposure through O; cross-ratio and geodesic-lamination sibling exposure through X; Patterson–Sullivan sibling exposure through L; refusal exactness through T; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7624.1. The displayed tuple exposes the Busemann row, visual metric row, shadow window, metric comparison, observer window, sibling rows, refusal row, and structural rows.

Read the geometric rows first. Rows B, V, W, M, O bind the horoball threshold, visual-shadow metric, finite aperture, metric comparison, and observer-window route to one finite ledger.

The sibling rows X, L then record the boundary comparison, lamination, and Patterson–Sullivan shadow routes without replacing the local carrier. Finally T, H, C, P, N refuse unlogged host geometry, transport the displayed fields, replay the route, record provenance, and name the packet. No further NameCert obligation is stored outside these rows. □

Theorem 7624.3 (Hyperbolic horoball-shadow ledger sibling independence)**.** *The* HyperbolicHoroballShadowLedge *packet is not bijective to any one of the cross-ratio, geodesic-lamination, Patterson–Sullivan shadow, visual-metric, or Busemann-boundary sibling packets. Each sibling may supply one row of Z, but the accepted ledger requires the joint Busemann threshold, visual-shadow window, metric comparison, observer-window route, sibling ledger rows, refusal row, transport, replay, provenance, and local naming.*

Proof. Compare the carrier fields. A $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ packet supplies boundary comparison data but not the Busemann threshold, observer window, or Patterson–Sullivan ledger row. A $\mathsf{HyperbolicGeodesicLamination}^{\uparrow}$ packet supplies lamination data but not the horoball threshold or visual-shadow aperture.

The $\mathsf{HyperbolicPattersonSullivanShadow}^{\uparrow}$ sibling supplies a counting and boundary-weight route, while $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ and $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ supply visual and Busemann rows. None of those packets alone contains all rows $B, V, W, M, O, X, L, T, H, C, P, N$.

Therefore each sibling is a dependency row rather than a replacement carrier, and no listed sibling is bijective to the accepted horoball-shadow ledger. □

Theorem 7624.4 (Hyperbolic horoball-shadow ledger observer-window nonescape)**.** *Every observer-expansion consumer of an accepted* $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ *packet must read the Busemann row* B*, visual-shadow rows* V, W*, metric row* M*, observer-window row* O*, and sibling ledger rows* X, L *before it can use the structural rows* H, C, P, N*. Consequently the packet exports no quotient ideal-boundary equality, selected geodesic ray, completed conformal density, ambient hyperbolic group action, physical observer trajectory, or global measure construction.*

Proof. Start with the observer-expansion consumer. Projection of Z gives the finite route through B, V, W, M, O, X, L before the structural rows are available.

The refusal row T is part of the same route. It blocks interpretations that replace the displayed horoball-shadow ledger by quotient boundary equality, selected rays, conformal densities, host group actions, physical trajectories, or global measures.

Rows H, C, P, N then transport, replay, source, and name only the displayed ledger. Since none of those rows adds a hidden geometry coordinate, the consumer cannot escape the finite observer-window surface. □

Falsifiable prediction: Any accepted $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ packet that omits the Busemann threshold row, the visual-shadow window row, or the observer-window row fails to produce the observer-window nonescape route of Definition 7624.4.

Independence witness: hyperbolic-cross-ratio, hyperbolic-geodesic-lamination, hyperbolic-patterson-sullivan-shadow, hyperbolic-visual-metric, hyperbolic-busemann-boundary: no listed sibling is bijective to $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ because the ledger jointly carries Busemann threshold, visual-shadow aperture, metric comparison, observer-window, sibling ledger, refusal, transport, replay, provenance, and local NameCert rows.

The future Lean TasteGate route must provide explicit $\mathsf{Nontrivial}\ \mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ instances in `lean4/BEDC/Derived/HyperbolicHoroballShado`
Those instances must preserve $B, V, W, M, O, X, L, T, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}$ packet is generated from Busemann-boundary rows, visual-shadow metric rows, a finite shadow window, metric comparison rows, an observer-window route, cross-ratio and geodesic-lamination sibling rows, a Patterson–Sullivan shadow sibling row, refusal exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7624.1, Definition 7624.2, Definition 7624.3, and Definition 7624.4 seed the finite horoball-shadow ledger through Busemann, visual-shadow, metric, observer-window, sibling, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroballShadowLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient ideal-boundary equality, selected geodesic rays, completed conformal densities, ambient hyperbolic group actions, physical observer trajectories, global measure constructions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Busemann exposure, visual-shadow exposure, metric comparison, observer-window nonescape, sibling independence, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicHoroballShadowLedgerUp.

Chapter 7625

A Concrete Naming Certificate for $\mathsf{EilenbergZilber}^{\uparrow}$

Following Eilenberg and Zilber, the $\mathsf{EilenbergZilber}^{\uparrow}$ packet records the finite chain-level comparison between the product of simplicial objects and the tensor product of their chain rows. It sits after the categorical source surface of chapter 61, the functorial transport surface of chapter 62, the face-and-degeneracy ledger of chapter 157, the homology consumer of chapter 98, the bilinear source row of chapter 87, and the finite product carrier of chapter 34. The packet names shuffle, Alexander–Whitney, boundary, chain-homotopy, transport, replay, provenance, and local naming rows; it does not choose simplices, quotient chain representatives, a host homotopy equivalence, unrestricted naturality, or ambient homological algebra.

Definition 7625.1 (Eilenberg-Zilber carrier)**.** *An* $\mathsf{EilenbergZilber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (C, F, S, H, T, P, B, A, W, R, Q, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Cat}^{\uparrow}$ *source row naming the finite chain-category and product-category readings used by the packet.*
2. *F is the* $\mathsf{Functor}^{\uparrow}$ *transport row carrying the chain functor readings from simplicial data to chain data.*
3. *S is the* $\mathsf{SimplicialSet}^{\uparrow}$ *row recording the finite face, degeneracy, and product-simplex windows inspected by the consumer.*
4. *H is the* $\mathsf{Homology}^{\uparrow}$ *boundary-consumer row that may be read only after the chain-level comparison rows have been displayed.*
5. *T is the* $\mathsf{TensorProduct}^{\uparrow}$ *row naming the tensor product of the two displayed chain rows.*
6. *P is the* $\mathsf{Prod}^{\uparrow}$ *row naming the product simplicial source before any tensor comparison is exported.*
7. *B records the boundary-compatibility ledger for the displayed shuffle and Alexander–Whitney rows.*
8. *A records the Alexander–Whitney projection row from the product-chain window to the tensor-chain window.*

9. *W records the shuffle row from the tensor-chain window back to the product-chain window.*
10. *R records componentwise* hsame *transport for categorical, functorial, simplicial, homology, tensor, product, boundary, comparison, provenance, and local naming rows.*
11. *Q records displayed* Cont *replay from a product-simplex request through the product, simplicial, functorial, tensor, boundary, and homology rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{EilenbergZilber}^{\uparrow}}$ *row.*

No coordinate stores a selected simplex representative, quotient chain equality, host chain-homotopy equivalence, unrestricted naturality theorem, or ambient homological-algebra principle.

Lean4 (statement) BEDC.Derived.EilenbergZilberUp

Theorem 7625.2 (Eilenberg-Zilber NameCert obligations)**.** *For every accepted* $\mathsf{EilenbergZilber}^{\uparrow}$ *carrier* $Z = (C, F, S, H, T, P, B, A, W, R, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EilenbergZilber}^{\uparrow}}$ *surface consists exactly of carrier admission, product-source display, simplicial face-and-degeneracy display, functorial chain transport, tensor readback, boundary compatibility, Alexander–Whitney route, shuffle route, chain-homotopy ledger, componentwise transport, displayed replay, and local naming. Every homology-facing consumer reads the* $\mathsf{Homology}^{\uparrow}$ *row only through these finite rows.*

Proof. Project the carrier of Definition 7625.1. The displayed tuple lists the categorical, functorial, simplicial, homology, tensor, product, boundary, comparison, transport, replay, and local naming rows.

The product-source display is forced by P and S. A consumer first reads the finite product and simplicial windows before the functor row F can expose chain data.

The tensor readback then passes through T, while A and W record the two comparison directions. Boundary compatibility is confined to B, and chain-homotopy evidence is read only as a ledger row attached to the displayed comparison data.

Finally R, Q, N transport, replay, and name the same packet. Since the carrier has no coordinate for selected simplices, quotient chain equality, host equivalence, unrestricted naturality, or ambient homological algebra, the listed rows exhaust the local NameCert obligations. □

Theorem 7625.3 (Eilenberg-Zilber chain-homotopy route)**.** *Let* $Z = (C, F, S, H, T, P, B, A, W, R, Q, N)$ *be an accepted* $\mathsf{EilenbergZilber}^{\uparrow}$ *carrier. Every chain-homotopy-facing consumer of* Z *factors through the finite route*

$$P \longmapsto S \longmapsto F \longmapsto T \longmapsto A, W \longmapsto B \longmapsto H \longmapsto R, Q, N.$$

Consequently the consumer receives the product-simplex row, the simplicial face-and-degeneracy row, the functorial chain row, the tensor row, the comparison rows, and the boundary ledger before any homology-facing reading is exported.

Proof. Begin with a chain-homotopy-facing request. Carrier admission exposes H only as a downstream row of the finite packet, not as a detached homology assertion.

Replay Q. The request first reads the product row P and the simplicial row S, then uses the functorial transport row F to reach the chain surface.

The tensor row T is consumed before the comparison rows A, W. Boundary compatibility is then checked by B, so the chain-homotopy ledger is attached to displayed chain data rather than to an ambient quotient object.

Only after these rows have been replayed can the consumer read H. The transport and naming rows R, Q, N preserve the same route, so no host chain-homotopy equivalence or unrestricted naturality theorem is exported. □

Falsifiable prediction: Every accepted $\mathsf{EilenbergZilber}^{\uparrow}$ read displays CategoryUp, FunctorUp, SimplicialSetUp, TensorProductUp, ProdUp, boundary, Alexander–Whitney, shuffle, transport, replay, and local naming rows before a HomologyUp consumer obtains a chain-homotopy-facing row.

Independence witness: category, functor, simplicialset, homology, tensorproduct, prod: $\mathsf{EilenbergZilber}^{\uparrow}$ is not bijective to any listed sibling because it packages the finite comparison route between product simplicial chains and tensor chains, while each sibling supplies only one source, transport, consumer, tensor, or product surface.

Closure status for $\mathsf{NameCert}_{\mathsf{EilenbergZilber}^{\uparrow}}$.

Constructive story: An $\mathsf{EilenbergZilber}^{\uparrow}$ packet is generated from displayed CategoryUp and FunctorUp rows, finite SimplicialSetUp product windows, TensorProductUp and ProdUp source rows, boundary compatibility, Alexander–Whitney and shuffle comparison rows, chain-homotopy ledger data, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EilenbergZilber}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7625.1, Definition 7625.2, and Definition 7625.3 seed the finite chain-homotopy comparison surface between product simplicial data and tensor-chain homology consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EilenbergZilber}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected simplex representatives, quotient chain equality, host chain-homotopy equivalence, unrestricted naturality, ambient homological algebra, bridge checking, or Lean theorem verification.

Upgrade path: Obligation closure requires checked carrier admission, product-source display, tensor readback, boundary compatibility, Alexander–Whitney and shuffle route exactness, chain-homotopy ledger, and local NameCert proofs for BEDC.Derived.EilenbergZilberUp.

Chapter 7626

A Concrete Naming Certificate for $\mathsf{UniformCompletionUniqueness}^{\uparrow}$

Following Bishop–Bridges constructive completion and Kelley uniform-space completion, the UniformCompletionUni packet records the finite NameCert surface where two uniform-completion presentations over the same displayed uniform source may be compared. It sits after the uniform source of chapter 339, the uniform completion boundary of chapter 1473, the Cauchy-filter route of chapter 333, the separated comparison ledger of chapter 1463, the metric-completion comparison of chapter 1506, the finite StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the terminal Real seal of chapter 38. The packet names uniqueness as finite routed comparison data rather than as quotient-completion equality, selected limits, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7626.1 (Uniform completion uniqueness carrier)**.** *A* $\mathsf{UniformCompletionUniqueness}^{\uparrow}$ *carrier is a finite packet*

$$K = (U, C, F, S, M, R, E, H, T, P, N)$$

with the following displayed rows.

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row, exposing the entourage ledger and separatedness data read by both completion presentations.*
2. *C stores the two* $\mathsf{UniformCompletion}^{\uparrow}$ *presentation rows over the same displayed source.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *route by which each presentation reads uniform Cauchy data.*
4. *S is the separated comparison row, read through* $\mathsf{CompletionUniqueness}^{\uparrow}$ *after the two presentations and the Cauchy-filter route have been displayed.*
5. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *comparison row used only as a metric handoff for consumers that enter through metric completion.*
6. *R is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row visible before regular readback.*
7. *E combines the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row and terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from the same finite windows.*
8. *H records componentwise* hsame *transport for U, C, F, S, M, R, E.*
9. *T records displayed* Cont *replay from the uniform source through the two presentations, Cauchy-filter route, separated comparison, metric handoff, finite windows, readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformCompletionUniqueness}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, C, F, S, M, R, E, H, T, P, N$. It has no coordinate for quotient-completion equality, selected limits, countable choice, host equality of completed points, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.UniformCompletionUniquenessUp.TasteGate.UniformCompletionUniquenessTasteGate`
`single carrier alignment`

Theorem 7626.2 (Uniform completion uniqueness NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompletionUniqueness}^{\uparrow}$ *carrier $K = (U, C, F, S, M, R, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionUnique}}$ *surface consists exactly of carrier admission for the uniform source row, two uniform-completion presentation rows, Cauchy-filter route, separated comparison row, metric-completion comparison row, StreamName windows, RegSeqRat readback and Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7626.1. The comparison data are the uniform source U, the two presentation rows in C, the Cauchy-filter route F, and the separated comparison row S.

The metric and Real-facing rows are downstream handoffs. Row M lets metric-completion consumers enter the same comparison surface, while R and E expose finite windows, regular readback, and the terminal Real seal.

Finally H, T, P, N transport, replay, source, and name exactly those rows. Since the carrier contains no quotient-completion equality, selected limit, countable-choice schedule, host equality, or ambient completeness row, none of those objects is a local NameCert obligation. □

Theorem 7626.3 (Uniform completion uniqueness separated comparison)**.** *Every uniqueness-facing comparison exported by an accepted* $\mathsf{UniformCompletionUniqueness}^{\uparrow}$ *packet first reads the common* $\mathsf{UniformSpace}^{\uparrow}$ *source row U, the two* $\mathsf{UniformCompletion}^{\uparrow}$ *presentation rows C, the* $\mathsf{CauchyFilter}^{\uparrow}$ *route F, and then the separated comparison row S through* $\mathsf{CompletionUniqueness}^{\uparrow}$. *The comparison is therefore a finite separated-comparison route, not a quotient-completion equality or host equality of completed points.*

Proof. Start with Definition 7626.2. It orders carrier admission through the source, presentation, Cauchy-filter, and separated comparison rows before any downstream handoff can be read.

Read the separated comparison row S. Its role is to compare the two displayed completion presentations after the shared uniform Cauchy route is visible, so it cannot be replaced by equality of quotient representatives.

The structural rows H, T, P, N preserve and replay that order. Thus every uniqueness-facing consumer receives a displayed separated comparison and no host equality witness. □

Theorem 7626.4 (Uniform completion uniqueness Real metric handoff)**.** *Every metric-facing or Real-facing consumer of an accepted* $\mathsf{UniformCompletionUniqueness}^{\uparrow}$ *packet factors through the same comparison route*

$\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CompletionUniqueness}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Re

The handoff exposes the metric-completion comparison row, finite StreamName windows, RegSeqRat readback, terminal Real seal, componentwise transport, replay, provenance, and local naming,

but it does not export selected limits, quotient completion equality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 7626.3. The metric-facing and Real-facing reads cannot reach M, R, E until the common uniform source, the two completion presentations, the Cauchy-filter route, and the separated comparison row have been displayed.

The row M is only a comparison handoff for metric-completion consumers. Rows R and E then expose finite windows, regular rational readback, and the Real seal attached to the same comparison route.

Use Definition 7626.2 for the structural rows. Since transport, replay, provenance, and local naming preserve the same finite route and the excluded objects are absent from the carrier, the handoff remains inside the displayed NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionUniqueness}^{\uparrow}$ packet is generated from a UniformSpace source row, two UniformCompletion presentation rows, a CauchyFilter route, separated CompletionUniqueness comparison, MetricCompletion comparison, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7626.1, Definition 7626.2, Definition 7626.3, and Definition 7626.4 seed the finite uniform-completion uniqueness route from uniform Cauchy data through separated comparison and metric or Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, two-presentation order, Cauchy-filter route exactness, separated comparison, metric and Real handoff, transport replay, provenance non-escape, and local naming for BEDC.Derived.UniformCompletionUniquenessUp.

Chapter 7627

A Concrete Naming Certificate for $\mathsf{FiniteRealPicardIteration}^{\uparrow}$

Following Picard and Bishop–Bridges constructive metric iteration, the $\mathsf{FiniteRealPicardIteration}^{\uparrow}$ packet records the finite Real-facing Picard window used before a contraction, completion, or fixed-point consumer may read a terminal real-name seal. It sits over the broader Picard iteration surface of chapter 2359, the contraction-real modulus row of chapter 7615, the finite completion handoff of chapter 1559, the Bishop comparison route of chapter 1508, and the real-completion spine of chapter 291, chapter 126, chapter 301, and chapter 38. The packet is a finite iteration certificate; it is not a proof of Banach fixed-point existence, quotient equality of Picard streams, a selected limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7627.1 (FiniteRealPicardIteration carrier)**.** *A* $\mathsf{FiniteRealPicardIteration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, F, D, W, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Real}^{\uparrow}$ *seal row naming the initial real or real-window datum from which the finite Picard run starts.*
2. *F is the contractive self-map row, carrying the displayed graph reads and the contraction witness consumed by* $\mathsf{ContractionRealModulus}^{\uparrow}$ *or the Picard sibling route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *contraction budget row, recording the dyadic radius, contraction slack, and finite request schedule used for the window.*
4. *W is the finite iterate-window row. It lists the displayed iterates from the source row through the chosen finite height and records the successor reads of F.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the source, iterate, and terminal-name windows opened by W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same observations and dyadic budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after X, F, D, W, S, R have all been displayed.*
8. *H records componentwise* hsame *transport for the source seal, contractive map, dyadic budget, iterate window, stream observations, regular readback, terminal seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a Picard-window request through*

$$X, F, D, W, S \longmapsto R \longmapsto E \longmapsto H, Q, N.$$

10. *Q is the* Pkg *provenance over* FiniteRealPicardIteration$^{\uparrow}$, PicardIteration$^{\uparrow}$, ContractionRealModulus$^{\uparrow}$, MetricCompletionFinite$^{\uparrow}$, BishopCompletionComparison$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{FiniteRealPicardIteration}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, D, W, S, R, E, H, C, Q, N$. It has no coordinate for a completed Picard limit, fixed-point selection, quotient stream equality, countable-choice schedule, host function extensionality, ambient completeness of Real$^{\uparrow}$*, Lean verification, or bridge checking.*

Theorem 7627.2 (FiniteRealPicardIteration NameCert obligations)**.** *For every accepted* FiniteRealPicardIteration$^{\uparrow}$ *carrier*

$$P = (X, F, D, W, S, R, E, H, C, Q, N),$$

the local NameCert$_{\text{FiniteRealPicardIteration}^{\uparrow}}$ *surface consists exactly of source Real-seal admission, contractive-map exposure, dyadic contraction-budget exposure, finite iterate-window exposure, stream-window readback, regular rational readback, terminal Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier coordinates. The analytic rows are exactly the source seal X, contractive map row F, dyadic budget D, finite iterate window W, stream observations S, regular readback R, and terminal seal E.

The structural rows then preserve the same finite route. The transport row H moves each coordinate componentwise, while C replays only the displayed request path from the source seal through the iterate window and readback.

The provenance and local name rows Q, N source and name this packet inside the cited Picard, contraction, completion, dyadic, stream, regular-readback, and Real chapters. Since no other coordinate is present, the listed rows exhaust the NameCert obligation surface and the excluded limit, fixed-point, quotient, choice, extensionality, completeness, verification, and bridge data have no export path. □

Theorem 7627.3 (FiniteRealPicardIteration contractive window)**.** *Every contraction-facing or completion-facing consumer of an accepted* FiniteRealPicardIteration$^{\uparrow}$ *carrier must read the finite route*

$$X \longrightarrow F \longrightarrow D \longrightarrow W \longrightarrow S \longrightarrow R \longrightarrow E$$

before it may consume the terminal Real$^{\uparrow}$ *seal. The route exports a finite Picard-window certificate only; it does not export a completed fixed point, quotient equality of iterate streams, countable choice, host equality of maps, or an ambient completeness theorem.*

Proof. Start with the terminal seal request. The carrier definition places E after the source seal, contractive map, dyadic budget, finite iterate window, stream observations, and regular rational readback.

The contraction data are finite. The row F is read only against the displayed source row and the row D supplies the dyadic contraction budget for the finite height recorded by W.

The Real-facing handoff is downstream. The rows S and R expose the observed finite windows and regular rational readback before E is available, while H, C, Q, N transport, replay, source, and name the same route.

Thus every consumer receives only the finite Picard-window certificate. The absent fixed point, quotient stream equality, choice schedule, host map equality, and ambient completeness theorem cannot be recovered from the displayed packet. □

Theorem 7627.4 (FiniteRealPicardIteration Real seal nonescape)**.** *In every accepted* $\mathsf{FiniteRealPicardIteration}^{\uparrow}$ *carrier, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row E is a seal for the displayed finite route*

$$X, F, D, W, S, R, H, C, Q, N.$$

Any downstream Real or Completion consumer may cite E only as the endpoint of that route, and cannot detach it into ambient $\mathsf{Real}^{\uparrow}$ *completeness, host equality of completed reals, a selected Picard limit, or quotient equality of iterate streams.*

Proof. Read E from the carrier. It appears only after the finite Picard data X, F, D, W, S, R and is transported only through the componentwise row H.

Replay is equally local. The continuation row C repeats the same finite order of exposure, and the provenance and local naming rows Q, N record no further Real object.

Therefore the seal is terminal for the displayed finite packet. Since the carrier contains no coordinate for completeness, host equality, selected limits, or quotient stream equality, no consumer can detach E into one of those claims. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealPicardIteration}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteRealPicardIteration}^{\uparrow}$ packet is generated from a source Real seal, a contractive map row, a dyadic contraction budget, a finite Picard iterate window, StreamName observations, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteRealPicardIteration}^{\uparrow}}$, seed)

Scope closed: Definition 7627.1, Definition 7627.2, Definition 7627.3, and Definition 7627.4 seed the finite Picard-window route over Real, contraction, dyadic budget, StreamName, RegSeqRat, completion comparison, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteRealPicardIteration}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach fixed-point existence, completed Picard limits, quotient equality of iterate streams, countable choice, host function extensionality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contractive-map exposure, dyadic budget exactness, finite iterate-window replay, StreamName observation, RegSeqRat readback, Real-seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRealPicardIterationUp.

Chapter 7628

A Concrete Naming Certificate for $\mathsf{WeilUniformity}^{\uparrow}$

Following Weil and Kelley on the left and right uniformities of a topological group, the $\mathsf{WeilUniformity}^{\uparrow}$ packet records the finite BEDC surface on which the two entourage directions are read together. It sits between the entourage rows of chapter 339, the multiplication and inversion continuity rows of chapter 204, the open-neighbourhood source of chapter 88, and the completion-facing consumers of chapter 95 and chapter 2211. The packet explains why Raikov-style completion and topological-group completion require a two-sided uniformity surface rather than an anonymous uniform-space row.

Definition 7628.1 (Weil uniformity carrier)**.** *A* $\mathsf{WeilUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (G, T, U, L, R, M, I, C_L, C_R, Q, V, H, C, P, N)$$

with the following displayed rows:

1. *G is the underlying group-object row whose multiplication and unit are read only through the topological-group packet.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row supplying the open identity-neighbourhood requests.*
3. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row exposing finite entourage requests, diagonal rows, symmetry rows, and composition refinements.*
4. *L is the left-entourage ledger generated by rows of the form $x^{-1}y$ lying in a displayed identity neighbourhood.*
5. *R is the right-entourage ledger generated by rows of the form xy^{-1} lying in a displayed identity neighbourhood.*
6. *M records the* $\mathsf{TopGroup}^{\uparrow}$ *multiplication-continuity transport for the left and right ledgers.*
7. *I records the* $\mathsf{TopGroup}^{\uparrow}$ *inversion-continuity transport exchanging the left and right ledgers.*
8. *C_L is the* $\mathsf{Completion}^{\uparrow}$ *consumer row that can read Cauchy data only after the left ledger is displayed.*
9. *C_R is the* $\mathsf{UniformCompleteSpace}^{\uparrow}$ *consumer row that can read completion data only after the right ledger is displayed.*

10. *Q records the comparison boundary with* $\mathsf{HausdorffUniformity}^{\uparrow}$ *when separated completion or uniqueness consumers require diagonal separation.*
11. *V records the two-sided completion handoff used by Raikov-style consumers without selecting a quotient completion point.*
12. *H stores componentwise* hsame *transport for all displayed rows.*
13. *C stores displayed* Cont *replay for neighbourhood admission, left and right entourage generation, multiplication transport, inversion transport, completion handoff, and separated comparison.*
14. *P is the* Pkg *provenance over* $\mathsf{WeilUniformity}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{UniformCompleteSpace}^{\uparrow}$, $\mathsf{HausdorffUniformity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{WeilUniformity}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through $G, T, U, L, R, M, I, C_L, C_R, Q, V, H, C, P, N$. It has no coordinate for a host topological group, a chosen completion, quotient equality of Cauchy filters, ambient uniform completeness, or a one-sided replacement for the two-sided uniformity route.

Theorem 7628.2 (Weil uniformity NameCert obligations)**.** *For every accepted* $\mathsf{WeilUniformity}^{\uparrow}$ *carrier*

$$W = (G, T, U, L, R, M, I, C_L, C_R, Q, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeilUniformity}^{\uparrow}}$ *surface consists exactly of carrier admission, identity-neighbourhood access, left-entourage generation, right-entourage generation, multiplication transport, inversion transport, completion-facing handoff, separated-uniform comparison, two-sided completion provenance, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion or topological-group consumer must read both L and R before it may inspect C_L, C_R, or V.*

Proof. Project the accepted carrier through Definition 7628.1. The rows G, T, U supply the group, topology, and ambient uniform-space requests, while L and R are distinct displayed ledgers for the left and right entourages.

Read the topological-group transport rows. Multiplication continuity in M keeps products compatible with both ledgers, and inversion continuity in I exchanges the two directions instead of allowing one direction to stand for the other.

The completion-facing rows C_L, C_R, Q, V occur only after the two ledgers have been displayed. The structural rows H, C, P, N then transport, replay, source, and name the same packet, so the listed obligations exhaust the local NameCert surface. □

Theorem 7628.3 (Weil uniformity topological-group handoff)**.** *Every* $\mathsf{TopGroup}^{\uparrow}$ *consumer of an accepted* $\mathsf{WeilUniformity}^{\uparrow}$ *packet reads multiplication and inversion through the finite route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{UniformSpace}^{\uparrow},\ L,\ R,\ M,\ I \longrightarrow \mathsf{Completion}^{\uparrow},\ \mathsf{UniformCompleteSpace}^{\uparrow}.$$

The handoff keeps the left and right entourage ledgers visible until completion-facing rows are reached. Consequently the packet may feed Raikov-style completion, separated-uniform comparison, and uniform-complete-space consumers, but it does not identify the carrier with a host completion, choose Cauchy representatives, assert ambient completeness, or collapse the two ledgers to a single anonymous uniform-space row.

Proof. Start with the topology and uniform-space source rows. The open identity-neighbourhood requests in T and the finite entourage data in U are the only source rows from which the left and right ledgers can be generated.

Use the $\mathsf{TopGroup}^{\uparrow}$ transport rows M and I. Multiplication reads both directions through the same finite packet, while inversion swaps the direction of an entourage request and therefore requires both L and R to remain present.

Finally inspect $C_L, C_R, Q, V, H, C, P, N$. These rows hand the two-sided packet to completion and separated-uniform consumers while preserving componentwise transport, replay, provenance, and local naming. Since no host completion or quotient representative is a coordinate of the carrier, the handoff cannot bypass the displayed two-sided route. □

Closure status for $\mathsf{NameCert}_{\mathsf{WeilUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{WeilUniformity}^{\uparrow}$ packet is generated from a topological-group source, a topology row, a uniform-space row, left and right entourage ledgers, multiplication and inversion continuity transports, completion-facing handoff rows, separated-uniform comparison, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeilUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7628.1, Definition 7628.2, and Definition 7628.3 seed the two-sided uniformity surface between $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, and $\mathsf{UniformCompleteSpace}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeilUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, Raikov completion, quotient Cauchy-filter equality, selected completion points, ambient uniform completeness, host topological-group equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, left and right entourage exactness, multiplication and inversion transport, completion handoff, separated comparison, two-sided non-escape, transport, replay, provenance, and local naming for BEDC.Derived.WeilUniformityUp.

Chapter 7629

A Concrete Naming Certificate for $\mathsf{CapProduct}^{\uparrow}$

Following Eilenberg–Steenrod and the chain-level treatments in Hatcher, the $\mathsf{CapProduct}^{\uparrow}$ packet records the finite action route by which a displayed cochain row acts on a displayed chain row before the resulting chain class is read. It sits between the homology carrier of chapter 98 and the cohomology carrier of chapter 99. The packet names chain, cochain, degree-window, boundary/coboundary compatibility, transport, replay, provenance, and local naming rows; it is not a full homology operation calculus, not a cup-product theory, not quotient chain equality, and not an ambient algebraic-topology theorem.

Definition 7629.1 (Cap product carrier)**.** *A* $\mathsf{CapProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, B, D, E, H, G, T, R, P, N)$$

with the following displayed rows:

1. *A is the chain row, recording the finite chain window on which the action is evaluated.*
2. *B is the cochain row, recording the finite cochain window and coefficient readback used by the action.*
3. *D is the degree-window row, naming the source chain degree, cochain degree, and output chain degree inspected by the packet.*
4. *E is the boundary/coboundary compatibility row, recording the displayed sign and face-boundary ledger used by the action check.*
5. *H is the* $\mathsf{Homology}^{\uparrow}$ *row read only after the chain row and compatibility row have been displayed.*
6. *G is the* $\mathsf{Cohomology}^{\uparrow}$ *row read only through the cochain row and coboundary side of E.*
7. *T records componentwise* hsame *transport for chain, cochain, degree-window, compatibility, homology, cohomology, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a cap-product request through $A, B, D, E, H, G, T, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CapProduct}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CapProduct}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, D, E, H, G, T, R, P, N$. It has no coordinate for chosen chain representatives, quotient chain equality, unrestricted naturality, a cup-product algebra, or ambient homological algebra.

Theorem 7629.2 (Cap product NameCert obligations)**.** *For every accepted* $\mathsf{CapProduct}^{\uparrow}$ *carrier* $Q = (A, B, D, E, H, G, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CapProduct}^{\uparrow}}$ *surface consists exactly of chain-row admission, cochain-row admission, degree-window admission, boundary/coboundary compatibility, the downstream* $\mathsf{Homology}^{\uparrow}$ *read, the downstream* $\mathsf{Cohomology}^{\uparrow}$ *read, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7629.1. The displayed tuple is the complete inventory of rows available to a cap-product consumer.

The chain and cochain sides are separated by A and B, while D fixes the degree window in which the action is inspected. The compatibility row E is the only place where the boundary and coboundary ledgers meet.

The rows H and G can be read only after those finite rows have been displayed. Finally T, R, P, N transport, replay, source, and name the same route, so no chosen representative, quotient equality, unrestricted naturality, cup-product algebra, or ambient homological-algebra principle is introduced. □

Theorem 7629.3 (Cap product chain-cochain handoff)**.** *Every accepted* $\mathsf{CapProduct}^{\uparrow}$ *consumer that hands a cohomology-facing row to a homology-facing row factors through*

$$A, B, D, E, T, R, P, N.$$

The exported handoff reads $\mathsf{Cohomology}^{\uparrow}$ *through the displayed cochain and coboundary side, reads* $\mathsf{Homology}^{\uparrow}$ *through the displayed chain and boundary side, and exposes only the finite compatibility route named by the carrier.*

Proof. Begin with a chain-cochain handoff request. Carrier admission exposes the chain row A, cochain row B, degree-window row D, and compatibility row E before either downstream algebraic-topology row may be consumed.

Read $\mathsf{Cohomology}^{\uparrow}$ through B and the coboundary side of E. Read $\mathsf{Homology}^{\uparrow}$ through A and the boundary side of E.

The structural rows T, R, P, N then preserve and replay this finite route. Since the carrier contains no selected representative, quotient equality, full operation calculus, or unrestricted naturality coordinate, the handoff is exactly the displayed chain-cochain route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CapProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{CapProduct}^{\uparrow}$ packet is generated from chain rows, cochain rows, degree-window rows, boundary/coboundary compatibility rows, HomologyUp and CohomologyUp consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CapProduct}^{\uparrow}}$, seed)

Scope closed: Definition 7629.1, Definition 7629.2, and Definition 7629.3 seed the finite chain-cochain action route between displayed HomologyUp and CohomologyUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CapProduct}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full homology operations, cup-product theory, quotient chain equality, unrestricted naturality, ambient homological algebra, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, chain-row and cochain-row exposure, degree-window exposure, boundary/coboundary compatibility, homology and cohomology handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.CapProductUp.

Chapter 7630

A Concrete Naming Certificate for $\mathsf{WindowSixDecorationDefect}^{\uparrow}$

The $\mathsf{WindowSixDecorationDefect}^{\uparrow}$ packet realizes the defect-refined decoration polynomial of Definition 9462.1702 inside the DNA window-six private/shared boundary-tile route. It consumes the private/shared decoration packet of chapter 5881, the private/shared model packet of chapter 5896, and the Alexander-dual trigger algebra of chapter 3555. The packet records private/shared decomposition, shared row-set arity, defect exponents, polynomial coefficients, trigger coverage, transport, replay, provenance, and local naming as finite rows; it is not a biological mechanism, stochastic model, hidden enumeration oracle, or quotient codon semantics.

Definition 7630.1 (Window-six decoration defect carrier)**.** *A* $\mathsf{WindowSixDecorationDefect}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, S, A, E, K, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the private/shared decomposition row, read through the displayed private-block and shared-coordinate split.*
2. *S is the shared row-set arity row, assigning each shared coordinate to a finite row set of size at least two.*
3. *A is the defect exponent ledger, recording the contribution $r - 1$ attached to a shared row set of arity r.*
4. *E is the decoration-polynomial coefficient row, recording the finite coefficient data used by the defect-refined polynomial.*
5. *K is the trigger-coverage row, tying the decomposition to accepted window-six boundary-trigger coverage.*
6. *T records componentwise* hsame *transport for decomposition, arity, exponent, coefficient, trigger, replay, provenance, and local naming rows.*
7. *H records displayed* Cont *replay from a defect-polynomial request through B, S, A, E, K, T, P, N.*
8. *C is the* Pkg *provenance over* $\mathsf{WindowSixDecorationDefect}^{\uparrow}$, $\mathsf{WindowSixPrivateSharedDecoration}^{\uparrow}$, $\mathsf{PrivateSharedDecorationModel}^{\uparrow}$, $\mathsf{AlexanderDualTriggerAlgebra}^{\uparrow}$, *the source theorem of Definition 9462.1702,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

9. *P is the trigger-polynomial readback row that keeps coefficient reads attached to displayed trigger coverage rather than to a hidden enumeration oracle.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{WindowSixDecorationDefect}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, A, E, K, T, H, C, P, N$. It has no coordinate for biological semantics, stochastic fitness, quotient codon equality, hidden global enumeration, or unrecorded trigger search.

Theorem 7630.2 (Window-six decoration defect NameCert obligations)**.** *For every accepted* $\mathsf{WindowSixDecorationDefect}^{\uparrow}$ *carrier $W = (B, S, A, E, K, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WindowSixDecorationDefect}^{\uparrow}}$ *surface consists exactly of private/shared decomposition exposure, shared row-set arity exposure, defect-exponent exposure, decoration-polynomial coefficient exposure, trigger-coverage exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, trigger-polynomial readback, and local naming.*

Proof. Project the accepted carrier of Definition 7630.1. The decomposition, arity, exponent, coefficient, trigger, transport, replay, provenance, readback, and local naming data are precisely $B, S, A, E, K, T, H, C, P, N$.

The rows B, S expose the private/shared split and the finite arities of shared row sets. The row A records the defect contribution for each shared coordinate, and E records the coefficient ledger read by the polynomial.

The trigger row K keeps the polynomial attached to the accepted window-six coverage route. Finally T, H, C, P, N transport, replay, source, read back, and name the same finite packet, leaving no carrier coordinate for biological semantics, stochastic fitness, quotient codon equality, hidden enumeration, or unrecorded trigger search. □

Theorem 7630.3 (Window-six decoration defect polynomial handoff)**.** *Every accepted* WindowSixDecorationDefect *consumer that reads the defect-refined decoration polynomial must first expose*

$$B, S, A, E, K, T, H, C, P, N.$$

The handoff realizes Definition 9462.1702 as finite private/shared row-set arity, defect-exponent, coefficient, trigger-coverage, transport, replay, provenance, readback, and local NameCert rows.

Proof. Read the private/shared decomposition through B and the shared row-set arities through S. These rows determine which shared coordinates contribute to the defect ledger.

Use A to expose the exponent contribution attached to each shared arity and E to expose the corresponding coefficient row. The trigger row K ensures that the coefficient read remains tied to the window-six boundary-trigger surface.

The remaining rows T, H, C, P, N transport, replay, source, read back, and locally name the same finite route. Hence the consumer receives the finite polynomial handoff described by the theorem rather than a hidden enumeration oracle or external biological semantics. □

Falsifiable prediction: Every accepted $\mathsf{WindowSixDecorationDefect}^{\uparrow}$ consumer must display private/shared decomposition rows, shared row-set arity rows, defect-exponent ledger rows, coefficient rows, trigger-coverage rows, hsame transport, Cont replay, Pkg provenance, trigger-polynomial readback, and local NameCert rows before the defect-refined decoration polynomial is read.

Independence witness: window-six-private-shared-decoration, private-shared-decoration-model, alexander-dual-trigger-algebra, dna-window-six-boundary-tile, dna-boundary-trigger-closure: WindowSixDecoratior

is not bijective to any listed sibling because it jointly carries arity, exponent, coefficient, trigger, transport, replay, provenance, readback, and local naming rows for the defect-refined polynomial.

The Lean TasteGate route for `BEDC.Derived.WindowSixDecorationDefectUp` must provide explicit Nontrivial WindowSixDecorationDefect$^{\uparrow}$ and FieldFaithful WindowSixDecorationDefect$^{\uparrow}$ instances preserving $B, S, A, E, K, T, H, C, P, N$ as separate displayed fields.

Closure status for NameCert$_{\text{WindowSixDecorationDefect}^{\uparrow}}$.

Constructive story: A WindowSixDecorationDefect$^{\uparrow}$ packet is generated from private/shared decomposition rows, shared row-set arity rows, defect-exponent ledgers, decoration-polynomial coefficient rows, trigger-coverage rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, trigger-polynomial readback, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{WindowSixDecorationDefect}^{\uparrow}}$, seed)

Scope closed: Definition 7630.1, Definition 7630.2, and Definition 7630.3 seed the finite defect-refined decoration polynomial packet over displayed private/shared, trigger, transport, replay, provenance, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{WindowSixDecorationDefect}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close biological mechanism, stochastic fitness, quotient codon equality, hidden global enumeration, unrestricted trigger search, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, private/shared decomposition, shared row-set arity, defect-exponent ledger, coefficient exposure, trigger-coverage routing, TasteGate nontriviality, field faithfulness, transport, replay, provenance, readback, and local naming for BEDC.Derived.WindowSixDecorationDefectUp.

Chapter 7631

A Concrete Naming Certificate for $\mathsf{ConstructiveContractionModulus}^{\uparrow}$

Following Bishop and Bridges constructive metric fixed-point theory, the $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ packet records the finite modulus data a Picard or Banach contraction consumer must display before a Cauchy tail is handed to completion. It sits after the complete-metric boundary of chapter 128, the continuous-map row of chapter 130, the Cauchy-modulus ledger of chapter 292, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The carrier names contraction shrinkage as displayed finite data; it does not select a fixed point, quotient a completion, use countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7631.1 (Constructive contraction-modulus carrier)**.** *A* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, F, L, Q, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row naming the metric source on which the Picard route is allowed to ask for completion-facing data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row, displayed as a graph or local evaluation ledger rather than as an extensional host function.*
3. *L is the contraction ledger, recording the finite shrinkage factor or stagewise contraction budget consumed by later tail estimates.*
4. *Q is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row produced from L and the displayed iterate-distance windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for finite Picard prefixes and tolerance requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distances and tail comparisons named by Q.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after X, F, L, Q, W, R have been replayed.*
8. *H records componentwise* hsame *transport for the metric, self-map, contraction ledger, modulus, window, readback, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a contraction request through the finite Picard windows, modulus lookup, regular readback, and Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveContractionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected fixed point, quotient completion equality, host function extensionality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.ConstructiveContractionModulusUp.ConstructiveContractionModulusTasteGate`
`single carrier alignment`

Theorem 7631.2 (Constructive contraction-modulus NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ *carrier* $M = (X, F, L, Q, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveContracti}}$ *surface consists exactly of carrier admission for the complete-metric boundary, continuous self-map row, contraction ledger, CauchyModulus row, finite window row, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming. Every Picard or fixed-point consumer must read* $X, F, L, Q, W, R, E, H, C, P, N$ *in that displayed route before it can consume the contraction modulus.*

Proof. Project the carrier of Definition 7631.1. The displayed tuple contains the complete-metric source, continuous self-map row, contraction ledger, Cauchy modulus, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Read the contraction route. The self-map row F is meaningful only over the metric boundary X, and the shrinkage ledger L is the only row from which the CauchyModulus row Q can be read.

The window and readback rows W, R then expose the finite Picard prefixes and rational tail comparisons. Transport, replay, provenance, and local naming preserve this same route, so no further NameCert obligation is stored outside the listed rows. □

Theorem 7631.3 (Constructive contraction-modulus Picard Cauchy route)**.** *Every Picard or Banach fixed-point consumer of an accepted* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ *packet must factor through*

$$\mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto L \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route supplies a finite Cauchy-tail modulus for downstream Picard iteration and fixed-point packets. It exports no selected fixed point, quotient completion equality, host equality of maps, countable-choice schedule, or ambient completeness theorem beyond the displayed $\mathsf{CompleteMetric}^{\uparrow}$ *row.*

Proof. Begin with a fixed-point-facing request. The only metric source is X, and the only self-map data is the displayed continuous-map row F.

The contraction ledger L is then read as the finite shrinkage budget. The CauchyModulus row Q is obtained from that ledger and can be inspected only through the finite StreamName windows W and RegSeqRat readback R.

Finally the terminal Real seal E is downstream of the same replay. Since the carrier contains no fixed-point selector, quotient completion equality, host map equality, or choice schedule, the Picard consumer receives only the displayed Cauchy-tail route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveContractionModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ packet is generated from a CompleteMetric boundary, a ContinuousMap self-map row, a finite contraction ledger, a CauchyModulus row, StreamName windows, RegSeqRat

readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveContractionModulus}\uparrow}$, seed)

Scope closed: Definition 7631.1, Definition 7631.2, and Definition 7631.3 seed the finite contraction-modulus route consumed by Picard and fixed-point packets.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveContractionModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close fixed-point existence, selected limits, quotient completion equality, host function extensionality, countable choice, ambient Real completeness, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-ledger exactness, CauchyModulus extraction, StreamName and RegSeqRat readback stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveContractionModulusUp.

Chapter 7632

A Concrete Naming Certificate for $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$

The $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ packet realizes the conditional MetaCIC confluence audit frontier of chapter 9378 as a finite scheduler carrier. It consumes the audit rows of chapter 743, the normal-fragment rows of chapter 737, the closed-normal seal of chapter 741, classifier boundary rows of chapter 595, and subject-reduction rows of chapter 483. The packet separates component diamonds, residual boundaries, atom joins, closed-source guards, and star-confluence handoff rows without exporting closed star confluence as an unconditional theorem.

Definition 7632.1 (MetaCIC parallel-diamond scheduler carrier)**.** *A* $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, B, A, G, T, H, C, P, N)$$

with the following visible rows:

1. *D is the component-diamond row listing the checked local parallel-diamond fragments available to the scheduler.*
2. *B is the residual-substitution boundary row retained from the confluence audit map.*
3. *A is the atom-join row for closed atom fragments already accepted by the normal-fragment and closed-normal seal packets.*
4. *G is the closed-source guard row, ensuring that a star-confluence request is made only after the closed-source hypotheses have been displayed.*
5. *T is the star-confluence handoff row, exposed as a conditional target whose residual-substitution boundary is still visible.*
6. *H records componentwise* hsame *transport for the component-diamond, residual-boundary, atom-join, closed-guard, handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an audit request through the scheduler rows.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$*, the MetaCIC confluence audit packet, the MetaCIC confluence normal-fragment packet,* $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$*,* $\mathsf{ClassifierBoundary}^{\uparrow}$*,* $\mathsf{SubjectReduction}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}}$ *row.*

The classifier compares accepted schedulers only through $D, B, A, G, T, H, C, P, N$. It has no coordinate for unconditional closed star confluence, global substitution compatibility, erased residual data, or a host confluence theorem.

Theorem 7632.2 (MetaCIC parallel-diamond scheduler NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ *carrier* $S = (D, B, A, G, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDia}}$ *surface consists exactly of component-diamond exposure through D, residual-boundary exposure through B, atom-join exposure through A, closed-source guarding through G, star-confluence handoff through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the scheduler carrier. The displayed rows are precisely the component-diamond, residual-boundary, atom-join, closed-source guard, conditional handoff, transport, replay, provenance, and local naming rows.

Read the audit route. Component diamonds in D and atom joins in A may be scheduled only with the residual boundary B still present, and the closed-source guard G controls when the star-confluence handoff T is exposed.

Transport, replay, provenance, and naming preserve those same rows. Since no carrier coordinate erases B or replaces it by a global substitution theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 7632.3 (MetaCIC parallel-diamond residual boundary)**.** *No* $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ *consumer may export closed star confluence unless its route displays an explicit residual-substitution boundary row. The visible handoff is*

$$D, B, A, G \longmapsto T,$$

and the row B remains part of the exported scheduler packet.

Proof. Start from an accepted scheduler $S = (D, B, A, G, T, H, C, P, N)$. The only star-confluence-facing coordinate is T.

The carrier definition places T downstream of the component-diamond row D, residual-boundary row B, atom-join row A, and closed-source guard G. Thus the handoff cannot be read without B.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. They do not add a substitution-compatibility theorem or remove the residual row, so closed star confluence is never exported without the displayed boundary. □

Falsifiable prediction: No $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ scheduler may export closed star confluence without an explicit residual-substitution boundary row.

Independence witness: metacic-confluence-audit, metacicconfluencenormalfragment, closednormalconfluenceseal, classifierboundary, subjectreduction: $\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries component-diamond rows, residual-substitution boundary rows, atom-join rows, closed-source guards, star-confluence handoff, transport, replay, provenance, and local NameCert data.

Lean development for this route must later supply $\mathsf{Nontrivial}\ \mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}$ TasteGate instances after the residual-substitution boundary is represented as a displayed scheduler row.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondScheduler}^{\uparrow}}$.

Constructive story: A MetaCICParallelDiamondScheduler$^{\uparrow}$ packet is generated from component-diamond rows, residual-substitution boundary rows, atom-join rows, closed-source guards, star-confluence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICParallelDiamondScheduler}\uparrow}$, seed)

Scope closed: Definition 7632.1, Definition 7632.2, and Definition 7632.3 seed the finite scheduler surface for the conditional MetaCIC confluence audit map.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICParallelDiamondScheduler}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global substitution compatibility, unconditional closed star confluence, host confluence, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, component-diamond exposure, residual-boundary retention, atom-join exposure, closed-source guarding, star-confluence handoff, transport, replay, provenance, and local naming for BEDC.Derived.MetacicParallelDiamondSchedulerUp.

Chapter 7633

A Concrete Naming Certificate for $\mathsf{SierpinskiGasket}^{\uparrow}$

Following Sierpinski and Hutchinson-style iterated function systems, the $\mathsf{SierpinskiGasket}^{\uparrow}$ packet records the triangular three-map self-similar gasket as finite BEDC naming data. It sits after the finite contraction-family surface of chapter 7342, beside the stagewise fractal routes of chapter 3995 and chapter 6486, and before any consumer asks for a completed attractor subset. The packet names only triangular vertex data, three displayed contraction rows, finite address windows, stage-cell readback, dyadic coordinate seals, transport, replay, provenance, and local naming; it does not import an ambient planar compact set, a hyperspace fixed point, Hausdorff dimension, area measure, selected infinite branch, or host equality of points.

Definition 7633.1 (Sierpinski gasket carrier)**.** *A* $\mathsf{SierpinskiGasket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, I, F, A, S, W, D, R, E, H, C, P, N)$$

with the following visible rows:

1. *T is the triangular vertex row, recording the three displayed corner seals and the orientation used by stage cells.*
2. *I is the* $\mathsf{IteratedFunctionSystem}^{\uparrow}$ *dependency row. It supplies the compact complete metric source, finite map family, contraction ledger, modulus thresholds, and Real-facing constants inherited from chapter 7342.*
3. *F is the three-map contraction-family row, addressed by the finite indices $0, 1, 2$ and read only through the IFS packet I.*
4. *A is the finite address row for inspected words over the three symbols, with no selected infinite branch.*
5. *S is the stage-cell row. It records the displayed triangular subcell reached by an address word and the three endpoint rows carried by that cell.*
6. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for the inspected address, stage, and endpoint-coordinate reads.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *stage and midpoint ledger used to route the half-scale triangular contractions and coordinate tolerances.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the scheduled coordinate windows.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *coordinate-seal family for the displayed vertices and stage-cell endpoints.*
10. *H records componentwise* hsame *transport for $T, I, F, A, S, W, D, R, E, C, P, N$.*
11. *C records displayed* Cont *replay from a gasket request through the finite address, contraction-family, stage-cell, coordinate, and structural rows.*
12. *P is the* Pkg *provenance over* $\mathsf{SierpinskiGasket}^{\uparrow}$, $\mathsf{IteratedFunctionSystem}^{\uparrow}$, $\mathsf{KochCurve}^{\uparrow}$, $\mathsf{KochSnowflake}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}$ *row.*

The classifier accepts a packet only through the displayed tuple $T, I, F, A, S, W, D, R, E, H, C, P, N$. It has no coordinate for a completed attractor subset, hyperspace quotient, Hausdorff dimension, area computation, selected infinite address, or ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.SierpinskiGasketUp.SierpinskiGasketTasteGate single carrier alignment`

Theorem 7633.2 (Sierpinski gasket NameCert obligations)**.** *For every accepted* $\mathsf{SierpinskiGasket}^{\uparrow}$ *carrier*

$$G = (T, I, F, A, S, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; triangular vertex exposure through T; finite IFS exposure through I; three contraction rows through F; finite address exposure through A; stage-cell exactness through S; finite window scheduling through W; dyadic stage and midpoint exactness through D; regular rational readback through R; terminal* $\mathsf{Real}^{\uparrow}$ *coordinate sealing through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7633.1. The visible rows are exactly $T, I, F, A, S, W, D, R, E, H, C, P, N$, and the classifier compares only those rows by componentwise hsame.

The IFS-facing obligations are exhausted by I and F. The dependency row I supplies the finite contraction-family interface named in chapter 7342, while F fixes the three displayed half-scale maps by finite index.

The gasket-specific readback is exhausted by A, S, W, D, R, E. A consumer first reads a finite address word, then the corresponding displayed stage cell, then the scheduled coordinate windows and dyadic midpoint ledger before the regular rational and Real-seal rows are inspected.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no completed attractor subset, hyperspace quotient, dimension row, area row, selected infinite branch, or ambient compactness row, no such object can become a local $\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}$ obligation. □

Theorem 7633.3 (Sierpinski gasket finite IFS route)**.** *Every accepted stage-cell, address, or coordinate read of a* $\mathsf{SierpinskiGasket}^{\uparrow}$ *packet factors through the finite route*

$$T \longmapsto I, F \longmapsto A, S \longmapsto W, D, R, E \longmapsto H, C, P, N.$$

The route exports only the triangular vertex row, finite IFS dependency, three contraction rows, finite address and stage-cell rows, StreamName windows, dyadic midpoint ledger, regular rational readback, terminal Real seals, and the structural rows. It exports no completed planar fractal, host attractor subset, hyperspace fixed point, selected infinite branch, area computation, Hausdorff dimension, or ambient compactness principle.

Proof. Begin with an accepted consumer of a gasket stage-cell, address, or coordinate read. By Definition 7633.1, the consumer can enter the packet only through the triangular vertex row T, the IFS row I, and the three-map row F.

Apply Definition 7633.2. It forces every finite address read through A, every stage-cell read through S, and every coordinate read through W, D, R, E before the structural rows are inspected.

The IFS packet of chapter 7342 supplies only a finite contraction-family route, and the nearby Koch packets supply only displayed stagewise readbacks. None adds a carrier coordinate for a completed attractor, hyperspace fixed point, selected infinite branch, dimension, area, or compactness theorem. Hence every accepted consumer remains on the finite IFS route. □

Theorem 7633.4 (Sierpinski gasket nonescape)**.** *An accepted* $\mathsf{SierpinskiGasket}^{\uparrow}$ *consumer cannot reach a Real coordinate seal for a stage-cell endpoint without first displaying* $T, I, F, A, S, W, D, R, E$*. In particular, any coordinate read that skips the finite address row, the three-map IFS row, the stage-cell row, or the dyadic midpoint ledger is outside the local NameCert surface.*

Proof. Read the accepted carrier through Definition 7633.1. The terminal coordinate seals occur only in the row E, and E is downstream of the displayed stage and coordinate rows A, S, W, D, R.

Use Definition 7633.3. The route places T, I, F, A, S, W, D, R before E, so a Real coordinate seal has no independent entry point.

The structural rows H, C, P, N can only transport, replay, source, and name the same packet. They do not create a second coordinate-seal route, and the carrier has no host planar subset or selected attractor row that could bypass the finite address and stage-cell data. □

Falsifiable prediction: An accepted $\mathsf{SierpinskiGasket}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ coordinate seal without first displaying the triangular vertex row, IFS row, three contraction rows, finite address row, stage-cell row, StreamName windows, dyadic midpoint ledger, and RegSeqRat readback refutes the carrier surface.

Independence witness: iteratedfunctionsystem, kochcurve, kochsnowflake, streamname, dyadicratcore, regseqrat, real: no listed sibling supplies the whole $\mathsf{SierpinskiGasket}^{\uparrow}$ packet, because the gasket certificate binds triangular vertices, three half-scale contraction rows, finite address and stage-cell data, coordinate readback, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SierpinskiGasket}^{\uparrow}$ packet is generated from triangular vertex data, an IteratedFunctionSystem dependency row, three contraction rows, finite address and stage-cell rows, StreamName windows, dyadic midpoint ledgers, RegSeqRat readbacks, RealUp coordinate seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7633.1, Definition 7633.2, Definition 7633.3, and Definition 7633.4 seed the finite triangular IFS gasket carrier and its displayed coordinate nonescape route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SierpinskiGasket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host attractor subsets, hyperspace completion, Hausdorff-metric fixed-set existence, invariant measures, area or dimension computation, selected infinite branches, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires a Lean-side SierpinskiGasketUp carrier with checked triangular vertex exposure, three contraction rows, finite address and stage-cell exactness, coordinate readback, Real coordinate sealing, transport, replay, provenance, and local naming.

Chapter 7634

A Concrete Naming Certificate for $\mathsf{DoldKan}^{\uparrow}$

Following Dold and Kan on the equivalence between simplicial abelian groups and nonnegatively graded chain complexes, the $\mathsf{DoldKan}^{\uparrow}$ packet records the finite BEDC naming surface for the normalized-chain handoff. It sits after the face-and-degeneracy ledger of chapter 157, the chain comparison route of chapter 7625, the cycle-boundary consumer of chapter 98, and the additive exactness rows of chapter 176. The packet names only displayed simplicial-object rows, normalized-chain rows, abelian-category rows, homology readback, componentwise transport, replay, provenance, and a local naming row; it does not select quotient representatives, assert a host categorical equivalence, import ambient derived-category machinery, or choose an unbounded normalization procedure.

Definition 7634.1 (Dold-Kan carrier)**.** *A* $\mathsf{DoldKan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, N, C, H, E, R, T, Q, P, L)$$

with the following displayed rows:

1. *S is the* $\mathsf{SimplicialSet}^{\uparrow}$ *source row, specialized to the visible simplicial abelian-object window inspected by the packet.*
2. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *ambient additive row in which kernels, cokernels, sums, and zero morphisms are read.*
3. *N is the normalized-chain row, recording the finite intersection of displayed degeneracy kernels and the quotient-free normalized endpoint used by the consumer.*
4. *C is the chain-complex row whose differential is read from the displayed face maps and whose square-zero check is routed through the same finite window.*
5. *H is the* $\mathsf{Homology}^{\uparrow}$ *readback row reached only after the normalized-chain and differential rows have been displayed.*
6. *E records the Eilenberg-Zilber compatibility row consumed from chapter 7625 when tensor or product consumers ask for a chain-level comparison.*
7. *R stores componentwise* hsame *transport for the simplicial-object, abelian-category, normalized-chain, differential, homology, comparison, provenance, and local naming rows.*

8. *T stores displayed* Cont *replay from a finite simplicial window through normalization, differential readback, homology handoff, and comparison rows.*
9. *Q is the* Pkg *provenance row over* $\mathsf{DoldKan}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{EilenbergZilber}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *P records the public dependency boundary: every accepted read passes through the sibling chapters named above before a consumer may inspect the normalized-chain handoff.*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{DoldKan}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through the displayed tuple $S, A, N, C, H, E, R, T, Q, P, L$.

Theorem 7634.2 (Dold-Kan NameCert obligations)**.** *For every accepted* $\mathsf{DoldKan}^{\uparrow}$ *carrier $D = (S, A, N, C, H, E, R, T, Q, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{DoldKan}^{\uparrow}}$ *surface consists exactly of simplicial-object admission, abelian-category source admission, normalized-chain row admission, differential readback, homology handoff, Eilenberg-Zilber compatibility, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, dependency-boundary exposure, and local naming. A consumer cannot read the normalized-chain handoff without first exposing the* $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, *and* $\mathsf{EilenbergZilber}^{\uparrow}$ *sibling surfaces named by the carrier.*

Proof. Project the accepted carrier through Definition 7634.1. The source rows S and A expose the finite simplicial-object window and the additive ambient rows before any normalized chain row is reachable.

Next read N and C. The normalized-chain endpoint is tied to the displayed degeneracy-kernel window, and the differential row is tied to the displayed face maps in the same packet. The homology row H can therefore be consumed only after those rows have been displayed.

Finally inspect E, R, T, Q, P, L. The comparison row E supplies the Eilenberg-Zilber sibling route, while transport, replay, provenance, dependency boundary, and local naming keep all reads on the same finite carrier. Since no coordinate supplies host equivalence, quotient representative choice, derived-category machinery, or unbounded normalization, the listed rows exhaust the local NameCert obligations. □

Theorem 7634.3 (Dold-Kan normalized-chain handoff)**.** *Every accepted* $\mathsf{DoldKan}^{\uparrow}$ *packet exports its normalized-chain handoff through the finite route*

$$\mathsf{SimplicialSet}^{\uparrow},\ \mathsf{AbelianCat}^{\uparrow} \longmapsto N, C \longmapsto \mathsf{Homology}^{\uparrow} \longmapsto \mathsf{EilenbergZilber}^{\uparrow} \longmapsto R, T, Q, P, L.$$

The route reads finite face and degeneracy rows, additive kernel and zero rows, the normalized-chain endpoint, the differential row, homology readback, Eilenberg-Zilber comparison, componentwise transport, replay, provenance, and local naming before any downstream chain or homology consumer receives the handoff.

Proof. Begin with the carrier rows S and A. They are the only source rows for the simplicial object and abelian ambient data, so a normalized-chain request first opens those finite windows.

Use the normalized-chain and chain rows N and C. These rows display the degeneracy-kernel intersection and the differential readback before the homology row H can be inspected.

Attach the comparison and structural rows. The Eilenberg-Zilber row E is downstream of the chain window, and R, T, Q, P, L transport, replay, source, bound, and name the same packet. Thus the handoff remains finite and cannot be replaced by a host Dold-Kan equivalence, a quotient-chain representative, or an unbounded normalization oracle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DoldKan}^{\uparrow}}$.

Constructive story: A $\mathsf{DoldKan}^{\uparrow}$ packet is generated from displayed SimplicialSetUp face-and-degeneracy rows, AbelianCatUp additive rows, normalized-chain rows, chain differential rows, HomologyUp readback, EilenbergZilberUp comparison, componentwise hsame transport, Cont replay, Pkg provenance, a dependency boundary, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DoldKan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7634.1, Definition 7634.2, and Definition 7634.3 seed the finite normalized-chain handoff over $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, and $\mathsf{EilenbergZilber}^{\uparrow}$ sibling surfaces.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DoldKan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, a host categorical equivalence, quotient chain equality, selected chain representatives, derived-category exactness, ambient homological algebra, unbounded normalization, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, normalized-chain row exactness, differential readback, homology handoff, Eilenberg-Zilber compatibility, transport, replay, provenance, dependency-boundary exposure, and local naming for BEDC.Derived.DoldKanUp.

Chapter 7635

A Concrete Naming Certificate for $\mathsf{StoneCechRemainder}^{\uparrow}$

Following Gillman–Jerison and Engelking on Stone–Cech compactification remainders, the $\mathsf{StoneCechRemainder}^{\uparrow}$ packet records the compactification-boundary object read from a displayed $\mathsf{StoneCechCompactification}^{\uparrow}$ source without forming a host set difference or quotient compactification equality. It sits after the Stone–Cech compactification carrier of chapter 2344, the topology rows of chapter 88, the compact rows of chapter 60, and the compact-metric witness discipline of chapter 129. The packet names only the local boundary ledger for the complement-facing read; it does not assert an ambient corona space, select ultrafilters, identify quotient points, or import standard open-cover compactness.

Definition 7635.1 (Stone–Cech remainder carrier)**.** *A* $\mathsf{StoneCechRemainder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (B, D, C, Q, T, K, H, L, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{StoneCechCompactification}^{\uparrow}$ *source row, including the bounded-continuous-probe windows and compact-target seal rows already named in chapter 2344.*
2. *D is the dense embedding and source-object row, recording the displayed source carrier, its generated topology, and the embedding route into the compactification packet.*
3. *C is the compactification boundary row, naming the boundary-facing read attached to B and D without identifying it with a host complement.*
4. *Q is the local complement and remainder ledger, recording which finite probes see the source row and which finite probes are routed to the remainder-facing boundary row.*
5. *T is the* $\mathsf{Topology}^{\uparrow}$ *row for the generated neighbourhood and closure tests used by the boundary ledger.*
6. *K is the* $\mathsf{Compact}^{\uparrow}$ *and* $\mathsf{CompactMetric}^{\uparrow}$ *compact-target row consumed by the compactification source and boundary readback.*
7. *H records componentwise* hsame *transport for the compactification source, dense embedding, boundary row, complement ledger, topology row, compact row, continuation, provenance, and local naming rows.*
8. *L records displayed* Cont *replay from the dense source route through the Stone–Cech compactification row to the boundary and remainder ledger.*

9. *P is the* Pkg *provenance over* StoneCechRemainder$^{\uparrow}$, StoneCechCompactification$^{\uparrow}$, Topology$^{\uparrow}$, Compact$^{\uparrow}$, CompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{StoneCechRemainder}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host set difference, quotient compactification equality, an ultrafilter selector, ambient corona-space equality, selected boundary points, or standard open-cover compactness.

Theorem 7635.2 (Stone–Cech remainder NameCert obligations)**.** *For every accepted* StoneCechRemainder$^{\uparrow}$ *carrier $R = (B, D, C, Q, T, K, H, L, P, N)$, the local* NameCert$_{\text{StoneCechRemainder}^{\uparrow}}$ *surface consists exactly of carrier admission,* StoneCechCompactification$^{\uparrow}$ *source exposure through B, dense embedding and source-object exposure through D, compactification boundary exposure through C, local complement ledger exposure through Q,* Topology$^{\uparrow}$ *and* Compact$^{\uparrow}$ *row exposure through T, K, componentwise* hsame *transport through H, displayed* Cont *replay through L,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7635.1. The only analytic rows are the Stone–Cech compactification source, dense embedding, boundary row, complement ledger, topology row, and compact row.

The source row B is read through the existing compactification certificate of chapter 2344. The embedding row D and boundary row C then display the compactification-boundary route, while Q records the finite local complement ledger used by remainder-facing probes.

Finally inspect H, L, P, N. These rows transport, replay, source, and name the same displayed packet. Since none of them stores host set difference, quotient compactification equality, ultrafilter choice, ambient corona equality, selected boundary points, or standard open-cover compactness, the listed rows exhaust the local NameCert surface. □

Theorem 7635.3 (Stone–Cech remainder boundary non-escape)**.** *Every boundary-facing consumer of an accepted* StoneCechRemainder$^{\uparrow}$ *packet must read the finite route*

$$B, D, T, K \longmapsto C, Q \longmapsto H, L, P, N.$$

Thus the remainder boundary is exposed only through the displayed Stone–Cech compactification source, dense embedding, topology and compact rows, local complement ledger, componentwise transport, continuation replay, provenance, and local naming. It exports no host set difference, quotient compactification equality, ultrafilter selector, ambient corona-space equality, selected boundary point, or standard open-cover compactness theorem.

Proof. Start with the carrier of Definition 7635.1. A boundary-facing read has access to C and Q only as rows of the displayed tuple, so it cannot begin from a host complement or an external corona-space object.

Apply the NameCert obligations of Definition 7635.2. They require the compactification source row B, dense embedding row D, topology row T, and compact row K to be exposed before the boundary row and complement ledger are public.

The structural rows H, L, P, N preserve that route. Transport is componentwise, replay follows the displayed continuation, provenance cites the same source packets, and local naming adds no extra coordinate. Therefore every boundary read remains inside the finite route $B, D, T, K \longmapsto C, Q \longmapsto H, L, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{StoneCechRemainder}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneCechRemainder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7635.1, Definition 7635.2, and Definition 7635.3 seed the compactification-boundary packet over Stone–Cech compactification, dense embedding, topology, compactness, local complement ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneCechRemainder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host set difference, quotient compactification equality, ultrafilter selection, ambient corona-space equality, selected boundary points, standard open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, compactification-source exposure, dense-embedding exposure, boundary-ledger exactness, topology and compact row stability, transport, replay, provenance, and local naming for the same packet.

Constructive story: A $\mathsf{StoneCechRemainder}^{\uparrow}$ packet is generated from a StoneCechCompactification row, a dense embedding and source-object row, a compactification boundary row, a local complement ledger, Topology and Compact rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7636

A Concrete Naming Certificate for $\mathsf{NewtonInterpolation}^{\uparrow}$

Following Newton's divided-difference interpolation, the $\mathsf{NewtonInterpolation}^{\uparrow}$ packet records the finite route from ordered interpolation nodes and displayed values to the Newton-basis polynomial row whose coefficients are the divided differences. It sits beside the basis-polynomial route of chapter 4206 and the confluent jet route of chapter 6668, while consuming the scalar, coefficient-list, and finite-table surfaces of chapter 45, chapter 50, and chapter 49. The packet names only finite node, value, divided-difference, polynomial-row, transport, replay, provenance, and local naming data.

Definition 7636.1 (Newton interpolation carrier)**.** *A* $\mathsf{NewtonInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, V, T, R, A, H, C, P, N)$$

with the following displayed rows:

1. *X is a nonempty finite node list with an order row and pairwise-distinctness ledger over the displayed* $\mathsf{Field}^{\uparrow}$ *scalar source.*
2. *V is the value list, indexed by the same finite node list and classified together with X under componentwise endpoint transport.*
3. *T is the divided-difference table, stored as a finite triangular* $\mathsf{Mat}^{\uparrow}$ *row whose first column is V and whose higher columns are computed from displayed field subtraction and inverse rows.*
4. *R is the interpolation polynomial row, assembling the Newton basis products*

$$1, \quad (Z - X_0), \quad (Z - X_0)(Z - X_1), \quad \ldots$$

   with coefficients read from the top row of T as a normalized $\mathsf{Poly}^{\uparrow}$ *coefficient list.*
5. *A is the classifier-transport and agreement row, recording that the polynomial row evaluates to the displayed values at the node list and agrees with the sibling* $\mathsf{LagrangeInterpolation}^{\uparrow}$ *route whenever the same finite node-value ledger is read.*
6. *H records componentwise* hsame *transport for nodes, values, table entries, basis products, polynomial coefficients, agreement rows, replay routes, provenance, and local naming.*
7. *C records displayed* Cont *replay for forming table entries, extending the polynomial by one Newton basis factor, evaluating at displayed nodes, and reading the sibling interpolation anchors.*

8. *P is the* Pkg *provenance over* $\mathsf{NewtonInterpolation}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LagrangeInterpolation}^{\uparrow}$, $\mathsf{HermiteInterpolation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{NewtonInterpolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets by transporting exactly these rows through H and replaying the same finite table and polynomial-row routes through C and P. It has no coordinate for a host polynomial function, unstated matrix inverse, quotient polynomial equality, infinite node family, analytic limiting table, or field-completion principle.

Theorem 7636.2 (Newton interpolation NameCert obligations)**.** *For every accepted* $\mathsf{NewtonInterpolation}^{\uparrow}$ *carrier $W = (X, V, T, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{NewtonInterpolation}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the finite node list, value list, divided-difference table, interpolation polynomial row, classifier transport, displayed replay, package provenance, and local naming. The table row T must read* $\mathsf{Field}^{\uparrow}$ *subtraction and inverse data before any higher divided difference is exposed; the polynomial row R must read* $\mathsf{Poly}^{\uparrow}$ *coefficient-list assembly before a consumer obtains the interpolant; and the agreement row A may compare with the sibling* $\mathsf{LagrangeInterpolation}^{\uparrow}$ *and* $\mathsf{HermiteInterpolation}^{\uparrow}$ *anchors only through their displayed finite interpolation rows.*

Proof. Project the carrier of Definition 7636.1. The rows X and V supply the ordered node-value ledger, while T stores the triangular divided-difference table as finite matrix data.

The polynomial row R is downstream of T. Each coefficient is read from the displayed top row of the table, and each Newton basis product is assembled as a finite $\mathsf{Poly}^{\uparrow}$ coefficient-list operation.

The agreement row A records only classifier transport and sibling comparison. It may point to the Lagrange node-value route or to the Hermite confluent route, but it does not import a host interpolation theorem or an external analytic table.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no additional coordinate for quotient polynomial equality, hidden matrix inversion, infinite node families, selected Real representatives, or field completion, the listed rows exhaust the local NameCert obligations. □

Theorem 7636.3 (Newton divided-difference stability)**.** *Let $W = (X, V, T, R, A, H, C, P, N)$ be an accepted* $\mathsf{NewtonInterpolation}^{\uparrow}$ *carrier. Any transported read of the node list, value list, or top-row divided-difference coefficients determines the same polynomial row after replaying the displayed* hsame *and* Cont *routes. In particular, extending the finite node-value ledger by one displayed node appends one triangular column of T and one Newton basis factor to R, without changing the already displayed lower-stage polynomial rows.*

Proof. Start with the componentwise transport row H. It transports the node list, value list, table entries, basis products, and polynomial coefficients together, so a transported divided-difference entry remains attached to the same finite table position.

Replay C. The recurrence for the next divided difference uses only displayed field subtraction and inverse rows from the existing node list, and the appended polynomial term uses the next top-row coefficient with the next finite Newton basis product.

The lower-stage rows are already named in T and R. Adding a later table column and basis factor appends data to the finite carrier but does not rewrite the earlier table entries or coefficient-list reads.

The agreement and provenance rows A, P, N then name the transported packet as the same Newton interpolation surface. Thus divided-difference stability is a statement about finite carrier transport and replay, not about host polynomial equality, an analytic limiting process, or a hidden matrix inverse. □

Falsifiable prediction: Every accepted $\mathsf{NewtonInterpolation}^{\uparrow}$ read displays a finite node list, value list, divided-difference table, interpolation polynomial row, classifier transport, $\mathsf{Field}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LagrangeInterpolation}^{\uparrow}$, $\mathsf{HermiteInterpolation}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows before any Newton interpolant is available.

Independence witness: field, polynomial, matrix, lagrange-interpolation, hermite-interpolation: $\mathsf{NewtonInterpolation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an ordered node-value ledger, a triangular divided-difference table, a Newton-basis polynomial row, sibling agreement rows, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{NewtonInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{NewtonInterpolation}^{\uparrow}$ packet is generated from an ordered finite node list, displayed value list, triangular divided-difference table, Newton-basis polynomial row, classifier transport, Lagrange and Hermite sibling anchors, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NewtonInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7636.1, Definition 7636.2, and Definition 7636.3 seed the finite Newton interpolation carrier, local NameCert obligation surface, and divided-difference stability route over displayed FieldUp, PolynomialUp, MatrixUp, LagrangeInterpolationUp, HermiteInterpolationUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NewtonInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, quotient polynomial equality, host interpolation functions, hidden matrix inverses, infinite node families, analytic limiting tables, selected Real representatives, or field-completion arguments.

Upgrade path: Obligation closure requires checked carrier admission, divided-difference table formation, Newton basis assembly, node evaluation stability, sibling agreement, transport, replay, provenance, and local naming for BEDC.Derived.NewtonInterpolationUp.NewtonInterpolationUp.

Chapter 7637

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$ packet records the regular completion monad as finite name data over the L10 Real and Completion stack. It reads the dyadic tolerance surface of chapter 291, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet uses the displayed $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ law row only as a finite unit-and-multiplication ledger; it does not introduce quotient completion, countable choice, trichotomy, selected host limits, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7637.1 (Bishop regular completion monad carrier)**.** *A* $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, E, L, U, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger. It records the dyadic scales, triangle-budget entries, and composition slack used by every regular completion request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family. It records source windows, unit windows, multiplication windows, and seal-facing observation cuts.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback family attached to the displayed stream windows and dyadic tolerances.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R and the monad-law rows have been displayed.*
5. *L is the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *law ledger naming the finite unit, multiplication, left-unit, right-unit, and associativity comparisons.*
6. *U is the unit row. It admits a displayed regular rational name by copying the relevant stream, dyadic, readback, transport, replay, provenance, and local naming rows into the completion surface.*
7. *J is the join or multiplication row. It flattens a displayed completion-of-completion request by replaying the outer and inner windows through the same dyadic ledger before exposing the Real seal.*

8. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readbacks, Real seal, law ledger, unit row, multiplication row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay of the route*

$$D, S \longmapsto R \longmapsto L, U, J \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionMonad}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, E, L, U, J, H, C, P, N$. It has no coordinate for quotient completion equality, quotient stream equality, selected representatives, countable-choice schedules, trichotomy, host real equality, or full completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7637.2 (Bishop regular completion monad NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$ *carrier*

$$B = (D, S, R, E, L, U, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionMonad}^{\uparrow}}$ *surface consists of exactly five finite obligation rows:*

1. *carrier admission: the accepted object is the displayed* BHist *packet over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *and* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$*;*
2. *source routing: every request reads the finite stream-window row S, the dyadic tolerance ledger D, and the regular rational readback row R before a Real seal is available;*
3. *unit ledger: the row U copies displayed regular rational names into the completion surface without changing D, S, R, H, C, P, N;*
4. *multiplication ledger: the row J flattens nested completion requests only by replaying the law ledger L and the displayed D, S, R rows;*
5. *structural closure: H, C, P, N provide componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming for the same rows.*

No obligation is stored in quotient completion, quotient stream equality, countable choice, trichotomy, selected host limits, or full $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7637.1. The projection exposes exactly the dyadic ledger, stream windows, regular readbacks, Real seal, monad-law ledger, unit row, multiplication row, transport, replay, provenance, and local naming.

The source-routing row is finite because S lists the inspected windows and D lists the dyadic budgets before R repacks the observations. The seal row E is downstream of those rows and has no independent host-limit coordinate.

The unit and multiplication obligations are read from U, J together with L. The unit row copies the displayed source data, while the multiplication row replays the nested request through the same finite ledger.

Finally H, C, P, N preserve, replay, source, and name the displayed packet. Since the excluded principles have no carrier coordinate, the five listed rows exhaust the local NameCert obligations. □

Theorem 7637.3 (Bishop regular completion monad unit and multiplication ledger)**.** *Every unit, multiplication, left-unit, right-unit, and associativity comparison exported by an accepted* $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$ *carrier is a comparison of the displayed ledger*

$$D, S, R, E, L, U, J, H, C, P, N.$$

The unit row U *embeds source regular rational data through the same* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, and the multiplication row* J *flattens nested completion requests only after the law ledger* L *has replayed the relevant finite windows and dyadic tolerances. The comparison exports no quotient completion, quotient stream equality, countable choice, trichotomy, selected host limit, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the unit side first. The row U is available only after the displayed dyadic ledger D, stream-window row S, and regular readback row R have been projected, so source data enter the completion surface by copying those rows.

For multiplication, read the law ledger L and then the row J. A nested completion request supplies outer and inner finite windows; J flattens them by replaying the same dyadic budget and regular readback route rather than by selecting a quotient representative.

The left-unit and right-unit comparisons are therefore comparisons of copied finite rows. Associativity compares the two finite replays of a three-stage request, and both replays enumerate the same dyadic tolerances, stream windows, readbacks, law ledger rows, and Real-seal handoff.

Transport, replay, provenance, and local naming close the ledger through H, C, P, N. Since the carrier has no row for the excluded principles, none of the exported monad comparisons can depend on them. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionMonad}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletionMonad}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName finite windows, RegSeqRat readbacks, a RealUp seal, a CauchyCompletionMonadLaw ledger, unit and multiplication rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRegularCompletionMonad}^{\uparrow}}$, seed)

Scope closed: Definition 7637.1, Definition 7637.2, and Definition 7637.3 seed the finite Bishop regular completion monad surface over the L10 Real and Completion stack.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRegularCompletionMonad}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, quotient stream equality, countable choice, trichotomy, selected host limits, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source routing, unit exactness, multiplication exactness, law-ledger replay, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletionMo

Chapter 7638

A Concrete Naming Certificate for $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$

Following Blaschke and Hausdorff, the $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$ packet records the finite-net interface by which compact subsets of a compact metric source are compared inside the compact hyperspace without passing through host powersets, quotient hyperspaces, selected representatives, or choice. It sits after the Hausdorff-distance interface of chapter 2086, the compact metric source of chapter 129, the compact-subset ledger of chapter 1660, the compact metric hyperspace route of chapter 5184, and the Blaschke selection surface of chapter 2370.

Definition 7638.1 (Compact hyperspace finite-net carrier)**.** *A* $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, H, D, E, U, S, T, C, P, N)$$

with the following displayed rows:

1. X *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the metric, finite-net, total-boundedness, and completion data of the ambient compact metric object.*
2. H *is the* $\mathsf{Hyperspace}^{\uparrow}$ *compact-subset ledger over* X*.*
3. D *is the* $\mathsf{HausdorffMetric}^{\uparrow}$ *bidirectional distance ledger for displayed compact-subset names.*
4. E *is the tolerance-indexed finite-net family in the hyperspace: each entry records a positive tolerance, finitely many compact-subset names, and Hausdorff coverage witnesses for the inspected compact-subset rows.*
5. U *is the finite-union row, recording the finite union of selected compact-subset names and its displayed compact-subset readback through* H*.*
6. S *is the stability ledger showing that Hausdorff finite-net matching is preserved when finitely many accepted compact-subset rows are united.*
7. T *records componentwise* hsame *transport for* X, H, D, E, U, S, P, N*.*
8. C *records displayed* Cont *replay through*

$$X, H, D, E \longmapsto U, S.$$

9. P *is the* Pkg *provenance over* $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{CompactMetricHyperspace}^{\uparrow}$, $\mathsf{BlaschkeSelectionCompactHyperspace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $X, H, D, E, U, S, T, C, P, N$. It has no coordinate for host subsets, powerset quotients, open-cover compactness, selected dense families, selected Hausdorff minimizers, or ambient hyperspace completion.

Theorem 7638.2 (Compact hyperspace finite-net NameCert obligations)**.** *For every accepted* $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$ *carrier*

$$F = (X, H, D, E, U, S, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}}$ *surface consists exactly of the following five finite obligation rows:*

1. *source admission, requiring X to expose the compact metric finite-net and completion rows before any hyperspace net is public;*
2. *compact-subset admission, requiring every named compact subset in H and every finite-net center in E to be read through the same* $\mathsf{Hyperspace}^{\uparrow}$ *ledger;*
3. *Hausdorff finite-net matching, requiring D and E to display bidirectional finite coverage at each requested tolerance;*
4. *finite-union stability, requiring U, S to keep finite unions inside the same compact-subset ledger and to preserve the displayed Hausdorff finite-net matching;*
5. *structural exhaustion, requiring T, C, P, N to transport, replay, source, and name only the displayed finite route.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier. The source row X is the only entry point for the compact metric, finite-net, total-boundedness, and completion data, and the compact-subset ledger H is the only entry point for hyperspace names.

Read the Hausdorff and finite-net rows next. The row D supplies bidirectional distance witnesses, while E lists finitely many compact-subset centers and coverage witnesses at the requested tolerances. Both rows are tied to X and H, so the matching cannot range over a host powerset.

The finite-union row U and stability ledger S are then read as the only union-facing coordinates. They certify that finite unions of accepted centers remain named compact-subset rows and that the Hausdorff finite-net matching is preserved under that finite operation.

Finally T, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no additional coordinate for host subsets, quotient hyperspaces, selected dense families, selected minimizers, or ambient hyperspace completion, the five rows exhaust the local NameCert surface. □

Theorem 7638.3 (Compact hyperspace finite-net finite-union stability)**.** *Let $F = (X, H, D, E, U, S, T, C, P, N)$ be an accepted* $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$ *carrier. If a finite family of compact-subset rows is matched by the Hausdorff finite-net row E at a displayed tolerance, then the finite union named by U is matched at the same hyperspace read through the stability ledger S. The stability uses only the* $\mathsf{HausdorffMetric}^{\uparrow}$ *ledger of chapter 2086, the compact metric source of chapter 129, the hyperspace ledger of chapter 1660, the compact metric hyperspace route of chapter 5184, and the Blaschke finite-selection surface of chapter 2370.*

Proof. Start with the finite family named in E. Each member is a displayed compact-subset row in H, and each matching witness is a bidirectional Hausdorff read through D over the compact metric source X.

Apply the finite-union row U. It records the union as another compact-subset row over the same source, rather than as a host subset or quotient object.

Now use the stability ledger S. For each requested tolerance, the matching witnesses for the finitely many members are replayed through the same Hausdorff ledger, and the union read is accepted because every constituent row is already displayed in H.

The structural rows keep the operation inside the packet. Componentwise hsame transport and Cont replay preserve X, H, D, E, U, S, while P, N source and name the route. Thus finite-union stability is a finite NameCert consequence, not an open-cover compactness theorem or a choice-selected hyperspace argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}$ packet is generated from a CompactMetricUp source, a HyperspaceUp compact-subset ledger, HausdorffMetricUp distance rows, hyperspace finite-net centers, finite-union rows, stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7638.1, Definition 7638.2, and Definition 7638.3 seed the finite-net and finite-union stability surface for compact hyperspace packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactHyperspaceFiniteNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets, quotient hyperspaces, selected dense families, selected Hausdorff minimizers, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-subset admission, Hausdorff finite-net matching, finite-union stability, transport, replay, provenance, and local naming for BEDC.Derived.CompactHyperspaceFiniteNetUp.

Chapter 7639

A Concrete Naming Certificate for $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$

Following Whitney's stratification conditions and the finite control viewpoint of Goresky–MacPherson stratified Morse theory, the $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ packet records a finite-atlas stratification surface as BEDC NameCert data. It sits over the manifold carrier of chapter 96, the finite jet compatibility rows of chapter 3679, the finite embedding-candidate rows of chapter 6532, and the filtration consumer boundary of chapter 239. The packet names the finite strata, frontier incidences, chart compatibility checks, transport, replay, provenance, and local naming visible to stratified-space consumers; it is not a host Whitney theorem, selected tubular-neighborhood system, quotient realization, global triangulation, or ambient transversality principle.

Definition 7639.1 (Whitney stratification finite-atlas carrier)**.** *A* $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, A, S, F, Q, J, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *source row, carrying the ambient finite-atlas manifold data read by local stratified charts;*
2. *A is the finite atlas row, listing the chart domains and coordinate windows used to inspect each stratum;*
3. *S is the finite stratum-list row, naming the displayed strata, their depth tags, and their admitted chart windows;*
4. *F is the frontier-incidence row, recording which stratum closures may meet lower-depth strata;*
5. *Q is the chart-compatibility row, checking that overlapping chart windows preserve the finite stratum labels and frontier incidences;*
6. *J is the* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ *compatibility row, retaining finite jet comparisons as boundary data rather than as a selected smooth extension;*
7. *E is the* $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$ *and* $\mathsf{PersistentHom}^{\uparrow}$ *consumer row, exposing embedding-candidate and filtration-facing reads only after M, A, S, F, Q, J are displayed;*
8. *H is the componentwise* hsame *transport row for the manifold, atlas, stratum, frontier, chart, jet, and consumer rows;*

9. *C records displayed* Cont *replay from a stratification request through M, A, S, F, Q, J, E, H;*
10. *P is the* Pkg *provenance over* $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$, $\mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow}$, $\mathsf{PersistentHom}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, A, S, F, Q, J, E, H, C, P, N$. It has no coordinate for a host Whitney condition theorem, selected tubular neighborhoods, quotient strata, global triangulation choice, ambient transversality, or persistent-homology completeness.

Theorem 7639.2 (Whitney stratification finite-atlas NameCert obligations)**.** *For every accepted* $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ *carrier $W = (M, A, S, F, Q, J, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WhitneyStratificationFi}}$ *surface consists exactly of carrier admission for the ambient manifold row, finite atlas, finite stratum list, frontier incidence, chart compatibility, finite jet boundary, embedding and filtration consumer row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every stratified-space consumer must read those rows before it may treat the packet as a finite Whitney stratification certificate.*

Proof. Project the carrier of Definition 7639.1. The manifold row M, atlas row A, stratum row S, and frontier row F are displayed coordinates, so the packet exposes the ambient chart source, finite chart inventory, finite stratum list, and allowed closure incidences before any downstream read.

Read the compatibility and consumer rows next. The chart row Q keeps the stratum labels stable across overlaps, the finite jet row J imports only the bounded compatibility surface of chapter 3679, and the consumer row E routes embedding-candidate and filtration-facing reads through chapter 6532 and chapter 239.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier contains no coordinates for host Whitney-condition theorems, selected tubular neighborhoods, quotient strata, global triangulation, ambient transversality, or persistent-homology completeness, the listed rows exhaust the NameCert obligation surface. □

Theorem 7639.3 (Whitney stratification frontier condition route)**.** *Every frontier-condition read exported by an accepted* $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ *packet factors through*

$$\mathsf{Manifold}^{\uparrow} \longmapsto A, S, F, Q \longmapsto \mathsf{WhitneyExtensionFiniteJet}^{\uparrow}, \mathsf{WhitneyEmbeddingFiniteAtlas}^{\uparrow} \longmapsto \mathsf{PersistentHom}^{\uparrow}.$$

The route supplies a finite atlas, finite stratum list, displayed frontier incidence, chart compatibility, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *data. It exports no quotient completion of strata, selected limit, choice schedule, host equality of stratified spaces, selected tubular neighborhood, ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle, or global Whitney stratification theorem.*

Proof. Start from the carrier projection. The frontier row F is not available by itself: it is read after the ambient manifold row M, finite atlas row A, and finite stratum-list row S have fixed the displayed chart windows and stratum names.

Use the chart-compatibility row Q to transport the frontier incidence across overlapping atlas windows. The finite jet row J then supplies only the bounded Whitney-extension compatibility surface, while the consumer row E keeps embedding-candidate and filtration reads downstream of the displayed stratification rows.

The structural rows H, C, P, N do not add a second frontier source. They preserve the same finite route by componentwise transport, replay it for consumers, record provenance, and name

the packet locally. The absent quotient, selected-limit, choice, host-equality, tubular-neighborhood, ambient-completeness, and global Whitney-theorem endpoints therefore cannot be read from the packet. □

Falsifiable prediction: Every accepted $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ read exposes the ManifoldUp source, finite atlas, finite stratum list, frontier-incidence row, chart-compatibility row, WhitneyExtensionFiniteJetUp boundary, WhitneyEmbeddingFiniteAtlasUp consumer route, PersistentHomUp filtration-facing route, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a frontier-condition consumer receives the packet.

Independence witness: manifold, whitney-extension-finite-jet, whitney-embedding-finite-atlas, persistenthom: no listed sibling supplies the joint finite-atlas stratification packet $W = (M, A, S, F, Q, J, E, H, C, P,$ because each sibling contributes only an ambient chart carrier, finite jet boundary, embedding-candidate route, or filtration-facing consumer surface while this chapter binds the finite stratum and frontier rows into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}}$.

Constructive story: A $\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}$ packet is generated from a ManifoldUp finite-atlas source, finite stratum list, frontier-incidence row, chart-compatibility row, WhitneyExtensionFiniteJetUp compatibility boundary, WhitneyEmbeddingFiniteAtlasUp and PersistentHomUp consumer route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7639.1, Definition 7639.2, and Definition 7639.3 seed the finite Whitney stratification packet over displayed finite-atlas, stratum, frontier, chart-compatibility, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WhitneyStratificationFiniteAtlas}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Whitney-condition theorems, selected tubular neighborhoods, quotient strata, global triangulation choice, ambient transversality, persistent-homology completeness, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, finite-atlas exposure, stratum inventory, frontier-incidence exactness, chart compatibility, finite jet boundary routing, embedding and filtration consumer routing, transport, replay, provenance, and local naming for BEDC.Derived.WhitneyStratificationFiniteAtlasUp.

Chapter 7640

A Concrete Naming Certificate for $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$

Following Haar's invariant integration principle in the finite-group case, the $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ packet records normalized averaging over a displayed finite group action as finite NameCert data. It consumes the finite action rows of chapter 41, the probability-mass interface of chapter 184, and the finite measure ledger of chapter 92. The packet names only the finite invariant average; it does not import sigma-additive Haar measure, a choice of representatives, quotient orbit equality, host sums, or ambient locally compact groups.

Definition 7640.1 (HaarIntegralFiniteGroup averaging carrier)**.** *A* $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, X, F, Q, L, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{Group}^{\uparrow}$ *action row, including the finite multiplication, unit, inverse, and action table entries needed to translate samples.*
2. *X is the finite support enumeration row listing exactly the points whose values are averaged.*
3. *F is the value row assigning a named scalar or probability-readable value to each enumerated support point.*
4. *Q is the normalized averaging row, recording the finite numerator ledger and denominator schedule read through the* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{Measure}^{\uparrow}$ *interfaces.*
5. *L and R are the left- and right-translation rows, showing how the finite action table permutes the support enumeration before the same average row is read again.*
6. *H records componentwise* hsame *transport for the group action, support enumeration, value, normalized average, translation, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the group action and support enumeration through finite averaging and both translation checks.*
8. *P is the* Pkg *provenance over* $\mathsf{Group}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HaarIntegralFiniteGroup}^{\uparrow}}$ *row.*

The carrier has no coordinate for sigma-additive Haar measure, selected orbit representatives, quotient orbit equality, host summation operators, or ambient locally compact groups.

Theorem 7640.2 (HaarIntegralFiniteGroup finite invariance)**.** *For every accepted* $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ *carrier* $A = (G, X, F, Q, L, R, H, C, P, N)$*, the finite average row* Q *is invariant under the displayed left- and right-translation rows* L *and* R*. The comparison is made only by replaying the finite support enumeration* X*, the action table in* G*, and the componentwise* hsame *transport row* H*.*

Proof. Project the carrier of Definition 7640.1. The support row X is finite and displayed, so a translation row can only reorder named support entries already present in the packet.

Read the normalized average row Q. Its numerator ledger and denominator schedule are tied to the displayed support enumeration and to the probability and measure rows consumed by the packet.

Replay the continuation row C first through the left-translation row and then through the right-translation row. In both cases the action table from G permutes the same finite entries, and the transport row H carries the value and average rows componentwise. Hence the translated readback is the same finite average row, without invoking any ambient Haar measure or host summation theorem. □

Theorem 7640.3 (HaarIntegralFiniteGroup NameCert obligations)**.** *For every accepted* $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ *carrier, the local* $\mathsf{NameCert}_{\mathsf{HaarIntegralFiniteGroup}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the displayed group action, support enumeration, value, normalized average, translation, transport, continuation, provenance, and local naming rows;*
2. *finite support exposure, requiring the support enumeration* X *to be public before any average or translation row is consumed;*
3. *averaging normalization, requiring* Q *to display the numerator ledger and denominator schedule read through the finite probability and measure interfaces;*
4. *translation invariance, requiring* L *and* R *to replay the same finite support through the action table of* G*;*
5. *ledger non-escape, excluding sigma-additive Haar measure, choice of representatives, quotient orbit equality, host sums, and ambient locally compact groups.*

Proof. Carrier admission is the tuple of Definition 7640.1; no row outside $G, X, F, Q, L, R, H, C, P, N$ is admitted.

Finite support exposure and averaging normalization are the two rows that make the average readable. The support enumeration fixes the entries, while the normalized average row records the finite ledger and denominator schedule.

Translation invariance is Definition 7640.2. The final ledger row is exact because the carrier contains no sigma-additive, representative-choice, quotient-orbit, host-sum, or locally compact group coordinate. □

Theorem 7640.4 (HaarIntegralFiniteGroup non-escape)**.** *An accepted* $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ *packet exports no sigma-additive Haar measure, no choice of orbit representatives, no quotient orbit equality, no host summation operator, and no ambient locally compact group. Every invariant-average consumer must read only the displayed rows* $G, X, F, Q, L, R, H, C, P, N$*.*

Proof. The carrier of Definition 7640.1 lists the complete public packet. The only average row is the finite normalized row Q, and the only invariance rows are the displayed left and right translation rows.

The obligation theorem Definition 7640.3 requires every consumer to pass through support exposure, normalization, and translation replay. Since no further coordinate is present, the excluded

measure-theoretic, quotient, representative, host-sum, and locally compact group data cannot be projected from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{HaarIntegralFiniteGroup}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HaarIntegralFiniteGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7640.1, Definition 7640.2, and Definition 7640.3 seed the finite invariant-averaging packet over displayed group, probability, and measure rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HaarIntegralFiniteGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-additive Haar measure, representative choice, quotient orbit equality, host summation, ambient locally compact groups, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite support exposure, averaging normalization, left and right translation invariance, transport, replay, provenance, local NameCert coverage, and ledger non-escape for the same packet.

Constructive story: A $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$ packet is generated from a finite GroupUp action row, a finite support enumeration row, a value row, a normalized averaging row, left and right translation rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7641

A Concrete Naming Certificate for $\mathsf{CauchyRealNegation}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyRealNegation}^{\uparrow}$ packet records additive inverse as a finite Real-seal route rather than as completed-real algebra. It sits above the regular sign-flip surface of chapter 459 and reads the same StreamName, DyadicRatCore, RegSeqRat, and Real rows before exporting a unary $\mathsf{Real}^{\uparrow}$ boundary.

Definition 7641.1 (CauchyRealNegation carrier)**.** *A* $\mathsf{CauchyRealNegation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegularCauchyNegation}^{\uparrow}$ *row naming the finite sign-flip route of chapter 459;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window surface read by the source regular Cauchy name and by the negated packet;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and signed-observation ledger consumed by the sign-flip route;*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the sign-flipped dyadic observations have been routed through the regular rational classifier;*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from Q and from no independent completed-real inverse operation;*
6. *H stores componentwise* hsame *transport for R, S, D, Q, E;*
7. *C stores displayed* Cont *replay for the source windows, dyadic sign flip, regular readback, and Real-seal handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealNegation}^{\uparrow}$, $\mathsf{RegularCauchyNegation}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealNegation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, host real equality, selected limits, trichotomy, ambient completeness, or a completed-real inverse law.

Theorem 7641.2 (CauchyRealNegation NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyRealNegation}^{\uparrow}}$ *surface for Definition 7641.1 consists of carrier admission for $G = (R, S, D, Q, E, H, C, P, N)$,*

source binding to the RegularCauchyNegation$^{\uparrow}$ *sign-flip packet, finite-window binding through* StreamName$^{\uparrow}$, *dyadic tolerance binding through* DyadicRatCore$^{\uparrow}$, *regular rational readback through* RegSeqRat$^{\uparrow}$, *Real-seal delivery through* E, *componentwise* hsame *transport through* H, *displayed* Cont *replay through* C, Pkg *provenance through* P, *and local naming through* N.

Proof. Project the displayed carrier. Its first five rows expose the regular sign-flip source, stream-window surface, dyadic observation ledger, regular rational readback, and terminal Real seal.

Bind the source route to chapter 459. That sibling already names the regular sign-flip surface; this packet only records the Real-seal consumer route that reads it through S, D, Q, E.

The transport, replay, provenance, and local naming rows preserve exactly that finite route. Since no remaining carrier coordinate exists, the excluded quotient, host-equality, selected-limit, trichotomy, completeness, and completed inverse objects cannot be read from the certificate. □

Theorem 7641.3 (CauchyRealNegation Real seal route)**.** *Every additive-inverse consumer of an accepted* CauchyRealNegation$^{\uparrow}$ *carrier must read the route*

$$R, S, D, Q, E, H, C, P, N$$

before it can consume the Real$^{\uparrow}$ *seal. The row* R *supplies the regular sign-flip certificate,* S *supplies the finite windows,* D *supplies the dyadic tolerance and sign data,* Q *supplies the* RegSeqRat$^{\uparrow}$ *readback, and* E *is the only Real-seal boundary exported to the consumer.*

Proof. Start with the carrier order in Definition 7641.1. The Real seal E appears only after the regular sign-flip route, finite window surface, dyadic ledger, and regular rational readback rows have been named.

Apply the obligation surface of Definition 7641.2. It binds every consumer route to R, S, D, Q before E is visible, and it keeps H, C, P, N as transport, replay, provenance, and local naming rows for the same data.

Thus the additive-inverse route is a seal-level BEDC handoff over Real$^{\uparrow}$. It does not assert completed real arithmetic, quotient equality of Cauchy names, host sequence equality, selected limits, trichotomy, or ambient completeness. □

Closure status for NameCert$_{\text{CauchyRealNegation}^{\uparrow}}$.

Constructive story: A CauchyRealNegation$^{\uparrow}$ packet is generated from a regular sign-flip row, StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a Real seal, displayed transport, replay, provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRealNegation}^{\uparrow}}$, seed)

Scope closed: Definition 7641.1, Definition 7641.2, and Definition 7641.3 expose the seed carrier, obligation surface, and Real-seal additive-inverse route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRealNegation}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close completed real additive-inverse laws, quotient Cauchy equality, host real equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission and exact source-row binding for the regular sign-flip, StreamName, DyadicRatCore, RegSeqRat, Real-seal, transport, replay, provenance, and local naming rows.

Chapter 7642

A Concrete Naming Certificate for $\mathsf{ToeplitzSilverman}^{\uparrow}$

Following Toeplitz and Silverman on regular matrix summability, the $\mathsf{ToeplitzSilverman}^{\uparrow}$ packet names the finite matrix-window bridge that sits between the Toeplitz transform route of chapter 1682, the regular matrix certificate of chapter 2126, the Hardy–Cesaro averaging row of chapter 1765, the convergence-window row of chapter 1827, the Kronecker tail-control consumer of chapter 1879, the regular rational readback of chapter 301, and the terminal seal of chapter 38. It is a finite NameCert surface for the shared regular-matrix handoff; it is not a host summability theorem, a completed infinite matrix, quotient equality of real-name streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7642.1 (Toeplitz–Silverman carrier)**.** *A* $\mathsf{ToeplitzSilverman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, B, V, W, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite matrix-window row, listing the inspected coefficient rows, finite column windows, truncation thresholds, and row-index requests.*
2. *B is the row-bound ledger, recording the dyadic row-sum bounds used before any transformed read is exposed.*
3. *V is the vanishing-column ledger, recording the finite small-entry requests that make the inspected matrix compatible with the convergence-window route.*
4. *W is the source-window row, listing only the finite input observations read from the regular name.*
5. *F is the transformed finite-row surface obtained from M, B, V, W.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source windows and transformed rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, B, V, W, F, R have been displayed.*
8. *H stores componentwise* hsame *transport for the matrix, bound, vanishing, source, transformed, readback, seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from matrix inspection to source-window selection, transformed-row formation, regular readback, and real sealing.*

10. *P is the* Pkg *provenance over* ToeplitzSilverman$^{\uparrow}$, SilvermanToeplitz$^{\uparrow}$, ToeplitzLemma$^{\uparrow}$, HardyCesaroMean$^{\uparrow}$, CesaroConvergence$^{\uparrow}$, KroneckerLemma$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{ToeplitzSilverman}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, B, V, W, F, R, E, H, C, P, N$. It has no coordinate for a host summability theorem, completed infinite matrix, selected external limit, quotient equality of real-name streams, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.ToeplitzSilvermanUp`

Theorem 7642.2 (Toeplitz–Silverman NameCert obligations)**.** *For every accepted* ToeplitzSilverman$^{\uparrow}$ *carrier $T = (M, B, V, W, F, R, E, H, C, P, N)$, the local* NameCert$_{\text{ToeplitzSilverman}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the matrix-window, row-bound, vanishing-column, source-window, transformed-row, readback, seal, transport, continuation, provenance, and naming rows;*
2. *matrix-window exactness, requiring every transformed row to read coefficient data from M before any regular handoff is available;*
3. *boundedness and vanishing exactness, requiring the row-sum ledger B and the column-vanishing ledger V to be displayed before the transformed finite row F is exposed;*
4. *source-to-transform handoff, requiring W and F to be routed through the same finite matrix window;*
5. *regular readback and real sealing, requiring every completion-facing read to pass through R and then E;*
6. *sibling-route provenance, requiring P to cite the finite summability anchors* ToeplitzLemma$^{\uparrow}$, HardyCesaroMean$^{\uparrow}$, CesaroConvergence$^{\uparrow}$, KroneckerLemma$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *without adding a host analytic principle.*

Proof. Project the carrier of Definition 7642.1. Carrier admission is exactly the displayed inventory $M, B, V, W, F, R, E, H, C, P, N$, so the local certificate has no detached coordinate for a completed matrix or a host summability method.

The matrix-window clause is read from M. The boundedness and vanishing clauses are read from B and V, and the source data are the finite observations in W. Hence the transformed row F is downstream of the same finite window data that supply the regular matrix conditions.

The completion-facing part of the route is forced through R and then E. The rows H, C, P, N transport, replay, source, and name this route, while P records the sibling anchors rather than another analytic path. □

Theorem 7642.3 (Toeplitz–Silverman regular handoff)**.** *Every accepted* ToeplitzSilverman$^{\uparrow}$ *read that reaches a* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer factors through the finite route*

$$M \longmapsto (B, V) \longmapsto W \longmapsto F \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

The route refines the ToeplitzLemma$^{\uparrow}$ *matrix-window discipline, records the* HardyCesaroMean$^{\uparrow}$ *and* CesaroConvergence$^{\uparrow}$ *special surfaces, leaves* KroneckerLemma$^{\uparrow}$ *with a named finite-matrix bridge, and exposes no readback except through* RegSeqRat$^{\uparrow}$ *before the* Real$^{\uparrow}$ *seal.*

Proof. Start with a regular or real-facing consumer. By Definition 7642.1, the only coefficient data visible to the classifier are the finite rows in M, with regularity checks held in B and V.

The source sequence is then inspected through W, and the transformed row is displayed as F. Thus the consumer cannot reach regular rational readback before the matrix window, bounded-row ledger, vanishing-column ledger, source window, and transformed row have all been exposed.

The handoff to regular names is R, and the terminal real-facing seal is E. The structural rows H, C, P, N preserve and name the same path, while the sibling anchors in P identify the Toeplitz, Hardy–Cesaro, Cesaro-convergence, and Kronecker routes as provenance rather than bypasses. □

Falsifiable prediction: Every accepted $\mathsf{ToeplitzSilverman}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ while omitting the finite matrix window, row-bound ledger, vanishing-column ledger, source window, transformed finite row, readback row, real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: silvermantoeplitz, toeplitzlemma, hardycesaromean, cesaroconvergence, kroneckerlemma, regseqrat, real: $\mathsf{ToeplitzSilverman}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite matrix-window bridge, bounded-row and vanishing-column ledgers, source windows, transformed rows, regular readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ToeplitzSilverman}^{\uparrow}}$.

Constructive story: A $\mathsf{ToeplitzSilverman}^{\uparrow}$ packet is generated from a finite matrix window, row-bound ledger, vanishing-column ledger, source windows, transformed finite rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ToeplitzSilverman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7642.1, Definition 7642.2, and Definition 7642.3 seed the finite matrix-window bridge from regular summability data to Real-facing seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ToeplitzSilverman}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close host summability theorems, completed infinite matrices, selected limits, quotient equality of real-name streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, matrix-window exactness, boundedness and vanishing exactness, source-to-transform handoff, regular readback, Real-seal nonescape, sibling-route provenance, and TasteGate field faithfulness for BEDC.Derived.ToeplitzSilvermanUp.

Chapter 7643

A Concrete Naming Certificate for $\mathsf{KrullIntersection}^{\uparrow}$

Following Atiyah–Macdonald style Noetherian commutative algebra, the $\mathsf{KrullIntersection}^{\uparrow}$ packet records the finite BEDC naming surface for the ideal-adic tail condition that a displayed module element disappears from all sufficiently exposed tail-power rows. It sits after the ring, ideal, module, and Noetherian module carriers of chapter 43, chapter 81, chapter 46, and chapter 3648; it is a sibling of the Artin–Rees filtration route in chapter 6899 and a source for completion-facing algebra packets. The packet names only finite I-adic tail-power rows, transport, replay, provenance, and local naming; it does not import quotient completion equality, a selected infinite intersection, separatedness of a completion, or an ambient host theorem.

Definition 7643.1 (Krull intersection carrier)**.** *A* $\mathsf{KrullIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{KrullIntersection}(R, I, M, N, T, G, H, C, P, Z)$$

with the following displayed rows:

1. *R is the* $\mathsf{Ring}^{\uparrow}$ *or* $\mathsf{CommRing}^{\uparrow}$ *source row read by the algebra consumer.*
2. *I is the* $\mathsf{Ideal}^{\uparrow}$ *row over the same ring classifier, carrying the ideal-power requests.*
3. *M is the* $\mathsf{Module}^{\uparrow}$ *row, together with the* $\mathsf{NoetherianModule}^{\uparrow}$ *surface needed by the finite tail-power route.*
4. *N is the Noetherian control row, exposing only the finite generator and stabilization ledgers consumed by ideal-adic powers.*
5. *T is the I-adic tail-power ledger, recording requested powers $I^n M$, later windows $I^{n+k} M$, and the finite comparison rows between them.*
6. *G is the Krull-intersection classifier row, comparing accepted packets by R, I, M, N, T and by the declared tail membership route.*
7. *H records componentwise* hsame *transport for the ring, ideal, module, Noetherian, tail-power, and classifier rows.*
8. *C records displayed* Cont *replay from an algebra or completion-facing request through the same finite tail-power rows.*
9. *P is the* Pkg *provenance over* $\mathsf{KrullIntersection}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{Ideal}^{\uparrow}$*,* $\mathsf{Module}^{\uparrow}$*,* $\mathsf{NoetherianModule}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. Z is the local $\mathsf{NameCert}_{\mathsf{KrullIntersection}^{\uparrow}}$ *row binding the packet.*

The carrier has no coordinate for quotient completion equality, a selected element of an infinite intersection, host separatedness, countable choice, or an external Krull intersection theorem.

Theorem 7643.2 (Krull intersection NameCert obligations)**.** *For every accepted* $\mathsf{KrullIntersection}^{\uparrow}$ *carrier* $\mathsf{KrullIntersection}(R, I, M, N, T, G, H, C, P, Z)$*, the local* $\mathsf{NameCert}_{\mathsf{KrullIntersection}^{\uparrow}}$ *surface consists exactly of ring-source exposure, ideal exposure, module exposure, Noetherian control, finite I-adic tail-power rows, classifier stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A completion-facing or algebra-facing consumer may inspect only the finite route*

$$R, I, M, N \longrightarrow T, G \longrightarrow H, C, P, Z.$$

It receives no quotient completion equality, no selected infinite intersection element, no host separatedness theorem, no countable-choice selector, and no ambient equality of all ideal-power intersections.

Proof. Carrier admission is projection from Definition 7643.1. The rows R, I, M, N expose the Noetherian ring, ideal, module, and control surfaces before any ideal-power tail can be read.

The row T supplies only finite I-adic tail-power windows. Each inspected tail comparison is therefore a displayed row of the packet, not an appeal to a selected infinite intersection or to quotient completion equality.

The classifier G compares packets through the same source and tail-power rows. Componentwise hsame transport H and displayed Cont replay C preserve those rows, while P records provenance and Z repacks them as the local NameCert.

Since no carrier coordinate names quotient completion equality, a selected infinite intersection element, host separatedness, countable choice, or ambient equality of all ideal-power intersections, the listed rows exhaust the local certificate surface. □

Falsifiable prediction: Any accepted $\mathsf{KrullIntersection}^{\uparrow}$ consumer that cites an ideal-adic tail conclusion without exposing $R, I, M, N, T, G, H, C, P, Z$ refutes the carrier surface of Definition 7643.1.

Independence witness: ring, ideal, module, noetherian-module, artin-rees, completion: no listed sibling is bijective to $\mathsf{KrullIntersection}^{\uparrow}$, because this packet jointly binds finite ideal-power tail rows, Noetherian control, classifier stability, transport, replay, provenance, and local NameCert rows while refusing quotient completion equality and selected infinite intersections.

Closure status for $\mathsf{NameCert}_{\mathsf{KrullIntersection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{KrullIntersection}^{\uparrow}$ packet is generated from a ring source, ideal source, module source, Noetherian control row, finite ideal-adic tail-power ledger, classifier row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KrullIntersection}^{\uparrow}}$, seed)

Scope closed: Definition 7643.1 and Definition 7643.2 seed the finite Krull-intersection certificate over RingUp, IdealUp, ModuleUp, NoetherianModuleUp, ArtinReesUp-adjacent filtration rows, completion-facing consumers, and local NameCert data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KrullIntersection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected infinite intersections, host separatedness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source compatibility, finite ideal-adic tail-power exposure, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.KrullIntersectionUp.

Chapter 7644

A Concrete Naming Certificate for $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ packet records the finite dyadic interval-selection surface used when a Real or completion route needs a displayed local interval but must not import a hidden countable-choice operator. It sits between the dyadic rational core of chapter 291, the finite stream windows of chapter 126, the regular rational readbacks of chapter 301, the terminal real-name seals of chapter 38, and the located interval carrier of chapter 394. The packet names only a finite request ledger, a displayed dyadic candidate family, a local selection row, a located-interval handoff, structural transport, replay, provenance, and local naming; it does not choose an infinite subsequence, a global Cauchy selector, a completed real endpoint, or a countable family of intervals.

Definition 7644.1 (Choice-free dyadic interval selection carrier)**.** *A* $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (Q, D, W, R, E, L, H, C, P, N)$$

with the following visible rows:

1. *Q is the finite request row. It records the inspected tolerance, endpoint-side flag, and consumer route that asked for a dyadic interval witness.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *candidate ledger. It supplies only the finitely displayed dyadic endpoints and containment comparisons named by Q.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the inspected real-name or completion-name prefixes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximants exposed by those windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected endpoint names, with no selected completed real.*
6. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *handoff row, packaging the displayed dyadic endpoints as a located interval cell when the consumer asks for interval-shaped output.*
7. *H records componentwise* hsame *transport for $Q, D, W, R, E, L, C, P, N$.*
8. *C records displayed* Cont *replay from the interval-selection request through the finite dyadic, window, readback, Real-seal, and located-interval rows.*

9. *P is the* Pkg *provenance over* ChoiceFreeDyadicIntervalSelection$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, LocatedInterval$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}$ *row.*

The classifier accepts a packet only through the displayed tuple $Q, D, W, R, E, L, H, C, P, N$. It has no coordinate for countable choice, dependent choice, a selected infinite branch, a global interval selector, a completed endpoint value, or a quotient of real names.

Theorem 7644.2 (Choice-free dyadic interval selection obligations)**.** *For every accepted* ChoiceFreeDyadicIntervalSe *carrier*

$$S = (Q, D, W, R, E, L, H, C, P, N),$$

the local NameCert$_{\text{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}$ *obligation surface has exactly five finite rows:*

1. *carrier admission for the displayed packet S and its finite request row Q;*
2. *dyadic candidate exposure through D together with window and rational readback exposure through W and R;*
3. *terminal real-name sealing through E and located-interval handoff through L;*
4. *componentwise transport and displayed replay through H and C;*
5. *provenance and local naming through P and N.*

No additional obligation asks for a countable selection function, an infinite chain of interval choices, a quotient-real endpoint, or a host-completion choice principle.

Proof. Project the carrier of Definition 7644.1. Its accepted rows are exactly $Q, D, W, R, E, L, H, C, P, N$, and the classifier compares only these displayed components by hsame.

The computational part of the obligation surface is exhausted by Q, D, W, R, E, L. The request row fixes one finite inspection, the dyadic core supplies the displayed endpoint candidates, the stream and regular rational rows expose the requested prefixes, the Real row seals the inspected endpoint names, and the located interval row repacks the same finite dyadic cell.

The structural part is exhausted by H, C, P, N. These rows transport, replay, source, and name the same packet. Since no row contains a function selecting intervals for all tolerances or all request histories, the local certificate cannot smuggle countable choice into the Real or completion-facing route. □

Theorem 7644.3 (Choice-free dyadic interval selection finite route)**.** *Every accepted* ChoiceFreeDyadicIntervalSelect *read factors through the finite route*

$$Q \longmapsto D \longmapsto W, R, E \longmapsto L \longmapsto H, C, P, N.$$

The route exports only the inspected request, displayed dyadic candidates, finite stream windows, regular rational readbacks, terminal Real seals, located-interval handoff, transport, replay, provenance, and local naming. It exports no countable selector, dependent-choice tree, completed real endpoint, or global interval-selection oracle.

Proof. Begin with an accepted consumer of an interval-selection read. By Definition 7644.1, the consumer enters through the finite request row Q and reaches dyadic data only through D.

Apply Definition 7644.2. The only rows downstream of D are the finite window and readback rows W, R, the terminal seal row E, and the located-interval handoff L before the structural rows are inspected.

The sibling packets $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{LocatedInterval}^{\uparrow}$ provide their own finite NameCert surfaces. None adds a selected infinite interval family or a host choice operator to this packet. Hence every accepted read remains on the displayed finite route. □

Theorem 7644.4 (Choice-free dyadic interval selection nonescape)**.** *An accepted* $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ *consumer cannot obtain a* $\mathsf{LocatedInterval}^{\uparrow}$ *handoff or a* $\mathsf{Real}^{\uparrow}$ *endpoint seal without first displaying* Q, D, W, R, E *as appropriate to the request. In particular, any route that produces an interval cell by choosing a member of an infinite dyadic family is outside the local* $\mathsf{NameCert}_{\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}$ *surface.*

Proof. Read the accepted carrier through Definition 7644.1. The located-interval output occurs only in L, and L is downstream of the finite request, dyadic candidate, window, readback, and Real-seal rows.

Use Definition 7644.3. The route places Q, D, W, R, E before L and then proceeds only to H, C, P, N, so the carrier has no independent interval-output entry point.

The structural rows can only transport, replay, source, and name the same displayed packet. They do not create a choice function over all tolerances, all histories, or all dyadic refinements. □

Falsifiable prediction: An accepted $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ consumer that reaches a $\mathsf{LocatedInterval}^{\uparrow}$ handoff or $\mathsf{Real}^{\uparrow}$ seal without the finite request row, dyadic candidate ledger, StreamName windows, and RegSeqRat readback refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, locatedinterval: no listed sibling supplies the whole $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ packet, because the selector certificate binds a finite request row, dyadic candidate ledger, window and readback rows, terminal Real seals, a located-interval handoff, transport, replay, provenance, and local naming without a countable-choice coordinate.

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}$ packet is generated from one finite request row, displayed DyadicRatCore candidates, StreamName windows, RegSeqRat readbacks, RealUp endpoint seals, a LocatedInterval handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7644.1, Definition 7644.2, Definition 7644.3, and Definition 7644.4 seed the finite choice-free dyadic interval-selection carrier and its nonescape route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceFreeDyadicIntervalSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, dependent choice, total interval selection over all tolerances, quotient-real endpoint equality, completion existence, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires a Lean-side ChoiceFreeDyadicIntervalSelectionUp carrier with checked request admission, dyadic candidate exposure, finite window readback, Real endpoint sealing, LocatedInterval handoff, transport, replay, provenance, and local naming.

Chapter 7645

A Concrete Naming Certificate for ClosedAtDecisionRefusalBoundary$^{\uparrow}$

The ClosedAtDecisionRefusalBoundary$^{\uparrow}$ packet realizes the Closed-MetaCIC decidability frontier of section 9386.5 as finite NameCert data. It sits beside the decidability witness of chapter 751, the bounded normal-equality checker of chapter 752, the finite beta closedness route of chapter 6876, and the subject-reduction obstruction of chapter 9377. The packet names checker input, bounded normal output, explicit refusal, transport, replay, provenance, and local naming; it does not turn bounded normal equality into a standalone ClosedAt decider or a global closed beta-conversion oracle.

Definition 7645.1 (ClosedAt decision refusal boundary carrier)**.** *A* ClosedAtDecisionRefusalBoundary$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, K, N_b, R, T, C, P, G, H, N)$$

with the following visible rows:

1. *Q is the request row, recording whether the consumer asked for standalone* ClosedAt *decision, global closed beta-conversion, or bounded normal comparison.*
2. *K is the finite checker row. It exposes the closed typing, structural equality, and represented-term checks available in the existing MetaCIC decidability surface.*
3. *N_b is the bounded-normal row, carrying only displayed fuel, bounded normalizer outputs, and finished-normal witnesses when those witnesses are explicitly present.*
4. *R is the refusal row. It rejects standalone* ClosedAt *decision and unrestricted closed beta-conversion requests before any bounded checker row is consumed.*
5. *T is the transport row from accepted bounded evidence to downstream normal-form or decidability packets, with the refusal row still visible.*
6. *C records displayed* Cont *replay through the request, refusal, checker, bounded-normal, and transport rows.*
7. *P is the* Pkg *provenance over* ClosedAtDecisionRefusalBoundary$^{\uparrow}$, MetaCICDecidabilityWitness$^{\uparrow}$, BoundedNormalEqualityChecker$^{\uparrow}$, FiniteBetaClosednessIteration$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
8. *G records the later Lean TasteGate surface for* Nontrivial ClosedAtDecisionRefusalBoundary$^{\uparrow}$ *and* FieldFaithful ClosedAtDecisionRefusalBoundary$^{\uparrow}$ *instances.*

9. *H records componentwise* hsame *transport for $Q, K, N_b, R, T, C, P, G, N$.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedAtDecisionRefusalBoundary}^{\uparrow}}$ *row.*

The classifier accepts a packet only through $Q, K, N_b, R, T, C, P, G, H, N$. It has no coordinate for a total closedness decider, fuel-erased normalizer, unrestricted conversion oracle, quotient equality of terms, subject-reduction discharge, or kernel-consistency theorem.

Theorem 7645.2 (ClosedAt decision refusal boundary obligations)**.** *For every accepted* ClosedAtDecisionRefusalBou *carrier*

$$B = (Q, K, N_b, R, T, C, P, G, H, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedAtDecisionRefusalBoundary}^{\uparrow}}$ *surface consists exactly of checker request admission through Q; finite checker exposure through K; bounded-normal exposure through N_b; refusal of standalone* ClosedAt *decision and global closed beta-conversion through R; transport through T; replay through C; provenance through P; later* Nontrivial *and* FieldFaithful *instance obligations through G; componentwise transport through H; and local naming through N.*

Proof. Project the carrier of Definition 7645.1. The visible rows are exactly $Q, K, N_b, R, T, C, P, G, H, N$, and the classifier compares only those rows componentwise.

The boundary row R is part of the accepted packet, not an external warning. Therefore a request for standalone ClosedAt decision or unrestricted closed beta-conversion is classified before K or N_b can be consumed as positive evidence.

Rows K and N_b still expose the bounded checks that the existing MetaCIC decidability surface permits. Rows T, C, P, G, H, N transport, replay, source, record the later Lean instance obligations, and name the same finite packet. None adds a total decider or fuel-erased conversion oracle. □

Theorem 7645.3 (ClosedAt decision refusal first)**.** *Every accepted* $\mathsf{ClosedAtDecisionRefusalBoundary}^{\uparrow}$ *read routes standalone* ClosedAt*-decision and global closed beta-conversion requests to R before any bounded checker row K or bounded-normal row N_b is consumed. Bounded checker evidence may be read only after the request row has not been classified as one of those global requests.*

Proof. Read the request component Q of the accepted carrier in Definition 7645.1. The only row that classifies a standalone closedness decision or unrestricted conversion request is R.

Apply Definition 7645.2. It places the refusal row in the local NameCert surface together with, but logically before use of, the checker and bounded-normal rows for requests that ask for global decision power.

Thus a bounded checker read is available only for bounded requests. A consumer that skips R and reads K or N_b as a total closedness or conversion oracle is outside the packet. □

Theorem 7645.4 (ClosedAt decision refusal nonescape)**.** *An accepted* $\mathsf{ClosedAtDecisionRefusalBoundary}^{\uparrow}$ *packet cannot export a standalone* ClosedAt *decider, global closed beta-conversion oracle, or fuel-erased normalizer. Any downstream use of K or N_b remains bounded by the displayed request, fuel, finished-normal evidence, refusal row, transport, replay, provenance, and local naming.*

Proof. Use Definition 7645.3. Global requests are routed to R, while bounded reads proceed only through the displayed checker and bounded-normal rows.

The transport row T keeps R visible when bounded evidence is forwarded to sibling packets. The replay and provenance rows C and P record the same route, and G, H, N only record later Lean instance obligations, componentwise transport, and local naming.

Since the carrier has no total-decision coordinate and no fuel-erased normalizer coordinate, no accepted read can escape from bounded evidence into a global theorem. □

The later Lean side must provide explicit Nontrivial ClosedAtDecisionRefusalBoundary$^{\uparrow}$ and FieldFaithful ClosedAtDecisionRefusalBoundary$^{\uparrow}$ instances in `lean4/BEDC/Derived/ClosedAtDecisionRefusalBou` These instances must preserve $Q, K, N_b, R, T, C, P, G, H, N$ as distinct rows before any checked marker can cite the packet as a TasteGate witness.

Falsifiable prediction: Every accepted ClosedAtDecisionRefusalBoundary$^{\uparrow}$ read routes standalone ClosedAt-decision and global beta-conversion requests to the refusal row before any bounded checker row is consumed.

Independence witness: metacicdecidableboundary, normalfalseexclusion, closednormalconfluenceseal, metacic-subject-reduction-obstruction: no listed sibling supplies the whole ClosedAtDecisionRefusalBounda packet, because the refusal boundary binds checker request, bounded-normal output, refusal, transport, replay, provenance, later Lean instance obligations, componentwise transport, and local naming as one carrier.

Closure status for NameCert$_{\text{ClosedAtDecisionRefusalBoundary}^{\uparrow}}$.

Constructive story: A ClosedAtDecisionRefusalBoundary$^{\uparrow}$ packet is generated from checker request data, finite MetaCIC checker rows, bounded-normal rows, an explicit refusal row, transport, replay, provenance, later Nontrivial and FieldFaithful instance obligations, componentwise hsame transport, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ClosedAtDecisionRefusalBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 7645.1, Definition 7645.2, Definition 7645.3, and Definition 7645.4 seed the finite refusal boundary for standalone ClosedAt decision and global closed beta-conversion requests.

Formal verification: FormalStatus(NameCert$_{\text{ClosedAtDecisionRefusalBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close standalone ClosedAt decidability, unrestricted closed beta-conversion decidability, fuel-erased normalization, subject reduction, confluence, kernel consistency, Lean theorem coverage, or bridge checking.

Upgrade path: Obligation closure requires a Lean-side ClosedAtDecisionRefusalBoundaryUp carrier with checked request classification, refusal-first routing, bounded checker exposure, bounded-normal exposure, transport, replay, provenance, Nontrivial and FieldFaithful instances, componentwise transport, and local naming.

Chapter 7646

A Concrete Naming Certificate for $\mathsf{RadstromEmbedding}^{\uparrow}$

Following Radstrom's embedding of convex compact sets into an ordered vector group, the $\mathsf{RadstromEmbedding}^{\uparrow}$ packet records the finite BEDC surface on which convex compact-set addition and Hausdorff-distance reads become a cancellative embedding route. It sits beside the compact-subset hyperspace carrier of chapter 1660, the compact metric source of chapter 129, the convex-set carrier of chapter 208, the Hausdorff metric route of chapter 2086, the Vietoris topology route of chapter 2375, and the real seal of chapter 38. The chapter names only finite compact, convex, Hausdorff, Vietoris, and real-valued rows; it is not a host Banach-space completion, quotient equality of compact sets, selected support functional, or ambient compactness theorem.

Definition 7646.1 (Radstrom embedding carrier)**.** *A* $\mathsf{RadstromEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, V, H, T, E, D, S, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying the finite compact metric presentation from which compact-set names are read.*
2. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row recording the inspected convex compact-set operations and finite Minkowski-sum windows.*
3. *H is the* $\mathsf{HausdorffMetric}^{\uparrow}$ *row recording the finite Hausdorff comparison ledger on compact subsets.*
4. *T is the* $\mathsf{VietorisTopology}^{\uparrow}$ *row recording the hit–miss compatibility windows used before the embedding row is exposed.*
5. *E is the embedding row, displaying the cancellative difference-class name determined by K, V, H, T.*
6. *D is the distance-readback row into* $\mathsf{Real}^{\uparrow}$*, exposed only after the compact, convex, Hausdorff, Vietoris, and embedding rows have been displayed.*
7. *S stores componentwise* hsame *transport for compact, convex, Hausdorff, Vietoris, embedding, distance, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from compact-set inspection to convex operation windows, Hausdorff comparison, Vietoris compatibility, embedding exposure, and real-valued distance readback.*

9. *P is the* Pkg *provenance over* $\mathsf{RadstromEmbedding}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{HausdorffMetric}^{\uparrow}$, $\mathsf{VietorisTopology}^{\uparrow}$, $\mathsf{Hyperspace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RadstromEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, H, T, E, D, S, C, P, N$. It has no coordinate for host quotient spaces, selected support functions, external Banach completions, powerset equality, countable choice, or open-cover compactness.

Theorem 7646.2 (Radstrom embedding NameCert obligations)**.** *For every accepted* $\mathsf{RadstromEmbedding}^{\uparrow}$ *carrier $R = (K, V, H, T, E, D, S, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RadstromEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, convex compact-set operations, Hausdorff comparison ledger, Vietoris compatibility row, embedding row, real-valued distance readback, componentwise transport, replay, provenance, and local naming rows. The obligations require the embedding row E to be downstream of K, V, H, T, and they require the* $\mathsf{Real}^{\uparrow}$ *distance readback D to be downstream of E.*

Proof. Project the carrier of Definition 7646.1. Carrier admission is the displayed tuple $K, V, H, T, E, D, S, C, P, N$, so the local certificate has no detached coordinate for an ambient quotient space or external completion.

The compact, convex, Hausdorff, and Vietoris obligations are read from K, V, H, T. Since E is the only embedding row, every embedding exposure is downstream of those four rows.

The real-valued readback is D, and its only source is the displayed embedding row. The rows S, C, P, N transport, replay, source, and name the same route, so the NameCert surface is exhausted by the listed finite rows. □

Theorem 7646.3 (Radstrom embedding hyperspace route)**.** *Every accepted* $\mathsf{RadstromEmbedding}^{\uparrow}$ *consumer that reads the embedding row or the* $\mathsf{Real}^{\uparrow}$ *distance readback factors through the finite hyperspace route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{Hyperspace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{HausdorffMetric}^{\uparrow} \longmapsto \mathsf{VietorisTopology}^{\uparrow} \longmapsto E \longmapsto D.$$

The route uses the compact-subset carrier of chapter 1660 as the neighbour through which convex compact-set and Hausdorff-metric requests are inspected. It exposes no quotient equality of compact sets, host linear-space completion, selected support functional, choice principle, or open-cover compactness proof.

Proof. Begin with the compact-subset side. The carrier row K supplies the compact metric presentation, and the provenance row P routes compact-subset inspection through the sibling hyperspace chapter before any convex operation is read.

Next read the convex and metric rows. The rows V, H, T display convex compact-set operations, finite Hausdorff comparisons, and Vietoris compatibility windows. Thus the embedding row E cannot be inspected before the compact hyperspace, convex, Hausdorff, and Vietoris rows are all present.

Finally read the real-facing row D. Since D is downstream of E and the transport and replay rows preserve the same order, any consumer of the Radstrom surface factors through the displayed hyperspace route and cannot recover any excluded host principle. □

Falsifiable prediction: Any accepted $\mathsf{RadstromEmbedding}^{\uparrow}$ carrier that reaches the embedding row or the $\mathsf{Real}^{\uparrow}$ readback while omitting the compact metric row, hyperspace route, convex

compact-set row, Hausdorff metric row, Vietoris compatibility row, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: hyperspace, compactmetric, convexset, hausdorffmetric, vietoristopology, real: $\mathsf{RadstromEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries convex compact-set operations, Hausdorff comparison, Vietoris compatibility, a cancellative embedding row, real-valued readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RadstromEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{RadstromEmbedding}^{\uparrow}$ packet is generated from CompactMetric, Hyperspace, ConvexSet, HausdorffMetric, VietorisTopology, embedding, Real readback, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RadstromEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7646.1, Definition 7646.2, and Definition 7646.3 seed the finite convex compact hyperspace route into Radstrom embedding data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RadstromEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of compact sets, host Banach completions, selected support functionals, countable choice, open-cover compactness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convex compact-set operation exposure, Hausdorff comparison exactness, Vietoris compatibility, embedding nonescape, Real readback, provenance, and local NameCert exhaustion for BEDC.Derived.RadstromEmbeddingUp.

Chapter 7647

A Concrete Naming Certificate for $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$ packet records the finite route by which compact located metric data and apartness-sensitive separation data are read before a completion or Real-facing consumer asks for distinctness. It sits beside the located-limit route of chapter 1420 and the separated-metric route of chapter 1411. The packet keeps the constructive distinction between positive apartness evidence and equality refusal: it names finite compact windows, located comparison rows, separated metric tests, transport, replay, provenance, and local NameCert data without importing classical trichotomy, quotient equality, selected limit points, host equality, or an ambient completed metric object.

Definition 7647.1 (Compact apartness located separation carrier)**.** *A* $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, A, S, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the consumed* $\mathsf{CompactMetric}^{\uparrow}$ *or* $\mathsf{Compact}^{\uparrow}$ *finite-window row whose compact reads are presented by displayed probe or finite-net data.*
2. *M is the underlying* $\mathsf{Met}^{\uparrow}$ *row carrying the located metric-distance comparisons used by the packet.*
3. *A is the positive apartness ledger, recording finite evidence that two displayed compact-window reads are separated by a rational lower-bound row.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *comparison row that turns the positive apartness evidence into the separation-facing public test used by downstream consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *readback row for the rational lower bound and the terminal numerical seal.*
6. *H records componentwise* hsame *transport for compact windows, metric rows, apartness ledgers, separated comparisons, readback rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from compact finite windows through located metric comparison, apartness evidence, separated comparison, and rational or Real readback.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}}$ *row.*

The carrier has no coordinate for classical trichotomy of equality and apartness, quotient equality, selected limit representatives, countable choice, host equality, or an ambient completed metric space.

Theorem 7647.2 (CompactApartnessLocatedSeparation NameCert obligations)**.** *For every accepted* $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$ *carrier* $L = (K, M, A, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactApartn}}$ *surface consists exactly of carrier admission, compact finite-window exposure, located metric comparison, positive apartness lower-bound exposure, separated-metric handoff, rational or Real readback, transport, replay, provenance, and local naming. A consumer may read a separated compact comparison only after the compact row K, metric row M, apartness row A, and separated row S have been displayed.*

The same surface exports no classical trichotomy, quotient equality, selected limit point, countable-choice schedule, host equality, ambient completion object, or Real completeness row.

Proof. Project the carrier of Definition 7647.1. The displayed rows $K, M, A, S, R, H, C, P, N$ are the complete public inventory of the packet.

The compact and located rows are read first. The compact finite-window row K supplies the bounded testing window, and the metric row M supplies located distance comparisons internal to that window.

The apartness and separation rows are downstream. The row A records positive rational lower-bound evidence, while S packages the same evidence as the separated-metric handoff consumed by sibling separation routes such as chapter 1411.

Finally R, H, C, P, N read back, transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for trichotomy, quotient equality, selected limits, choice schedules, host equality, ambient completions, or Real completeness, none of those objects can become a NameCert obligation. □

Falsifiable prediction: A compact separation consumer that reads apartness without first displaying the compact finite-window row, located metric comparison row, separated-metric handoff, and rational or Real readback row is not a $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$ packet.

Independence witness: compactmetric, locatedlimit, separatedmetric, regseqrat, real: the packet is not bijective to these siblings because it binds compact finite windows, located metric comparison, positive apartness lower bounds, separated-metric handoff, numerical readback, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$ packet is generated from compact finite-window data, located metric comparisons, positive apartness lower-bound rows, SeparatedMetric handoff data, RegSeqRat or Real readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}}$, seed)

Scope closed: Definition 7647.1 and Definition 7647.2 seed the compact apartness/separation carrier and its NameCert obligation surface over displayed CompactMetricUp, LocatedLimitUp, SeparatedMetricUp, MetricSpaceUp, RegSeqRatUp, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, classical trichotomy, quotient equality, selected limit representatives, countable choice, host equality, ambient completed metric spaces, or Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-window exposure, located metric comparison, apartness lower-bound exposure, separated-metric handoff, numerical readback, transport, replay, provenance, and local naming for the same packet.

Chapter 7648

A Concrete Naming Certificate for $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$

Following Heine–Cantor and Bishop compact-uniform-continuity, the $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$ packet records a finite oscillation envelope extracted from compact finite-cover data, pointwise continuity moduli, and rational lower-bound folds. It consumes the compact source rows of chapter 60, the metric rows of chapter 57, the continuous-map rows of chapter 130, the uniform-modulus handoff of chapter 369, and the numerical readback routes of chapter 37 and chapter 38. The packet names finite ProbeBundle radii and oscillation bounds without selecting an external modulus function, invoking open-cover compactness, importing host function equality, or asserting an ambient completed metric object.

Definition 7648.1 (Finite oscillation-envelope carrier)**.** *A* $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, X, Y, F, B, R, Q, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *finite cover row for the source object.*
2. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, and Y is the target metric row used to read oscillation bounds.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row whose local pointwise modulus data are consumed on the compact finite cover.*
4. *B is the finite* $\mathsf{ProbeBundle}$ *of source centers and radius rows read from the compact witness.*
5. *R is the finite* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold over the positive local radius histories carried by B.*
6. *Q is the oscillation-bound ledger, assigning each displayed probe center a target-distance bound read through F, X, Y, and R.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced from the finite envelope after the rational fold has been replayed.*
8. *H records componentwise* hsame *transport for compact, metric, continuous-map, ProbeBundle, rational-fold, oscillation-bound, uniform-modulus, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the compact finite-cover row through local modulus reads, rational lower-bound folds, oscillation estimates, and uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationEnvelope}^{\uparrow}}$ *row.*

The carrier contains no external modulus selector, no open-cover compactness row, no host function equality, no countable-choice schedule, no quotient metric equality, and no ambient complete metric object.

Lean4 ✓ `BEDC.Derived.FiniteOscillationEnvelopeUp.FiniteOscillationEnvelopeTasteGate single carrier alignment`

Theorem 7648.2 (FiniteOscillationEnvelope NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$ *carrier* $O = (K, X, Y, F, B, R, Q, U, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-cover exposure, source and target metric reads, continuous-map pointwise modulus reads, finite ProbeBundle radius rows,* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold exposure, oscillation-bound ledger rows,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, transport, replay, provenance, and local naming.*

Every uniform-modulus consumer must read the finite route

$$K, X, Y, F, B, R, Q \longmapsto U \longmapsto H, C, P, N$$

before a tolerance-only modulus row is public. The packet exports no external modulus selector, open-cover compactness, host function equality, countable-choice schedule, quotient metric equality, or ambient complete metric object.

Proof. Project the carrier of Definition 7648.1. The rows $K, X, Y, F, B, R, Q, U, H, C, P, N$ are the complete public inventory.

The compact and continuous rows provide the local data. The finite cover row K supplies the displayed ProbeBundle B, while the continuous-map row F supplies pointwise modulus reads over the source and target metric rows X, Y.

The rational fold and oscillation ledger are the finite envelope. The row R folds the positive radius histories through $\mathsf{Rat}^{\uparrow}$, and Q records the resulting oscillation bounds at the displayed probe centers.

Finally the uniform-modulus row U is readable only after the finite envelope has been replayed. The transport, continuation, provenance, and naming rows preserve that dependency order, and the missing coordinates exclude external selectors, open-cover compactness, host function equality, choice schedules, quotient metric equality, and ambient completion objects. □

Falsifiable prediction: A compact-uniform-continuity consumer that reads a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying compact finite-cover data, ContinuousMap pointwise modulus rows, finite ProbeBundle radii, RatUp folds, and oscillation-bound ledgers is not a $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$ packet.

Independence witness: compact, continuousmap, uniformmodulus, metricspace, rat, real: FiniteOscillationEnvelo is not bijective to any listed sibling because it jointly carries finite compact-cover centers, local oscillation bounds, rational lower-bound folds, a uniform-modulus handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationEnvelope}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{FiniteOscillationEnvelope}^{\uparrow}$ packet is generated from compact finite-cover data, source and target MetricSpace rows, a ContinuousMap pointwise-modulus row, finite ProbeBundle radius rows, RatUp lower-bound folds,

oscillation-bound ledger rows, a UniformModulus handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteOscillationEnvelope}\uparrow}$, seed)

Scope closed: Definition 7648.1 and Definition 7648.2 seed the finite oscillation-envelope carrier and NameCert obligation surface over displayed CompactUp, ContinuousMapUp, UniformModulusUp, MetricSpaceUp, RatUp, and RealUp rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteOscillationEnvelope}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, open-cover compactness, host function equality, external modulus selection, countable choice, quotient metric equality, ambient complete metric spaces, or Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite compact-cover exposure, pointwise modulus reads, ProbeBundle radius rows, RatUp lower-bound folds, oscillation-bound ledgers, UniformModulus handoff, transport, replay, provenance, and local naming for the same packet.

Chapter 7649

A Concrete Naming Certificate for $\mathsf{CauchyReblocking}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy tails, the $\mathsf{CauchyReblocking}^{\uparrow}$ packet records finite reblocking of regular rational Cauchy data before any real-name seal is exported. It sits beside the finite-window and tail packets of chapter 126, chapter 301, chapter 291, chapter 5916, and chapter 1420. The packet exposes a finite block schedule and a monotone tail selector; it does not introduce a new real, a quotient completion, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7649.1 (CauchyReblocking carrier)**.** *A* $\mathsf{CauchyReblocking}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, K, T, S, D, H, C, P, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose regular rational readings supply the Cauchy tail data to be reblocked.*
2. *K is the finite block partition row, listing the displayed consecutive blocks and their endpoints.*
3. *T is the monotone tail selector row, assigning each requested tolerance to the block from which all later reads are taken.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing exactly the finite observations consumed by the selected block.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii and comparison cells attached to the selected tail.*
6. *H records componentwise* hsame *transport for the regular source, block partition, tail selector, finite window, dyadic tolerance row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay from a tail request through R, K, T, S, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyReblocking}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyReblocking}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $R, K, T, S, D, H, C, P, N$. No coordinate stores an independent limit, quotient completion, choice-selected subsequence, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 7649.2 (CauchyReblocking NameCert obligations)**.** *For every accepted* $\mathsf{CauchyReblocking}^{\uparrow}$ *carrier* $B = (R, K, T, S, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyReblocking}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, block-schedule exactness for the finite partition* K*, tail selector monotonicity for* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback preservation for* R*, and Real-seal nonescape for every downstream* $\mathsf{Real}^{\uparrow}$ *consumer. The finite-window and tolerance rows* S, D *are consumed only after* K *and* T *have been displayed, while* H, C, P, N *preserve the same route under transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7649.1. The displayed rows are exactly the regular rational source, finite block partition, monotone selector, finite window, dyadic tolerance row, transport, replay, provenance, and local naming.

Block-schedule exactness is read from K. A downstream consumer may inspect only the finite blocks listed there, and the selected tail is recorded by T rather than by a hidden subsequence or an external choice function.

The regular readback is preserved because R remains the only source row. The finite window S and tolerance row D can be reached only after K and T expose the selected block, so the reblocked read is still a read of the same $\mathsf{RegSeqRat}^{\uparrow}$ source.

Finally, the rows H, C, P, N transport, replay, name, and cite the same finite route. Since the carrier has no coordinate for an independent limit, quotient completion, trichotomy branch, choice schedule, or ambient completeness principle, no downstream $\mathsf{Real}^{\uparrow}$ seal can escape the displayed packet. □

Theorem 7649.3 (CauchyReblocking regular tail selection)**.** *Every tail read exported by an accepted* $\mathsf{CauchyReblocking}^{\uparrow}$ *carrier* $B = (R, K, T, S, D, H, C, P, N)$ *factors through the same finite block schedule before any* $\mathsf{Real}^{\uparrow}$ *seal can be read:*

$$R, K, T, S, D, H, C, P, N.$$

Thus the reblocked tail is a finite reindexing of the source $\mathsf{RegSeqRat}^{\uparrow}$ *row through* K *and* T*, followed by the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, transport, replay, provenance, and local naming rows.*

Proof. Read the carrier of Definition 7649.1. The only rows available before a tail-facing consumer reaches a finite window or tolerance comparison are the source row R, the block partition K, and the selector T.

Use Definition 7649.2. Block-schedule exactness fixes the finite partition, and tail selector monotonicity forces later tail requests to remain inside the scheduled reblocking route.

After the selected block is visible, the consumer may read the finite window S and the dyadic tolerance row D. Transport and replay through H and C preserve the same route, while P and N record provenance and local naming.

Therefore every reblocked tail read factors through $R, K, T, S, D, H, C, P, N$ before any $\mathsf{Real}^{\uparrow}$ seal. The packet supplies finite reindexing data only, not a separate completion or host limit. □

Falsifiable prediction: Every accepted $\mathsf{CauchyReblocking}^{\uparrow}$ read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the $\mathsf{RegSeqRat}^{\uparrow}$ source row, finite block partition, monotone tail selector, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ evidence.

Independence witness: regseqrat, streamname, dyadicratcore, finite-stream, locatedlimit: $\mathsf{CauchyReblocking}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source regular rational row, a

finite block partition, a monotone tail selector, finite-window and tolerance rows, transport, replay, provenance, and local naming as one reblocking packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyReblocking}\uparrow}$.

Constructive story: A $\mathsf{CauchyReblocking}^{\uparrow}$ packet is generated from a RegSeqRat source row, a finite block partition, a monotone tail selector, a StreamName finite window, a DyadicRatCore tolerance row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyReblocking}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7649.1, Definition 7649.2, and Definition 7649.3 seed the finite reblocking route for regular rational Cauchy tails before any Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyReblocking}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected host limits, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, block-schedule exactness, tail selector monotonicity, RegSeqRat readback preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyReblockingUp.

Chapter 7650

A Concrete Naming Certificate for $\mathsf{RegulatedDarbouxSum}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ packet records finite lower and upper Darboux-sum data for a displayed regulated real function without importing host-level real equality, selected suprema, or measure completion. It sits beside the regulated-function carrier of chapter 1906, the bounded-variation ledger of chapter 398, the dyadic tolerance core of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite integration ledger for later Riemann and Darboux consumers; it names no quotient integral and chooses no ambient completion principle.

Definition 7650.1 (Regulated Darboux-sum carrier)**.** *A* $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, T, L, U, M, O, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, exposing the regulated real function only through its displayed finite window and regulated-approximation interface.*
2. *T is the tagged partition row, listing finitely many subintervals, tags, endpoint order data, and the cell incidence relation read by the Darboux consumer.*
3. *L is the lower-sum row, storing the finite cellwise lower estimates and the displayed addition route by which they are accumulated.*
4. *U is the upper-sum row, storing the finite cellwise upper estimates and the displayed addition route by which they are accumulated.*
5. *M is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh row, carrying cell widths, requested dyadic tolerance, refinement radius, and endpoint comparison budget.*
6. *O is the oscillation row, recording for each cell the finite readback that bounds the gap between the corresponding upper and lower estimates.*
7. *R is the refinement row, comparing the partition T with a displayed common refinement and transporting the lower, upper, mesh, and oscillation ledgers along the refinement map.*
8. *H records componentwise* hsame *transport for F, T, L, U, M, O, R and for the replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from an integration request through the regulated-function source, tagged partition, lower and upper sums, dyadic mesh, oscillation ledger, and refinement row.*
10. *P is the* Pkg *provenance over* $\mathsf{RegulatedDarbouxSum}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedDarbouxSum}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, T, L, U, M, O, R, H, C, P, N$. It has no coordinate for selected suprema, Lebesgue measure, host real equality, quotient integration, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7650.2 (Regulated Darboux-sum NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ *carrier $D = (F, T, L, U, M, O, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedDarbouxSum}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the regulated-function source, tagged partition, lower-sum row, upper-sum row, dyadic mesh row, oscillation row, refinement row, transport, replay, provenance, and local naming;*
2. *common-refinement stability, requiring every refinement consumer to read the partition row T and refinement row R before comparing lower and upper sums;*
3. *oscillation-ledger confinement, requiring the gap between the lower and upper rows to be witnessed only by the displayed cellwise oscillation row O;*
4. *dyadic tolerance readback, requiring all mesh widths, slack comparisons, and requested tolerances to pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row M;*
5. $\mathsf{Real}^{\uparrow}$ *seal nonescape, requiring every real-facing value read to pass through $F, T, L, U, M, O, R, H, C, P, N$ and exporting no selected supremum, measure completion, host real equality, quotient integral, or choice principle.*

Proof. Project the carrier of Definition 7650.1. The analytic rows are the regulated-function source F, the tagged partition T, the lower and upper sums L, U, the dyadic mesh M, the oscillation ledger O, and the refinement row R; the structural rows are H, C, P, N.

Carrier admission is therefore finite. Each admitted packet exposes exactly the listed rows, so the local NameCert surface has no hidden coordinate from which a selected supremum, measure object, quotient integral, or host equality test could be read.

Common-refinement stability is read through T and R. The refinement row compares two displayed finite partitions and transports only the lower, upper, mesh, and oscillation ledgers already present in the carrier.

The oscillation and tolerance clauses are separate ledger checks. The row O bounds the cellwise upper-lower gap, while the row M carries the dyadic mesh widths, slack, and comparison budget used by that check.

Finally the structural rows H, C, P, N preserve the same order under transport, replay, provenance, and local naming. Any $\mathsf{Real}^{\uparrow}$-facing consumer can therefore see only the displayed finite Darboux-sum route and cannot project selected suprema, Lebesgue measure, host real equality, quotient integration, or countable choice from the packet. □

Theorem 7650.3 (Regulated Darboux-sum finite route)**.** *Every accepted* $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ *read that reaches a real-facing lower or upper value factors through the finite route*

$$\mathsf{RegulatedFunction}^{\uparrow}, \quad T, \quad L, \quad U, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad O, \quad R, \quad \mathsf{Real}^{\uparrow}.$$

Thus the handoff to later Darboux or Riemann integration chapters is only a finite ledger over displayed regulated-function, partition, mesh, oscillation, refinement, transport, replay, provenance, and local naming rows.

Proof. Start from an accepted consumer read. By Definition 7650.1, the only source for real-facing lower and upper values is the pair of finite rows L, U attached to the displayed tagged partition T.

The mesh and oscillation controls are forced before the value rows can be used. The dyadic row M records cell widths and tolerance data, while O records the displayed oscillation gap on each cell.

Apply Definition 7650.2. It makes common refinement pass through R and makes the real-facing seal pass through the same finite rows.

The transport, replay, provenance, and naming rows add no analytic coordinates. Hence the consumer receives exactly the finite route stated in the theorem and receives no selected supremum, Lebesgue measure, quotient integral, host real equality, countable choice, or ambient completeness principle. □

Falsifiable prediction: An accepted $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ consumer that reaches a lower or upper real-facing value without displaying the regulated-function source, tagged partition, lower sum, upper sum, dyadic mesh, oscillation ledger, refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: regulated-function, boundedvariation, dyadicratcore, real: $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries tagged partition data, lower and upper sum rows, a dyadic mesh, an oscillation ledger, a common-refinement row, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedDarbouxSum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegulatedDarbouxSum}^{\uparrow}$ packet is generated from a RegulatedFunction source row, a tagged partition row, lower and upper finite-sum rows, a DyadicRatCore mesh and tolerance row, a cellwise oscillation ledger, a common-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedDarbouxSum}^{\uparrow}}$, seed)

Scope closed: Definition 7650.1, Definition 7650.2, and Definition 7650.3 seed the finite regulated Darboux-sum ledger over regulated-function, dyadic-mesh, oscillation, refinement, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedDarbouxSum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected suprema, Lebesgue measure, host real equality, quotient integration, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-refinement stability, oscillation-ledger confinement, dyadic tolerance readback, RealUp seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.RegulatedDarbouxSumUp.

Chapter 7651

A Concrete Naming Certificate for $\mathsf{ClosedIntervalCompactness}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ packet records the finite dyadic-net test object used by closed real intervals before any open-cover or sequential compactness principle is available. It reads dyadic mesh data from chapter 291, finite name observations from chapter 126, regular rational readback from chapter 301, endpoint seals from chapter 38, and completion-facing finite windows from chapter 1559. The packet names only a finite interval-net route; it is not general Heine–Borel compactness, not open-cover compactness, not sequential compactness, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7651.1 (Closed interval compactness carrier)**.** *A* $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, O, D, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper endpoint rows, each sealed through* $\mathsf{Real}^{\uparrow}$ *after finite name inspection.*
2. *O is the endpoint-order row binding the displayed closed interval boundary.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh ledger for the requested tolerance and the finite subdivision cells.*
4. *M is the finite dyadic-net row listing the displayed mesh points and cell radii.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row used to inspect endpoint and mesh-point names.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the observed rational windows.*
7. *E is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *handoff row for completion-facing consumers that ask for finite coverage data.*
8. *H records componentwise* hsame *transport for endpoint, order, mesh, window, readback, handoff, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a tolerance request through $A, B, O, D, M, S, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{ClosedIntervalCompactness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletionFinite}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for arbitrary open covers, selected subcovers, convergent subsequences, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7651.2 (Closed interval compactness NameCert obligations)**.** *For every accepted* ClosedIntervalCompactn *carrier*

$$K = (A, B, O, D, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactness}^{\uparrow}}$ *surface consists exactly of endpoint admission through* A, B, O*; dyadic mesh admission through* D, M*; finite observation and regular-rational readback through* S, R*; completion-facing finite-window handoff through* E*; componentwise transport through* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 7651.1. The endpoint rows A, B, O are the only interval-boundary data available to the local classifier.

Next read the finite mesh route. The dyadic ledger D fixes the inspected tolerance and subdivision cells, while M lists the displayed mesh points and radii. The window and readback rows S, R are the only way those finite observations reach rational data.

Finally read E, H, C, P, N. The completion-facing handoff is finite because it consumes the same displayed mesh and window rows before any downstream completion read. The structural rows transport, replay, source, and name that route, so no open-cover, subsequence, choice, quotient, or ambient-completeness obligation remains outside the packet. □

Theorem 7651.3 (Closed interval compactness dyadic-net route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ *packet must read the finite route*

$$A, B, O \longmapsto D, M \longmapsto S, R, E \longmapsto H, C, P, N$$

before using the interval as compact finite data. The route exports finite dyadic mesh coverage and readback rows only; it exports no general Heine–Borel theorem, no open-cover compactness, no sequential compactness, no selected subcover, and no $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with endpoint admission. The lower endpoint, upper endpoint, and order row fix the closed interval boundary through displayed $\mathsf{Real}^{\uparrow}$ name seals.

Read the mesh route next. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger supplies the tolerance cells, and the finite net row records the mesh points inspected by the consumer. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows expose only the finite observation windows and rational readbacks attached to those cells.

The $\mathsf{MetricCompletionFinite}^{\uparrow}$ row then repacks the same finite data for completion-facing reads. The transport, continuation, provenance, and local naming rows preserve the displayed route, so the consumer receives a finite dyadic-net packet rather than any excluded compactness or completeness principle. □

Falsifiable prediction: An accepted $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ consumer is refuted if it reaches compact interval data without first displaying endpoint rows, a DyadicRatCore mesh ledger, finite StreamName observations, RegSeqRat readback, and a MetricCompletionFinite handoff.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletionfinite: none is bijective to the closed-interval compactness packet because only $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ binds endpoint Real rows, dyadic mesh coverage, finite observation windows, regular readback, completion-facing handoff, transport, replay, provenance, and local naming as one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedIntervalCompactness}^{\uparrow}$ packet is generated from Real endpoint rows, endpoint order, DyadicRatCore mesh ledgers, finite dyadic-net rows, StreamName observations, RegSeqRat readback, MetricCompletionFinite handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7651.1, Definition 7651.2, and Definition 7651.3 seed the finite closed-interval dyadic-net compactness test object.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedIntervalCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general Heine–Borel compactness, open-cover compactness, sequential compactness, selected subcovers, countable choice, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order admission, dyadic mesh coverage, finite observation readback, completion-facing handoff, transport, replay, provenance, and local naming for BEDC.Derived.ClosedIntervalC

Chapter 7652

A Concrete Naming Certificate for $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ packet records real-completeness evidence as finite modulus-ledger data. It consumes the regular Cauchy surface of chapter 1611, the finite completion boundary of chapter 1559, finite stream observations from chapter 126, regular rational readback from chapter 301, and terminal real-name seals from chapter 38. The packet is a ledger for a displayed regular Cauchy request; it is not a selected limit operator, not quotient stream equality, not countable choice, and not an ambient assertion that every host real sequence has a limit.

Definition 7652.1 (Real completeness modulus ledger carrier)**.** *A* $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, K, F, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row naming the precision and regular Cauchy datum being inspected.*
2. *K is the* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *row that exposes the modulus-controlled tail criterion.*
3. *F is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *row that keeps the completion-facing read inside finite windows.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the inspected rational windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, K, F, S, R have been displayed.*
7. *H records componentwise* hsame *transport for request, criterion, finite-completion, observation, readback, seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a precision request through $Q, K, F, S, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{MetricCompletionFinite}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host-selected limit, a quotient of streams, a countable-choice schedule, trichotomy, open-cover compactness, or ambient real completeness.

Theorem 7652.2 (Real completeness modulus ledger NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ *carrier*

$$L = (Q, K, F, S, R, E, H, C, P, N),$$

the finite NameCert obligation surface is exactly the RegularCauchyCriterion row K*, MetricCompletionFinite row* F*, RegSeqRat readback row* R*, StreamName observation row* S*, RealUp seal row* E*, componentwise* hsame *transport row* H*, displayed* Cont *replay row* C*,* Pkg *provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}$ *row* N*, all bound to the same request row* Q*. No obligation is discharged by an ambient completeness theorem, quotient stream equality, countable choice schedule, selected limit, or host real-number comparison.*

Proof. Project the carrier of Definition 7652.1. The request row Q fixes the displayed precision and regular Cauchy datum, so every downstream row is read on that same finite ledger entry.

Read K, F, S, R, E in the displayed order. The RegularCauchyCriterion row supplies the tail criterion, the MetricCompletionFinite row keeps the completion read windowed, the StreamName and RegSeqRat rows expose the observed rational data, and the RealUp row seals only that readback.

Finally use H, C, P, N. These rows preserve the request, criterion, completion window, observation, readback, and seal under transport, replay, provenance, and local naming. Because no carrier coordinate stores ambient completeness or selected limits, the named rows exhaust the local obligation surface. □

Theorem 7652.3 (Real completeness modulus ledger obligations)**.** *For every accepted* RealCompletenessModulusLe *carrier*

$$L = (Q, K, F, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}$ *surface consists exactly of finite request admission through* Q*; regular Cauchy criterion exposure through* K*; finite completion-window exposure through* F*; stream observation and regular-rational readback through* S, R*; terminal real-name sealing through* E*; componentwise transport through* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 7652.1. The request row Q fixes one inspected precision and regular Cauchy datum, so the packet begins with finite input rather than an all-sequences completeness principle.

The analytic rows are K, F, S, R, E. The regular Cauchy criterion row supplies the modulus-controlled tail surface, the finite completion row keeps the completion read windowed, the stream and regular-rational rows expose the inspected observations, and the Real row seals only the displayed readback.

The structural rows H, C, P, N transport, replay, source, and name the same ledger. Since the carrier contains no selected limit operator, quotient-stream equality, choice schedule, trichotomy, open-cover compactness, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7652.4 (Real completeness modulus ledger finite route)**.** *Every Real-facing consumer of an accepted* $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ *packet must read the finite ledger route*

$$Q \longmapsto K, F \longmapsto S, R, E \longmapsto H, C, P, N$$

before it can use completion data. The route realizes real-completeness evidence as displayed RegularCauchyCriterion, MetricCompletionFinite, StreamName, RegSeqRat, and RealUp rows, not as a selected limit, quotient stream equality, countable choice, or ambient host completeness theorem.

Proof. Begin with the request row Q. It names the inspected precision and regular Cauchy datum, so the consumer starts from one finite ledger entry.

Next read the criterion and completion boundary. The $\mathsf{RegularCauchyCriterion}^{\uparrow}$ row provides the modulus-controlled tail test, while the $\mathsf{MetricCompletionFinite}^{\uparrow}$ row prevents the completion-facing read from bypassing finite windows.

Finally read the observation, readback, seal, and structural rows. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows expose only finite rational windows before the $\mathsf{Real}^{\uparrow}$ seal is available, and H, C, P, N preserve the same route under transport, replay, provenance, and local naming. □

Falsifiable prediction: An accepted $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ consumer is refuted if it reaches a RealUp seal from completion data without first displaying a regular Cauchy criterion row, finite completion-window row, StreamName observations, and RegSeqRat readback.

Independence witness: regularcauchycriterion, metriccompletionfinite, streamname, regseqrat, real: no listed sibling supplies the full real-completeness modulus ledger, because only RealCompletenessModulusLedg binds a finite request row, regular Cauchy criterion, finite completion window, stream observations, regular readback, Real seal, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletenessModulusLedger}^{\uparrow}$ packet is generated from a finite precision request, RegularCauchyCriterion tail data, MetricCompletionFinite windows, StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7652.1, Definition 7652.3, and Definition 7652.4 seed the finite real-completeness modulus ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessModulusLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, trichotomy, open-cover compactness, ambient host real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked request admission, RegularCauchyCriterion exposure, MetricCompletionFinite handoff, StreamName observation, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletenessModulusLedgerUp.

Chapter 7653

A Concrete Naming Certificate for $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis on inverse functions over compact real intervals, the $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$ packet records the finite modulus data needed to read a monotone inverse branch without invoking host inverse functions or quotient real equality. It sits over the compact interval route of chapter 3969, the monotone inverse branch of chapter 1929, the uniform-modulus consumer of chapter 369, the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is a compact-interval inverse-modulus certificate for Real and Completion consumers; it is not an open-cover compactness theorem, a trichotomy principle, a selected inverse function, or an ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 7653.1 (Compact interval inverse modulus carrier)**.** *A* $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (K, M, F, L, W, D, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$ *compact interval source row, exposing the closed bounded interval, finite-net compactness route, compact-metric row, and endpoint* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *M is the* $\mathsf{MonotoneInverse}^{\uparrow}$ *branch row, naming the monotone inverse branch only through displayed source, target, and order rows.*
3. *F is the finite-net row over K, listing the net centers, interval cells, image comparisons, and radius data inspected by the inverse-modulus route.*
4. *L is the inverse-modulus ledger, recording how target separation requests are discharged by finite source cells, monotone branch data, and compact interval bounds.*
5. *W stores the finite* $\mathsf{StreamName}^{\uparrow}$ *windows opened on source endpoints, net centers, branch values, and target requests.*
6. *D stores the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows for endpoint radii, image gaps, requested target tolerances, and residual readback error.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from W and D before any real-facing seal is exposed.*
8. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the source interval and the inverse-modulus readback.*

9. *H records componentwise* hsame *transport for the compact interval source, monotone inverse branch, finite-net row, inverse-modulus ledger, stream windows, dyadic tolerance rows, regular readback, Real seal, provenance, and local naming row.*

10. *C records displayed* Cont *replay from compact interval inspection through monotone branch routing, finite-net handoff, tolerance accounting, regular readback, and Real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, $\mathsf{MonotoneInverse}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalInverseModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, F, L, W, D, R, S, H, C, P, N$. It has no coordinate for a host inverse function, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7653.2 (Compact interval inverse modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$ *carrier $I = (K, M, F, L, W, D, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalInverseModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, compact interval exposure, monotone inverse branch exposure, finite-net handoff, inverse-modulus ledger exactness,* $\mathsf{StreamName}^{\uparrow}$ *window visibility,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7653.1. Its analytic rows are K, M, F, L, W, D, R, S, and its structural rows are H, C, P, N.

The compact interval source is upstream. A consumer must first read K, then the monotone branch row M, before the finite-net row F and inverse-modulus ledger L can be inspected.

The finite real-name rows are downstream of that ledger. The stream windows W and dyadic tolerance rows D feed the regular readback R, and the real-facing seal S is reached only after that finite readback is displayed.

Finally H, C, P, N preserve, replay, source, and name the same packet. Since the refused host objects are not carrier coordinates, none can appear as a local NameCert obligation. □

Theorem 7653.3 (Compact interval inverse modulus finite-net handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{ClosedBoundedIntervalCompact}^{\uparrow} \longmapsto \mathsf{MonotoneInverse}^{\uparrow} \longmapsto F, L \longmapsto W, D, R, S \longmapsto H, C, P, N.$$

The handoff supplies compact interval data, monotone inverse branch data, finite-net cells, inverse-modulus ledger rows, stream windows, dyadic tolerances, regular readback, and Real sealing as one finite packet. It exports no host inverse function, quotient real equality, trichotomy, countable choice, open-cover compactness, or ambient Real completeness.

Proof. Start with the compact interval source and branch rows. The rows K and M force any inverse-modulus read to expose the compact interval certificate and the monotone inverse branch before a modulus request is evaluated.

Next read the finite-net and ledger rows. The row F lists the finite cells and image comparisons, while L records the inverse-modulus accounting used by the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer.

Then attach the finite real-name handoff. The stream windows W and dyadic tolerances D produce the regular readback R, and the terminal seal S is available only after that readback.

The structural rows H, C, P, N preserve this order. Hence the consumer receives a finite inverse-modulus route, not a host inverse map or an ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalInverseModulus}\uparrow}$.

Constructive story: A $\mathsf{CompactIntervalInverseModulus}^{\uparrow}$ packet is generated from a compact interval source, monotone inverse branch, finite-net row, inverse-modulus ledger, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalInverseModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7653.1, Definition 7653.2, and Definition 7653.3 seed the compact-interval inverse-modulus carrier and its finite-net handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalInverseModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host inverse functions, quotient real equality, trichotomy, countable choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval exposure, monotone branch exposure, finite-net handoff, inverse-modulus ledger exactness, finite real-name readback, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalInverseModulusUp.

Chapter 7654

A Concrete Naming Certificate for $\mathsf{GelfandMazur}^{\uparrow}$

Following Gelfand and Mazur's theorem for complex Banach division algebras, the $\mathsf{GelfandMazur}^{\uparrow}$ packet records the finite certificate surface by which a displayed complex Banach division algebra can be read as scalar-complex data. It sits after the field packet of chapter 45, the complex-number carrier of chapter 39, the norm boundary of chapter 89, the Banach completion surface of chapter 90, and the scalar-linear map rows of chapter 48. The chapter records the visible NameCert rows for that classical route; it does not assert spectral theory, quotient equality, host algebra equality, selected spectrum points, or a complete Banach-algebra library.

Definition 7654.1 (Gelfand-Mazur carrier)**.** *A* $\mathsf{GelfandMazur}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K_{\mathrm{gm}} = (A, F, C, N, B, I, H, T, P, L)$$

with the following displayed rows:

1. *A is the algebra row carrying the multiplication, unit, distributivity, and scalar-action interface over a displayed complex scalar source.*
2. *F is the* $\mathsf{Field}^{\uparrow}$ *row recording the nonzero division surface for the algebra's invertible part.*
3. *C is the* $\mathsf{Complex}^{\uparrow}$ *scalar row used for scalar embedding, scalar comparison, and terminal complex readback.*
4. *N is the* $\mathsf{Norm}^{\uparrow}$ *row recording the multiplicative norm bound, unit norm readback, and norm comparison ledger.*
5. *B is the* $\mathsf{Banach}^{\uparrow}$ *row exposing the complete normed carrier surface consumed by completion-facing readers.*
6. *I is the nonzero inverse row, displaying the inverse operation only after the nonzero classifier and field row have been read.*
7. *H records componentwise* hsame *transport for $A, F, C, N, B, I, T, P, L$.*
8. *T records displayed* Cont *replay from the algebra, scalar, norm, Banach, and inverse rows to the scalar-complex readback.*
9. *P is the* Pkg *provenance over* $\mathsf{GelfandMazur}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. L is the local $\mathsf{NameCert}_{\mathsf{GelfandMazur}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows and exposes no spectrum selector, host algebra equality, quotient representative, external Banach-algebra library, or detached complex scalar object.

Theorem 7654.2 (Gelfand-Mazur NameCert obligations)**.** *For every accepted* $\mathsf{GelfandMazur}^{\uparrow}$ *carrier* $K_{\mathrm{gm}} = (A, F, C, N, B, I, H, T, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{GelfandMazur}^{\uparrow}}$ *surface consists exactly of algebra admission, field and nonzero-inverse exposure,* $\mathsf{Complex}^{\uparrow}$ *scalar rows, norm and Banach rows, scalar-linear readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Any consumer that reads a Gelfand-Mazur conclusion must first display the sibling routes through chapter 45, chapter 39, chapter 89, chapter 90, and chapter 48. Replacing one of those rows by spectral theory, quotient equality, host algebra equality, selected spectrum points, or a complete Banach-algebra library leaves the accepted carrier.

Proof. Project the carrier of Definition 7654.1. The rows A, F, C, N, B, I display the algebra, division, complex scalar, norm, Banach, and inverse surfaces before any structural row is read.

The sibling dependency surface is explicit. The field row supplies division, the complex row supplies scalar readback, the norm row supplies bounded comparison, the Banach row supplies completion-facing stability, and the linear-map row records the scalar-linear route used by the algebra consumer.

The rows H, T, P, L transport, replay, source, and name the same finite inventory. Since the carrier has no coordinate for spectral theory, quotient equality, host algebra equality, selected spectrum points, or a complete Banach-algebra library, the listed rows exhaust the local NameCert obligations. □

Theorem 7654.3 (Gelfand-Mazur complex scalar collapse)**.** *Every scalar-collapse read from an accepted* $\mathsf{GelfandMazur}^{\uparrow}$ *packet factors through the finite route*

$$A, F, C, N, B, I \longrightarrow H, T, P, L.$$

The read first exposes the algebra and nonzero-inverse rows, then the $\mathsf{Complex}^{\uparrow}$ *scalar row, then the norm and Banach rows, and only then the transport, replay, provenance, and local naming rows. The resulting scalar-complex comparison is a NameCert readback over* K_{gm}*, not a claim of host algebra equality, quotient equality, selected spectrum points, spectral theory, or a complete Banach-algebra library.*

Proof. Start with the algebra row A and the field row F. They display the multiplication, unit, scalar action, and nonzero division surface that a Gelfand-Mazur consumer is allowed to inspect.

Next read the complex, norm, Banach, and inverse rows C, N, B, I. These rows attach scalar-complex comparison to the displayed normed complete carrier and to the nonzero inverse route; they do not introduce a spectrum selector or a host algebra-equality principle.

Finally apply H, T, P, L. Componentwise transport, displayed replay, provenance, and local naming preserve exactly the finite packet, so the scalar-collapse read cannot escape to quotient equality, selected spectrum points, spectral theory, or an external Banach-algebra library. □

Falsifiable prediction: An accepted $\mathsf{GelfandMazur}^{\uparrow}$ read is refuted if a scalar-complex conclusion is reached without displaying the algebra row, FieldUp division row, ComplexUp scalar row, NormUp row, BanachUp row, nonzero inverse row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: field, complex, norm, banach, and linearmap: none is bijective to the Gelfand-Mazur packet because only $\mathsf{GelfandMazur}^{\uparrow}$ simultaneously records algebra admission, complex scalar readback, Banach norm completion, nonzero inverse exposure, scalar-linear comparison, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GelfandMazur}^{\uparrow}}$.

Constructive story: A $\mathsf{GelfandMazur}^{\uparrow}$ packet is generated from an algebra row, FieldUp division row, ComplexUp scalar row, NormUp row, BanachUp row, nonzero inverse row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GelfandMazur}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7654.1, Definition 7654.2, and Definition 7654.3 seed the finite scalar-collapse route for complex Banach division algebra consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GelfandMazur}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, spectral theory, quotient equality, host algebra equality, selected spectrum points, or a complete Banach-algebra library.

Upgrade path: Obligation closure requires checked carrier admission, scalar-collapse route determinacy, nonzero inverse exposure, Banach and norm row compatibility, transport, replay, provenance, and local naming for BEDC.Derived.GelfandMazurUp.

Chapter 7655

A Concrete Naming Certificate for $\mathsf{IntervalArzelaAscoli}^{\uparrow}$

Following Arzela and Ascoli, and Bishop and Bridges, the $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ packet records the closed-interval, compact-metric, and equicontinuity rows needed for a constructive Arzela–Ascoli handoff as finite BEDC data. It consumes the real-name seal of chapter 38, the regular rational readback of chapter 301, the compact-metric finite-net surface of chapter 129, the continuous-map carrier of chapter 130, and the final metric-triangle estimate of chapter 1159. The packet is a compact-uniform handoff for interval-indexed families; it is not an open-cover compactness theorem, not a selected-subsequence construction, not quotient real equality, and not an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7655.1 (Interval Arzela–Ascoli carrier)**.** *An* $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, K, F, W, R, D, T, U, H, C, P, N)$$

with the following displayed rows:

1. *I is the displayed closed interval source row, read through* $\mathsf{Real}^{\uparrow}$ *endpoint seals and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite readback windows.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row for the interval source.*
3. *F is the finite family of* $\mathsf{ContinuousMap}^{\uparrow}$ *rows whose pointwise reads are inspected on the same interval carrier.*
4. *W is the shared finite window ledger for interval points, family indices, and target-value reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *D is the dyadic tolerance row used to compare interval mesh, equicontinuity radius, and target-value error.*
7. *T is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *row that transports local pointwise estimates to a uniform compact-metric estimate.*
8. *U is the compact-uniform handoff row exported to Real or Completion consumers after I, K, F, W, R, D, T have been displayed.*
9. *H records componentwise* hsame *transport for source, compact-metric, map-family, window, readback, tolerance, triangle, handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a precision request through the same interval family route.*
11. *P is the* Pkg *provenance over* $\mathsf{IntervalArzelaAscoli}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IntervalArzelaAscoli}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, K, F, W, R, D, T, U, H, C, P, N$. It has no coordinate for open-cover compactness, selected subsequences, quotient equality of real names or function names, countable choice, host compact-open topology, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7655.2 (Interval Arzela–Ascoli NameCert obligations)**.** *For every accepted* $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ *carrier $A = (I, K, F, W, R, D, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IntervalArzelaAscoli}^{\uparrow}}$ *surface consists exactly of interval-source admission through I, compact-metric finite-net admission through K, continuous-map family admission through F, finite-window exposure through W, regular rational readback through R, dyadic tolerance exposure through D, metric-triangle uniform-estimate exposure through T, compact-uniform handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7655.1. The source rows are the interval row I, compact-metric row K, and continuous-map family row F.

Read the finite numerical surface next. The window row W, readback row R, and dyadic tolerance row D attach each interval point and each inspected map value to finite data before any uniform estimate is considered.

The row T supplies the only metric-triangle uniform estimate, and U is downstream of that row. The structural rows H, C, P, N preserve, replay, source, and name the same packet.

Since the carrier has no open-cover, selected-subsequence, quotient-equality, countable-choice, compact-open host, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7655.3 (Interval Arzela–Ascoli compact-uniform handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ *carrier must read the finite route*

$$I, K, F \longmapsto W, R, D \longmapsto T, U \longmapsto H, C, P, N$$

before treating the interval-indexed family as compact-uniform data. The route consumes $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *and* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *as displayed sibling rows; it exports no open-cover compactness principle, selected subsequence, quotient real equality, host compact-open equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the interval and compact-metric rows. The source interval is read through displayed real-name seals and regular rational endpoint windows, while the compact-metric row supplies only finite-net coverage.

Next inspect the continuous family through F and the shared finite windows W, R, D. These rows keep each pointwise value and tolerance comparison inside the same finite route.

Apply the metric-triangle uniform-estimate row T. It is the only row that transports the pointwise estimates across the compact-metric net into the compact-uniform handoff U.

Thus any consumer that reaches Real or Completion data through the packet receives exactly the displayed finite handoff. A selected subsequence, an open cover, a quotient equality oracle, or an ambient completeness theorem would require a coordinate not present in the carrier. □

Falsifiable prediction: An accepted $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ consumer is refuted if it reads compact-uniform interval-family data without displaying the interval row, compact-metric finite-net row, continuous-map family row, finite windows, RegSeqRat readback, dyadic tolerance row, and metric-triangle uniform-estimate row.

Independence witness: real, regseqrat, compactmetric, continuousmap, metric-triangle-uniform-estimate: none is bijective to the interval Arzela–Ascoli packet because only $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ binds interval source, compact-metric finite nets, continuous family reads, finite windows, rational readback, dyadic tolerances, metric-triangle handoff, transport, replay, provenance, and local naming in one route.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalArzelaAscoli}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalArzelaAscoli}^{\uparrow}$ packet is generated from interval Real rows, RegSeqRat finite readback, compact-metric finite nets, continuous-map family rows, dyadic tolerances, a metric-triangle uniform-estimate row, compact-uniform handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalArzelaAscoli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7655.1, Definition 7655.2, and Definition 7655.3 seed the compact-uniform interval-family carrier surface over Real, RegSeqRat, CompactMetric, ContinuousMap, MetricTriangleUniformEstimate, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalArzelaAscoli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequences, quotient real equality, quotient function equality, host compact-open topology, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-source admission, compact-metric finite-net exposure, continuous-map family exposure, finite-window readback, dyadic tolerance exactness, metric-triangle uniform-estimate handoff, structural replay, provenance, and local naming for BEDC.Derived.IntervalArzelaAscoliUp.

Chapter 7656

A Concrete Naming Certificate for DunfordSchwartzMeanErgodicFinite$^{\uparrow}$

Following Dunford–Schwartz and Krengel, the DunfordSchwartzMeanErgodicFinite$^{\uparrow}$ packet records the finite Cesaro-window surface of a contraction-facing mean ergodic route. It sits after the averaging packet of chapter 1840, the observable pullback row of chapter 7271, the finite orbit-average ledger of chapter 6982, the Banach carrier surface of chapter 90, and the terminal real-name seal of chapter 38. The chapter names only finite windows, bounded operator rows, rational Cesaro readbacks, Real sealing, transport, replay, provenance, and local naming; it does not assert strong convergence, invariant projections, quotient ergodic components, almost-everywhere limits, spectral decomposition, or a host Banach-space limit theorem.

Definition 7656.1 (Dunford-Schwartz mean ergodic finite carrier)**.** *A* DunfordSchwartzMeanErgodicFinite$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, O, K, F, W, S, R, A, H, C, P, N)$$

with the following visible rows:

1. *B is the* Banach$^{\uparrow}$ *source row exposing the normed carrier only through displayed finite samples.*
2. *O is the Dunford–Schwartz operator row, recording the contraction and positivity-facing bounds used by the finite averaging request.*
3. *K is the* KoopmanOperator$^{\uparrow}$ *or transfer-facing observable route through which the operator row may be compared with measure-preserving dynamics.*
4. *F is the* BirkhoffErgodicFiniteAverage$^{\uparrow}$ *row carrying finite orbit averages when the request comes from an ergodic observable.*
5. *W is the* MeanErgodic$^{\uparrow}$ *Cesaro-window row, available only as a finite prefix-average ledger.*
6. *S is the* StreamName$^{\uparrow}$ *window row for inspected operator iterates and averaged endpoints.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row for rational norm and endpoint comparisons.*
8. *A is the* Real$^{\uparrow}$ *boundary row sealing the displayed rational comparisons as Real-facing names.*
9. *H records componentwise* hsame *transport for the Banach, operator, Koopman or transfer, finite-average, Cesaro-window, stream, readback, Real, continuation, provenance, and naming rows.*
10. *C records displayed* Cont *replay from an averaging request through $B, O, K, F, W, S, R, A, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}$, $\mathsf{MeanErgodic}^{\uparrow}$, $\mathsf{KoopmanOperator}^{\uparrow}$, $\mathsf{BirkhoffErgodicFiniteAverage}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these twelve rows. It has no coordinate for an invariant projection, selected limit, quotient ergodic component, almost-everywhere convergence theorem, spectral resolution, or ambient Banach-space completeness assertion.

Theorem 7656.2 (Dunford-Schwartz mean ergodic finite NameCert obligations)**.** *For every accepted* $\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}$ *carrier* $G = (B, O, K, F, W, S, R, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}}$ *surface consists exactly of carrier admission, Banach source exposure, Dunford–Schwartz operator bound exposure, Koopman or transfer comparison, Birkhoff finite-average handoff, MeanErgodic Cesaro-window handoff, StreamName window routing, RegSeqRat readback, Real seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7656.1. Its visible coordinates are precisely the Banach source, operator bound, Koopman or transfer comparison, finite-average handoff, Cesaro-window handoff, stream, readback, Real boundary, transport, replay, provenance, and local naming rows.

Read the analytic rows in order. The Banach row fixes the sampled normed carrier, the operator row records the Dunford–Schwartz finite bound surface, and the Koopman or transfer row explains how observable dynamics feed that operator without identifying the packet with a dynamics chapter.

The averaging rows are downstream of those sources. The Birkhoff row supplies finite orbit averages when present, while the MeanErgodic row supplies the Cesaro prefix ledger. StreamName and RegSeqRat then expose only finite windows and rational readbacks before the Real row seals the displayed endpoint.

Since the carrier has no coordinate for invariant projections, selected limits, quotient ergodic components, almost-everywhere convergence, spectral data, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7656.3 (Dunford-Schwartz mean ergodic finite Cesaro route)**.** *Every Cesaro-facing consumer of an accepted* $\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}$ *carrier factors through the finite route*

$$B \longmapsto O \longmapsto K \longmapsto F \longmapsto W \longmapsto S \longmapsto R \longmapsto A \longmapsto H, C, P, N.$$

Thus a consumer receives the Banach sample row, Dunford–Schwartz operator bounds, Koopman or transfer comparison, Birkhoff finite averages, MeanErgodic Cesaro windows, StreamName windows, RegSeqRat readback, and Real sealing before it can export an averaged endpoint.

Proof. Begin with the carrier definition. The only averaging-facing coordinates are the finite Birkhoff row F and the finite MeanErgodic Cesaro row W, and both are downstream of the Banach, operator, and Koopman or transfer rows.

Apply the NameCert obligations of Definition 7656.2. They force every Cesaro-facing read to expose B, O, K, F, W before the window and readback rows are used.

The StreamName row S and RegSeqRat row R then provide the finite inspected windows and rational comparisons. The Real boundary A is reached only after those finite rows, while H, C, P, N preserve the same route under transport, replay, provenance, and naming.

Therefore the exported endpoint is a finite Cesaro-window readback and not a strong convergence theorem, invariant projection, quotient ergodic component, almost-everywhere limit, spectral decomposition, or host Banach-space limit. □

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}}$.

Constructive story: A $\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}$ packet is generated from a Banach source row, a Dunford–Schwartz finite operator-bound row, a Koopman or transfer comparison row, a Birkhoff finite-average row, a MeanErgodic Cesaro-window row, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7656.1, Definition 7656.2, and Definition 7656.3 seed the finite route from Banach and Dunford–Schwartz operator rows through Koopman or transfer comparison, Birkhoff finite averages, MeanErgodic Cesaro windows, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DunfordSchwartzMeanErgodicFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close strong convergence, invariant projections, quotient ergodic components, almost-everywhere limits, spectral decomposition, host Banach-space limit operators, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operator-bound exposure, observable comparison, finite-average handoff, Cesaro-window routing, readback stability, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.DunfordSchwartzMeanErgodicFiniteUp.

Chapter 7657

A Concrete Naming Certificate for $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ packet records finite bilinear product-window data over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{CauchyProduct}^{\uparrow}$. It sits beside the product source of chapter 464, the product-stability route of chapter 6271, the finite stream-window surface of chapter 126, the dyadic product ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite bilinear product surface for later Real algebra; it does not use quotient streams, host multiplication, trichotomy, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7657.1 (Regular Cauchy bilinear product carrier)**.** *A* $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, Y, W, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, each read through finite* $\mathsf{StreamName}^{\uparrow}$ *windows before a product request is admitted.*
2. *W is the paired product-window row, recording the synchronized finite observations used for the two inputs.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, displaying the requested tolerance, endpoint bounds, cross-error budget, and output tolerance for the paired window.*
4. *Q is the* $\mathsf{CauchyProduct}^{\uparrow}$ *route row that consumes X, Y, W, D as finite product data.*
5. *R is the regular readback row asserting that the product route remains a* $\mathsf{RegSeqRat}^{\uparrow}$ *read rather than a host multiplication result.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the product window, dyadic budget, Cauchy-product route, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the two source rows, product window, dyadic budget, product route, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bilinear product request through $X, Y, W, D, Q, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBilinearProduct}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $X, Y, W, D, Q, R, E, H, C, P, N$ and has no coordinate for quotient streams, host multiplication, trichotomy, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7657.2 (Regular Cauchy bilinear product NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ *carrier $B = (X, Y, W, D, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBilinearPro}}$ *surface consists exactly of carrier admission for the two regular rational source rows, paired product-window exposure, dyadic product-budget exactness, Cauchy-product route admission, regular readback preservation, Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7657.1. The analytic rows are exactly the two source rows X, Y, the paired window W, the dyadic budget D, the product route Q, the readback row R, and the seal row E.

Read the product-window side first. The row W exposes only finite observations of the two source names, and D records the product tolerance budget used by that window.

The route row Q consumes those displayed rows as a $\mathsf{CauchyProduct}^{\uparrow}$ handoff. The readback row R keeps the result inside the regular rational surface, and the seal row E is available only after that readback.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no refused object appears as a coordinate, the listed obligations exhaust the local certificate. □

Theorem 7657.3 (Regular Cauchy bilinear product window bilinearity)**.** *Every accepted* $\mathsf{RegularCauchyBilinearProd}$ *packet reads bilinearity only through the finite route*

$$X, Y, W, D \longmapsto Q \longmapsto R, E, H, C, P, N.$$

Thus a downstream algebra consumer may vary either displayed source row inside the same paired window and dyadic budget only by replaying the corresponding $\mathsf{CauchyProduct}^{\uparrow}$ *route and regular readback; it receives no host multiplication operation, quotient-stream equality, trichotomy branch, selected limit, or ambient completeness principle.*

Proof. Start from the carrier $B = (X, Y, W, D, Q, R, E, H, C, P, N)$. The only product-facing source rows are X and Y, and the only joint observation row is W.

The dyadic budget D records the finite tolerance accounting for the displayed window. Therefore any left-source or right-source product read must pass through the same visible budget before the product route can be consumed.

The row Q is the sole $\mathsf{CauchyProduct}^{\uparrow}$ handoff, while R and E are downstream of that handoff. Transport and replay through H and C preserve this order, and P, N only record provenance and local naming.

Since the carrier has no coordinate for host multiplication or quotient equality, the bilinear behavior available to consumers is exactly the window-level replay route described above. □

Theorem 7657.4 (Regular Cauchy bilinear product Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ *packet factors through the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, the paired* $\mathsf{StreamName}^{\uparrow}$ *product window, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product-budget row, the* $\mathsf{CauchyProduct}^{\uparrow}$ *route, and the regular readback row before the terminal seal E is exposed. The packet therefore supplies a non-quotient bilinear product certificate and cannot export quotient streams, host multiplication, trichotomy, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7657.1. The terminal seal E is downstream of X, Y, W, D, Q, R in the displayed tuple.

Apply Definition 7657.2. The local certificate requires paired window exposure, dyadic product-budget exactness, Cauchy-product route admission, and regular readback preservation before any seal handoff.

Use Definition 7657.3. A downstream algebra consumer can replay only the finite window route through Q and R, so it cannot replace the packet by host multiplication or a selected completed product.

The structural rows H, C, P, N preserve the same route. Row exhaustion blocks quotient streams, trichotomy, selected limits, and ambient completeness from crossing the seal boundary. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ read reaching a $\mathsf{Real}^{\uparrow}$ seal must display both $\mathsf{RegSeqRat}^{\uparrow}$ source rows, the paired $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ product budget, the $\mathsf{CauchyProduct}^{\uparrow}$ route, the regular readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: streamname, dyadicratcore, regseqrat, cauchyproduct, real: RegularCauchyBilinearProdu is not bijective to any listed sibling because it jointly carries two source regular rational rows, a paired product window, dyadic product-budget accounting, a Cauchy-product route, regular readback, terminal Real sealing, transport, replay, provenance, and local naming as one bilinear product packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBilinearProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBilinearProduct}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName product windows, a DyadicRatCore product budget, a CauchyProduct route, a regular readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBilinearProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7657.1, Definition 7657.2, Definition 7657.3, and Definition 7657.4 seed the finite bilinear product-window route from regular rational sources to product readback and Real seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBilinearProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, host multiplication, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired product-window exposure, dyadic product-budget exactness, CauchyProduct route admission, regular readback preservation, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBilinearProductUp.

Chapter 7658

A Concrete Naming Certificate for SeparatingHyperplane$^{\uparrow}$

Following Rockafellar and finite-dimensional convex separation theory, the SeparatingHyperplane$^{\uparrow}$ packet records the finite affine-functional surface by which two displayed convex rows are separated inside a finite vector-space window. It sits after the finite alternative row of chapter 6185, the convex carrier of chapter 208, the linear-map row of chapter 48, the vector-space carrier of chapter 47, and the supporting-hyperplane packet of chapter 6895. The packet names only displayed coefficient, inequality, and transport rows; it does not import a host dual space, arbitrary topological separation, selected support points, quotient dual equality, or choice.

Definition 7658.1 (Separating hyperplane carrier)**.** *A* SeparatingHyperplane$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, C_0, C_1, L, a_0, a_1, F, W, H, R, P, N)$$

with the following displayed rows:

1. *V is the finite-dimensional* VecSpace$^{\uparrow}$ *row on which every vector and scalar-action read is performed.*
2. *C_0 and C_1 are the two* ConvexSet$^{\uparrow}$ *rows whose displayed convex-combination operations and inspected point rows are visible to the packet.*
3. *L is the* LinMap$^{\uparrow}$ *functional row, recorded by the finite coefficient list read over V.*
4. *a_0 and a_1 are the scalar level rows marking the two displayed affine sides of the hyperplane comparison.*
5. *F is the* FarkasLemma$^{\uparrow}$ *alternative row used when the separating comparison is obtained from a finite inequality system.*
6. *W is the finite witness ledger saying that every inspected row of C_0 lies on the first side of L and every inspected row of C_1 lies on the second side, with the displayed located slack between a_0 and a_1.*
7. *H records componentwise* hsame *transport for vector, convex, functional, scalar-level, Farkas, witness, replay, package, and local naming rows.*
8. *R records displayed* Cont *replay from a separation request through $V, C_0, C_1, L, a_0, a_1, F, W, H, P, N$.*
9. *P is the* Pkg *provenance over* SeparatingHyperplane$^{\uparrow}$*,* FarkasLemma$^{\uparrow}$*,* ConvexSet$^{\uparrow}$*,* LinMap$^{\uparrow}$*,* VecSpace$^{\uparrow}$*,* FiniteSupportingHyperplane$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SeparatingHyperplane}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a selected ambient dual vector, an arbitrary topological separation theorem, a quotient dual-space equality, or a global family of separating functionals.

Theorem 7658.2 (Separating hyperplane NameCert obligations)**.** *For every accepted* $\mathsf{SeparatingHyperplane}^{\uparrow}$ *carrier* $S = (V, C_0, C_1, L, a_0, a_1, F, W, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatingHyperplane}^{\uparrow}}$ *surface consists exactly of finite vector-space admission, two convex-set admissions, linear-functional display, scalar-level display, finite alternative handoff, one-sided witness exactness, componentwise transport, displayed replay, package provenance, and local naming. The certificate exports no host dual-space object, arbitrary topological separation theorem, selected support point, quotient dual equality, or choice principle.*

Proof. Project the carrier of Definition 7658.1. The rows $V, C_0, C_1, L, a_0, a_1, F, W$ provide the entire geometric and scalar surface of the packet.

The separation read is finite. The functional row L is read through the displayed vector-space row V, the convex information is read through C_0 and C_1, and the finite alternative row F supplies only the multiplier or feasibility ledger already visible to the packet.

Rows H, R, P, N transport, replay, source, and name the same finite data. Since the carrier lacks any coordinate for the excluded ambient or choice-based objects, the listed rows exhaust the local NameCert obligations. □

Theorem 7658.3 (Separating hyperplane Farkas route)**.** *Every Farkas-facing consumer of an accepted* $\mathsf{SeparatingHyperplane}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{VecSpace}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{LinMap}^{\uparrow} \longmapsto \mathsf{FarkasLemma}^{\uparrow} \longmapsto \mathsf{FiniteSupportingHyperplane}^{\uparrow}.$$

The consumer receives the same finite vector window, two convex rows, a displayed linear functional, scalar levels, the finite alternative row, the one-sided witness ledger, transport, replay, provenance, and local naming. It receives no detached separation principle and no selected ambient dual object.

Proof. Begin with a Farkas-facing separation request. The vector and convex data are read through V, C_0, C_1, so all subsequent coefficient rows remain tied to the displayed finite-dimensional surface.

Read L, a_0, a_1 next. These rows provide the affine comparison seen by the consumer, while the finite alternative row F explains the inequality ledger without invoking a topological separation theorem.

Finally compare the witness row W with the supporting-hyperplane sibling surface. The supporting packet supplies the one-sided boundary reading, and the present packet carries the two-sided separation ledger through the same structural rows H, R, P, N.

Therefore the public route is the displayed finite chain above. Any read bypassing those rows would require a carrier coordinate that the packet does not contain. □

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatingHyperplane}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatingHyperplane}^{\uparrow}$ packet is generated from finite VecSpaceUp data, two ConvexSetUp rows, a LinearMapUp functional row, scalar-level rows, a FarkasLemmaUp alternative handoff, a finite one-sided witness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SeparatingHyperplane}^{\uparrow}}$, seed)

Scope closed: Definition 7658.1, Definition 7658.2, and Definition 7658.3 seed the finite separating-hyperplane packet over FarkasLemmaUp, ConvexSetUp, LinearMapUp, VecSpaceUp, FiniteSupportingHyperplaneUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{SeparatingHyperplane}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary topological separation, selected ambient dual vectors, quotient dual equality, selected support points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite alternative handoff, one-sided witness exactness, componentwise transport, replay, provenance, and local naming for BEDC.Derived.SeparatingHyperplaneUp.

Chapter 7659

A Concrete Naming Certificate for $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$

The $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ packet realizes the boundary-quadruple branch of chapter 9463 as finite NameCert data. It sits beside the disk carrier of chapter 377, the metric row of chapter 3474, the boundary row of chapter 3491, the cross-ratio packet of chapter 3948, and the ideal-triangle packet of chapter 6544. The packet names four displayed boundary ends, their side and diagonal incidence, a finite cross-ratio read, transport, replay, provenance, and local naming; it does not complete the disk, quotient boundary endpoints, select global geodesic representatives, or identify observer expansion with physical spacetime.

Definition 7659.1 (Hyperbolic ideal quadrilateral carrier)**.** *A* $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (U, M, B, E, D, X, T, J, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for the inspected disk probes and four boundary-end reads.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *B is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *row naming four cyclically ordered boundary ends and the finite incidence data used by the packet.*
4. *E records the four boundary-to-boundary side rows and the two diagonal rows as displayed geodesic-boundary data.*
5. *D is the diagonal-splitting row that reads the two ideal triangles cut from the quadrilateral through the sibling* $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$ *surface.*
6. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row carrying the finite boundary cross-ratio comparison attached to the same four-end boundary surface.*
7. *T is the transport row preserving disk coordinates, metric reads, boundary incidence, side rows, diagonal rows, triangle-splitting data, and cross-ratio data.*
8. *J is the classifier-stability row for cyclic order, side incidence, diagonal incidence, cross-ratio readback, and triangle-splitting reads.*
9. *H records componentwise* hsame *transport for disk, metric, boundary, side, diagonal, cross-ratio, classifier, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from an ideal-quadrilateral request through* $U, M, B, E, D, X, T, J, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBou}$ $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed hyperbolic disks, quotient ideal-boundary equality, selected global geodesics, host analytic flow, or physical cosmology.

Theorem 7659.2 (Hyperbolic ideal quadrilateral NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ *carrier* $Q = (U, M, B, E, D, X, T, J, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{HyperbolicIdealQuadrilat}}$ *surface is exhausted by disk-coordinate admission, hyperbolic metric visibility, four-end boundary incidence, side and diagonal visibility, triangle-splitting readback, finite cross-ratio readback, transport, classifier stability, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7659.1. The rows $U, M, B, E, D, X, T, J, H, C, P, N$ are the only displayed coordinates.

The geometric read begins with U, M, B, E. Disk coordinates and metric reads are visible before the four boundary ends, side rows, and diagonal rows are inspected.

The finite boundary-quadruple structure is carried by D, X, T, J. Triangle splitting reads the two diagonal pieces through the ideal-triangle sibling, while the cross-ratio row attaches one finite four-end comparison to the same boundary surface. Transport and classifier stability keep these rows on the same packet.

Rows H, C, P, N preserve, replay, source, and name the finite carrier. Since no row stores the excluded completed or host-level objects, the listed rows exhaust the local NameCert surface. □

Theorem 7659.3 (Hyperbolic ideal quadrilateral boundary-quadruple handoff)**.** *Every boundary-quadruple consumer of an accepted* $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ *packet factors through*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicCrossRatio}^{\uparrow} \longmapsto \mathsf{HyperbolicIdealT}$$

The consumer receives four displayed boundary ends, side and diagonal incidence, the finite cross-ratio row, triangle-splitting readback, transport, classifier stability, componentwise transport, replay, provenance, and local naming. It obtains no completed disk, quotient ideal-boundary equality, selected global geodesic, host analytic flow, physical cosmology, or observer substance.

Proof. Begin with a boundary-quadruple request. The disk-coordinate row U and metric row M provide the only geometric source data available to the request.

Read B and E next. The four boundary ends, four sides, and two diagonals are displayed as finite incidence and geodesic-boundary rows, not as quotient endpoints or selected global geodesics.

Use X, D, T, J for the handoff. The cross-ratio row records the finite four-end comparison, the diagonal-splitting row exposes the two ideal-triangle reads, and transport plus classifier stability preserve the same boundary commitments.

Finally replay the structural rows H, C, P, N. They preserve the same finite packet, and the carrier has no coordinate for the excluded completed or host-level objects, so the boundary-quadruple handoff cannot leave the displayed route. □

Falsifiable prediction: Any accepted $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ consumer that exports a boundary-quadruple comparison without the four-end boundary row B and the cross-ratio row X refutes the carrier surface.

Independence witness: unitdisk, hyperbolic-metric, hyperbolic-geodesic-boundary, hyperbolic-cross-ratio, hyperbolic-ideal-triangle: none is bijective to $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ because this packet alone binds four boundary ends, side and diagonal incidence, triangle-splitting readback, cross-ratio comparison, transport, classifier stability, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}$ packet is generated from UnitDiskUp coordinate rows, HyperbolicMetricUp metric reads, HyperbolicGeodesicBoundaryUp four-end boundary incidence, side and diagonal rows, HyperbolicIdealTriangleUp splitting readback, HyperbolicCrossRatioUp comparison, transport, classifier stability, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7659.1, Definition 7659.2, and Definition 7659.3 seed the finite boundary-quadruple route over disk, metric, boundary, side, diagonal, triangle-splitting, cross-ratio, transport, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicIdealQuadrilateral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic disks, quotient ideal-boundary equality, selected global geodesics, host analytic flows, physical cosmology, observer-substance readings, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk visibility, metric-read visibility, four-end boundary incidence, side and diagonal visibility, triangle splitting, cross-ratio readback, transport, classifier stability, ledger nonescape, and local naming for BEDC.Derived.HyperbolicIdealQuadrilateralUp.

Chapter 7660

A Concrete Naming Certificate for $\mathsf{BishopRegularRealLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularRealLimit}^{\uparrow}$ packet records the finite limit data carried by a regular rational real name. It sits over the dyadic tolerance arithmetic of chapter 291, the finite schedule rows of chapter 126, the regular rational source of chapter 301, the uniqueness boundary of chapter 3942, and the terminal real-name seal of chapter 38. The packet names a Bishop-style limit route; it does not quotient streams, select a limit representative, use countable choice, assert host equality of real objects, or claim full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7660.1 (Bishop regular real limit carrier)**.** *A* $\mathsf{BishopRegularRealLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, T, U, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the inspected tail scales.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite schedule row for reading rational observations.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row over the displayed schedule.*
4. *T is the Bishop tail-test row recording that later displayed reads stay within the dyadic tolerance demanded by D.*
5. *U is the* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *comparison row, available only when two displayed candidate-limit reads are compared through the same regular route.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, R, T, U have been exposed.*
7. *H records componentwise* hsame *transport for the tolerance, schedule, readback, tail-test, uniqueness, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from finite schedules and dyadic tolerances to the regular readback, tail-test, uniqueness boundary, and real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRegularRealLimit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealLimit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected representatives, countable-choice schedules, host real equality, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 7660.2 (Bishop regular real limit NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularRealLimit}^{\uparrow}$ *carrier* $L = (D, S, R, T, U, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRegularRealLimit}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance visibility, finite schedule admission, regular rational readback, Bishop tail-test exposure, regular Cauchy uniqueness boundary exposure, terminal real sealing, componentwise transport, displayed replay, provenance, and local naming. Every limit-facing read passes through*

$$D, S, R, T, U, E, H, C, P, N$$

and through no quotient stream equality, selected limit, countable-choice selector, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7660.1. The rows D, S, R display the tolerance ledger, schedule, and regular readback before any limit-facing row is inspected.

Read the Bishop tail test next. The row T is attached to the same displayed schedule and dyadic ledger, so it records only finite tail data. When two candidate-limit reads are compared, U routes the comparison through $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ before the real seal E is public.

The structural rows H, C, P, N transport, replay, source, and locally name this route. Since the excluded principles have no carrier coordinate, the listed rows exhaust the local $\mathsf{NameCert}$ obligations. □

Theorem 7660.3 (Bishop regular real limit regularity induction)**.** *Every accepted* $\mathsf{BishopRegularRealLimit}^{\uparrow}$ *packet supports induction on displayed finite schedules: the base read is the first* $\mathsf{StreamName}^{\uparrow}$ *window checked against* D*, and the induction step appends one later window whose* $\mathsf{RegSeqRat}^{\uparrow}$ *readback satisfies the same Bishop tail-test row* T*. The induction exports only the preserved route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchyLimitUniqueness}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

and no quotient, selector, choice, host equality, or ambient completeness data.

Proof. The base case is the displayed schedule row S read against the dyadic ledger D. Its regular rational readback is the row R, and the tail-test row T records the admitted tolerance.

For the induction step, append one finite window to S and read it through the same dyadic ledger. Regularity is preserved because the appended read is admitted only when it satisfies T and therefore remains on the displayed $\mathsf{RegSeqRat}^{\uparrow}$ route.

The uniqueness and seal rows are downstream. The row U compares only displayed candidate-limit reads, and E is reached only through the same finite route. The excluded completion principles are absent from the carrier, so the induction cannot export them. □

Theorem 7660.4 (Bishop regular real limit seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{BishopRegularRealLimit}^{\uparrow}$ *carrier receives the terminal seal* E *only after the displayed dyadic tolerance ledger, stream schedule, regular rational readback, Bishop tail-test row, and* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *boundary have been exposed. The handoff exports finite regular real limit data and not quotient streams, selected limits, countable-choice schedules, host real equality, or full* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the obligation theorem to read D, S, R, T, U before E. This places the terminal real seal behind the same finite tolerance, schedule, readback, and uniqueness route.

Apply regularity induction to the inspected finite schedule. It preserves the route through appended windows and prevents the consumer from replacing the displayed rows by a selected representative or quotient stream.

Finally use H, C, P, N to transport, replay, source, and locally name the same handoff. No excluded completion coordinate is present, so the public seal is only the displayed regular real limit route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularRealLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularRealLimit}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite schedules, RegSeqRat readback, Bishop tail-test data, a RegularCauchyLimitUniqueness boundary, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularRealLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7660.1, Definition 7660.2, Definition 7660.3, and Definition 7660.4 seed the finite Bishop regular real limit route over dyadic tolerances, stream schedules, regular rational readback, uniqueness, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularRealLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule locality, regular rational readback, Bishop tail-test exposure, uniqueness-boundary exposure, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularRealLimitUp.

Chapter 7661

A Concrete Naming Certificate for $\mathsf{LayeredRelationCertificate}^{\uparrow}$

The $\mathsf{LayeredRelationCertificate}^{\uparrow}$ packet realizes the relation-before-identity discipline of chapter 9416 as finite NameCert data. It sits beside the compact same-schema packet of chapter 1090, the gate verdict of chapter 1099, the open-problem ledger of chapter 780, and the observer-history identity surface of chapter 479. The packet is deliberately larger than a same-schema row: it stores source, carrier, classifier, preserved, not-preserved, exactness, failure-boundary, refusal, and local naming data in one auditable surface.

Definition 7661.1 (Layered relation certificate carrier)**.** *A* $\mathsf{LayeredRelationCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, B, K, M, V, W, E, F, Q, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two source-domain rows being compared.*
2. *K is the finite carrier ledger for the layers read from both sources.*
3. *M is the classifier row assigning each layer to its displayed relation role.*
4. *V is the preserved-structure row.*
5. *W is the not-preserved row.*
6. *E is the exactness row stating the admitted same-schema strength.*
7. *F is the failure-boundary row naming when the relation weakens or is rejected.*
8. *Q is the refusal row excluding object identity, empirical transfer, subject-substance transfer, global-frame transfer, hidden axioms, and unlisted bridge evidence.*
9. *H records componentwise* hsame *transport for all source, carrier, classifier, preservation, refusal, exactness, boundary, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same rows.*
11. *P is the* Pkg *provenance over* $\mathsf{LayeredRelationCertificate}^{\uparrow}$, $\mathsf{LayeredRelationCert}^{\uparrow}$, $\mathsf{LayeredRelationGate}^{\uparrow}$, $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$, $\mathsf{ObserverHistIdentity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LayeredRelationCertificate}^{\uparrow}}$ *row.*

The classifier admits a relation read only when W is present with V, F is present with E, and Q is present with A, B, K, M. It has no coordinate for identity collapse or unrecorded bridge transfer.

Theorem 7661.2 (Layered relation certificate gate obligations)**.** *For every accepted* $\mathsf{LayeredRelationCertificate}^{\uparrow}$ *carrier* $R = (A, B, K, M, V, W, E, F, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LayeredRelationCertificate}^{\uparrow}}$ *surface consists exactly of finite source admission, carrier ledger admission, classifier exposure, preserved-row exposure, not-preserved-row exposure, exactness exposure, failure-boundary exposure, refusal exposure, componentwise transport, displayed replay, provenance, and local naming. A packet without the not-preserved row W is rejected by the gate.*

Proof. Project the carrier of Definition 7661.1. The source rows A, B, carrier ledger K, and classifier row M determine which relation is being read.

The gate then reads preservation and refusal together. The row V can be consumed only with the not-preserved row W, and the exactness row E can be consumed only with the failure-boundary row F. The refusal row Q blocks identity collapse and hidden bridge transfer.

Finally H, C, P, N transport, replay, source, and name the same finite packet. If W is absent, the preserved-row read lacks its refusal boundary, so the packet is not an accepted layered relation certificate. □

Theorem 7661.3 (Layered relation certificate exactness boundary)**.** *Every downstream consumer of an accepted* $\mathsf{LayeredRelationCertificate}^{\uparrow}$ *packet reads same-schema exactness only through*

$$A, B, K, M, V, W, E, F, Q, H, C, P, N.$$

The consumer may reuse the packet as relation evidence, but it may not replace either source by the other, infer preservation of a row listed in W, ignore the failure boundary F, bypass the refusal row Q, or treat the certificate as bridge-checked data.

Proof. Start from the gate obligations. They force the consumer to read the two sources, carrier ledger, classifier, preserved row, not-preserved row, exactness row, failure boundary, and refusal row before any relation evidence is exported.

The exactness row is therefore bounded by the not-preserved and failure rows. If a consumer asks for object identity, empirical transfer, subject-substance transfer, global-frame transfer, hidden axiom support, or bridge evidence, the request is routed to Q rather than to E.

The transport and replay rows preserve this boundary. Provenance and local naming record the packet as relation evidence only, so the exactness read cannot become an unlisted bridge or identity claim. □

Theorem 7661.4 (Layered relation certificate sibling independence)**.** *The* $\mathsf{LayeredRelationCertificate}^{\uparrow}$ *carrier is not bijective, under NameCert-row preservation, to* $\mathsf{LayeredRelationCert}^{\uparrow}$, $\mathsf{LayeredRelationGate}^{\uparrow}$, $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$, *or* $\mathsf{ObserverHistIdentity}^{\uparrow}$. *The simultaneous presence of two source rows, a carrier ledger, a classifier row, preserved and not-preserved rows, exactness, failure boundary, refusal, transport, replay, provenance, and local naming is required for this packet.*

Proof. The compact $\mathsf{LayeredRelationCert}^{\uparrow}$ sibling supplies same-schema relation scope, but it does not by itself store the full gate refusal and open-ledger boundary used here.

The $\mathsf{LayeredRelationGate}^{\uparrow}$ sibling supplies a verdict route, while $\mathsf{MetaCICOpenProblemLedger}^{\uparrow}$ supplies unresolved-boundary ledgers and $\mathsf{ObserverHistIdentity}^{\uparrow}$ supplies observer-history identity discipline. Each omits at least one of $A, B, K, M, V, W, E, F, Q, H, C, P, N$.

Therefore no listed sibling is bijective to the packet while preserving all NameCert rows. The independence witness is the combined surface named by the carrier. □

Falsifiable prediction: Any proposed $\mathsf{LayeredRelationCertificate}^{\uparrow}$ packet without a displayed not-preserved row W fails the gate and must be routed to the refusal row rather than consumed as same-schema relation evidence.

Independence witness: layeredrelationcert, layered-relation-gate, metacicopenproblemledger, observerhistidentity: none is bijective to $\mathsf{LayeredRelationCertificate}^{\uparrow}$ because none carries the simultaneous source, carrier, classifier, preserved, not-preserved, exactness, failure-boundary, refusal, transport, replay, provenance, and local NameCert rows.

Future Lean work should provide Nontrivial and FieldFaithful instances for $\mathsf{LayeredRelationCertificate}^{\uparrow}$ inside BEDC.Derived.LayeredRelationCertificateUp.TasteGate.

Closure status for $\mathsf{NameCert}_{\mathsf{LayeredRelationCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{LayeredRelationCertificate}^{\uparrow}$ packet is generated from two source rows, a carrier ledger, a classifier row, preserved and not-preserved rows, exactness, failure-boundary, refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LayeredRelationCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7661.1, Definition 7661.2, Definition 7661.3, and Definition 7661.4 seed the finite relation-certificate surface that separates same-schema evidence from identity and hidden bridge transfer.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LayeredRelationCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close object identity, empirical transfer, subject-substance transfer, global-frame transfer, hidden axiom support, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, preserved and not-preserved row pairing, exactness and failure-boundary pairing, refusal, transport, replay, provenance, and local naming for BEDC.Derived.LayeredRelation

Chapter 7662

A Concrete Naming Certificate for $\mathsf{DeterministicPushdownAutomaton}^{\uparrow}$

Following Hopcroft–Ullman and Sipser, the $\mathsf{DeterministicPushdownAutomaton}^{\uparrow}$ packet records the deterministic finite-control stack recognizer surface as displayed BEDC data. It refines the stack-recognizer carrier of chapter 6018, reads terminal words through the $\mathsf{List}^{\uparrow}$ spine of chapter 36, uses the $\mathsf{Nat}^{\uparrow}$ cursor discipline of chapter 28, and sits beside the $\mathsf{ContextFreeGrammar}^{\uparrow}$ and $\mathsf{RegularLanguage}^{\uparrow}$ language interfaces of chapter 356 and chapter 351. The packet names a single deterministic accepting computation; it does not import a host language set, an ambiguity quotient, or an infinite trace.

Definition 7662.1 (Deterministic pushdown automaton carrier)**.** *A* $\mathsf{DeterministicPushdownAutomaton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F, w, \rho, \sigma, e, \chi, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite control-state carrier row.*
2. *Σ is the finite input alphabet row.*
3. *Γ is the finite stack alphabet row.*
4. *δ is the deterministic transition ledger. Each row reads one control state, either one input symbol or ε, and one top stack-symbol row, then returns one next-state row and one finite stack-word replacement row.*
5. *q_0 is the start-state row inside Q.*
6. *Z_0 is the initial-stack row inside Γ.*
7. *F is the accepting-state row inside Q.*
8. *w is the finite input word as a $\mathsf{List}^{\uparrow}$ row over Σ.*
9. *ρ is the finite run ledger beginning at (q_0, Z_0) and consuming w through the displayed deterministic transition rows.*
10. *σ is the stack-history ledger whose entries are finite $\mathsf{List}^{\uparrow}$ rows over Γ.*
11. *e is the endpoint readback for the run ledger.*

12. *χ is the acceptance readback, by final state or by the displayed empty-stack convention named by the packet.*
13. *H stores componentwise* hsame *transports for state, input, stack, transition, run, stack-history, endpoint, acceptance, and classifier rows.*
14. *C stores the* Cont *replay routes for reading input symbols, ε choices, stack-top rows, transition entries, and the finite run ledger.*
15. *P stores the* Pkg *provenance over* $\mathsf{PushdownAutomaton}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{RegularLanguage}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
16. *N stores the local* $\mathsf{NameCert}_{\mathsf{DeterministicPushdownAutomaton}^{\uparrow}}$ *rows.*

The carrier predicate is $\mathsf{DeterministicPushdownAutomatonPacket}(D)$. *It contains no coordinate for a host language set, nondeterministic branch choice, ambiguity witness, selected parse tree, or infinite accepting trace.*

Lean4 (definition) `BEDC.Derived.DeterministicPushdownAutomatonUp.TasteGate.DeterministicPushdownAutomatonU`
Lean4 ✓ `BEDC.Derived.DeterministicPushdownAutomatonUp.TasteGate.DeterministicPushdownAutomatonTasteGate`
`single carrier alignment`

Theorem 7662.2 (Deterministic pushdown automaton NameCert obligations)**.** *For every accepted* $\mathsf{DeterministicPushdownAutomaton}^{\uparrow}$ *carrier*

$$D = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F, w, \rho, \sigma, e, \chi, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DeterministicPushdownAutomaton}^{\uparrow}}$ *surface consists exactly of carrier admission, deterministic transition uniqueness for each state/input-or-ε/stack-top row, stack-row stability, run replay exactness, acceptance readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer must read through the finite rows in Definition 7662.1; no consumer obtains a host language set, a nondeterministic branch selector, a selected parse tree, or an infinite trace.*

Proof. Project the accepted carrier D. The rows $Q, \Sigma, \Gamma, \delta, q_0, Z_0, F$ name the finite control, input alphabet, stack alphabet, deterministic transition table, start state, initial stack, and accepting states. The rows w, ρ, σ, e, χ name the inspected input, the unique run ledger, the stack-history ledger, the endpoint, and the acceptance readback.

For transition uniqueness, fix a displayed state, either an input-symbol row or ε, and a top stack-symbol row. The ledger δ has at most one matching entry, and the run row ρ records only that entry at the corresponding cursor and stack position.

Stack-row stability follows by reading each step of ρ together with the matching stack row of σ. The next stack row is obtained by popping the displayed top symbol and pushing the finite $\mathsf{List}^{\uparrow}$ replacement named by the unique transition entry.

Run replay exactness is the finite induction over the displayed word and ε-step cursor ledger. At the endpoint, χ reads only the final control state or the displayed empty-stack row named by the carrier.

The rows H, C, P, N transport, replay, source, and locally name exactly these coordinates. Since the carrier has no coordinate for a host language set, branch selector, parse-tree choice, or infinite trace, the listed obligations exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DeterministicPushdownAutomaton}^{\uparrow}}$.

Constructive story: A DeterministicPushdownAutomaton$^{\uparrow}$ packet is generated from finite control rows, input alphabet rows, stack alphabet rows, a deterministic transition ledger, start and initial-stack rows, accepting rows, a finite input word, a finite run ledger, a stack-history ledger, an endpoint readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{DeterministicPushdownAutomaton}^{\uparrow}}$, seed)

Scope closed: Definition 7662.1 and Definition 7662.2 seed the deterministic finite stack-recognizer route over PushdownAutomatonUp, ContextFreeGrammarUp, RegularLanguageUp, ListUp, NatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{DeterministicPushdownAutomaton}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, equivalence with all context-free grammars, language-set semantics, ambiguity analysis, selected parse trees, nondeterministic branch choice, or infinite trace semantics.

Upgrade path: Obligation closure requires checked carrier admission, deterministic transition uniqueness, stack-row stability, run replay exactness, acceptance readback, and ledger nonescape for BEDC.Derived.DeterministicPushdownAutomatonUp.

Chapter 7663

A Concrete Naming Certificate for $\mathsf{HamiltonJacobi}^{\uparrow}$

Following Evans and Fleming, the $\mathsf{HamiltonJacobi}^{\uparrow}$ packet records a finite dynamic-programming and variational-control surface for Hamilton-Jacobi readback. It sits beside the $\mathsf{Ode}^{\uparrow}$ flow rows of chapter 193, the $\mathsf{DynSystem}^{\uparrow}$ transition rows of chapter 195, the finite quadratic-control ledger of chapter 296, the Riccati dependency row of chapter 307, the $\mathsf{Real}^{\uparrow}$ scalar surface of chapter 38, the $\mathsf{Mat}^{\uparrow}$ coefficient rows of chapter 49, and the $\mathsf{VecSpace}^{\uparrow}$ state rows of chapter 47. The packet names the finite carrier through which later optimal-control consumers may request a Hamiltonian row, value-slope row, and dynamic-programming replay without importing analytic viscosity solutions, global PDE existence, selected optimal controls, host differentiability, or ambient completeness.

Definition 7663.1 (Hamilton-Jacobi carrier)**.** *A* $\mathsf{HamiltonJacobi}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (X, U, F, L, H, V, D, R, Q, A, T, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{VecSpace}^{\uparrow}$ *state row and U is the control-row domain visible to the finite dynamic-programming request.*
2. *F is the* $\mathsf{DynSystem}^{\uparrow}$ *or* $\mathsf{Ode}^{\uparrow}$ *transition row tying a state-control pair to the displayed successor row.*
3. *L is the* $\mathsf{Real}^{\uparrow}$ *running-cost row, and H is the Hamiltonian row computed from the displayed transition and cost rows.*
4. *V is the value-row name and D is the finite slope or subgradient witness row used only as packet data.*
5. *R is the* $\mathsf{Riccati}^{\uparrow}$ *comparison row available when the displayed data come from a quadratic linear-control packet.*
6. *Q is the* $\mathsf{LQR}^{\uparrow}$ *dependency row recording the finite dynamic-programming route for the quadratic specialization.*
7. *A is the* $\mathsf{Mat}^{\uparrow}$ *coefficient row used by the linear and quadratic control fragments.*
8. *T records componentwise* hsame *transport for $X, U, F, L, H, V, D, R, Q, A, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{HamiltonJacobi}^{\uparrow}$*,* $\mathsf{Ode}^{\uparrow}$*,* $\mathsf{DynSystem}^{\uparrow}$*,* $\mathsf{LQR}^{\uparrow}$*,* $\mathsf{Riccati}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{VecSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HamiltonJacobi}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $X, U, F, L, H, V, D, R, Q, A, T, P, N$ and has no coordinate for analytic viscosity solutions, global PDE existence, selected optimal controls, host differentiability, or ambient completeness.

Theorem 7663.2 (Hamilton-Jacobi NameCert obligations)**.** *For every accepted* $\mathsf{HamiltonJacobi}^{\uparrow}$ *carrier $J = (X, U, F, L, H, V, D, R, Q, A, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HamiltonJacobi}^{\uparrow}}$ *surface consists exactly of carrier admission, state-control exposure, transition or ODE route admission, running-cost and Hamiltonian row exposure, value and slope-row readback, Riccati and LQR dependency availability, matrix-coefficient exposure, componentwise* hsame *transport,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7663.1. The state-control rows are X, U, the transition side is F, the scalar cost and Hamiltonian rows are L, H, and the value-readback rows are V, D.

The finite control dependencies are displayed separately. Rows R and Q expose the Riccati and LQR routes only when a quadratic linear-control packet is being read, while A records the matrix coefficients used by that comparison.

The structural rows T, P, N transport, source, and name the same packet. Since the carrier contains no additional coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7663.3 (Hamilton-Jacobi LQR-Riccati route)**.** *Every downstream* $\mathsf{LQR}^{\uparrow}$ *or* $\mathsf{Riccati}^{\uparrow}$ *consumer of an accepted* $\mathsf{HamiltonJacobi}^{\uparrow}$ *packet must pass through the displayed state row X, control row U, transition row F, cost row L, Hamiltonian row H, value row V, slope row D, matrix row A, transport row T, provenance row P, and local naming row N before it can read the quadratic-control rows Q and R. The route exports no analytic viscosity solution, global PDE existence theorem, selected optimal controller, host differentiability, or ambient completeness principle.*

Proof. Begin with the NameCert obligations of Definition 7663.2. They require the state-control, transition, cost, Hamiltonian, value, slope, matrix, transport, provenance, and local naming rows to be visible in the same finite packet.

The LQR and Riccati rows are dependency rows of that packet, not external solvers. A consumer that wants the quadratic-control face must therefore read Q and R through the displayed Hamilton-Jacobi carrier rather than through a host optimal-control theorem.

Because no carrier coordinate stores analytic viscosity solutions, global PDE existence, selected optimal controls, host differentiability, or ambient completeness, the only available LQR-Riccati route is the finite route displayed by $X, U, F, L, H, V, D, R, Q, A, T, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{HamiltonJacobi}^{\uparrow}$ read reaching an $\mathsf{LQR}^{\uparrow}$ or $\mathsf{Riccati}^{\uparrow}$ dependency must display the state row, control row, transition or ODE row, cost row, Hamiltonian row, value row, slope row, matrix row, componentwise hsame transport, Pkg provenance, and local NameCert row.

Independence witness: ode, dynsystem, lqr, riccati, real, matrix, vecspace: $\mathsf{HamiltonJacobi}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite state-control row, transition route, Hamiltonian readback, value and slope rows, LQR and Riccati dependency rows, matrix coefficient row, transport, provenance, and local naming as one variational-control packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HamiltonJacobi}^{\uparrow}}$.

Constructive story: A $\mathsf{HamiltonJacobi}^{\uparrow}$ packet is generated from finite state-control rows, an Ode or DynSystem transition row, a RealUp running-cost row, a Hamiltonian row, value and slope rows, Riccati and LQR dependency rows, a MatrixUp coefficient row, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{HamiltonJacobi}\uparrow}$, seed)

Scope closed: Definition 7663.1, Definition 7663.2, and Definition 7663.3 seed the finite variational-control carrier, NameCert obligation surface, and LQR-Riccati dependency route.

Formal verification: FormalStatus(NameCert$_{\mathsf{HamiltonJacobi}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic viscosity solutions, global PDE existence, selected optimal controls, host differentiability, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, state-control exposure, transition route admission, running-cost and Hamiltonian row exposure, value and slope-row readback, Riccati and LQR dependency availability, matrix-coefficient exposure, transport, provenance, and local naming for BEDC.Derived.HamiltonJacobiUp.

Chapter 7664

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ packet records the filter-facing universal-property route for regular Cauchy real names in the L10 Real and Completion spine. It sits after the finite observation surface of chapter 126, the regular rational readback of chapter 301, the criterion surface of chapter 1611, the Cauchy-filter source of chapter 333, and the terminal real-name seal of chapter 38. The packet names a universal readout through displayed rows only; it does not quotient streams, select limits, compare host real equality, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7664.1 (RegularCauchyFilterUniversalProperty carrier)**.** *A* $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (W, R, K, F, B, T, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window ledger, recording the inspected stream stages and filter requests.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values observed through W.*
3. *K is the* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *row certifying that the same windows and readbacks meet the regular Cauchy tail discipline.*
4. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row reached from W, R, K and used as the filter-facing input to the universal property.*
5. *B is the* $\mathsf{Real}^{\uparrow}$ *boundary row reached only after the regular Cauchy criterion and Cauchy-filter source rows have been displayed.*
6. *T records componentwise* hsame *transport for the window, readback, criterion, filter source, Real boundary, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$W, R, K, F \longmapsto B, T, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $W, R, K, F, B, T, C, P, N$. It has no coordinate for quotient stream equality, a selected limit representative, host real equality, countable choice, or ambient Real completeness.

Theorem 7664.2 (RegularCauchyFilterUniversalProperty NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ *carrier $U = (W, R, K, F, B, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchy}}$ *surface consists exactly of StreamName window exposure through W, RegSeqRat readback through R, RegularCauchyCriterion tail testing through K, CauchyFilter source exposure through F, Real boundary exposure through B, componentwise* hsame *transport through T, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. Its rows are precisely the finite window ledger, regular rational readback, regular Cauchy criterion, Cauchy-filter source, Real boundary, transport, replay, provenance, and naming rows.

Read the source route in order. The window row W supplies the inspected stages, R reads their regular rational values, and K checks the regular Cauchy tail discipline before any filter-facing row is available.

The filter and Real rows are then confined to the same route. The source row F is reached from W, R, K, and B is read only as the terminal Real boundary of that displayed source.

Finally T, C, P, N transport, replay, source, and name the same packet. Since the carrier has no quotient stream, selected limit, host equality, countable-choice, or ambient-completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 7664.3 (RegularCauchyFilterUniversalProperty route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ *packet reads the finite route*

$$W, R, K, F \longmapsto B, T, C, P, N.$$

Thus the universal-property handoff starts with StreamName windows, RegSeqRat readback, and RegularCauchyCriterion rows, reaches the CauchyFilter source only after those rows are visible, and reaches the Real boundary only through the same displayed packet.

Proof. Start with the NameCert obligations. They order the consumer read from W to R to K before the Cauchy-filter row F can be inspected.

The terminal boundary is likewise displayed. The Real row B is not an ambient completeness theorem; it is the boundary row reached by replaying the regular Cauchy filter route.

Transport, replay, provenance, and local naming preserve that order. Hence any universal-property handoff exported by the packet factors through $W, R, K, F, B, T, C, P, N$. □

Theorem 7664.4 (RegularCauchyFilterUniversalProperty nonescape)**.** *An accepted* $\mathsf{RegularCauchyFilterUniversalP}$ *packet cannot export quotient stream equality, a selected limit representative, host equality of real names, countable choice, or ambient Real completeness. Any consumer claiming such data must supply it from a different certificate, because the local carrier stores only $W, R, K, F, B, T, C, P, N$.*

Proof. Inspect the carrier coordinates. The source data are finite StreamName windows, RegSeqRat readbacks, a RegularCauchyCriterion row, and a CauchyFilter row; the target data are a displayed Real boundary together with transport, replay, provenance, and naming.

None of these rows is a quotient-stream representative, a selected limit, a host equality proof, a choice selector, or an ambient completeness theorem. Componentwise hsame transport and displayed Cont replay preserve the listed rows rather than adding new host-side objects.

Therefore a consumer can escape the packet only by citing an additional certificate. The local $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ NameCert itself exports exactly the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ consumer that exports a filter-facing universal property while omitting one of the displayed StreamName, RegSeqRat, RegularCauchyCriterion, CauchyFilter, Real boundary, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: streamname, regseqrat, regularcauchycriterion, cauchyfilter, real: none is bijective because $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ jointly carries finite windows, regular rational readback, regular Cauchy tail testing, Cauchy-filter source exposure, terminal Real boundary, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7664.1, Definition 7664.2, Definition 7664.3, and Definition 7664.4 seed the filter-facing universal-property route over StreamName, RegSeqRat, RegularCauchyCriterion, CauchyFilter, Real boundary, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, countable choice, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, route ordering, transport stability, replay exactness, and non-escape proofs for BEDC.Derived.RegularCauchyFilterUniversalPropertyUp.

Constructive story: A $\mathsf{RegularCauchyFilterUniversalProperty}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, RegularCauchyCriterion rows, a CauchyFilter source row, a RealUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7665

A Concrete Naming Certificate for $\mathsf{PositiveSeriesComparison}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PositiveSeriesComparison}^{\uparrow}$ packet records the comparison test for real series with nonnegative terms as finite BEDC data. It sits after the partial-sum surface of chapter 1581, the tail criterion of chapter 2015, the majorant ledger of chapter 1774, the dyadic tolerance arithmetic of chapter 291, and the terminal real-name seal of chapter 38. The packet names a constructive comparison route; it is not a host infinite-sum theorem, a quotient of term streams, a trichotomy principle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7665.1 (Positive series comparison carrier)**.** *A* $\mathsf{PositiveSeriesComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (A, B, S, M, D, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{RealSeries}^{\uparrow}$ *row whose terms are read through finite partial-sum windows.*
2. *B is the comparison* $\mathsf{RealSeries}^{\uparrow}$ *row whose displayed nonnegative terms dominate the source terms on the accepted window.*
3. *S is the* $\mathsf{CauchySeriesCriterion}^{\uparrow}$ *row attached to the source partial sums.*
4. *M is the* $\mathsf{CauchyMajorantSeries}^{\uparrow}$ *row supplied by the comparison series.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and inequality ledger used to compare the two term rows and their partial-sum tails.*
6. *R is the finite regular readback route through which the compared partial sums are inspected before any real seal is visible.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source series, comparison series, criterion row, majorant row, dyadic ledger, and readback route have been displayed.*
8. *H records componentwise* hsame *transport for the two series rows, criterion row, majorant row, dyadic ledger, readback route, real seal, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from term comparison to partial sums, from partial sums to the Cauchy criterion, from the majorant series to the tail bound, and from those rows to the real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{PositiveSeriesComparison}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchySeriesCriterion}^{\uparrow}$, $\mathsf{CauchyMajorantSeries}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveSeriesComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, S, M, D, R, E, H, K, P, N$. It has no coordinate for a host convergence theorem, selected infinite sum, quotient stream equality, order trichotomy, countable-choice schedule, or ambient completeness principle.

Theorem 7665.2 (Positive series comparison NameCert obligations)**.** *For every accepted* $\mathsf{PositiveSeriesComparison}^{\uparrow}$ *carrier $C = (A, B, S, M, D, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PositiveSeriesComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, nonnegative comparison-window admission through A, B, D, source Cauchy-tail exposure through S, majorant-tail exposure through M, regular readback through R, terminal real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through K,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7665.1. The packet displays exactly the two series rows, the criterion row, the majorant row, dyadic comparison data, readback data, real seal, transport, replay, provenance, and naming rows.

The comparison-window obligations are finite. The source and comparison series are inspected only through their displayed windows, and the dyadic ledger D is the only row that records nonnegativity and domination evidence for those windows.

The tail obligations then use the sibling criterion and majorant rows. The row S exposes the source Cauchy-tail request, while M supplies the displayed majorant schedule that bounds the requested tail.

Finally R, E, H, K, P, N read back, seal, transport, replay, source, and name the same route. Since no excluded host-side object is present in the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7665.3 (Positive series comparison majorant route)**.** *Every Real- or Completion-facing comparison read from an accepted* $\mathsf{PositiveSeriesComparison}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyMajorantSeries}^{\uparrow} \longmapsto \mathsf{CauchySeriesCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a positive-term source series reaches its terminal real-facing tail conclusion only by displaying the comparison series, the dyadic domination ledger, the majorant tail schedule, the source Cauchy criterion, and the real seal.

Proof. Start with the source and comparison rows A and B. Their term windows are visible only as $\mathsf{RealSeries}^{\uparrow}$ packets, so the comparison read begins with displayed partial-sum and term-window data.

Next read the dyadic ledger D. This row records the nonnegative comparison evidence and the tolerance budget used to compare the source term windows against the majorant windows.

Apply the majorant and criterion rows M and S. The majorant row supplies the tail bound, and the criterion row consumes that bound as the source Cauchy-tail route before the real-facing seal is available.

Finally inspect R, E, H, K, P, N. These rows read back, seal, transport, replay, source, and name the same finite route, so the comparison test exports no host convergence theorem, selected infinite sum, quotient stream equality, trichotomy, countable choice, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{PositiveSeriesComparison}^{\uparrow}$ read displays two RealSeries rows, one CauchySeriesCriterion row, one CauchyMajorantSeries row, one DyadicRatCore comparison ledger, one regular readback route, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a comparison conclusion is consumed.

Independence witness: realseries, cauchy-series-criterion, cauchy-majorant-series, dyadicrat-core, real: $\mathsf{PositiveSeriesComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds positive-term domination, majorant tail control, source Cauchy criterion data, dyadic tolerance evidence, and real-facing sealing in one comparison packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveSeriesComparison}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveSeriesComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7665.1, Definition 7665.2, and Definition 7665.3 seed the finite positive-series comparison route over source series rows, comparison series rows, Cauchy criterion data, majorant tail schedules, dyadic tolerance evidence, readback, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveSeriesComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host infinite-sum theorems, quotient stream equality, selected sums, order trichotomy, countable choice, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, nonnegative comparison-window admission, majorant-tail exposure, source Cauchy-tail exposure, real-seal nonescape, transport stability, replay stability, and local naming for BEDC.Derived.PositiveSeriesComparisonUp.

Constructive story: A $\mathsf{PositiveSeriesComparison}^{\uparrow}$ packet is generated from source and comparison RealSeries rows, CauchySeriesCriterion data, CauchyMajorantSeries data, a DyadicRatCore comparison ledger, a regular readback route, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7666

A Concrete Naming Certificate for HyperbolicDirichletDomain$^{\uparrow}$

Following Poincare, Klein, and classical Fuchsian fundamental-domain theory, the HyperbolicDirichletDomain$^{\uparrow}$ packet records a finite Dirichlet-domain surface inside displayed Poincare disk data. It sits after the metric-read surface of chapter 6209, the action-word surface of chapter 7282, the visual-boundary packet of chapter 4181, and the hyperbolic metric route of chapter 3474. The packet names finite side-pairing, metric-read, boundary-refusal, and local NameCert rows; it does not construct a quotient surface, a selected tessellation, a global moduli object, or host-level discreteness theorem.

Definition 7666.1 (Hyperbolic Dirichlet domain carrier)**.** *A* HyperbolicDirichletDomain$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, G, S, M, B, V, H, C, P, N)$$

with the following displayed rows:

1. *O is the displayed basepoint and disk-coordinate row inside the* PoincareDiskMetric$^{\uparrow}$ *surface.*
2. *G is the finite* FuchsianGroupAction$^{\uparrow}$ *action-word row whose inspected translates determine the displayed side candidates.*
3. *S is the side-pairing ledger, recording the finite bisector or boundary-side rows, their paired action words, and the local incidence data read from the disk model.*
4. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row used to compare the basepoint with the inspected translates along the displayed side candidates.*
5. *B is the boundary-refusal row: ideal endpoints, visual-boundary contacts, and exterior reads are exposed only as finite refusal or boundary-facing data, not as a completed quotient boundary.*
6. *V is the* HyperbolicVisualBoundary$^{\uparrow}$ *row available to consumers that inspect visible boundary arcs of the displayed sides.*
7. *H records componentwise* hsame *transport for basepoint, action-word, side-pairing, metric-read, boundary-refusal, visual-boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from basepoint inspection through action words, metric reads, side-pairing checks, boundary refusal, visual-boundary reads, provenance, and local naming.*
9. *P is the* Pkg *provenance over* HyperbolicDirichletDomain$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, FuchsianGroupAction$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicDirichletDomain}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $O, G, S, M, B, V, H, C, P, N$. It has no coordinate for a quotient hyperbolic surface, selected global tessellation, host discreteness proof, moduli point, or completed ideal-boundary equality.

Theorem 7666.2 (Hyperbolic Dirichlet domain NameCert obligations)**.** *For every accepted* HyperbolicDirichletDom *carrier $D = (O, G, S, M, B, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicDirichletDomain}^{\uparrow}}$ *surface consists exactly of basepoint admission through O, finite action-word admission through G, side-pairing ledger exactness through S, hyperbolic metric-read exactness through M, boundary-refusal exposure through B, visual-boundary exposure through V, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7666.1. The packet displays exactly the basepoint, finite action-word, side-pairing, metric-read, boundary-refusal, visual-boundary, transport, replay, provenance, and naming rows.

The geometric obligations are finite. The basepoint row is read through the Poincare disk metric surface, the action words through the Fuchsian action surface, and the side-pairing ledger through the displayed bisector and incidence rows.

The metric and boundary rows are downstream of those displayed data. The row M gives the hyperbolic metric comparisons, B records refusal of quotient and ideal-boundary data, and V is the only visual-boundary route available to boundary-facing consumers.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the excluded global objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7666.3 (Hyperbolic Dirichlet domain side route)**.** *Every side-pairing or boundary-facing read from an accepted* $\mathsf{HyperbolicDirichletDomain}^{\uparrow}$ *carrier factors through*

$$\mathsf{PoincareDiskMetric}^{\uparrow} \longmapsto \mathsf{FuchsianGroupAction}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicVisualBoundary}^{\uparrow}.$$

Thus the Dirichlet-domain packet exposes finite basepoint, action-word, side-pairing, metric-read, boundary-refusal, and visual-boundary rows before any consumer can inspect a domain side.

Proof. Start with the basepoint row O. It is read through the Poincare disk metric packet, so the domain begins as displayed disk-coordinate and metric-read data rather than as a completed hyperbolic plane.

Next inspect the action row G and side ledger S. The finite Fuchsian action words determine which displayed translates and side candidates are available to the packet.

Read the metric and boundary rows M, B, V. The metric row compares the displayed basepoint with inspected translates, while B and V restrict boundary-facing data to refusal and visual-boundary rows.

The remaining rows H, C, P, N preserve, replay, source, and name the same route. No quotient surface, selected tessellation, host discreteness proof, moduli point, or completed boundary equality can be read from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicDirichletDomain}^{\uparrow}$ side read displays a PoincareDiskMetric basepoint row, a FuchsianGroupAction word row, a side-pairing ledger, a HyperbolicMetric comparison row, a boundary-refusal row, a HyperbolicVisualBoundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: poincare-disk-metric, fuchsian-group-action, hyperbolic-metric, hyperbolic-visual-boundary: $\mathsf{HyperbolicDirichletDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly

binds a basepoint, finite action words, side-pairing ledger, metric comparisons, boundary refusal, and visual-boundary exposure as one finite domain packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicDirichletDomain}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicDirichletDomain}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7666.1, Definition 7666.2, and Definition 7666.3 seed the finite Dirichlet-domain packet over Poincare disk metric rows, Fuchsian action words, side-pairing data, hyperbolic metric reads, boundary refusal, visual-boundary exposure, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicDirichletDomain}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient hyperbolic surfaces, selected tessellations, host discreteness theorems, global moduli objects, bridge checking, or completed ideal-boundary equality.

Upgrade path: Obligation closure requires checked basepoint admission, action-word admission, side-pairing exactness, metric-read exactness, boundary-refusal exposure, visual-boundary exposure, transport stability, replay stability, and local naming for BEDC.Derived.HyperbolicDirichletDomainUp.

Constructive story: A $\mathsf{HyperbolicDirichletDomain}^{\uparrow}$ packet is generated from a PoincareDiskMetric basepoint row, a FuchsianGroupAction word row, a finite side-pairing ledger, HyperbolicMetric comparisons, boundary-refusal data, a HyperbolicVisualBoundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7667

A Concrete Naming Certificate for $\mathsf{LocatedCauchySubnet}^{\uparrow}$

Following Kelley and Moore–Smith subnet terminology together with Bishop–Bridges located Cauchy completion, the $\mathsf{LocatedCauchySubnet}^{\uparrow}$ packet records the finite route by which a cofinal subnet of a Cauchy source remains located before the Real seal is inspected. It consumes the Moore–Smith subnet surface of chapter 5098, the Cauchy restriction surface of chapter 1592, the located-distance request of chapter 2043, the regular rational readback of chapter 301, and the terminal Real boundary of chapter 38. The packet names a finite completion-neighbourhood route; it is not a selected limit, quotient net, countable-choice schedule, host equality statement, or ambient Real completeness theorem.

Definition 7667.1 (Located Cauchy subnet carrier)**.** *A* $\mathsf{LocatedCauchySubnet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, Q, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MooreSmithSubnet}^{\uparrow}$ *cofinal-window row, recording the source index window, subnet index window, and displayed cofinal tail route.*
2. *S is the* $\mathsf{CauchySubnet}^{\uparrow}$ *row, requiring the source Cauchy request to pass through the same cofinal subnet ledger before any completion-facing handoff is read.*
3. *Q is the located-distance request row, read through* $\mathsf{LocatedSpace}^{\uparrow}$ *and carrying the finite source, target, and tolerance request.*
4. *D is the dyadic tolerance ledger attached to the located request and the Cauchy comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the subnet windows and located-distance comparison.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after M, S, Q, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the subnet window, Cauchy request, located request, tolerance ledger, regular readback, Real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of every accepted read through*

$$M, S, Q, D, R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCauchySubnet}^{\uparrow}$, $\mathsf{MooreSmithSubnet}^{\uparrow}$, $\mathsf{CauchySubnet}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchySubnet}^{\uparrow}}$ *row.*

The carrier exports no selected subnet representative, quotient net, countable-choice selector, host equality row, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness object.*

Theorem 7667.2 (Located Cauchy subnet NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCauchySubnet}^{\uparrow}$ *carrier* $L = (M, S, Q, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCauchySubnet}^{\uparrow}}$ *surface consists exactly of the subnet cofinal window, Cauchy request, located-distance request, RegSeqRat readback, Real seal,* hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert rows displayed in Definition 7667.1.*

Proof. Project the carrier. The cofinal-window row M is the only subnet route, and the Cauchy row S is read through that same route before any completion-facing consumer can inspect the packet.

The located-distance request is then exposed by Q together with the tolerance ledger D. The regular rational readback R is the only row translating the displayed subnet windows and located comparison into finite rational data.

Only after those rows have been replayed may the packet reach the Real seal E. Componentwise transport, continuation replay, provenance, and local naming are confined to H, C, P, N, so the listed rows exhaust the NameCert surface and leave no coordinate for selected limits, quotient nets, choice, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchySubnet}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCauchySubnet}^{\uparrow}}$, seed)

Scope closed: Definition 7667.1 and Definition 7667.2 seed the finite located Cauchy subnet route from cofinal Moore–Smith windows through Cauchy restriction, located-distance request, regular readback, and the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCauchySubnet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected limits, quotient nets, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-window exactness, Cauchy request stability, located-distance request stability, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchySubnetUp.

Constructive story: A $\mathsf{LocatedCauchySubnet}^{\uparrow}$ packet is generated from a Moore–Smith subnet window, a CauchySubnet request, a LocatedSpace distance request, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7668

A Concrete Naming Certificate for $\mathsf{MedianDepthSealingCorner}^{\uparrow}$

The $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ packet realizes the two-layer median closure and unique ACG sealing corner of Definition 9462.1329 as finite NameCert data. It consumes the DNA window-six boundary tile packet of chapter 3393, the trigger-blocker route of chapter 3801, the stop/Trp face deficiency packet of chapter 4090, and the Boolean trigger lattice of chapter 3704. The packet records a median-layer route and a unique-corner seal; it is not a biological mechanism, stochastic fitness model, quotient codon semantics, or unbounded support-closure oracle.

Definition 7668.1 (Median depth sealing corner carrier)**.** *A* $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, L, U, F, W, H, C, P, N)$$

with the following displayed rows:

1. *B is the DNA window-six boundary-tile source row.*
2. *L is the median-layer ledger, displaying the active reassignment support, the first median layer, and the second median layer.*
3. *U is the unique sealing-corner witness row, naming* ACG *as the sole strict second-layer median point.*
4. *F is the f-vector transition row recording the passage from the punctured main* WNR *4-cube to the sealed cube.*
5. *W is the witness row displaying the median witnesses for the first layer and the* ACG *second-layer witness before F is read.*
6. *H records componentwise* hsame *transport for the boundary tile, median-layer, unique-corner, f-vector, witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through*

$$B, L, U, W \longmapsto F.$$

8. *P is the* Pkg *provenance over* $\mathsf{MedianDepthSealingCorner}^{\uparrow}$, $\mathsf{DnaWindowSixBoundaryTile}^{\uparrow}$, $\mathsf{TriggerBlockerDuality}^{\uparrow}$, ***??***, $\mathsf{BooleanTriggerLattice}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MedianDepthSealingCorner}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $B, L, U, F, W, H, C, P, N$ and has no coordinate for hidden codon semantics, stochastic biology, unrestricted median search, or host cubical-complex equality.

Theorem 7668.2 (Median depth sealing corner NameCert obligations)**.** *For every accepted* MedianDepthSealingCor *carrier $K = (B, L, U, F, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MedianDepthSealingCorner}^{\uparrow}}$ *surface consists exactly of finite median-layer admission, unique* ACG *corner exposure, f-vector transition exposure, witness-row exposure, componentwise transport, continuation replay, provenance, and local naming rows.*

Proof. Project the carrier. The boundary-tile row B is the source, while L records the two median layers and U names the unique strict second-layer corner.

The witness row W must be read before the f-vector transition F. Thus an accepted read displays both median layers and the ACG witness before it consumes the cubical transition from the punctured main WNR cell to the sealed cell.

The structural rows H, C, P, N transport, replay, source, and name only this finite packet. Since no row stores hidden codon semantics, stochastic dynamics, an unrestricted median oracle, or host cubical equality, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ read displays the two median layers and the ACG witness row before the f-vector transition row is consumed.

Independence witness: dna-window-six-boundary-tile, trigger-blocker-duality, stop-trp-face-rank-deficiency, boolean-trigger-lattice: none is bijective with $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ because this packet jointly carries the two median layers, the unique ACG corner, the f-vector transition, witness rows, transport, replay, provenance, and local naming.

The Lean follow-up must provide explicit Nontrivial $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ and FieldFaithful MedianDepthSe TasteGate instances so that $B, L, U, F, W, H, C, P, N$ remain separate displayed fields.

Closure status for $\mathsf{NameCert}_{\mathsf{MedianDepthSealingCorner}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MedianDepthSealingCorner}^{\uparrow}}$, seed)

Scope closed: Definition 7668.1 and Definition 7668.2 seed the finite median-layer and unique sealing-corner packet for the DNA window-six boundary-tile route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MedianDepthSealingCorner}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim biological mechanism, stochastic fitness, quotient codon semantics, unrestricted median search, host cubical equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, median-layer exposure, unique-corner exposure, f-vector transition exposure, witness exposure, Nontrivial MedianDepthSealingCornerUp, and FieldFaithful MedianDepthSealingCornerUp for BEDC.Derived.MedianDepthSealingCornerUp.

Constructive story: A $\mathsf{MedianDepthSealingCorner}^{\uparrow}$ packet is generated from a DNA boundary-tile source, median-layer rows, a unique ACG sealing-corner row, f-vector transition data, witness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7669

A Concrete Naming Certificate for $\mathsf{EulerConstant}^{\uparrow}$

Following Euler and Bishop–Bridges constructive analysis, the $\mathsf{EulerConstant}^{\uparrow}$ packet records the Euler–Mascheroni constant as a finite harmonic-log comparison route rather than as a host real constant. It sits after the harmonic-window divergence surface of chapter 3711, the logarithm comparison packet of chapter 2315, the dyadic tolerance ledger of chapter 291, the regular rational readback boundary of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite comparison data for $H_n - \log(n)$ windows; it is not a host limit, quotient real equality, selected convergence oracle, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7669.1 (Euler constant carrier)**.** *An* $\mathsf{EulerConstant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (H, L, D, R, E, T, C, P, N)$$

with the following displayed rows:

1. *H is the harmonic partial-sum window ledger. It records the inspected finite indices, the displayed partial sums $1 + \cdots + 1/n$, and the Oresme-facing comparison evidence inherited from* $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$*.*
2. *L is the* $\mathsf{RealLogarithm}^{\uparrow}$ *comparison row for the same displayed indices, read as $\log(n)$ only after the harmonic window has been fixed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the positive dyadic budget used to compare the displayed harmonic-log difference windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational windows obtained from H, L, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row naming the Euler-constant candidate after the harmonic, logarithm, dyadic, and regular rational rows have been displayed.*
6. *T records componentwise* hsame *transport for the harmonic windows, logarithm comparisons, dyadic budgets, readback rows, real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$H, L, D, R \longmapsto E, T, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{EulerConstant}^{\uparrow}$*,* $\mathsf{OresmeHarmonicDivergence}^{\uparrow}$*,* $\mathsf{RealLogarithm}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{EulerConstant}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $H, L, D, R, E, T, C, P, N$. It has no coordinate for an ambient real limit, a quotient equality of real names, countable choice, a selected convergence oracle, or host-side logarithm completeness.

Theorem 7669.2 (Euler constant NameCert obligations)**.** *For every accepted* $\mathsf{EulerConstant}^{\uparrow}$ *carrier $G = (H, L, D, R, E, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{EulerConstant}^{\uparrow}}$ *surface consists exactly of harmonic partial-sum windows through H,* $\mathsf{RealLogarithm}^{\uparrow}$ *comparisons through L, positive dyadic comparison budgets through D, regular rational readback through R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal through E, componentwise* hsame *transport through T, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. Its coordinates are precisely the harmonic window, logarithm comparison, dyadic tolerance, regular readback, real seal, transport, replay, provenance, and naming rows.

The comparison route starts with finite harmonic data. The row H exposes only inspected partial sums and the Oresme-facing harmonic comparison surface; it does not provide a completed infinite series.

The logarithm and tolerance rows are then read against the same windows. The row L supplies the $\mathsf{RealLogarithm}^{\uparrow}$ comparison for the displayed index, and D gives the dyadic budget before R can read the harmonic-log difference as regular rational data.

Finally E, T, C, P, N seal, transport, replay, source, and name the same route. Since the carrier stores no ambient limit selector, quotient real equality, countable-choice schedule, or host completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 7669.3 (Euler constant regular Cauchy handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{EulerConstant}^{\uparrow}$ *carrier reads the Euler-constant candidate only through the finite route*

$$\mathsf{OresmeHarmonicDivergence}^{\uparrow},\ \mathsf{RealLogarithm}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In particular, the $\mathsf{Real}^{\uparrow}$ *seal E is available only after the harmonic window H, logarithm comparison L, dyadic tolerance row D, and regular rational readback row R have been displayed through T, C, P, N.*

Proof. Start from an accepted carrier $G = (H, L, D, R, E, T, C, P, N)$. A consumer can read the real seal only at the row E.

The row E is downstream of the finite harmonic-log comparison route. The consumer must first inspect the harmonic window H, compare the same index through L, attach a positive dyadic budget through D, and read the resulting difference through R.

Transport and replay preserve this order. The rows T and C identify and replay the displayed route, while P and N record provenance and local naming. Hence the handoff reaches $\mathsf{Real}^{\uparrow}$ through regular Cauchy readback data rather than through an ambient completeness theorem. □

Theorem 7669.4 (Euler constant nonescape)**.** *An accepted* $\mathsf{EulerConstant}^{\uparrow}$ *packet cannot export a host-level Euler–Mascheroni constant, quotient equality of real names, countable choice, a selected convergence oracle, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any consumer claiming such data must supply it from a different certificate, because the local carrier stores only $H, L, D, R, E, T, C, P, N$.*

Proof. Inspect the carrier coordinates. The source data are finite harmonic windows, logarithm comparisons, dyadic budgets, and regular rational readbacks; the target data are a displayed real seal together with transport, replay, provenance, and naming.

None of these rows is a host real constant, quotient representative, choice selector, convergence oracle, or ambient completeness theorem. Componentwise hsame transport and displayed Cont replay preserve the listed rows rather than adding new host-side objects.

Therefore a consumer can obtain such data only by citing an additional certificate. The local $\mathsf{EulerConstant}^{\uparrow}$ NameCert itself exports exactly the displayed harmonic-log route. □

Falsifiable prediction: Every accepted $\mathsf{EulerConstant}^{\uparrow}$ consumer that exports an Euler-constant real while omitting one of the displayed harmonic-window, RealLogarithm, DyadicRatCore, RegSeqRat, Real seal, transport, replay, provenance, or local naming rows refutes the packet.

Independence witness: harmonic, logarithm, dyadic, regseqrat, real: none is bijective because $\mathsf{EulerConstant}^{\uparrow}$ jointly carries harmonic partial-sum windows, RealLogarithm comparisons, DyadicRatCore budgets, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{EulerConstant}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EulerConstant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7669.1, Definition 7669.2, Definition 7669.3, and Definition 7669.4 seed the finite harmonic-log comparison route over Oresme harmonic windows, RealLogarithm comparisons, DyadicRatCore budgets, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EulerConstant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host-level Euler–Mascheroni constant, quotient real equality, countable choice, selected convergence oracles, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, harmonic-log route ordering, dyadic tolerance stability, regular Cauchy readback, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.EulerConstantUp.

Constructive story: An $\mathsf{EulerConstant}^{\uparrow}$ packet is generated from harmonic partial-sum windows, RealLogarithm comparison rows, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7670

A Concrete Naming Certificate for $\mathsf{AlternatingHarmonic}^{\uparrow}$

Following Hardy's summability treatment of alternating series and Bishop–Bridges constructive analysis, the $\mathsf{AlternatingHarmonic}^{\uparrow}$ packet names the finite endpoint route for the alternating reciprocal series before any ambient real completeness principle is read. It sits after the Leibniz-series certificate of chapter 3723, the regular rational readback of chapter 301, the finite stream naming surface of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet records the known alternating harmonic endpoint as finite NameCert data; it is not a host analytic theorem, a quotient of series streams, a selected real representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7670.1 (Alternating harmonic carrier)**.** *An* $\mathsf{AlternatingHarmonic}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, L, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the alternating reciprocal source-window row, listing the inspected signs, reciprocal denominators, partial-sum windows, and tail requests.*
2. *L is the* $\mathsf{LeibnizSeriesTest}^{\uparrow}$ *row certifying monotone reciprocal magnitudes and alternating tail control for the inspected windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *remainder and tolerance ledger, recording the dyadic budget attached to each admitted tail request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite partial sums and dyadic remainders exposed by S, L, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source windows, Leibniz row, dyadic ledger, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the source, Leibniz, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, L, D \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{AlternatingHarmonic}^{\uparrow}$, $\mathsf{LeibnizSeriesTest}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{AlternatingHarmonic}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, D, R, E, H, C, P, N$. It has no coordinate for host convergence, a selected value of $\log 2$, quotient equality of streams, countable choice, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.AlternatingHarmonicUp.AlternatingHarmonicTasteGate single carrier alignment`

Theorem 7670.2 (Alternating harmonic NameCert obligations)**.** *For every accepted* $\mathsf{AlternatingHarmonic}^{\uparrow}$ *carrier $A = (S, L, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlternatingHarmonic}^{\uparrow}}$ *surface consists exactly of alternating reciprocal source-window admission, LeibnizSeriesTest row exposure, dyadic remainder and tolerance exactness, RegSeqRat readback, Real seal routing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7670.1. The source row S supplies the inspected alternating reciprocal windows, while L records the Leibniz monotonicity and alternating-tail discipline on those windows.

The dyadic ledger D is then the only tolerance source available to the packet. Regular rational readback R consumes S, L, D, and the Real seal E is downstream from that readback.

The remaining rows H, C, P, N transport, replay, source, and name the same finite route. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7670.3 (Alternating harmonic Leibniz real seal)**.** *Every Real-facing consumer of an accepted* $\mathsf{AlternatingHarmonic}^{\uparrow}$ *packet factors through*

$$S, L, D \longmapsto R \longmapsto E.$$

Thus the alternating reciprocal source windows are first checked by the $\mathsf{LeibnizSeriesTest}^{\uparrow}$ *row, then budgeted by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger, then read through* $\mathsf{RegSeqRat}^{\uparrow}$*, and only then sealed as a* $\mathsf{Real}^{\uparrow}$ *endpoint.*

Proof. Start with a Real-facing request. The carrier gives no direct Real coordinate except E, and E is named as the seal reached after the source, test, ledger, and readback rows.

The Leibniz row L verifies the alternating-tail discipline on the same windows S that feed the dyadic budget D. The readback row R therefore receives exactly the finite partial-sum and remainder data displayed by the packet.

Transport and replay preserve that order through H and C, while P, N source and name it. Hence any Real-facing read must pass through S, L, D, R before it can consume E. □

Theorem 7670.4 (Alternating harmonic ledger nonescape)**.** *An accepted* $\mathsf{AlternatingHarmonic}^{\uparrow}$ *carrier cannot export host convergence, a selected value for the infinite sum, quotient equality of series streams, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any such consumer must cite a separate certificate, because the local carrier stores only $S, L, D, R, E, H, C, P, N$.*

Proof. Inspect the carrier coordinates. The analytic data are finite alternating reciprocal windows, a Leibniz row, a dyadic tolerance ledger, regular rational readback, and a terminal Real seal.

The structural data are componentwise transport, displayed replay, provenance, and local naming. None of these rows stores a host convergence theorem, a chosen real representative, quotient-stream equality, a choice selector, or a completeness principle.

Therefore every accepted read remains inside the finite ledger route. Any stronger assertion must be supplied by another named packet rather than by $\mathsf{AlternatingHarmonic}^{\uparrow}$ itself. □

Falsifiable prediction: Every proposed $\mathsf{AlternatingHarmonic}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ while omitting the alternating reciprocal source windows, LeibnizSeriesTest row, DyadicRatCore tolerance ledger, RegSeqRat readback, Real seal, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: leibniz-series-test, streamname, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{AlternatingHarmonic}^{\uparrow}$ because the packet jointly carries alternating reciprocal source windows, Leibniz tail control, dyadic remainders, regular rational readback, terminal sealing, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{AlternatingHarmonic}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlternatingHarmonic}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7670.1, Definition 7670.2, Definition 7670.3, and Definition 7670.4 seed the finite alternating-series endpoint packet over Leibniz, dyadic tolerance, regular readback, Real sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlternatingHarmonic}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convergence, the equality of the endpoint with $\log 2$, quotient equality of series streams, countable choice, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Leibniz row exposure, dyadic ledger exactness, regular readback, Real-seal routing, transport, replay, provenance, and non-escape proofs for BEDC.Derived.AlternatingHarmonicUp.

Constructive story: An $\mathsf{AlternatingHarmonic}^{\uparrow}$ packet is generated from alternating reciprocal source windows, a LeibnizSeriesTest row, a DyadicRatCore remainder and tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7671

A Concrete Naming Certificate for $\mathsf{UnconditionalBasis}^{\uparrow}$

Following Banach-space basis theory as in Lindenstrauss–Tzafriri and Wojtaszczyk, the $\mathsf{UnconditionalBasis}^{\uparrow}$ packet records the finite BEDC naming surface for basis coordinates whose inspected partial sums remain stable under displayed sign changes. It refines the coordinate route of chapter 3669, sits beside the frame-bound stability of chapter 7602, and uses the finite orthonormal comparison discipline of chapter 4758. The packet names only finite sign-window stability data; it is not a full Banach-space basis theorem, not countable choice, not a selected infinite series, and not quotient equality.

Definition 7671.1 (Unconditional basis carrier)**.** *An* $\mathsf{UnconditionalBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, V, N, W, S, K, Q, \Gamma, H, C, P, Z)$$

with the following displayed rows:

1. *B is the* $\mathsf{SchauderBasis}^{\uparrow}$ *source row, exposing the basis-vector stream, coordinate readback, finite partial sums, tail estimates, and reconstruction route consumed by the packet.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row over the same endpoint, recording the vector operations and finite linear-combination syntax used by signed sums.*
3. *N is the* $\mathsf{Norm}^{\uparrow}$ *row naming norm evaluations, triangle ledgers, and comparison rows for the displayed signed partial sums.*
4. *W is the finite window row, listing the inspected index set, coefficient names, truncation bound, and every sign pattern $\sigma_i \in \{-1, 1\}$ admitted inside the packet.*
5. *S is the signed partial-sum row, recording the displayed sums $\sum_{i \in W} \sigma_i c_i b_i$ and their unsigned comparison sums.*
6. *K is the unconditional-stability budget row, displaying the finite bound or modulus by which every signed sum in S remains controlled by the same coordinate window.*
7. *Q is the coordinate reconstruction ledger, requiring every consumer read to pass through the Schauder source row, the finite sign window, the signed-sum row, and the stability budget before reaching a named vector endpoint.*

8. Γ *is the local classifier, comparing accepted packets only by the shared Schauder source, vector and norm source rows, sign-window rows, signed sums, stability budget, reconstruction ledger, and structural rows.*
9. H *records componentwise* hsame *transport for* $B, V, N, W, S, K, Q, \Gamma, C, P, Z$.
10. C *records displayed* Cont *replay from a coordinate request through the same finite sign-window route.*
11. P *is the* Pkg *provenance over* $\mathsf{UnconditionalBasis}^{\uparrow}$, $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. Z *is the local* $\mathsf{NameCert}_{\mathsf{UnconditionalBasis}^{\uparrow}}$ *row binding the packet.*

The carrier has no coordinate for a host unconditional convergence theorem, countable-choice schedule, selected infinite series, quotient vector equality, or ambient Banach-space completion proof.

Theorem 7671.2 (Unconditional basis NameCert obligations)**.** *For every accepted* $\mathsf{UnconditionalBasis}^{\uparrow}$ *carrier* $U = (B, V, N, W, S, K, Q, \Gamma, H, C, P, Z)$*, the local* $\mathsf{NameCert}_{\mathsf{UnconditionalBasis}^{\uparrow}}$ *surface consists exactly of carrier admission, Schauder source compatibility, vector and norm source compatibility, finite sign-window exposure, signed partial-sum exposure, unconditional-stability budget display, coordinate reconstruction routing, classifier stability, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A consumer may inspect signed coordinates only along the displayed route*

$$B, V, N, W \longrightarrow S, K \longrightarrow Q, \Gamma \longrightarrow H, C, P, Z.$$

It receives no host unconditional convergence theorem, no countable-choice selector, no selected infinite synthesis series, no quotient vector equality, and no ambient completion coordinate.

Proof. Carrier admission is projection from Definition 7671.1. The rows B, V, N expose the Schauder source, vector operations, and norm comparisons, while W exposes the only finite sign windows on which signed coefficient reads may be requested.

The signed partial-sum row S and the stability budget row K are displayed beside the same window row. Thus a sign-changed read can compare only the inspected signed sums with their named coordinate window, and it cannot appeal to an external unconditional convergence theorem.

The reconstruction row Q is downstream of B, V, N, W, S, K. The classifier Γ compares packets by the same displayed rows, and the structural rows H, C, P, Z preserve that route under transport, replay, provenance, and local naming.

Since the carrier contains no host unconditional convergence coordinate, countable-choice selector, selected infinite synthesis series, quotient vector equality, or ambient completion proof, the listed rows exhaust the local naming surface. □

Theorem 7671.3 (Unconditional basis finite sign-window stability)**.** *Every coordinate consumer exported by an accepted* $\mathsf{UnconditionalBasis}^{\uparrow}$ *carrier reads sign stability through a finite inspected window. For each displayed sign pattern* $\sigma_i \in \{-1, 1\}$ *in* W*, the signed partial sum* $\sum_{i \in W} \sigma_i c_i b_i$ *is admitted only through the signed-sum row* S *and the stability budget row* K*, after the* $\mathsf{SchauderBasis}^{\uparrow}$ *source row* B*, the vector row* V*, and the norm row* N *have been exposed. The exported read is therefore a finite-window stability certificate, not a Banach-space theorem about all signs, not an infinite series selector, not countable choice, and not quotient equality.*

Proof. Start with an accepted carrier $U = (B, V, N, W, S, K, Q, \Gamma, H, C, P, Z)$. The carrier definition places every sign pattern in the finite window row W and every signed partial sum in S, so a consumer has no source for signs outside the inspected window.

Use Definition 7671.2. It forces the consumer to read the Schauder source and the vector and norm rows before any signed sum can be compared, then to pass through the budget row K for the displayed stability check.

The reconstruction ledger Q and classifier Γ keep the read on the same finite surface. The transport, replay, provenance, and local naming rows preserve that surface, while the carrier omits host unconditional convergence, countable choice, selected infinite synthesis, quotient equality, and ambient completion. Hence the exported stability statement is exactly the finite sign-window certificate named by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UnconditionalBasis}^{\uparrow}}$**.**

Constructive story: An $\mathsf{UnconditionalBasis}^{\uparrow}$ packet is generated from a SchauderBasisUp source row, VecSpaceUp and NormUp source rows, finite sign-window rows, signed partial-sum rows, a stability budget, a coordinate reconstruction ledger, classifier data, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UnconditionalBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7671.1, Definition 7671.2, and Definition 7671.3 seed the finite sign-window stability packet over $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UnconditionalBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a full Banach-space basis theorem, unconditional convergence over all signs, countable choice, selected infinite series, quotient vector equality, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Schauder source compatibility, finite sign-window exposure, signed partial-sum exposure, stability-budget display, reconstruction routing, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.UnconditionalBasisUp.

Chapter 7672

A Concrete Naming Certificate for $\mathsf{ForceLikeRelation}^{\uparrow}$

Following Newtonian force language and Cartan-style relation discipline, the $\mathsf{ForceLikeRelation}^{\uparrow}$ packet realizes the finite inter-Hist classifier described in Definition 9416.15 without turning force into a source-free primitive. It sits beside the relation-certificate source of chapter 9416, the MetaCIC relation surface of chapter 7661, the inter-Hist locality discipline of chapter 9419, and the records-side primitives BHist, hsame, Cont, and NameCert. The packet names finite change rows, classifier rows, preservation rows, and failure boundaries; it is not empirical physical force itself, not a hidden cause, not a global field primitive, and not a standard-physics bridge.

Definition 7672.1 (Force-like relation carrier)**.** *A* $\mathsf{ForceLikeRelation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, K, V, W, M, E, B, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite inter-*Hist *change row, listing source histories, observed changes, and local measurement or continuation requests.*
2. *K is the classifier row assigning admitted changes to the same-force-pattern surface.*
3. *V is the preserved-structure row, recording the relation data stable under the admitted classifier.*
4. *W is the not-preserved row, recording empirical constants, numerical laws, global-field readings, and physical semantics not carried by the records-side packet.*
5. *M is the layer map from source change rows to relation-certificate rows.*
6. *E is the exactness row stating when classifier sameness reflects the displayed inter-*Hist *relation rather than object identity.*
7. *B is the failure-boundary row naming the conditions under which the relation weakens, refuses, or asks for a separate standard bridge.*
8. *H records componentwise* hsame *transport for the change, classifier, preserved, not-preserved, layer, exactness, boundary, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same finite relation rows.*
10. *P is the* Pkg *provenance over* $\mathsf{ForceLikeRelation}^{\uparrow}$*,* $\mathsf{LayeredRelationCertificate}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{ForceLikeRelation}^{\uparrow}}$ *row.*

The classifier admits force-like language only through $I, K, V, W, M, E, B, H, C, P, N$. It has no coordinate for empirical physical force, a hidden causal substance, global field identity, host physics, or an unrecorded bridge.

Theorem 7672.2 (Force-like relation NameCert obligations)**.** *For every accepted* $\mathsf{ForceLikeRelation}^{\uparrow}$ *carrier $F = (I, K, V, W, M, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ForceLikeRelation}^{\uparrow}}$ *surface consists exactly of inter-*Hist *change-row admission, classifier exposure, preserved-row exposure, not-preserved-row exposure, layer-map exposure, exactness exposure, failure-boundary exposure, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7672.1. The source data are the finite inter-Hist change rows I, and the admissible force-like classifier is K.

The certificate then reads preservation and refusal together. The preserved row V is bounded by the not-preserved row W, while the layer map M and exactness row E are bounded by the failure row B.

Transport, replay, provenance, and naming are exhausted by H, C, P, N. Thus the local certificate has exactly the displayed relation rows and no hidden physics coordinate. □

Theorem 7672.3 (Force-like relation MetaCIC boundary)**.** *Every MetaCIC or relation-certificate consumer of an accepted* $\mathsf{ForceLikeRelation}^{\uparrow}$ *packet reads force-like language only through*

$$I, K, V, W, M, E, B, H, C, P, N.$$

*The consumer may reuse the packet as a finite inter-*Hist *relation certificate, but it may not infer empirical force laws, global field identity, hidden causal substance, object identity between histories, or bridge-checked standard physics.*

Proof. Start with the relation route. The inter-Hist change row I and classifier row K supply the only source from which force-like language can be read.

The preserved row V is paired with the not-preserved row W, so no empirical or global-field content can be silently carried across the relation. The layer map M and exactness row E are likewise constrained by the failure-boundary row B.

The rows H, C, P, N preserve, replay, source, and name the same finite packet. Since the carrier lacks a standard bridge or host-physics coordinate, the consumer remains at relation-certificate strength. □

Falsifiable prediction: Every accepted $\mathsf{ForceLikeRelation}^{\uparrow}$ packet without a displayed not-preserved row or failure-boundary row fails as force-like relation evidence and must be routed to refusal rather than to standard physical force.

Independence witness: layered-relation-certificate, inter-hist-locality, bhist, hsame, cont: none is bijective to $\mathsf{ForceLikeRelation}^{\uparrow}$ because the packet jointly carries inter-Hist change rows, a force-like classifier, preserved and not-preserved rows, a layer map, exactness, failure boundary, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{ForceLikeRelation}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ForceLikeRelation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7672.1, Definition 7672.2, and Definition 7672.3 seed the finite inter-Hist relation-certificate packet that separates force-like classifier evidence from empirical force and bridge-checked physics.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ForceLikeRelation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close empirical physical force, global field identity, hidden causal substance, object identity between histories, standard-physics bridge checking, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, preserved and not-preserved row pairing, layer-map exactness, failure-boundary routing, transport, replay, provenance, and non-escape proofs for BEDC.Derived.ForceLikeRelationUp.

Constructive story: A ForceLikeRelation$^{\uparrow}$ packet is generated from finite inter-Hist change rows, classifier rows, preserved and not-preserved rows, a layer map, exactness row, failure-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7673

A Concrete Naming Certificate for $\mathsf{FiniteCardinal}^{\uparrow}$

Following Dedekind and Cantor on finite equipotence, the $\mathsf{FiniteCardinal}^{\uparrow}$ packet records cardinal comparison only through displayed finite bijection and counting ledgers. It sits after the membership discipline of chapter 3668, the natural-number endpoint of chapter 28, the Kuratowski finite-set presentation of chapter 7157, and the finite-net consumer route of chapter 7638. The packet names finite cardinality without importing unrestricted cardinal arithmetic, quotient sets, chosen representatives, powersets, or choice.

Definition 7673.1 (Finite cardinal carrier)**.** *A* $\mathsf{FiniteCardinal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, T, n, L, R, B, Q, \Gamma, H, C, P, N)$$

with the following displayed rows:

1. *S is the source finite-object row, read through* $\mathsf{SetLike}^{\uparrow}$ *and* $\mathsf{KuratowskiFiniteSet}^{\uparrow}$*, exposing membership, finite generation, and the inspected element names.*
2. *T is the target initial-segment row over* $\mathsf{Nat}^{\uparrow}$*, naming the displayed positions $0, \ldots, n-1$ as finite endpoints rather than as a host ordinal quotient.*
3. *n is the cardinality readback row, a named natural-number endpoint whose only public meaning is the length of the displayed target segment T.*
4. *L is the forward ledger, listing for each displayed source element its target position in T.*
5. *R is the reverse ledger, listing for each displayed target position the source element in S that occupies it.*
6. *B is the bijection ledger, recording the two finite round-trip checks $R(L(s)) = s$ for displayed source entries and $L(R(i)) = i$ for displayed target entries.*
7. *Q is the cardinality-use ledger, forcing every consumer of the number n to pass through S, T, L, R, B before citing the cardinality row.*
8. *Γ is the local classifier, comparing accepted packets only by source membership rows, target segment rows, the named natural endpoint, the two ledgers, the round-trip checks, and the consumer route.*
9. *H records componentwise* hsame *transport for $S, T, n, L, R, B, Q, \Gamma, C, P, N$.*

10. *C records displayed* Cont *replay through*

$$S, T, n \longrightarrow L, R, B \longrightarrow Q, \Gamma.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteCardinal}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{KuratowskiFiniteSet}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCardinal}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted cardinal arithmetic, quotient extensionality of subsets, selected representatives, host powersets, or choice-based enumeration.

Theorem 7673.2 (Finite cardinal NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCardinal}^{\uparrow}$ *carrier*

$$F = (S, T, n, L, R, B, Q, \Gamma, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCardinal}^{\uparrow}}$ *surface consists exactly of source finite-object admission, initial-segment admission, natural-number cardinality readback, forward ledger exposure, reverse ledger exposure, finite round-trip verification, cardinality-use routing, classifier stability, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. A consumer receives the public cardinality only along the route*

$$S, T, n \longrightarrow L, R, B \longrightarrow Q, \Gamma, H, C, P, N.$$

Proof. Project the carrier F. The rows S, T, n are the only entries that name the source finite object, the target initial segment, and the natural-number readback.

The rows L and R display the two directions of the finite comparison. The row B records the two round-trip checks on exactly the displayed source entries and target positions, so no ambient quotient or selected enumeration is available outside the packet.

The consumer route Q and classifier Γ force every cardinality read to preserve the same finite ledgers. The structural rows H, C, P, N transport, replay, source, and name only those rows, so the listed obligations exhaust the local NameCert surface. □

Theorem 7673.3 (Finite cardinal classifier stability)**.** *Let* $F = (S, T, n, L, R, B, Q, \Gamma, H, C, P, N)$ *and* $F' = (S', T', n', L', R', B', Q', \Gamma', H', C', P', N')$ *be accepted* $\mathsf{FiniteCardinal}^{\uparrow}$ *carriers. If the source rows, target segment rows, named natural endpoints, forward ledgers, reverse ledgers, round-trip ledgers, and consumer routes are componentwise* hsame*, then* Γ *and* Γ' *classify the same finite cardinality packet. Conversely, a classifier agreement for* $\mathsf{FiniteCardinal}^{\uparrow}$ *exposes precisely those displayed rows as its comparison surface.*

Proof. In the forward direction, read the componentwise hsame data through H and H'. The classifier rows are defined over the source row, target segment, natural endpoint, both ledger directions, their round-trip checks, and the consumer route, so agreement on those coordinates gives the same classifier read.

For the reverse direction, open the classifier rows Γ and Γ'. By the carrier definition, they have no coordinates other than S, T, n, L, R, B, Q and their primed counterparts. Therefore classifier agreement can expose only those displayed rows, together with the structural transport and replay rows that preserve them. □

Theorem 7673.4 (Finite cardinal bijection ledger)**.** *Every accepted* $\mathsf{FiniteCardinal}^{\uparrow}$ *carrier exports cardinality as a finite bijection ledger. The number n may be cited only after the packet displays the*

forward assignments L, reverse assignments R, and the round-trip row B over the finite source row S and the initial segment T. Thus the packet supplies a constructive finite-cardinality interface for finite-net, compactness, and bounded-family consumers, but it does not supply unrestricted cardinal arithmetic, quotient-set equality, selected representatives, host powersets, or choice.

Proof. Start with the accepted carrier and use Definition 7673.2. The public route to n passes through S, T, L, R, B before it reaches any consumer ledger.

The bijection row B contains both finite round-trip checks, so each source element and each target position is accounted for inside the displayed packet. A compact finite-net consumer such as chapter 7638 can therefore cite the finite count as a ledger-backed size row.

Since the carrier omits unrestricted cardinal arithmetic, quotient extensionality, selected representatives, powersets, and choice, the exported statement is exactly the finite bijection ledger, not an ambient cardinal theory. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCardinal}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCardinal}^{\uparrow}$ packet is generated from a displayed finite source row, an initial-segment row over NatUp, a natural-number readback, forward and reverse finite ledgers, two round-trip checks, a consumer route, classifier data, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCardinal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7673.1, Definition 7673.2, Definition 7673.3, and Definition 7673.4 seed the finite bijection and cardinality-ledger surface for $\mathsf{FiniteCardinal}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCardinal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted cardinal arithmetic, quotient sets, selected representatives, host powersets, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-object admission, initial-segment admission, forward and reverse ledger exposure, round-trip verification, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCardinalUp.

Chapter 7674

A Concrete Naming Certificate for $\mathsf{FiniteLimitCone}^{\uparrow}$

Following Mac Lane's category-theoretic account of limits, the $\mathsf{FiniteLimitCone}^{\uparrow}$ packet records the finite cone data needed by limit arguments as BEDC NameCert rows rather than as an imported universal-property object. It sits after the certified $\mathsf{Cat}^{\uparrow}$ surface of chapter 61, the diagram map discipline of $\mathsf{Functor}^{\uparrow}$ in chapter 62, the componentwise comparison discipline of $\mathsf{NatTrans}^{\uparrow}$ in chapter 63, the binary-product route of **??** in chapter 34, the finite pullback route of $\mathsf{Pullback}^{\uparrow}$ in chapter 2240, and the finite-limit refusal boundary of $\mathsf{FiniteLimitSeal}^{\uparrow}$ in chapter 5722. The packet names cone legs and finite naturality checks; it is not a host finite-limit theorem, a selected terminal cone, quotient equality of diagrams, or an ambient category library object.

Definition 7674.1 (Finite-limit cone carrier)**.** *A* $\mathsf{FiniteLimitCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, J, D, A, L, V, H, R, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{Cat}^{\uparrow}$ *codomain certificate, exposing object, hom, identity, composition, associativity, unit, classifier, and transport rows for the category in which the cone is read.*
2. *J is the finite* $\mathsf{Cat}^{\uparrow}$ *shape row, naming the inspected indexing objects and arrows of the diagram shape.*
3. *D is the* $\mathsf{Functor}^{\uparrow}$ *diagram row $J \to C$, including object images, arrow images, identity and composition preservation, and the diagram classifier.*
4. *A is the apex row, naming the candidate cone apex as an object of C through the same* $\mathsf{Cat}^{\uparrow}$ *classifier.*
5. *L is the finite leg row, listing the displayed arrows $A \to D(j)$ for every inspected object j of J.*
6. *V is the cone-visibility row, recording the finite naturality squares for every inspected arrow of J and the adjacent* $\mathsf{NatTrans}^{\uparrow}$ *comparison route when the cone is transported along a certified diagram comparison.*
7. *H is componentwise* hsame *transport for $C, J, D, A, L, V, R, P, N$.*
8. *R is the displayed* Cont *replay route through the category, diagram, apex, leg, and visibility rows.*
9. *P is* Pkg *provenance over* $\mathsf{FiniteLimitCone}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, ***??***, $\mathsf{Pullback}^{\uparrow}$, $\mathsf{FiniteLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitCone}^\uparrow}$ *row.*

The carrier has no coordinate for a universal cone, a selected limiting object, quotient equality of diagrams, all finite shapes at once, ambient finite products, ambient pullbacks, or an external category-theory library.

Theorem 7674.2 (Finite-limit cone NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLimitCone}^\uparrow$ *carrier* $K = (C, J, D, A, L, V, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteLimitCone}^\uparrow}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the codomain* $\mathsf{Cat}^\uparrow$ *row, finite shape* $\mathsf{Cat}^\uparrow$ *row,* $\mathsf{Functor}^\uparrow$ *diagram row, apex row, leg row, and cone-visibility row;*
2. *classifier exposure, comparing cones only through the same codomain, shape, diagram, apex, leg, and visibility data under the displayed category and functor classifiers;*
3. *finite cone exactness, requiring every inspected shape arrow to satisfy its displayed naturality square before the leg family is exported;*
4. *sibling compatibility, allowing* ***??****,* $\mathsf{Pullback}^\uparrow$*, and* $\mathsf{FiniteLimitSeal}^\uparrow$ *consumers to read the cone only as finite cone data and not as a completed universal limit;*
5. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* H, R, P, N*.*

Thus a consumer may inspect the finite route

$$\mathsf{Cat}^\uparrow,\ \mathsf{Functor}^\uparrow,\ \mathsf{NatTrans}^\uparrow,\ \textbf{??},\ \mathsf{Pullback}^\uparrow,\ \mathsf{FiniteLimitSeal}^\uparrow \longmapsto \mathsf{FiniteLimitCone}^\uparrow$$

only through the displayed cone rows. It receives no host finite-limit theorem, selected terminal cone, quotient diagram equality, or ambient category-library object.

Proof. Project the accepted carrier. The rows C, J, D, A, L, V are exactly the codomain, finite shape, diagram, apex, leg family, and cone-visibility data, so every exported cone read starts from the finite category and functor surfaces.

The naturality checks are finite because J supplies only the inspected shape rows. The visibility row V records the squares for those rows and the adjacent $\mathsf{NatTrans}^\uparrow$ comparison route, while the product and pullback siblings may consume only the displayed finite legs and square data.

The structural rows H, R, P, N preserve the same packet by transport, replay, provenance, and local naming. Since the carrier contains no universal-cone coordinate, selected limiting object, quotient diagram equality, all-shapes quantifier, ambient finite products, ambient pullbacks, or external category library, the five listed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{FiniteLimitCone}^\uparrow$ consumer that reads a finite-limit cone while omitting the displayed codomain category, finite shape, diagram functor, apex, leg family, cone-visibility, transport, replay, provenance, or local naming rows refutes the carrier of Definition 7674.1.

Independence witness: category, functor, nattrans, product, pullback, finite-limit-seal: none is bijective because $\mathsf{FiniteLimitCone}^\uparrow$ jointly carries codomain, finite shape, diagram, apex, leg, finite naturality, sibling compatibility, transport, replay, provenance, and local NameCert rows. Each listed sibling exposes an adjacent surface without the full cone packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLimitCone}^\uparrow}$**.**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLimitCone}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 7674.1 and Definition 7674.2 seed the finite cone carrier and its five-row NameCert surface over Category, Functor, NatTrans, Product, Pullback, FiniteLimitSeal, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteLimitCone}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a host finite-limit theorem, a selected terminal cone, quotient diagram equality, all finite shapes at once, or an ambient category-library object.

Upgrade path: Obligation closure requires checked carrier admission, classifier exposure, finite cone exactness, sibling compatibility, transport, replay, provenance, and local naming for BEDC.Derived.FiniteLimitConeUp.

Constructive story: A $\mathsf{FiniteLimitCone}^{\uparrow}$ packet is generated from CategoryUp codomain and finite-shape rows, a FunctorUp diagram row, apex and leg rows, finite NatTrans-facing cone-visibility rows, ProductUp/PullbackUp/FiniteLimitSealUp sibling compatibility, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7675

A Concrete Naming Certificate for $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ packet records the bridge from bounded monotone real windows to located Cauchy-filter completion data as finite BEDC rows. It consumes the monotone-window surface of chapter 3750, the located filter surface of chapter 1661, the basis route of chapter 1501, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal seal of chapter 38. The packet names the bounded monotone route into located Cauchy-filter completion without invoking selected subsequences, quotient filters, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7675.1 (CauchyFilterBoundedMonotone carrier)**.** *A* $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, L, F, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$ *window row naming the bounded monotone finite observations.*
2. *L is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row that answers located filter requests generated from those windows.*
3. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *basis row used by L for refinement and meet data.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the bounded monotone observations.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the monotone comparisons and located filter balls.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, L, F, S, Q, D have been displayed.*
8. *H records componentwise* hsame *transport for the bounded-window, located-filter, basis, stream, readback, dyadic, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a bounded monotone precision request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$, $\mathsf{BoundedMonotoneSubsequence}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, L, F, S, Q, D, E, H, C, P, N$. It has no coordinate for an externally selected subsequence, quotient filter equality, countable choice, hidden basis selection, host limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7675.2 (CauchyFilterBoundedMonotone NameCert obligations)**.** *For every accepted* $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ *carrier $M = (B, L, F, S, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyFilterBoundedMo}}$ *surface consists exactly of carrier admission, bounded monotone window exposure through B, located filter exposure through L, basis refinement through F, finite stream-window exposure through S, regular rational readback through Q, dyadic tolerance accounting through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7675.1. The analytic rows are exactly the bounded monotone window, located Cauchy filter, filter basis, stream window, regular rational readback, dyadic tolerance ledger, and real seal.

The structural rows H, C, P, N preserve, replay, source, and name that same finite tuple. Since the carrier contains no coordinate for a selected infinite subsequence, quotient filter, countable-choice schedule, hidden basis selector, or ambient completeness theorem, the listed rows exhaust the local certificate surface. □

Theorem 7675.3 (CauchyFilterBoundedMonotone regular extraction)**.** *Every accepted* CauchyFilterBoundedMono *packet extracts regular readback data from bounded monotone windows only through the displayed route*

$$B \longmapsto S \longmapsto D \longmapsto Q.$$

The route may then be consumed by the located filter row L and its basis row F, but it cannot be replaced by a selected subsequence, quotient stream equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the bounded monotone row B. It supplies only finite monotone windows, so any readback request must open the stream-window row S and compare the displayed observations through the dyadic ledger D.

The regular rational row Q is downstream of those windows and comparisons. It is therefore a readback surface for the displayed bounded monotone data, not a selected infinite subsequence.

The located filter rows L and F consume the same readback route. Transport, replay, provenance, and local naming preserve the route through H, C, P, N, and none of those rows adds quotient equality, choice, trichotomy, or ambient completeness. □

Theorem 7675.4 (CauchyFilterBoundedMonotone located-filter handoff)**.** *Every located Cauchy-filter consumer of an accepted* $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ *carrier must read the bounded monotone window row B, the stream-window row S, the regular readback row Q, the dyadic tolerance ledger D, and the basis row F before consuming the located filter row L and terminal seal E. The handoff exports no quotient filter, selected limit, countable-choice schedule, hidden basis selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Apply the NameCert obligations of Definition 7675.2. They place the located filter row L in the same finite packet as the bounded monotone, stream, readback, dyadic, basis, and seal rows.

Use the regular extraction theorem Definition 7675.3. The regular readback is already routed through B, S, D, Q, so a located filter request cannot bypass the bounded monotone windows.

Finally read the basis row F and seal row E from the carrier. The basis row supplies the refinement surface for L, and the seal is available only after the displayed route has been consumed. Thus the handoff remains inside the finite rows $B, L, F, S, Q, D, E, H, C, P, N$. □

Falsifiable prediction: Every accepted $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ read displays one bounded monotone window row, one located Cauchy filter row, one CauchyFilterBasis row, one StreamName window row, one RegSeqRat readback row, one DyadicRatCore tolerance ledger, one RealUp seal, transport, replay, provenance, and local naming before completion-facing data are consumed.

Independence witness: bounded-monotone-subsequence, located-cauchy-filter, cauchy-filter-basis, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds bounded monotone window extraction, located filter requests, basis refinement, regular readback, dyadic tolerance accounting, and terminal real sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}$ packet is generated from bounded monotone windows, located Cauchy-filter rows, CauchyFilterBasis refinement, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise transport, displayed replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7675.1, Definition 7675.2, Definition 7675.3, and Definition 7675.4 seed the finite bridge from bounded monotone real windows to located Cauchy-filter completion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyFilterBoundedMonotone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subsequences, quotient filters, countable choice, hidden basis selection, host limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded monotone window exposure, located filter exposure, basis refinement, regular readback, dyadic tolerance accounting, seal nonescape, transport, replay, provenance, and local naming for the same finite packet.

Chapter 7676

A Concrete Naming Certificate for $\mathsf{TychonoffProductWindow}^{\uparrow}$

Following Tychonoff and Kelley, the $\mathsf{TychonoffProductWindow}^{\uparrow}$ packet records only the finite product-window compactness data that can be displayed inside BEDC NameCert rows. It sits after the finite product certificate of **??**, the compact metric product route of chapter 1822, the product-distance ledger of chapter 424, the compact source boundary of chapter 60, and the topology carrier of chapter 88. The packet is a finite inspection window for product compactness consumers, not a proof of full product compactness.

Definition 7676.1 (Tychonoff product-window carrier)**.** *A* $\mathsf{TychonoffProductWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, U, K, M, F, T, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-window row, listing exactly the coordinates visible to the packet.*
2. *U is the topology-window row, reading each listed coordinate through the finite open-row interface of* $\mathsf{Topology}^{\uparrow}$*.*
3. *K is the compact-source row, exposing for each listed coordinate only the displayed compact data admitted by* $\mathsf{Compact}^{\uparrow}$*.*
4. *M is the metric product handoff, using* $\mathsf{CompactMetricProduct}^{\uparrow}$ *and* $\mathsf{ProductMetric}^{\uparrow}$ *only when the displayed window is metric.*
5. *F is the finite-product compactness row inherited from* $\mathsf{TychonoffFiniteProduct}^{\uparrow}$ *for the same listed coordinates.*
6. *T is the finite cover-window ledger, naming the visible cover requests and finite response rows inside the displayed product window.*
7. *L is the local compactness-read ledger, recording which compact-source row is read by each visible product-window request.*
8. *H stores componentwise* hsame *transport for $I, U, K, M, F, T, L, C, P, N$.*
9. *C stores displayed* Cont *replay from a consumer request through the same finite product-window rows.*

10. *P is the* Pkg *provenance over* $\mathsf{TychonoffProductWindow}^{\uparrow}$, $\mathsf{TychonoffFiniteProduct}^{\uparrow}$, $\mathsf{CompactMetricProduct}^{\uparrow}$, $\mathsf{ProductMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TychonoffProductWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an arbitrary product family, a countable product, an ultrafilter, a selected subcover, a host product point, or open-cover compactness beyond the displayed finite window.

Theorem 7676.2 (Tychonoff product-window NameCert obligations)**.** *For an accepted* $\mathsf{TychonoffProductWindow}^{\uparrow}$ *carrier*

$$W = (I, U, K, M, F, T, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TychonoffProductWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index window, topology rows, compact-source rows, metric product handoff, finite-product compactness row, cover-window ledger, local compactness-read ledger, componentwise transport, replay, provenance, and local naming. Every compactness read must first expose the displayed route*

$$\mathsf{Topology}^{\uparrow}, \mathsf{Compact}^{\uparrow}, \mathsf{TychonoffFiniteProduct}^{\uparrow}, \mathsf{CompactMetricProduct}^{\uparrow}, \mathsf{ProductMetric}^{\uparrow} \longmapsto I, U, K, M, F, T, L, H, C$$

The certificate exports finite product-window compactness data only; it does not assert arbitrary Tychonoff products, countable products, choice-selected subcovers, ultrafilters, host product points, or open-cover compactness beyond displayed finite windows.

Proof. Project the carrier of Definition 7676.1. The index row I fixes the visible coordinates, and the topology, compact, metric-product, finite-product, cover-window, and local compactness rows are all displayed before the structural rows are read.

Read U and K first. They expose the finite topology and compact-source data supplied by chapter 88 and chapter 60, without forming an ambient product of all coordinate points.

Next read F through **??**. In metric windows, the same request may also pass through M using chapter 1822 and chapter 424. These rows provide only the finite product-window route already named by I.

Finally, T, L, H, C, P, N record the cover-window request, local compactness reads, transport, replay, provenance, and local naming. Since the packet contains no row for countable products, arbitrary products, selected subcovers, ultrafilters, host product points, or open-cover compactness outside the finite window, the NameCert surface is exhausted by the displayed data. □

Closure status for $\mathsf{NameCert}_{\mathsf{TychonoffProductWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{TychonoffProductWindow}^{\uparrow}$ packet is generated from a finite index window, topology rows, compact-source rows, metric product handoff, TychonoffFiniteProduct finite-product rows, finite cover-window ledgers, local compactness-read ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TychonoffProductWindow}^{\uparrow}}$, seed)

Scope closed: Definition 7676.1 and Definition 7676.2 define only the finite product-window carrier and its displayed NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TychonoffProductWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary Tychonoff products, countable products, choice-selected subcovers, ultrafilters, host product points, or open-cover compactness beyond displayed finite windows.

Upgrade path: The next step is Lean alignment of the finite index window, topology rows, compact-source rows, metric product handoff, finite-product row, cover-window ledger, local compactness-read ledger, transport, replay, provenance, and local naming for BEDC.Derived.TychonoffProductWindowUp.

Chapter 7677

A Concrete Naming Certificate for $\mathsf{CauchyProductTheorem}^{\uparrow}$

Following Bishop and Bridges on constructive real arithmetic, the $\mathsf{CauchyProductTheorem}^{\uparrow}$ packet records the finite L10 route saying that two displayed regular Cauchy rational sources admit a product name once the source windows, dyadic product ledger, regular readback, and terminal Real seal are all visible. It sits between the local product-budget packet of chapter 676, the regular rational source surface of chapter 301, the finite stream-window discipline of chapter 126, the tolerance arithmetic of chapter 291, and the terminal real-name boundary of chapter 38. The chapter names only the finite product theorem corridor for regular Cauchy names; it does not assert quotient real multiplication, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7677.1 (Cauchy product theorem carrier)**.** *A* $\mathsf{CauchyProductTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, S, T, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows. Each row exposes the finite rational windows and regularity witnesses consumed by the product request.*
2. *S and T are paired* $\mathsf{StreamName}^{\uparrow}$ *window rows for the same two sources, indexed by the visible tolerance requests used by the product route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *product row. It records the finite dyadic product cells, denominator refinements, and tolerance comparisons needed to multiply the inspected source windows.*
4. *L is the* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger binding the source moduli, dyadic product row, and terminal tolerance request into one displayed error account.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *product handoff row obtained from A, B, S, T, D, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the product handoff row R is visible.*
7. *H records componentwise* hsame *transport for the source rows, stream windows, dyadic product row, error ledger, product handoff, Real seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay from a product-theorem request through $A, B, S, T, D, L, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyProductTheorem}^{\uparrow}$, $\mathsf{RegularCauchyProductBudget}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteErrorBudget}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyProductTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their replay path. It has no coordinate for quotient equality of completed reals, host real multiplication, selected limiting products, countable-choice schedules, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.CauchyProductTheoremUp.CauchyProductTheoremUp`
Lean4 ✓ `BEDC.Derived.CauchyProductTheoremUp.CauchyProductTheoremTasteGate single carrier alignment`

Theorem 7677.2 (Cauchy product theorem finite route)**.** *For every accepted* $\mathsf{CauchyProductTheorem}^{\uparrow}$ *carrier* $K = (A, B, S, T, D, L, R, E, H, C, P, N)$*, every* $\mathsf{Real}^{\uparrow}$*-facing product read factors through the finite route*

$$A, B \longmapsto S, T \longmapsto D, L \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the theorem packet exposes two $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *product row, a* $\mathsf{FiniteErrorBudget}^{\uparrow}$ *ledger, the* $\mathsf{RegSeqRat}^{\uparrow}$ *product handoff, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the* hsame/Cont/Pkg/NameCert *support rows before any product name can be consumed.*

Proof. Project the carrier of Definition 7677.1. The accepted packet exposes exactly the two source rows, the paired stream windows, the dyadic product row, the finite error ledger, the product handoff row, and the terminal Real seal.

The source stage is A, B, S, T. The two $\mathsf{RegSeqRat}^{\uparrow}$ rows supply the rational Cauchy data, while the two $\mathsf{StreamName}^{\uparrow}$ rows display the finite windows requested by the product consumer.

The arithmetic stage is D, L. The $\mathsf{DyadicRatCore}^{\uparrow}$ row records the finite product cells and tolerance comparisons, and the $\mathsf{FiniteErrorBudget}^{\uparrow}$ ledger binds those comparisons to the source moduli and the requested output tolerance.

The handoff stage is R, E. The product handoff row repacks the displayed budget as a regular rational product name, and the terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after that row is visible.

Finally H, C, P, N transport, replay, package, and locally name the same route. Since no excluded object is a carrier coordinate, a product consumer cannot bypass the displayed regular source rows, stream windows, dyadic product row, error ledger, handoff, or Real seal. □

Theorem 7677.3 (Cauchy product theorem budget support)**.** *Every accepted* $\mathsf{CauchyProductTheorem}^{\uparrow}$ *packet consumes the* $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ *surface before its product handoff row can be read as* $\mathsf{RegSeqRat}^{\uparrow}$ *data. In the carrier* $K = (A, B, S, T, D, L, R, E, H, C, P, N)$*, the budget surface is read through* A, B, S, T, D, L*, while* R, E, H, C, P, N *only expose the resulting regular product name, Real seal, and structural support.*

Proof. Start with the finite route of Definition 7677.2. Its first two stages contain the source regular Cauchy rows, paired stream windows, dyadic product arithmetic, and finite error ledger.

These are exactly the rows inspected by the $\mathsf{RegularCauchyProductBudget}^{\uparrow}$ packet: source moduli, product cells, and tolerance bookkeeping appear before the product handoff row R is available.

The remaining rows do not create a second product computation. They read back the displayed budget as a regular product name, seal it as $\mathsf{Real}^{\uparrow}$ data, and preserve the route under transport, replay, provenance, and local naming. □

Falsifiable prediction: Every accepted $\mathsf{CauchyProductTheorem}^{\uparrow}$ consumer that reaches a terminal $\mathsf{Real}^{\uparrow}$ seal while omitting a $\mathsf{RegSeqRat}^{\uparrow}$ source row, a $\mathsf{StreamName}^{\uparrow}$ window row, the $\mathsf{DyadicRatCore}^{\uparrow}$ product row, the $\mathsf{FiniteErrorBudget}^{\uparrow}$ ledger, the $\mathsf{RegSeqRat}^{\uparrow}$ product handoff, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: regularcauchyproductbudget, regseqrat, streamname, dyadicratcore, real: no listed sibling supplies the whole theorem packet $K = (A, B, S, T, D, L, R, E, H, C, P, N)$, because each sibling contributes only the budget, source readback, stream windows, arithmetic ledger, or terminal seal while this chapter binds them as one finite Cauchy product theorem certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductTheorem}^{\uparrow}$ packet is generated from two RegSeqRat source rows, paired StreamName windows, a DyadicRatCore product row, a FiniteErrorBudget ledger, a RegSeqRat product handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7677.1, Definition 7677.2, and Definition 7677.3 seed the finite Cauchy product theorem route from regular Cauchy source rows to stream windows, dyadic product arithmetic, finite error budgeting, regular product handoff, Real sealing, transport, replay, provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real multiplication, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, source-window stability, dyadic product arithmetic, finite error budgeting, RegSeqRat product handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductTheoremUp.

Chapter 7678

A Concrete Naming Certificate for $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$

Following Kock and Zoberlein on lax idempotent monads, the $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ packet records the finite doctrine-level certificate by which Cauchy completion flattening is consumed as an idempotent handoff rather than as quotient completed objects. It sits beside the Cauchy completion monad join of chapter 7559, the completion idempotence surface of chapter 2381, the Yoneda completion packet of chapter 2148, the Lawvere metric completion profile of chapter 3947, and the finite readback stack of chapter 126, chapter 301, chapter 291, chapter 38, and chapter 360. The packet names the doctrine row that lets downstream completion consumers read repeated completion through the same finite carrier surface, without host equality of completed objects, quotient representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7678.1 (Kock–Zoberlein Cauchy completion carrier)**.** *A* $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, M, J, I, Y, L, S, R, Q, E, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the lax-idempotent doctrine row naming the Kock–Zoberlein orientation of the completion read.*
2. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *source row recording the unit-and-bind schedule read before any flattening.*
3. *J is the* $\mathsf{CauchyCompletionMonadJoin}^{\uparrow}$ *row that exposes the completion-of-completion join.*
4. *I is the* $\mathsf{CompletionIdempotence}^{\uparrow}$ *row requiring the repeated completion read to reuse the same finite completion boundary.*
5. *Y is the* $\mathsf{YonedaCompletion}^{\uparrow}$ *profile row that supplies presheaf-style completion observations.*
6. *L is the* $\mathsf{LawvereMetricCompletion}^{\uparrow}$ *directed-profile row used when the doctrine is read over one-sided enriched metrics.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row.*
9. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the completion join and idempotence rows.*

10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row.*
11. *F is the* $\mathsf{RealCauchyCompletion}^{\uparrow}$ *handoff row available only after $M, J, I, Y, L, S, R, Q, E$ have been displayed.*
12. *H records componentwise* hsame *transport for the displayed doctrine and completion rows.*
13. *C records displayed* Cont *replay from doctrine orientation through monad join, idempotence, profile, finite-window, readback, tolerance, Real seal, and completion handoff.*
14. *P is the* Pkg *provenance over* $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, CauchyCompletionMo $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{YonedaCompletion}^{\uparrow}$, $\mathsf{LawvereMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
15. *N is the local* $\mathsf{NameCert}_{\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}}$ *row.*

The carrier exports no quotient completion object, selected completion representative, host equality of completed objects, countable-choice schedule, global colimit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 7678.2 (Kock–Zoberlein Cauchy completion NameCert obligations)**.** *For every accepted* $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ *carrier $K = (D, M, J, I, Y, L, S, R, Q, E, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}}$ *surface consists exactly of doctrine orientation through D, Cauchy completion monad exposure through M, monad join exposure through J, completion idempotence through I, Yoneda profile exposure through Y, Lawvere metric completion exposure through L, finite window exposure through S, regular-rational readback through R, dyadic tolerance accounting through Q, Real sealing through E, Real Cauchy completion handoff through F, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier. Its coordinates display the doctrine row, monad row, join row, idempotence row, Yoneda profile, Lawvere directed profile, finite-window route, regular-rational readback, dyadic ledger, Real seal, Real Cauchy completion handoff, and structural support rows.

The completion rows are consumed in doctrine order. The monad source M is read before the join row J, the idempotence row I constrains the repeated completion read, and the profile rows Y, L provide the Yoneda and Lawvere observations that downstream completion consumers may inspect.

The finite analytic rows S, R, Q, E, F supply the BEDC readback boundary after the doctrine rows have been displayed. Transport, replay, provenance, and local naming preserve that same packet, so the listed rows exhaust the local NameCert obligations. □

Theorem 7678.3 (Kock–Zoberlein Cauchy completion idempotent handoff)**.** *Every completion-of-completion consumer of an accepted* $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ *packet must factor through the finite route*

$$D, M, J, I, Y, L, S, R, Q, E, F, H, C, P, N.$$

The consumer receives the Cauchy completion monad row, monad join row, completion idempotence row, Yoneda profile row, Lawvere metric completion row, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, and RealCauchyCompletion handoff before it can treat the repeated completion read as flattened. The route supplies an idempotent handoff surface, not a quotient completed object, selected representative, host equality of completed objects, countable choice, global colimit, or ambient completeness theorem.

Proof. Begin with the doctrine and monad rows. The Kock–Zoberlein orientation D can be consumed only together with the displayed completion monad row M and the join row J, so no consumer reaches a flattened completion read before the completion-of-completion input has been named.

Next read the idempotence and profile rows. The row I forces the repeated completion request to reuse the displayed completion boundary, while Y and L expose the Yoneda and Lawvere profile data that make the handoff visible to completion-facing readers.

Finally pass through $S, R, Q, E, F, H, C, P, N$. These rows provide the finite observation windows, regular readback, tolerance accounting, terminal Real seal, Real Cauchy completion handoff, transport, replay, provenance, and local naming. Since the carrier contains no quotient object, selected representative, host equality, choice schedule, colimit coordinate, or ambient completeness row, the idempotent handoff cannot export any of those endpoints. □

Falsifiable prediction: Every accepted $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ read exposes the Cauchy completion monad, monad join, completion idempotence, Yoneda profile, Lawvere metric completion profile, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, and RealCauchyCompletion handoff before any repeated completion read is consumed as flattened.

Independence witness: cauchy-completion-monad-join, completion-idempotence, yoneda-completion, lawvere-metric-completion, streamname, regseqrat, dyadicratcore, real, real-cauchy-completion: none is bijective to $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ because this packet jointly binds lax-idempotent doctrine orientation, completion monad source, monad join, idempotence reuse, Yoneda and Lawvere profile rows, finite readback rows, Real sealing, Real Cauchy completion handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}$ packet is generated from a lax-idempotent doctrine row, CauchyCompletionMonad row, CauchyCompletionMonadJoin row, CompletionIdempotence row, YonedaCompletion row, LawvereMetricCompletion row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerances, RealUp seal, RealCauchyCompletion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7678.1, Definition 7678.2, and Definition 7678.3 seed the finite lax-idempotent completion-flattening route over completion monad, join, idempotence, profile, finite-window, readback, tolerance, Real seal, and Real Cauchy completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KockZoberleinCauchyCompletion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.KockZoberleinCauchyCompletionUp.KockZoberleinCauchyCompletionUp`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completed objects, selected representatives, host equality of completed objects, countable choice, global colimits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, doctrine-orientation exactness, completion monad join exposure, idempotent handoff non-escape, Yoneda and Lawvere profile compatibility, finite readback preservation, Real seal preservation, RealCauchyCompletion handoff, transport, replay, provenance, and local naming for BEDC.Derived.KockZoberleinCauchyCompletionUp.

Chapter 7679

A Concrete Naming Certificate for $\mathsf{RiemannStieltjesSum}^{\uparrow}$

Following Riemann and Stieltjes, the $\mathsf{RiemannStieltjesSum}^{\uparrow}$ packet records the finite product-sum ledger used when a displayed integrand window is read against displayed integrator differences. It sits beside the tagged finite-sum surface of chapter 1615, the upper and lower Stieltjes-sum boundary of chapter 7558, and the terminal real-name seal of chapter 38. The packet gives Real-facing finite integration consumers a named row for one displayed Riemann–Stieltjes sum; it does not assert an integral value, bounded-variation completeness, a refinement limit, a quotient of functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7679.1 (Riemann–Stieltjes sum carrier)**.** *A* $\mathsf{RiemannStieltjesSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, F, G, L, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the tagged partition row, exposing ordered cells, endpoints, tags, and tag-containment witnesses through the finite* $\mathsf{RiemannSum}^{\uparrow}$ *surface.*
2. *F is the integrand window row, recording exactly the finitely many displayed integrand reads required at the carried tags.*
3. *G is the integrator-difference row, recording for each carried cell the displayed endpoint difference of the integrator between the cell endpoints.*
4. *L is the finite product-sum ledger, pairing each integrand read in F with the matching integrator difference in G and recording the carried arithmetic sum over T.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, fixing the dyadic budget used to compare the product-sum ledger with later regulated-integral or Darboux–Stieltjes consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed finite product-sum and tolerance ledger.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the tagged partition, integrand window, integrator differences, product-sum ledger, dyadic budget, and regular readback are displayed.*
8. *H records componentwise* hsame *transport for the tagged partition, integrand window, integrator differences, product-sum ledger, tolerance row, readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the tagged partition through*

$$T, F, G \longmapsto L \longmapsto D \longmapsto R \longmapsto E$$

and then through the structural rows.

10. *P is the* Pkg *provenance over* $\mathsf{RiemannStieltjesSum}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxStieltjesSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, F, G, L, D, R, E, H, C, P, N$. It has no coordinate for a completed integral, a limit over all refinements, bounded-variation completeness, quotient function equality, a selected tag family outside T, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7679.2 (Riemann–Stieltjes sum NameCert obligations)**.** *For every accepted* $\mathsf{RiemannStieltjesSum}^{\uparrow}$ *carrier $S = (T, F, G, L, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannStieltjesSum}^{\uparrow}}$ *surface consists exactly of carrier admission for the tagged partition, integrand window, integrator-difference row, finite product-sum ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every accepted read follows the finite route*

$$T, F, G \longmapsto L \longmapsto D \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Project the carrier of Definition 7679.1. Its displayed rows are exactly the tagged partition, integrand reads, integrator differences, finite product-sum ledger, dyadic tolerance, regular readback, Real seal, and structural rows.

The arithmetic route is cellwise. Each summand is admitted only when the tag comes from T, the value comes from F, and the matching integrator difference comes from G on the same displayed cell.

The ledger L records only the finite product-sum built from those rows. The tolerance row D and readback row R make the numerical comparison visible before the terminal seal E can be consumed.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same route. Since no carrier coordinate names a completed integral, refinement limit, quotient function, hidden tag selector, countable-choice principle, or ambient completeness theorem, the listed rows exhaust the obligation surface. □

Theorem 7679.3 (Riemann–Stieltjes sum Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RiemannStieltjesSum}^{\uparrow}$ *packet must read the tagged partition row, integrand window, integrator-difference row, finite product-sum ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the terminal seal is inspected. The seal exports only the displayed finite Riemann–Stieltjes sum route, not an integral value, a refinement limit, bounded-variation completeness, quotient function equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the obligation surface of Definition 7679.2. It orders the visible route through T, F, G, L, D, R, E, with the structural rows attached afterward.

The $\mathsf{Real}^{\uparrow}$ seal row E is downstream from the regular readback row R. Thus a consumer cannot inspect the seal until the finite product-sum ledger and dyadic tolerance row have already been displayed.

The sibling $\mathsf{RiemannSum}^{\uparrow}$ surface supplies the finite tagged-partition reading, and the $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ surface supplies a comparison boundary for upper and lower Stieltjes rows. Neither sibling adds a completed integral coordinate to this carrier.

Therefore the terminal seal is only a Real-facing seal for the displayed finite sum route. All completed integration, refinement-limit, quotient-function, choice, and ambient-completeness readings remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{RiemannStieltjesSum}^{\uparrow}$ read exposes tagged partition, integrand window, integrator-difference, finite product-sum, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before any Real-facing consumer inspects the seal.

Independence witness: riemannsum, darboux-stieltjes-sum, real: $\mathsf{RiemannSum}^{\uparrow}$ supplies tagged finite-sum rows without integrator differences, $\mathsf{DarbouxStieltjesSum}^{\uparrow}$ supplies upper and lower Stieltjes comparison rows rather than one tagged product-sum ledger, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal. None is bijective with the complete tagged partition, integrand-window, integrator-difference, finite product-sum, tolerance, readback, transport, replay, provenance, and local NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannStieltjesSum}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannStieltjesSum}^{\uparrow}$ packet is generated from a tagged partition row, integrand window, integrator differences, finite product-sum ledger, DyadicRatCore tolerance row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesSum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7679.1, Definition 7679.2, and Definition 7679.3 seed the finite Riemann–Stieltjes product-sum route over tagged partition, integrand-window, integrator-difference, tolerance, readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannStieltjesSum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Riemann–Stieltjes integration, bounded-variation completeness, refinement limits, quotient function equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged partition exposure, integrand-window readback, integrator-difference exposure, finite product-sum exactness, DyadicRatCore tolerance control, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannStieltjesSumUp.

Chapter 7680

A Concrete Naming Certificate for $\mathsf{SequentialMetricSpace}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{SequentialMetricSpace}^{\uparrow}$ packet records a sequence-indexed metric interface as finite BEDC NameCert data. It sits between the $\mathsf{Met}^{\uparrow}$ carrier of chapter 57, the stream naming discipline of chapter 126, the regular rational readback of chapter 301, the $\mathsf{Real}^{\uparrow}$ completion seal of chapter 38, and the filter-side completion route of chapter 333. The packet names sequential Cauchy observations without importing host sequences, quotient completions, or an ambient completeness theorem.

Definition 7680.1 (SequentialMetricSpace carrier)**.** *A* $\mathsf{SequentialMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, M, U, O, C, S, R, H, Q, P, N)$$

with the following displayed rows:

1. *X is the named point carrier read from the underlying* $\mathsf{Met}^{\uparrow}$ *surface;*
2. *M is the metric observation row, recording only displayed distance comparisons and no host metric library object;*
3. *U is the finite* UnaryHistory *index row used to address the observed sequence windows;*
4. *O is the observation table pairing each displayed unary index window with metric reads in M;*
5. *C is the sequential Cauchy ledger, expressed as finite tolerance-to-window data over U, O;*
6. *S is the stream-name handoff row consumed by* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readers;*
7. *R is the real-readback row consumed by* $\mathsf{Real}^{\uparrow}$ *and by the* $\mathsf{CauchyFilter}^{\uparrow}$ *comparison route;*
8. *H records componentwise* hsame *transport for point, metric, index, observation, Cauchy, stream, real-readback, continuation, provenance, and naming rows;*
9. *Q records the displayed* Cont *routes from metric observations to stream, regular rational, real, and Cauchy-filter consumers;*
10. *P is the* Pkg *provenance over* $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, BHist, hsame, Cont, *and the local certificate;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialMetricSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host infinite sequence, quotient completion, selected representative of a Cauchy class, classical choice principle, or ambient theorem asserting that every sequential Cauchy object has a limit.

Theorem 7680.2 (SequentialMetricSpace NameCert obligations)**.** *For an accepted* $\mathsf{SequentialMetricSpace}^{\uparrow}$ *carrier* $B = (X, M, U, O, C, S, R, H, Q, P, N)$*, the local* NameCert *surface exposes exactly the point carrier* X*, metric observation row* M*, unary history index row* U*, observation table* O*, sequential Cauchy ledger* C*, stream-name handoff* S*, real-readback row* R*, componentwise transport* H*, displayed continuation routes* Q*, provenance* P*, and local naming* N*. Every* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer must read through those displayed rows.*

Proof. Project the carrier. The rows X, M, U, O, C give the finite metric and sequential observation surface, while S and R are the only rows that export the sequence-indexed data to downstream completion readers.

The transport and continuation rows preserve the same inventory. Componentwise hsame movement through H can move an accepted packet only row by row, and every Cont route in Q begins with the displayed metric observations and sequential Cauchy ledger.

Finally inspect P and N. Provenance names the metric, stream, regular rational, real, and Cauchy-filter consumers, and local naming records that no host sequence, quotient completion, selected representative, or ambient completeness theorem is part of the certificate. □

Theorem 7680.3 (SequentialMetricSpace Cauchy readback)**.** *For an accepted* $\mathsf{SequentialMetricSpace}^{\uparrow}$ *carrier* $B = (X, M, U, O, C, S, R, H, Q, P, N)$*, every Cauchy readback consumed by* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or* $\mathsf{CauchyFilter}^{\uparrow}$ *factors through the finite ledger*

$$U, O, C, S, R.$$

The readback may use the displayed metric observations and the sequential Cauchy ledger, but it cannot replace them by a host sequence, quotient class, unindexed filter, or a completed real supplied outside the packet.

Proof. Start with the index and observation rows. The row U supplies the displayed unary windows, and O attaches the finite metric observations used by the Cauchy ledger C.

The handoff rows then determine the downstream reads. Stream and regular rational consumers read through S, while real and Cauchy-filter consumers read through R together with the same ledger data.

The support rows H, Q, P, N transport, replay, package, and name that finite route. Since the carrier lists no host sequence, quotient completion, unindexed filter, or external completed real coordinate, every accepted Cauchy readback remains inside U, O, C, S, R. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialMetricSpace}^{\uparrow}$ packet is generated from a point carrier row, metric observation row, finite unary history index row, observation table, sequential Cauchy ledger, stream-name handoff, real-readback row, componentwise hsame transport, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialMetricSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7680.1, Definition 7680.2, and Definition 7680.3 bind the finite sequence-indexed metric carrier and its Cauchy readback route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialMetricSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove metric completion, quotient completion, selected limits for all Cauchy sequences, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric observation stability, sequential Cauchy ledger exactness, stream and regular rational handoff, real and Cauchy-filter readback, and non-escape for the displayed finite packet.

Chapter 7681

A Concrete Naming Certificate for $\mathsf{EulerianNumber}^{\uparrow}$

Following Euler and standard enumerative combinatorics, the $\mathsf{EulerianNumber}^{\uparrow}$ packet records descent-count data for finite permutations as a displayed NameCert surface. It sits after the natural-number endpoint of chapter 28, the finite spine discipline of chapter 36, the polynomial table surface of chapter 50, and the Young-ledger partition interface of chapter 201. The packet names Eulerian-number rows without importing host finite sets, quotient permutation equality, selected representatives, infinite generating functions, or ambient representation theory.

Definition 7681.1 (Eulerian number carrier)**.** *An* $\mathsf{EulerianNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (n, k, \Pi, D, A, R, V, H, C, P, N)$$

with the following displayed rows:

1. *n and k are* $\mathsf{Nat}^{\uparrow}$ *rows naming the permutation length and requested descent count.*
2. *Π is the finite permutation-window row, represented as a* $\mathsf{List}^{\uparrow}$ *ledger of displayed one-line permutation names over the initial segment* $0, \ldots, n-1$*.*
3. *D is the descent-position row, listing for each displayed permutation the adjacent positions where the next entry is smaller.*
4. *A is the descent-count row, reading each displayed descent list through* $\mathsf{Nat}^{\uparrow}$ *and comparing it with k.*
5. *R is the recurrence-table row, recording the finite Eulerian recurrence cells used to compute the entry indexed by (n, k).*
6. *V is the polynomial and table provenance row, reading Eulerian polynomial coefficients through* $\mathsf{Poly}^{\uparrow}$ *and recording the compatible triangular table readback.*
7. *H records componentwise* hsame *transport for length, descent count, permutation window, descent positions, count row, recurrence table, provenance row, continuation row, package row, and local naming row.*
8. *C records displayed* Cont *replay from Π to D, from D to A, from the table row R to the polynomial row V, and from all public rows to the local certificate.*
9. *P is the* Pkg *provenance over* $\mathsf{EulerianNumber}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{Partition}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{EulerianNumber}^{\uparrow}}$ *row.*
The carrier has no coordinate for host finite-set quotients, unbounded permutation spaces, selected representative permutations, analytic generating functions, or representation-ring equality.

Lean4 (definition) `BEDC.Derived.EulerianNumberUp.EulerianNumberUp`
Lean4 ✓ `BEDC.Derived.EulerianNumberUp.EulerianNumberTasteGate single carrier alignment`

Theorem 7681.2 (Eulerian number NameCert obligations)**.** *For every accepted* $\mathsf{EulerianNumber}^{\uparrow}$ *carrier*

$$E = (n, k, \Pi, D, A, R, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EulerianNumber}^{\uparrow}}$ *surface consists exactly of length and descent-count admission, finite permutation-window exposure, descent-position extraction, descent-count comparison, recurrence-table readback, polynomial and table provenance, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every consumer of the number $A(n, k)$ must read*

$$n, k, \Pi, D, A, R, V, H, C, P, N$$

before citing the Eulerian entry.

Proof. Project the carrier E. The rows n, k, Π give the only admissible length, count, and finite permutation-window data.

The rows D and A compute descent positions and descent counts inside the displayed window. The recurrence row R and polynomial provenance row V supply the table-facing and coefficient-facing readbacks for the same entry.

Transport, replay, package provenance, and local naming are confined to H, C, P, N. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7681.3 (Eulerian number descent recurrence)**.** *Let $E = (n, k, \Pi, D, A, R, V, H, C, P, N)$ be an accepted* $\mathsf{EulerianNumber}^{\uparrow}$ *carrier. Every recurrence-facing read of the Eulerian entry indexed by (n, k) factors through the finite table row R and the descent ledger rows Π, D, A. The recurrence table may be replayed as the usual finite split by the last insertion position: entries preserving a descent are read from the cell indexed by $(n-1, k)$, and entries creating a descent are read from the cell indexed by $(n-1, k-1)$. The polynomial provenance row V records the same table as coefficients of the Eulerian polynomial before any* $\mathsf{Partition}^{\uparrow}$ *or representation-facing consumer may cite it.*

Proof. Start with the displayed permutation window Π. The descent rows D and A classify each listed permutation by the number of descents, so the requested entry is counted only through the finite window and the requested $\mathsf{Nat}^{\uparrow}$ row k.

Read the recurrence table R. The insertion-position split is a finite table operation over displayed rows: one branch preserves the descent count and reads $(n-1, k)$, while the other branch creates the displayed descent and reads $(n-1, k-1)$.

Finally read V, H, C, P, N. The polynomial row records the same triangular table as coefficients, while transport, replay, provenance, and naming preserve the displayed recurrence route for downstream $\mathsf{Poly}^{\uparrow}$ and $\mathsf{Partition}^{\uparrow}$ consumers. □

Closure status for $\mathsf{NameCert}_{\mathsf{EulerianNumber}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EulerianNumber}^{\uparrow}$ packet is generated from NatUp length and descent-count rows, a ListUp finite permutation window, descent-position and descent-count ledgers, a finite recurrence table, polynomial/table provenance, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{EulerianNumber}\uparrow}$, seed)

Scope closed: Definition 7681.1, Definition 7681.2, and Definition 7681.3 seed the finite Eulerian descent-count certificate over displayed permutation windows and recurrence-table rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{EulerianNumber}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host finite-set quotients, unrestricted permutation equality, selected representatives, infinite generating functions, representation-ring equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, permutation-window admission, descent-position extraction, descent-count comparison, recurrence-table readback, polynomial provenance, transport, replay, package provenance, and local naming for BEDC.Derived.EulerianNumberUp.

Chapter 7682

A Concrete Naming Certificate for MetaCICClosureSubstitutionFrontier$^{\uparrow}$

The MetaCICClosureSubstitutionFrontier$^{\uparrow}$ packet realizes the beta-audit obstruction route of section 9384.4 as finite beta-trigger, closedness, substitution-boundary, and subject-reduction frontier rows. It sits between the beta audit packet of chapter 761, the closure-preservation audit packet of chapter 791, the subject-reduction discharge socket of chapter 719, the confluence substitution boundary of chapter 3791, and the normal-form consistency seal of chapter 740. The packet records the finite frontier where beta movement remains closed but still has to cross typed substitution and subject-reduction boundaries; it does not assert subject reduction, confluence, normalization, conversion typing, quotient syntax equality, or kernel consistency.

Definition 7682.1 (MetaCIC closure-substitution frontier carrier)**.** *A* MetaCICClosureSubstitutionFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, K, S, O, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the beta-trigger row, exposing the direct beta contraction, application-argument congruence, lambda-domain congruence, and Pi-domain congruence triggers named by the beta audit map.*
2. *K is the* ClosedAt *preservation row, recording the closedness-preservation route through shift, substitution, one-step beta, and finite beta-chain audit rows.*
3. *S is the substitution-boundary row, retaining the point where substitution through binders must be inspected before a typed preservation consumer may proceed.*
4. *O is the obstruction row, recording dependent-codomain, lambda-domain, Pi-domain, and beta-substitution typing boundaries that are not discharged by closedness alone.*
5. *R is the subject-reduction frontier row, exposing the discharge socket route before any subject-reduction consumer may inspect the packet.*
6. *H records componentwise* hsame *transport for beta-trigger, closedness, substitution-boundary, obstruction, subject-reduction, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$B, K, S, O \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* MetaCICClosureSubstitutionFrontier$^{\uparrow}$, MetaCICBetaAudit$^{\uparrow}$, *chapter 791,* SubjectReductionDischargeSocket$^{\uparrow}$, MetaCICConfluenceSubstitutionBoundary$^{\uparrow}$, NormalFormConsistencySe BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{MetaCICClosureSubstitutionFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, K, S, O, R, H, C, P, N$. It has no coordinate for closed subject reduction, full confluence, normalization, conversion typing, quotient equality of terms, hidden substitution admissibility, or kernel consistency.

Theorem 7682.2 (MetaCIC closure-substitution frontier NameCert obligations)**.** *For every accepted* MetaCICClosureSubstitutionFrontier$^{\uparrow}$ *carrier $F = (B, K, S, O, R, H, C, P, N)$, the local* NameCert$_{\text{MetaCICClosureS}}$ *surface consists exactly of carrier admission for beta triggers,* ClosedAt *preservation, substitution-boundary retention, obstruction retention, subject-reduction frontier exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any subject-reduction consumer must read the route*

$$B, K, S, O \longmapsto R$$

before it may consume the socket-facing row.

Proof. Project the carrier of Definition 7682.1. The displayed rows are exactly the beta triggers, closedness-preservation row, substitution-boundary row, obstruction row, subject-reduction frontier row, and structural rows.

The beta audit contributes B. Its direct beta trigger and binder-domain triggers identify where reduction starts, but they do not by themselves provide typed preservation.

The closure-preservation audit contributes K. It keeps ClosedAt stable through shift, substitution, one-step beta, and finite beta chains, while leaving the typed substitution boundary S visible.

The obstruction row O records the dependent-codomain and binder-domain typing boundaries. The subject-reduction frontier row R can therefore be read only after B, K, S, O are displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores subject reduction, confluence, normalization, conversion typing, quotient equality, hidden substitution admissibility, or kernel consistency, the listed rows exhaust the local obligation surface. □

Theorem 7682.3 (MetaCIC closure-substitution frontier subject-reduction boundary)**.** *Every subject-reduction-facing consumer of an accepted* MetaCICClosureSubstitutionFrontier$^{\uparrow}$ *packet must expose the beta-trigger row B, the* ClosedAt *preservation row K, the substitution-boundary row S, and the obstruction row O before the discharge socket row R is available. The packet may hand closed beta-trigger data to the subject-reduction socket, confluence substitution boundary, or normal-form consistency seal, but it does not discharge beta-substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, confluence, normalization, or consistency.*

Proof. Begin with the beta-trigger row B. It names the syntactic redex and congruence sources from the beta audit map, so it fixes where the consumer is allowed to inspect reduction.

Read the closedness row K next. This row supplies ClosedAt preservation through the closure-preservation audit route, but the row is still a closedness statement rather than a typed preservation statement.

The substitution-boundary row S and obstruction row O retain the typed interfaces touched by substitution through binders, dependent codomains, lambda domains, and Pi domains. They must remain visible before R can be read.

The discharge socket row R is therefore only a frontier exposure. It may feed the sibling socket and boundary chapters, but none of the missing preservation, confluence, normalization, or consistency claims is a coordinate of the carrier. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}$ read exposes BetaStep trigger, ClosedAt preservation, substitution-boundary, obstruction, transport, replay, provenance, and local NameCert rows before any subject-reduction consumer inspects the socket-facing row.

Independence witness: metacicbetaaudit, metacicclosurepreservationaudit, subject-reduction-discharge-socket, metacic-confluence-substitution-boundary, normal-form-consistency-seal: the beta audit records reduction triggers without the closedness-to-substitution frontier, the closure-preservation audit records ClosedAt stability without typed discharge, the subject-reduction socket records discharge rows without beta-trigger provenance, the confluence substitution boundary records residual substitution premises without the subject-reduction frontier row, and the normal-form consistency seal records endpoint consistency boundaries without the substitution-frontier carrier. None is bijective with the complete beta-trigger, closedness, substitution-boundary, obstruction, subject-reduction, transport, replay, provenance, and local NameCert packet.

The later Lean TasteGate file for this route must include explicit Nontrivial $\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}$ and FieldFaithful $\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}$ instances whose fields project $B, K, S, O, R, H, C, P, N$ separately.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}$ packet is generated from beta-trigger rows, ClosedAt preservation rows, substitution-boundary rows, obstruction rows, subject-reduction frontier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7682.1, Definition 7682.2, and Definition 7682.3 seed the finite closure-substitution frontier over beta-trigger, ClosedAt, substitution-boundary, obstruction, subject-reduction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close beta-substitution preservation, application-argument stability, lambda-domain preservation, Pi-domain preservation, subject reduction, confluence, normalization, conversion typing, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, BetaStep trigger exposure, ClosedAt preservation, substitution-boundary retention, obstruction retention, subject-reduction frontier exposure, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICClosureSubstitutionFrontierUp.

Chapter 7683

A Concrete Naming Certificate for $\mathsf{VitaliCoveringLemma}^{\uparrow}$

Following Vitali and Bishop–Bridges finite covering practice, the $\mathsf{VitaliCoveringLemma}^{\uparrow}$ packet records the displayed finite-gauge route by which admissible cover rows yield a disjoint finite subfamily and a finite covering handoff. It sits after the gauge presentation of chapter 4302, the disjoint selection surface of chapter 2184, the finite subcover ledger of chapter 6125, the regular rational readback rows of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite gauge requests, candidate cover rows, disjoint selection rows, coverage handoff rows, rational readback, real sealing, componentwise transport, displayed replay, provenance, and local naming; it does not import a host Vitali theorem, countable choice, measure completion, selected infinite subfamilies, quotient point equality, or ambient real completeness.

Definition 7683.1 (Vitali covering lemma carrier)**.** *A* $\mathsf{VitaliCoveringLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, V, A, S, C, F, R, E, H, K, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GaugeSpace}^{\uparrow}$ *row naming the finite gauge family and tolerance request.*
2. *V is the* $\mathsf{VitaliCover}^{\uparrow}$ *cover row that admits candidate cells for the displayed gauge request.*
3. *A is the candidate-admission ledger; each accepted cell carries its source point, gauge radius, and membership witness.*
4. *S is the selected disjoint finite subfamily, stored as a closed* $\mathsf{ProbeBundle}$ *over rows from A.*
5. *C is the coverage ledger recording which displayed request windows are covered after S has been read.*
6. *F is the* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *handoff row exposed to compactness, differentiation, maximal-function, or integration consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for radius and tolerance comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for real-valued radius, size, or bound reads.*
9. *H records componentwise* hsame *transport for gauge, cover, candidate, selection, coverage, subcover, readback, seal, replay, provenance, and naming rows.*

10. *K records displayed* Cont *replay from a finite-gauge Vitali request through G, V, A, S, C, F, R, E in that order.*
11. *P is the* Pkg *provenance over* $\mathsf{VitaliCoveringLemma}^{\uparrow}$, $\mathsf{GaugeSpace}^{\uparrow}$, $\mathsf{VitaliCover}^{\uparrow}$, $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VitaliCoveringLemma}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host-level Vitali selection, measure completion, selected countable subfamilies, quotient point equality, selected representatives, or ambient real completeness.

Theorem 7683.2 (Vitali covering lemma NameCert obligations)**.** *For every accepted* $\mathsf{VitaliCoveringLemma}^{\uparrow}$ *carrier $L = (G, V, A, S, C, F, R, E, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VitaliCoveringLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite gauge row, Vitali cover row, candidate-admission ledger, selected disjoint finite subfamily, coverage ledger, finite subcover handoff, regular-rational readback, real seal, componentwise transport, displayed replay, package provenance, and local naming. No obligation is discharged by host Vitali selection, countable choice, measure completion, selected infinite subfamilies, quotient point equality, selected representatives, or ambient real completeness.*

Proof. Project the carrier of Definition 7683.1. The projection exposes exactly the gauge row G, cover row V, candidate ledger A, selected disjoint subfamily S, coverage ledger C, finite subcover handoff F, readback row R, seal row E, and structural rows H, K, P, N.

The continuation row K fixes the order of inspection. A covering request first reads the finite gauge row and the Vitali cover row, then admits candidate cells, selects a displayed disjoint finite subfamily, records its coverage ledger, and only then exposes the finite subcover handoff.

Since the carrier contains no row for host-level Vitali selection, countable choice, measure completion, selected infinite subfamilies, quotient point equality, selected representatives, or ambient real completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7683.3 (Vitali covering lemma finite disjoint handoff)**.** *Every compactness, differentiation, maximal-function, or integration consumer of an accepted* $\mathsf{VitaliCoveringLemma}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{GaugeSpace}^{\uparrow},\ \mathsf{VitaliCover}^{\uparrow},\ A,\ S,\ C,\ \mathsf{FiniteSubcoverLedger}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before it receives a covering handoff. Thus the public output is a displayed disjoint finite subfamily together with a finite coverage ledger, not a host theorem, selected infinite subfamily, measure-completion object, quotient point equality, or ambient completeness assertion.

Proof. Begin with a consumer request. By Definition 7683.2, the request must inspect the gauge row, the Vitali cover row, the candidate ledger, and the selected finite subfamily before any coverage ledger is available.

The coverage row C is the only source for the finite subcover handoff F. The regular rational row R and the real seal E read radius and bound comparisons only after this finite route has been displayed.

The structural rows H, K, P, N preserve the same order under transport, replay, provenance, and local naming. Therefore no downstream consumer can bypass the disjoint finite subfamily or read excluded host-level selection and completeness data from the packet. □

Falsifiable prediction: Every accepted $\mathsf{VitaliCoveringLemma}^{\uparrow}$ read displays one GaugeSpaceUp row, one VitaliCoverUp row, one candidate-admission ledger, one selected disjoint finite ProbeBundle subfamily, one coverage ledger, one FiniteSubcoverLedgerUp handoff, one RegSeqRatUp readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: gauge-space, vitali-cover, finite-subcover-ledger, regseqrat, real: $\mathsf{VitaliCoveringLemma}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite gauge requests, cover candidates, disjoint selected subfamilies, finite coverage handoff, rational readback, real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{VitaliCoveringLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{VitaliCoveringLemma}^{\uparrow}$ packet is generated from a finite GaugeSpace row, a VitaliCover row, candidate-admission ledger, selected disjoint finite subfamily, coverage ledger, FiniteSubcoverLedger handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VitaliCoveringLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7683.1, Definition 7683.2, and Definition 7683.3 seed the finite gauge-controlled Vitali covering lemma packet over GaugeSpaceUp, VitaliCoverUp, FiniteSubcoverLedgerUp, RegSeqRatUp, RealUp, ProbeBundle, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VitaliCoveringLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable Vitali selection, measure completion, selected infinite subfamilies, quotient point equality, selected representatives, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate-cell admissibility, disjoint finite selection, coverage exactness, finite-subcover handoff, readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.VitaliCoveringLemmaUp.

Chapter 7684

A Concrete Naming Certificate for $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$

Following Riemann and Darboux, the $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$ packet records the finite discontinuity ledger by which a bounded real function on a displayed compact interval is admitted to the Riemann-integrability route. It sits beside the Riemann integral readback of chapter 1526, the Darboux finite-sum surface of chapter 1880, the regulated Darboux ledger of chapter 7650, and the regular rational seal of chapter 301. The packet names only a finite discontinuity ledger and its Darboux cover; it does not import measure-zero sets, a Lebesgue criterion, quotient function equality, selected partitions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7684.1 (Riemann integrability discontinuity carrier)**.** *A* $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, L, C, U, V, G, R, E, H, Q, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval-domain row, naming the endpoints, orientation, and compact interval on which the read is made.*
2. *F is the bounded-function window row, exposing only the finitely many function observations requested by the surrounding Riemann and Darboux consumers.*
3. *L is the finite discontinuity ledger, listing the displayed discontinuity names and the local interval windows assigned to them.*
4. *C is the continuity-off-ledger cover row, recording that every cell outside the windows carried by L is read through a displayed continuity certificate.*
5. *U is the upper-window row, carrying the Darboux upper estimates over the ledger windows and the continuity cells.*
6. *V is the lower-window row, carrying the Darboux lower estimates over the same displayed partition cells.*
7. *G is the finite gap row, comparing the upper and lower Darboux rows against a requested dyadic tolerance.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed finite gap budget.*

9. *E is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *handoff row, exposed only after I, F, L, C, U, V, G, R are visible.*
10. *H records componentwise* hsame *transport for the interval, bounded-function window, discontinuity ledger, cover, Darboux rows, gap, readback, handoff, replay, provenance, and local naming rows.*
11. *Q records displayed* Cont *replay from the interval and bounded-function request through the discontinuity ledger, continuity cover, Darboux finite sums, gap readback, and Riemann handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, L, C, U, V, G, R, E, H, Q, P, N$. It has no coordinate for measure completion, a countable discontinuity set, selected refinement limits, quotient function equality, a host integral operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RiemannIntegrabilityDiscontinuityUp.RiemannIntegrabilityDiscontinuityTasteGate`
`single carrier alignment`

Theorem 7684.2 (Riemann integrability discontinuity NameCert obligations)**.** *For every accepted* $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$ *carrier*

$$D = (I, F, L, C, U, V, G, R, E, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval-domain, bounded-function window, finite discontinuity ledger, continuity-off-ledger cover, upper and lower Darboux rows, gap row, regular readback, Riemann handoff, transport, replay, provenance, and local naming rows;*
2. *ledger finiteness, requiring L to list only finitely many displayed discontinuity windows over the interval row I;*
3. *continuity cover exactness, requiring C to cover every displayed partition cell not assigned to a row of L;*
4. *Darboux gap control, requiring U, V, G to compare lower and upper finite sums only over the displayed ledger windows and continuity cells;*
5. *Riemann handoff nonescape, requiring E to be read only after the finite ledger, cover, Darboux gap, and regular readback rows are visible.*

Thus the packet supplies a finite discontinuity route into Riemann integrability, not a measure-theoretic criterion, quotient-function theorem, selected partition limit, or ambient completeness principle.

Proof. Project the carrier of Definition 7684.1. The only analytic rows are $I, F, L, C, U, V, G, R, E$; the remaining rows H, Q, P, N transport, replay, source, and name that same packet.

First read the discontinuity ledger. The row L is finite and names exactly the discontinuity windows that may contribute exceptional oscillation. The row C covers the complement of those displayed windows by local continuity data, so no hidden discontinuity set is available.

Next read the Darboux comparison. The rows U and V compute upper and lower finite sums over the same displayed cells, and G compares their gap against the requested dyadic budget. The

regular readback row R makes that comparison visible before any Riemann-facing handoff can be consumed.

Finally read E, H, Q, P, N. The handoff E is downstream of the ledger, cover, Darboux gap, and readback rows, while the structural rows preserve only the same finite route. Since the carrier has no coordinate for measure-zero reasoning, quotient functions, selected limits, countable choice, or ambient completeness, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}$ surface. □

Theorem 7684.3 (Riemann integrability finite-discontinuity cover)**.** *Every accepted* RiemannIntegrabilityDiscontinu *packet that exposes a finite discontinuity ledger L and continuity-off-ledger cover C routes any* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer through the finite Darboux comparison*

$$I, F, L, C \longmapsto U, V \longmapsto G \longmapsto R \longmapsto E.$$

Consequently a finite discontinuity ledger over a displayed compact interval is enough BEDC data for the Riemann handoff row, while measure-zero sets, countable exceptional families, selected mesh limits, quotient function equality, host integration, and ambient $\mathsf{Real}^{\uparrow}$ *completeness remain outside the packet.*

Proof. Start from the NameCert obligations of Definition 7684.2. They force the ledger row L and the continuity cover row C to be visible before the Darboux upper and lower rows are read.

The Darboux rows U, V are finite rows over the same displayed interval and partition cells. Their comparison row G is therefore a finite upper-minus-lower budget, and the regular readback R exposes that budget to the Riemann-facing row.

Apply the Riemann handoff nonescape clause. The row E can be inspected only after I, F, L, C, U, V, G, R have been displayed, with H, Q, P, N preserving the same packet. This proves the stated finite cover route and blocks all measure, quotient, choice, host-integration, and ambient-completeness readings. □

Falsifiable prediction: An accepted $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$ read that reaches a $\mathsf{RiemannIntegral}^{\uparrow}$ handoff without displaying the interval row, bounded-function window, finite discontinuity ledger, continuity-off-ledger cover, Darboux upper and lower rows, finite gap row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 7684.1.

Independence witness: riemannintegral, darbouxsum, regulated-darboux-sum, regseqrat: RiemannIntegrabilityD is not bijective with any listed sibling because it jointly carries a finite discontinuity ledger, an off-ledger continuity cover, paired Darboux rows, a finite gap readback, a Riemann handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$ packet is generated from a Real interval-domain row, bounded-function window, finite discontinuity ledger, continuity-off-ledger cover, Darboux upper and lower rows, finite gap row, RegSeqRat readback, RiemannIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7684.1, Definition 7684.2, and Definition 7684.3 seed the finite discontinuity-ledger route into Riemann integrability over interval, Darboux, regular readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-zero criteria, countable exceptional families, quotient function equality, selected refinement limits, host integration, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite ledger finiteness, continuity-off-ledger cover exactness, Darboux gap control, Riemann handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannIntegrabilityDiscontinuityUp.

Chapter 7685

A Concrete Naming Certificate for $\mathsf{FiniteHausdorffMetric}^{\uparrow}$

Following Hausdorff and Bishop–Bridges constructive metric analysis, the $\mathsf{FiniteHausdorffMetric}^{\uparrow}$ packet records the finite separated metric surface on which a finite point family carries displayed pairwise distance rows before any Hausdorff or completion-facing consumer reads it. It sits over the metric carrier of chapter 57, the separated comparison boundary of chapter 1411, the finite-cardinal row of chapter 7673, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite metric certificate; it is not an open-cover compactness theorem, quotient completion object, selected dense subset, countable-choice schedule, or ambient completeness claim for $\mathsf{Real}^{\uparrow}$.

Definition 7685.1 (Finite Hausdorff metric carrier)**.** *A* $\mathsf{FiniteHausdorffMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, E, D, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row, carrying the point classifier and distance observations used by the finite family.*
2. *E is the finite enumeration row naming the admitted points and the finite-cardinal boundary through which the carrier is inspected.*
3. *D is the full pairwise distance ledger on the enumerated points, with every distance read through the same* $\mathsf{Met}^{\uparrow}$ *row.*
4. *S is the separatedness ledger: every zero-distance row in D is routed back to point-classifier identity on the enumerated carrier.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for positive-radius, equality-threshold, and Hausdorff-facing comparisons.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for X, E, D, S, Q, R and the local certificate row.*
8. *C records displayed* Cont *replay of the finite route from the metric source and enumeration through the pairwise ledger, separatedness ledger, dyadic tolerance ledger, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteHausdorffMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, $\mathsf{FiniteCardinal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetric}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient point equality, open-cover compactness, selected dense subsets, host finite subsets, countable choice, completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7685.2 (Finite Hausdorff metric NameCert obligations)**.** *For every accepted* $\mathsf{FiniteHausdorffMetric}^{\uparrow}$ *carrier* $F = (X, E, D, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed metric source, finite enumeration, pairwise distance ledger, separatedness ledger, dyadic tolerance ledger, Real seal row, componentwise transport, displayed replay, package provenance, and local naming. Every Hausdorff-facing read must expose* E, D, S, Q *before* R *can be consumed, and the ledger exports no quotient equality, open-cover compactness, selected dense subset, host finite subset, countable-choice schedule, completion class, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 7685.1. The metric row is X, the finite carrier row is E, and the metric data are exactly the pairwise ledger D together with the separatedness ledger S and dyadic tolerance ledger Q.

The finite enumeration is prerequisite data. A Hausdorff-facing or completion-facing consumer can read a point only after it appears in E, and can read a distance only after the corresponding pairwise row in D has been displayed.

Separatedness is internal to the same finite route. The row S routes zero-distance witnesses back through the point classifier of X, while Q records the dyadic tolerance comparisons used by positive-radius and Hausdorff bounds. Thus the route cannot be replaced by quotient equality or a host finite subset.

Finally read the Real seal and structural rows. The $\mathsf{Real}^{\uparrow}$ seal R exposes only the already displayed finite metric data, while H, C, P, N transport, replay, source, and name the same packet. □

Theorem 7685.3 (Finite separated metric Hausdorff handoff)**.** *Every metric, Hausdorff-metric, or completion-facing consumer of an accepted* $\mathsf{FiniteHausdorffMetric}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{Met}^{\uparrow},\ E,\ D,\ S \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer receives enumerated points, pairwise distance rows, zero-distance classifier return, dyadic tolerance comparisons, and the terminal Real seal as displayed rows. It receives no quotient completion object, selected dense subset, open-cover compactness theorem, countable-choice schedule, host finite subset, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a consumer of the accepted packet. Carrier admission forces the entry point to be the displayed $\mathsf{Met}^{\uparrow}$ row X and the finite enumeration row E.

Open the pairwise ledger next. The row D supplies all distance reads on the enumerated carrier, and S supplies the separatedness return from zero distance to classifier identity on that same finite carrier.

The dyadic and Real rows are downstream. The $\mathsf{DyadicRatCore}^{\uparrow}$ ledger Q records the comparison budget used by Hausdorff-facing reads, and the $\mathsf{Real}^{\uparrow}$ seal R is reached only after the finite metric and separatedness rows have already been displayed. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetric}^{\uparrow}}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteHausdorffMetric}^{\uparrow}}, \mathsf{seed})$
Scope closed: Definition 7685.1, Definition 7685.2, and Definition 7685.3 seed the finite separated metric route over displayed MetricSpace, separatedness, finite enumeration, dyadic tolerance, and Real seal rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteHausdorffMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality, open-cover compactness, selected dense subsets, host finite subsets, countable choice, completion classes, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, pairwise distance ledger exactness, separatedness return, dyadic tolerance transport, Real seal nonescape, replay, provenance, and local naming for BEDC.Derived.FiniteHausdorffMetricUp.

Constructive story: A FiniteHausdorffMetric$^{\uparrow}$ packet is generated from a MetricSpaceUp row, finite enumeration, pairwise distance ledger, separatedness ledger, DyadicRatCoreUp tolerance row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 7686

A Concrete Naming Certificate for $\mathsf{AsymptoticCone}^{\uparrow}$

Following Gromov's asymptotic-cone large-scale metric construction, the $\mathsf{AsymptoticCone}^{\uparrow}$ packet records the finite scaling-window surface by which a pointed metric family is read at increasing scales. It replaces nonprincipal ultrafilters and selected limiting cones by explicit scale ledgers, finite metric-ball windows, dyadic tolerance rows, regular rational readback, and a terminal Real seal. The packet sits beside the metric carrier of chapter 57, the ball-window surface of chapter 1450, the dyadic ledger of chapter 291, the finite observation discipline of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38.

Definition 7686.1 (AsymptoticCone carrier)**.** *An* $\mathsf{AsymptoticCone}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, o, S, B, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, naming only the displayed distance comparisons available to the packet.*
2. *o is the basepoint row attached to the same metric source.*
3. *S is the scaling ledger, a finite list of scale requests and comparison budgets.*
4. *B is the* $\mathsf{MetricBall}^{\uparrow}$ *window row, recording which bounded metric balls are inspected after rescaling.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the finite window schedule.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare rescaled distances.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distance families.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, B, W, D, R have been displayed.*
9. *H records componentwise* hsame *transport for the metric, basepoint, scale, ball-window, stream, dyadic, regular-rational, Real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a scaling-window request through the same rows.*
11. *P is the* Pkg *provenance over* $\mathsf{AsymptoticCone}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{AsymptoticCone}^\uparrow}$ *row.*
The carrier has no coordinate for a nonprincipal ultrafilter, a selected metric limit, a quotient cone, host real equality, or ambient completeness of the source metric or $\mathsf{Real}^\uparrow$*.*

Theorem 7686.2 (AsymptoticCone NameCert obligations)**.** *For every accepted* $\mathsf{AsymptoticCone}^\uparrow$ *carrier*

$$A = (M, o, S, B, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AsymptoticCone}^\uparrow}$ *surface consists exactly of metric-source admission through M, o, scaling-window exposure through S, bounded ball-window exposure through B, finite stream observation through W, dyadic tolerance comparison through D, regular rational readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7686.1. The metric and basepoint rows M, o are the only source rows, and the scaling ledger S names exactly the scale requests visible to the packet.

The bounded windows are displayed before any Real-facing read. The row B supplies the metric balls, W lists the finite observation schedule, D supplies dyadic tolerance comparisons, and R supplies the regular rational readback used by the terminal seal E.

Finally H, C, P, N transport, replay, source, and name the same displayed packet. Since no coordinate contains an ultrafilter, selected limit, quotient cone, host equality, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 7686.3 (AsymptoticCone scaling window)**.** *Every coarse-metric consumer of an accepted* $\mathsf{AsymptoticCone}^\uparrow$ *carrier must read the finite route*

$$\mathsf{Met}^\uparrow,\ \mathsf{MetricBall}^\uparrow,\ \mathsf{DyadicRatCore}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow,\ \mathsf{Real}^\uparrow$$

through the scale ledger S before treating a rescaled distance family as cone-facing data. The route exposes only displayed scale requests, bounded ball windows, finite stream observations, dyadic tolerances, regular rational readbacks, and terminal Real seals; it exports no nonprincipal ultrafilter, selected limiting point, quotient cone equality, host real equality, or ambient completeness principle.

Proof. Start from the NameCert obligations of Definition 7686.2. They force every accepted read through the metric source, basepoint, scaling ledger, ball-window row, finite observation row, dyadic tolerance row, regular readback row, Real seal, and structural rows.

The scale ledger S controls the order of the read. A consumer can inspect a rescaled distance only after the matching $\mathsf{MetricBall}^\uparrow$ window has been displayed and the dyadic tolerance row has attached a finite comparison budget to that window.

The StreamName, RegSeqRat, and Real rows then provide readback rather than a completed cone object. Because the carrier has no ultrafilter, selected-limit, quotient, host-equality, or completeness coordinate, the scaling-window route cannot export any of those endpoints. □

Falsifiable prediction: Every accepted $\mathsf{AsymptoticCone}^\uparrow$ read exposes MetricUp source data, a basepoint, finite scaling ledgers, MetricBallUp windows, StreamName observations, DyadicRatCore tolerances, RegSeqRat readbacks, RealUp seals, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any cone-facing consumer reads the packet.

Independence witness: metric, metricball, dyadicratcore, streamname, regseqrat, real: none is bijective with $\mathsf{AsymptoticCone}^\uparrow$ because this packet alone binds a pointed metric source, finite scaling ledgers, bounded ball windows, dyadic tolerance budgets, regular rational readbacks, terminal Real seals, transport, replay, provenance, and local naming as one large-scale metric surface.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticCone}^{\uparrow}}$.

Constructive story: An $\mathsf{AsymptoticCone}^{\uparrow}$ packet is generated from a MetricUp source row, a basepoint row, finite scaling ledgers, MetricBallUp bounded windows, StreamName finite observations, DyadicRatCore tolerance rows, RegSeqRat readback rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AsymptoticCone}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7686.1, Definition 7686.2, and Definition 7686.3 seed the finite scaling-window metric packet over displayed metric, ball-window, dyadic, stream, regular-rational, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AsymptoticCone}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close nonprincipal ultrafilters, selected limits, quotient cones, host real equality, ambient metric completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scale-ledger exactness, bounded-window coverage, dyadic tolerance preservation, regular rational readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AsymptoticConeUp.

Chapter 7687

A Concrete Naming Certificate for $\mathsf{RiemannTaggedMesh}^{\uparrow}$

Following Bishop and Bridges on constructive Riemann integration, the $\mathsf{RiemannTaggedMesh}^{\uparrow}$ packet records the finite tagged-mesh surface that sits between displayed interval partitions, tagged cells, Riemann sums, Darboux brackets, and the terminal Riemann-integral handoff. It reads the tagged real partition of chapter 4296, the generic tagged-partition carrier of chapter 7449, the finite Riemann-sum row of chapter 1615, the Darboux bracket row of chapter 1880, the integration endpoint of chapter 1526, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names only a displayed mesh-refinement interface; it does not select a limiting partition family, identify integrands by quotient equality, import measure integration, use countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7687.1 (Riemann tagged mesh carrier)**.** *A* $\mathsf{RiemannTaggedMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, T, U, S, B, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row, exposing the two* $\mathsf{Real}^{\uparrow}$ *endpoints and their displayed orientation.*
2. *T is the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row, listing the finite cells, endpoint reads, tags, and tag-containment witnesses.*
3. *U is the* $\mathsf{TaggedPartition}^{\uparrow}$ *refinement row, recording the finite subdivision comparison between an incoming tagged partition and the carried mesh.*
4. *S is the* $\mathsf{RiemannSum}^{\uparrow}$ *row, carrying the finite tagged-sum reads over the cells of T.*
5. *B is the* $\mathsf{DarbouxSum}^{\uparrow}$ *bracket row, carrying the lower and upper finite-sum comparisons over the same displayed mesh.*
6. *G is the gap ledger, comparing the Riemann-sum row and the Darboux bracket row against the displayed mesh refinement and tolerance request.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite gap and sum data.*
8. *E is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *handoff row, exposed only after I, T, U, S, B, G, R are visible.*
9. *H records componentwise* hsame *transport for interval, tagged partition, refinement, sum, bracket, gap, readback, handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the finite route*

$$I, T, U \longmapsto S, B \longmapsto G \longmapsto R \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{RiemannTaggedMesh}^{\uparrow}$, $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{TaggedPartition}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannTaggedMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, T, U, S, B, G, R, E, H, C, P, N$. It has no coordinate for a selected refinement sequence, a host function space, quotient equality of integrands, measure integration, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7687.2 (Riemann tagged mesh NameCert obligations)**.** *For every accepted* $\mathsf{RiemannTaggedMesh}^{\uparrow}$ *carrier $M = (I, T, U, S, B, G, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannTaggedMesh}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval, tagged real partition, tagged refinement, finite Riemann-sum, Darboux bracket, gap ledger, regular rational readback, Riemann-integral handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every accepted integration-facing read follows the finite route*

$$I, T, U \longmapsto S, B \longmapsto G \longmapsto R \longmapsto E$$

together with H, C, P, N.

Proof. Project the carrier of Definition 7687.1. Its analytic rows are exactly the interval row, tagged real partition, tagged refinement row, finite sum row, Darboux bracket row, gap ledger, regular readback, and integral handoff.

The mesh row is not detached from the partition rows. The row U compares the incoming tagged partition with the carried finite mesh, while T supplies the cells, endpoint reads, and tags on which S and B are evaluated.

The rows S and B are then read over the same displayed cells. The gap row G compares those finite rows against the requested mesh tolerance before R can expose regular rational readback.

Finally E, H, C, P, N preserve the same route toward the Riemann-integral handoff. Since no carrier coordinate stores a selected refinement sequence, host function space, quotient integrand equality, measure integral, choice principle, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 7687.3 (Riemann tagged mesh refinement handoff)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{RiemannTaggedMesh}^{\uparrow}$ *packet must read the* $\mathsf{TaggedRealPartition}^{\uparrow}$ *row, the* $\mathsf{TaggedPartition}^{\uparrow}$ *refinement row, the* $\mathsf{RiemannSum}^{\uparrow}$ *finite-sum row, the* $\mathsf{DarbouxSum}^{\uparrow}$ *bracket row, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before the handoff row E is public. Thus mesh refinement is exposed as finite tagged data and not as a hidden sequence of partitions.*

Proof. Start with the obligation route of Definition 7687.2. It places the handoff row E downstream from I, T, U, S, B, G, R.

The partition data comes first. The tagged real partition T provides cells, tags, and endpoint reads, while the tagged refinement row U records how the carried mesh compares with the incoming finite partition.

The analytic comparison is finite. The Riemann-sum row S and Darboux bracket row B are both read over the displayed mesh, and G records their finite gap before R presents the regular rational readback.

Therefore any Riemann-integral consumer that reaches E has already inspected the finite tagged-mesh interface. A hidden refinement sequence or selected limiting partition is not available in the carrier. □

Theorem 7687.4 (Riemann tagged mesh nonescape)**.** *The* $\mathsf{RiemannTaggedMesh}^{\uparrow}$ *packet exports no selected partition family, host function space, quotient equality of integrands, measure-space integration, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every public read remains inside the displayed interval, tagged partition, refinement, Riemann-sum, Darboux-bracket, gap, regular-readback, integral-handoff, transport, replay, provenance, and local naming rows.*

Proof. Compare the refused objects with the carrier inventory of Definition 7687.1. None is one of $I, T, U, S, B, G, R, E, H, C, P, N$.

The positive route is supplied by Definition 7687.3. It keeps every integration-facing read behind the finite tagged partition, refinement, sum, bracket, gap, and readback rows before the handoff is consumed.

Transport through H, replay through C, provenance through P, and local naming through N do not add new analytic coordinates. The packet therefore cannot escape to host partitions, quotient functions, measure integration, choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RiemannTaggedMesh}^{\uparrow}$ read that reaches a $\mathsf{RiemannIntegral}^{\uparrow}$ handoff exposes $\mathsf{TaggedRealPartition}^{\uparrow}$, $\mathsf{TaggedPartition}^{\uparrow}$, $\mathsf{RiemannSum}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows before the handoff is public.

Independence witness: tagged-real-partition, tagged-partition, riemannsum, darboux-sum, riemannintegral, regseqrat, real: $\mathsf{RiemannTaggedMesh}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries interval endpoints, tagged cells, refinement comparison, finite Riemann sums, Darboux brackets, gap readback, integral handoff, transport, replay, provenance, and local naming as one mesh-refinement packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannTaggedMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannTaggedMesh}^{\uparrow}$ packet is generated from interval, TaggedRealPartition, TaggedPartition refinement, RiemannSum, DarbouxSum, gap, RegSeqRat readback, RiemannIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RiemannTaggedMesh}^{\uparrow}}$, seed)

Scope closed: Definition 7687.1, Definition 7687.2, Definition 7687.3, and Definition 7687.4 seed the finite tagged-mesh refinement route over partition, sum, bracket, readback, handoff, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RiemannTaggedMesh}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected partition sequences, host function spaces, quotient integrand equality, measure integration, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tagged-partition exposure, refinement exactness, Riemann-sum exposure, Darboux-bracket exposure, gap readback, Riemann-integral handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannTaggedMeshUp.

Chapter 7688

A Concrete Naming Certificate for $\mathsf{PhysicalTowerRealization}^{\uparrow}$

The $\mathsf{PhysicalTowerRealization}^{\uparrow}$ packet realizes the approximation-tower and ledgered-compression route of section 9414.20 as finite NameCert data. It turns approximation levels, compression arrows, visible endpoints, composite tower ledgers, and endpoint descent checks into one displayed carrier, sitting beside the tower-compression packet of chapter 1142, the regular rational readback of chapter 301, the dyadic tolerance surface of chapter 291, the calculus consumer of chapter 3632, and the terminal real-name seal of chapter 38. The packet records a finite physical approximation tower as a BEDC-native object; it does not identify the physical source with the endpoint, erase hidden ledgers, choose a preferred model, add host physics, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7688.1 (Physical tower realization carrier)**.** *A* $\mathsf{PhysicalTowerRealization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, L, A, E, D, G, R, V, H, C, P, N)$$

with the following displayed rows:

1. *S is the source row, naming the finite physical observation history or finite source window from which the tower is read.*
2. *L is the level row, listing the displayed approximation levels and the classifier bundle visible at each level.*
3. *A is the compression-arrow row, recording source, pattern, classifier, stability, and local ledger fields for each displayed arrow.*
4. *E is the endpoint row, naming the final visible object without identifying it with the source row.*
5. *D is the descent-audit row, recording which endpoint operations descend through the displayed compression classifiers.*
6. *G is the composite-ledger row, pulling every local ledger in A back to the source row S.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for quantitative tolerance, prediction, or comparison entries carried by the tower.*
8. *V is the visible-result row, exposing only the endpoint, descent, ledger, and readback data that the tower makes public.*
9. *H records componentwise* hsame *transport for source, level, arrow, endpoint, descent, ledger, readback, result, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the finite route*

$$S, L, A \longmapsto E, D, G \longmapsto R \longmapsto V.$$

11. *P is the* Pkg *provenance over* PhysicalTowerRealization$^{\uparrow}$, RealityConstrainedTowerCompression$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Calculus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{PhysicalTowerRealization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, L, A, E, D, G, R, V, H, C, P, N$. It has no coordinate for endpoint-source identity, hidden-ledger erasure, a selected best model, host physical law, quotient equality of models, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7688.2 (Physical tower realization NameCert obligations)**.** *For every accepted* PhysicalTowerRealization$^{\uparrow}$ *carrier $T = (S, L, A, E, D, G, R, V, H, C, P, N)$, the local* NameCert$_{\text{PhysicalTowerRealization}^{\uparrow}}$ *surface consists exactly of carrier admission for the source, level, compression-arrow, endpoint, descent-audit, composite-ledger, regular readback, visible-result, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Every public tower read follows the finite route*

$$S, L, A \longmapsto E, D, G \longmapsto R \longmapsto V$$

together with H, C, P, N.

Proof. Project the carrier of Definition 7688.1. The source row, level row, and compression-arrow row provide the displayed tower skeleton.

The endpoint row E is downstream from that skeleton. It names the visible endpoint but does not identify it with S, because the arrow row A keeps the classifiers and local ledgers visible.

The descent-audit row D and composite-ledger row G are the certification rows. They record which endpoint operations descend through the tower and which source-side residues remain after all compression arrows have been composed.

The readback row R and visible-result row V expose only the finite data already carried by S, L, A, E, D, G. Transport, replay, provenance, and local naming preserve that route, so the listed rows exhaust the local NameCert surface. □

Theorem 7688.3 (Physical tower realization vision handoff)**.** *The finite definitions of approximation level, compression arrow, physical approximation tower, visible endpoint, and tower ledger in section 9414.20 are realized by the rows L, A, S, E, G of any accepted* PhysicalTowerRealization$^{\uparrow}$ *carrier. Endpoint claims are public only after the descent-audit row D, composite-ledger row G, regular readback row R, and visible-result row V have been displayed.*

Proof. Read the vision-side tower vocabulary through the carrier rows. Approximation levels are recorded by L, compression arrows by A, the physical source by S, the visible endpoint by E, and the tower ledger by G.

The endpoint row is not self-certifying. The descent-audit row D records which endpoint operations are licensed by the compression classifiers, and the composite-ledger row G keeps the hidden source residues visible.

The public result is then exposed through R and V, with H, C, P, N preserving the same route. Hence the vision route becomes a finite NameCert packet rather than a prose-only modelling claim. □

Theorem 7688.4 (Physical tower realization nonescape)**.** *The* $\mathsf{PhysicalTowerRealization}^{\uparrow}$ *packet exports no endpoint-source identity, no hidden-ledger erasure, no selected preferred model, no host physical law, no quotient equality of models, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Every public read remains inside the displayed source, level, compression-arrow, endpoint, descent-audit, composite-ledger, regular-readback, visible-result, transport, replay, provenance, and local naming rows.*

Proof. Compare the refused objects with the carrier rows of Definition 7688.1. None is a coordinate of $S, L, A, E, D, G, R, V, H, C, P, N$.

The positive public route is supplied by Definition 7688.3. It keeps endpoint claims downstream from the source, level, arrow, descent-audit, composite-ledger, and readback rows.

The structural rows H, C, P, N preserve only that finite route. Therefore a consumer cannot obtain an erased ledger, privileged model selector, host physics law, quotient model equality, or ambient real-completeness principle from the packet. □

Falsifiable prediction: An accepted $\mathsf{PhysicalTowerRealization}^{\uparrow}$ read that exposes an endpoint result without first displaying source, level, compression-arrow, descent-audit, composite-ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ rows refutes the carrier of Definition 7688.1.

Independence witness: reality-constrained-tower-compression, compression-ledger-functor, compression-descent-audit, towerendpointreflection, calculus: $\mathsf{PhysicalTowerRealization}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries a physical source row, approximation levels, compression arrows, endpoint, descent audit, composite ledger, quantitative readback, visible result, transport, replay, provenance, and local naming in one finite packet.

The later Lean TasteGate file for this route must include explicit $\mathsf{Nontrivial}\ \mathsf{PhysicalTowerRealization}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{PhysicalTowerRealization}^{\uparrow}$ instances whose fields project $S, L, A, E, D, G, R, V, H, C, P, N$ separately.

Closure status for $\mathsf{NameCert}_{\mathsf{PhysicalTowerRealization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PhysicalTowerRealization}^{\uparrow}$ packet is generated from finite source, approximation-level, compression-arrow, endpoint, descent-audit, composite-ledger, RegSeqRat readback, visible-result, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PhysicalTowerRealization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7688.1, Definition 7688.2, Definition 7688.3, and Definition 7688.4 seed the finite approximation-tower realization over source, level, compression-arrow, endpoint, descent, ledger, readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PhysicalTowerRealization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close endpoint-source identity, hidden-ledger erasure, preferred-model selection, host physical law, quotient model equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximation-level exposure, compression-arrow ledger exactness, endpoint nonidentity, descent-audit routing, composite-ledger readback, visible-result nonescape, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.PhysicalTowerRealizationU

Chapter 7689

A Concrete Naming Certificate for $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ packet records a bounded map on regular rational names by exposing finite source windows, regular-rational input and output readbacks, a dyadic bound ledger, and the terminal real-name seal before any completion-facing consumer reads the map. It sits over the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the graph replay route of chapter 130. The packet is a bounded regular-sequence map certificate; it is not an ambient function-space object, quotient equality of real names, selected modulus of continuity, countable-choice schedule, or global completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7689.1 (Bounded RegSeqRat map carrier)**.** *A* $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, I, O, B, T, R, G, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, listing exactly the input coordinates inspected before the map graph is replayed.*
2. *I is the* $\mathsf{RegSeqRat}^{\uparrow}$ *input readback row attached to the displayed source windows.*
3. *O is the* $\mathsf{RegSeqRat}^{\uparrow}$ *output readback row produced from the same inspected windows.*
4. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound ledger, carrying the displayed dyadic radius that bounds every output row exposed by O.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the precision requests used to compare input windows, output windows, and the bound row.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, I, O, B, T have been displayed.*
7. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph replay row, exposing the finite graph route from source windows through regular-rational input and output readbacks.*
8. *H records componentwise* hsame *transport for source windows, input readback, output readback, bound ledger, tolerance ledger, real seal, graph replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from* $\mathsf{StreamName}^{\uparrow}$ *windows through* $\mathsf{RegSeqRat}^{\uparrow}$ *input and output readbacks,* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound and tolerance ledgers, the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedRegSeqRatMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient function space, quotient equality of real names, an externally selected continuity modulus, countable choice, host boundedness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7689.2 (Bounded RegSeqRat map NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ *carrier $M = (S, I, O, B, T, R, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedRegSeqRatMap}^{\uparrow}}$ *surface consists exactly of carrier admission for source windows, regular-rational input readback, regular-rational output readback, dyadic bound ledger, dyadic tolerance ledger, terminal real seal, ContinuousMap graph replay, componentwise transport, displayed replay, package provenance, and local naming. Every map-facing read must expose S, I, O, B, T, G before R can be consumed, and the ledger exports no ambient function space, quotient real-name equality, externally selected modulus of continuity, countable-choice schedule, host boundedness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 7689.1. The source row is S, the input and output regular-rational readbacks are I and O, and the dyadic boundedness data are exactly the rows B and T.

The graph route is finite. A map-facing consumer can replay the $\mathsf{ContinuousMap}^{\uparrow}$ row G only after the inspected source windows and both $\mathsf{RegSeqRat}^{\uparrow}$ readbacks have been exposed. Thus the graph is tied to displayed windows rather than to a hidden function-space element.

The terminal seal is downstream. The $\mathsf{Real}^{\uparrow}$ row R is reached only after the bound and tolerance ledgers have been read, while H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient equality, an external continuity modulus, a choice schedule, host boundedness, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7689.3 (Bounded RegSeqRat map uniform bound handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow}_{\mathrm{in}},\quad \mathsf{RegSeqRat}^{\uparrow}_{\mathrm{out}},\quad \mathsf{DyadicRatCore}^{\uparrow}_{\mathrm{bound}},\quad \mathsf{DyadicRatCore}^{\uparrow}_{\mathrm{tol}},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{Re}$$

The bound handoff is the displayed dyadic ledger B, T over the same source windows that produce the output readback. It is not an ambient bounded-function assumption, quotient equality of real names, selected continuity modulus, countable-choice schedule, or global completeness principle.

Proof. Start with a consumer of the terminal seal or completion-facing route. Carrier admission forces the read to begin with the finite source-window row S and the input regular-rational readback I.

Open the map graph next. The $\mathsf{ContinuousMap}^{\uparrow}$ row G replays the route from S and I to the output readback O, so the output cannot be inspected independently of the displayed source windows.

The boundedness handoff is then forced by the dyadic rows. The ledger B supplies the displayed bound and T supplies the tolerance comparisons needed to read that bound against O. Only after these rows are exposed may the consumer reach the $\mathsf{Real}^{\uparrow}$ seal R. □

Falsifiable prediction: An accepted $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ consumer is refuted if it reaches a RealUp seal or completion-facing output without first displaying the StreamName source windows, RegSeqRat input readback, RegSeqRat output readback, DyadicRatCore bound and tolerance ledgers, ContinuousMap graph replay, transport, displayed replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, continuousmap: no listed sibling supplies the full bounded regular-sequence map packet, because only $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ binds source windows, input and output regular-rational readbacks, dyadic bound and tolerance ledgers, graph replay, Real seal, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRegSeqRatMap}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRegSeqRatMap}^{\uparrow}$ packet is generated from StreamName source windows, RegSeqRat input and output readbacks, DyadicRatCore bound and tolerance ledgers, a ContinuousMap graph replay row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRegSeqRatMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7689.1, Definition 7689.2, and Definition 7689.3 seed the finite bounded-map route over StreamName, RegSeqRat, DyadicRatCore, ContinuousMap, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRegSeqRatMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function spaces, quotient real-name equality, selected continuity moduli, countable choice, host boundedness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-window admission, input and output RegSeqRat readback, dyadic bound and tolerance exactness, ContinuousMap graph replay, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BoundedRegSeqRatMapUp.

Chapter 7690

A Concrete Naming Certificate for $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$

Following Schoenflies' planar extension theorem and Jordan's simple closed curve boundary theorem, the $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$ packet records only the finite window in which a displayed Jordan curve, a bounded side ledger, and a compact planar support can be consumed as local planar-domain data. It sits after the side-classification surface of chapter 4365, the degree obstruction rows of chapter 3745, the compact-metric source of chapter 129, the topology carrier of chapter 88, and the circle source of chapter 58. The packet names a finite Jordan-window certificate; it does not assert the full classical Schoenflies extension theorem, a global homeomorphism of the plane, selected complementary components, quotient boundary equality, or open-cover compactness.

Definition 7690.1 (Schoenflies finite Jordan-window carrier)**.** *A* $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (J, D, K, T, S, A, E, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{JordanCurve}^{\uparrow}$ *row naming the simple closed curve, its circle source, polygonal subdivision, winding ledger, orientation row, and side-classification boundary.*
2. *D is the* $\mathsf{BrouwerDegree}^{\uparrow}$ *row used only as a finite obstruction ledger for the displayed boundary orientation.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *support window in which the curve, side ledger, and finite planar cells are inspected.*
4. *T is the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row recording the finite open and closed windows visible to the local domain read.*
5. *S is the* $\mathsf{S}^{1\uparrow}$ *source-boundary row whose parameter windows are consumed by J.*
6. *A is the finite annular collar ledger around the displayed curve, including inside-window, outside-window, and boundary-window rows.*
7. *E is the finite extension-obligation ledger; each row records a local cell correspondence required before a Schoenflies-style handoff may be read.*

8. *H records componentwise* hsame *transport for the Jordan curve, degree, compact-metric, topology, circle, collar, extension-obligation, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from the circle source through the Jordan curve row, the collar ledger, the compact support, and the local topology window before any extension-obligation row is exposed.*
10. *P is the* Pkg *provenance over* $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$, $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host planar homeomorphism, selected complementary component, quotient boundary equality, open-cover compactness theorem, ambient plane completion, or unrestricted Schoenflies extension.

Theorem 7690.2 (Schoenflies finite Jordan-window NameCert obligations)**.** *For every accepted* $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$ *carrier* $W = (J, D, K, T, S, A, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SchoenfliesFiniteJordanW}}$ *surface consists exactly of carrier admission for the Jordan curve row, Brouwer-degree obstruction row, compact-metric support window, topology neighbourhood row, circle source row, finite annular collar ledger, finite extension-obligation ledger, componentwise transport, displayed replay, package provenance, and local naming. Every planar-domain consumer must read the* $\mathsf{JordanCurve}^{\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, *and* $\mathsf{S}^{1\uparrow}$ *rows before it can inspect the collar or extension-obligation rows, and no obligation is discharged by a global Schoenflies theorem.*

Proof. Project the carrier of Definition 7690.1. The projection exposes exactly the Jordan curve row J, degree row D, compact support K, topology window T, circle source S, collar ledger A, extension-obligation ledger E, and structural rows H, C, P, N.

The continuation row C fixes the inspection order. A local planar-domain read starts from the $\mathsf{S}^{1\uparrow}$ source boundary, consumes the $\mathsf{JordanCurve}^{\uparrow}$ side-classification route, reads the $\mathsf{BrouwerDegree}^{\uparrow}$ obstruction ledger and $\mathsf{CompactMetric}^{\uparrow}$ support, and only then inspects the $\mathsf{Topology}^{\uparrow}$ neighbourhood windows, collar rows, and finite extension obligations.

Since the carrier contains no row for a host planar homeomorphism, selected complementary component, quotient boundary equality, open-cover compactness theorem, ambient plane completion, or unrestricted Schoenflies extension, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$ read displays one JordanCurveUp row, one BrouwerDegreeUp obstruction row, one CompactMetricUp support window, one TopologyUp neighbourhood row, one SOneUp source-boundary row, one finite annular collar ledger, one finite extension-obligation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: jordan-curve, brouwer-degree, compactmetric, topology, s1: SchoenfliesFiniteJordanWind is not bijective to any listed sibling because it jointly carries side-classified Jordan boundary data, degree obstruction data, compact support, topology windows, circle source windows, collar rows, finite extension obligations, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchoenfliesFiniteJordanWindow}^{\uparrow}$ packet is generated from a JordanCurve row, BrouwerDegree obstruction row, CompactMetric support window, Topology neighbourhood row, SOne source-boundary row, finite annular collar ledger, finite extension-obligation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SchoenfliesFiniteJordanWindow}\uparrow}$, seed)

Scope closed: Definition 7690.1 and Definition 7690.2 seed the finite Jordan-window packet over JordanCurveUp, BrouwerDegreeUp, CompactMetricUp, TopologyUp, SOneUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{SchoenfliesFiniteJordanWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the full classical Schoenflies extension theorem, a global planar homeomorphism, selected complementary components, quotient boundary equality, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side-classified Jordan boundary routing, degree-obstruction stability, compact support, topology-window exactness, circle-source readback, collar ledger exactness, finite extension obligations, transport, replay, provenance, and local naming for BEDC.Derived.SchoenfliesFiniteJordanWindowUp.

Chapter 7691

A Concrete Naming Certificate for $\mathsf{RationalIntervalTree}^{\uparrow}$

Following Bishop–Bridges constructive real analysis and Farey interval-refinement practice, the $\mathsf{RationalIntervalTree}^{\uparrow}$ packet records a finite tree of rational brackets whose boundary rows refine an interval without selecting a host real representative. It sits between the dyadic arithmetic surface of chapter 291, the finite observation windows of chapter 126, the regular-rational readback route of chapter 301, the terminal real-name seal of chapter 38, the located interval boundary of chapter 1709, and the Farey tree source of chapter 1704. The packet names only finite rational interval nodes, bisection rows, tolerance ledgers, stream windows, regular-rational readback, Real sealing, transport, replay, provenance, and local naming.

Definition 7691.1 (Rational interval-tree carrier)**.** *A* $\mathsf{RationalIntervalTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, L, U, M, B, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite address row naming the inspected refinement path.*
2. *L and U are the lower and upper rational boundary rows for the current node.*
3. *M is the displayed rational midpoint or Farey mediant row used to split the current bracket.*
4. *B is the branch ledger recording which child interval is retained at each inspected refinement step.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint width, midpoint comparison, and child-width budget.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which consumers inspect the finite bracket trace.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational endpoints and displayed tolerance comparisons.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the interval tree, stream window, readback, and dyadic tolerance rows have been displayed.*
9. *H records componentwise* hsame *transport for address, endpoint, midpoint, branch, tolerance, stream, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an interval request through finite refinement, branch selection, tolerance readback, stream exposure, and Real sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It contains no selected real representative, quotient-real equality, host trichotomy, unrestricted nested-interval principle, countable-choice selector, or ambient completeness witness.

Theorem 7691.2 (Rational interval-tree NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalTree}^{\uparrow}$ *carrier* $T = (A, L, U, M, B, Q, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite address row, rational boundary rows, midpoint or mediant row, branch ledger, dyadic tolerance ledger, stream window, regular-rational readback, Real seal, componentwise transport, displayed replay, package provenance, and local naming. No obligation is discharged by selected real representatives, quotient equality, host trichotomy, ambient completeness, or an unlisted infinite refinement object.*

Proof. Project the accepted carrier. The analytic coordinates are $A, L, U, M, B, Q, S, R, E$, and the structural coordinates are H, C, P, N.

The interval-facing rows determine the local obligation surface. The address row names the finite path, the boundary rows name the current bracket, the midpoint or mediant row names the split, and the branch ledger records the retained child.

The readback rows determine every downstream approximation. The dyadic tolerance ledger supplies the width and comparison budgets; the stream row exposes finite windows; the regular-rational row reads the endpoints; and the Real seal is reached only after those rows have been displayed.

Transport, replay, provenance, and naming preserve the same inventory. Since the carrier has no coordinate for selected representatives, quotient equality, trichotomy, ambient completeness, or an unlisted infinite refinement object, the listed rows exhaust the local certificate. □

Theorem 7691.3 (Rational interval-tree bisection window)**.** *Every finite bisection or Farey-refinement read of an accepted* $\mathsf{RationalIntervalTree}^{\uparrow}$ *carrier factors through the displayed route*

$$A, L, U, M, B, Q, S, R, E, H, C, P, N.$$

Before any Real-facing approximation is public, the consumer has already read the boundary pair L, U, the split row M, the retained-child ledger B, the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row Q, the* $\mathsf{StreamName}^{\uparrow}$ *window S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The route exports no selected limit, quotient equality, host order trichotomy, or ambient Real completeness.*

Proof. Induct over the finite address row A. At the root window, the packet displays the initial rational boundary pair L, U together with its tolerance ledger Q.

For a successor window, read the split row M and the branch ledger B. The retained child interval is one of the two displayed rational brackets, and the dyadic row records the corresponding width and comparison budget.

The public approximation boundary is then forced by the readback rows. The stream window S exposes the inspected finite trace, the regular-rational row R reads the rational endpoints, and the Real seal E is downstream of both.

Thus every finite bisection or Farey-refinement consumer sees the displayed interval-tree window before it can read a Real-facing approximation, and the excluded host-level objects have no carrier coordinate from which they could be recovered. □

Falsifiable prediction: Every accepted RationalIntervalTreeUp packet exposes a finite rational boundary pair, one split row, one retained-child ledger, one dyadic tolerance row, one StreamName window, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-real-interval, sternbrocot: $\mathsf{RationalIntervalTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite interval-tree addresses, rational boundary rows, split rows, retained-child ledgers, dyadic tolerances, finite observation windows, regular-rational readback, Real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalTree}\uparrow}$.

Constructive story: A $\mathsf{RationalIntervalTree}^{\uparrow}$ packet is generated from a finite address row, rational lower and upper boundary rows, a midpoint or Farey-mediant split row, retained-child ledger, DyadicRatCore tolerance row, StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalTree}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7691.1, Definition 7691.2, and Definition 7691.3 seed the finite rational interval-refinement tree packet between dyadic interval arithmetic, regular-rational readback, located intervals, Stern–Brocot refinement, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalTree}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected real representatives, quotient-real equality, host trichotomy, unrestricted nested-interval completeness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, split exactness, branch retention, dyadic tolerance readback, stream-window exposure, regular-rational readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RationalIntervalTreeUp.

Chapter 7692

A Concrete Naming Certificate for $\mathsf{TakagiFunction}^{\uparrow}$

Following Takagi's continuous nowhere-differentiable dyadic tent-map example, the $\mathsf{TakagiFunction}^{\uparrow}$ packet records the finite BEDC carrier needed to read a dyadic polygonal stage, its uniform tail budget, and the terminal real-function seal without importing host real equality. It sits over the dyadic arithmetic of chapter 291, the dyadic subdivision surface of chapter 1863, the uniform-limit route of chapter 463, the real-name seal of chapter 38, and the graph replay discipline of chapter 130. The packet is a constructive real-analysis boundary object for the finite dyadic-to-Real route; it is not a completed differentiability theory, quotient equality of functions, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7692.1 (Takagi function carrier)**.** *A* $\mathsf{TakagiFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, S, A, B, U, R, G, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, carrying dyadic endpoints, midpoint distances, powers of two, and comparison slack used by every displayed tent-map stage.*
2. *S is the* $\mathsf{DyadicPartition}^{\uparrow}$ *subdivision row, listing the finite dyadic cells on which the carried stage is affine.*
3. *A is the stage-amplitude row, recording the displayed tent contribution*

   $$2^{-k}\tau(2^k x)$$

   only through dyadic rational reads on the cells supplied by S.
4. *B is the finite partial-sum ledger, adding the displayed stage contributions through a bounded dyadic sum over the carried stage window.*
5. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *tail row, carrying the displayed dyadic estimate that the remaining stages after the window have total size at most the requested tolerance.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after D, S, A, B, U have been displayed.*
7. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph replay row, exposing the finite polygonal route from dyadic input windows to real-name output windows.*

8. *H records componentwise* hsame *transport for dyadic arithmetic, subdivision, stage amplitudes, partial sums, uniform tail estimates, real seal, graph replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from*

$$D, S \longmapsto A \longmapsto B \longmapsto U \longmapsto G \longmapsto R$$

and then through the structural rows.

10. *P is the* Pkg *provenance over* $\mathsf{TakagiFunction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TakagiFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, A, B, U, R, G, H, C, P, N$. It has no coordinate for a global differentiability predicate, derivative values, host real equality, quotient equality of functions, countable choice, selected infinite series witnesses, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7692.2 (Takagi function NameCert obligations)**.** *For every accepted* $\mathsf{TakagiFunction}^{\uparrow}$ *carrier $T = (D, S, A, B, U, R, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TakagiFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row,* $\mathsf{DyadicPartition}^{\uparrow}$ *subdivision row, stage-amplitude row, finite partial-sum ledger,* $\mathsf{UniformLimit}^{\uparrow}$ *tail row, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph replay row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real-facing read follows the displayed route*

$$D, S \longmapsto A \longmapsto B \longmapsto U \longmapsto G \longmapsto R$$

together with H, C, P, N.

Proof. Project the carrier of Definition 7692.1. Its displayed rows are exactly dyadic arithmetic, dyadic subdivision, stage amplitudes, finite partial sums, uniform tail estimates, the terminal real seal, graph replay, transport, replay, provenance, and local naming.

The stage route is finite. The subdivision row supplies the cells, the dyadic arithmetic row supplies the midpoint-distance and scale comparisons, and the stage-amplitude row reads the tent contribution only on those displayed cells.

The partial-sum and tail rows control the handoff to the real-name surface. The ledger B exposes the finite sum actually carried by the packet, while U exposes the dyadic bound for the omitted stage tail before any consumer reaches G or R.

Transport through H, replay through C, provenance through P, and local naming through N preserve the same route. Since no carrier coordinate stores a derivative predicate, host real equality, quotient function equality, countable-choice schedule, selected infinite series witness, or ambient completeness theorem, the listed rows exhaust the local NameCert surface. □

Theorem 7692.3 (Takagi function dyadic uniform-limit boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or* $\mathsf{ContinuousMap}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{TakagiFunction}^{\uparrow}$ *packet must pass through the finite dyadic route*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, stage amplitude, partial sum, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$

The boundary exported by the packet is the displayed uniform-limit estimate for dyadic tent-map stages. It is not a proof of full nowhere-differentiability, host real equality, quotient equality of functions, countable choice, selected infinite series data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with any consumer of the graph row or terminal seal. Carrier admission forces the read to expose D and S, so the dyadic cells and arithmetic comparisons are visible before any stage value is inspected.

Next read A and B. These rows record only finitely many tent-map stage contributions and their displayed dyadic partial sum, so the consumer receives a finite polygonal approximation rather than an external infinite series object.

Finally read U, G, R. The uniform-limit row supplies the dyadic tail estimate that permits the graph replay and real-name seal to be consumed. Because the carrier has no coordinate for derivative data, quotient equality, choice, selected series witnesses, or ambient completeness, the exported boundary is exactly the dyadic uniform-limit route. □

Falsifiable prediction: An accepted $\mathsf{TakagiFunction}^{\uparrow}$ consumer is refuted if it reaches a $\mathsf{ContinuousMap}^{\uparrow}$ graph row or $\mathsf{Real}^{\uparrow}$ seal without first displaying the $\mathsf{DyadicRatCore}^{\uparrow}$ arithmetic row, $\mathsf{DyadicPartition}^{\uparrow}$ subdivision row, stage amplitudes, finite partial-sum ledger, $\mathsf{UniformLimit}^{\uparrow}$ tail estimate, transport, displayed replay, provenance, and local naming rows.

Independence witness: dyadicratcore, dyadic-partition, uniform-limit, real, continuousmap: no listed sibling supplies the complete Takagi-function packet, because only $\mathsf{TakagiFunction}^{\uparrow}$ binds dyadic arithmetic, dyadic subdivision, tent-map stage amplitudes, finite partial sums, uniform tail estimates, graph replay, Real seal, transport, replay, provenance, and local naming as one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{TakagiFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{TakagiFunction}^{\uparrow}$ packet is generated from DyadicRatCore arithmetic, dyadic subdivision rows, tent-map stage amplitudes, finite partial sums, a UniformLimit tail estimate, a ContinuousMap graph replay row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TakagiFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7692.1, Definition 7692.2, and Definition 7692.3 seed the finite dyadic tent-map route over DyadicRatCore, dyadic subdivision, partial sums, uniform tail estimates, ContinuousMap, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TakagiFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full differentiability theory, host real equality, quotient equality of functions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic arithmetic admission, dyadic subdivision exposure, stage-amplitude readback, finite partial-sum exactness, UniformLimit tail control, ContinuousMap graph replay, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TakagiFunctionUp.

Chapter 7693

A Concrete Naming Certificate for $\mathsf{KirchhoffMatrixTree}^{\uparrow}$

Following Kirchhoff's matrix-tree theorem, the $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ packet records the finite route that turns a graph incidence ledger into a Laplacian matrix, deletes one row and one column, reads the determinant of the minor, and exposes the resulting spanning-tree count as a displayed certificate. It sits over the graph carrier of chapter 118, the acyclic connected carrier of chapter 119, the spanning-tree selection surface of chapter 237, the finite matrix row of chapter 49, and the determinant row of chapter 84. The packet is a finite combinatorics bridge; it does not import spectral graph theory, quotient graph isomorphism, host linear algebra, an infinite graph limit, or a selected external enumeration of all spanning trees.

Definition 7693.1 (Kirchhoff matrix-tree carrier)**.** *A* $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, E, L, M, D, S, T, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *row naming the finite vertex and edge incidence data.*
2. *E is the edge-incidence ledger used to compute vertex degrees and adjacency counts from G.*
3. *L is the Laplacian ledger whose diagonal rows are degree counts and whose off-diagonal rows are the displayed negative adjacency counts.*
4. *M is the* $\mathsf{Mat}^{\uparrow}$ *row storing a principal Laplacian minor after one displayed vertex row and column have been removed.*
5. *D is the* $\mathsf{Determinant}^{\uparrow}$ *row reading* $\det(M)$ *by the finite determinant certificate.*
6. *S is the* $\mathsf{SpanningTree}^{\uparrow}$ *row naming the finite family of admitted spanning-tree witnesses.*
7. *T is the* $\mathsf{Tree}^{\uparrow}$ *route used to certify that each admitted spanning-tree witness is connected, acyclic, and vertex-spanning inside G.*
8. *H records componentwise* hsame *transport for graph, incidence, Laplacian, minor, determinant, spanning-tree, tree, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the graph incidence row through the Laplacian ledger, matrix minor, determinant row, spanning-tree row, and tree route.*

10. *P is the* Pkg *provenance over* $\mathsf{KirchhoffMatrixTree}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{KirchhoffMatrixTree}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host graph isomorphism, spectral eigenvalues, quotient linear algebra, an infinite graph limit, selected external tree enumeration, or ambient determinant algorithms outside the displayed $\mathsf{Mat}^{\uparrow}$ *and* $\mathsf{Determinant}^{\uparrow}$ *routes.*

Lean4 ✓ `BEDC.Derived.KirchhoffMatrixTreeUp.TasteGate.KirchhoffMatrixTreeTasteGate single carrier alignment`

Theorem 7693.2 (Kirchhoff matrix-tree NameCert obligations)**.** *For every accepted* $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ *carrier* $K = (G, E, L, M, D, S, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KirchhoffMatrixTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed graph row, incidence ledger, Laplacian ledger, principal minor matrix, determinant row, spanning-tree family, tree-validity route, componentwise transport, displayed replay, package provenance, and local naming. No obligation is discharged by host spectral theory, graph isomorphism, quotient linear algebra, selected external enumeration of spanning trees, infinite graph limits, or determinant computations outside the displayed finite rows.*

Proof. Project the carrier of Definition 7693.1. The graph row is G, the incidence data are E, the Laplacian row is L, the principal minor is M, the determinant certificate is D, and the spanning-tree surface is S together with the tree-validity route T.

The determinant side is finite. The row L is computed only from the displayed incidence ledger, the row M removes one displayed vertex row and column from L, and D reads the determinant of that minor through $\mathsf{Determinant}^{\uparrow}$.

The tree side is also finite. The row S exposes only admitted spanning-tree witnesses over G, and T checks connectedness, acyclicity, and vertex coverage through the $\mathsf{Tree}^{\uparrow}$ route.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no row for host spectral theory, graph isomorphism, quotient linear algebra, selected external enumeration, infinite graph limits, or external determinant algorithms, the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.KirchhoffMatrixTreeUp.KirchhoffMatrixTreeNameCertObligations`

Theorem 7693.3 (Kirchhoff matrix-tree Laplacian minor route)**.** *Every determinant-facing or spanning-tree-facing consumer of an accepted* $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Graph}^{\uparrow} \longmapsto E \longmapsto L \longmapsto \mathsf{Mat}^{\uparrow} \longmapsto \mathsf{Determinant}^{\uparrow}$$

and the parallel spanning-tree route

$$\mathsf{Graph}^{\uparrow} \longmapsto \mathsf{SpanningTree}^{\uparrow} \longmapsto \mathsf{Tree}^{\uparrow}.$$

The packet binds these two routes at the same graph row G, so the determinant read and the spanning-tree read cannot refer to different finite graphs or to an external enumeration.

Proof. Start with a consumer of the determinant side. Carrier admission forces the consumer to read G and the incidence ledger E before any Laplacian entry is available.

The minor is downstream of the same graph. The Laplacian ledger L is formed from E, the matrix row M is a principal minor of L, and the determinant row D reads only that displayed matrix.

Now read the spanning-tree side. The row S is indexed by the same graph row G, and T checks each admitted witness through the $\mathsf{Tree}^{\uparrow}$ route over that graph.

The transport and replay rows H and C preserve this shared source under classifier comparison. Thus a consumer cannot mix a determinant computed from one graph with spanning-tree witnesses from another graph, nor can it replace the displayed rows with a host enumeration. □

Falsifiable prediction: An accepted $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ consumer is refuted if it reaches a determinant row without first displaying the GraphUp incidence ledger, Laplacian ledger, principal MatrixUp minor, DeterminantUp row, SpanningTreeUp family, TreeUp validity route, transport, replay, provenance, and local naming rows.

Independence witness: graph, tree, spanningtree, matrix, determinant: no listed sibling supplies the full matrix-tree bridge, because only $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ binds one finite graph incidence ledger to both a Laplacian determinant minor and a spanning-tree family in the same NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{KirchhoffMatrixTree}^{\uparrow}}$.

Constructive story: A $\mathsf{KirchhoffMatrixTree}^{\uparrow}$ packet is generated from a finite GraphUp row, an incidence ledger, a Laplacian ledger, a principal MatrixUp minor, a DeterminantUp row, a SpanningTreeUp family, a TreeUp validity route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KirchhoffMatrixTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7693.1, Definition 7693.2, and Definition 7693.3 seed the finite matrix-tree route over GraphUp, TreeUp, SpanningTreeUp, MatrixUp, DeterminantUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KirchhoffMatrixTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, spectral graph theory, quotient graph isomorphism, host linear algebra, infinite graph limits, selected external tree enumeration, or determinant algorithms outside displayed finite rows.

Upgrade path: Obligation closure requires checked carrier admission, incidence exactness, Laplacian construction, principal minor routing, determinant readback, spanning-tree family validity, tree-route exactness, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.KirchhoffMatrixTreeUp.

Chapter 7694

A Concrete Naming Certificate for $\mathsf{PastingLemma}^{\uparrow}$

Following Kelley and Munkres on the topological pasting lemma, the $\mathsf{PastingLemma}^{\uparrow}$ packet records the finite BEDC route by which a map is certified from local continuous rows on a finite closed cover. It sits after the indexed-open carrier of chapter 88, the graph-and-modulus interface of chapter 130, and the generated-open discipline of chapter 2000. The packet names only the finite gluing certificate needed by continuous-map, sheaf, manifold, and bundle consumers; it is not host function extensionality, a selected representative theorem, a quotient-space construction, open-cover compactness, or ambient real completeness.

Definition 7694.1 (PastingLemma carrier)**.** *A* $\mathsf{PastingLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, Y, T_X, T_Y, I, U, F, A, L, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the source and target carrier histories, read only through their displayed classifiers.*
2. *T_X and T_Y are the* $\mathsf{Topology}^{\uparrow}$ *indexed-open rows on the source and target carriers.*
3. *I is a finite closed-cover index ledger for the source, with one displayed closed cover row for each $i \in I$ and a finite membership replay for every carried source observation.*
4. *U records the local domain row U_i for each index i, including its inclusion route into X and its induced* $\mathsf{Topology}^{\uparrow}$ *row from T_X.*
5. *F records a local* $\mathsf{ContinuousMap}^{\uparrow}$ *row $f_i : U_i \to Y$ for each $i \in I$, read through U_i, T_Y and the displayed continuity witness.*
6. *A records overlap-agreement rows: for every displayed pair $i, j \in I$, the two local maps agree on the carried overlap $U_i \cap U_j$ by componentwise observation transport.*
7. *L is the glued-map ledger whose source observation first chooses a cover row, then reads the corresponding local map, and whose well-definedness is certified only by A.*
8. *H records componentwise* hsame *transport for the source, target, topology rows, finite cover ledger, local domains, local maps, overlap rows, glued-map ledger, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a target-open request through the chosen local* $\mathsf{ContinuousMap}^{\uparrow}$ *row, the cover membership row, overlap agreement, and the glued-map ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{PastingLemma}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PastingLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, T_X, T_Y, I, U, F, A, L, H, C, P, N$. The carrier has no coordinate for host function extensionality, selected representatives, quotient spaces, open-cover compactness, ambient real completeness, or hidden point choice.

Theorem 7694.2 (PastingLemma NameCert obligations)**.** *For every accepted* $\mathsf{PastingLemma}^{\uparrow}$ *carrier*

$$G = (X, Y, T_X, T_Y, I, U, F, A, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PastingLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the thirteen displayed rows; finite cover exposure through I; induced local-domain topology through U; local continuity through F; overlap agreement through A; glued-map well-definedness and continuity replay through L and C; componentwise transport through H; provenance through P; and local naming through N.*

Proof. Project the accepted packet. The only available rows are the two carriers, the two topology rows, the finite cover ledger, the local domain rows, the local continuous maps, the overlap-agreement ledger, the glued-map ledger, and the structural rows.

Carrier admission is therefore exhausted by those rows. The cover surface is read from I, and each local domain is read from U together with its induced topology from T_X.

Local continuity is read from F. Whenever two cover choices meet, the pairwise row in A is the only available witness that the two local reads produce the same target observation on the carried overlap.

The glued-map ledger L uses that agreement to remove dependence on the displayed cover choice, while C replays continuity by restricting a target-open request to each local map and then repacking the finite cover rows. Finally, H, P, N transport, source, and name the same finite route, so the listed rows exhaust the local certificate surface. □

Theorem 7694.3 (PastingLemma continuity gluing route)**.** *Every continuity read exported by an accepted* $\mathsf{PastingLemma}^{\uparrow}$ *carrier factors through*

$$I, U, F, A, L, H, C, P, N.$$

More explicitly, a target-open request is checked locally by the $\mathsf{ContinuousMap}^{\uparrow}$ *rows in F, transported across overlaps by A, assembled by the finite cover ledger I, and exported by the glued-map ledger L. No consumer obtains a continuity witness for the glued map except through those displayed rows.*

Proof. Start with a target-open request against the glued map. The only global map coordinate is L, so the request must enter the glued-map ledger.

The ledger first reads a finite cover row from I and the corresponding local domain row from U. On that local domain, continuity is exactly the $\mathsf{ContinuousMap}^{\uparrow}$ row recorded in F.

If two cover rows can account for the same source observation, the request is transported through the corresponding overlap row in A. This is the only row that compares local map outputs on overlaps.

The replay row C then repacks the local continuity reads into the global request, and H, P, N preserve the same route under transport, provenance, and naming. Since no other continuity coordinate is present, every exported gluing route factors through the displayed finite ledger. □

Theorem 7694.4 (PastingLemma non-escape boundary)**.** *An accepted* $\mathsf{PastingLemma}^{\uparrow}$ *packet exports no host function extensionality principle, selected representative of a local map, quotient-space construction, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem. Any downstream consumer of the glued continuity certificate receives only the finite rows*

$$X, Y, T_X, T_Y, I, U, F, A, L, H, C, P, N.$$

Proof. Inspect the carrier inventory of Definition 7694.1. The packet contains source and target carriers, topology rows, finite cover data, local domains, local continuous maps, overlap agreement, a glued-map ledger, and the structural transport, replay, provenance, and naming rows.

Host function extensionality is not among those coordinates. The only equality-like data are the displayed overlap-agreement rows in A, and they apply only on carried overlaps.

Selected representatives and quotient spaces are also absent. The glued-map ledger records a cover-mediated readback, not a quotient representative or a choice of canonical local index.

Open-cover compactness and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent for the same reason: the cover is finite by construction, and no completeness row appears in G. Therefore the exported certificate cannot escape the stated finite route. □

Falsifiable prediction: An accepted $\mathsf{PastingLemma}^{\uparrow}$ consumer that obtains a global continuity read without first reading the finite cover ledger, a local $\mathsf{ContinuousMap}^{\uparrow}$ row, and the relevant overlap-agreement row refutes the carrier surface.

Independence witness: topology, continuousmap, product-topology: no listed sibling supplies the whole packet $G = (X, Y, T_X, T_Y, I, U, F, A, L, H, C, P, N)$, because Topology supplies indexed-open rows, ContinuousMap supplies local continuity rows, and ProductTopology supplies a separate binary generated-open route, while this chapter binds finite cover rows and overlap agreement into one pasting NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PastingLemma}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PastingLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7694.1, Definition 7694.2, Definition 7694.3, and Definition 7694.4 seed the finite pasting route from local continuous rows and overlap agreement to a global continuity certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PastingLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host function extensionality, selected representatives, quotient spaces, open-cover compactness, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a BEDC.Derived.PastingLemmaUp carrier with checked carrier admission, finite cover exposure, local-domain topology, local continuity, overlap agreement, glued-map well-definedness, continuity replay, transport, provenance, and local naming.

Constructive story: A $\mathsf{PastingLemma}^{\uparrow}$ packet is generated from source and target carrier histories, two $\mathsf{Topology}^{\uparrow}$ rows, a finite cover ledger, local domain rows, local $\mathsf{ContinuousMap}^{\uparrow}$ rows, pairwise overlap-agreement rows, a glued-map ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7695

A Concrete Naming Certificate for $\mathsf{CayleyTreePruferCode}^{\uparrow}$

Following Cayley and Prufer, the $\mathsf{CayleyTreePruferCode}^{\uparrow}$ packet records the finite correspondence between labelled trees on a displayed vertex set and length-adjusted code lists. It sits over the graph carrier of chapter 118, the tree carrier of chapter 119, the spanning-tree surface of chapter 237, and the unary/list discipline of chapter 28 and chapter 36. The packet names only finite vertex labels, finite tree-edge ledgers, leaf-removal steps, code-list rows, replay rows, and local naming; it is not the matrix-tree theorem, a host graph isomorphism quotient, an unordered ambient tree set, or a choice principle selecting representatives.

Definition 7695.1 (Cayley tree Prufer-code carrier)**.** *A* $\mathsf{CayleyTreePruferCode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (V, G, T, S, L, C, R, H, K, Q, N)$$

with the following displayed rows:

1. *V is the finite labelled-vertex row, read through* $\mathsf{Nat}^{\uparrow}$ *size data and* $\mathsf{List}^{\uparrow}$ *finite label enumeration.*
2. *G is the* $\mathsf{Graph}^{\uparrow}$ *edge-incidence row over those displayed labels.*
3. *T is the* $\mathsf{Tree}^{\uparrow}$ *acyclicity and connectedness row carried by the displayed graph data.*
4. *S is the* $\mathsf{SpanningTree}^{\uparrow}$ *witness tying the tree rows to the graph rows.*
5. *L is the finite leaf-removal ledger, listing at each step the least displayed leaf and its unique neighbour.*
6. *C is the Prufer code-list row, a* $\mathsf{List}^{\uparrow}$ *row whose entries are displayed labels and whose length is the unary predecessor predecessor of the vertex count when that count is at least two.*
7. *R is the reconstruction ledger, replaying the code list back to the same labelled tree rows.*
8. *H records componentwise* hsame *transport for vertex labels, graph edges, tree rows, spanning-tree rows, leaf-removal rows, code rows, reconstruction rows, replay, provenance, and local naming.*
9. *K records displayed* Cont *replay from tree-to-code removal and code-to-tree reconstruction.*
10. *Q is the* Pkg *provenance over* $\mathsf{CayleyTreePruferCode}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CayleyTreePruferCode}^{\uparrow}}$ *row.*

The classifier accepts only packets in which the leaf-removal ledger and reconstruction ledger consume the same displayed vertex labels and tree rows. It has no coordinate for quotienting labelled trees by graph isomorphism, choosing representatives from an ambient tree set, invoking the matrix-tree determinant, or importing an infinite graph space.

Theorem 7695.2 (Cayley tree Prufer-code NameCert obligations)**.** *For every accepted* $\mathsf{CayleyTreePruferCode}^{\uparrow}$ *carrier*

$$P = (V, G, T, S, L, C, R, H, K, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CayleyTreePruferCode}^{\uparrow}}$ *surface consists exactly of labelled-vertex exposure, graph-incidence exposure, tree exposure, spanning-tree compatibility, finite leaf-removal accounting, Prufer code-list exposure, reconstruction replay, componentwise transport, displayed continuation replay, package provenance, and local naming through* N*.*

Proof. Project the carrier tuple in Definition 7695.1. The rows V, G, T, S expose the labelled graph and tree data, while L records the finite removal route that reads leaves and neighbours as displayed labels.

The code row C is a finite $\mathsf{List}^{\uparrow}$ row controlled by the same unary size data in V. The reconstruction row R consumes that list and the remaining displayed labels, so it cannot introduce a hidden tree or an unlisted vertex.

The structural rows H, K, Q, N transport, replay, source, and name the same packet. Since no excluded host coordinate occurs in the carrier, the local NameCert surface is exactly the finite Cayley–Prufer correspondence route. □

Theorem 7695.3 (Cayley tree Prufer-code replay)**.** *Every accepted* $\mathsf{CayleyTreePruferCode}^{\uparrow}$ *packet replays in both finite directions:*

$$V, G, T, S \longmapsto L, C, H, K, Q, N$$

for leaf-removal encoding, and

$$V, C \longmapsto R, G, T, S, H, K, Q, N$$

for reconstruction. The replay preserves the displayed labelled vertices, tree edges, and code entries, and it exports no matrix-tree determinant, graph-isomorphism quotient, ambient set of trees, or representative-selection principle.

Proof. For encoding, read the displayed tree rows G, T, S over the vertex row V. The leaf-removal ledger L chooses leaves only from the finite displayed label list and records the neighbour label placed into the code row C.

For reconstruction, start from V and C. The reconstruction ledger R attaches each code entry to the least displayed label not currently blocked by the remaining code list, then appends the final edge between the two remaining displayed labels.

Both directions use the same transport, replay, provenance, and local naming rows H, K, Q, N. Therefore the replay is a finite labelled-tree/code correspondence inside the listed BEDC rows, with no appeal to determinant enumeration, quotient tree equality, ambient tree sets, or choice. □

Falsifiable prediction: A $\mathsf{CayleyTreePruferCode}^{\uparrow}$ consumer is refuted if it reads a Prufer code entry or reconstructed edge that is not attached to the displayed vertex-label row, graph row, tree row, spanning-tree row, leaf-removal ledger, reconstruction ledger, transport, replay, provenance, and local naming rows.

Independence witness: graph, tree, spanningtree, nat, list: no listed sibling alone supplies the complete Cayley–Prufer packet, because only $\mathsf{CayleyTreePruferCode}^{\uparrow}$ binds labelled vertices, graph incidence, tree rows, spanning-tree compatibility, leaf-removal encoding, code-list reconstruction, transport, replay, provenance, and local naming as one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{CayleyTreePruferCode}^{\uparrow}}$.

Constructive story: A $\mathsf{CayleyTreePruferCode}^{\uparrow}$ packet is generated from finite labelled vertices, displayed graph incidence, displayed tree rows, spanning-tree compatibility, a finite leaf-removal ledger, a Prufer code-list row, a reconstruction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CayleyTreePruferCode}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7695.1, Definition 7695.2, and Definition 7695.3 seed the finite labelled-tree and Prufer-code correspondence over Graph, Tree, SpanningTree, Nat, List, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CayleyTreePruferCode}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the matrix-tree theorem, quotient graph isomorphism, an ambient set of all trees, representative choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, leaf-removal exactness, code-list length accounting, reconstruction replay, labelled-edge preservation, transport, replay, provenance, and local naming for BEDC.Derived.CayleyTreePruferCode

Chapter 7696

A Concrete Naming Certificate for LadyzhenskayaInequality$^{\uparrow}$

Following Ladyzhenskaya and the standard Sobolev-energy route for two-dimensional fluid estimates, the LadyzhenskayaInequality$^{\uparrow}$ packet records the finite BEDC surface by which a Sobolev row, an L^2 mass row, a weak-gradient energy row, and a terminal real bound are displayed before a PDE regularity consumer reads the mixed-norm estimate. It sits beside the Sobolev source of chapter 440, the Poincare control route of chapter 2329, the finite interpolation window of chapter 6814, the iteration surfaces of chapter 6969 and chapter 7036, and the scalar seal of chapter 38. The packet names only displayed finite rows; it is not a host compact embedding, selected weak solution, quotient function-space equality, or ambient PDE regularity theorem.

Definition 7696.1 (LadyzhenskayaInequality Sobolev-energy carrier)**.** *A* LadyzhenskayaInequality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, M, G, P_2, I, B, H, C, K, N)$$

with the following displayed rows:

1. *D is the displayed bounded two-dimensional domain or finite coordinate-window row on which all reads are scoped.*
2. *S is the consumed* Sobolev$^{\uparrow}$ *row exposing the function carrier and weak-gradient data.*
3. *M is the L^2 mass row for the displayed function.*
4. *G is the weak-gradient L^2 energy row read through S.*
5. *P_2 is the two-dimensional Sobolev-energy profile row that records the exponent pattern $2, 4, 2$ and the finite interpolation window.*
6. *I is the* GagliardoNirenbergFiniteWindow$^{\uparrow}$ *or Sobolev-interpolation handoff row used to combine M and G.*
7. *B is the terminal* Real$^{\uparrow}$ *bound row for the Ladyzhenskaya estimate over the displayed domain window.*
8. *H records componentwise* hsame *transport for the domain, Sobolev, mass, energy, profile, interpolation, bound, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a mixed-norm request through M, G, P_2, I, and B.*

10. *K is the* Pkg *provenance over* LadyzhenskayaInequality$^{\uparrow}$, Sobolev$^{\uparrow}$, PoincareInequality$^{\uparrow}$, GagliardoNirenbergFiniteW MoserIteration$^{\uparrow}$, DeGiorgiIteration$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LadyzhenskayaInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, M, G, P_2, I, B, H, C, K, N$. It has no coordinate for a host Sobolev space quotient, compactness theorem, selected PDE solution, or ambient regularity principle.

Theorem 7696.2 (LadyzhenskayaInequality NameCert obligations)**.** *For every accepted* LadyzhenskayaInequality$^{\uparrow}$ *carrier*

$$L = (D, S, M, G, P_2, I, B, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{LadyzhenskayaInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; bounded domain-window exposure through D; Sobolev and weak-gradient exposure through S and G; mass exposure through M; two-dimensional exponent-profile exposure through P_2; finite interpolation handoff through I; terminal real-bound exposure through B; componentwise transport through H; mixed-norm replay through C; provenance through K; and local naming through N.*

Proof. Project the accepted packet. The only analytic rows are the domain window, Sobolev row, mass row, gradient-energy row, exponent profile, interpolation handoff, and terminal real bound.

Carrier admission is therefore exhausted by those rows. The Sobolev row supplies the function and weak-gradient carrier, while M and G supply the two energy quantities read by the estimate.

The two-dimensional profile P_2 fixes the exponent pattern before interpolation is invoked. The handoff I combines the mass and gradient rows inside the displayed window, and B records the resulting real bound.

The structural rows add no hidden analytic content. They transport, replay, source, and name the same finite route, so the listed clauses exhaust the local certificate surface. □

Theorem 7696.3 (LadyzhenskayaInequality Sobolev-energy route)**.** *Every mixed-norm estimate exported by an accepted* LadyzhenskayaInequality$^{\uparrow}$ *packet factors through the finite route*

$$D, S, M, G, P_2, I, B, H, C, K, N.$$

The consumer must read the displayed Sobolev row, the L^2 mass row, the weak-gradient energy row, the two-dimensional exponent profile, and the finite interpolation handoff before it can receive the terminal Real$^{\uparrow}$ *bound.*

Proof. Begin with a mixed-norm request. The only route from that request to a real bound is the replay row C, so the request must pass through the rows named by the carrier.

The Sobolev row S exposes the function and weak-gradient surface. The mass row M and energy row G are read through that same displayed carrier, and the profile row P_2 fixes the two-dimensional exponent pattern before any bound is formed.

The interpolation handoff I consumes exactly those finite rows. The bound row B is then the terminal Real$^{\uparrow}$ seal for the estimate, with H, K, N preserving transport, provenance, and local naming. Since no compactness, selected solution, or quotient coordinate is present, every exported estimate remains inside the Sobolev-energy route. □

Theorem 7696.4 (LadyzhenskayaInequality non-escape boundary)**.** *An accepted* LadyzhenskayaInequality$^{\uparrow}$ *packet exports no ambient function-space compactness, no host PDE regularity theorem, no selected weak solution, no quotient equality of Sobolev representatives, and no unscoped domain extension. Any downstream* MoserIteration$^{\uparrow}$, DeGiorgiIteration$^{\uparrow}$, *or* HarnackInequality$^{\uparrow}$ *consumer receives only the displayed finite Sobolev-energy rows of Definition 7696.1.*

Proof. Inspect the carrier inventory. It contains a domain window, Sobolev row, mass row, gradient-energy row, exponent profile, interpolation handoff, real bound, and structural rows.

Compactness and quotient equality require additional coordinates absent from the carrier. A selected weak solution or host PDE regularity theorem would likewise need solution and equation rows not displayed by $\mathsf{LadyzhenskayaInequality}^{\uparrow}$.

The iteration consumers can therefore read only the finite energy estimate and its transport, replay, provenance, and naming rows. The packet supplies a Sobolev-energy estimate surface, not an ambient analytic theorem. □

Falsifiable prediction: An accepted $\mathsf{LadyzhenskayaInequality}^{\uparrow}$ consumer that obtains a mixed L^4-type estimate without displaying the Sobolev row, L^2 mass row, weak-gradient energy row, two-dimensional exponent profile, interpolation handoff, and terminal $\mathsf{Real}^{\uparrow}$ bound refutes the carrier surface.

Independence witness: sobolev, poincare-inequality, gagliardo-nirenberg-finite-window, moser-iteration, de-giorgi-iteration: no listed sibling supplies the whole packet $L = (D, S, M, G, P_2, I, B, H, C, K, N)$, because Sobolev supplies weak-gradient data, Poincare supplies a separate norm-control route, GagliardoNirenbergFiniteWindow supplies a broader interpolation window, and the Moser and De Giorgi packets consume iteration budgets while this chapter binds the two-dimensional mass-gradient Ladyzhenskaya estimate as one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{LadyzhenskayaInequality}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LadyzhenskayaInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7696.1, Definition 7696.2, Definition 7696.3, and Definition 7696.4 seed the finite Sobolev-energy estimate route over mass, weak-gradient energy, interpolation, real-bound, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LadyzhenskayaInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient compactness, host PDE regularity, selected weak solutions, quotient Sobolev equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a BEDC.Derived.LadyzhenskayaInequalityUp carrier with checked carrier admission, Sobolev-energy exposure, interpolation handoff, real-bound replay, transport, provenance, and local naming.

Constructive story: A $\mathsf{LadyzhenskayaInequality}^{\uparrow}$ packet is generated from a bounded domain window, Sobolev row, mass row, weak-gradient energy row, two-dimensional exponent profile, interpolation handoff, Real bound, componentwise transport, displayed replay, provenance, and local NameCert row.

Chapter 7697

A Concrete Naming Certificate for $\mathsf{SchurFunction}^{\uparrow}$

Following Macdonald on symmetric functions and Fulton–Harris on representation theory, the $\mathsf{SchurFunction}^{\uparrow}$ packet records the finite tableau-expansion interface for Schur functions as BEDC NameCert data. It sits after the Young-tableau carrier of chapter 7178, the partition-shape surface of chapter 201, the polynomial carrier of chapter 50, the ring row of chapter 43, and the representation-ring consumer of chapter 246. The packet names finite shape, tableau, monomial, coefficient, algebra, transport, replay, provenance, and local certificate rows; it does not import a host symmetric-function algebra, quotient polynomial equality, an infinite tableau enumeration, a selected basis theorem, or representation-theoretic semisimplicity.

Definition 7697.1 (Schur function carrier)**.** *A* $\mathsf{SchurFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\lambda, T, M, K, A, R, H, C, P, N)$$

with the following displayed rows:

1. λ *is the* $\mathsf{Partition}^{\uparrow}$ *row naming the finite Young shape.*
2. T *is the* $\mathsf{YoungTableau}^{\uparrow}$ *tableau ledger over* λ*, including the displayed row and column constraints used by semistandard reads.*
3. M *is the finite monomial ledger. It records the content vector read from each admitted tableau before any polynomial coefficient is exposed.*
4. K *is the coefficient ledger, storing the finite multiplicity count attached to each displayed content vector.*
5. A *is the* $\mathsf{Poly}^{\uparrow}$ *row that packages the finite monomial-coefficient data as a polynomial expression.*
6. R *is the* $\mathsf{Ring}^{\uparrow}$ *row through which addition and multiplication of the displayed monomial terms are replayed.*
7. H *records componentwise* hsame *transport for partition, tableau, monomial, coefficient, polynomial, ring, representation-ring, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from the partition shape through tableau rows, monomial content, coefficient rows, polynomial assembly, and ring operations.*
9. P *is the* Pkg *provenance over* $\mathsf{SchurFunction}^{\uparrow}$, $\mathsf{YoungTableau}^{\uparrow}$, $\mathsf{Partition}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{SchurFunction}^\uparrow}$ *row.*
The classifier compares accepted carriers only through these rows. It has no coordinate for a host symmetric-function algebra, quotient equality of polynomials, infinite tableau enumeration, selected basis theorem, Littlewood–Richardson multiplication rule, or semisimplicity theorem.

Theorem 7697.2 (Schur function NameCert obligations)**.** *For every accepted* $\mathsf{SchurFunction}^\uparrow$ *carrier* $S = (\lambda, T, M, K, A, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SchurFunction}^\uparrow}$ *surface consists exactly of carrier admission for the displayed partition shape, Young-tableau ledger, monomial-content ledger, coefficient ledger, polynomial assembly row, ring-operation row, componentwise transport, displayed replay, package provenance, and local naming. Every representation-ring-facing read must consume the same rows before treating the carrier as a Schur-function row.*

Proof. Project the carrier of Definition 7697.1. The partition shape, tableau ledger, monomial ledger, coefficient ledger, polynomial row, and ring row are the only mathematical rows available to the local certificate.

The tableau expansion is finite. A read starts with the shape row λ, opens the tableau ledger T, extracts the content vector through M, records its displayed multiplicity in K, and only then assembles the polynomial row A through the ring row R.

The structural rows H, C, P, N transport, replay, source, and name that same route for downstream consumers. Since no carrier coordinate names a host symmetric-function algebra, quotient polynomial equality, infinite tableau enumeration, selected basis theorem, Littlewood–Richardson multiplication rule, or semisimplicity theorem, the listed obligations exhaust the local NameCert surface. □

Theorem 7697.3 (Schur function tableau expansion handoff)**.** *Every* $\mathsf{RepresentationRing}^\uparrow$ *or character-theory consumer of an accepted* $\mathsf{SchurFunction}^\uparrow$ *carrier must read the finite tableau-expansion route*

$$\mathsf{Partition}^\uparrow \longmapsto \mathsf{YoungTableau}^\uparrow \longmapsto M, K \longmapsto \mathsf{Poly}^\uparrow \longmapsto \mathsf{Ring}^\uparrow \longmapsto \mathsf{RepresentationRing}^\uparrow.$$

Thus the Schur-function row handed to representation-ring consumers is a displayed finite polynomial route over partition and tableau data, not a host symmetric-function basis theorem or an unrecorded representation-theoretic decomposition.

Proof. Begin with a representation-ring-facing consumer. Carrier admission forces the consumer to read the partition shape and the Young-tableau ledger before any monomial content is available.

The expansion rows are then fixed. The monomial ledger M reads content from displayed tableaux, the coefficient ledger K records finite multiplicities, and the polynomial row A packages those cells through the ring row R.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. The $\mathsf{RepresentationRing}^\uparrow$ consumer therefore receives a finite Schur-function expansion over the displayed sibling rows, with no access to a host symmetric-function algebra, quotient polynomial equality, infinite tableau enumeration, selected basis theorem, Littlewood–Richardson multiplication rule, or semisimplicity theorem. □

Falsifiable prediction: An accepted $\mathsf{SchurFunction}^\uparrow$ consumer is refuted if it reaches a RepresentationRingUp or character-theory row without first displaying the PartitionUp shape, YoungTableauUp tableau ledger, finite monomial-content ledger, coefficient ledger, PolynomialUp assembly row, RingUp replay row, transport, replay, provenance, and local naming rows.

Independence witness: youngtableau, partition, polynomial, ring, representationring: no listed sibling supplies the full Schur-function tableau-expansion carrier, because only $\mathsf{SchurFunction}^{\uparrow}$ binds a partition shape, tableau ledger, monomial content, coefficient multiplicities, polynomial assembly, ring replay, and representation-ring handoff in one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SchurFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{SchurFunction}^{\uparrow}$ packet is generated from a PartitionUp shape row, a YoungTableauUp tableau ledger, finite monomial-content rows, coefficient rows, a PolynomialUp assembly row, a RingUp replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurFunction}^{\uparrow}}$, seed)

Scope closed: Definition 7697.1, Definition 7697.2, and Definition 7697.3 seed the finite tableau-expansion route over YoungTableauUp, PartitionUp, PolynomialUp, RingUp, RepresentationRingUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host symmetric-function algebra, quotient polynomial equality, infinite tableau enumeration, selected basis theorems, Littlewood–Richardson multiplication, or representation-theoretic semisimplicity.

Upgrade path: Obligation closure requires checked carrier admission, tableau-ledger exactness, monomial-content extraction, coefficient exactness, polynomial assembly, ring replay, representation-ring handoff, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.SchurFunctionUp.

Chapter 7698

A Concrete Naming Certificate for HardyLittlewoodMaximalFinite$^{\uparrow}$

Following Hardy–Littlewood and Bishop–Bridges finite covering practice, the HardyLittlewoodMaximalFinite$^{\uparrow}$ packet records the weak-window maximal-function route in which every local average, threshold comparison, and covering handoff is displayed by finite data. It is a finite-window sibling of chapter 3581, with covering reads through chapter 7683, finite-net reads through chapter 1767, dyadic threshold reads through chapter 291, and terminal numerical sealing through chapter 38. The packet refuses sigma-measure, host measurable functions, choice-selected level sets, quotient level sets, ambient integration completeness, and any selected supremum outside the finite window ledger.

Definition 7698.1 (Hardy-Littlewood finite weak-window carrier)**.** *A* HardyLittlewoodMaximalFinite$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, I, B, D, A, T, V, F, G, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite metric-source row. It records the inspected points, displayed distance reads, and the finite ambient window in which all later probes live.*
2. *I is the finite interval-window row. It stores bounded interval names, endpoint comparisons, and the membership probes that allow an interval read to be replayed without a host measurable set.*
3. *B is the finite ball-window row. Each ball record stores a center, a positive radius witness, the inspected membership probes, and the inclusion comparisons with the interval windows in I.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *threshold row. It stores the dyadic level λ, dyadic tolerance budgets, and the rational comparison witnesses used by the weak-level ledger.*
5. *A is the local-average row. For every displayed interval or ball window it records the finite summation route, denominator witness, and comparison against the dyadic threshold from D.*
6. *T is the weak-level trace row. It records exactly which displayed windows have local average above the dyadic threshold and keeps the witness tied to A and D.*
7. *V is the* VitaliCoveringLemma$^{\uparrow}$ *finite cover row. It records the selected disjoint finite subfamily, the finite overlap budget, and the cover cells used to dominate the weak-level trace.*

8. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *finite-net row. It records the tolerance-visible net cells that make the cover route compact and finite before any weak-level output is exported.*
9. *G is the weak-window ledger. It stores the finite list of covered threshold windows, their dyadic weight comparisons, and the resulting weak-type bound as a displayed ledger row rather than a measure-theoretic inequality.*
10. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It exposes only the real-name windows reached from A, D, G.*
11. *H records componentwise* hsame *transport for source, interval, ball, threshold, average, weak trace, cover, finite-net, ledger, seal, replay, provenance, and local name rows.*
12. *C records displayed* Cont *replay of the route*

$$\mathsf{HardyLittlewoodMaximal}^{\uparrow},\ \mathsf{VitaliCoveringLemma}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist} \longmapsto \mathsf{HardyLit}$$

13. *P is the* Pkg *provenance over* $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$, $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$, $\mathsf{VitaliCoveringLemma}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these fourteen rows. Its classifier compares accepted packets only through $X, I, B, D, A, T, V, F, G, E, H, C, P, N$ and has no coordinate for sigma-measure, host measurable functions, choice, quotient level sets, ambient integration completeness, a selected supremum, or an infinite covering family.

Theorem 7698.2 (Hardy-Littlewood finite weak-window NameCert obligations)**.** *For an accepted* $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$ *carrier*

$$W = (X, I, B, D, A, T, V, F, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite metric source, finite interval windows, finite ball windows, dyadic thresholds, local-average rows, weak-level trace, Vitali finite-cover row, finite-net row, weak-window ledger, real seal, componentwise transport, displayed replay, package provenance, and local naming. Every weak-level read must inspect D, A, T, V, F, G in that order, and no obligation is discharged by sigma-measure, host measurable functions, choice, quotient level sets, ambient integration completeness, selected suprema, or infinite covering families.*

Proof. Project the carrier of Definition 7698.1. The projection exposes exactly the source row X, interval row I, ball row B, threshold row D, average row A, weak trace T, cover row V, finite-net row F, ledger row G, seal row E, and structural rows H, C, P, N.

The weak-level route is ordered by the rows themselves. A threshold comparison must first read the dyadic data in D and the matching local-average record in A; only then can the trace row T mark a displayed window as above the threshold.

The cover step is also finite. The Vitali row V supplies a selected disjoint finite subfamily, the finite-net row F supplies the tolerance-visible compact handoff, and the weak-window ledger G records the finite bound exported to consumers.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier contains no row for sigma-measure, host measurable functions, choice, quotient level sets, ambient integration completeness, selected suprema, or infinite covering families, the listed rows exhaust the local NameCert surface. □

Theorem 7698.3 (Hardy-Littlewood finite weak-window bound)**.** *Every accepted* $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$ *packet exports a weak-window ledger only along the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ A,\ T,\ \mathsf{VitaliCoveringLemma}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ G,\ \mathsf{Real}^{\uparrow}.$$

Thus a consumer receives a finite dyadic threshold ledger for displayed interval and ball windows, not a sigma-measure statement, a host measurable-function theorem, a choice-selected level set, a quotient level-set object, or an ambient integration-completeness assertion.

Proof. Begin with a consumer request for a weak-level read. By Definition 7698.2, the request must inspect the dyadic threshold row D, the local-average row A, and the weak trace T before any cover ledger can be read.

The cover route then passes through V and F. The Vitali covering row supplies only a disjoint finite subfamily and finite overlap budget, while the finite-net row supplies only tolerance-visible compact cells.

The output row G records the weak-window ledger over those displayed cells, and E seals the numerical read as a $\mathsf{Real}^{\uparrow}$ window. Componentwise transport, displayed replay, provenance, and local naming preserve that route without adding measure, choice, quotient, integration-completeness, selected-supremum, or infinite-family data. □

Falsifiable prediction: Every accepted $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$ read displays one finite metric-source row, one finite interval-window row, one finite ball-window row, one DyadicRatCoreUp threshold row, one local-average row, one weak-level trace, one VitaliCoveringLemmaUp finite-cover row, one FiniteEpsilonNetUp finite-net row, one weak-window ledger, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: hardy-littlewood-maximal, vitali-covering-lemma, finite-epsilon-net, dyadicratcore, real: $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite interval and ball windows, dyadic thresholds, local averages, weak-level traces, finite cover rows, finite-net handoffs, weak-window ledger rows, real sealing, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}$ packet is generated from finite metric-source data, interval windows, ball windows, dyadic thresholds, local-average rows, weak-level traces, finite Vitali-cover rows, finite-net rows, a weak-window ledger, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7698.1, Definition 7698.2, and Definition 7698.3 seed the finite weak-window maximal-function carrier and obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HardyLittlewoodMaximalFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sigma-measure, host measurable functions, choice-selected level sets, quotient level sets, ambient integration completeness, selected suprema, infinite covering families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-threshold exactness, local-average replay, weak-trace exactness, finite-cover discipline, finite-net handoff, ledger non-escape, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HardyLittlewoodMaximalFiniteUp.

Chapter 7699

A Concrete Naming Certificate for $\mathsf{FarEndBoundaryCospan}^{\uparrow}$

The $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ packet realizes the boundary-cospan branch of the apophatic far-end diagrammatics route in chapter 9403 as finite NameCert data. It sits beside the far-end diagram packet of chapter 4163, the far-end diagrammatics packet of chapter 4165, and the boundary-style transport rows used by adjacent hyperbolic and observer chapters. The packet names a finite cospan of left boundary, right boundary, apex far-end name, leg provenance, and compatibility rows; it is not a global universe, not an infinite object, not an observer, and not a selected terminal object in a host category.

Definition 7699.1 (FarEndBoundaryCospan carrier)**.** *A* $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, R, A, \lambda, \rho, B_L, B_R, J, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right boundary-name rows read from admissible far-end diagram data.*
2. *A is the apex far-end name row common to the two boundary legs.*
3. *λ and ρ are the left and right leg rows from L and R into A.*
4. *B_L and B_R are the boundary-provenance rows recording which observation-fiber or socket route produced the two boundary names.*
5. *J is the cospan-compatibility row asserting that both legs name the same apophatic far end only through the displayed apex row.*
6. *H records componentwise* hsame *transport for the boundary rows, apex row, leg rows, provenance rows, compatibility row, replay, package, and local naming.*
7. *C records displayed* Cont *replay from a boundary comparison request through $B_L, B_R, \lambda, \rho, J$ and the apex row A.*
8. *P is the* Pkg *provenance over* $\mathsf{FarEndBoundaryCospan}^{\uparrow}$*,* $\mathsf{FarEndDiagram}^{\uparrow}$*,* $\mathsf{FarEndDiagrammatics}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FarEndBoundaryCospan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, R, A, \lambda, \rho, B_L, B_R, J, H, C, P, N$. It has no coordinate for an ambient terminal object, global category of observers, selected boundary quotient, or infinite far-end completion.

Theorem 7699.2 (FarEndBoundaryCospan NameCert obligations)**.** *For every accepted* $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ *carrier*

$$F = (L, R, A, \lambda, \rho, B_L, B_R, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FarEndBoundaryCospan}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; left and right boundary exposure through* L, R*; apex far-end exposure through* A*; leg exposure through* λ, ρ*; provenance exposure through* B_L, B_R*; cospan compatibility through* J*; componentwise transport through* H*; boundary-comparison replay through* C*; package provenance through* P*; and local naming through* N*.*

Proof. Project the accepted packet. The only boundary data are the left row, right row, apex row, two legs, two provenance rows, and compatibility row.

Carrier admission is therefore exhausted by those rows. The two legs cannot be compared without the apex A, and the two boundary names cannot be sourced without the provenance rows B_L and B_R.

The compatibility row J records the cospan condition inside the displayed packet. The structural rows transport, replay, source, and name the same finite route, so no ambient terminal object or observer category is added by the certificate. □

Theorem 7699.3 (FarEndBoundaryCospan diagrammatic route)**.** *Every boundary comparison exported by an accepted* $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ *packet factors through the finite route*

$$L, R, A, \lambda, \rho, B_L, B_R, J, H, C, P, N.$$

The consumer must read the two boundary names, their provenance rows, the two legs, and the apex far-end name before the compatibility row can be consumed.

Proof. Start with a boundary comparison request. The only replay row is C, so the request must follow the displayed cospan route.

The boundary rows L and R are read together with their provenance rows B_L and B_R. The leg rows λ and ρ then map those boundary names into the apex row A.

Only after both legs have reached A can the compatibility row J be read. Transport and provenance remain componentwise through H and P, and the local name N records the same finite cospan. Thus the exported comparison is diagrammatic finite data, not a host categorical terminality claim. □

Theorem 7699.4 (FarEndBoundaryCospan non-escape boundary)**.** *An accepted* $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ *packet exports no global universe, no infinite far-end object, no observer identity, no selected terminal object, and no quotient of boundary names. It exports only the displayed boundary rows, apex row, leg rows, provenance rows, compatibility row, transport, replay, package provenance, and local naming rows of Definition 7699.1.*

Proof. Inspect the carrier inventory. Every row is either a boundary name, an apex far-end name, a leg, a provenance row, a compatibility row, or structural support.

A global universe or infinite far-end object would require a completion or totality coordinate absent from the carrier. An observer identity or terminal-object claim would require host category data absent from the packet.

The only equality-like information is the displayed cospan compatibility through J, and it is scoped by the apex row A. Therefore no consumer can escape from the finite cospan surface to an ambient quotient or terminality principle. □

Falsifiable prediction: An accepted $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ consumer that compares two far-end boundary names without displaying both boundary provenance rows, both cospan legs, the apex far-end name, and the compatibility row refutes the carrier surface.

Independence witness: far-end-diagram, far-end-diagrammatics, hyperbolic-boundary-transport, poincare-disk-boundary-transport, vision-coverage-index: no listed sibling supplies the whole packet $F = (L, R, A, \lambda, \rho, B_L, B_R, J, H, C, P, N)$, because far-end diagram rows name socket and fiber data, far-end diagrammatics names observation stratification, hyperbolic and Poincare boundary transports name geometric boundary movement, and the vision coverage index names marker coverage, while this chapter binds a two-leg boundary cospan with apex compatibility as one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FarEndBoundaryCospan}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FarEndBoundaryCospan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7699.1, Definition 7699.2, Definition 7699.3, and Definition 7699.4 seed the finite boundary-cospan route over two boundary names, an apex far-end name, two legs, provenance, compatibility, transport, replay, package, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FarEndBoundaryCospan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global universe, infinite far-end object, observer identity, selected terminal object, boundary quotient, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires BEDC.Derived.FarEndBoundaryCospanUp carrier admission, boundary provenance, cospan-leg compatibility, diagrammatic replay, and future TasteGate Nontrivial and FieldFaithful instances.

Constructive story: A $\mathsf{FarEndBoundaryCospan}^{\uparrow}$ packet is generated from left and right boundary-name rows, an apex far-end name, two leg rows, boundary-provenance rows, a compatibility row, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Chapter 7700

A Concrete Naming Certificate for $\mathsf{HahnSeries}^{\uparrow}$

Following Hahn and Kaplansky, the $\mathsf{HahnSeries}^{\uparrow}$ packet records a Hahn-series name as finite BEDC rows: coefficient-field data, an ordered exponent carrier, an inspected support ledger, and a valuation readback. It sits after the field certificate of chapter 45, the total-order route of chapter 54, the polynomial carrier of chapter 50, the coefficient-only formal-power-series surface of chapter 51, and the certificate transport discipline of chapter 481. The packet names the displayed non-Archimedean carrier surface; it does not import a host ordered group, a quotient field of fractions, a selected infinite summation, or an ambient completeness theorem.

Definition 7700.1 (Hahn-series carrier)**.** *A* $\mathsf{HahnSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (F, G, S, W, V, R, T, C, P, N)$$

with the following rows:

1. *F is the coefficient-field row, read through a displayed* $\mathsf{Field}^{\uparrow}$ *certificate and its scalar classifier.*
2. *G is the ordered exponent row, read through a displayed* $\mathsf{TotalOrder}^{\uparrow}$ *comparison surface, with the additive-exponent operations kept as named BEDC data rather than as a host ordered group.*
3. *S is the support row, recording the finite inspected exponent cells and the coefficient cell attached to each inspected exponent.*
4. *W is the well-ordered-support ledger, recording that every finite downward query exposed by the carrier has a first occupied exponent among the inspected cells or is explicitly empty.*
5. *V is the valuation row, recording the least occupied exponent returned by W when the support is nonempty and the formal infinity tag when the support is empty.*
6. *R is the coefficient readback row, recording the scalar returned at an inspected exponent and the displayed zero scalar returned outside the inspected support.*
7. *T records componentwise* hsame *transport for the field row, ordered exponent row, support ledger, valuation row, and coefficient readback.*
8. *C records displayed* Cont *replay from series admission through support inspection, valuation readback, coefficient readback, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HahnSeries}^{\uparrow}$*,* $\mathsf{Field}^{\uparrow}$*,* $\mathsf{TotalOrder}^{\uparrow}$*,* $\mathsf{Poly}^{\uparrow}$*,* $\mathsf{FPS}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}$ *row.*
The carrier contains no coordinate for an uninspected nonzero coefficient, a hidden support selector, a valuation outside the displayed ordered exponent row, or a coefficient comparison outside the scalar classifier of F.

Theorem 7700.2 (Hahn-series NameCert obligations)**.** *For the carrier of Definition 7700.1, the local* $\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}$ *surface consists exactly of carrier admission for $H = (F, G, S, W, V, R, T, C, P, N)$, coefficient-field readback through F, ordered-exponent readback through G, inspected-support readback through S, well-ordered-support ledger exposure through W, valuation readback through V, coefficient readback through R, componentwise* hsame *transport through T, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the displayed packet $H = (F, G, S, W, V, R, T, C, P, N)$. The first six rows expose the algebraic and order-facing data: a coefficient field, an ordered exponent surface, inspected support cells, the well-ordered-support ledger, the valuation endpoint, and coefficient readback.

The structural rows are then forced. Transport T preserves the rows componentwise under hsame, replay C orders the consumer read from admission to local naming, provenance P records the sibling certificates, and N supplies the local name. There is no additional row from which a consumer could read hidden support or an external summation operation, so the listed groups exhaust the local NameCert surface. □

Theorem 7700.3 (Hahn-series support route)**.** *Every permitted consumer read of an accepted* $\mathsf{HahnSeries}^{\uparrow}$ *carrier reaches a coefficient cell only through the ordered-exponent row G, inspected-support row S, well-ordered-support ledger W, and coefficient readback row R. In particular, support membership is a displayed BEDC ledger route, not a host subset of an ambient ordered group.*

Proof. Begin with an accepted carrier $H = (F, G, S, W, V, R, T, C, P, N)$. By Definition 7700.1, all exponent comparisons are read through G, and all occupied cells available to the consumer are listed in S.

The ledger W controls support exposure. A finite downward query either returns the first occupied exponent among the displayed cells or records the query as empty, so the consumer cannot introduce an uninspected exponent while preserving the packet.

Finally read R through the replay row C. Coefficients are returned only from the inspected cells or as the displayed zero scalar outside the inspected support. Thus any support-dependent read factors through G, S, W, R and cannot use an external subset predicate. □

Theorem 7700.4 (Hahn-series valuation nonescape)**.** *For every accepted* $\mathsf{HahnSeries}^{\uparrow}$ *carrier $H = (F, G, S, W, V, R, T, C, P, N)$, the valuation endpoint carried by V is either the least occupied exponent certified by the well-ordered-support ledger W or the formal infinity tag for empty support. No consumer read may replace V by a smaller exponent, an uninspected support element, or a host valuation map while preserving the local* $\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}$ *row.*

Proof. Inspect the two branches recorded by W. In the nonempty branch, W supplies the first occupied exponent among the inspected cells and V records exactly that endpoint. In the empty branch, W exposes the absence of occupied inspected cells and V records the formal infinity tag.

Transport and replay do not add new valuation data. The row T preserves the displayed field, order, support, ledger, valuation, and coefficient rows under hsame, while C replays the valuation read only after support inspection. Replacing V by a smaller exponent or by a host valuation map would require a row absent from H, so the local name no longer certifies the read. □

Falsifiable prediction: An accepted $\mathsf{HahnSeries}^{\uparrow}$ consumer must expose $F, G, S, W, V, R, T, C, P, N$ before using any coefficient readback or valuation endpoint.

Independence witness: field, totalorder, polynomial, formalpowerseries, namecertmorphism: none is bijective to $\mathsf{HahnSeries}^{\uparrow}$ because the field certificate lacks ordered support, the total-order certificate lacks coefficient rows, the polynomial carrier has finite ordinary exponent support, the formal-power-series carrier lacks well-ordered exponent support and valuation readback, and the certificate-morphism route transports certificates without supplying a Hahn-series carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}$.

Constructive story: The Hahn-series packet is generated from finite BEDC rows naming a coefficient field, an ordered exponent surface, inspected support cells, a well-ordered-support ledger, a valuation row, coefficient readback, transport, replay, provenance, and local naming. The construction records the classical Hahn-series carrier as a seed NameCert surface whose support and valuation reads are ledgered before any non-Archimedean consumer may use them.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: The seed scope is exactly the carrier of Definition 7700.1, the obligation surface of Definition 7700.2, the support route of Definition 7700.3, and the valuation nonescape boundary of Definition 7700.4.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HahnSeries}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not claim field operations on all Hahn series, convergence, spherical completeness, algebraic closure, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier rows for coefficient readback, well-ordered support, valuation readback, and componentwise transport.

Chapter 7701

A Concrete Naming Certificate for $\mathsf{DyadicModulusRegularity}^{\uparrow}$

Following Bishop and Bridges on constructive real moduli, the $\mathsf{DyadicModulusRegularity}^{\uparrow}$ packet records a finite dyadic-modulus regularity surface for Real-facing Cauchy reads. It sits over the dyadic tolerance data of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet binds those siblings into one displayed route from dyadic tolerance requests to finite windows, regular Cauchy readback, and Real sealing before any completion consumer reads a modulus claim.

Definition 7701.1 (Dyadic modulus regularity carrier)**.** *A* $\mathsf{DyadicModulusRegularity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, including the dyadic radius ledger and the comparison rows used by the modulus request.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row listing exactly the inspected stream coordinates at the requested dyadic tolerance.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the displayed window into a regular rational Cauchy read.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the dyadic tolerance, finite window, and regular readback rows have been displayed.*
5. *H records componentwise* hsame *transport for D, W, R, E and the structural rows.*
6. *C records displayed* Cont *replay from dyadic tolerance data through finite windows, regular readback, and the real seal.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicModulusRegularity}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusRegularity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient streams, selected representatives, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7701.2 (Dyadic modulus regularity NameCert obligations)**.** *For every accepted* DyadicModulusRegularity *carrier* $M = (D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusRegularity}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission, finite stream-window exposure, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming. No consumer of the packet can read a modulus obligation without first exposing* D, W, R, E, H, C, P, N *in that order.*

Proof. Project the carrier of Definition 7701.1. The dyadic tolerance row D is the only source of radius data, and the finite window row W is the only schedule by which that radius is inspected.

The regular readback row R is downstream of W, so any Cauchy-facing read has already exposed the finite stream coordinates it uses. The real seal row E is downstream of D, W, R, and therefore cannot be consumed as a host limit detached from the displayed modulus route.

Transport, replay, provenance, and naming are carried only by H, C, P, N. These rows preserve the same finite route and do not add quotient streams, selected representatives, trichotomy, countable choice, host real equality, or ambient completeness. The listed rows therefore exhaust the local NameCert obligation surface. □

Theorem 7701.3 (Dyadic modulus regularity stream handoff)**.** *Every accepted* $\mathsf{DyadicModulusRegularity}^{\uparrow}$ *packet hands a Real-facing regularity read to downstream consumers only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The handoff exports a displayed dyadic-modulus route for one finite regular Cauchy read; it does not export quotient-stream equality, a selected representative, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $M = (D, W, R, E, H, C, P, N)$. A downstream consumer sees the real seal only at E.

The row E is named after D, W, R have been displayed. Thus the consumer must first read the dyadic tolerance ledger, then the finite stream window selected for that tolerance, and then the regular rational readback attached to the same window.

The structural rows H, C, P, N replay and name this route without adding another equality or completeness coordinate. Hence the public handoff is the finite dyadic-modulus regularity route stated above, not any of the excluded host or choice principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulusRegularity}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicModulusRegularity}^{\uparrow}}$, seed)

Scope closed: Definition 7701.1, Definition 7701.2, and Definition 7701.3 seed the finite dyadic-modulus regularity route over DyadicRatCore, StreamName, RegSeqRat, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicModulusRegularity}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DyadicModulusRegularityUp`

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, trichotomy, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance coverage, finite window readback, regular Cauchy handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicModulusRegularityUp.

Constructive story: A $\mathsf{DyadicModulusRegularity}^{\uparrow}$ packet is generated from DyadicRatCore tolerance data, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7702

A Concrete Naming Certificate for $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$

Following Isbell and Mrowka on almost-disjoint families and Ψ-spaces, the $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ packet records the classical countable-row construction as finite BEDC topology data. It sits beside the indexed-open carrier of chapter 88, the observable-open classifier of chapter 1860, the membership discipline of chapter 3668, and the finite observation windows of chapter 126. The packet names isolated natural-number rows and almost-disjoint-family point rows only through displayed neighbourhood evidence; it does not import a host powerset of $\mathsf{Nat}^{\uparrow}$, a selected infinite almost-disjoint family, quotient point equality, or choice over neighbourhood tails.

Definition 7702.1 (Isbell–Mrowka Psi-space carrier)**.** *An* $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Psi = (N, A, T, I, F, O, S, W, H, C, P, L)$$

with the following displayed rows:

1. *N is the isolated natural-number row, recording the displayed natural-number names whose singleton neighbourhoods are admitted.*
2. *A is the almost-disjoint-family point row, recording the displayed family-name rows and their finite intersection witnesses without selecting an ambient infinite family.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *admission row, exposing the indexed open rows generated by isolated singletons and cofinite-tail neighbourhoods around family points.*
4. *I is the isolated-point exactness row: a natural-number point is open exactly through its displayed singleton row and not through a hidden host subset.*
5. *F is the cofinite-tail neighbourhood exactness row. For a displayed family point, an accepted neighbourhood is a displayed family row together with a finite forbidden subrow of that family; the remaining tail is read only through the carried membership rows.*
6. *O is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open handoff, recording every open-membership read as a displayed truth row.*
7. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership-provenance row for natural-number membership, family membership, finite forbidden tails, and generated open rows.*
8. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window replay row for the inspected singleton and tail-neighbourhood requests.*

9. *H records componentwise* hsame *transport for isolated rows, family rows, topology admission, exactness rows, observable truth, membership provenance, finite-window replay, package provenance, and local naming.*
10. *C records displayed* Cont *replay from point-row admission through topology rows, observable-open handoff, membership provenance, and finite-window inspection.*
11. *P is the* Pkg *provenance over* $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, A, T, I, F, O, S, W, H, C, P, L$. It has no coordinate for a host powerset topology, an unrestricted subset of $\mathsf{Nat}^{\uparrow}$*, a choice-selected almost-disjoint family, a quotient of points, or an external separation theorem.*

Lean4 ✓ `BEDC.Derived.IsbellMrowkaPsiSpaceUp.IsbellMrowkaPsiSpaceTasteGate single carrier alignment`

Theorem 7702.2 (Isbell–Mrowka Psi-space NameCert obligations)**.** *For every accepted* $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ *carrier*

$$\Psi = (N, A, T, I, F, O, S, W, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}}$ *surface consists exactly of topology-row admission through T, isolated-point exactness through I, cofinite-tail neighbourhood exactness through F, observable-open handoff through O, SetLike membership provenance through S, StreamName finite-window replay through W, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through L. Natural-number rows and almost-disjoint-family point rows are admitted only through N and A, and no obligation is stored outside the displayed tuple.*

Proof. Project the carrier of Definition 7702.1. The rows N and A are the only point-source rows, so an accepted packet can expose either an isolated natural-number point or a family point only through those displayed histories.

The topology obligations are local. Row T admits the generated open rows; row I fixes singleton exactness for isolated natural-number points; and row F fixes cofinite-tail neighbourhood exactness for displayed family points by carrying the finite forbidden subrow.

The observational obligations then pass through O, S, W. Open membership is read as a $\mathsf{SierpinskiSpace}^{\uparrow}$ truth row, all element and tail claims are sourced by $\mathsf{SetLike}^{\uparrow}$ membership provenance, and every inspected singleton or tail request is replayed through a finite $\mathsf{StreamName}^{\uparrow}$ window.

Finally H, C, P, L transport, replay, source, and name the same finite route. Since the classifier has no coordinate for host powersets, unrestricted subsets of $\mathsf{Nat}^{\uparrow}$, choice-selected almost-disjoint families, quotient points, or ambient separation theorems, the listed rows exhaust the local NameCert surface. □

Theorem 7702.3 (Isbell–Mrowka Psi-space topology route)**.** *Every* $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, *or* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ *packet receives neighbourhood data only through the finite route*

$$N, A \longrightarrow T \longrightarrow I, F \longrightarrow O, S, W \longrightarrow H, C, P, L.$$

In particular, an isolated-point read must display the singleton row I, and a family-point neighbourhood read must display the cofinite-tail row F with its finite forbidden subrow before any observable-open or membership-facing read is exported.

Proof. Start with the point-source rows. The natural-number row N and the family row A determine which displayed points can be inspected; no ambient point set is available outside them.

Next read T, I, F. The topology admission row exposes only generated open rows, while the two exactness rows distinguish isolated singleton reads from family-point cofinite-tail reads.

Then consume O, S, W. These rows make each open-membership observation visible as a Sierpinski truth read, bind membership and finite forbidden tails to SetLike provenance, and replay the inspected requests through StreamName windows.

The structural rows H, C, P, L preserve the same route. They add no host powerset, unrestricted almost-disjoint family, selected infinite subfamily, quotient point equality, or choice principle. □

Falsifiable prediction: An accepted $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ consumer is refuted if it reads an isolated singleton, a family-point cofinite-tail neighbourhood, an observable-open truth value, or a membership claim without first displaying the corresponding $N, A, T, I, F, O, S, W, H, C, P, L$ rows.

Independence witness: topology, sierpinski-space, setlike, streamname: no listed sibling is bijective to $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ because the packet jointly carries isolated natural-number point rows, almost-disjoint-family point rows, generated topology admission, singleton exactness, cofinite-tail neighbourhood exactness, observable-open handoff, membership provenance, finite-window replay, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}$ packet is generated from isolated natural-number rows, almost-disjoint-family point rows, TopologyUp admission, singleton exactness, cofinite-tail neighbourhood exactness, SierpinskiSpaceUp observable-open handoff, SetLikeUp membership provenance, StreamNameUp finite windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7702.1, Definition 7702.2, and Definition 7702.3 seed the finite Psi-space route over isolated rows, almost-disjoint-family point rows, topology admission, observable truth, membership provenance, and finite windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IsbellMrowkaPsiSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powerset topologies, unrestricted subsets of NatUp, selected infinite almost-disjoint families, quotient point equality, ambient separation theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology-row admission, isolated-point exactness, cofinite-tail neighbourhood exactness, observable-open handoff, membership provenance, finite-window replay, transport, replay, provenance, and local naming for BEDC.Derived.IsbellMrowkaPsiSpaceUp.

Chapter 7703

A Concrete Naming Certificate for $\mathsf{BaireClassOneRealFunction}^{\uparrow}$

Following Baire and Bishop-Bridges on pointwise limits of continuous real functions, the $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ packet records a constructive Baire class one real-valued function as an explicit sequence of continuous real functions with finite pointwise readback. It sits after the real-name carrier of chapter 38, the stream-name interface of chapter 126, the regular-rational readback surface of chapter 301, the continuous-map packet of chapter 130, and the pointwise stream metric route of chapter 4139. The packet gives later $\mathsf{Real}^{\uparrow}$ consumers a sequence-of-continuous-functions target without host function equality, a quotient function space, selected representatives, countable choice, or an ambient measurability theorem.

Definition 7703.1 (Baire class one real-function carrier)**.** *A* $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, S, A, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the source real-domain row whose point requests are read through* $\mathsf{Real}^{\uparrow}$ *names.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule listing the inspected stages of the approximating function sequence.*
3. *A is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row assigning each inspected stage to a displayed continuous real-valued map.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to each pointwise real output produced by the inspected continuous maps.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the pointwise limiting value.*
6. *M is the* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *row comparing the stage outputs only through finite pointwise windows.*
7. *H records componentwise* hsame *transport for source, schedule, continuous-map, readback, Real-seal, metric, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point request through $X, S, A, R, E, M, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireClassOneRealFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{PointwiseStreamMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BaireClassOneRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host equality of functions, a completed function space quotient, an externally selected pointwise limit, countable choice, arbitrary measurability, or an ambient theorem identifying all Baire class one maps.

Theorem 7703.2 (Baire class one real-function NameCert obligations)**.** *For every accepted* BaireClassOneRealFunct *carrier $F = (X, S, A, R, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BaireClassOneRealFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the source real-domain row, the* $\mathsf{StreamName}^{\uparrow}$ *stage schedule, the* $\mathsf{ContinuousMap}^{\uparrow}$ *sequence row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *pointwise readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, the* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *comparison row, componentwise transport, displayed replay, package provenance, and local naming. Every downstream real-analysis consumer must consume those rows before treating the packet as a Baire class one real-valued function.*

Proof. Project the carrier of Definition 7703.1. The accepted packet exposes only the source row, inspected stage schedule, continuous-map sequence row, regular-rational readback, Real seal, pointwise metric row, transport, replay, provenance, and local naming.

The constructive pointwise-limit route starts with X and S. A consumer first names the point request and the inspected stages, then reads the continuous-map row A at those stages.

The output route is then forced through R, E, M. The regular-rational readback records the displayed numerical data, the Real seal records the terminal pointwise value, and the pointwise stream metric row compares the stage outputs only through finite windows.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores host function equality, a quotient function space, selected representatives, countable choice, arbitrary measurability, or an ambient classification theorem, the listed obligations exhaust the local certificate surface. □

Theorem 7703.3 (Baire class one sequence handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*, completion-facing, or pointwise-metric consumer of an accepted* $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{PointwiseStreamMetric}^{\uparrow}.$$

Thus the Baire class one row is a displayed sequence of continuous real-valued maps with pointwise readback, not a host function equality class, a selected limit map, or an imported measurable-function hierarchy.

Proof. Begin with a downstream consumer. Carrier admission forces the consumer to read the $\mathsf{StreamName}^{\uparrow}$ schedule before any stage of the approximating sequence can be inspected.

The inspected stage is then a $\mathsf{ContinuousMap}^{\uparrow}$ row. Its numerical output is not exposed directly as a host function value; it passes through the $\mathsf{RegSeqRat}^{\uparrow}$ readback and the terminal $\mathsf{Real}^{\uparrow}$ seal.

The pointwise comparison is supplied by $\mathsf{PointwiseStreamMetric}^{\uparrow}$. That row keeps finite windows visible while the sequence handoff is transported and replayed by H and C.

Consequently the consumer receives only the displayed sequence route over the named sibling packets. The carrier inventory excludes host function equality, quotient function spaces, selected pointwise limits, countable choice, and imported measurability structure. □

Falsifiable prediction: An accepted $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ consumer is refuted if it treats a pointwise limit as public before displaying the StreamName stage schedule, ContinuousMap sequence row, RegSeqRat readback, Real seal, PointwiseStreamMetric comparison, transport, replay, provenance, and local NameCert rows.

Independence witness: real, streamname, regseqrat, continuousmap, pointwisestreammetric: none is bijective because $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ binds a real-domain source, explicit stage schedule, continuous real-valued maps, pointwise readback, Real seal, pointwise metric comparison, transport, replay, provenance, and local NameCert rows in one packet. Each sibling supplies one constituent surface, while only this packet names the sequence-of-continuous-functions route.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireClassOneRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ packet is generated from a RealUp source row, a StreamName finite stage schedule, ContinuousMap sequence rows, RegSeqRat pointwise readback, a RealUp seal, a PointwiseStreamMetric comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireClassOneRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7703.1, Definition 7703.2, and Definition 7703.3 seed the explicit sequence-of-continuous-real-functions route over RealUp, StreamNameUp, RegSeqRatUp, ContinuousMapUp, PointwiseStreamMetricUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireClassOneRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function equality, quotient function spaces, selected pointwise limits, countable choice, arbitrary measurability, or a full Baire hierarchy.

Upgrade path: Obligation closure requires checked carrier admission, stage-schedule exactness, continuous-map sequence exposure, pointwise readback, Real seal nonescape, pointwise metric handoff, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BaireClassOneRealFunctionUp.

Chapter 7704

A Concrete Naming Certificate for $\mathsf{StationaryDistribution}^{\uparrow}$

Following Kemeny–Snell finite Markov-chain terminology, the $\mathsf{StationaryDistribution}^{\uparrow}$ packet records an invariant law for a displayed finite transition matrix. It sits downstream of the transition-packet surface of chapter 189, the probability measure rows of chapter 184 and chapter 186, the finite matrix carrier of chapter 49, and the scalar seal of chapter 38. The packet names the finite invariant-law surface only; it is not an ergodic theorem, limiting distribution theorem, Perron–Frobenius argument, or host stochastic-process construction.

Definition 7704.1 (Stationary distribution carrier)**.** *A* $\mathsf{StationaryDistribution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Pi = (S, M, \pi, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state ledger over a displayed* $\mathsf{ProbSpace}^{\uparrow}$ *source.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *transition row whose entries are nonnegative* $\mathsf{Real}^{\uparrow}$ *scalars and whose displayed rows sum to the probability unit.*
3. *π is the* $\mathsf{Distribution}^{\uparrow}$ *law row on the same finite state ledger.*
4. *L is the finite left-invariance ledger recording the row equations*

$$\pi_j = \sum_{i \in S} \pi_i M_{ij}$$

   for every displayed state j.

5. *E records the endpoint compatibility between the transition row, the probability source, and the displayed law row.*
6. *H records componentwise* hsame *transport for S, M, π, L, E and the local naming row.*
7. *C records displayed* Cont *replay from the Markov transition packet through the matrix row and invariant-law equations.*
8. *P is the* Pkg *provenance over* $\mathsf{StationaryDistribution}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StationaryDistribution}^{\uparrow}}$ *row.*

The carrier exports no convergence rate, recurrence classifier, irreducibility argument, uniqueness proof, host limiting law, countable-choice selector, or standard Markov-kernel bridge.

Theorem 7704.2 (Stationary distribution NameCert obligations)**.** *For the carrier of Definition 7704.1, the local* $\mathsf{NameCert}_{\mathsf{StationaryDistribution}^{\uparrow}}$ *surface consists exactly of carrier admission for* $\Pi = (S, M, \pi, L, E, H, C, P, N)$*, finite state exposure through* S*, transition-matrix admission through* M*, invariant-law admission through* π*, finite left-invariance equations through* L*, endpoint compatibility through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. Its coordinates display the finite state ledger, matrix transition row, law row, invariance equations, endpoint compatibility, transport, replay, provenance, and local name.

The dependency certificates account for the data-bearing rows. The $\mathsf{ProbSpace}^{\uparrow}$ row supplies the source ledger, $\mathsf{Mat}^{\uparrow}$ supplies the finite transition entries, $\mathsf{Real}^{\uparrow}$ supplies the scalar seals, and $\mathsf{Distribution}^{\uparrow}$ supplies the law row π.

The remaining rows transport, replay, source, and name the same finite data. Since the carrier contains no convergence, recurrence, uniqueness, limiting, choice, or standard-kernel coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7704.3 (Stationary distribution invariance scope)**.** *Every invariant-law read of an accepted* $\mathsf{StationaryDistribution}^{\uparrow}$ *carrier factors through the finite route*

$$S, M, \pi, L, E, H, C, P, N.$$

The read inspects the finite $\mathsf{Mat}^{\uparrow}$ *transition row and the* $\mathsf{Distribution}^{\uparrow}$ *law row before it can use the equations in* L*, and those equations are interpreted only through the displayed* $\mathsf{Real}^{\uparrow}$ *scalar seals and the shared* $\mathsf{ProbSpace}^{\uparrow}$ *state ledger.*

Proof. Begin with the carrier rows S, M, π. They fix the finite state ledger, the transition matrix, and the law whose invariance is being certified.

Next read the equation ledger L. Each displayed equation has endpoints in the same finite state ledger and uses only the transition entries and law weights already exposed by M and π.

Finally pass through E, H, C, P, N. These rows keep the endpoint compatibility, transport, replay, provenance, and naming attached to the same finite route. Thus an invariant-law consumer has no alternate path through a host chain, limiting distribution, or uniqueness theorem. □

Theorem 7704.4 (Stationary distribution Markov consumer handoff)**.** *Whenever a* $\mathsf{MarkovChain}^{\uparrow}$ *transition packet consumes an accepted* $\mathsf{StationaryDistribution}^{\uparrow}$ *carrier, the handoff reads the displayed finite state ledger* S*, transition row* M*, invariant law* π*, invariance ledger* L*, endpoint row* E*, and structural rows* H, C, P, N*. The consumer may treat* π *as a stationary law for the displayed finite transition packet, but it does not receive a convergence theorem, recurrence decomposition, irreducibility witness, uniqueness classifier, or standard Markov-kernel object.*

Proof. Use the Markov transition-packet source boundary from Definition 189.5. It keeps the probability source, random-variable rows, distribution laws, and transition rows inside the displayed $\mathsf{MarkovChain}^{\uparrow}$ packet.

Attach the stationary carrier along the common finite transition row. The matrix row M supplies the finite transition entries, while π and L record the invariant law and its finite equations over the same state ledger.

The structural rows then replay the handoff without adding host stochastic process data. Since neither carrier contains a convergence, recurrence, irreducibility, uniqueness, or standard-kernel coordinate, the Markov consumer receives exactly the displayed stationary-law surface. □

Falsifiable prediction: Every accepted StationaryDistribution$^{\uparrow}$ packet exposes a finite invariant-law equation ledger over a displayed transition matrix and exports no convergence, recurrence, irreducibility, uniqueness, or host limiting-law coordinate.

Independence witness: markovchain, distribution, probspace, matrix, real: no listed sibling is bijective to StationaryDistribution$^{\uparrow}$ because this packet binds one finite transition matrix, one law row, and one left-invariance equation ledger in a single Markov-consumer handoff. The MarkovChain sibling lacks a distinguished invariant law; DistributionUp lacks transition equations; ProbSpaceUp lacks matrix dynamics; MatrixUp lacks probability-law admission; RealUp lacks the finite invariant-law route.

Closure status for $\mathsf{NameCert}_{\mathsf{StationaryDistribution}^{\uparrow}}$.

Constructive story: A StationaryDistribution$^{\uparrow}$ packet is generated from a finite state ledger, a transition MatrixUp row, a DistributionUp law row, a finite left-invariance equation ledger, endpoint compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StationaryDistribution}^{\uparrow}}$, seed)

Scope closed: Definition 7704.1, Definition 7704.2, Definition 7704.3, and Definition 7704.4 seed the finite invariant-law surface over MarkovChain, ProbSpace, Distribution, Matrix, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{StationaryDistribution}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim convergence to stationarity, recurrence decomposition, irreducibility, uniqueness, limiting distributions, standard Markov kernels, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, matrix stochasticity, invariant-law equation coverage, endpoint compatibility, and local NameCert registration for BEDC.Derived.StationaryDistributionUp.

Chapter 7705

A Concrete Naming Certificate for $\mathsf{ReflectionGapAudit}^{\uparrow}$

The $\mathsf{ReflectionGapAudit}^{\uparrow}$ packet realizes the reflection-gap surface of Definition 9414.413 as a finite audit carrier for observation-reflection and MetaCIC self-study. It sits beside the observation-reflection packet of chapter 1126, the finite observation-reflection surface of chapter 5109, the reflective inquiry carrier of chapter 1151, and the reflection-gap boundary of chapter 1161. The audit records inquiry rows, ledger rows, continuation rows, non-finalization rows, transport, replay, provenance, and local naming without asserting a total truth predicate, final oracle, physical-formal identity, or closed meta loop.

Definition 7705.1 (Reflection gap audit carrier)**.** *A* $\mathsf{ReflectionGapAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, G, L, Q, F, T, R, P, N)$$

with the following displayed rows:

1. *I is the finite inquiry row, read from the observation-reflection source, finite trace, signature, classifier, and package data.*
2. *G is the reflection-gap row, naming the displayed difference between finite certified self-description and total truth.*
3. *L is the audit ledger row, recording accepted finite self-description claims, rejected totalizing claims, and still-open audit residues.*
4. *Q is the continuation row, listing the finite continuations under which the audit may be replayed.*
5. *F is the non-finalization row, recording that no row in the packet certifies final truth, total fit, closed prediction, or internal truth for the whole system.*
6. *T records componentwise* hsame *transport for inquiry, gap, ledger, continuation, non-finalization, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay of the route from inquiry rows through the audit ledger and open continuation into the non-finalization row.*
8. *P is the* Pkg *provenance over* $\mathsf{ReflectionGapAudit}^{\uparrow}$, $\mathsf{ObservationReflectionPacket}^{\uparrow}$, $\mathsf{FiniteObservationReflection}^{\uparrow}$, $\mathsf{ReflectiveInquiry}^{\uparrow}$, $\mathsf{ReflectionGapBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ReflectionGapAudit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, L, Q, F, T, R, P, N$. It has no coordinate for a total truth predicate, final physical oracle, final MetaCIC oracle, physical-formal source identity, closed continuation exhaustion, or host-level validation.

Theorem 7705.2 (Reflection gap audit non-escape)**.** *Every accepted* $\mathsf{ReflectionGapAudit}^{\uparrow}$ *packet exports only the finite route*

$$I, G, L, Q, F, T, R, P, N.$$

A consumer may read the inquiry row, reflection-gap row, audit ledger, open-continuation row, non-finalization row, transport, replay, provenance, and local NameCert row. It cannot recover a total truth predicate, final physical oracle, final MetaCIC oracle, source-domain identity, closed continuation exhaustion, or host validation from the packet.

Lean4 ✓ `BEDC.Derived.ReflectionGapAuditUp.ReflectionGapAuditNonescape`

Proof. Inspect the carrier of Definition 7705.1. The only readable coordinates are the displayed inquiry, gap, ledger, continuation, non-finalization, transport, replay, provenance, and local naming rows.

The audit ledger L records finite claims and rejected totalizing claims. The continuation row Q records replayable continuations, while the non-finalization row F keeps the finality refusal as data inside the packet.

The structural rows T, R, P, N preserve the same finite route. Since no row stores total truth, final physical or MetaCIC oracles, source identity, closed continuation exhaustion, or host validation, those endpoints cannot escape from the audit packet. □

Theorem 7705.3 (Reflection gap audit bridge)**.** *The* $\mathsf{ReflectionGapAudit}^{\uparrow}$ *carrier bridges the observation-reflection vision to concrete NameCert data by reading* $\mathsf{ObservationReflectionPacket}^{\uparrow}$*,* $\mathsf{FiniteObservationReflection}^{\uparrow}$*,* $\mathsf{ReflectiveInquiry}^{\uparrow}$*, and* $\mathsf{ReflectionGapBoundary}^{\uparrow}$ *only through finite inquiry, gap, ledger, continuation, non-finalization, transport, replay, provenance, and local naming rows. The bridge is an audit surface, not a totalizing truth predicate or a final oracle.*

Proof. Start with the originating reflection-gap definition. Its role is the difference between finite certified self-description and total truth, so the concrete audit needs both a finite inquiry row and a non-finalization row.

The sibling chapters supply the visible rows. $\mathsf{ObservationReflectionPacket}^{\uparrow}$ supplies source, history, signature, classifier, package, ledger, and continuation roles; $\mathsf{FiniteObservationReflection}^{\uparrow}$ supplies the finite trace route; $\mathsf{ReflectiveInquiry}^{\uparrow}$ supplies the paired physical and formal inquiry route; and $\mathsf{ReflectionGapBoundary}^{\uparrow}$ supplies the boundary row refusing total truth.

The audit carrier repacks those rows as $I, G, L, Q, F, T, R, P, N$. Because the repacking preserves the open continuation and non-finalization rows, the bridge records a finite audit surface and not a final truth oracle, source identity claim, or closed meta loop. □

Falsifiable prediction: Every accepted $\mathsf{ReflectionGapAudit}^{\uparrow}$ read exposes finite inquiry, reflection-gap, audit ledger, open-continuation, non-finalization, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows before any reflection-gap audit judgment is exported.

Independence witness: observationreflectionpacket, finite-observation-reflection, reflectiveinquiry, reflectiongapboundary: $\mathsf{ReflectionGapAudit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the audit ledger and non-finalization rows with the finite inquiry, reflection-gap, continuation, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ReflectionGapAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{ReflectionGapAudit}^{\uparrow}$ packet is generated from finite inquiry, reflection-gap, audit-ledger, open-continuation, non-finalization, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReflectionGapAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7705.1, Definition 7705.2, and Definition 7705.3 seed the finite reflection-gap audit surface over inquiry, gap, ledger, continuation, non-finalization, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReflectionGapAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total truth, final physical or MetaCIC oracles, physical-formal source identity, closed continuation exhaustion, host validation, Lean verification, or bridge checking for $\mathsf{ReflectionGapAudit}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, inquiry exposure, gap-ledger exactness, continuation replay, non-finalization non-escape, transport, provenance, and local naming for BEDC.Derived.ReflectionGapAuditUp.

Chapter 7706

A Concrete Naming Certificate for $\mathsf{DyadicSpread}^{\uparrow}$

Following Bishop on located real approximations and Kleene on finite spread laws, the $\mathsf{DyadicSpread}^{\uparrow}$ packet records a finite dyadic-prefix spread whose windows may be read by stream, regular-sequence, real, tree, and Cantor-space consumers. It is a finite-prefix sibling of $\mathsf{RegularCauchySpread}^{\uparrow}$ in chapter 2072, the dyadic interval net of chapter 5966, and the regular sequence space of chapter 5965. The packet names displayed prefix windows; it does not select an infinite branch, complete a real, decide bar coverage, or claim compactness.

Definition 7706.1 (Dyadic spread finite-prefix carrier)**.** *A* $\mathsf{DyadicSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (P, W, I, S, R, A, K, C, H, Q, L, N)$$

with the following displayed rows:

1. *P is the finite prefix tree row, listing dyadic words closed under initial segment;*
2. *W is the finite window schedule, recording which prefix lengths are visible to a consumer;*
3. *I is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *interval row attached to each displayed prefix;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row that reads a prefix window as a finite name segment;*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for the dyadic windows whose moduli are displayed in W;*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the regular readback row has supplied the displayed tolerance data;*
7. *K is the* $\mathsf{KleeneTree}^{\uparrow}$ *law row naming the finite spread-law closure under prefix extension and rejection;*
8. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *cylinder row for binary-prefix consumers that read only the displayed branch window;*
9. *H stores componentwise* hsame *transport for prefix, window, dyadic interval, stream-name, regular readback, real-seal, tree-law, and cylinder rows;*
10. *Q stores the finite* Cont *replay routes from prefixes to dyadic intervals, stream windows, regular readback, real sealing, tree-law checks, and cylinder reads;*

11. *L is the* Pkg *provenance over* DyadicSpread$^\uparrow$, DyadicRatCore$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, KleeneTree$^\uparrow$, CantorSpace$^\uparrow$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* NameCert$_{\text{DyadicSpread}^\uparrow}$ *row.*

The classifier compares two carriers only by transporting the displayed finite prefix tree, dyadic windows, consumer rows, replay routes, provenance, and local certificate. No coordinate stores an infinite choice sequence, a quotient of branch names, or ambient completeness of Real$^\uparrow$*.*

Theorem 7706.2 (Dyadic spread window stability)**.** *For every accepted* DyadicSpread$^\uparrow$ *carrier $D = (P, W, I, S, R, A, K, C, H, Q, L, N)$, each finite window read used by the* StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, KleeneTree$^\uparrow$, *and* CantorSpace$^\uparrow$ *rows is stable under the displayed* hsame *transport and replays through the displayed* Cont *routes. Thus any consumer that reads a prefix window after transport receives the same finite dyadic interval data, the same regular readback obligation, the same real-seal boundary, the same tree-law decision, and the same Cantor cylinder row, with no route to an uncarried branch or completion principle.*

Proof. Project the carrier of Definition 7706.1. The only rows available to a window consumer are the finite prefix tree P, the window schedule W, the dyadic interval row I, the stream, regular, real, tree, and cylinder rows S, R, A, K, C, and the support rows H, Q, L, N.

Use the transport row H componentwise. A transported prefix remains a displayed prefix of the transported finite tree, a transported dyadic interval remains the corresponding DyadicRatCore$^\uparrow$ window, and the stream-name, regular readback, real-seal, tree-law, and Cantor-cylinder rows are transported with the same finite index in W.

Use the continuation row Q to replay the same read after transport. The replay starts from the displayed prefix window and reaches only the displayed rows I, S, R, A, K, C; it cannot create an infinite branch, select a representative stream, or insert a completion theorem.

Therefore finite window transport preserves exactly the visible dyadic-prefix data and its consumer-facing obligations. The result is the window stability needed by RegularCauchySpread$^\uparrow$ and RegularSequenceSpace$^\uparrow$ consumers, while the chapter remains a finite NameCert packet. □

Lean4 ✓ `BEDC.Derived.DyadicSpreadUp.DyadicSpreadWindowStability`

Falsifiable prediction: Every accepted DyadicSpread$^\uparrow$ consumer read is determined by a displayed finite prefix window. A read that selects an infinite branch, imports countable choice, or uses ambient Real$^\uparrow$ completeness is not a valid read of the carrier of Definition 7706.1.

Independence witness: regular-cauchy-spread, regular-sequence-space, dyadic-interval-net, kleene-tree, cantor-space: DyadicSpread$^\uparrow$ is not bijective to any listed sibling because it stores the finite dyadic-prefix spread law together with stream-name, regular readback, real-seal, tree-law, and cylinder consumer rows in one packet.

Closure status for NameCert$_{\text{DyadicSpread}^\uparrow}$.

Constructive story: A DyadicSpread$^\uparrow$ packet is generated from a finite prefix tree, displayed dyadic windows, DyadicRatCore interval rows, StreamName windows, RegSeqRat readback, a Real seal boundary, KleeneTree spread-law checks, CantorSpace cylinders, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicSpread}^\uparrow}$, seed)

Scope closed: Definition 7706.1 and Definition 7706.2 seed the finite dyadic-prefix spread route over DyadicRatCore$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, KleeneTree$^\uparrow$, and CantorSpace$^\uparrow$ rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicSpread}^\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not select an infinite branch, prove bar induction, close compactness, assert ambient real completeness, or provide Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix-law exactness, dyadic window replay, regular readback, real-seal boundary, cylinder stability, provenance accounting, and non-escape for the same packet.

Chapter 7707

A Concrete Naming Certificate for $\mathsf{HoarePowerdomain}^{\uparrow}$

Following Hoare and Smyth domain-theoretic powerdomain semantics, the $\mathsf{HoarePowerdomain}^{\uparrow}$ packet records the lower powerdomain side of finite nondeterministic observation as a hit-oriented NameCert surface. It sits below the open-set classifier of chapter 5950, the order carrier of chapter 53, and the compact-family comparison route of chapter 2375. The packet gives domain-topology consumers a lower hit window without importing an upper powerdomain, a convex powerdomain law, ideal completion, or host-level set equality.

Definition 7707.1 (Hoare powerdomain carrier)**.** *A* $\mathsf{HoarePowerdomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (D, O, K, L, W, R, T, C, P, N)$$

with the following displayed rows:

1. *D is the underlying domain row, read through the ordered carrier surface of* $\mathsf{Poset}^{\uparrow}$*.*
2. *O is the Scott-open observation row, read through* $\mathsf{ScottTopology}^{\uparrow}$*.*
3. *K is the compact-or-finite lower witness row, comparable with the hyperspace route of* $\mathsf{VietorisTopology}^{\uparrow}$*.*
4. *L is the lower hit predicate row: an observation is public only when the packet displays a witness that the lower set meets the inspected open.*
5. *W is the finite hit-window ledger listing the inspected open rows and the associated witnesses.*
6. *R records monotone readback along the displayed order row of D.*
7. *T records componentwise* hsame *transport for $D, O, K, L, W, R, C, P, N$.*
8. *C records displayed* Cont *replay from the domain row through Scott opens, lower hits, finite windows, order readback, transport, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HoarePowerdomain}^{\uparrow}$*,* $\mathsf{ScottTopology}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*,* $\mathsf{VietorisTopology}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HoarePowerdomain}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for upper misses, convex combination, ideal completion, saturated-set equality, arbitrary unions of host subsets, or a quotient by extensional set equality.

Theorem 7707.2 (Hoare powerdomain NameCert obligations)**.** *For every accepted* $\mathsf{HoarePowerdomain}^{\uparrow}$ *carrier* $H = (D, O, K, L, W, R, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HoarePowerdomain}^{\uparrow}}$ *surface consists exactly of carrier admission for the domain row, Scott-open observation row, compact-or-finite lower witness row, lower hit predicate row, finite hit-window ledger, monotone readback row, componentwise transport, displayed replay, package provenance, and local naming. Every downstream domain-topology consumer must read those rows before treating the packet as a lower powerdomain object.*

Proof. Project the carrier of Definition 7707.1. The accepted packet exposes the domain row, Scott-open row, compact-or-finite witness row, lower hit predicate, finite hit-window ledger, monotone readback, transport, replay, provenance, and local naming.

Read the lower observation route first. The domain row D supplies the ordered carrier surface, while O restricts observations to displayed Scott opens and K supplies the finite or compact witness data that can meet such opens.

The hit information is then forced through L, W, R. The row L records lower hit admission, W lists the inspected windows and witnesses, and R keeps the readback monotone along the displayed order.

Finally T, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores upper misses, convex powerdomain operations, ideal completion, arbitrary host subsets, or set-extensional quotient data, the listed rows exhaust the local certificate surface. □

Theorem 7707.3 (Hoare lower hit window)**.** *Every* $\mathsf{ScottTopology}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*, or* $\mathsf{VietorisTopology}^{\uparrow}$ *consumer of an accepted* $\mathsf{HoarePowerdomain}^{\uparrow}$ *carrier must read the finite lower-hit route*

$$\mathsf{Poset}^{\uparrow} \longmapsto \mathsf{ScottTopology}^{\uparrow} \longmapsto \mathsf{VietorisTopology}^{\uparrow} \longmapsto \mathsf{HoarePowerdomain}^{\uparrow}.$$

Thus the public observation is a displayed lower hit of an inspected Scott open, not an upper miss, a convex powerdomain comparison, a completed ideal, or a host subset equality claim.

Proof. Begin with the ordered carrier. The consumer receives D before any lower-powerdomain observation is available, so the packet is anchored in the displayed $\mathsf{Poset}^{\uparrow}$ surface rather than in host subset equality.

The open observation is then a $\mathsf{ScottTopology}^{\uparrow}$ row. The lower hit predicate can be read only against such an inspected open, and the compact-or-finite witness row supplies the visible meet data comparable with $\mathsf{VietorisTopology}^{\uparrow}$.

The finite window ledger W prevents the hit from becoming an arbitrary host-level union or a hidden ideal completion. Transport, replay, provenance, and local naming preserve the same lower-hit packet for downstream consumers, so the only public observation is the stated finite route. □

Falsifiable prediction: An accepted $\mathsf{HoarePowerdomain}^{\uparrow}$ consumer is refuted if it reports a lower hit before displaying the Poset domain row, Scott-open observation row, compact-or-finite witness row, finite hit-window ledger, monotone readback, transport, replay, provenance, and local NameCert rows.

Independence witness: scotttopology, poset, vietoristopology: none is bijective because $\mathsf{HoarePowerdomain}^{\uparrow}$ binds an ordered domain row, Scott-open observation row, compact-or-finite lower witness row, lower hit predicate, finite hit-window ledger, monotone readback, transport, replay, provenance, and local NameCert row in one packet. Each sibling supplies one constituent surface, while only this packet names the lower powerdomain hit route.

Closure status for $\mathsf{NameCert}_{\mathsf{HoarePowerdomain}^{\uparrow}}$.

Constructive story: A $\mathsf{HoarePowerdomain}^{\uparrow}$ packet is generated from a Poset domain row, ScottTopology open row, compact-or-finite lower witness row, lower hit predicate row, finite hit-window ledger, monotone readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HoarePowerdomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7707.1, Definition 7707.2, and Definition 7707.3 seed the lower hit route over PosetUp, ScottTopologyUp, VietorisTopologyUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HoarePowerdomain}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.HoarePowerdomainUp`

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, upper misses, convex powerdomain laws, ideal completion, host subset equality, arbitrary unions of host subsets, or an extensional quotient surface.

Upgrade path: Obligation closure requires checked carrier admission, Scott-open hit exactness, compact-or-finite lower witness exposure, finite hit-window readback, monotone order transport, displayed replay, provenance, and local naming for BEDC.Derived.HoarePowerdomainUp.

Chapter 7708

A Concrete Naming Certificate for $\mathsf{GromovCompactness}^{\uparrow}$

Following Gromov's compactness theorem for families of compact metric spaces, the $\mathsf{GromovCompactness}^{\uparrow}$ packet records the finite epsilon-net compactness route as NameCert data. It sits beside the compact metric carrier of chapter 129, the Gromov–Hausdorff naming surface of chapter 2104, and the Gromov–Hausdorff distance packet of chapter 5200. The packet packages finite radius ledgers and finite net comparisons; it does not import open-cover compactness, selected subsequences, quotient metric spaces, or a host compactness theorem.

Definition 7708.1 (Gromov compactness carrier)**.** *A* $\mathsf{GromovCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, E, N, D, G, H, C, P, L)$$

whose rows are the family index row F, the finite epsilon-scale row E, the finite net row N, the distance-comparison row D, the $\mathsf{GromovHausdorff}^{\uparrow}$ *handoff row G, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{GromovCompactness}^{\uparrow}}$ *row L. The classifier compares accepted packets only through these displayed rows. It has no coordinate for an open-cover compactness theorem, a chosen subsequence, a quotient metric-space construction, a host hyperspace compactness object, or ambient completeness.*

Theorem 7708.2 (Gromov compactness NameCert obligations)**.** *For every accepted* $\mathsf{GromovCompactness}^{\uparrow}$ *carrier $K = (F, E, N, D, G, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{GromovCompactness}^{\uparrow}}$ *surface consists exactly of family-index admission through F, finite epsilon-scale admission through E, finite net admission through N, distance-comparison admission through D, Gromov–Hausdorff handoff through G, transport through H, replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 7708.1. The compactness-facing rows are F, E, N, D, G, and the structural rows are H, C, P, L.

The finite epsilon-scale row E is read before the finite net row N and distance-comparison row D. This keeps the compactness route inside inspected finite nets instead of replacing it by an open-cover compactness theorem.

Finally G, H, C, P, L hand the same finite route to the Gromov–Hausdorff and compact metric neighbours, transport it, replay it, source it, and name it. Since no carrier coordinate contains a selected subsequence, quotient metric space, host hyperspace compactness theorem, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7708.3 (Gromov compactness finite epsilon-net route)**.** *Every compactness-facing consumer of an accepted* $\mathsf{GromovCompactness}^{\uparrow}$ *carrier receives only the finite route*

$$F, E, N, D, G, H, C, P, L.$$

The route may be handed to $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{GromovHausdorff}^{\uparrow}$*, or* $\mathsf{PointedGromovHausdorff}^{\uparrow}$ *consumers as finite epsilon-net evidence with displayed distance comparisons, but it does not export open-cover compactness, selected subsequences, quotient metric spaces, host hyperspace compactness, or ambient completeness.*

Proof. Start with the family and epsilon rows F, E. They name the inspected family slice and the finite scale ledger before any compactness-facing read is public.

Read the finite net and distance-comparison rows N, D next. These rows provide the finite witnesses consumed by compact metric and Gromov–Hausdorff neighbours, while keeping the route within displayed comparisons.

The handoff and structural rows G, H, C, P, L preserve the same finite route. Therefore a downstream consumer receives finite epsilon-net compactness data, not an open-cover theorem, a selected subsequence, a quotient metric-space object, or an ambient completeness principle. □

Falsifiable prediction: A $\mathsf{GromovCompactness}^{\uparrow}$ compactness-facing read that exposes a public conclusion without the displayed family row F, epsilon-scale row E, finite-net row N, distance-comparison row D, Gromov–Hausdorff handoff row G, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: compactmetric, gromov-hausdorff, gromov-hausdorff-distance: no listed sibling is bijective to $\mathsf{GromovCompactness}^{\uparrow}$ because this packet jointly carries family indices, finite epsilon scales, finite net ledgers, distance comparisons, Gromov–Hausdorff handoff, transport, replay, provenance, and local naming while refusing open-cover compactness and selected subsequences.

Closure status for $\mathsf{NameCert}_{\mathsf{GromovCompactness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{GromovCompactness}^{\uparrow}$ packet is generated from family indices, finite epsilon-scale rows, finite net ledgers, distance comparisons, Gromov–Hausdorff handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GromovCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7708.1, Definition 7708.2, and Definition 7708.3 seed the finite epsilon-net compactness route for metric-family consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GromovCompactness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, subsequence selection, quotient metric-space construction, host hyperspace compactness, Lean verification, or bridge checking for $\mathsf{GromovCompactness}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite epsilon-scale admission, finite net admission, distance-comparison admission, Gromov–Hausdorff handoff, transport, replay, provenance, and local naming for BEDC.Derived.GromovCompactnessUp.

Chapter 7709

A Concrete Naming Certificate for $\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}$

The $\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}$ packet realizes the residual critical-pair budget branch of the MetaCIC confluence audit map as finite NameCert data. It sits after the residual critical-pair carrier of chapter 7291, the confluence audit packet of chapter 735, and the local-diamond witness of chapter 3595. The packet records a bounded residual-frontier budget, candidate local joins, closed-check rows, obstruction retention, TasteGate readiness, replay, provenance, and local naming; it does not claim global confluence, unrestricted residual-substitution compatibility, subject reduction, quotient syntax equality, or a hidden evaluator.

Definition 7709.1 (MetaCIC residual critical-pair budget carrier)**.** *A* $\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, K, J, D, O, T, H, C, P, N)$$

whose rows are the residual critical-pair source row R, the finite budget row K, the candidate local-join row J, the closed-check row D, the obstruction row O, the TasteGate readiness row T, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}}$ *row N. The classifier compares accepted packets only through these rows. It has no coordinate for global Church–Rosser, arbitrary substitution compatibility, subject reduction, quotient syntax equality, or host evaluator soundness.*

Theorem 7709.2 (MetaCIC residual critical-pair budget obligations)**.** *For every accepted* $\mathsf{MetaCICResidualCriticalP}$ *carrier $B = (R, K, J, D, O, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}}$ *surface consists exactly of residual critical-pair source admission through R, finite budget admission through K, candidate local-join admission through J, closed-check admission through D, obstruction retention through O, TasteGate readiness through T, transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7709.1. The confluence-facing rows are R, K, J, D, O, and the structural rows are T, H, C, P, N.

The residual source row R is read before the finite budget row K and candidate local-join row J. This keeps each critical-pair read inside a displayed residual frontier rather than treating a local join as an unbounded confluence theorem.

The closed-check row D and obstruction row O then separate the inspected closed fragment from the missing residual-substitution and parallel-diamond inputs. Finally T, H, C, P, N reserve the TasteGate instance boundary, transport, replay, source, and name the same finite route. □

Theorem 7709.3 (MetaCIC residual critical-pair budget boundary)**.** *Every confluence-audit consumer of an accepted* MetaCICResidualCriticalPairBudget$^{\uparrow}$ *carrier receives only the finite route*

$$R, K, J, D, O, T, H, C, P, N.$$

The route may budget residual critical-pair inspections and candidate local joins, but it cannot erase the obstruction row O, manufacture unrestricted residual-substitution compatibility, prove a parallel diamond, export global confluence, or supply subject reduction.

Proof. Start with the residual source and finite budget rows R, K. They bind the consumer to an inspected residual frontier and a displayed budget before any candidate join is read.

Read the candidate local-join and closed-check rows J, D. These rows may admit a bounded local join for the displayed frontier, but they do not contain arbitrary substitution compatibility or a global diamond.

The obstruction and structural rows O, T, H, C, P, N preserve the boundary. The Lean Nontrivial and FieldFaithful TasteGate instances required by T must be supplied before the packet can be consumed as a checked bridge; until then the route remains finite residual-budget evidence with the obstruction visible. □

Falsifiable prediction: An accepted MetaCICResidualCriticalPairBudget$^{\uparrow}$ confluence-audit read that consumes a residual critical-pair budget without displaying rows $R, K, J, D, O, T, H, C, P, N$ refutes the carrier surface.

Independence witness: metacic-residual-critical-pair, metacic-confluence-audit-packet, metacic-local-diamond-witness: MetaCICResidualCriticalPairBudget$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries residual critical-pair source rows, finite budget rows, candidate joins, closed checks, obstruction retention, Nontrivial and FieldFaithful TasteGate readiness, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{MetaCICResidualCriticalPairBudget}^{\uparrow}}$.

Constructive story: A MetaCICResidualCriticalPairBudget$^{\uparrow}$ packet is generated from residual critical-pair source rows, finite budget rows, candidate local joins, closed checks, obstruction rows, Nontrivial and FieldFaithful TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICResidualCriticalPairBudget}^{\uparrow}}$, seed)

Scope closed: Definition 7709.1, Definition 7709.2, and Definition 7709.3 seed the finite residual critical-pair budget route for the MetaCIC confluence audit map.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICResidualCriticalPairBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global confluence, unrestricted residual-substitution compatibility, parallel diamond, subject reduction, quotient syntax equality, Lean verification, or bridge checking for MetaCICResidualCriticalPairBudget$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, residual-source admission, finite-budget admission, candidate-join admission, closed-check admission, obstruction retention, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualCriticalPairBudgetUp.

Chapter 7710

A Concrete Naming Certificate for $\mathsf{BarTheorem}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen, the $\mathsf{BarTheorem}^{\uparrow}$ packet records a constructive stream/bar boundary as finite NameCert data rather than as a selected infinite branch or a countable-choice principle. It sits after the fan-bar boundary of chapter 400, the inductive bar route of chapter 1675, the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-seal boundary of chapter 38. The packet gives Real and Completion consumers a displayed finite bar interface before they read a stream boundary as a real endpoint.

Definition 7710.1 (Bar theorem carrier)**.** *A* $\mathsf{BarTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, T, M, U, S, R, D, A, H, C, P, N)$$

over $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BrouwerBarInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *with the following displayed rows:*

1. *F is the finite bar predicate row, naming the decidable prefix checks admitted by the packet.*
2. *T is the finite prefix tree row whose nodes are the stream prefixes inspected before a bar hit is claimed.*
3. *M records monotone coverage: once a displayed prefix is accepted by F, every displayed extension inside T remains covered.*
4. *U is the fan-bound handoff row, exposing the finite bound supplied through the* $\mathsf{FanTheorem}^{\uparrow}$ *and* $\mathsf{BrouwerBarInduction}^{\uparrow}$ *surfaces.*
5. *S records the* $\mathsf{StreamName}^{\uparrow}$ *windows inspected by the prefix tree.*
6. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback associated with the displayed stream windows.*
7. *D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used when the readback is compared across covered prefixes.*
8. *A is the downstream* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the bar predicate, tree, coverage, fan-bound handoff, stream windows, regular readback, and dyadic tolerance rows have been replayed.*
9. *H records componentwise* hsame *transport for the bar predicate, prefix tree, monotone coverage, bound, window, readback, tolerance, seal, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a Real or Completion request back through A, D, R, S, U, M, T, F.*
11. *P is the* Pkg *provenance over the listed constructive bar, stream, rational, dyadic, real, transport, continuation, package, and naming dependencies.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BarTheorem}^{\uparrow}}$ *row.*

The carrier exports no selected infinite branch, no countable-choice functional, no quotient stream, and no ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.BarTheoremUp.BarTheoremTasteGate single carrier alignment`

Theorem 7710.2 (Bar theorem NameCert obligations)**.** *For every accepted* $\mathsf{BarTheorem}^{\uparrow}$ *carrier $B = (F, T, M, U, S, R, D, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BarTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite bar predicate, prefix tree, monotone coverage, fan-bound handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise transport, displayed replay, provenance, and local naming rows. A consumer may inspect the bar theorem boundary only through those displayed rows.*

Proof. Project the carrier. The rows $F, T, M, U, S, R, D, A, H, C, P, N$ are the complete finite inventory available to a NameCert consumer.

The constructive bar part is read through F, T, M, U. The predicate row names the accepted prefix checks, the tree row displays the inspected prefixes, the monotone row keeps coverage stable under displayed extension, and the handoff row exposes the finite bound through the fan and bar-induction siblings.

The stream and Real-facing part is read through S, R, D, A. StreamName windows supply the inspected stream prefixes, RegSeqRat gives the regular rational readback, DyadicRatCore records the tolerance ledger, and the Real seal is downstream of those rows.

Finally H, C, P, N transport, replay, cite, and name only the same coordinates. Since the carrier has no selected branch, countable-choice, quotient-stream, or ambient-completeness coordinate, none of those objects is exported by the local NameCert surface. □

Theorem 7710.3 (Bar theorem Real and Completion boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BarTheorem}^{\uparrow}$ *packet must expose the displayed route*

$$F, T, M, U, S, R, D \longmapsto A.$$

Thus a completion-facing read of the bar boundary passes through the finite bar predicate, prefix tree, monotone coverage, fan-bound handoff, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance ledger before it may read the $\mathsf{Real}^{\uparrow}$ *seal. The route is finite NameCert replay, not a selected infinite branch, countable choice, quotient stream, or ambient Real completeness claim.*

Proof. Start with a consumer that asks for the Real seal row A. Carrier admission shows that A is not standalone; it is a coordinate of the same packet as F, T, M, U, S, R, D.

Replay the bar route first. The prefix request is checked against T, coverage is certified through F and M, and the finite handoff bound is supplied by U through the fan and bar-induction provenance rows.

Replay the stream route next. The inspected prefixes are read through S, their regular rational data through R, and their dyadic tolerance comparisons through D.

Transport by H preserves this route componentwise, while C, P, N only replay, cite, and name the displayed packet. Therefore a Real or Completion consumer receives the seal row only after

the finite bar route has been exposed, and no hidden branch, choice functional, quotient stream, or ambient completeness theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{BarTheorem}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BarTheorem}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7710.1, Definition 7710.2, and Definition 7710.3 seed the finite constructive bar boundary consumed by Real and Completion chapters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BarTheorem}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, countable choice, quotient streams, ambient Real completeness, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone coverage, fan-bound handoff, Real-seal boundary replay, and refusal of hidden branch or choice data for the same packet.

Constructive story: A $\mathsf{BarTheorem}^{\uparrow}$ packet is generated from a finite bar predicate, prefix tree, monotone coverage row, fan-bound handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise transport, continuation replay, package provenance, and a local NameCert row.

Chapter 7711

A Concrete Naming Certificate for $\mathsf{CauchyCompletionNaturality}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CauchyCompletionNaturality}^{\uparrow}$ packet records the naturality surface for completion when a displayed uniformly continuous map carries regular rational Cauchy names to regular rational Cauchy names. It sits after the finite stream interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the functorial completion packet of chapter 423, and the uniform-continuity carrier of chapter 391. The packet names only the displayed comparison rows needed by later Real and Completion consumers; it does not select representatives, quotient Cauchy names, or assert ambient completeness.

Definition 7711.1 (Cauchy-completion naturality carrier)**.** *A* $\mathsf{CauchyCompletionNaturality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, T, F, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source completion row, exposing the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used to name the source regular-Cauchy family.*
2. *T is the target completion row, exposing the target* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, and terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
3. *F is the* $\mathsf{UniformContinuity}^{\uparrow}$ *map row, including the finite modulus and replay schedule that turns a source tolerance request into a target tolerance request.*
4. *R is the regular-Cauchy transport row. It records that applying F to the source regular-Cauchy windows produces the target regular-Cauchy windows named in T.*
5. *E is the equality-of-route ledger comparing the two displayed completion reads: first complete then map, or first map the regular-Cauchy data and then complete.*
6. *H is componentwise* hsame *transport for S, T, F, R, E, C, P, N.*
7. *C is the displayed* Cont *replay from a completion-naturality request through the source windows, the uniform-continuity modulus, the target readback, and the route ledger.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionNaturality}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionNaturality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a quotient completion, a selected representative of a Cauchy class, a host function between completed metric spaces, countable choice, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 7711.2 (Cauchy-completion naturality NameCert obligations)**.** *For every accepted* CauchyCompletionNa *packet $K = (S, T, F, R, E, H, C, P, N)$, the local* NameCert *surface consists exactly of carrier admission, source-window admission, target-window admission, uniform-continuity replay, regular-Cauchy transport, route-ledger comparison, componentwise transport, continuation replay, provenance, and local naming. Each obligation is read from one of the displayed rows of Definition 7711.1.*

Proof. Carrier admission is projection of the tuple in Definition 7711.1. The source and target completion rows are the coordinates S and T, and the map row is the coordinate F.

The regular-Cauchy transport obligation is the row R. It ties the finite source windows to the finite target windows by the modulus and replay data in F, so no representative choice is introduced.

The route comparison is the ledger E, transported componentwise by H and replayed by C. Provenance and local naming are the rows P and N. Since the carrier has no other coordinate, these rows exhaust the local NameCert obligations. □

Theorem 7711.3 (Cauchy-completion naturality handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CauchyCompletionNaturality}^{\uparrow}$ *packet reads the naturality square through*

$\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cor

The consumer first reads the source regular-Cauchy windows, then the uniform-continuity modulus, then the target regular-Cauchy readback and $\mathsf{Real}^{\uparrow}$ *seal, and only then the route ledger comparing the two completion reads.*

Proof. Start with a completion-facing consumer and project the packet $K = (S, T, F, R, E, H, C, P, N)$. The source route is stored in S, and the target route is stored in T.

The map can be used only through F. Its modulus and replay schedule feed the transport row R, which displays the target regular-Cauchy windows before the terminal Real seal is consumed.

Finally compare the two displayed reads with E, then attach H, C, P, N for transport, replay, provenance, and local naming. The packet contains no quotient-completion equality, selected limit, host completed function, countable choice, or ambient completeness field, so no such datum is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionNaturality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyCompletionNaturality}^{\uparrow}$ packet is generated from source completion windows, target completion windows, a displayed $\mathsf{UniformContinuity}^{\uparrow}$ modulus row, regular-Cauchy transport, a route-comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyCompletionNaturality}^{\uparrow}}$, seed)

Scope closed: Definition 7711.1, Definition 7711.2, and Definition 7711.3 seed the finite naturality surface for regular-Cauchy completion under uniformly continuous maps.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyCompletionNaturality}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected Cauchy representatives, host completed function spaces, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: A formal route can encode BEDC.Derived.CauchyCompletionNaturalityUp and prove carrier admission, regular-Cauchy transport, route-ledger comparison, provenance, and local NameCert exactness.

Chapter 7712

A Concrete Naming Certificate for $\mathsf{FrontierCompileHardProblem}^{\uparrow}$

The $\mathsf{FrontierCompileHardProblem}^{\uparrow}$ packet realizes the frontier-synthesis route of Definition 9414.75 as finite NameCert data. It binds the hard-problem row, layered-relation row, and cook-compile route into one packet before any consumer treats an unresolved frontier as a compiled theorem obligation. The packet sits beside the MetaCIC decidability witness of chapter 751, the MetaCIC critical-path packet of chapter 765, the computability carrier of chapter 199, and the lambda-calculus source grammar of chapter 200. These siblings supply decidability pressure, critical-path accounting, computable presentation, and term syntax; this chapter records the finite frontier package that keeps them jointly inspectable.

Falsifiable prediction: An accepted $\mathsf{FrontierCompileHardProblem}^{\uparrow}$ consumer that exports a compiled hard-problem result without displaying the hard-problem row, layered-relation row, cook-compile route, obstruction ledger, transport, replay, provenance, and local $\mathsf{NameCert}$ rows refutes the carrier surface.

Independence witness: metacicdecidabilitywitness, metaciccriticalpath, computable, lambdacalc, frontiercompilehardproblem: none is bijective with $\mathsf{FrontierCompileHardProblem}^{\uparrow}$ because the packet jointly carries frontier source, hard-problem classifier, layered relation, cook-compile route, obstruction ledger, transport, replay, provenance, and local NameCert rows in one carrier, while each sibling supplies only one constituent surface.

Definition 7712.1 (FrontierCompileHardProblem carrier)**.** *A* $\mathsf{FrontierCompileHardProblem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, H, L, K, O, T, C, P, N)$$

with the following displayed rows:

1. *S is the frontier-source row, naming the visible problem family and the finite syntax or computation window from which the frontier is read.*
2. *H is the hard-problem classifier row. It records the exact blocked problem surface and the local reason it is not discharged by the current compiled route.*
3. *L is the layered-relation row, separating source relation, compiled relation, witness relation, and refusal relation before any cook-style read is attempted.*
4. *K is the cook-compile route row. It records the displayed reduction schedule from the source frontier to the compiled check surface.*

5. *O is the obstruction ledger. It records which decision, normalization, subject-reduction, confluence, or computability row is still exposed as a boundary rather than as a solved theorem.*
6. *T is componentwise* hsame *transport for S, H, L, K, O, C, P, N.*
7. *C is the displayed* Cont *replay from a frontier request through the layered relation, cook-compile route, and obstruction ledger.*
8. *P is the* Pkg *provenance over* FrontierCompileHardProblem$^{\uparrow}$, MetaCICDecidabilityWitness$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, Computable$^{\uparrow}$, LambdaCalc$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\text{FrontierCompileHardProblem}^{\uparrow}}$ *row.*

The classifier has no coordinate for a solved hard problem, an oracle decision procedure, global normalization, global confluence, subject-reduction discharge, or an untracked compiler theorem.

Theorem 7712.2 (FrontierCompileHardProblem NameCert obligations)**.** *For every accepted* FrontierCompileHardP *packet $F = (S, H, L, K, O, T, C, P, N)$, the local* NameCert *surface consists exactly of carrier admission, hard-problem classifier exposure, layered-relation separation, cook-compile route replay, obstruction-ledger non-escape, componentwise transport, continuation replay, provenance, and local naming. A consumer that changes any exported frontier read must change one of these displayed rows.*

Proof. Carrier admission is projection of Definition 7712.1. The frontier source is S, the hard-problem classifier is H, the layered-relation surface is L, and the compile route is K.

The obstruction ledger is the row O. It records the remaining boundary as a finite row, so the packet does not silently turn an exposed problem into a solved theorem.

Transport and replay are exactly T and C, while provenance and local naming are P and N. Since the carrier contains no oracle, global normalization, global confluence, subject-reduction discharge, or hidden compiler theorem, these rows exhaust the obligation surface. □

Theorem 7712.3 (FrontierCompileHardProblem consumer boundary)**.** *Every hard-problem, layered-relation, or cook-compile consumer of an accepted* FrontierCompileHardProblem$^{\uparrow}$ *packet factors through the displayed rows*

$$S, \quad H, \quad L, \quad K, \quad O, \quad T, \quad C, \quad P, \quad N.$$

The consumer may inspect the source frontier, the hard-problem classifier, the layered relation, and the compile route, but it cannot export a solved theorem unless the obstruction ledger itself displays the required discharge.

Proof. Begin with a frontier consumer and project the packet. The only source data are in S, and the only hard-problem classifier is H.

The consumer then reads L and K. The layered-relation row separates the source, compiled, witness, and refusal relations; the cook-compile row records only the displayed reduction schedule.

Finally the consumer reads O, T, C, P, N. If the obstruction ledger does not contain a discharge row, the carrier has no other place from which a solved theorem, oracle decision procedure, global normalization theorem, confluence theorem, subject-reduction theorem, or hidden compiler theorem could be recovered. □

Closure status for NameCert$_{\text{FrontierCompileHardProblem}^{\uparrow}}$**.**

Constructive story: A FrontierCompileHardProblem$^{\uparrow}$ packet is generated from a frontier-source row, hard-problem classifier row, layered-relation row, cook-compile route row, obstruction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FrontierCompileHardProblem}\uparrow}$, seed)

Scope closed: Definition 7712.1, Definition 7712.2, and Definition 7712.3 seed the finite frontier compile surface over hard-problem, layered-relation, and cook-compile rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FrontierCompileHardProblem}\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim a solved hard problem, oracle decidability, global normalization, global confluence, subject-reduction discharge, or an untracked compiler theorem.

Upgrade path: A formal route can encode BEDC.Derived.FrontierCompileHardProblemUp and prove carrier admission, layered-relation separation, cook-compile route replay, obstruction non-escape, provenance, and local NameCert exactness.

Chapter 7713

A Concrete Naming Certificate for $\mathsf{TuttePolynomial}^{\uparrow}$

Following Tutte's deletion-contraction treatment of finite graph invariants, the $\mathsf{TuttePolynomial}^{\uparrow}$ packet records the polynomial ledger that a graph or matroid consumer may inspect before using the two-variable Tutte polynomial. It sits over the finite graph carrier of chapter 118, the rank and independence surface of chapter 202, the coefficient-list discipline of chapter 50, and the edge-ledger comparison route of chapter 233. The packet names only finite deletion, contraction, base-case, coefficient, classifier, transport, replay, provenance, and local naming rows; it does not assert graph-minor structure, universal invariant uniqueness, or an ambient host polynomial quotient.

Definition 7713.1 (Tutte polynomial carrier)**.** *A* $\mathsf{TuttePolynomial}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, M, E, D, C, B, L, K, H, R, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{Graph}^{\uparrow}$ *row, including vertex, edge, incidence, loop, bridge, and endpoint readback data.*
2. *M is the optional* $\mathsf{Matroid}^{\uparrow}$ *rank-dependence row used when the deletion-contraction read is routed through a displayed matroid carrier.*
3. *E is the inspected edge row naming the finite edge whose deletion or contraction branch is being read.*
4. *D is the deletion row, carrying the graph or matroid packet obtained by removing E from the same displayed support.*
5. *C is the contraction row, carrying the graph or matroid packet obtained by contracting E with its endpoint or rank bookkeeping displayed.*
6. *B is the base-case row for empty support, loop, bridge, and isolated component cases.*
7. *L is the finite coefficient ledger in the* $\mathsf{Poly}^{\uparrow}$ *surface, with the two variables and all inspected coefficient cells named as rows.*
8. *K is the classifier-stability row requiring deletion, contraction, base-case, and coefficient reads to remain stable under the displayed* hsame *witnesses.*
9. *H stores componentwise* hsame *transports for $G, M, E, D, C, B, L, K, R, P, N$.*

10. *R stores displayed* Cont *replay through graph or matroid inspection, deletion, contraction, base cases, coefficient extraction, classifier stability, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{TuttePolynomial}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TuttePolynomial}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for a host graph-minor theorem, a universal invariant proof, quotient equality of polynomials, arbitrary edge-set selection, or an ambient deletion-contraction oracle.

Theorem 7713.2 (Tutte polynomial deletion-contraction obligations)**.** *For every accepted* $\mathsf{TuttePolynomial}^{\uparrow}$ *carrier $T = (G, M, E, D, C, B, L, K, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TuttePolynomial}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite graph row, optional matroid row, inspected edge row, deletion row, contraction row, base-case row, coefficient ledger, classifier-stability row, componentwise transport, displayed replay, package provenance, and local naming. Every polynomial-facing consumer must expose the deletion branch, contraction branch, base cases, coefficient ledger, and classifier-stability row before it reads the Tutte-polynomial packet as a finite invariant.*

Proof. Project the carrier of Definition 7713.1. The source rows are G, M, E, the recursive polynomial rows are D, C, B, L, and the structural rows are K, H, R, P, N.

Read the deletion and contraction branches first. The inspected edge row E determines which finite support is removed or contracted, while D and C keep both resulting packets inside the displayed $\mathsf{Graph}^{\uparrow}$ or $\mathsf{Matroid}^{\uparrow}$ dependency surface.

Next read the base and coefficient rows. The row B records the empty-support, loop, bridge, and isolated-component cases, and L records the two-variable coefficient ledger through $\mathsf{Poly}^{\uparrow}$ rather than through host polynomial equality.

Finally apply the classifier and structural rows. The stability row K makes the deletion, contraction, base-case, and coefficient data invariant under the displayed hsame transports, while H, R, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores a graph-minor theorem, a universal invariant proof, or an ambient polynomial quotient, the listed rows exhaust the local certificate obligations. □

Falsifiable prediction: Any accepted $\mathsf{TuttePolynomial}^{\uparrow}$ packet is refuted if a consumer reads a polynomial coefficient before displaying the finite graph or matroid source row, inspected edge row, deletion row, contraction row, base-case row, coefficient ledger, classifier-stability row, transport, replay, provenance, and local NameCert rows.

Independence witness: graph, matroid, polynomial, networkflow: $\mathsf{TuttePolynomial}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries deletion, contraction, base-case, coefficient-ledger, classifier-stability, transport, replay, provenance, and local NameCert rows. The siblings supply source graph incidence, rank-dependence, coefficient storage, or edge-ledger routing separately, while only this packet binds them as the finite deletion-contraction polynomial surface.

Closure status for $\mathsf{NameCert}_{\mathsf{TuttePolynomial}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TuttePolynomial}^{\uparrow}$ packet is generated from finite GraphUp rows, optional MatroidUp rank-dependence rows, inspected edge rows, deletion rows, contraction rows, base-case rows, PolynomialUp coefficient ledgers, classifier-stability rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TuttePolynomial}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7713.1 and Definition 7713.2 seed the finite deletion-contraction polynomial route over GraphUp, MatroidUp, PolynomialUp, NetworkFlowUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{TuttePolynomial}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, full graph-minor theory, universal Tutte invariant uniqueness, quotient equality of polynomials, arbitrary edge-set selection, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deletion and contraction branch exposure, base-case exactness, coefficient-ledger exactness, classifier stability, transport, replay, provenance, and local naming for BEDC.Derived.TuttePolynomialUp.

Chapter 7714

A Concrete Naming Certificate for MetaCICSubstitutionDiamondFrontier$^{\uparrow}$

The MetaCICSubstitutionDiamondFrontier$^{\uparrow}$ packet realizes the substitution-sensitive boundary of the MetaCIC beta audit map of chapter 9384 as finite NameCert data. It sits beside the residual checker of chapter 3827, the residual-diamond budget of chapter 7407, the beta-step boundary of chapter 754, and the subject-reduction packet of chapter 483. The packet records a beta peak, residual rows, candidate joins, substitution-boundary rows, checker rows, obstruction rows, transport, replay, provenance, and local naming; it does not claim full confluence, subject reduction, unrestricted substitution compatibility, quotient syntax equality, or a hidden evaluator.

Definition 7714.1 (MetaCIC substitution-diamond frontier carrier)**.** *A* MetaCICSubstitutionDiamondFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, P, R, J, S, K, O, H, C, Q, N)$$

with the following displayed rows:

1. *T is the MetaCIC term and context row naming the finite source of the beta peak.*
2. *P is the beta-peak row, read through the displayed* BetaStep *and* BetaConv *boundary of chapter 9384.*
3. *R is the residual row naming the branch residuals that remain after each beta step.*
4. *J is the candidate-join row listing the finite terms proposed as local joins for the displayed peak.*
5. *S is the substitution-boundary row, recording which substitution, shift, and closedness data must stay visible for the candidate join to be inspected.*
6. *K is the bounded checker row, read through the residual-checker and residual-diamond-budget sibling packets.*
7. *O is the obstruction row, keeping subject reduction, unrestricted substitution compatibility, and global confluence outside the carrier.*
8. *H stores componentwise* hsame *transport for $T, P, R, J, S, K, O, C, Q, N$.*
9. *C stores displayed* Cont *replay through the beta peak, residuals, candidate joins, substitution boundary, bounded checker, obstruction, provenance, and local naming.*

10. *Q is the* Pkg *provenance over* $\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$, $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$, $\mathsf{BetaStepBoundary}^{\uparrow}$, $\mathsf{SubjectReduction}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for global Church–Rosser, closed subject reduction, unrestricted substitution compatibility, quotient syntax equality, or an external evaluator.

Theorem 7714.2 (MetaCIC substitution-diamond frontier obligations)**.** *For every accepted* MetaCICSubstitutionDi *carrier $F = (T, P, R, J, S, K, O, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}}$ *surface consists exactly of source-term admission, beta-peak admission, residual exposure, candidate-join exposure, substitution-boundary exposure, bounded-checker admission, obstruction retention, componentwise transport, displayed replay, package provenance, and local naming. Every displayed candidate join must retain the named substitution-boundary row S before the checker row K may inspect it.*

Proof. Project the carrier of Definition 7714.1. The beta-facing rows are T, P, R, J, the substitution and checker rows are S, K, O, and the structural rows are H, C, Q, N.

Read the peak and residual rows first. The term row T and beta-peak row P name the finite local peak, while R records the residual data that remain visible on each branch.

Next inspect the candidate joins through J, S, K. The candidate-join row J is not accepted alone; it is paired with the substitution-boundary row S, and the bounded checker K reads the pair only while the substitution, shift, and closedness data remain displayed.

Finally retain the obstruction and structural rows. The row O prevents the local frontier from becoming a proof of full confluence or subject reduction, while H, C, Q, N transport, replay, source, and name the same finite packet. Since no coordinate stores global Church–Rosser, unrestricted substitution compatibility, quotient syntax equality, or an external evaluator, the listed rows exhaust the local obligation surface. □

Falsifiable prediction: If the frontier is accepted, every displayed candidate join must retain a named substitution-boundary row; deleting that row invalidates the local diamond packet.

Independence witness: metacic-confluence-residual-checker, metacic-residual-diamond-budget, betastepboundary, subjectreduction: $\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}$ is not bijective to these siblings because it jointly carries beta peaks, residual rows, candidate joins, substitution-boundary rows, bounded checker rows, obstruction retention, transport, replay, provenance, and local naming. The siblings supply checker, budget, beta-step, or preservation surfaces separately, while only this packet binds substitution visibility to each candidate local join.

The Lean follow-up must provide explicit Nontrivial $\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}$ and FieldFaithful $\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}$ instances in `BEDC/Derived/MetaCICSubstitutionDiamondFron` preserving the distinct rows $T, P, R, J, S, K, O, H, C, Q, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}$ packet is generated from MetaCIC term and context rows, beta-peak rows, residual rows, candidate-join rows, substitution-boundary rows, bounded checker rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}}$, seed)

Scope closed: Definition 7714.1 and Definition 7714.2 seed the finite substitution-sensitive beta diamond frontier for the MetaCIC beta audit map.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionDiamondFrontier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full confluence, subject reduction, unrestricted substitution compatibility, quotient syntax equality, external evaluator soundness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source-term admission, beta-peak admission, residual exposure, candidate-join exposure, substitution-boundary exposure, bounded-checker admission, obstruction retention, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICSubstitutionDiamondFrontierUp

Chapter 7715

A Concrete Naming Certificate for $\mathsf{BareissFractionFreeElimination}^{\uparrow}$

Following Bareiss and standard fraction-free linear algebra, the $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ packet records determinant-preserving elimination as a finite pivot ledger over displayed matrix, ring, polynomial, and determinant rows. It consumes the matrix carrier of chapter 49, the determinant surface of chapter 84, the commutative ring source of chapter 43, and the coefficient-polynomial route of chapter 50. The packet names only finite pivot rows, fraction-free update rows, exact-divisibility witnesses, determinant handoff rows, transport, replay, provenance, and local naming; it exports no host field division, quotient matrix equality, row-equivalence theorem, or ambient Gaussian elimination algorithm.

Definition 7715.1 (Bareiss fraction-free elimination carrier)**.** *A* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, M, P, D, I, L, U, Q, X, H, C, K, N)$$

with the following displayed rows:

1. *R is the consumed* $\mathsf{Ring}^{\uparrow}$ *scalar row, naming the addition, multiplication, zero, one, and sign data used by the ledger.*
2. *M is the consumed* $\mathsf{Mat}^{\uparrow}$ *row, including the finite row-column index set and the initial entry readbacks.*
3. *P is the optional* $\mathsf{Poly}^{\uparrow}$ *coefficient row when the matrix entries are read as displayed polynomial coefficients rather than as opaque ring elements.*
4. *D is the* $\mathsf{Determinant}^{\uparrow}$ *handoff row for the input matrix and the terminal diagonal product read.*
5. *I lists the pivot indices selected by the ledger and the previous-pivot denominator row attached to each step.*
6. *L records the fraction-free update equation for every displayed entry:*

$$a_{ij}^{(k+1)} p_{k-1} = a_{kk}^{(k)} a_{ij}^{(k)} - a_{ik}^{(k)} a_{kj}^{(k)}.$$

7. *U records the exact-divisibility witness that the right-hand side is divisible by the previous pivot row inside the displayed ring surface.*

8. *Q records the zero-pivot branch ledger: if a displayed pivot is absent, the packet stores the row or column swap evidence that precedes the next update row, rather than selecting an ambient inverse.*
9. *X is the determinant-scale exactness row tying the terminal pivot product and sign ledger to the consumed* $\mathsf{Determinant}^{\uparrow}$ *route.*
10. *H records componentwise* hsame *transport for the ring, matrix, polynomial, determinant, pivot, update, divisibility, branch, exactness, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay from a linear-algebra consumer back through $X, Q, U, L, I, D, P, M, R$.*
12. *K is the* Pkg *provenance over* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BareissFractionFreeElimination}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host field division, quotient matrix equality, a global row-equivalence theorem, an unlogged pivot inverse, or a selected elimination trace outside the finite ledger.

Lean4 ✓ `BEDC.Derived.BareissFractionFreeEliminationUp.TasteGate.BareissFractionFreeEliminationTasteGate`
`single carrier alignment`

Theorem 7715.2 (Bareiss fraction-free elimination NameCert obligations)**.** *For every accepted* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ *carrier $E = (R, M, P, D, I, L, U, Q, X, H, C, K, N)$, the local* $\mathsf{NameCert}_{\mathsf{BareissFractionFre}}$ *surface consists exactly of carrier admission, ring and matrix exposure, polynomial-coefficient exposure when present, determinant-source exposure, pivot-index exposure, fraction-free update exposure, exact-divisibility exposure, zero-pivot branch exposure, determinant exactness handoff, componentwise transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7715.1. The rows $R, M, P, D, I, L, U, Q, X, H, C, K, N$ are the complete finite inventory available to a NameCert consumer.

The algebraic source is read through R, M, P, D. The update path is then read through I, L, U, Q: pivots and previous denominators are displayed, each update equation is logged, exact divisibility is witnessed inside the ring row, and a zero-pivot event is routed through displayed swap evidence.

The consumer-facing surface is X, H, C, K, N. These rows hand the terminal determinant read to $\mathsf{Determinant}^{\uparrow}$, transport the displayed ledger componentwise, replay the same route for downstream consumers, and record provenance and local naming. Since no row contains a host inverse, quotient matrix equality, or an unlogged row-equivalence theorem, none of those objects is exported. □

Theorem 7715.3 (Bareiss pivot ledger)**.** *Every determinant, rank-sensitive, or finite linear-system consumer of an accepted* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ *packet must first read the finite pivot ledger*

$$R, M, P, D, I, L, U, Q, X, H, C, K, N.$$

In particular, each update step is available only after the displayed pivot row, previous-pivot denominator row, fraction-free numerator row, exact-divisibility witness, and zero-pivot branch row have been exposed.

Proof. Let a downstream consumer route be given. Carrier projection exposes the ring, matrix, polynomial, and determinant source rows before any pivot update can be replayed.

For each pivot step, the consumer reads I for the chosen pivot and previous denominator, then L for the displayed numerator equation, then U for exact divisibility. If the pivot branch is not direct, Q supplies the finite swap evidence before the next update is read.

The route then passes through X, H, C, K, N. These rows preserve the same finite ledger and do not add a field of fractions, quotient matrix equality, a selected row-reduction theorem, or an ambient elimination algorithm. □

Theorem 7715.4 (Bareiss determinant handoff)**.** *The determinant read exported by an accepted* $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Ring}^{\uparrow},\ \mathsf{Mat}^{\uparrow},\ \mathsf{Poly}^{\uparrow},\ \mathsf{Determinant}^{\uparrow} \longmapsto I, L, U, Q, X \longmapsto H, C, K, N.$$

Thus the terminal determinant handoff is a finite fraction-free ledger over the consumed sibling rows, not a host Gaussian elimination theorem, field-division computation, or quotient matrix equality principle.

Proof. Start with the determinant-facing row X. It is not standalone: by carrier admission it depends on the consumed ring, matrix, optional polynomial, determinant, pivot, update, divisibility, and branch rows.

Replay the fraction-free ledger. The update equation in L is meaningful only after the pivot data in I is displayed, and its division step is allowed only through the exact-divisibility witness U inside the ring row. The branch row Q records any finite swap before the next pivot ledger is read.

Finally use H, C, K, N to transport, replay, cite, and name the same data. Therefore the determinant handoff reaches $\mathsf{Determinant}^{\uparrow}$ through displayed finite rows, and no host field division, quotient matrix equality, or ambient Gaussian elimination theorem is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{BareissFractionFreeElimination}^{\uparrow}}$.

Constructive story: A $\mathsf{BareissFractionFreeElimination}^{\uparrow}$ packet is generated from RingUp scalar rows, MatrixUp entry rows, optional PolynomialUp coefficient rows, DeterminantUp source rows, finite pivot indices, fraction-free update equations, exact-divisibility witnesses, zero-pivot branch rows, determinant exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BareissFractionFreeElimination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7715.1, Definition 7715.2, Definition 7715.3, and Definition 7715.4 seed the finite fraction-free elimination route over displayed matrix, determinant, ring, polynomial, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BareissFractionFreeElimination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host field division, quotient matrix equality, arbitrary Gaussian elimination, rank theory, Smith normal form, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pivot-ledger exactness, exact-divisibility replay, determinant handoff, transport stability, and consumer non-escape for BEDC.Derived.BareissFractionFreeEliminationUp.

Chapter 7716

A Concrete Naming Certificate for $\mathsf{ProofMiningMetastability}^{\uparrow}$

Following Kohlenbach proof mining and Tao metastability, the $\mathsf{ProofMiningMetastability}^{\uparrow}$ packet records the finite-bound extraction route by which a convergence or compactness argument is read as explicit metastable data. It sits beside the finite tail-window packet of chapter 2093, the Cauchy carrier of chapter 3413, the regular rational readback of chapter 301, the finite observation windows of chapter 126, the compact finite-subcover boundary of chapter 60, and the terminal real-name seal of chapter 38. The packet packages a human-standard proof-mining mechanism as finite NameCert data: proofs may export bounds, control windows, and compactness handoffs, but they do not import selected limits, countable choice, host real equality, or ambient completeness.

Definition 7716.1 (Proof-mining metastability carrier)**.** *A* $\mathsf{ProofMiningMetastability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (F, B, W, D, S, Q, C, K, R, H, T, L, N)$$

with the following displayed rows:

1. *F is the formal proof input row, naming the proof object or proof skeleton whose quantitative content is inspected.*
2. *B is the extracted bound row, recording the finite counterfunction or majorant data read from F.*
3. *W is the metastable window row, displaying the finite interval or finite cover segment controlled by B.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used when the window is Cauchy-facing or real-facing.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row for inspected stream positions.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational tail row for rational readback inside the window.*
7. *C is the* $\mathsf{Cauchy}^{\uparrow}$ *consumer row, recording when the mined data is read as a Cauchy-facing tail statement.*
8. *K is the* $\mathsf{Compact}^{\uparrow}$ *consumer row, recording when the mined data is read as a compact finite-subcover or finite-choice boundary.*
9. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after B, W, D, S, Q, C, K have been displayed.*

10. *H records componentwise* hsame *transport for proof input, bound, window, tolerance, stream, regular-rational, Cauchy, compact, real-seal, replay, provenance, and naming rows.*
11. *T records displayed* Cont *replay from proof input to extracted finite data and then to the Cauchy, compact, and Real-facing consumers.*
12. *L is the* Pkg *provenance over* $\mathsf{ProofMiningMetastability}^{\uparrow}$, $\mathsf{CauchyMetastability}^{\uparrow}$, $\mathsf{Cauchy}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ProofMiningMetastability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, B, W, D, S, Q, C, K, R, H, T, L, N$. It has no coordinate for selected limits, countable choice, quotient equality, host real equality, excluded-middle search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7716.2 (Proof-mining metastability NameCert obligations)**.** *For every accepted* ProofMiningMetastability *carrier $P = (F, B, W, D, S, Q, C, K, R, H, T, L, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProofMiningMetastability}^{\uparrow}}$ *surface consists exactly of the proof input row F, extracted bound row B, finite metastable window W, dyadic tolerance ledger D, StreamName observations S, RegSeqRat readback Q, Cauchy consumer row C, Compact consumer row K, Real seal row R, componentwise transport H, displayed replay T, provenance L, and local naming N. Every public read of a mined convergence or compactness consequence factors through those rows before it can cite a metastable bound.*

Proof. Project the accepted carrier of Definition 7716.1. Its only proof-facing coordinates are F, B, W, so the proof input may be read only through the extracted finite bound and the window it controls.

Read the analytic rows next. The tolerance ledger D, StreamName row S, and RegSeqRat row Q provide the finite comparison data consumed by Cauchy and Real-facing readers, while the Cauchy row C and compact row K record the two public consumer surfaces.

Finally inspect R, H, T, L, N. The real seal is downstream of the extracted finite data, and the structural rows transport, replay, source, and name that same packet. Since no other row is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7716.3 (Proof-mining metastability compact Cauchy handoff)**.** *Every accepted* ProofMiningMetastability *read that is consumed by a* $\mathsf{Compact}^{\uparrow}$ *or* $\mathsf{Cauchy}^{\uparrow}$ *route exports only the finite bound B, metastable window W, dyadic tolerance ledger D,* $\mathsf{StreamName}^{\uparrow}$ *observations S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the displayed consumer rows C, K, and the downstream* $\mathsf{Real}^{\uparrow}$ *seal R. The handoff exports no selected limit, no countable choice object, no host compactness selector, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from Definition 7716.2. A public consumer must read the extracted finite data B, W before it can inspect any analytic endpoint.

For a Cauchy-facing read, use the sibling route through chapter 2093 and chapter 3413. The rows D, S, Q provide tolerance accounting, finite observations, and regular-rational readback before C reaches the $\mathsf{Real}^{\uparrow}$ seal.

For a compact-facing read, use the $\mathsf{Compact}^{\uparrow}$ row K. It receives the same finite window as a finite-subcover or finite-choice boundary, not as a host selector or countable choice principle.

The remaining rows H, T, L, N preserve the same handoff under transport, replay, provenance, and local naming. Therefore the compact and Cauchy consumers receive a finite proof-mined metastability packet and no stronger completion or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProofMiningMetastability}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofMiningMetastability}^{\uparrow}$ packet is generated from a proof input row, extracted finite bound, metastable window, dyadic tolerance ledger, StreamName observations, RegSeqRat readback, Cauchy consumer row, Compact consumer row, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofMiningMetastability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7716.1, Definition 7716.2, and Definition 7716.3 seed the finite proof-mining metastability route for Cauchy, Compact, and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofMiningMetastability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected limits, countable choice, host compactness selectors, quotient equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, extracted-bound exactness, finite-window replay, Cauchy and Compact handoff stability, Real-seal boundary, transport, provenance, and local naming for BEDC.Derived.ProofMiningMetastabilit

Chapter 7717

A Concrete Naming Certificate for $\mathsf{RadonTheorem}^{\uparrow}$

Following Radon and the standard finite convexity theorem, the $\mathsf{RadonTheorem}^{\uparrow}$ packet records the finite certificate surface for a Radon partition of a point family in an affine space. It consumes the convex membership carrier of chapter 208, the affine-dependence and translation surface of chapter 206, the finite face and hull ledger of chapter 209, and the finite simplex inventory of chapter 238. The packet exposes only the displayed finite point family, the affine-dependence witness, the two-block partition, the convex-hull overlap row, transport, replay, provenance, and local naming; it does not export an ambient Euclidean topology, a selected separating hyperplane, Helly closure, or a Caratheodory reduction.

Definition 7717.1 (Radon theorem finite convex-geometry carrier)**.** *A* $\mathsf{RadonTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, F, D, L, U, V, H, Q, P, N)$$

with the following displayed rows:

1. *A is the finite-dimensional* $\mathsf{AffineSpace}^{\uparrow}$ *ambient row that scopes point differences, affine combinations, and the displayed dependence witness.*
2. *F is the finite point-family row, listing the inspected points as* BHist *entries and recording their finite index surface.*
3. *D is the affine-dependence witness row, with coefficients read through the scalar and affine rows and with total coefficient sum classified as zero.*
4. *L is the two-block partition row, splitting the finite index surface into the positive and negative coefficient blocks used by the Radon construction.*
5. *U is the* $\mathsf{ConvexSet}^{\uparrow}$ *row reading the positive-block normalized affine combination as a convex-hull point.*
6. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *row reading the negative-block normalized affine combination as the same convex-hull point after affine-dependence transport.*
7. *H records componentwise* hsame *transport for $A, F, D, L, U, V, Q, P, N$.*
8. *Q records displayed* Cont *replay of the affine-dependence calculation and of the two convex-hull membership reads.*

9. *P is the* Pkg *provenance over* RadonTheorem$^{\uparrow}$, AffineSpace$^{\uparrow}$, ConvexSet$^{\uparrow}$, Polytope$^{\uparrow}$, SimplicialComplex$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{RadonTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host convex hull, a topological compactness assertion, a separating hyperplane, or a full Helly-family theorem.

Lean4 ✓ `BEDC.Derived.RadonTheoremUp.RadonTheoremTasteGate single carrier alignment`

Theorem 7717.2 (Radon theorem NameCert obligations)**.** *For the carrier of Definition 7717.1, the local* NameCert$_{\text{RadonTheorem}^{\uparrow}}$ *surface consists exactly of the finite point family row F, the affine-dependence witness row D, the two-block partition row L, the positive and negative convex-hull overlap rows U, V, componentwise* hsame *transport through H, displayed* Cont *replay through Q,* Pkg *provenance through P, and local naming through N.*

Proof. Project the packet $R = (A, F, D, L, U, V, H, Q, P, N)$. The finite point family F gives the only inspected points, while the affine row A is the only ambient structure available for dependence and affine-combination reads.

Use the dependence witness D to split the finite index surface into the two blocks recorded by L. The signs of the displayed coefficients determine the blocks, and the zero-sum affine-dependence row is the calculation that identifies the two normalized affine combinations.

Read the positive block through U and the negative block through V. Both rows are ConvexSet$^{\uparrow}$ reads, while the finite face and simplex bookkeeping is supplied only through the Polytope$^{\uparrow}$ and SimplicialComplex$^{\uparrow}$ provenance rows carried by P. Thus the overlap point is exposed as two convex-hull membership rows classified by the displayed affine-dependence calculation, not as a host geometric object.

Finally transport and replay preserve the same surface. The H row transports every displayed component by hsame, the Q row replays the affine-dependence calculation and convex-hull membership reads by Cont, and P, N bind those rows to the local name. No additional coordinate remains from which to read Helly, Caratheodory, topology, or separation data, so the listed rows exhaust the local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.RadonTheoremUp.RadonTheoremNameCertObligations`

Closure status for NameCert$_{\text{RadonTheorem}^{\uparrow}}$**.**

Constructive story: A RadonTheorem$^{\uparrow}$ packet is generated from a finite affine-space point family, an affine-dependence witness, a two-block partition of the finite index surface, positive and negative convex-hull membership rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RadonTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 7717.1 and Definition 7717.2 seed the finite Radon partition NameCert surface over AffineSpace$^{\uparrow}$, ConvexSet$^{\uparrow}$, Polytope$^{\uparrow}$, and SimplicialComplex$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{RadonTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not assert a Lean theorem, Helly closure, Caratheodory reduction, topological compactness, separating hyperplane, or bridge checking.

Upgrade path: Obligation closure requires checked carrier and NameCert rows for the finite point family, affine-dependence witness, two-block partition, convex-hull overlap, transport, replay, and provenance surface.

Chapter 7718

A Concrete Naming Certificate for $\mathsf{FiniteBorelCantelli}^{\uparrow}$

Following Borel and constructive probability treatments, the $\mathsf{FiniteBorelCantelli}^{\uparrow}$ packet records the finite-union probability boundary that a bounded Borel–Cantelli window may consume before any countable almost-sure conclusion is visible. It sits after the probability-space surface of chapter 184, the measure event-value surface of chapter 92, the finite union-bound ledger of chapter 6696, and the first-lemma boundary of chapter 2357. The packet names only finite event rows, finite union ledgers, and displayed probability bounds.

Definition 7718.1 (Finite Borel–Cantelli carrier)**.** *A* $\mathsf{FiniteBorelCantelli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (\Omega, M, E, W, U, B, T, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the normalized probability carrier.*
2. M *is the* $\mathsf{Measure}^{\uparrow}$ *event-value row through which each displayed probability read is exposed.*
3. E *is the finite event-row packet, listing the inspected event names, membership readbacks, and measurable-event witnesses.*
4. W *is the finite Borel–Cantelli window row, recording the bounded index set and the repeated-hit request restricted to that window.*
5. U *is the* $\mathsf{FiniteUnionBound}^{\uparrow}$ *ledger row, exposing the finite union event and the corresponding probability-sum ledger.*
6. B *is the probability-bound row, recording that the finite repeated-hit event is bounded by the finite sum named by* U*.*
7. T *is the local tail-budget row for the same bounded window; it is a finite comparison row, not a countable summability assertion.*
8. H *records componentwise* hsame *transport for* $\Omega, M, E, W, U, B, T, P, N$*.*
9. C *records displayed* Cont *replay from* Ω *through* M, E, W, U, B, T *before any consumer sees the finite Borel–Cantelli conclusion.*
10. P *is the* Pkg *provenance over* $\mathsf{FiniteBorelCantelli}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{FiniteUnionBound}^{\uparrow}$*,* $\mathsf{BorelCantelli}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{FiniteBorelCantelli}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $\Omega, M, E, W, U, B, T, H, C, P, N$. It contains no coordinate for countable choice, host sigma-algebra completion, quotient almost-sure equality, a selected infinite tail, or the second Borel–Cantelli converse.

Lean4 ✓ `BEDC.Derived.FiniteBorelCantelliUp.FiniteBorelCantelliTasteGate single carrier alignment`

Theorem 7718.2 (Finite Borel–Cantelli NameCert obligations)**.** *For every accepted* $\mathsf{FiniteBorelCantelli}^{\uparrow}$ *carrier $F = (\Omega, M, E, W, U, B, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteBorelCantelli}^{\uparrow}}$ *surface consists exactly of probability-source admission through Ω, measure event-value exposure through M, finite event-row admission through E, bounded-window exposure through W, finite union-bound ledger exposure through U, probability-bound exactness through B, local tail-budget comparison through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7718.1. The displayed tuple exposes the probability source, measure event-value row, finite event rows, bounded window, union ledger, probability bound, local tail budget, transport, replay, provenance, and local naming.

Read the event rows before the bound. The window W restricts the repeated-hit request to the finite family E, while M supplies the probability values over the same measurable-event surface named by Ω.

The union-bound ledger U and probability-bound row B provide the only estimate used by the packet, and T records only the bounded tail comparison attached to that estimate. The rows H, C, P, N transport, replay, source, and name the same finite data.

Since the carrier has no further coordinate, the listed rows exhaust the NameCert obligations. In particular, no countable-choice tail selector, completed sigma-algebra, almost-sure quotient, infinite summability theorem, or converse independence route is exported. □

Theorem 7718.3 (Finite Borel–Cantelli union-bound route)**.** *Every finite Borel–Cantelli read of an accepted* $\mathsf{FiniteBorelCantelli}^{\uparrow}$ *packet factors through the route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \mathsf{FiniteUnionBound}^{\uparrow},\ \mathsf{BorelCantelli}^{\uparrow}.$$

The finite event-row packet E and bounded window W must be exposed before the finite union ledger U and probability-bound row B are read, and the local tail-budget row T can inspect only that finite union-bound estimate.

Proof. Start with the probability and measure rows Ω and M. They provide the source probability carrier and the event-value reads used by the finite event packet E.

Next expose the bounded window W. This fixes the finite repeated-hit request before any bound is available, so the estimate is attached to a displayed finite family rather than to an ambient countable event sequence.

Apply the finite union-bound handoff of Definition 6696.4. The row U supplies the finite union event and probability-sum ledger, while B records the corresponding probability comparison for the window selected by W.

The tail row T can therefore read only the finite estimate just produced by U and B. Componentwise transport, replay, provenance, and local naming through H, C, P, N preserve that same route, so no countable choice, sigma-completion, almost-sure quotient, selected infinite tail, or second-lemma converse is introduced. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteBorelCantelli}\uparrow}$.

Constructive story: A $\mathsf{FiniteBorelCantelli}^{\uparrow}$ packet is generated from a ProbSpace source row, Measure event-value row, finite event rows, bounded window row, FiniteUnionBound ledger, probability-bound row, local tail-budget comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteBorelCantelli}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7718.1, Definition 7718.2, and Definition 7718.3 seed the finite-union probability boundary for bounded Borel–Cantelli windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteBorelCantelli}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, host sigma-algebra completion, quotient almost-sure equality, selected infinite tails, the second Borel–Cantelli converse, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite event-row exactness, bounded-window routing, finite union-bound ledger exactness, probability-bound exposure, local tail-budget non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteBorelCantelliUp.

Chapter 7719

A Concrete Naming Certificate for $\mathsf{Detectability}^{\uparrow}$

Following Kalman's finite-dimensional control theory, the $\mathsf{Detectability}^{\uparrow}$ packet records the finite boundary between full observation and estimator-consumable decay. It sits after the state-space carrier of chapter 329, the observation surface of chapter 294, the reachability-side control surface of chapter 297, the finite dual readback of chapter 5787, the deterministic observer ledger of chapter 5909, and the prediction-update surface of chapter 5102. The chapter names the finite rows that let observer and filter consumers read unobservable modes only through a displayed decay ledger; it does not import host spectral theory, quotient state spaces, or ambient asymptotic semantics.

Definition 7719.1 (Detectability carrier)**.** *A* $\mathsf{Detectability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, C, U, E, O, L, H, T, P, N)$$

with the following displayed rows:

1. *S is the state-space source row consumed from* $\mathsf{StateSpaceModel}^{\uparrow}$*;*
2. *A is the transition-matrix row over the displayed state coordinates;*
3. *C is the output-map row consumed through* $\mathsf{ControlObservability}^{\uparrow}$*;*
4. *U is the unobservable-mode witness row naming the finite part of the state row not separated by the displayed observation surface;*
5. *E is the decay ledger for the A-evolution on the displayed unobservable-mode witness;*
6. *O is the observer/filter handoff row consumed by* $\mathsf{LuenbergerObserver}^{\uparrow}$ *and* $\mathsf{KalmanFilter}^{\uparrow}$*;*
7. *L is the componentwise* hsame *ledger for the state-space source, transition matrix, output map, unobservable-mode witness, decay ledger, and observer/filter handoff rows;*
8. *H is the displayed* Cont *route for observation readback, decay-ledger readback, and handoff replay;*
9. *T is the* Pkg *provenance over* $\mathsf{Detectability}^{\uparrow}$*,* $\mathsf{StateSpaceModel}^{\uparrow}$*,* $\mathsf{ControlObservability}^{\uparrow}$*,* $\mathsf{ControlControllability}^{\uparrow}$*,* $\mathsf{ObservabilityGramian}^{\uparrow}$*,* $\mathsf{LuenbergerObserver}^{\uparrow}$*,* $\mathsf{KalmanFilter}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
10. *P records the local package replay for the same rows after representative change;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}$ *row.*

The classifier identifies two accepted packets only when the displayed state-space, transition, output, unobservable-mode, decay, and handoff rows match componentwise through L, with the same Cont *and* Pkg *provenance.*

Theorem 7719.2 (Detectability NameCert obligations)**.** *For every accepted* $\mathsf{Detectability}^{\uparrow}$ *carrier $D = (S, A, C, U, E, O, L, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}$ *surface has exactly five finite rows:*

1. *carrier admission for the displayed state-space source, transition matrix, output map, unobservable-mode witness, decay ledger, and observer/filter handoff rows;*
2. *classifier admission through componentwise* hsame *transport over those displayed rows;*
3. *observability and Gramian readback saying that C, U, E are consumed only through* $\mathsf{ControlObservability}^{\uparrow}$ *and* $\mathsf{ObservabilityGramian}^{\uparrow}$ *rows;*
4. *observer/filter boundary replay saying that O is the sole route from detectability data to* $\mathsf{LuenbergerObserver}^{\uparrow}$ *or* $\mathsf{KalmanFilter}^{\uparrow}$ *consumers;*
5. *provenance and local naming through the displayed* Cont*,* Pkg*, replay, and* $\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}$ *rows.*

Proof. Project the carrier of Definition 7719.1. The rows S, A, C, U, E, O are the only control-facing data, while L, H, T, P, N transport, replay, source, and name the same finite packet.

The classifier row is componentwise because the carrier has no coordinate for a quotient state space or hidden spectral decomposition. Any comparison of unobservable modes must therefore pass through the displayed hsame ledger L.

The observation and handoff rows are already named as dependencies. The rows C, U, E read through $\mathsf{ControlObservability}^{\uparrow}$ and $\mathsf{ObservabilityGramian}^{\uparrow}$, and the row O is the only observer/filter handoff. Repacking these projections with H, T, P, N gives the stated five-row surface. □

Theorem 7719.3 (Detectability observer/filter boundary)**.** *Every* $\mathsf{LuenbergerObserver}^{\uparrow}$ *or* $\mathsf{KalmanFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{Detectability}^{\uparrow}$ *packet may read detectability only through the displayed observability rows C, U and the decay ledger E, transported through L and replayed through H, T, P, N. The handoff supplies no host spectral radius, no quotient unobservable subspace, no selected observer gain, no stochastic convergence theorem, and no ambient asymptotic stability claim outside the finite packet of Definition 7719.1.*

Proof. Start with the NameCert surface of Definition 7719.2. It exposes the observer/filter handoff row only after the state-space, transition, output, unobservable-mode, and decay rows have been displayed.

The observer consumer reads O as a deterministic boundary for the $\mathsf{LuenbergerObserver}^{\uparrow}$ ledger, while the filter consumer reads the same handoff as finite provenance for the $\mathsf{KalmanFilter}^{\uparrow}$ observation branch. In both cases the rows C, U, E remain attached to $\mathsf{ControlObservability}^{\uparrow}$ and $\mathsf{ObservabilityGramian}^{\uparrow}$ readback rather than to a host spectral object.

Because the carrier contains no row for a spectral radius, quotient unobservable subspace, selected observer gain, stochastic convergence theorem, or ambient asymptotic stability claim, no such object can be exported by the detectability handoff. □

Falsifiable prediction: Any observer or filter consumer that reads $\mathsf{Detectability}^{\uparrow}$ while bypassing the displayed observability rows C, U, the decay ledger E, or the handoff row O violates the local certificate boundary.

Independence witness: statespacemodel, controlobservability, controlcontrollability, observability-gramian, luenberger-observer, kalman-filter: none is bijective to $\mathsf{Detectability}^{\uparrow}$ because the detectability packet jointly carries the state-space source, transition matrix, output map, unobservable-mode witness, decay ledger, observer/filter handoff, transport, replay, provenance, and local NameCert rows while excluding host spectral and quotient semantics.

Closure status for $\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}$.

Constructive story: A $\mathsf{Detectability}^{\uparrow}$ packet is generated from a finite state-space source, transition matrix, output map, unobservable-mode witness, decay ledger, observer/filter handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, package replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7719.1, Definition 7719.2, Definition 7719.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite detectability NameCert surface over state-space, observability, Gramian, observer, and filter rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Detectability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host spectral criteria, quotient unobservable subspaces, selected observer gains, stochastic convergence theorems, or ambient asymptotic stability.

Upgrade path: Obligation closure requires checked carrier admission, observability readback, unobservable-mode witness exactness, decay-ledger exactness, observer/filter handoff stability, transport, replay, provenance, and local naming for BEDC.Derived.DetectabilityUp.

Chapter 7720

A Concrete Naming Certificate for $\mathsf{PicardIterationCauchy}^{\uparrow}$

Following Picard and Banach fixed-point iteration, the $\mathsf{PicardIterationCauchy}^{\uparrow}$ packet records the constructive route from a contractive Picard orbit to regular Cauchy completion data. It sits after the finite orbit surface of chapter 2359, the contraction endpoint surface of chapter 3529, the modulus route of chapter 292, the regular rational handoff of chapter 301, the Cauchy completion reflector of chapter 1585, and the terminal real-name boundary of chapter 38. The packet names the no-choice completion-neighbour exposed by the Picard residuals; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, select a fixed point, or identify quotient representatives.

Definition 7720.1 (PicardIterationCauchy carrier)**.** *A* $\mathsf{PicardIterationCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, B, M, R, F, E, H, C, Q, N)$$

whose coordinates are exactly:

1. *I is the accepted* $\mathsf{PicardIteration}^{\uparrow}$ *row displaying the finite orbit, residual-distance ledger, Cauchy-modulus extraction, and regular-sequence handoff.*
2. *B is the* $\mathsf{BanachContraction}^{\uparrow}$ *row recording that the orbit is consumed only through the contraction fixed-point route and not through a selected host endpoint.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row extracted from the Picard residual comparisons.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that exposes the regular rational name generated by I and M.*
5. *F is the* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *row that admits the regular Cauchy name to the completion-facing reflector surface.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after the regular handoff and reflector route have been displayed.*
7. *H records componentwise* hsame *transport for I, B, M, R, F, E and for the continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from Picard iteration through contraction residuals, Cauchy modulus extraction, regular rational readback, completion reflection, and the real seal boundary.*
9. *Q is the* Pkg *provenance over* $\mathsf{PicardIterationCauchy}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{PicardIterationCauchy}^{\uparrow}}$ *row.*
The carrier exposes a constructive completion-neighbour for the Picard orbit. It contains no coordinate for a selected fixed point, a selected limit, quotient completion equality, countable choice, host function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7720.2 (PicardIterationCauchy NameCert obligations)**.** *For every accepted* $\mathsf{PicardIterationCauchy}^{\uparrow}$ *carrier* $P = (I, B, M, R, F, E, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{PicardIterationCauchy}^{\uparrow}}$ *surface consists exactly of Picard-iteration admission, Banach-contraction route visibility, Cauchy-modulus exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff visibility,* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *admission,* $\mathsf{Real}^{\uparrow}$ *seal separation, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 7720.1.*

Proof. Project the carrier. The mathematical rows I, B, M, R, F, E are the only completion-facing coordinates, while H, C, Q, N are the only structural coordinates.

The Picard and contraction rows are read first. The row I exposes the finite orbit, residual-distance ledger, and Cauchy-modulus handoff of chapter 2359; the row B keeps the same orbit inside the constructive Banach route of chapter 3529.

Next read the completion-neighbour rows. The modulus row M is the source of the regular handoff R, the reflector row F consumes that regular handoff, and the seal row E is downstream of F.

Finally H, C, Q, N transport, replay, source, and name exactly these displayed rows. Since the carrier inventory has no selected endpoint, quotient representative, countable-choice schedule, host extensionality row, or ambient real-completeness row, the NameCert surface cannot export one. □

Theorem 7720.3 (PicardIterationCauchy contraction route)**.** *Every completion-facing read of an accepted* $\mathsf{PicardIterationCauchy}^{\uparrow}$ *carrier must pass through the displayed chain*

$$\mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{BanachContraction}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyCompletionReflector}^{\uparrow} \longmapsto$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *row is generated by the Picard residual-modulus route, the reflector row is generated by that regular handoff, and the* $\mathsf{Real}^{\uparrow}$ *seal is available only after the reflector has been displayed. No consumer may replace this route by a selected fixed point, selected limit, quotient stream, countable-choice schedule, host equality, or ambient real-completeness principle.*

Proof. Begin with the Picard row I. By Definition 2359.5, the regular handoff is downstream of the finite orbit ledger, residual-distance row, and Cauchy-modulus row.

Read the Banach row B next. By Definition 3529.4, a fixed-point-facing consumer must keep the same Picard tail modulus upstream of the regular rational completion boundary.

Now project M, R, F, E from the carrier. The modulus row M is the only source for R, the reflector row F is the only completion-facing consumer of R, and E is only a downstream real-name seal.

The structural rows H, C, Q, N preserve this order under transport, replay, provenance, and local naming. Because no excluded object is a coordinate of the carrier, the displayed chain is the whole completion-neighbour route. □

Falsifiable prediction: Every accepted $\mathsf{PicardIterationCauchy}^{\uparrow}$ read factors through one PicardIteration row, one BanachContraction row, one CauchyModulus row, one RegSeqRat handoff, one CauchyCompletionReflector row, one RealUp seal boundary, hsame transport, Cont replay, Pkg provenance, and NameCert row before any completion-facing consumer reads a Picard endpoint.

Independence witness: picard-iteration, banach-contraction, cauchymodulus, regseqrat, cauchy-completionreflector, real: none is bijective with $\mathsf{PicardIterationCauchy}^{\uparrow}$ because the packet jointly stores the Picard orbit, contraction route, residual modulus, regular handoff, completion reflector, real seal boundary, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PicardIterationCauchy}^{\uparrow}}$.

Constructive story: A $\mathsf{PicardIterationCauchy}^{\uparrow}$ packet is generated from a PicardIteration row, a BanachContraction row, a CauchyModulus row, a RegSeqRat handoff, a CauchyCompletionReflector row, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PicardIterationCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7720.1, Definition 7720.2, and Definition 7720.3 seed the constructive route from contractive Picard iteration to regular Cauchy completion-neighbour data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PicardIterationCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, selected fixed points, selected limits, quotient completion equality, countable choice, host equality, host function extensionality, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked Picard-iteration admission, Banach-contraction route visibility, Cauchy-modulus exposure, RegSeqRat handoff visibility, CauchyCompletionReflector admission, Real seal separation, transport, replay, provenance, and local naming.

Chapter 7721

A Concrete Naming Certificate for $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$ packet records the finite BEDC surface by which the harmonic reciprocal schedule $n \mapsto 1/(n+1)$ is read as a regular Cauchy tail estimate before a $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the tail-estimate route of chapter 1487. The packet names only the displayed harmonic threshold, the inspected finite window, the dyadic tolerance, the regular readback, the real seal, transport, replay, provenance, and local naming rows; it does not import quotient streams, selected limits, host real equality, choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7721.1 (Regular Cauchy harmonic estimate carrier)**.** *A* $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, W, D, R, E, T, C, P, N)$$

with the following displayed rows:

1. *S is the harmonic reciprocal schedule row. It stores the finite threshold calculation by which a requested dyadic tolerance is met by the displayed tail bound $1/(n+1)$.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected at and beyond the threshold exposed by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the dyadic error budget used for the harmonic tail read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row reached from the window W under the schedule and tolerance rows S, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row that is available only after the harmonic schedule, window, tolerance, and regular readback rows have been displayed.*
6. *T records componentwise* hsame *transport for S, W, D, R, E, C, P, N.*
7. *C records displayed* Cont *replay from a tolerance request through the harmonic threshold, finite window, dyadic tolerance, regular readback, and real seal route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through those finite rows. It has no coordinate for quotient stream equality, a chosen limit, host real equality, trichotomy, open-cover compactness, or an ambient completeness principle.

Theorem 7721.2 (Regular Cauchy harmonic estimate NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$ *carrier* $H = (S, W, D, R, E, T, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyHarmonicEstim}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the harmonic reciprocal schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *classifier transport to the common* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *finite surface;*
3. *stability of S, W, D, R, E under the componentwise* hsame *rows recorded in T;*
4. *route exactness requiring every harmonic tail read to pass through S, W, D, R, E in that order;*
5. *refusal rows excluding quotient streams, selected limits, host real equality, choice, trichotomy, open-cover compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier $H = (S, W, D, R, E, T, C, P, N)$. The displayed analytic inventory is exactly the harmonic schedule, the finite stream window, the dyadic tolerance, the regular readback, and the terminal real seal.

Classifier transport is componentwise. The T row moves S, W, D, R, E and the administrative rows C, P, N to the same finite comparison surface, so any accepted comparison is already a comparison of the listed rows.

Route exactness is supplied by the replay row C. A tolerance request first reads the harmonic threshold in S, then the finite observations in W, then the dyadic tolerance ledger D, then the regular readback R, and only then the seal E.

The refusal row follows from the carrier inventory. Since no row stores quotient streams, selected limits, host real equality, choice, trichotomy, open-cover compactness, or ambient completeness, the local name cannot export any of those principles. □

Theorem 7721.3 (Regular Cauchy harmonic tail window factorization)**.** *For every accepted* $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$ *carrier* $H = (S, W, D, R, E, T, C, P, N)$*, every harmonic tail read factors through the finite threshold, window, tolerance, readback, and seal route*

$$S \longrightarrow W \longrightarrow D \longrightarrow R \longrightarrow E$$

before any consumer may inspect the transport, replay, provenance, or local naming rows T, C, P, N. In particular, the read cannot bypass the finite $\mathsf{StreamName}^{\uparrow}$ *window, cannot replace the dyadic tolerance by a host real comparison, and cannot obtain a selected limit or quotient-stream equality.*

Proof. Start with a harmonic tail read of an accepted carrier. The carrier exposes the harmonic reciprocal schedule only through S, so the first available threshold is the finite threshold row stored there.

Replay the route recorded in C. After S has exposed the threshold, the read is sent to the finite observations in W, then to the dyadic tolerance ledger D, then to the regular rational readback R, and finally to the real seal E.

Transport through T preserves this displayed order. The provenance row P and local name N bind the same route to $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$; they do not introduce another value-facing coordinate.

Thus every harmonic tail read factors through S, W, D, R, E before reaching T, C, P, N. The carrier has no row from which a bypass could read host real comparison, selected limits, quotient streams, choice, trichotomy, open-cover compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}$ packet is generated from a harmonic reciprocal schedule, a finite $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7721.1, Definition 7721.2, and Definition 7721.3 seed the finite harmonic-tail estimate surface for the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyHarmonicEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host real equality, choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, hsame stability, harmonic tail-window exactness, refusal rows, and provenance faithfulness for $S, W, D, R, E, T, C, P, N$.

Chapter 7722

A Concrete Naming Certificate for $\mathsf{CubicSpline}^{\uparrow}$

Following de Boor and Bishop-style constructive approximation, the $\mathsf{CubicSpline}^{\uparrow}$ packet records the finite Real-window route for a piecewise cubic spline over displayed knot windows. It refines the finite spline-space carrier of chapter 6894, the dyadic spline route of chapter 382, and the endpoint-jet surface of chapter 6668. Its readback boundary is routed through chapter 301, its stream-facing windows through chapter 126, and its terminal Real seal through chapter 38.

Definition 7722.1 (Cubic spline Real-window carrier)**.** *A* $\mathsf{CubicSpline}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, C, J, R, E, H, T, P, N)$$

with the following displayed rows:

1. *W is the knot-window row. It stores a finite increasing dyadic knot list, adjacent window membership tests, endpoint order evidence, and the displayed source window read by each consumer.*
2. *C is the dyadic cubic coefficient row. For every adjacent knot window it stores the four displayed dyadic coefficients of the local cubic polynomial, together with the cell index that selects that tuple.*
3. *J is the Hermite endpoint data row. It records the left and right value and first-derivative reads attached to each local cubic piece, and it identifies the shared endpoint data used by neighboring cells.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It turns each requested finite window and its selected cubic coefficient tuple into the regular rational observation used by downstream Real-window consumers.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the tolerance tokens and Real-name boundary obtained from the same readback row R.*
6. *H records componentwise* hsame *transport for knot windows, coefficient tuples, Hermite endpoint data, regular rational readbacks, Real seals, displayed replay, package provenance, and the local naming row.*
7. *T records displayed* Cont *replay of the route*

$$W, C, J \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{CubicSpline}^{\uparrow}$, $\mathsf{BishopSplineSpace}^{\uparrow}$, $\mathsf{DyadicSpline}^{\uparrow}$, $\mathsf{HermiteInterpolation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{CubicSpline}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed knot windows, dyadic cubic coefficients, Hermite endpoint data, regular rational readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows.

Theorem 7722.2 (Cubic spline Real-window NameCert obligations)**.** *For every accepted* $\mathsf{CubicSpline}^{\uparrow}$ *carrier*

$$S = (W, C, J, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CubicSpline}^{\uparrow}}$ *surface consists exactly of knot-window admission, dyadic cubic coefficient admission, Hermite endpoint-data admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public cubic-spline Real-window read must pass through the finite rows $W, C, J, R, E, H, T, P, N$ before it names a cell value, endpoint jet, or Real-sealed observation.*

Proof. Project the carrier of Definition 7722.1. The analytic rows are W, C, J, R, E: the displayed knot windows, dyadic cubic coefficients, Hermite endpoint data, regular rational readback, and Real seal.

The structural rows keep that route finite. The transport row H moves the selected window, coefficient tuple, endpoint jet, readback, and seal together, while T replays the displayed route from local cubic data to Real-sealed observations.

Finally the provenance and local naming rows P, N certify that the public object is exactly this packet. Since the classifier has no coordinate for a host spline function, quotient graph equality, global smoothness oracle, selected limit, or ambient completion, those objects cannot be read from the local NameCert surface. □

Theorem 7722.3 (Cubic spline piecewise-cubic handoff)**.** *For every accepted* $\mathsf{CubicSpline}^{\uparrow}$ *carrier $S = (W, C, J, R, E, H, T, P, N)$ and every displayed consumer window in W, the Real-facing read is obtained by selecting the adjacent knot cell, reading its dyadic cubic coefficient tuple from C, checking the corresponding Hermite endpoint row in J, routing the resulting finite cubic observation through R, and sealing that same observation in E. Neighboring cells meet only through their shared displayed endpoint data and the componentwise transports in H.*

Proof. Start with the requested displayed window. The finite knot-window row W either selects one adjacent cell or moves by finite inspection to the next displayed edge, using only the stored dyadic order evidence.

Once the cell is selected, project its coefficient tuple from C and its endpoint values and first-derivative reads from J. The shared endpoint entries in J are the only handoff data between neighboring cubic pieces.

Route the local cubic observation through the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R and then through the $\mathsf{Real}^{\uparrow}$ seal row E. Transport along H and replay through T preserve the same selected cell, coefficient tuple, endpoint data, readback, and seal.

Repack the result through P, N. The handoff therefore exports a finite piecewise-cubic Real-window reading and does not export a host spline function, quotient graph, global differentiability oracle, infinite knot row, selected limit, or ambient completion datum. □

Falsifiable prediction: An accepted $\mathsf{CubicSpline}^{\uparrow}$ read is refuted if a consumer obtains a Real-window cubic-spline value, endpoint jet, or piecewise-cubic handoff without first displaying the knot-window, coefficient, Hermite endpoint, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: bishop-spline-space, dyadicspline, hermite-interpolation, regseqrat, stream-name, real: $\mathsf{CubicSpline}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite knot windows, dyadic cubic coefficient rows, Hermite endpoint data, regular rational readback, Real sealing, stream-facing window provenance, transport, replay, package provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CubicSpline}^{\uparrow}}$.

Constructive story: A $\mathsf{CubicSpline}^{\uparrow}$ packet is generated from finite knot-window rows, dyadic cubic coefficient rows, Hermite endpoint-data rows, RegSeqRat readback rows, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CubicSpline}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7722.1, Definition 7722.2, and Definition 7722.3 seed the constructive Real-window cubic-spline route over displayed knot windows, dyadic cubic pieces, Hermite endpoint data, regular rational readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CubicSpline}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host spline functions, quotient graph equality, global differentiability, selected limits, infinite knot rows, or ambient completion.

Upgrade path: Obligation closure requires checked carrier admission, knot-window selection, dyadic cubic coefficient readback, Hermite endpoint handoff, Real sealing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.CubicSplineUp.

Chapter 7723

A Concrete Naming Certificate for RegularCauchyOscillationModulusExtraction$^{\uparrow}$

Following Bishop and Bridges on Cauchy criteria and oscillation moduli, the RegularCauchyOscillationModulusExtrac packet records the finite route from a regular Cauchy tail-oscillation ledger to an explicit modulus-extraction row. It sits after the finite observation names of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the threshold extraction surface of chapter 641, and the oscillation-modulus surface of chapter 2224. The packet names the tail-window induction that turns inspected oscillation bounds into a modulus row before any quotient stream, selected limit, host convergence theorem, or ambient Real$^{\uparrow}$ completeness principle is read.

Definition 7723.1 (Regular-Cauchy oscillation modulus extraction carrier)**.** *A* RegularCauchyOscillationModulusEx *carrier is a finite* BHist *packet*

$$M = (S, R, D, O, E, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *source schedule naming the finite tail windows inspected by the request.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback row used to compare the stream values inside those windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, carrying the requested dyadic bound and the halving data used by the tail estimate.*
4. *O is the* OscillationModulus$^{\uparrow}$ *row that records the tail-oscillation bound on each displayed window.*
5. *E is the* CauchyModulusExtraction$^{\uparrow}$ *row that extracts a threshold from the displayed schedule, readback, tolerance, and oscillation rows.*
6. *W is the terminal* Real$^{\uparrow}$ *seal available only after the extracted threshold row has been displayed.*
7. *H stores componentwise* hsame *transport for the source, readback, dyadic, oscillation, extraction, seal, provenance, and local naming rows.*
8. *C stores the displayed* Cont *replay that moves a tolerance request through tail-window inspection, oscillation comparison, threshold extraction, and Real-facing sealing.*
9. *P is the* Pkg *provenance over* RegularCauchyOscillationModulusExtraction$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, OscillationModulus$^{\uparrow}$, CauchyModulusExtraction$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, R, D, O, E, W, H, C, P, N$.

Theorem 7723.2 (Regular-Cauchy oscillation modulus extraction NameCert obligations)**.** *For an accepted* $\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}$ *carrier $M = (S, R, D, O, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission, finite source-window admission through* $\mathsf{StreamName}^{\uparrow}$*, regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, dyadic tolerance budgeting through* $\mathsf{DyadicRatCore}^{\uparrow}$*, tail-oscillation exposure through* $\mathsf{OscillationModulus}^{\uparrow}$*, threshold extraction through* $\mathsf{CauchyModulusExtraction}^{\uparrow}$*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It exports no quotient stream equality, selected modulus oracle, countable-choice selector, host convergence theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier. The analytic rows are S, R, D, O, E, W, and the structural rows are H, C, P, N.

The source side is finite. A tolerance request first reads the $\mathsf{StreamName}^{\uparrow}$ row S, then compares the requested tail values through the $\mathsf{RegSeqRat}^{\uparrow}$ row R and the $\mathsf{DyadicRatCore}^{\uparrow}$ budget D.

The oscillation side is also finite. The row O records the tail-oscillation bound on the displayed windows, and the extraction row E is read only after S, R, D, O have all been displayed. The terminal row W is therefore downstream of the extracted threshold, not a separate completeness principle.

Finally H, C, P, N preserve this same route under transport, replay, provenance, and local naming. Since no other coordinate occurs in the carrier, the listed rows exhaust the NameCert obligations. □

Theorem 7723.3 (Regular-Cauchy oscillation modulus extraction tail route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}$ *packet must read the finite tail route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{OscillationModulus}^{\uparrow} \longmapsto \mathsf{CauchyModulusExtraction}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with H, C, P, N before any modulus threshold is public. The route is obtained by finite tail-window induction over the displayed source schedule, and it does not use quotient streams, a selected limit, a host Cauchy theorem, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct over the finite tail-window schedule stored in S. In the base window, the tolerance request reads D and the regular-rational comparison in R, so the first oscillation bound is an explicit row of O.

For the induction step, assume the earlier inspected windows already route through S, R, D, O. The next displayed window is added by the same $\mathsf{StreamName}^{\uparrow}$ schedule, its rational comparisons are read through R, and its dyadic budget is read through D. The oscillation row O supplies the matching bound for that window.

After the finite schedule is exhausted, the extraction row E receives exactly the inspected windows and their oscillation bounds. The $\mathsf{Real}^{\uparrow}$ seal W is read only after E, while H, C, P, N replay the same route componentwise. Thus every consumer reaches the public threshold through the displayed tail-window induction and no excluded host or choice coordinate is available. □

Falsifiable prediction: Every $\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}$ consumer read must expose a StreamName tail schedule, RegSeqRat readback, DyadicRatCore tolerance budget, OscillationModulus tail ledger, CauchyModulusExtraction threshold row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, oscillationmodulus, cauchymodulusextraction, real: $\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the inspected tail schedule, rational readback, dyadic budget, oscillation ledger, extracted threshold, Real-facing seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}$ packet is generated from StreamName tail windows, RegSeqRat readback, DyadicRatCore tolerance data, an OscillationModulus tail ledger, a CauchyModulusExtraction threshold row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7723.1, Definition 7723.2, and Definition 7723.3 seed the finite tail-window route from regular Cauchy oscillation bounds to modulus extraction over StreamName, RegSeqRat, DyadicRatCore, OscillationModulus, CauchyModulusExtraction, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationModulusExtraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean-side verification, bridge checking, quotient stream equality, selected moduli, host convergence, countable choice, trichotomy, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, tail-window induction, dyadic tolerance exactness, oscillation ledger compatibility, extraction locality, RealUp seal non-escape, transport, replay, provenance, and local naming for the displayed packet.

Chapter 7724

A Concrete Naming Certificate for $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy names, the $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$ packet records the finite normal-form surface by which a displayed rational name is read before the terminal $\mathsf{Real}^{\uparrow}$ seal is available. It sits over the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the real-name boundary of chapter 38, the sealing discipline of chapter 6749, and the modulus ledger of chapter 7483. The packet names only the displayed normal-form rows; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, trichotomy, countable choice, or host real equality.

Definition 7724.1 (Regular Cauchy name normal-form carrier)**.** *A* $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, S, R, M, E, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare rational observations at the requested precision.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposing exactly the inspected rational-name observations.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to the same finite windows.*
4. *M is the* $\mathsf{RegularSequenceModulus}^{\uparrow}$ *row that records the displayed regularity modulus for the rational name.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, S, R, M have been displayed.*
6. *B is the* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *row that records the Bishop-style Cauchy-name admission boundary for the same route.*
7. *H records componentwise* hsame *transport for the tolerance, window, readback, modulus, seal, Bishop admission, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a name-normalization request through $D, S, R, M, E, B, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularSequenceModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopCauchyNameSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyNameNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, M, E, B, H, C, P, N$. It has no coordinate for quotient stream equality, a selected limit, host real equality, trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RegularCauchyNameNormalFormUp.RegularCauchyNameNormalFormTasteGate single carrier alignment`

Theorem 7724.2 (Regular Cauchy name normal-form NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$ *carrier $F = (D, S, R, M, E, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyNameNorm}}$ *surface consists exactly of carrier admission for the dyadic tolerance ledger, finite stream window, regular rational readback, regular-sequence modulus, real seal, Bishop Cauchy-name seal, componentwise transport, displayed replay, package provenance, and local naming rows. Every real-facing read from the packet must pass through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularSequenceModulus}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before the Bishop seal and structural rows can be consumed.

Proof. Project the carrier $F = (D, S, R, M, E, B, H, C, P, N)$. The visible analytic inventory is exactly the dyadic tolerance row, finite stream window, regular rational readback, regularity modulus, real seal, and Bishop Cauchy-name admission row.

The replay row C fixes the order of use. A name-normalization request first reads the tolerance ledger D, then the finite window S, then the regular readback R, then the regularity modulus M, and only then exposes the terminal real seal E and the Bishop admission boundary B.

Transport and provenance preserve the same packet. The rows H, P, N move, source, and name the displayed normal-form surface, but they do not add quotient stream equality, a selected limit, host real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 7724.3 (Regular Cauchy normal-form route nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$ *packet receives a finite normal-form route through $D, S, R, M, E, B, H, C, P, N$. The consumer cannot bypass the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, the* $\mathsf{StreamName}^{\uparrow}$ *finite window, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the* $\mathsf{RegularSequenceModulus}^{\uparrow}$ *modulus row, or the* $\mathsf{BishopCauchyNameSeal}^{\uparrow}$ *admission boundary by appealing to quotient stream equality, selected limits, trichotomy, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a real-facing read of an accepted carrier. The only terminal real row is E, and the carrier places it after the displayed tolerance, stream, readback, and modulus rows.

Read the continuation row C. It sends the request through D, S, R, M before E and B are available. Componentwise transport through H preserves those fields rather than replacing them by a host comparison or a quotient equality.

The provenance and naming rows P, N bind the same finite route to the local certificate. Since the carrier contains no coordinate for selected limits, trichotomy, countable choice, host real equality, quotient stream equality, or completeness of all $\mathsf{Real}^{\uparrow}$ names, no consumer can obtain such data from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyNameNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyNameNormalForm}^{\uparrow}$ packet is generated from a DyadicRatCoreUp tolerance ledger, StreamNameUp finite windows, RegSeqRatUp readback, a RegularSequenceModulusUp row, a RealUp seal, a BishopCauchyNameSealUp admission row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyNameNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7724.1, Definition 7724.2, and Definition 7724.3 seed the finite normal-form route over DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RegularSequenceModulusUp, RealUp, BishopCauchyNameSealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyNameNormalForm}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, quotient stream equality, selected limits, trichotomy, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, route exactness, transport stability, Bishop admission stability, refusal rows, and provenance faithfulness for BEDC.Derived.RegularCauchyNameNormalFormUp.

Chapter 7725

A Concrete Naming Certificate for HyperbolicVisualAngle$^{\uparrow}$

The HyperbolicVisualAngle$^{\uparrow}$ packet realizes the boundary-triple and visual readback surface of chapter 9463 as finite hyperbolic phase data. It sits after the disk-coordinate surface of chapter 377, the metric-read surface of chapter 3474, the boundary-geodesic packet of chapter 3491, the cross-ratio route of chapter 3948, and the terminal Real$^{\uparrow}$ seal of chapter 38. The packet names a finite visual-angle carrier; it does not complete the disk, quotient boundary triples, select a host geodesic, identify visual angle with physical observation, or import real completeness.

Definition 7725.1 (Hyperbolic visual-angle carrier)**.** *A* HyperbolicVisualAngle$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, T, M, B, X, R, J, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UnitDisk$^{\uparrow}$ *disk-coordinate row for the observer point and the inspected boundary data.*
2. *T is the boundary-triple row naming the ordered finite boundary ends used by the visual-angle read.*
3. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-read row over the same displayed disk data.*
4. *B is the* HyperbolicGeodesicBoundary$^{\uparrow}$ *row that exposes geodesic-boundary incidence for the triple.*
5. *X is the* HyperbolicCrossRatio$^{\uparrow}$ *row carrying the finite cross-ratio comparison attached to the same boundary triple.*
6. *R is the* Real$^{\uparrow}$ *seal row for the angle value, available only after U, T, M, B, X have been displayed.*
7. *J records classifier stability for disk coordinates, boundary triples, metric reads, geodesic-boundary incidence, cross-ratio data, and the real seal.*
8. *H records componentwise* hsame *transport for $U, T, M, B, X, R, J, C, P, N$.*
9. *C records displayed* Cont *replay from a visual-angle request through boundary triple, hyperbolic metric, geodesic-boundary, cross-ratio, real-seal, transport, provenance, and naming rows.*
10. *P is the* Pkg *provenance over* HyperbolicVisualAngle$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBoundary$^{\uparrow}$, HyperbolicCrossRatio$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicVisualAngle}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $U, T, M, B, X, R, J, H, C, P, N$. It has no coordinate for a completed Poincare disk, a Klein-model equality, quotient ideal-boundary equality, selected geodesic representatives, physical observation laws, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7725.2 (Hyperbolic visual-angle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicVisualAngle}^{\uparrow}$ *carrier $A = (U, T, M, B, X, R, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicVisualAngle}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission through U, boundary-triple admission through T, hyperbolic metric-read exactness through M, geodesic-boundary incidence through B, cross-ratio comparison through X, real-seal exposure through R, classifier stability through J, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7725.1. The accepted rows are exactly $U, T, M, B, X, R, J, H, C, P, N$, so carrier admission exposes disk coordinates, a boundary triple, metric reads, geodesic-boundary incidence, cross-ratio data, a real seal, classifier stability, transport, replay, provenance, and local naming.

The geometric obligations are ordered by the replay row C. A visual-angle request first reads the disk-coordinate and boundary-triple data, then the hyperbolic metric and geodesic-boundary incidence, then the cross-ratio comparison, and only then the real-valued seal.

The structural rows preserve that same surface. Classifier stability, componentwise transport, provenance, and local naming cannot add a completed disk, quotient boundary equality, selected geodesic representative, physical observation law, or ambient real-completeness row, so the listed obligations exhaust the local certificate. □

Theorem 7725.3 (Hyperbolic visual-angle route nonescape)**.** *Every visual-angle read from an accepted* $\mathsf{HyperbolicVisualAngle}^{\uparrow}$ *packet factors through*

$$\mathsf{UnitDisk}^{\uparrow} \longmapsto \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{HyperbolicGeodesicBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicCrossRatio}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $U, T, M, B, X, R, J, H, C, P, N$. Thus the packet exposes finite boundary-triple, hyperbolic metric, cross-ratio, real-seal, transport, provenance, and NameCert rows, but it exports no completed disk, quotient boundary triple, selected host geodesic, physical-observation equality, Klein-model equality, or ambient real-completeness principle.

Proof. Start with an accepted visual-angle request. The disk-coordinate row U and boundary-triple row T give the only available source data for the angle read.

Replay the route recorded in C. The metric row M and boundary row B make the geodesic incidence visible, the cross-ratio row X carries the boundary comparison, and the real seal R is exposed only after those rows are present.

The classifier, transport, provenance, and naming rows J, H, P, N preserve the same finite packet. Since the carrier lacks any coordinate for completed disk objects, quotient boundary triples, selected host geodesics, physical-observation equality, Klein-model equality, or real completeness, no visual-angle consumer can read such data from the packet. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicVisualAngle}^{\uparrow}$ read displays a UnitDisk observer row, a boundary-triple row, a HyperbolicMetric row, a HyperbolicGeodesicBoundary row, a HyperbolicCrossRatio row, a RealUp seal, classifier stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before exporting a visual-angle value.

Independence witness: unitdisk, hyperbolic-metric, hyperbolic-geodesic-boundary, hyperbolic-cross-ratio, real: $\mathsf{HyperbolicVisualAngle}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an observer disk coordinate, ordered boundary triple, metric read, geodesic-boundary incidence, cross-ratio comparison, Real seal, classifier stability, transport, replay, provenance, and local NameCert rows.

Lean `TasteGate.lean` for this packet will provide `Nontrivial HyperbolicVisualAngleUp` and `FieldFaithful HyperbolicVisualAngleUp` instances for the same displayed carrier. Those instances must keep $U, T, M, B, X, R, J, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicVisualAngle}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicVisualAngle}^{\uparrow}$ packet is generated from UnitDiskUp observer rows, boundary-triple rows, HyperbolicMetricUp reads, HyperbolicGeodesicBoundaryUp incidence, HyperbolicCrossRatioUp comparison data, a RealUp seal, classifier stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualAngle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7725.1, Definition 7725.2, and Definition 7725.3 seed the finite visual-angle route over boundary triple, hyperbolic metric, geodesic-boundary, cross-ratio, Real seal, transport, provenance, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicVisualAngle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed disks, quotient boundary triples, selected host geodesics, physical-observation equality, Klein-model equality, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-coordinate admission, boundary-triple admission, metric-read exactness, geodesic-boundary incidence, cross-ratio comparison, Real-seal exposure, classifier stability, TasteGate nontriviality, field faithfulness, and local naming for BEDC.Derived.HyperbolicVisualAngleUp.

Chapter 7726

A Concrete Naming Certificate for $\mathsf{CauchyRealRegularization}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{CauchyRealRegularization}^{\uparrow}$ packet records the finite BEDC route that turns a displayed Cauchy-real name into a regular rational sequence row before the terminal real seal is read. It sits after the finite-window discipline of chapter 126, the dyadic tolerance arithmetic of chapter 291, the regular rational readback surface of chapter 301, and the terminal seal of chapter 38. For fast or modulus-indexed presentations it also aligns with chapter 1589 and chapter 7427, but it does not identify quotient classes or choose limits outside the displayed packet.

Definition 7726.1 (CauchyRealRegularization carrier)**.** *A* $\mathsf{CauchyRealRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, S, D, R, E, H, T, P, N)$$

with the following displayed rows:

1. *C is the source Cauchy-real name row, available only as finite precision requests and responses.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected stages, requested tolerances, and replay addresses.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that accounts for every comparison made while regularizing the source name.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularization row produced from the same windows and dyadic ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after S, D, R have been displayed.*
6. *H records componentwise* hsame *transport for source name, windows, tolerances, regularization row, real seal, replay, provenance, and local naming.*
7. *T records displayed* Cont *replay from a source precision request through S, D, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRealRegularization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these nine rows. It has no coordinate for quotient streams, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7726.2 (CauchyRealRegularization NameCert obligations)**.** *For every accepted* CauchyRealRegularization *carrier* $K = (C, S, D, R, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealRegularization}^{\uparrow}}$ *surface consists exactly of carrier admission for the source Cauchy-real name row; finite window exposure through* S*; dyadic tolerance accounting through* D*; handoff to the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*; terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary through* E*; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; local naming; and non-escape from quotient streams, selected limits, countable choice, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7726.1. The only source-name, window, dyadic-ledger, regularization, and real-seal data available to a consumer are C, S, D, R, E.

The regularization route first exposes the finite windows in S and accounts for every tolerance comparison in D. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of those two rows, so no regular readback can be obtained from a detached Cauchy stream or a selected subsequence.

The terminal seal is then read through E, with H, T, P, N preserving, replaying, sourcing, and naming the same finite route. Since the carrier contains no quotient, selected-limit, choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyRealRegularization}^{\uparrow}$ packet is generated from a source Cauchy-real name row, finite StreamName windows, a DyadicRatCore tolerance ledger, a RegSeqRat regularization row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRealRegularization}^{\uparrow}}$, seed)

Scope closed: Definition 7726.1 and Definition 7726.2 seed the finite route from Cauchy-real names to regular rational readback and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRealRegularization}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completeness of RealUp, quotient stream equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, dyadic tolerance accounting, RegSeqRat handoff, Real seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRealRegularizationUp.

Chapter 7727

A Concrete Naming Certificate for $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$

Following Tietze and Urysohn, the $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$ packet isolates one finite bounded correction stage inside the Tietze route. It reads the normal-space separation source of chapter 1866, the Urysohn separator certificate of **??**, the graph replay surface of chapter 130, the bounded value seal of chapter 38, and the full extension route of chapter 1956. The packet also keeps the zero and cozero boundary discipline visible through chapter 1858 and chapter 1857. It names only one displayed correction row, not the full extension theorem.

Definition 7727.1 (Tietze finite-step carrier)**.** *A* $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (N, D, B, U, M, G, R, H, K, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *source row, exposing the ambient topology and the closed-pair separation discipline used by the correction stage.*
2. *D is the closed-domain row on which the current bounded partial extension is compared with the input data.*
3. *B is the bounded* $\mathsf{Real}^{\uparrow}$ *interval row for the current error scale, including endpoint bounds for the stage.*
4. *U is one* $\mathsf{UrysohnLemma}^{\uparrow}$ *separator and correction row. It records the closed positive and negative error regions, the separator graph, and the bounded correction amplitude.*
5. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the current partial graph before the correction is applied.*
6. *G is the corrected* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row after adding the Urysohn correction to the current partial graph.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the corrected values and the decreased error bound.*
8. *H records componentwise* hsame *transport for the normal-space source, closed-domain row, bounded interval, separator row, current graph, corrected graph, Real seal, replay, provenance, and local naming.*
9. *K records displayed* Cont *replay from a finite-step request through $N, D, B, U, M, G, R, H, P, L$.*

10. *P is the* Pkg *provenance over* $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ZeroSet}^{\uparrow}$, $\mathsf{CozeroSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{TietzeExtensionFiniteStep}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $N, D, B, U, M, G, R, H, K, P, L$. It has no coordinate for the completed Tietze extension, selected complements, excluded middle, host function extensionality, open-cover compactness, or ambient Real completeness.

Theorem 7727.2 (Tietze finite-step NameCert obligations)**.** *For every accepted* $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$ *carrier*

$$S = (N, D, B, U, M, G, R, H, K, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{TietzeExtensionFiniteStep}^{\uparrow}}$ *surface consists exactly of carrier admission, closed-domain exposure, separator-stage routing, endpoint agreement, bounded-error decrease, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Carrier admission is the projection of Definition 7727.1. The accepted packet displays exactly the normal-space source, closed-domain row, bounded interval, one Urysohn correction row, current graph, corrected graph, Real seal, and structural support.

Closed-domain exposure is read through N and D. A finite correction stage may compare the current graph with the input data only after the displayed closed-domain row is available over the same normal-space source.

Separator-stage routing is the projection to U. The correction amplitude and the separating graph are supplied by the $\mathsf{UrysohnLemma}^{\uparrow}$ row, so no selected complement or excluded-middle branch can be consumed.

Endpoint agreement and bounded-error decrease are read through M, G, B, R. The current and corrected graphs are both $\mathsf{ContinuousMap}^{\uparrow}$ rows, while the Real seal records that the corrected graph remains inside the bounded interval and decreases the displayed error scale.

Transport, replay, provenance, and naming are exhausted by H, K, P, L. Since the classifier has no further coordinate, the listed rows are the whole local NameCert surface. □

Theorem 7727.3 (Tietze finite-step Urysohn stage)**.** *Every correction-stage consumer of an accepted* $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$ *packet factors through*

$$\mathsf{NormalSpace}^{\uparrow} \longrightarrow \mathsf{UrysohnLemma}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

before the surrounding $\mathsf{TietzeExtension}^{\uparrow}$ *route can consume the corrected graph. The stage exports a bounded corrected graph and an error-decrease row, not a completed extension theorem.*

Proof. Start with an accepted carrier $S = (N, D, B, U, M, G, R, H, K, P, L)$. The normal-space source N and closed-domain row D must be visible before a correction request has a domain on which the current error can be read.

The next row is U. It is the unique Urysohn separator and correction coordinate in the packet, so every correction-stage consumer reaches the separator through $\mathsf{NormalSpace}^{\uparrow}$ and $\mathsf{UrysohnLemma}^{\uparrow}$.

The corrected graph is then read through M and G. Both are $\mathsf{ContinuousMap}^{\uparrow}$ graph rows, and their agreement along the displayed domain is preserved by the structural rows.

Finally B and R supply the $\mathsf{Real}^{\uparrow}$ boundary for the decreased error scale. Only after these rows are displayed may the surrounding $\mathsf{TietzeExtension}^{\uparrow}$ carrier consume the corrected graph as one ladder stage. □

Closure status for $\mathsf{NameCert}_{\mathsf{TietzeExtensionFiniteStep}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TietzeExtensionFiniteStep}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7727.1, Definition 7727.2, and Definition 7727.3 seed the finite bounded Urysohn correction stage inside the Tietze extension route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TietzeExtensionFiniteStep}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full Tietze extension theorem, host function extensionality, selected complements, excluded middle, open-cover compactness, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, closed-domain exposure, separator-stage routing, endpoint agreement, bounded-error decrease, transport, replay, provenance, and local naming for BEDC.Derived.TietzeExtensionFiniteStep

Constructive story: A $\mathsf{TietzeExtensionFiniteStep}^{\uparrow}$ packet is generated from a normal-space source row, closed-domain row, bounded Real interval row, one Urysohn separator row, current and corrected ContinuousMap graph rows, a Real error seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7728

Mankiewicz Extension NameCert Construction

Following Mankiewicz, the $\mathsf{MankiewiczExtension}^{\uparrow}$ packet records the finite BEDC surface on which an isometry defined on an open convex subset of a real normed space is inspected before it is handed to an affine isometry route. It is a standard neighbor of the Mazur–Ulam surface of chapter 5194: Mazur–Ulam names the surjective whole-space route, while this chapter names the open-convex-domain route whose midpoint and affine ledgers are visible before any global function equality is read. The packet sits over $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and a local $\mathsf{NameCert}$ row; it does not import host function extensionality, choice of an external extension, quotient point equality, or ambient completeness.

Definition 7728.1 (Mankiewicz extension carrier)**.** *A* $\mathsf{MankiewiczExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, F, U, V, I, J, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the source normed carrier row, exposing its* $\mathsf{Norm}^{\uparrow}$ *read, induced* $\mathsf{Met}^{\uparrow}$ *distance row, vector operations,* $\mathsf{Real}^{\uparrow}$ *scalar reads, transport, replay, provenance, and local naming.*
2. *F is the target normed carrier row with the same norm, metric, vector, scalar, transport, replay, provenance, and local naming surface.*
3. *U is the open convex source row: it records the displayed* $\mathsf{ConvexSet}^{\uparrow}$ *membership ledger, the open-ball witnesses used by local midpoint reads, and the source-domain inclusion into E.*
4. *V is the image-domain row in F, carrying the accepted target points reached from the source row and the displayed range membership used by later affine reads.*
5. *I is the isometry row over U and V, storing accepted source histories, accepted target histories, and* $\mathsf{Met}^{\uparrow}$ *distance equality through the rows of E and F.*
6. *J is the local midpoint and segment ledger, recording when midpoint and dyadic convex reads remain inside the open convex source row and how their image rows are compared in the target.*
7. *A is the affine ledger, recording the local affine rule extracted from isometry, midpoint, dyadic convex, additive, and* $\mathsf{Real}^{\uparrow}$ *scalar readback rows.*
8. *Q is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row, exposing the displayed continuous-map route by which the affine ledger is consumed by downstream normed-geometry packets.*

9. *H records componentwise* hsame *transport for E, F, U, V, I, J, A, Q and for the support rows.*
10. *C records displayed* Cont *replay for open-convex membership, distance comparison, midpoint inspection, affine readback, continuous-map handoff, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{MankiewiczExtension}^{\uparrow}$, $\mathsf{MazurUlamIsometry}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, F, U, V, I, J, A, Q, H, C, P, N$. It has no coordinate for host function extensionality, a selected extension outside the displayed rows, quotient equality of maps, external affine hulls, or ambient Banach completeness.

Theorem 7728.2 (Mankiewicz extension NameCert obligations)**.** *For every accepted* $\mathsf{MankiewiczExtension}^{\uparrow}$ *carrier $M = (E, F, U, V, I, J, A, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}$ *surface consists exactly of source and target normed-carrier admission, open convex source admission, image-domain admission, isometry-graph exactness, midpoint and segment stability inside the open convex row, affine-ledger readback,* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7728.1. The normed and metric rows are E, F, the open convex and image-domain rows are U, V, the isometry row is I, and the geometric readback rows are J, A, Q.

Open convex admission is read before any midpoint or affine claim. The row U supplies the local ball and convex membership data needed to keep midpoint and segment reads inside the displayed source surface, while V records the corresponding accepted target rows.

The isometry and affine obligations then follow the displayed order. The row I supplies $\mathsf{Met}^{\uparrow}$ distance equality, the row J records midpoint and dyadic convex stability, the row A records affine readback through finite $\mathsf{Real}^{\uparrow}$ scalar data, and Q hands the resulting route to $\mathsf{ContinuousMap}^{\uparrow}$.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no host extension coordinate, quotient equality of maps, selected external affine map, or ambient completeness row, the listed rows exhaust the local NameCert surface. □

Theorem 7728.3 (Mankiewicz affine isometry route)**.** *Every affine isometry read exported by an accepted* $\mathsf{MankiewiczExtension}^{\uparrow}$ *carrier factors through the open convex source row U, the source and target* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Met}^{\uparrow}$ *rows E, F, the isometry row I, the midpoint and segment ledger J, the affine ledger A, the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and the local* $\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}$ *row N.*

Consequently the packet exposes only a local open-convex affine-isometry route over the displayed finite histories. It exports no host function extensionality, selected extension outside the packet, quotient map equality, hidden inverse, or ambient completeness principle.

Proof. Begin with an affine isometry request. The carrier first exposes U, because the Mankiewicz route applies to an isometry on an open convex source surface rather than to a whole-space graph.

Read the distance and isometry data through E, F, I. These rows give the $\mathsf{Norm}^{\uparrow}$ and $\mathsf{Met}^{\uparrow}$ distances and the displayed equality data for accepted source and target histories.

Next use the midpoint and segment ledger J. It records the finite open-convex checks needed to keep midpoint and dyadic segment reads inside U, so the affine ledger A receives only displayed source-domain data and $\mathsf{Real}^{\uparrow}$ scalar reads.

The $\mathsf{ContinuousMap}^{\uparrow}$ row Q is then a handoff, not a second extension principle. Transport through H, replay through C, provenance through P, and local naming through N preserve the same route and add no host function-extensionality coordinate. The excluded global objects are absent from the carrier, so they cannot be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{MankiewiczExtension}^{\uparrow}$ packet is generated from source and target normed rows, an open convex source row, image-domain data, an isometry graph, midpoint and affine ledgers, a $\mathsf{ContinuousMap}^{\uparrow}$ handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7728.1, Definition 7728.2, and Definition 7728.3 seed the finite Mankiewicz open-convex isometry route over $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MankiewiczExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, selected extensions outside the displayed packet, quotient equality of maps, hidden inverses, ambient Banach completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, open-convex domain admission, isometry exactness, midpoint and affine ledger stability, continuous-map handoff, transport, replay, provenance, and local naming for the same finite packet.

Chapter 7729

A Concrete Naming Certificate for $\mathsf{NeronModel}^{\uparrow}$

Following Neron and Bosch-Lutkebohmert-Raynaud, the $\mathsf{NeronModel}^{\uparrow}$ packet records the local arithmetic-geometric surface by which an abelian variety over the fraction field of a discrete valuation ring extends to a smooth separated group scheme with a local universal mapping property. The chapter packages only the finite BEDC rows that name this local surface: it does not assert global existence of Neron models, choose a minimal regular model, or import a host valuative criterion beyond the displayed local packet.

The packet sits over the valued source of chapter 173, the arithmetic base row of chapter 169, the scheme carrier of chapter 153, the algebraic group surface of chapter 41, and the elliptic-curve example source of chapter 175. These dependencies are read as BEDC rows and not as detached host structures.

7729.1 Carrier definition

Definition 7729.1 (NeronModel local carrier)**.** *A* $\mathsf{NeronModel}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{N} = (K, \mathcal{O}, G, A, \eta, U, H, C, P, N)$$

with the following displayed rows:

1. *K is a* $\mathsf{LocalField}^{\uparrow}$ *or DVR fraction-field source row, carrying the valuation and residue boundary through a finite local-field certificate;*
2. *$\mathcal{O}$ is the* $\mathsf{RingOfIntegers}^{\uparrow}$ *or valuation-ring base row over which the local model is read;*
3. *G is a smooth separated group-scheme row over $\mathcal{O}$, with the scheme part routed through* $\mathsf{Scheme}^{\uparrow}$ *and the group law routed through* $\mathsf{Group}^{\uparrow}$*;*
4. *A is the generic-fiber abelian-variety row, with elliptic-curve inputs allowed through the* $\mathsf{EllipticCurve}^{\uparrow}$ *source when the generic fiber is one-dimensional;*
5. *η is the generic-fiber comparison row identifying the fraction-field fiber of G with the displayed row A;*
6. *U is the extension-across-valuation ledger: every smooth test scheme over $\mathcal{O}$ that is read by the packet carries a generic-fiber map to A and a displayed extension row to G;*

7. *H stores componentwise* hsame *transports for the local field, valuation ring, scheme, group law, generic fiber, extension ledger, provenance, and local naming rows;*
8. *C stores the* Cont *replay routes for source inspection, base change to the fraction field, group-scheme readback, extension-ledger readback, and local universal mapping readback;*
9. *P is the* Pkg *provenance over* $\mathsf{NeronModel}^{\uparrow}$, $\mathsf{LocalField}^{\uparrow}$, $\mathsf{RingOfIntegers}^{\uparrow}$, $\mathsf{Scheme}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{EllipticCurve}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $K, \mathcal{O}, G, A, \eta, U, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.NeronModelUp.NeronModelTasteGate single carrier alignment`

7729.2 The certificate

Theorem 7729.2 (NeronModel NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}$ *obligation surface consists exactly of the carrier of Definition 7729.1, the inherited* $\mathsf{LocalField}^{\uparrow}$ *and* $\mathsf{RingOfIntegers}^{\uparrow}$ *source rows, the* $\mathsf{Scheme}^{\uparrow}$ *and* $\mathsf{Group}^{\uparrow}$ *rows making G a smooth separated group scheme, the generic-fiber row A, the comparison row η, the extension ledger U, the componentwise* hsame *transports, the* Cont *replay rows, and the* Pkg *provenance. No accepted carrier exports a detached host scheme, a chosen regular model, an ambient abelian-variety equality, a global existence theorem, or a choice-heavy valuative selection.*

Proof. Project the carrier of Definition 7729.1. The source rows K and $\mathcal{O}$ bind the local valuation boundary, while the rows G and A bind the scheme, group, and generic-fiber data to displayed BEDC certificates.

Next read the comparison and extension rows. The row η names the generic-fiber comparison inside the finite packet, and U lists only the local extension attempts already routed through a smooth test scheme and the same valuation boundary.

The classifier and stability obligations are componentwise. The rows H and C transport and replay each visible coordinate, and P keeps the dependency provenance attached to the same packet. Repacking these rows gives the listed $\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}$ surface and leaves no coordinate for the excluded host data. □

Theorem 7729.3 (NeronModel local universal route)**.** *Every accepted* $\mathsf{NeronModel}^{\uparrow}$ *carrier that exports a local universal mapping readback must expose the local-field row K, the valuation-ring row $\mathcal{O}$, the smooth separated group-scheme row G, the generic-fiber row A, the comparison row η, and the extension ledger U. The readback is therefore a finite route*

$$K, \mathcal{O}, G, A, \eta, U, H, C, P, N$$

through displayed BEDC data, not a hidden appeal to a host Neron model or to an unrecorded extension theorem.

Proof. Start with the readback request. By the carrier definition, a universal mapping read can only enter through the extension ledger U, and that ledger is stored after the local field, valuation-ring base, group-scheme, generic-fiber, and comparison rows.

Project the source rows. The local valuation boundary comes from K and $\mathcal{O}$, while the target of the extension is the row G whose generic fiber is compared to A by η.

Finally apply the replay and provenance rows. The rows H, C, P, N transport, replay, and name the same finite packet; they add no further source of maps. Hence any accepted universal readback exposes the whole displayed route before the export is available. □

Closure status for $\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}$.

Constructive story: A $\mathsf{NeronModel}^{\uparrow}$ packet is generated from a local-field or DVR source row, a valuation-ring base row, a smooth separated group-scheme row, a generic-fiber abelian-variety row, a comparison row, a local extension ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7729.1, Definition 7729.2, and Definition 7729.3 bind the finite local carrier and its local universal-route surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeronModel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global Neron-model existence, minimal regular models, selected extensions, bridge data, or any choice-heavy valuative theorem beyond the displayed finite local packet.

Upgrade path: The next theory step is a scoped carrier theorem over the local extension ledger and its transport rows.

Chapter 7730

A Concrete Naming Certificate for $\mathsf{CofilteredLimit}^{\uparrow}$

Following Mac Lane's categorical treatment of limits and the Bourbaki–Kelley filter language for directed refinement, the $\mathsf{CofilteredLimit}^{\uparrow}$ packet records a finite cofiltered-cone limit surface rather than a host inverse limit. It sits after the category carrier of chapter 61, the displayed base and cofinality routes of chapter 1601 and chapter 3955, and the generic finite limit packet of chapter 1678. The packet names only the finite cone rows that a consumer may inspect before a limit-shaped read is admitted.

Definition 7730.1 (Cofiltered-limit carrier)**.** *A* $\mathsf{CofilteredLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, K, T, C, H, R, P, N)$$

with the following displayed rows:

1. *I is a finite cofiltered index row, listing the inspected objects, comparison arrows, and common-refinement witnesses.*
2. *D is the diagram row over* $\mathsf{Cat}^{\uparrow}$*, naming the object and morphism data read from the finite portion of the diagram.*
3. *K is the cone-component row, assigning each inspected index a component arrow into the diagram row.*
4. *T is the transition and cofinality row, recording the finite common-refinement requests through* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CofinalFilter}^{\uparrow}$*.*
5. *C is the cone-compatibility ledger, checking that every displayed transition square read by I, D, K, T commutes inside the named category surface.*
6. *H stores componentwise* hsame *transport for the index, diagram, cone, transition, compatibility, replay, provenance, and local naming rows.*
7. *R stores the displayed* Cont *replay from a cofiltered-cone request through I, D, K, T, C, H.*
8. *P is the* Pkg *provenance over* $\mathsf{CofilteredLimit}^{\uparrow}$*,* $\mathsf{Cat}^{\uparrow}$*,* $\mathsf{FilterBase}^{\uparrow}$*,* $\mathsf{CofinalFilter}^{\uparrow}$*,* $\mathsf{Limit}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CofilteredLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows, their transports, their displayed replay, package provenance, and local naming. The carrier has no coordinate for quotient limits, selected universal cones, full completeness, choice, or bridge checking.

Theorem 7730.2 (Cofiltered-limit NameCert obligations)**.** *For every accepted* $\mathsf{CofilteredLimit}^{\uparrow}$ *carrier* $L = (I, D, K, T, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CofilteredLimit}^{\uparrow}}$ *surface consists exactly of carrier admission, finite cofiltered-index admission, diagram-row admission over* $\mathsf{Cat}^{\uparrow}$*, cone-component exposure, transition and cofinality routing through* $\mathsf{FilterBase}^{\uparrow}$ *and* $\mathsf{CofinalFilter}^{\uparrow}$*, cone-compatibility ledger coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert obligation is stored outside* $I, D, K, T, C, H, R, P, N$*.*

Proof. Project the carrier. The analytic rows are I, D, K, T, C, and the structural rows are H, R, P, N.

The index side is finite. A cofiltered request first reads the displayed index row I, then obtains the diagram row D and the cone components K only for the inspected finite fragment.

The refinement side is finite as well. The row T records common-refinement and cofinality requests through the displayed filter-base routes, and the ledger C checks the corresponding cone-compatibility squares. The structural rows H, R, P, N transport, replay, source, and name exactly this same finite packet.

Since the carrier contains no further coordinate, the listed rows exhaust the NameCert surface and cannot export quotient limits, selected universal cones, full completeness, choice, or bridge checking. □

Theorem 7730.3 (Cofiltered-limit cone-ledger non-escape)**.** *Every consumer of an accepted* $\mathsf{CofilteredLimit}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Cat}^{\uparrow},\ \mathsf{FilterBase}^{\uparrow},\ \mathsf{CofinalFilter}^{\uparrow},\ \mathsf{Limit}^{\uparrow} \longmapsto I, D, K, T, C, H, R, P, N$$

before any cofiltered-cone limit claim is public. The route exposes the inspected index, diagram, cone components, transition and cofinality data, cone-compatibility ledger, componentwise transport, continuation replay, provenance, and local naming; it does not expose quotient limits, selected universal cones, full completeness, choice, or bridge checking.

Proof. Start with a consumer of the accepted packet. Carrier admission exposes the category diagram row D and the cone row K only after the finite cofiltered index row I has been displayed.

Next read the transition row T. Its common-refinement requests pass through the displayed filter-base and cofinal-filter routes, so the consumer cannot replace the finite cofiltered data by an ambient directed set or a hidden filter quotient.

Finally replay the cone ledger C through R and transport the same rows through H. The provenance and local naming rows P, N record the same dependency spine through $\mathsf{Cat}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CofinalFilter}^{\uparrow}$, and $\mathsf{Limit}^{\uparrow}$. Because no other coordinate is present, quotient limits, selected universal cones, full completeness, choice, and bridge checking cannot be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{CofilteredLimit}^{\uparrow}$ read must expose a finite cofiltered index row, a CategoryUp diagram row, cone components, transition and cofinality rows through FilterBaseUp and CofinalFilterUp, a cone-compatibility ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: category, filterbase, cofinalfilter, limit: $\mathsf{CofilteredLimit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite cofiltered index row, diagram row,

cone-component row, transition and cofinality row, cone-compatibility ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CofilteredLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{CofilteredLimit}^{\uparrow}$ packet is generated from a finite cofiltered index row, a CategoryUp diagram row, cone components, transition and cofinality rows through FilterBaseUp and CofinalFilterUp, a cone-compatibility ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CofilteredLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7730.1, Definition 7730.2, and Definition 7730.3 seed the finite cofiltered-cone route over CategoryUp, FilterBaseUp, CofinalFilterUp, LimitUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CofilteredLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient limits, selected universal cones, full completeness, choice, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cofiltered-index admission, diagram-row admission, cone-component exposure, transition cofinality, cone-compatibility ledger coverage, transport, replay, provenance, and local naming for BEDC.Derived.CofilteredLimitUp.

Chapter 7731

A Concrete Naming Certificate for RegularCauchyMinmaxLattice$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the RegularCauchyMinmaxLattice$^{\uparrow}$ packet records finite min–max lattice operations on displayed regular Cauchy rational names before any completed-real order principle is exposed. It sits over the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located/order L10 sibling of chapter 1681. The packet names the pointwise meet and join surface for two displayed regular Cauchy names; it does not assert trichotomy, quotient stream equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 7731.1 (Regular Cauchy minmax lattice carrier)**.** *A* RegularCauchyMinmaxLattice$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, W, D, O, m, j, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right* RegSeqRat$^{\uparrow}$ *regular rational name rows.*
2. *W is the shared* StreamName$^{\uparrow}$ *finite-window ledger used to inspect both names at the requested dyadic radius.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row recording the comparison radius, slack, and rational cells consumed by the lattice read.*
4. *O is the* RegularCauchyLocatedOrder$^{\uparrow}$ *sibling row that supplies the located comparison boundary for the same windows.*
5. *m and j are the displayed meet and join rows, respectively naming the regular Cauchy readbacks for $\min(L, R)$ and $\max(L, R)$ over the inspected window.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after L, R, W, D, O, m, j have been displayed.*
7. *H records componentwise* hsame *transport for the two source names, the shared window, dyadic tolerance, located-order row, meet row, join row, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from each lattice request through $L, R, W, D, O, m, j, E, H, P, N$.*
9. *P is the* Pkg *provenance over* RegularCauchyMinmaxLattice$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyLocatedOrder$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for a host lattice on completed reals, quotient stream equality, trichotomy, selected representatives, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$*.*

Theorem 7731.2 (Regular Cauchy minmax lattice NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}$ *carrier*

$$M = (L, R, W, D, O, m, j, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}}$ *surface consists exactly of carrier admission for the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, shared* $\mathsf{StreamName}^{\uparrow}$ *windows, dyadic tolerance data, the located-order sibling row, meet and join readback rows, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming; comparison visibility requiring every meet or join read to inspect O after W, D; and nonescape excluding trichotomy, host real lattice operations, quotient stream equality, selected limits, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7731.1. The analytic rows are L, R, W, D, O, m, j, E, while H, C, P, N transport, replay, source, and name the same finite packet.

Read the comparison route in order. A lattice request first inspects the two regular rational names L, R, then aligns them over the common finite window W, then consumes the dyadic tolerance row D, and only then reads the located-order sibling row O.

The meet and join rows are downstream of that comparison route. The row m records the lower regular Cauchy readback and the row j records the upper regular Cauchy readback, both over the same windows and tolerance data. Componentwise transport through H and replay through C preserve that shared input surface.

Since the carrier has no coordinate for trichotomy, quotient stream equality, selected limits, countable choice, host lattice operations on completed reals, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7731.3 (Regular Cauchy minmax lattice RegSeqRat stability)**.** *For every accepted* $\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}$ *packet $M = (L, R, W, D, O, m, j, E, H, C, P, N)$, the meet row m and join row j remain* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks over the same finite windows W and dyadic tolerance row D as the source rows L and R. Every* $\mathsf{Real}^{\uparrow}$ *consumer reaches E only after the route*

$$(L, R) \longmapsto W \longmapsto D \longmapsto O \longmapsto (m, j)$$

has been displayed.

Proof. Start with the NameCert obligations of Definition 7731.2. They force every lattice read to expose the source regular rational names, the shared stream window, and the dyadic tolerance row before either operation row is available.

Use the located-order sibling row O as the comparison boundary. It is read over the same W, D surface, so the lower and upper operation rows cannot switch to a different observation schedule or a different tolerance ledger.

The rows m and j are therefore regular rational readbacks attached to the displayed input surface. The structural rows H, C, P, N preserve and name that attachment, and the terminal seal E is downstream of it. Thus every Real-facing read receives the stated finite route and no extra completeness or quotient datum. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a shared StreamName window, DyadicRatCore tolerance data, a RegularCauchyLocatedOrder sibling row, meet and join RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7731.1, Definition 7731.2, and Definition 7731.3 seed the finite min–max lattice-operation surface over regular Cauchy rational names and the located/order L10 sibling.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMinmaxLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, host real lattice operations, quotient stream equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison visibility, meet and join RegSeqRat readback stability, Real-seal handoff, transport, replay, provenance, and local naming for the displayed min–max lattice packet.

Chapter 7732

A Concrete Naming Certificate for $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and binary interval bisection, the $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ packet records the finite route by which a regular rational name is inspected through dyadic half-windows before the terminal real-name seal is read. It sits after the finite windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the alternating route of chapter 414, and the terminal seal of chapter 38. The packet names a finite subdivision certificate; it does not identify quotient real names, select a host limit, decide trichotomy, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7732.1 (RegularCauchyBinarySubdivision carrier)**.** *A* $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, R, I, L, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row whose entries list the inspected binary subdivision stages.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the midpoint, lower half, upper half, and requested radius for each inspected stage.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same windows and dyadic ledger.*
4. *I is the* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *parity row that records how the left and right half-window reads are interleaved.*
5. *L is the left half-window row, read only through S, D, R, I.*
6. *U is the upper half-window row, read only through S, D, R, I.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after L and U have been displayed as half-window evidence for the same regular name.*
8. *H records componentwise* hsame *transport for windows, dyadic ledger, regular readback, interleaving, half-window rows, seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a binary-subdivision request through S, D, R, I, L, U, E.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, D, R, I, L, U, E, H, C, P, N$. There is no coordinate for quotient reals, selected limits, trichotomy, countable-choice schedules, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7732.2 (RegularCauchyBinarySubdivision NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ *carrier*

$$K = (S, D, R, I, L, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite windows, dyadic tolerance ledger, regular rational readback, parity interleaving row, left and upper half-window rows, terminal real seal, componentwise transport, displayed replay, package provenance, and local naming. A consumer may read binary subdivision only through the route $S, D, R, I, L, U, E, H, C, P, N$.*

Proof. Project the carrier of Definition 7732.1. The visible rows are precisely $S, D, R, I, L, U, E, H, C, P, N$.

The rows S, D, R, I display the inspected stream windows, dyadic midpoint accounting, regular rational readback, and parity route. The half-window rows L and U are downstream of that joint surface, so they cannot be detached from the same regular Cauchy data.

The terminal seal E and the support rows H, C, P, N preserve the same finite route. Since the carrier has no quotient, selected-limit, trichotomy, choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7732.3 (RegularCauchyBinarySubdivision window halving)**.** *Let $K = (S, D, R, I, L, U, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ *carrier. Every binary-window request from K first reads the* $\mathsf{StreamName}^{\uparrow}$ *row S, then the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and then the* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *parity row I before either half-window row L or U is public. Thus each half-window read is tied to the same displayed regular Cauchy name and the same dyadic subdivision ledger.*

Proof. Start with the continuation row C. Its displayed route sends a binary-subdivision request through the finite window row S and the dyadic ledger D before any half-window row can be inspected.

Next read the regular rational row R and the interleaving row I. They bind the left and upper half-window reads to the same regular name and to the same parity schedule.

The rows L and U are therefore not independent interval choices. They are the two displayed halves of the same finite subdivision route, transported and replayed only through H, C, P, N. □

Theorem 7732.4 (RegularCauchyBinarySubdivision Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ *carrier factors through*

$$S, D, R, I, L, U \longmapsto E \longmapsto H, C, P, N.$$

The handoff exports the terminal seal only after the finite StreamName windows, dyadic tolerance ledger, regular rational readback, interleaving route, and both half-window rows have been displayed. It exports no quotient real, selected limit, trichotomy decision, host real equality, countable-choice schedule, or ambient completeness theorem.

Proof. Apply Definition 7732.3. It forces each half-window request through S, D, R, I before L or U is public.

The terminal row E is downstream of both half-window rows. A Real-facing consumer therefore receives E only after the displayed binary subdivision route has been replayed.

Finally inspect the support rows. Componentwise transport through H, replay through C, provenance through P, and local naming through N carry the same finite packet and add no quotient, selected-limit, trichotomy, host-equality, choice, or ambient-completeness coordinate. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ read is refuted if a $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal without displaying StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readback, RegularCauchyInterleaving parity data, both half-window rows, transport, replay, provenance, and local naming.

Independence witness: streamname, dyadicratcore, regseqrat, regularcauchyinterleaving, real: none alone is bijective with $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ because the packet jointly records windows, dyadic halving, regular readback, interleaving, two half-window rows, terminal sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}$ packet is generated from finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RegularCauchyInterleaving parity row, left and upper half-window rows, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7732.1, Definition 7732.2, Definition 7732.3, and Definition 7732.4 seed the finite binary-subdivision route from regular Cauchy windows through dyadic halving and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBinarySubdivision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient reals, selected limits, trichotomy, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, binary window coverage, dyadic halving exactness, RegSeqRat readback, interleaving parity, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBinarySubdivisionUp.

Chapter 7733

A Concrete Naming Certificate for $\mathsf{ContextFreeLanguage}^{\uparrow}$

Following Hopcroft–Ullman and standard formal-language theory, the $\mathsf{ContextFreeLanguage}^{\uparrow}$ packet names a language by finite grammar and derivation data before any recognizer, pumping, or membership consumer reads a host language set. It sits beside the regular-language continuation surface of chapter 7361, the finite-control surface of chapter 2364, the stack-recognizer surface of chapter 6018, and the derivation-window certificate of chapter 2298. The packet records the grammar, derivation tree, yield, and classifier rows that those consumers may inspect; it is not an ambient set of words, a host-language equality principle, or a semantic closure theorem.

Definition 7733.1 (Context-free language carrier)**.** *A* $\mathsf{ContextFreeLanguage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, V, \Sigma, P, D, Y, M, H, C, Q, N)$$

with the following displayed rows:

1. *G is the grammar row naming the start symbol and the finite context-free grammar surface.*
2. *V is the finite nonterminal alphabet row.*
3. *Σ is the finite terminal alphabet row.*
4. *P is the production ledger, listing every admitted production as a finite row over V and Σ.*
5. *D is the derivation-tree row, recording the finite tree whose internal nodes read productions from P.*
6. *Y is the yield stream row, recording the terminal frontier obtained from D.*
7. *M is the membership classifier row, accepting a word only when it is the displayed yield of an admitted derivation tree.*
8. *H stores componentwise* hsame *transport for $G, V, \Sigma, P, D, Y, M, C, Q, N$.*
9. *C stores displayed* Cont *replay from grammar admission through productions, derivation tree, yield stream, and membership classifier.*
10. *Q is the* Pkg *provenance over* $\mathsf{ContextFreeLanguage}^{\uparrow}$, $\mathsf{ContextFreeGrammar}^{\uparrow}$, $\mathsf{PushdownAutomaton}^{\uparrow}$, $\mathsf{ContextFreePumpingLemma}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContextFreeLanguage}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite parse forest, host language equality, unrestricted grammar quotient, choice of a canonical derivation, complement closure, determinization, or ambient semantic set membership.

Lean4 (statement) `BEDC.Derived.ContextFreeLanguageUp`

Theorem 7733.2 (Context-free language NameCert obligations)**.** *For every accepted* $\mathsf{ContextFreeLanguage}^{\uparrow}$ *carrier* $L = (G, V, \Sigma, P, D, Y, M, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ContextFreeLanguage}^{\uparrow}}$ *surface consists exactly of grammar admission through* G, V, Σ, P*, derivation stability through* D *and* H*, yield exactness through* Y*, pumping-boundary nonescape through the* $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ *route, classifier transport through* M*, displayed replay through* C*, provenance through* Q*, and local naming through* N*.*

No accepted packet exports host language equality, an infinite parse forest, a grammar quotient, a selected canonical derivation, complement closure, determinization, or an ambient semantic language set.

Proof. Project the carrier of Definition 7733.1. The grammar, nonterminal, terminal, and production rows G, V, Σ, P are the only rows that admit grammar syntax.

The derivation tree and yield rows are downstream of that syntax. Componentwise transport through H preserves D and Y, and replay through C records the route from productions to the derivation tree and then to the terminal yield.

The membership classifier M reads only the displayed yield of an admitted derivation tree. The $\mathsf{ContextFreePumpingLemma}^{\uparrow}$ sibling may inspect finite derivation-window data, but it receives no infinite parse forest or semantic language quotient.

Finally Q and N preserve provenance and local naming for the same finite packet. Since none of the excluded objects is a carrier coordinate, no local NameCert obligation can export it. □

Theorem 7733.3 (Context-free language pushdown handoff)**.** *Every* $\mathsf{PushdownAutomaton}^{\uparrow}$ *consumer that accepts a language-membership row from an accepted* $\mathsf{ContextFreeLanguage}^{\uparrow}$ *packet must first read the grammar row* G*, the nonterminal row* V*, the terminal row* Σ*, the production ledger* P*, the derivation-tree row* D*, the yield row* Y*, and the classifier row* M*. The handoff exports only the displayed grammar-and-derivation surface and cannot replace it by a host language set, a hidden stack oracle, a canonical derivation selector, or grammar quotient equality.*

Proof. Start with the carrier projection. The only membership row is M, and it is listed after the grammar, production, derivation, and yield rows.

Apply Definition 7733.2. Classifier transport is bound to the same finite rows G, V, Σ, P, D, Y, M and to the componentwise hsame transport in H.

A pushdown consumer therefore reads the grammar and derivation surface before accepting a language-membership row. The continuation row C records that replay order, while Q and N preserve provenance and naming without adding a second membership source.

The excluded objects are absent from the carrier. Hence the pushdown handoff supplies a finite grammar-and-derivation interface rather than a host language set, stack oracle, derivation selector, or quotient equality principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ContextFreeLanguage}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContextFreeLanguage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7733.1, Definition 7733.2, and Definition 7733.3 seed the finite grammar, derivation, yield, classifier, pushdown-handoff, transport, replay, provenance, and local NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContextFreeLanguage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host language equality, infinite parse forests, grammar quotients, canonical derivation selection, complement closure, determinization, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked grammar admission, derivation stability, yield exactness, pumping-boundary nonescape, classifier transport, pushdown handoff, replay, provenance, and local naming for BEDC.Derived.ContextFreeLanguageUp.

Constructive story: A ContextFreeLanguage$^{\uparrow}$ packet is generated from a context-free grammar row, finite nonterminal and terminal alphabet rows, a production ledger, derivation tree, yield stream, membership classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7734

A Concrete Naming Certificate for $\mathsf{RationalCut}^{\uparrow}$

Following Dedekind and Bishop–Bridges constructive analysis, the $\mathsf{RationalCut}^{\uparrow}$ packet records finite located rational-cut rows used by the L10 Real and Completion route before any completed-real construction is read. It sits beside the rational arithmetic carrier of chapter 37, the dyadic tolerance core of chapter 291, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is finite located cut data for boundary and comparison consumers; it is not a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$.

Definition 7734.1 (Rational cut carrier)**.** *A* $\mathsf{RationalCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (L, U, D, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *L is the lower rational row, recording finite rational witnesses below the inspected boundary.*
2. *U is the upper rational row, recording finite rational witnesses above the inspected boundary.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that names the dyadic slack and comparison radius used by the located request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which a consumer inspects the lower and upper rational observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the rational rows and the dyadic tolerance row are visible.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after L, U, D, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the lower row, upper row, dyadic tolerance, stream window, readback, Real seal, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from each located cut request through the same finite rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RationalCut}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through those displayed rows and their transports. It has no coordinate for quotient cut equality, trichotomy, selected real representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7734.2 (Rational cut NameCert obligations)**.** *For every accepted* $\mathsf{RationalCut}^{\uparrow}$ *carrier* $C = (L, U, D, S, R, E, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RationalCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower and upper* $\mathsf{Rat}^{\uparrow}$ *rows, dyadic tolerance exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *inspection,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every located cut consumer must read* L, U, D, S *before it can read* R *or* E*, and the packet exports no Dedekind construction of* $\mathsf{Real}^{\uparrow}$*, quotient cut equality, selected representative, trichotomy, countable-choice selector, or ambient completeness principle.*

Proof. Project the accepted carrier of Definition 7734.1. Its analytic rows are exactly the lower rational row, upper rational row, dyadic tolerance row, finite stream window, regular rational readback, and terminal Real seal.

Read the finite route in order. A located cut request first exposes the rational rows L, U, then the dyadic tolerance row D, and then the finite observation window S. Only after those rows are visible can the regular rational readback R and the Real seal E be consumed.

The structural rows H, K, P, N do not add a completed cut. They transport, replay, source, and name the same finite rows. Since the carrier contains no quotient equality, selected representative, trichotomy, choice, or completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 7734.3 (Rational cut L10 handoff boundary)**.** *Every L10 Real and Completion consumer of an accepted* $\mathsf{RationalCut}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{Rat}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

The route supplies finite located rational-cut rows for comparison, regular-Cauchy readback, and Real-seal boundary arguments. It does not assert that $\mathsf{Real}^{\uparrow}$ *is constructed as a Dedekind cut, and it does not import quotient cut equality, selected limits, trichotomy, or ambient completeness.*

Proof. Start with the rational rows and the dyadic tolerance ledger. They are finite rows over $\mathsf{Rat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$, so a consumer receives only displayed rational cells and slack data.

Next read the stream and regular rational rows. The finite $\mathsf{StreamName}^{\uparrow}$ row schedules the inspected cells, and the $\mathsf{RegSeqRat}^{\uparrow}$ row gives the readback boundary used by completion-facing consumers.

Finally pass through the terminal $\mathsf{Real}^{\uparrow}$ seal and the structural rows. The Real seal is downstream of the finite cut data, while H, K, P, N preserve and name the same route. Thus the packet is cut-facing finite data inside L10, not a separate construction of $\mathsf{Real}^{\uparrow}$ by Dedekind cuts. □

Closure status for $\mathsf{NameCert}_{\mathsf{RationalCut}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalCut}^{\uparrow}$ packet is generated from lower and upper Rat rows, DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RationalCut}^{\uparrow}}$, seed)

Scope closed: Definition 7734.1, Definition 7734.2, and Definition 7734.3 seed the finite located rational-cut row used by L10 Real and Completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RationalCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, a Dedekind-cut construction of $\mathrm{Real}^{\uparrow}$, quotient cut equality, selected representatives, trichotomy, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, lower and upper rational-row exposure, dyadic tolerance exactness, finite-window scheduling, regular rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RationalCutUp.

Chapter 7735

A Concrete Naming Certificate for $\mathsf{CompactCauchyNet}^{\uparrow}$

Following Bishop–Bridges compact metric arguments, the $\mathsf{CompactCauchyNet}^{\uparrow}$ packet records the finite-net and Cauchy-tail route used to turn compact-source inspection into a regular rational and Real-facing handoff. It sits over compact metric finite-net data, the Cauchy-net source surface, the dyadic tolerance core of chapter 291, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet names the finite compact-net Cauchy-tail route; it is not open-cover compactness, not a selected limit theorem, and not an ambient completeness principle.

Definition 7735.1 (Compact Cauchy-net carrier)**.** *A* $\mathsf{CompactCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, F, T, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the compact metric source row whose finite-net coverage is inspected by the consumer.*
2. *F is the finite-net row, recording the selected finite cover cells and mesh witnesses used by the compact argument.*
3. *T is the Cauchy-tail row, recording the finite tail-window evidence over the net.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare mesh size, tail radius, and readback precision.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the inspected net and tail observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the same finite-net and tail-window surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, F, T, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for compact source, finite net, Cauchy tail, dyadic tolerance, stream window, readback, Real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from compact-source inspection through finite-net coverage, tail-window evidence, tolerance rows, readback, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactCauchyNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CauchyNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyNet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed finite-net, tail-window, readback, seal, and structural rows. It has no coordinate for open-cover compactness, selected subnet, selected limit, quotient net equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7735.2 (Compact Cauchy-net NameCert obligations)**.** *For every accepted* $\mathsf{CompactCauchyNet}^{\uparrow}$ *carrier* $K = (M, F, T, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyNet}^{\uparrow}}$ *surface consists exactly of compact-source carrier exposure, finite-net coverage exposure, Cauchy-tail evidence, dyadic tolerance exposure, finite* $\mathsf{StreamName}^{\uparrow}$ *scheduling,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7735.1. The compact source, finite-net row, Cauchy-tail row, dyadic tolerance row, stream window, regular rational readback, and Real seal are the only analytic rows.

The finite-net and Cauchy-tail rows are read before any regular rational or Real-facing handoff. The dyadic tolerance row binds the mesh and tail comparisons, while the stream window records exactly which finite observations have been inspected.

Transport through H, replay through C, provenance through P, and local naming through N preserve that same finite route. Since the carrier has no row for open-cover compactness, selected subnets, selected limits, quotient net equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7735.3 (Compact Cauchy-net finite-tail handoff)**.** *Every compact uniform-continuity or completion-facing consumer of an accepted* $\mathsf{CompactCauchyNet}^{\uparrow}$ *packet must read the finite-net row* F*, the Cauchy-tail row* T*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *before the* $\mathsf{Real}^{\uparrow}$ *seal* E *is available. Thus the consumer route factors through finite-net coverage, Cauchy-tail evidence, regular rational readback, dyadic tolerance, and Real sealing as NameCert data.*

Proof. Start with compact-source exposure. The row M supplies the compact metric source only through the finite-net row F, so a consumer cannot replace the packet by an open-cover compactness theorem.

Read the Cauchy-tail and tolerance rows next. The tail evidence T and tolerance ledger D determine the finite comparison surface, and the stream window S records the observations that feed the readback row R.

The terminal seal E is downstream of the same route. Componentwise transport, continuation replay, provenance, and naming preserve the displayed rows, so no selected subnet, selected limit, quotient net equality, choice principle, or ambient completeness coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchyNet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactCauchyNet}^{\uparrow}$ packet is generated from a compact metric source, finite-net coverage rows, Cauchy-tail evidence, DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactCauchyNet}^{\uparrow}}$, seed)

Scope closed: Definition 7735.1, Definition 7735.2, and Definition 7735.3 seed the finite compact-net Cauchy-tail route used by compact uniform-continuity and completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactCauchyNet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, open-cover compactness, selected subnets, selected limits, quotient net equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, finite-net coverage, Cauchy-tail evidence, dyadic tolerance exactness, readback routing, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactCauchyNetUp.

Chapter 7736

A Concrete Naming Certificate for $\mathsf{MooreMachine}^{\uparrow}$

Following Moore's finite-state machine tradition, the $\mathsf{MooreMachine}^{\uparrow}$ packet records a deterministic automaton with output attached to states as finite BEDC NameCert data. It sits beside the Myhill–Nerode classifier of chapter 5729 and the regular-language continuation surface of chapter 7361. The packet names state replay and output readout for finite input traces; it does not introduce infinite streams, nondeterministic branching, minimization uniqueness, quotient language equality, or a host evaluator.

Definition 7736.1 (Moore-machine carrier)**.** *A* $\mathsf{MooreMachine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, I, O, q_0, \delta, \omega, W, Y, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite state row.*
2. *I is the finite input-alphabet row.*
3. *O is the finite output-alphabet row.*
4. *q_0 is the initial-state row.*
5. *δ is the deterministic transition replay row, reading a current state and an input symbol into the next displayed state.*
6. *ω is the output readout row, reading each displayed state into an output symbol.*
7. *W is the finite input-trace row.*
8. *Y is the finite output-trace row obtained by replaying W from q_0 through δ and reading each visited state through ω.*
9. *H records componentwise* hsame *transport for states, alphabets, initial state, transition replay, output readout, traces, continuation replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from an input-trace request through $q_0, \delta, \omega, W, Y$.*
11. *P is the* Pkg *provenance over* $\mathsf{MooreMachine}^{\uparrow}$, $\mathsf{MyhillNerode}^{\uparrow}$, $\mathsf{RegularLanguageContinuation}^{\uparrow}$, *finite* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreMachine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows, their displayed transports, their continuation replay, package provenance, and local naming. It has no coordinate for nondeterministic choice, infinite input streams, quotient language equality, canonical minimization, or host evaluator soundness.

Theorem 7736.2 (Moore-machine NameCert obligations)**.** *For every accepted* $\mathsf{MooreMachine}^{\uparrow}$ *carrier* $M = (Q, I, O, q_0, \delta, \omega, W, Y, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MooreMachine}^{\uparrow}}$ *surface consists exactly of deterministic transition replay from* q_0 *along the finite input trace* W*, output trace stability through the state readout* ω*, comparison with the Myhill–Nerode state classifier of chapter 5729, and handoff to the regular-language continuation surface of chapter 7361. The packet exports finite state-output behavior only; it does not assert language quotient equality, minimal automaton uniqueness, infinite-stream acceptance, nondeterministic branching, or host evaluator soundness.*

Proof. Project the carrier of Definition 7736.1. The rows expose finite states, input and output alphabets, the initial state, deterministic transition replay, output readout, finite traces, transport, replay, provenance, and local naming.

Deterministic replay is supplied by δ and C. Starting from q_0, each displayed input symbol in W determines the next displayed state, so a trace consumer cannot branch outside the carrier rows.

Output trace stability is supplied by ω, Y, H. Transport preserves the same state readout under hsame, and the output trace Y is read only from the replayed finite state path.

Finally compare the displayed state behavior with the Myhill–Nerode classifier and hand it to the regular-language continuation surface. Those sibling routes consume the same finite state and continuation data, while no row adds quotient language equality, canonical minimization, infinite-stream acceptance, nondeterminism, or host evaluator soundness. □

Closure status for $\mathsf{NameCert}_{\mathsf{MooreMachine}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MooreMachine}^{\uparrow}$ packet is generated from finite state, input alphabet, output alphabet, initial-state, deterministic transition replay, output readout, finite trace, output trace, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MooreMachine}^{\uparrow}}$, seed)

Scope closed: Definition 7736.1 and Definition 7736.2 seed the finite Moore-machine surface over deterministic state replay, output readout, Myhill–Nerode comparison, regular-language continuation handoff, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MooreMachine}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close language quotient equality, minimal automaton uniqueness, infinite-stream acceptance, nondeterministic branching, host evaluator soundness, Lean proof obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deterministic transition replay, output trace stability, Myhill–Nerode comparison, regular-language continuation handoff, transport, replay, provenance, and local naming for BEDC.Derived.MooreMachineUp.

Chapter 7737

A Concrete Naming Certificate for $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ packet records the finite lower-bound readback surface through which a positive real name exposes an inspectable radius before reciprocal, reciprocal-modulus, or completion-facing consumers use the positivity witness. It sits after the real-name seal of chapter 38, the located-positive-real witness of chapter 2029, the positive dyadic row of chapter 291, the finite stream window of chapter 126, and the regular rational readback of chapter 301. The packet is a displayed radius-readback boundary; it is not trichotomy, quotient real equality, a total inverse, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7737.1 (Real positive radius readback surface)**.** *A* $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (R, L, D, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row for the positive real name whose radius is being read.*
2. *L is the* $\mathsf{LocatedPositiveReal}^{\uparrow}$ *witness that exposes the positivity route for the same real-name seal.*
3. *D is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row read from the located witness and displayed as the lower-bound budget.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which the source name and radius comparison are inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that records the rational observations supporting the finite radius read.*
6. *H records componentwise* hsame *transport for the real seal, located-positive witness, dyadic radius, finite window, regular readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$L, D, W, Q \longmapsto R.$$

8. *P is the* Pkg *provenance over* $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedPositiveReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RealPositiveRadiusReadback}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $R, L, D, W, Q, H, C, P, N$. It has no coordinate for trichotomy, quotient equality of real names, a total inverse operation, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7737.2 (Real positive radius readback obligations)**.** *For every accepted* $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ *carrier*

$$X = (R, L, D, W, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealPositiveRadiusReadback}^{\uparrow}}$ *surface consists exactly of real-seal admission through R, located-positive witness exposure through L, positive dyadic lower-bound readback through D, finite stream-window inspection through W, regular rational readback through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7737.1. The analytic rows are R, L, D, W, Q, and the structural rows are H, C, P, N.

The located witness L is the only route from the positive real name to a displayed radius. The dyadic row D, the finite window W, and the regular readback Q are downstream of that witness and therefore form the complete lower-bound readback surface.

The rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for the excluded order, quotient, inverse, selected-limit, or completeness data, the listed rows exhaust the local NameCert obligations. □

Theorem 7737.3 (Real positive radius readback route)**.** *Every reciprocal-facing or completion-facing read of an accepted* $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{LocatedPositiveReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

In particular, a consumer reaches the $\mathsf{Real}^{\uparrow}$ *seal only after the located-positive witness, positive dyadic radius, finite stream window, and regular rational readback have been displayed in the same packet.*

Proof. Inspect the route coordinates in Definition 7737.1. The $\mathsf{Real}^{\uparrow}$ row R is read through the located-positive witness L together with the radius, window, and readback rows D, W, Q.

Apply the obligation surface of Definition 7737.2. It binds L, D, W, Q to the same transport, replay, provenance, and local naming rows, so a downstream consumer cannot detach the positive-radius read from the source real-name seal.

Thus every accepted read reaches R through the displayed route. The packet contains no row for trichotomy, quotient real equality, total inversion, selected limits, or ambient completeness, so none of those endpoints is exported by the route. □

Falsifiable prediction: An accepted $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ packet cannot export the same positive-radius readback if it omits the LocatedPositiveReal witness, positive DyadicRatCore radius, StreamName finite window, RegSeqRat readback, transport, replay, provenance, or local naming row.

Independence witness: real, located-positive-real, dyadicratcore, streamname, and regseqrat: $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ is not bijective to any listed sibling because only this packet binds the positive real seal, located lower-bound witness, positive radius row, finite window, regular readback, transport, replay, provenance, and local NameCert surface as one readback boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{RealPositiveRadiusReadback}^{\uparrow}}$.

Constructive story: A $\mathsf{RealPositiveRadiusReadback}^{\uparrow}$ packet is generated from a RealUp seal, a LocatedPositiveRealUp witness, a positive DyadicRatCoreUp radius row, a StreamNameUp finite window, a RegSeqRatUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealPositiveRadiusReadback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7737.1, Definition 7737.2, and Definition 7737.3 seed the finite lower-bound readback route for positive real names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealPositiveRadiusReadback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient real equality, total inverse operations, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-positive witness exposure, positive dyadic radius exactness, finite stream-window inspection, regular readback, transport, replay, provenance, and local naming for BEDC.Derived.RealPositiveRadiusReadbackUp.

Chapter 7738

A Concrete Naming Certificate for $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy names and constructive real completion, the $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ packet records a shared finite modulus ledger for joining two regular Cauchy names before any terminal $\mathsf{Real}^{\uparrow}$ seal is read. It sits between the regular rational names of chapter 301, the stream windows of chapter 126, the dyadic tolerance core of chapter 291, the interleaving route of chapter 414, and the real-name boundary of chapter 38. The carrier is a finite ledger object, not a quotient equality of Cauchy names, an ambient completeness theorem, or a choice of global representative.

Definition 7738.1 (RegularCauchyCommonModulus carrier)**.** *A* $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, B, W, R, D, J, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows naming the regular Cauchy inputs whose comparison is being joined;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the prefixes of both names that are visible to the request;*
3. *R records the shared regular-readback ledger tying the two names to the same displayed window schedule;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row containing the dyadic budget used to compare both sides;*
5. *J is the common-modulus ledger stating that every accepted precision request is answered by the same finite window before the* $\mathsf{Real}^{\uparrow}$ *seal is available;*
6. *H records componentwise* hsame *transport for A, B, W, R, D, J;*
7. *C records displayed* Cont *replay for the common-window request and its downstream handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyInterleaving}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, W, R, D, J, H, C, P, N$. It has no coordinate for quotient equality of Cauchy names, selected representatives, hidden countable choice, ambient completeness, or a direct $\mathsf{Real}^{\uparrow}$ *equality proof.*

Theorem 7738.2 (RegularCauchyCommonModulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ *carrier* $G = (A, B, W, R, D, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonMo}}$ *surface is exhausted by five obligation rows:*

1. *carrier exposure for the two regular Cauchy input rows, finite stream window, shared readback ledger, dyadic tolerance row, common-modulus ledger, transport, replay, provenance, and local naming;*
2. *regular-name admission for A and B through the* $\mathsf{RegSeqRat}^{\uparrow}$ *rows already visible in the carrier;*
3. *finite-window exposure through W, R, D, J, requiring both names to answer the same displayed dyadic precision request before a consumer may continue;*
4. *interleaving compatibility, allowing* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *consumers to read the common ledger as a finite join of the two visible regular names;*
5. *ledger refusal, excluding quotient equality of Cauchy names, selected representatives, hidden choice schedules, ambient completeness, and direct* $\mathsf{Real}^{\uparrow}$ *equality.*

No local NameCert obligation is stored outside those rows.

Proof. Project the displayed carrier. The only regular-name inputs are A and B, and the only shared comparison data are the finite rows W, R, D, J.

The regular-name admission row first reads A and B as $\mathsf{RegSeqRat}^{\uparrow}$ data. The window row W then displays the prefixes of both names that the request can inspect.

Next the shared readback and tolerance rows bind the two sides to the same dyadic request. The common-modulus ledger J records that the request is answered by one finite window schedule rather than by two unrelated searches.

Finally H, C, P, N transport, replay, source, and name exactly that finite route. Since no carrier coordinate supplies quotient equality, selected representatives, hidden choice, ambient completeness, or direct $\mathsf{Real}^{\uparrow}$ equality, the five rows exhaust the local surface. □

Theorem 7738.3 (RegularCauchyCommonModulus finite-window handoff)**.** *Every* $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ *carrier must first expose the route*

$$A, B, W, R, D, J \longmapsto H, C, P, N.$$

Thus the consumer receives two regular rational names, a finite stream-window schedule, a shared readback ledger, a dyadic tolerance budget, a common-modulus row, componentwise transport, replay, provenance, and local naming before it can read any real-name seal. It receives no quotient equality of Cauchy names, selected representative, hidden choice schedule, ambient completeness theorem, or host real equality.

Proof. Begin with the carrier definition. Its Real-facing data are downstream of the two regular-name rows and the common finite-window ledger.

Use the NameCert obligations. The finite-window exposure row requires W, R, D, J to be displayed after A and B, and the interleaving-compatibility row allows only that displayed ledger to feed the $\mathsf{RegularCauchyInterleaving}^{\uparrow}$ side.

The structural rows then preserve the same route. Transport through H, replay through C, provenance through P, and local naming through N add no quotient, selected representative,

choice schedule, completeness theorem, or host real equality, so every downstream seal read is forced through the finite chain above. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ read is refuted if a $\mathsf{RegularCauchyInterleaving}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches a seal without displaying both $\mathsf{RegSeqRat}^{\uparrow}$ rows, the $\mathsf{StreamName}^{\uparrow}$ window row, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, the common-modulus ledger, transport, replay, provenance, and local naming.

Independence witness: Nearest siblings: regseqrat, streamname, dyadicratcore, regular-cauchy-interleaving, real. None alone records two regular Cauchy names together with a single shared finite modulus ledger before the Real seal; each lacks at least one of the input-pair, common-window, tolerance, or handoff coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCommonModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCommonModulus}^{\uparrow}$ packet is generated from two RegSeqRat rows, a finite StreamName window, a shared regular-readback ledger, a DyadicRatCore tolerance row, a common-modulus ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7738.1, Definition 7738.2, and Definition 7738.3 seed the shared finite-modulus ledger for two regular Cauchy names before Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCommonModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy names, selected representatives, hidden choice schedules, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-window exposure, interleaving compatibility, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCommonModulusUp.

Chapter 7739

A Concrete Naming Certificate for $\mathsf{DyadicTailComparison}^{\uparrow}$

Following Bishop and Bridges on explicit Cauchy moduli and rational tail estimates, the $\mathsf{DyadicTailComparison}^{\uparrow}$ packet records the finite dyadic layer below the regular Cauchy tail-comparison route. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the common-tail comparison packet of chapter 387, and the terminal real boundary of chapter 38. The packet stores the inspected dyadic windows and comparison budgets before any regular Cauchy or Real-facing consumer can read a tail comparison.

Definition 7739.1 (Dyadic tail-comparison carrier)**.** *A* $\mathsf{DyadicTailComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, W, E, T, R, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{StreamName}^{\uparrow}$ *tail windows whose dyadic endpoints are compared;*
2. *W is the shared late-window selector, recording the finite indices inspected for both tails;*
3. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger, including the requested dyadic radius, slack, and lower and upper endpoint rows;*
4. *T is the dyadic tail-comparison row, recording that the two inspected windows satisfy the displayed dyadic comparison at the requested precision;*
5. *R is the downstream readback row for* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyTailComparison}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *consumers;*
6. *H records componentwise* hsame *transport for the two windows, dyadic ledger, comparison row, downstream readback, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay for the finite dyadic comparison route;*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicTailComparison}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyTailComparison}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTailComparison}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limits, host real equality, trichotomy, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7739.2 (Dyadic tail-comparison NameCert obligations)**.** *For every accepted* $\mathsf{DyadicTailComparison}^{\uparrow}$ *carrier* $D = (X, Y, W, E, T, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicTailComparison}^{\uparrow}}$ *surface consists exactly of carrier admission, shared-window discipline, dyadic endpoint-ledger exactness, dyadic comparison readback, downstream nonescape to* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyTailComparison}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, componentwise transport, displayed replay, package provenance, local naming, and refusal of quotient streams, selected limits, host real equality, trichotomy, choice, and ambient real completeness.*

Proof. Project the carrier of Definition 7739.1. The rows $X, Y, W, E, T, R, H, C, P, N$ are the only available certificate coordinates, so carrier admission and local naming are read directly from the displayed packet.

The shared-window obligation is the row W. It forces both tails to be inspected at the same finite late window before the dyadic endpoint ledger is read.

The dyadic comparison obligations are E and T. The endpoint ledger E supplies the radius, slack, and endpoint rows, while T records the finite comparison of the two displayed windows at that precision.

The downstream and structural obligations are R, H, C, P, N. They transport, replay, source, and name the same finite dyadic comparison for $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyTailComparison}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers without adding a quotient, selected limit, host equality, trichotomy, choice, or ambient completeness row. □

Theorem 7739.3 (Dyadic tail-comparison regular Cauchy route)**.** *Every regular Cauchy or real-completion consumer of an accepted* $\mathsf{DyadicTailComparison}^{\uparrow}$ *packet factors through the finite route*

$$X, Y, W \longmapsto E \longmapsto T \longmapsto R, H, C, P, N.$$

Thus a $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyTailComparison}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *read can consume the packet only after the common stream window and dyadic endpoint ledger have been displayed. The route supplies finite dyadic tail-comparison data, not quotient stream equality, selected limits, host real equality, trichotomy, choice, or ambient real completeness.*

Proof. Start with an accepted carrier $D = (X, Y, W, E, T, R, H, C, P, N)$. The source rows X and Y expose only stream windows, and W records the shared late-window selector for both tails.

The dyadic endpoint row E is read next. It supplies the finite radius and endpoint ledger consumed by the comparison row T, so no consumer can bypass the dyadic layer and jump directly to a regular Cauchy or Real comparison.

The readback row R is downstream of T and is the only row addressed to $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyTailComparison}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ consumers. The structural rows H, C, P, N preserve and name that same route.

Since all rows have now been exhausted, the consumer has no coordinate from which to extract quotient stream equality, a selected limit, host real equality, trichotomy, choice, or ambient completeness. □

Falsifiable prediction: A $\mathsf{DyadicTailComparison}^{\uparrow}$ read is refuted whenever it exports a regular Cauchy or Real-facing comparison without the shared StreamName window and DyadicRatCore endpoint ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTailComparison}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicTailComparison}^{\uparrow}$ packet is generated from two StreamName tail-window rows, a shared late-window selector, a DyadicRatCore endpoint ledger, a dyadic comparison row, downstream readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicTailComparison}^{\uparrow}}$, seed)

Scope closed: Definition 7739.1, Definition 7739.2, and Definition 7739.3 seed the finite dyadic tail-comparison layer below regular Cauchy and Real readback consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicTailComparison}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, host real equality, trichotomy, choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window discipline, dyadic endpoint exactness, comparison readback, downstream nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicTailComparisonU

Chapter 7740

A Concrete Naming Certificate for $\mathsf{CauchyBicompletion}^{\uparrow}$

Following Isbell on injective envelopes and Nachbin on ordered uniform completions, the $\mathsf{CauchyBicompletion}^{\uparrow}$ packet records a finite two-sided regular Cauchy completion corridor. It sits over the stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real boundary of chapter 38, the uniform two-sided corridor of chapter 3613, and the completion coherence laws of chapter 3834. The packet keeps paired Cauchy windows, comparison transport, replay, provenance, and local naming finite before any real-completion consumer can read a bicompletion boundary.

Definition 7740.1 (Cauchy bicompletion carrier)**.** *A* $\mathsf{CauchyBicompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, R, W, Q, E, U, M, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right* $\mathsf{StreamName}^{\uparrow}$ *Cauchy-window rows;*
2. *W is the paired finite-window row, recording the common precision request and the inspected left and right tails;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the paired windows;*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *route reached only after the paired readback row has been displayed;*
5. *U is the* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *comparison row, used only as the uniform two-sided corridor for the same finite pair;*
6. *M is the* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *coherence row, recording unit, bind, and associativity readback for the displayed completion route;*
7. *H records componentwise* hsame *transport for the two sides, paired window, readback, Real route, uniform corridor, coherence row, replay, provenance, and local naming;*
8. *C records displayed* Cont *replay of the finite bicompletion route;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyBicompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCauchyBicompletio}$ $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBicompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected completion representatives, ambient host equality, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7740.2 (Cauchy bicompletion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBicompletion}^{\uparrow}$ *carrier* $B = (L, R, W, Q, E, U, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyBicompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, paired Cauchy-window discipline,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exactness,* $\mathsf{Real}^{\uparrow}$ *route nonescape,* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *corridor compatibility,* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *coherence, componentwise transport, displayed replay, package provenance, local naming, and refusal of quotient completions, selected representatives, ambient host equality, choice, and ambient real completeness.*

Proof. Project the carrier of Definition 7740.1. The rows $L, R, W, Q, E, U, M, H, C, P, N$ are the whole local certificate surface, so every obligation must be assigned to one of those coordinates.

The paired-window obligation is W over the two source rows L and R. It records the finite left and right tails inspected for the same precision request before readback can proceed.

The readback and completion-facing obligations are Q, E, U, M. The row Q supplies regular rational readback, E is the downstream real route, U records compatibility with the uniform two-sided corridor, and M records the completion monad-law coherence visible to consumers.

Finally H, C, P, N transport, replay, source, and name the same finite bicompletion packet. Since the carrier has no quotient-completion, selected-representative, host-equality, choice, or ambient-completeness coordinate, those objects cannot be exported by the local certificate. □

Theorem 7740.3 (Cauchy bicompletion real-completion route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or regular Cauchy completion consumer of an accepted* $\mathsf{CauchyBicompletion}^{\uparrow}$ *packet factors through the finite route*

$$L, R, W \longmapsto Q \longmapsto E, U, M \longmapsto H, C, P, N.$$

Thus the consumer receives paired Cauchy-window rows, $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *route, the* $\mathsf{UniformCauchyBicompletion}^{\uparrow}$ *corridor,* $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$ *coherence, transport, replay, provenance, and local naming. It receives no quotient completion, selected representative, ambient host equality, choice, or ambient real completeness.*

Proof. Start from an accepted packet $B = (L, R, W, Q, E, U, M, H, C, P, N)$. The left and right source rows are only stream-window data, and the paired row W forces them to answer the same finite precision request.

The regular rational readback row Q is then the only way to expose the paired Cauchy windows as completion data. The terminal real row E remains downstream of Q, so a real-completion consumer cannot skip the finite readback.

The uniform corridor U and coherence row M are parallel checks on the same displayed route. They record two-sided uniform compatibility and completion monad-law behavior without adding a quotient completion or selected representative.

The structural rows H, C, P, N preserve, replay, source, and name the route. Once those rows are exhausted, the packet has no remaining coordinate for ambient host equality, choice, or ambient real completeness. □

Falsifiable prediction: A $\mathsf{CauchyBicompletion}^{\uparrow}$ read is refuted whenever it reaches a $\mathsf{Real}^{\uparrow}$ or completion-facing boundary without paired Cauchy windows, RegSeqRat readback, the uniform corridor, and completion monad-law coherence.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBicompletion}^{\uparrow}}$**.**

Constructive story: A CauchyBicompletion$^{\uparrow}$ packet is generated from left and right StreamName Cauchy-window rows, a paired finite-window row, RegSeqRat readback, a RealUp route, a UniformCauchyBicompletion corridor, CauchyCompletionMonadLaw coherence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{CauchyBicompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7740.1, Definition 7740.2, and Definition 7740.3 seed the finite paired Cauchy-window bicompletion route into RegSeqRat and Real readback consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyBicompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, ambient host equality, choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-window discipline, RegSeqRat readback exactness, Real route nonescape, uniform corridor compatibility, completion monad-law coherence, transport, replay, provenance, and local naming for BEDC.Derived.CauchyBicompletionUp.

Chapter 7741

A Concrete Naming Certificate for $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$

Following Kelley and Bishop–Bridges compactness practice, the $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$ packet records the finite BEDC boundary at which an open-cover compactness reading is refused and replaced by compact-metric, totally-bounded, finite-net, radius-ledger, and uniform-modulus rows. It sits beside the compact metric source of chapter 129, the total-boundedness surface of chapter 127, the finite $\mathsf{FiniteEpsilonNet}^{\uparrow}$ witness of chapter 1767, the compact-uniform route of chapter 388, the $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is an L10 boundary: it names the finite rows available to later compact-uniform and Heine–Cantor routes, while it does not name an arbitrary open cover, a selected subcover, or an ambient compactness theorem.

Definition 7741.1 (Compact open-cover boundary carrier)**.** *A* $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, O, N, L, U, H, C, P, Q)$$

with the following displayed rows:

1. *K is the compact-metric source row. It exposes only the* $\mathsf{CompactMetric}^{\uparrow}$ *source data and the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-probe discipline used by the route.*
2. *O is the finite cover-request row. It records the cover-shaped request as finite* BHist *data rather than as an arbitrary open-cover family.*
3. *N is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness row, including the centers and finite membership checks visible to the compact-metric source.*
4. *L is the Lebesgue-number or radius ledger row. It records the rational radius lower-bound data consumed after the finite net has been displayed.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row used by compact-uniform and Heine–Cantor consumers after K, O, N, L have been replayed.*
6. *H records componentwise* hsame *transport for the compact source, finite cover request, finite net witness, radius ledger, uniform-modulus handoff, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from the cover-shaped request through the compact-metric source, finite net witness, radius ledger, and uniform-modulus handoff.*

8. *P is the* Pkg *provenance over* $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *Q is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenCoverBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, O, N, L, U, H, C, P, Q$. It has no coordinate for an arbitrary open-cover object, selected subcover, choice functional, quotient equality of cover families, host set equality, semantic compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7741.2 (Compact open-cover boundary NameCert obligations)**.** *For every accepted* $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$ *carrier $B = (K, O, N, L, U, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenCoverBoundary}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the compact-metric source, finite cover request, finite* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness, Lebesgue-number or radius ledger,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, transport, replay, provenance, and local name;*

2. *classifier transport to the common finite surface shared by* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$*;*

3. *stability of K, O, N, L, U under the componentwise* hsame *rows recorded in H;*

4. *replay exactness requiring each compact-uniform consumer to pass through K, O, N, L, U in that order;*

5. *refusal rows excluding arbitrary open covers, selected subcovers, choice functionals, quotient cover equality, host set equality, semantic compactness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 7741.1. The projection exposes the compact-metric source, finite cover request, finite epsilon-net witness, radius ledger, uniform-modulus handoff, transport, replay, provenance, and local naming rows.

Classifier transport is componentwise. The rows in H move the mathematical coordinates K, O, N, L, U and the administrative coordinates C, P, Q to the same finite comparison surface used by the cited compact, net, modulus, and Real chapters.

Replay exactness is read from C. A cover-shaped request reaches the compact source row, then the finite-net witness, then the radius ledger, and only then the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff.

The refusal clauses are exhausted by carrier inspection. Since the carrier has no coordinate for arbitrary open covers, selected subcovers, choice, quotient cover equality, host set equality, semantic compactness, or Real completeness, none of those data can be exported by the local certificate. □

Theorem 7741.3 (Compact open-cover boundary finite-net refusal)**.** *For every accepted* CompactOpenCoverBound *carrier $B = (K, O, N, L, U, H, C, P, Q)$, every compact-uniform or Heine–Cantor read that asks for open-cover compactness factors instead through the finite route*

$$K, O, N, L \longmapsto U.$$

Here K is the $\mathsf{CompactMetric}^{\uparrow}$ *source row, O is the finite cover-request row, N is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *witness row, L is the Lebesgue-number or radius ledger, and U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff. The route may be transported through H, replayed through C, packaged by P, and named by Q,*

but it exports no arbitrary open cover, selected subcover, host compactness object, choice schedule, quotient equality of covers, semantic continuity theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a compact-uniform read of the accepted carrier. By Definition 7741.2, every such read must expose the carrier rows $K, O, N, L, U, H, C, P, Q$ and no row outside that finite surface.

The finite cover-request row O is not an open-cover object. It is admitted only as the cover-shaped request displayed inside the compact-metric source discipline, so the next available witness row is the finite $\mathsf{FiniteEpsilonNet}^{\uparrow}$ coordinate N.

The radius ledger L records the Lebesgue-number or rational-radius lower bound used after the finite net is visible. The replay row C then sends this finite radius package to the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff U.

Transport, provenance, and local naming do not add analytic content. The rows H, P, Q preserve and record the same finite route rather than providing a selected subcover, host compactness theorem, semantic continuity principle, or Real completeness row.

Thus the accepted open-cover-shaped request is refused as a general open-cover compactness read and is replaced by the displayed finite-net route $K, O, N, L \longmapsto U$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenCoverBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOpenCoverBoundary}^{\uparrow}$ packet is generated from a compact-metric source row, finite cover-request row, finite epsilon-net witness, Lebesgue-number or radius ledger, uniform-modulus handoff, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenCoverBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7741.1, Definition 7741.2, and Definition 7741.3 bind the finite compact-open-cover boundary and its finite-net refusal route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenCoverBoundary}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CompactOpenCoverBoundaryUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, quotient cover equality, choice, semantic compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, finite-net exactness, radius-ledger exactness, uniform-modulus handoff, refusal rows, and TasteGate field faithfulness for $K, O, N, L, U, H, C, P, Q$.

Chapter 7742

A Concrete Naming Certificate for $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$

Following Bruck, Reich, and standard Hilbert projection theory, the $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ packet records the finite BEDC surface by which a closed convex Hilbert projection can be consumed as a firm nonexpansive operator. It sits after the projection endpoint of chapter 2356, the finite projection comparison route of chapter 7348, the proximal handoff of chapter 3713, the nonexpansive regular Cauchy route of chapter 2105, and the Chebyshev-center boundary of chapter 6623. The packet names the firm inequality ledger over $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows; it does not import a host projection map, a choice-selected nearest point, quotient Hilbert equality, or an ambient Hilbert projection theorem.

Definition 7742.1 (Firm nonexpansive projection carrier)**.** *A* $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (H, K, M, E, S, D, L, T, C, P, N)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, exposing the inner-product, norm, and induced metric ledgers needed for projection-facing comparisons.*
2. *K is the* $\mathsf{ConvexSet}^{\uparrow}$ *source row, recording the closed convex subset whose projection endpoint is being read.*
3. *M is the* $\mathsf{MetricProjection}^{\uparrow}$ *endpoint row, carrying the nearest-point endpoint only through the finite route of Definition 2356.1.*
4. *E is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row used to replay the minimizing-window endpoint admission without adding an ambient completeness principle.*
5. *S is the* $\mathsf{Real}^{\uparrow}$ *and RegSeqRat distance-readback row, exposing squared-distance and inner-product comparisons only through displayed rational windows.*
6. *D is the inequality ledger for the finite firm-nonexpansive comparison, recording that every inspected pair of inputs and projected endpoints is read through the displayed relation*

$$\langle p_x - p_y, x - y\rangle \geq \|p_x - p_y\|^2.$$

7. *L records componentwise* hsame *transport for the Hilbert, convex, projection endpoint, completeness service, real readback, inequality ledger, replay, provenance, and local naming rows.*

8. *T records displayed* Cont *replay from projection endpoint reads through the real comparison ledger and the firm inequality ledger.*
9. *P is the* Pkg *provenance over* $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FirmNonexpansiveProjection}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only by these rows. It has no coordinate for a host projector, selected nearest point, quotient equality of Hilbert points, trichotomy on real comparisons, countable choice, or a global fixed-point theorem.

Lean4 ✓ `BEDC.Derived.FirmNonexpansiveProjectionUp.FirmNonexpansiveProjectionTasteGate single carrier alignment`

Theorem 7742.2 (FirmNonexpansiveProjection NameCert obligations)**.** *For an accepted* $\mathsf{FirmNonexpansiveProject}$ *carrier $Q = (H, K, M, E, S, D, L, T, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FirmNonexpansiveProjection}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Hilbert source, closed convex source, MetricProjection endpoint, CompleteMetric service, real distance readback, inequality ledger, transport, replay, provenance, and local naming rows;*
2. *endpoint dependency, requiring every projected point used by the firm inequality to be read first through the* $\mathsf{MetricProjection}^{\uparrow}$ *endpoint row M;*
3. *real readback exactness, requiring every squared-distance and inner-product comparison to pass through the shared* $\mathsf{Real}^{\uparrow}$ *and RegSeqRat row S;*
4. *firm inequality visibility, requiring the ledger D to display the finite comparison before any consumer treats the projection as nonexpansive;*
5. *nonescape from host projection maps, choice-selected nearest points, quotient Hilbert equality, trichotomy, countable choice, and ambient fixed-point principles.*

Proof. Project the accepted carrier. The rows H, K, M, E, S, D are the complete mathematical surface, while L, T, C, P, N transport, replay, package, and name the same displayed packet.

The endpoint dependency is inherited from Definition 2356.2. The projection endpoint is read through the Hilbert source, closed convex source, distance ledger, minimizing window, and endpoint row before the firm comparison ledger can inspect it.

The real readback and firm inequality rows are then finite. The row S supplies the displayed real and regular-rational comparisons, and D records the inspected inequality

$$\langle p_x - p_y, x - y\rangle \geq \|p_x - p_y\|^2.$$

Transport, replay, provenance, and local naming preserve this route. Since no carrier row stores a host projector, a selected nearest point, quotient Hilbert equality, trichotomy, countable choice, or a fixed-point theorem, those principles cannot be exported by the local certificate. □

Theorem 7742.3 (FirmNonexpansiveProjection MetricProjection handoff)**.** *Every consumer that uses an accepted* $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ *packet as a nonexpansive projection must first read the* $\mathsf{MetricProjection}^{\uparrow}$ *endpoint row M and the firm inequality ledger D. The consumer may then use the projection only through the displayed route*

$$H, K, M, E, S, D \longmapsto L, T, C, P, N.$$

It receives no host Hilbert projection map, no selected nearest-point operator, no quotient equality of projected points, no trichotomy decision for real comparisons, and no global fixed-point conclusion.

Proof. Start with the projected endpoint. By Definition 7742.1, endpoint data enter the packet only through the $\mathsf{MetricProjection}^{\uparrow}$ row M, and Definition 2356.3 keeps that row inside the finite projection route.

Next read the inequality ledger. The row D may compare two projected endpoints only after H, K, M, E, S are displayed, so a nonexpansive use cannot bypass the Hilbert source, closed convex source, complete metric replay, or real readback.

The structural rows L, T, C, P, N only transport, replay, source, and name the same finite data. Thus the handoff exports a firm nonexpansive projection certificate, not a host projector, selected nearest-point operator, quotient equality principle, trichotomy decision, or fixed-point theorem. □

Falsifiable prediction: Every accepted $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ consumer read factors through a HilbertUp source, ConvexSetUp closed convex source, MetricProjectionUp endpoint row, CompleteMetricUp replay service, RealUp and RegSeqRat distance readback, finite firm inequality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert.

Independence witness: metricprojection, finite-metric-projection, proximal-map, regular-cauchy-nonexpansive-map, chebyshev-center: $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a MetricProjection endpoint, a CompleteMetric replay service, a RealUp distance-readback row, and an explicit firm inequality ledger before any nonexpansive consumer read.

Closure status for $\mathsf{NameCert}_{\mathsf{FirmNonexpansiveProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{FirmNonexpansiveProjection}^{\uparrow}$ packet is generated from a Hilbert source, closed convex source, MetricProjection endpoint row, CompleteMetric replay service, RealUp and RegSeqRat distance readback, finite firm inequality ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FirmNonexpansiveProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7742.1, Definition 7742.2, and Definition 7742.3 seed the finite firm-projection certificate surface over Hilbert, closed convex, metric projection, complete metric, real readback, and inequality-ledger rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FirmNonexpansiveProjection}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FirmNonexpansiveProjectionUp`

Bridge status: none

Not claimed: This chapter does not claim Lean verification, a host Hilbert projection map, selected nearest points, quotient equality of Hilbert points, trichotomy, countable choice, a Krasnoselskii–Mann convergence theorem, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint dependency, real readback exactness, firm inequality visibility, transport, replay, provenance, and local naming for BEDC.Derived.FirmNonexpansiveProjectionUp.

Chapter 7743

A Concrete Naming Certificate for $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real construction, the $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$ packet records the finite diagonal modulus row used when two regular rational names must be read together before a Real-facing seal is exposed. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ carriers of chapter 301, the finite schedules of chapter 126, the dyadic tolerance ledger of chapter 291, the generic limit route of chapter 1678, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite modulus selector, not quotient stream equality, selected representatives, host real equality, countable choice, or ambient completeness.

Definition 7743.1 (Real Cauchy diagonal modulus carrier)**.** *A* $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, S, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *name rows whose finite regular-rational readbacks are being compared.*
2. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *schedule row exposing the visible prefixes of both names.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger containing the requested radius, slack, and dyadic comparison budget.*
4. *Q is the diagonal selector row, requiring a single finite window to answer both regular names at the displayed tolerance.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row, available only after A, B, S, D, Q have been replayed.*
6. *H records componentwise* hsame *transport for the two regular names, schedules, tolerance ledger, diagonal selector, seal handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a diagonal request through the schedules, tolerance ledger, selector, and seal handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Limit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCauchyDiagonalModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, B, S, D, Q, R, H, C, P, N$. It has no coordinate for quotient equality of streams, selected representatives, host real equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Theorem 7743.2 (Real Cauchy diagonal modulus NameCert obligations)**.** *For every accepted* $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$ *carrier* $M = (A, B, S, D, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCauchyDiagonalModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, two* $\mathsf{RegSeqRat}^{\uparrow}$ *name admissions, paired* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-ledger exactness, diagonal selector exactness,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and refusal of quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 7743.1. The only input-name rows are A and B, and the only finite schedules visible to a request are stored in S.

Read the dyadic tolerance row D and the diagonal selector Q. The selector binds both regular names to the same displayed finite window before the downstream seal row R can be reached.

The rows H, C, P, N transport, replay, source, and name this same route. Since the carrier is exhausted by the displayed rows, it cannot export quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking. □

Theorem 7743.3 (Real Cauchy diagonal modulus window extraction)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Limit}^{\uparrow}$*, or regular Cauchy comparison consumer of an accepted* $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$ *carrier must factor through the finite route*

$$A, B \longmapsto S \longmapsto D \longmapsto Q \longmapsto R, H, C, P, N.$$

Thus the consumer receives two $\mathsf{RegSeqRat}^{\uparrow}$ *names, a paired* $\mathsf{StreamName}^{\uparrow}$ *schedule, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, a diagonal selector, a* $\mathsf{Real}^{\uparrow}$ *seal handoff, transport, replay, provenance, and local naming. It receives no quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking.*

Proof. Begin with a consumer of the accepted packet. The carrier exposes the two regular rational names A, B before any schedule or seal row can be read.

Replay the request through C. The paired schedule S supplies the finite windows, the tolerance ledger D supplies the dyadic budget, and the diagonal selector Q records the single window that answers both sides.

Only after that replay can the seal handoff R be consumed. Componentwise transport, provenance, and local naming through H, P, N preserve the same finite route and add no external equality, selector, choice, completeness, verification, or bridge coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCauchyDiagonalModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealCauchyDiagonalModulus}^{\uparrow}$ packet is generated from two RegSeqRat name rows, a paired StreamName schedule, a DyadicRatCore tolerance ledger, a diagonal selector, a RealUp seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCauchyDiagonalModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7743.1, Definition 7743.2, and Definition 7743.3 seed the finite diagonal-modulus packet used by Real and regular Cauchy comparison consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCauchyDiagonalModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, host real equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired schedule exposure, tolerance-ledger exactness, diagonal selector exactness, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealCauchyDiagonalMod

Chapter 7744

A Concrete Naming Certificate for MetaCICExtractionNormalizationSocket$^{\uparrow}$

The MetaCICExtractionNormalizationSocket$^{\uparrow}$ packet realizes the confluence audit boundary of chapter 9378 as finite socket data between extraction, candidate normalization, and residual confluence. It is consumed by chapter 4238 through its candidate-mediated strong-normalization socket and by chapter 765 through the retained residual-budget path. It does not assert a full parallel diamond. It records exactly the rows needed to keep the substitution-sensitive boundary visible while allowing checked fragments, candidate normal forms, and local joins to be handed to later MetaCIC consumers.

Definition 7744.1 (MetaCIC extraction-normalization socket carrier)**.** *A* MetaCICExtractionNormalizationSocket$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, R, J, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the extraction row, recording the finite MetaCIC redex, source, target, and closedness window inspected by the socket.*
2. *K is the candidate-normalization row, recording the candidate normal form or bounded normalizing trace supplied by the visible extraction window.*
3. *R is the residual-substitution row, recording the exact substitution-compatibility boundary that the confluence audit map keeps conditional.*
4. *J is the local-join row, recording candidate common reducts or local joins that are available inside the displayed window.*
5. *O is the obstruction row, retaining the cases where the residual-substitution row or local-join row is absent.*
6. *H records componentwise* hsame *transport for extraction, candidate-normalization, residual-substitution, local-join, obstruction, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an extracted peak through candidate normalization, residual substitution, local join, and obstruction retention.*
8. *P is* Pkg *provenance over* MetaCICExtractionNormalizationSocket$^{\uparrow}$*, the MetaCIC confluence audit map,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, K, R, J, O, H, C, P, N$. It has no coordinate for a global Church–Rosser theorem, an unqualified parallel diamond, hidden substitution compatibility, quotient syntax equality, host normalization, Lean verification, or bridge checking.

Theorem 7744.2 (MetaCIC extraction-normalization socket NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}$ *carrier $E = (X, K, R, J, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}}$ *surface is exhausted by carrier admission, extraction-window exposure, candidate-normalization exposure, residual-substitution boundary retention, local-join exposure, obstruction retention, componentwise transport, displayed replay, package provenance, local naming, and refusal of full closed parallel diamond, global Church–Rosser, hidden substitution compatibility, quotient syntax equality, host normalization, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 7744.1. The extraction row X supplies the only visible source and redex data, while K records the candidate-normalization evidence available for that extraction.

The residual-substitution row R and local-join row J are separate obligations. A socket may expose a candidate normalization without discharging residual substitution, and it may expose a local join only when that row is displayed.

The obstruction row O retains the complementary cases. The structural rows H, C, P, N transport, replay, source, and name the same finite surface, so the packet cannot silently export a full parallel diamond, global confluence theorem, hidden substitution compatibility, quotient syntax equality, host normalization, Lean verification, or bridge checking. □

Theorem 7744.3 (MetaCIC extraction-normalization residual handoff)**.** *Every confluence-audit consumer of an accepted* $\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}$ *packet receives only the finite route*

$$X \longmapsto K \longmapsto R, J, O \longmapsto H, C, P, N.$$

Consequently the packet can hand extraction and candidate-normalization evidence to the residual confluence frontier only with the residual-substitution row, local-join row, obstruction row, transport, replay, provenance, and local naming still attached. It cannot imply a full closed parallel diamond unless both R and J are displayed and separately discharged by the consumer.

Proof. Start with a confluence-audit consumer of the socket. The carrier exposes extraction data only through X and candidate-normalization data only through K.

Replay the socket through C. The replay reaches the residual-substitution row R, the local-join row J, and the obstruction row O before any downstream residual-confluence consumer can read the packet.

The sibling routes through chapter 4238 and chapter 765 are consumers of the displayed $X, K, R, J, O, H, C, P, N$ route, not extra discharge evidence.

Transport and provenance through H, P, N keep the same rows attached. Since the carrier has no additional global-diamond coordinate, the handoff is a finite residual socket rather than a closed parallel-diamond proof. □

Falsifiable prediction: A socket packet cannot imply a full closed parallel diamond unless the residual-substitution row and local-join row are both displayed.

Independence witness: metaciccriticalpath, metacicnormalizationaudit, metacicconfluenceauditpacket, metacic-parallel-diamond-frontier: none is bijective because the socket binds extraction,

candidate normalization, residual substitution, local join, obstruction, transport, replay, provenance, and NameCert rows in one carrier.

The Lean follow-up path is `lean4/BEDC/Derived/MetaCICExtractionNormalizationSocketUp/TasteGate.l` It must provide explicit Nontrivial MetaCICExtractionNormalizationSocket$^{\uparrow}$ and FieldFaithful MetaCICExtractionNorm instances preserving extraction, candidate-normalization, residual-substitution, local-join, obstruction, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}}$.

Constructive story: A MetaCICExtractionNormalizationSocket$^{\uparrow}$ packet is generated from extraction, candidate-normalization, residual-substitution, local-join, obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7744.1, Definition 7744.2, and Definition 7744.3 seed the finite socket between extraction, normalization evidence, and residual confluence.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICExtractionNormalizationSocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a full closed parallel diamond, global Church–Rosser, hidden substitution compatibility, quotient syntax equality, host normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, extraction exposure, candidate-normalization exposure, residual-substitution retention, local-join exposure, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICExtractionNormalizationSocketUp.

Chapter 7745

A Concrete Naming Certificate for $\mathsf{RealIntervalHalving}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealIntervalHalving}^{\uparrow}$ packet records the real-line bisection step as finite BEDC NameCert data rather than as trichotomy, selected limits, quotient reals, or an ambient completeness theorem. It sits over the constructive real-line interface of chapter 4041, the one-step located bisection packet of chapter 4288, the finite bisection tree of chapter 6701, the dyadic tolerance core of chapter 291, the finite stream observations of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38.

Definition 7745.1 (RealIntervalHalving carrier)**.** *A* $\mathsf{RealIntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (A, B, M, L, R_0, D, S, G, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the left and right endpoint rows of the input real interval;*
2. *M is the midpoint row exposed through dyadic arithmetic and finite regular-rational readback;*
3. *L is the* $\mathsf{LocatedIntervalHalving}^{\uparrow}$ *row recording the one-step located-halving decision at the displayed tolerance;*
4. *R_0 is the* $\mathsf{IntervalHalvingTree}^{\uparrow}$ *row recording the finite bisection-tree position reached by this step;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for the midpoint and side read;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the endpoint and midpoint observations;*
7. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows;*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after the dyadic endpoint windows, stream observations, and regular rational readback have been displayed;*
9. *H records componentwise* hsame *transport for the endpoint, midpoint, located-halving, tree, tolerance, stream, readback, Real-seal, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay for the endpoint-window request, midpoint readback, located side row, tree row, Real seal, and structural rows;*
11. *P is the* Pkg *provenance over* $\mathsf{RealIntervalHalving}^{\uparrow}$, $\mathsf{ConstructiveRealLine}^{\uparrow}$, $\mathsf{LocatedIntervalHalving}^{\uparrow}$, $\mathsf{IntervalHalvingTree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RealIntervalHalving}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for trichotomy, a selected limit, quotient real equality, an unrecorded completeness argument, or a Real-facing interval conclusion that bypasses the dyadic endpoint windows.

Theorem 7745.2 (RealIntervalHalving NameCert obligations)**.** *For every accepted* $\mathsf{RealIntervalHalving}^{\uparrow}$ *carrier*

$$R = (A, B, M, L, R_0, D, S, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealIntervalHalving}^{\uparrow}}$ *surface is exhausted by five finite obligation rows:*

1. *carrier exposure for the two endpoint rows, midpoint row, located-halving row, interval-halving tree row, dyadic tolerance, stream window, regular readback, Real seal, transport, replay, provenance, and local naming;*
2. *endpoint-window exactness, requiring A, B, D, and S to display the finite dyadic windows used by the bisection request;*
3. *midpoint and readback compatibility, requiring M and G to be read from the same displayed dyadic and stream data;*
4. *located-tree compatibility, requiring L and R_0 to record the selected half only as a finite located-halving row and finite tree row;*
5. *Real-seal nonescape, excluding trichotomy, selected limits, quotient real equality, hidden completeness, and any interval conclusion before D, S, G, E are visible.*

No local NameCert obligation is stored outside those rows.

Proof. Project the accepted carrier. The only interval endpoints are A and B, and the only midpoint data are the displayed rows M, D, S, G.

The endpoint-window exactness row first fixes the dyadic tolerance D and the stream window S. The midpoint and readback row then reads M through the same window and records the regular rational handoff in G.

The located side and tree position are separate finite rows. The row L records the one-step located halving decision, while R_0 records the corresponding finite tree position; neither row supplies trichotomy or a selected real limit.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since no coordinate supplies quotient real equality, hidden completeness, or a bypass interval conclusion, the five rows exhaust the local NameCert surface. □

Theorem 7745.3 (RealIntervalHalving RegSeqRat route)**.** *Every Real-facing halving read of an accepted* $\mathsf{RealIntervalHalving}^{\uparrow}$ *carrier factors through dyadic endpoint windows,* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and the* $\mathsf{Real}^{\uparrow}$ *seal before any interval conclusion is available. In carrier coordinates this route is*

$$A, B, D, S \longmapsto M, G \longmapsto L, R_0 \longmapsto E, H, C, P, N.$$

Thus the consumer receives the endpoint windows, midpoint readback, located-halving row, interval-tree row, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row before it can read the retained interval.*

Proof. Use the NameCert obligations. Endpoint-window exactness makes A, B, D, S visible before any midpoint or side read.

The midpoint and readback compatibility row then forces M and G to be read from the same dyadic endpoint windows and stream observations. This is the only regular-rational route available to the carrier.

The located-tree compatibility row consumes that readback through L and R_0. The Real seal E is downstream of these finite rows, and H, C, P, N only preserve the same route by transport, replay, provenance, and local naming.

Therefore a Real-facing halving consumer cannot reach an interval conclusion before the dyadic endpoint windows, StreamName observations, RegSeqRat readback, and Real seal have all been displayed. □

Falsifiable prediction: Every accepted $\mathsf{RealIntervalHalving}^{\uparrow}$ Real-facing interval read exposes endpoint rows, a midpoint row, one LocatedIntervalHalving row, one IntervalHalvingTree row, one DyadicRatCore tolerance row, one StreamName finite-window row, one RegSeqRat readback row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the retained interval is public.

Independence witness: constructive-real-line, located-interval-halving, interval-halving-tree, dyadicratcore, streamname, regseqrat, real: $\mathsf{RealIntervalHalving}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries real endpoint windows, midpoint data, a located side row, a finite tree row, dyadic tolerance, stream observations, regular rational readback, Real seal, transport, replay, provenance, and local naming as one finite bisection certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RealIntervalHalving}^{\uparrow}}$.

Constructive story: A $\mathsf{RealIntervalHalving}^{\uparrow}$ packet is generated from real endpoint rows, a midpoint row, LocatedIntervalHalving and IntervalHalvingTree rows, DyadicRatCore tolerance, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealIntervalHalving}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7745.1, Definition 7745.2, and Definition 7745.3 seed the finite Bishop real-interval bisection route over endpoint windows, midpoint readback, located side rows, interval-tree rows, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealIntervalHalving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, selected limits, quotient reals, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.RealIntervalHalvingUp.

Chapter 7746

A Concrete Naming Certificate for $\mathsf{LocatedTotalBoundedness}^{\uparrow}$

Following Bishop-style constructive metric compactness, the $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ packet records total boundedness with located finite-net selection data rather than with open-cover compactness, a host compactness theorem, or a choice-selected net. It sits over the metric carrier of chapter 57, the total-boundedness packet of chapter 127, the finite ε-net interface of chapter 1767, the dyadic tolerance core of chapter 291, the stream-window naming surface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. A consumer sees explicit finite centers, tolerance windows, and location rows; it does not receive an unbounded cover family or a hidden selector.

Definition 7746.1 (LocatedTotalBoundedness carrier)**.** *A* $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (X, T, F, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *point and distance row for the requested finite window.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *coverage row, naming the displayed tolerance and the finite family of candidate centers.*
3. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row whose entries list the actual finite net centers and their coverage ledger.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the requested radius, center distances, and coverage slack.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row recording which center and point windows are opened.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed distance and radius comparisons.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the distance comparisons after D, S, R have been replayed.*
8. *H records componentwise* hsame *transport for metric data, total-boundedness data, finite-net data, dyadic tolerances, stream windows, regular readback, Real sealing, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedTotalBoundedness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedTotalBoundedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, F, D, S, R, E, H, C, P, N$. There is no coordinate for open-cover compactness, a host compactness theorem, an unrecorded center selector, quotient stream equality, countable choice, or ambient real completeness.

Theorem 7746.2 (LocatedTotalBoundedness NameCert obligations)**.** *For every accepted* LocatedTotalBoundednes *carrier*

$$L = (X, T, F, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedTotalBoundedness}^{\uparrow}}$ *surface is exhausted by carrier exposure, total-bounded coverage, finite-net center listing, dyadic tolerance exactness, stream-window observation, regular rational readback, Real-seal nonescape, componentwise transport, displayed replay, package provenance, and local naming. The certificate refuses open-cover compactness, host compactness, hidden center selection, quotient stream equality, countable choice, and ambient completeness.*

Proof. Project the accepted carrier. The only ambient metric data are X, and the only total-bounded coverage data are the displayed rows T and F.

The dyadic and stream rows D and S fix the finite tolerance windows used to test the listed centers. The regular readback row R records those comparisons before the terminal real seal E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no open-cover, host-compactness, selector, quotient, countable-choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7746.3 (LocatedTotalBoundedness finite-net location route)**.** *Every compact-metric or completion-facing consumer of an accepted* $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ *carrier must read located finite-net data through the route*

$$X, T, F \longmapsto D, S \longmapsto R \longmapsto E, H, C, P, N.$$

Thus a finite-net location claim is available only after the Metric row, TotallyBounded row, FiniteEpsilonNet row, DyadicRatCore tolerance row, StreamName observation row, RegSeqRat readback row, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row have all been displayed.*

Proof. Start with the carrier of Definition 7746.1. The rows X, T, F expose the metric source, the total-bounded coverage request, and the finite list of net centers.

The rows D and S then determine the dyadic tolerances and finite observation windows used to locate a center for the request. The regular readback row R turns these finite comparisons into the rational data consumed by the downstream Real seal E.

The structural rows H, C, P, N preserve this same route under transport, replay, provenance, and local naming. A compact-metric or completion-facing consumer therefore cannot replace the displayed finite-net route by open-cover compactness, host compactness, hidden selection, quotient stream equality, countable choice, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ compact-metric or completion-facing read exposes a Metric row, a TotallyBounded coverage row, a FiniteEpsilonNet center row,

a DyadicRatCore tolerance row, a StreamName observation row, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it may use located finite-net data.

Independence witness: metric, totallybounded, finiteepsilonnet, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries metric source data, total-bounded coverage, located finite-net centers, dyadic tolerance comparison, stream observation, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one finite compactness-facing certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedTotalBoundedness}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedTotalBoundedness}^{\uparrow}$ packet is generated from a Metric row, TotallyBounded coverage row, FiniteEpsilonNet center row, DyadicRatCore tolerance row, StreamName observation row, RegSeqRat readback row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedTotalBoundedness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7746.1, Definition 7746.2, and Definition 7746.3 seed the located finite-net route for compact-metric and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedTotalBoundedness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host compactness, hidden center selection, quotient stream equality, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Formal verification requires a Lean carrier and checked NameCert obligations for BEDC.Derived.LocatedTotalBoundedness

Chapter 7747

Regular Cauchy Uniform Tail NameCert Construction

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ packet records the finite uniform tail-window surface by which one displayed threshold controls every later precision read before the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the real-name boundary of chapter 38, and the tail-estimate packet of chapter 1487. The packet names a finite uniform tail window for regular Cauchy names; it is not a quotient stream, selected limit, countable-choice schedule, trichotomy principle, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7747.1 (Regular Cauchy uniform tail carrier)**.** *A* $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (Q, M, W, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite family of precision requests whose common tail window is being certified;*
2. *M is the displayed modulus-threshold row, naming one index bound that serves every request in Q;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *tail-window row, listing exactly the stream observations at and beyond the threshold M that are consumed by the packet;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the dyadic comparison budgets attached to the requests in Q;*
5. *T is the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *row witnessing that the same threshold M controls all later windows in W;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the uniform tail window and dyadic ledger;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after Q, M, W, D, T, R have been displayed;*
8. *H records componentwise* hsame *transport for the request family, threshold, window, dyadic ledger, tail-estimate, regular readback, and real seal rows;*
9. *C records displayed* Cont *replay from each precision request in Q through the common threshold and downstream readback route;*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniformTail}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformTail}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, M, W, D, T, R, E, H, C, P, N$. No coordinate stores quotient stream equality, a selected real representative, a selected limit, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7747.2 (Regular Cauchy uniform tail NameCert obligations)**.** *For every accepted* RegularCauchyUniformT *carrier $U = (Q, M, W, D, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformTail}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite request family, common threshold, stream tail window, dyadic tolerance ledger, tail-estimate handoff, regular rational readback, real seal, componentwise transport, replay, provenance, and local naming; classifier transport to the same finite request-and-window surface; stability of every row under the displayed* hsame *data; exactness requiring all real-facing reads to pass through Q, M, W, D, T, R, E in that order; and ledger refusal for quotient streams, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, and ambient real completeness.*

Proof. Project the carrier of Definition 7747.1. The projection exposes the finite request family Q, the common threshold M, the tail-window row W, the dyadic ledger D, the tail-estimate row T, the regular readback R, the real seal E, and the structural rows H, C, P, N.

Classifier transport is componentwise. The rows in H compare the request family, common threshold, tail window, dyadic ledger, tail estimate, readback, and seal on the same finite surface, while C, P, N only replay, source, and name that surface.

Exactness is read from the displayed route. A precision request first enters Q, uses the shared threshold M, reads only the displayed windows in W, consumes the dyadic budget D, reaches the tail-estimate row T, then the regular readback R, and only then the real seal E.

The refusal rows are exhausted by the carrier inventory. Since the carrier has no coordinate for quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, open-cover compactness, or ambient completeness, no local NameCert obligation can export those data. □

Theorem 7747.3 (Regular Cauchy uniform tail Real seal nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ *carrier factors through the finite route*

$$Q, M \longmapsto W \longmapsto D \longmapsto T \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the package stays inside the displayed $\mathsf{Real}^{\uparrow}$ *seal route and does not assert ambient completeness, quotient streams, selected limits, countable choice, trichotomy, or open-cover compactness.*

Proof. Start with an accepted carrier $U = (Q, M, W, D, T, R, E, H, C, P, N)$. The rows Q and M supply the finite precision family and the common threshold; no real-facing read is available at this stage.

The stream and dyadic rows are next. The row W lists the inspected tail windows, and D records the dyadic comparison budgets tied to those windows, so a consumer cannot bypass the finite observation layer.

Apply the tail-estimate and regular readback rows. The row T certifies that the same threshold controls every later window in the displayed request family, and R converts that uniform tail evidence into the $\mathsf{RegSeqRat}^{\uparrow}$ readback consumed by the seal.

Finally inspect E, H, C, P, N. The real seal E is downstream of the displayed route, and the structural rows only transport, replay, source, and name that route. Because the carrier inventory contains no completeness, quotient, selected-limit, choice, trichotomy, or compactness coordinate, the package cannot export such a principle. □

Falsifiable prediction: A $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ read is refuted whenever a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches the real seal without displaying the finite precision family, common threshold, StreamName tail window, DyadicRatCore tolerance ledger, RegularCauchyTailEstimate row, RegSeqRat readback, componentwise transport, replay, provenance, and local naming.

Independence witness: regularcauchytailestimate, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ because the packet jointly records a finite request family, one shared tail threshold, the inspected StreamName windows, dyadic comparison budgets, tail-estimate handoff, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniformTail}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyUniformTail}^{\uparrow}$ packet is generated from a finite precision-request family, one shared tail threshold, StreamName tail windows, DyadicRatCore tolerance budgets, a RegularCauchyTailEstimate row, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7747.1, Definition 7747.2, and Definition 7747.3 seed the finite uniform tail-window route from regular Cauchy tail control to Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniformTail}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-threshold coverage, stream-window exactness, dyadic tolerance handoff, tail-estimate handoff, regular-name readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyUniformTailUp.

Chapter 7748

A Concrete Naming Certificate for $\mathsf{BishopPremetric}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopPremetric}^{\uparrow}$ packet isolates the premetric interface used before a constructive metric space asserts separated point identity. It sits after the distance-comparison surface of chapter 5565, before the Real-facing metric presentation of chapter 3673, and beside the completion routes of chapter 1506, chapter 2114, and chapter 38. The packet records zero-distance evidence as displayed data, not as quotient equality, representative selection, host point equality, or a completed Real object.

Definition 7748.1 (Bishop premetric carrier)**.** *A* $\mathsf{BishopPremetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, D, Z, S, Q, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the displayed point-window row for the source carrier.*
2. *D is the Bishop premetric distance row, exposing finite positive-radius comparisons between displayed point windows.*
3. *Z is the zero-distance evidence row, recording when all displayed radius requests along D are met.*
4. *S is the separation-boundary row, consumed by* $\mathsf{BishopMetricSpace}^{\uparrow}$ *only after Z has been displayed.*
5. *Q is the quotient-refusal row, retaining the fact that zero-distance evidence has not been collapsed into point equality.*
6. *M is the completion-facing row consumed by* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{LocatedMetricCompletion}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *only after X, D, Z, S, Q have been read.*
7. *H records componentwise* hsame *transport for point windows, premetric distances, zero-distance evidence, separation boundary, quotient refusal, completion-facing rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite distance request through zero-distance evidence and the separation boundary.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopPremetric}^{\uparrow}$*,* $\mathsf{Premetric}^{\uparrow}$*,* $\mathsf{BishopMetricSpace}^{\uparrow}$*,* $\mathsf{MetricCompletion}^{\uparrow}$*,* $\mathsf{LocatedMetricCompletion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopPremetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $X, D, Z, S, Q, M, H, C, P, N$. It has no coordinate for quotient point equality, selected representatives, host metric equality, completed points, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7748.2 (Bishop premetric NameCert obligations)**.** *For every accepted* $\mathsf{BishopPremetric}^{\uparrow}$ *carrier $B = (X, D, Z, S, Q, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopPremetric}^{\uparrow}}$ *surface consists exactly of source point-window admission, Bishop premetric distance exposure, zero-distance evidence, separation-boundary handoff, quotient-refusal retention, completion-facing nonescape, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Each obligation is read through the finite route*

$$X, D, Z \longrightarrow S, Q, M \longrightarrow H, C, P, N.$$

Proof. Project the carrier of Definition 7748.1. The source row X and distance row D are the only rows a consumer may inspect before asking whether two point windows have zero distance.

The zero-distance row Z records evidence from the displayed premetric comparisons. The separation row S is downstream of Z, while Q keeps the same evidence from being read as quotient equality.

The completion-facing row M can therefore expose only the finite premetric route X, D, Z, S, Q. Componentwise transport through H and replay through C preserve that order, and P, N record provenance and local naming.

Since quotient point equality, selected representatives, host metric equality, completed points, countable choice, trichotomy, and ambient Real completeness do not occur among the carrier coordinates, no NameCert obligation can be discharged outside the displayed finite route. □

Theorem 7748.3 (Bishop premetric Cauchy route)**.** *Every Cauchy, completion-facing, or Real-facing consumer of an accepted* $\mathsf{BishopPremetric}^{\uparrow}$ *packet reaches the premetric input only through*

$$\mathsf{Premetric}^{\uparrow}, \mathsf{BishopPremetric}^{\uparrow} \longmapsto \mathsf{BishopMetricSpace}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

In particular, the completion-facing row M exports finite zero-distance and separation-boundary data, not a selected Cauchy limit, quotient equality, host metric equality, or a detached completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Proof. Read the accepted carrier $B = (X, D, Z, S, Q, M, H, C, P, N)$. The row M is downstream of the point-window, distance, zero-distance, separation, and quotient-refusal rows.

Apply Definition 7748.2. The local certificate forces every Cauchy or completion-facing read to pass through X, D, Z, S, Q before the completion row can be inspected.

The downstream routes named by chapter 3673, chapter 1506, and chapter 38 may consume that displayed premetric boundary. They do not receive a completed point, selected limit, quotient equality, host metric equality, or ambient completeness principle from this packet. □

Theorem 7748.4 (Bishop premetric metric-separation boundary)**.** *Let $B = (X, D, Z, S, Q, M, H, C, P, N)$ be an accepted* $\mathsf{BishopPremetric}^{\uparrow}$ *packet. A* $\mathsf{BishopMetricSpace}^{\uparrow}$ *consumer can read metric separation from B only through the displayed row S, and S is available only after the zero-distance evidence Z has been read together with the quotient-refusal row Q. Thus the passage from premetric data to metric separation is a finite NameCert handoff, not an implicit quotient of the source points.*

Proof. Start from Definition 7748.1. The only row named as a separation boundary is S, and the only row that records refusal of quotient collapse is Q.

Use Definition 7748.2. It orders the local obligations as distance exposure, zero-distance evidence, separation handoff, quotient-refusal retention, and completion-facing nonescape.

Therefore a $\mathsf{BishopMetricSpace}^{\uparrow}$ consumer reaches metric separation only by reading D and Z first, then S with Q still visible. The structural rows H, C, P, N transport and name that same finite handoff; they do not add quotient equality, selected representatives, or host point equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopPremetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopPremetric}^{\uparrow}$ packet is generated from displayed point windows, Bishop premetric distance comparisons, zero-distance evidence, a separation-boundary handoff, quotient-refusal retention, a completion-facing row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopPremetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7748.1, Definition 7748.2, Definition 7748.3, and Definition 7748.4 seed the constructive boundary between premetric evidence, Bishop metric separation, completion-facing reads, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopPremetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient point equality, selected representatives, host metric equality, completed points, countable choice, trichotomy, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked source admission, distance exposure, zero-distance evidence, separation-boundary handoff, quotient-refusal retention, completion-facing nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopPremetricUp.

Chapter 7749

A Concrete Naming Certificate for $\mathsf{ContextSensitiveLanguage}^{\uparrow}$

Following Hopcroft–Ullman and the Chomsky hierarchy presentation of formal languages, the $\mathsf{ContextSensitiveLanguage}^{\uparrow}$ packet names accepted context-sensitive languages by finite noncontracting grammar rows and bounded acceptance ledgers before any consumer reads a host language set. It sits beside the accepted context-free language interface of chapter 7733, the noncontracting grammar carrier of chapter 6178, and the context-free grammar syntax surface of chapter 356. The packet records the accepted-language classifier induced by grammar production, length-nondecreasing derivation, and linear-bounded acceptance rows; it is not a host powerset of words, a grammar quotient, an unrestricted Turing-machine semantics, or an ambient decidability theorem.

Definition 7749.1 (Context-sensitive language carrier)**.** *A* $\mathsf{ContextSensitiveLanguage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (G, \Sigma, W, R, D, B, A, M, H, C, P, N)$$

with the following displayed rows:

1. *G is the source* $\mathsf{ContextSensitiveGrammar}^{\uparrow}$ *row, exposing the noncontracting grammar packet of chapter 6178.*
2. *Σ is the finite terminal alphabet row and W is the candidate word row, both read through finite list data before acceptance is inspected.*
3. *R is the grammar-production ledger, listing each production used by the acceptance certificate as a finite row over the displayed grammar.*
4. *D is the length-nondecreasing derivation ledger. Each derivation step records the predecessor word, successor word, occurrence window, production row from R, and the displayed length comparison.*
5. *B is the linear-bounded acceptance route, recording that the inspected sentential windows remain inside the finite bound determined by the input word and the displayed grammar rows.*
6. *A is the accepted-word row, available only after G, Σ, W, R, D, B have been replayed.*
7. *M is the comparison row for* $\mathsf{ContextFreeLanguage}^{\uparrow}$ *and* $\mathsf{ContextFreeGrammar}^{\uparrow}$ *consumers that request weaker grammar-side or language-side surfaces.*

8. *H records componentwise* hsame *transport for the grammar source, terminal alphabet, word row, production ledger, derivation ledger, bounded route, accepted-word row, comparison row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a language-membership request through $G, \Sigma, W, R, D, B, A, M, H, P, N$.*
10. *P is the* Pkg *provenance over* ContextSensitiveLanguage$^{\uparrow}$, ContextSensitiveGrammar$^{\uparrow}$, ContextFreeLanguage$^{\uparrow}$, ContextFreeGrammar$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, \Sigma, W, R, D, B, A, M, H, C, P, N$. It has no coordinate for a host language set, a selected infinite derivation, a grammar quotient, unrestricted machine computation, complement closure, or global decidability.

Theorem 7749.2 (Context-sensitive language NameCert obligations)**.** *For every accepted* ContextSensitiveLanguag *carrier*

$$L = (G, \Sigma, W, R, D, B, A, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}$ *surface consists exactly of source grammar admission through G, terminal and word admission through Σ, W, grammar-production admission through R, length-nondecreasing derivation replay through D, linear-bounded acceptance through B, accepted-word classification through A, sibling comparison through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No accepted packet exports host language equality, an unrestricted machine semantics, a grammar quotient, a selected infinite derivation, complement closure, or ambient decidability.

Proof. Project the carrier of Definition 7749.1. The source grammar row G, terminal alphabet row Σ, word row W, and production ledger R are the only rows that can admit grammar syntax for the accepted-language read.

The derivation and bounded-acceptance rows are downstream. The ledger D records the applied production and the length comparison for each displayed step, while B records that the inspected windows remain inside the linear bound attached to the input word and grammar rows.

The accepted-word classifier A is therefore available only after G, Σ, W, R, D, B have been displayed. The comparison row M may hand the finite surface to ContextFreeLanguage$^{\uparrow}$ or ContextFreeGrammar$^{\uparrow}$ consumers, but it cannot replace the local classifier by a host language set.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the refused objects are not carrier coordinates, no local NameCert obligation can export them. □

Theorem 7749.3 (Grammar acceptance scope)**.** *Every accepted-word read exported by a* ContextSensitiveLanguage$^{\uparrow}$ *packet factors through the* ContextSensitiveGrammar$^{\uparrow}$ *source row, the finite grammar-production ledger, the length-nondecreasing derivation ledger, and the linear-bounded acceptance route before any language-level consumer may inspect the accepted-word classifier. The handoff to* ContextFreeLanguage$^{\uparrow}$ *and* ContextFreeGrammar$^{\uparrow}$ *consumers preserves only that displayed grammar-and-acceptance route; it exports no host language set, unrestricted Turing-machine computation, quotient grammar equality, selected infinite derivation, or ambient decidability theorem.*

Proof. Start with the grammar source. By Definition 7749.1, every accepted-language packet reads G before it reads a production ledger or accepted-word classifier.

Apply Definition 7749.2. The production ledger R, derivation ledger D, and bounded route B are mandatory local obligations, so the accepted-word row A cannot be inspected until the noncontracting grammar route and length-nondecreasing derivation route have been replayed.

Now inspect the sibling comparison row M. It can expose the weaker context-free language or grammar-side surface only as a comparison of the displayed rows G, Σ, W, R, D, B, A; it has no coordinate for host language equality or a grammar quotient.

Transport and replay through H and C preserve the same order, while P and N record provenance and local naming. Thus every consumer receives the finite grammar acceptance scope stated in the theorem and no unrestricted machine or semantic language object. □

Falsifiable prediction: Every $\mathsf{ContextSensitiveLanguage}^{\uparrow}$ read factors through a $\mathsf{ContextSensitiveGrammar}^{\uparrow}$ source row, finite terminal and word rows, grammar-production ledger, length-nondecreasing derivation ledger, linear-bounded acceptance route, accepted-word classifier, sibling comparison row, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}$ rows.

Independence witness: contextfreelanguage, contextsensitivegrammar, contextfreegrammar: $\mathsf{ContextSensitiveLanguage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an accepted-language classifier, noncontracting grammar source, length-nondecreasing derivation ledger, and linear-bounded acceptance route, while the siblings separately record context-free acceptance, grammar production syntax, or context-free grammar derivation rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}$.

Constructive story: A $\mathsf{ContextSensitiveLanguage}^{\uparrow}$ packet is generated from a ContextSensitiveGrammarUp source row, finite terminal and word rows, grammar-production ledger, length-nondecreasing derivation ledger, linear-bounded acceptance route, accepted-word classifier, sibling comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7749.1, Definition 7749.2, and Definition 7749.3 seed the accepted context-sensitive language surface over grammar production, length-nondecreasing derivation, linear-bounded acceptance, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContextSensitiveLanguage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted Turing-machine semantics, host language equality, complement closure, grammar quotient equality, selected infinite derivations, or global decidability.

Upgrade path: Obligation closure requires checked source grammar admission, production-ledger exactness, derivation length monotonicity, linear-bounded acceptance replay, classifier transport, sibling comparison, provenance, and local naming for BEDC.Derived.ContextSensitiveLanguageUp.

Chapter 7750

A Concrete Naming Certificate for PoincareMirandaFinite$^{\uparrow}$

Following Poincare and Miranda, the PoincareMirandaFinite$^{\uparrow}$ packet records the finite cube-face sign data that a constructive Poincare–Miranda argument must display before any zero cell is read. It sits beside the finite Brouwer route of chapter 2030, the one-dimensional interval-return route of chapter 1437, and the continuous interval image handoff of chapter 1897. The packet names only a finite face-sign, subdivision, and readback certificate; it is not a host zero theorem, quotient equality of real names, selected root, open-cover compactness, countable choice, or ambient Real$^{\uparrow}$ completeness principle.

Definition 7750.1 (Poincare–Miranda finite carrier)**.** *A* PoincareMirandaFinite$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, F, S, D, I, L, B, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite cube row, carrying the displayed coordinate list, opposite face pairs, dyadic side windows, and the finite incidence table for the cube boundary.*
2. *F is the face-sign packet. For each displayed coordinate face it records the finite positive-side and negative-side sign rows read from the carried continuous map.*
3. *S is the boundary-sign stability row, requiring each face sign to remain stable under displayed* hsame *transport, dyadic refinement, and the finite window reads used by F.*
4. *D is the subdivision ledger, listing the dyadic cells, their face incidence, inherited sign rows, and the refinement route by which a sign conflict is localized.*
5. *I is the compact interval handoff row. It records that every coordinate edge and retained one-dimensional slice is read through the* CompactIntervalFixedPoint$^{\uparrow}$ *and* ContinuousIntervalImage$^{\uparrow}$ *surfaces before a Real-facing zero read is public.*
6. *L is the Brouwer-style labelled-cell row, routing the cube-face sign conflict through the finite labelled-subdivision discipline used by* BrouwerFixedPoint$^{\uparrow}$*.*
7. *B is the zero-cell refusal ledger. It records that any claimed zero cell must expose Q, F, S, D, I, L first and that every attempt to read a zero without those rows is outside the certificate.*
8. *W is the* StreamName$^{\uparrow}$ *finite-window row opened for cube coordinates, face probes, dyadic cells, interval slices, and zero-cell readback.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to those windows.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed candidate zero cell, available only after $Q, F, S, D, I, L, B, W, R$ have been replayed.*
11. *H records componentwise* hsame *transport for the cube row, face signs, stability row, subdivision ledger, interval handoff, labelled-cell row, refusal ledger, windows, readback, seal, replay, provenance, and local naming.*
12. *C records displayed* Cont *replay from a zero-cell request back through $E, R, W, B, L, I, D, S, F, Q$.*
13. *P is the* Pkg *provenance over* $\mathsf{PoincareMirandaFinite}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$, $\mathsf{ContinuousIntervalImage}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareMirandaFinite}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these finite coordinates. It has no coordinate for a selected host zero, an ambient cube theorem, quotient real equality, open-cover compactness, countable choice, Lean verification, or bridge checking.

Theorem 7750.2 (Poincare–Miranda finite NameCert obligations)**.** *For every accepted* $\mathsf{PoincareMirandaFinite}^{\uparrow}$ *carrier*

$$M = (Q, F, S, D, I, L, B, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareMirandaFinite}^{\uparrow}}$ *surface consists exactly of carrier admission, boundary-sign stability, subdivision-ledger exposure, compact interval handoff, Brouwer-style labelled-cell handoff, zero-cell refusal, finite-window readback, Real-seal nonescape, componentwise transport, displayed continuation replay, provenance, and local naming. In particular, a consumer may inspect a candidate zero cell only after the cube-face signs, stable boundary rows, dyadic subdivision ledger, interval slices, labelled-cell route, refusal ledger, stream windows, regular readback, and Real seal have all been displayed.*

Proof. Carrier admission is projection from Definition 7750.1. The visible packet lists the cube row Q, face-sign packet F, stability row S, subdivision ledger D, interval handoff I, labelled-cell row L, refusal ledger B, finite windows W, regular readback R, Real seal E, and the structural rows H, C, P, N.

Boundary-sign stability is read through F and S. The opposite-face signs are not semantic predicates on a host cube; they are displayed rows tied to the finite face incidence table in Q, and S records their preservation under the dyadic refinements and hsame transports used by the packet.

The subdivision obligation is the ledger D. It lists the dyadic cells and inherited face incidences before any sign conflict can be localized, while L routes the resulting labelled-cell read through the finite Brouwer-style surface rather than through an ambient fixed-point theorem.

The compact interval handoff is the row I. Coordinate edges and retained one-dimensional slices are exposed through the compact interval fixed-point and continuous interval image packets before their finite windows and regular rational readbacks are consumed.

Finally B, W, R, E, H, C, P, N enforce nonescape. The refusal ledger rejects any zero-cell read that bypasses the displayed rows; the window, readback, and seal rows expose the candidate as a finite Real-facing read; and the structural rows only transport, replay, source, and name the same packet. Thus no host zero selector, quotient equality, open-cover compactness, countable choice, Lean-side verification, or bridge datum is added. □

Theorem 7750.3 (Poincare–Miranda zero-cell refusal)**.** *Every Real-facing zero-cell read accepted by a* $\mathsf{PoincareMirandaFinite}^{\uparrow}$ *carrier factors through*

$$Q, F, S, D, I, L, B \longmapsto W, R, E, H, C, P, N.$$

The refusal ledger B is part of the route: a purported zero cell that bypasses the finite cube faces, boundary-sign stability, subdivision ledger, compact interval handoff, Brouwer-style labelled-cell row, finite windows, regular readback, or terminal $\mathsf{Real}^{\uparrow}$ *seal is not a read of this certificate.*

Proof. Begin with an accepted packet $M = (Q, F, S, D, I, L, B, W, R, E, H, C, P, N)$. The candidate zero-cell seal E is downstream of the finite-window and regular-readback rows W and R, so a consumer cannot inspect it as a free-standing Real object.

The readback rows are downstream of the geometric rows. The finite cube row Q supplies the face incidence table, F supplies the opposite-face sign rows, S preserves those signs under displayed refinement, D lists the dyadic cells, I exposes the compact interval slices, and L records the labelled-cell handoff.

The refusal ledger B binds those coordinates into a single public route. If a requested zero cell omits one of them, B classifies the request as outside the packet rather than repairing it with host topology or choice.

Transport, replay, provenance, and naming preserve the same route through H, C, P, N. Hence every accepted zero-cell read factors through the displayed finite packet and exports no selected host zero, quotient equality, open-cover compactness, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{PoincareMirandaFinite}^{\uparrow}$ zero-cell read displays a finite cube row, opposite face-sign rows, boundary-sign stability, a dyadic subdivision ledger, compact interval and continuous interval image handoff rows, a Brouwer-style labelled-cell row, a zero-cell refusal ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: brouwer-fixed-point, compactintervalfixedpoint, continuous-interval-image: $\mathsf{PoincareMirandaFinite}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries cube-face signs, boundary-sign stability, a dyadic subdivision ledger, one-dimensional interval handoffs, a labelled-cell handoff, a zero-cell refusal ledger, finite readback, and local NameCert routing as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareMirandaFinite}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareMirandaFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7750.1, Definition 7750.2, and Definition 7750.3 seed the finite cube-face sign route from Poincare–Miranda boundary data through subdivision, compact interval handoff, labelled-cell routing, refusal, finite readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareMirandaFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host zero existence, selected roots, quotient real equality, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-sign stability, subdivision-ledger exposure, compact interval handoff, labelled-cell routing, zero-cell refusal, finite readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PoincareMirandaFiniteUp.

Constructive story: A $\mathsf{PoincareMirandaFinite}^{\uparrow}$ packet is generated from a finite cube row, opposite face-sign rows, boundary-sign stability, a dyadic subdivision ledger, compact interval and continuous interval image handoffs, a Brouwer-style labelled-cell row, a zero-cell refusal ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7751

A Concrete Naming Certificate for $\mathsf{UltrafilterBoundary}^{\uparrow}$

Following Bourbaki and Kelley filter terminology, the $\mathsf{UltrafilterBoundary}^{\uparrow}$ packet records the finite boundary at which a filter or completion argument would have to leave BEDC's displayed rows in order to invoke a maximal filter. It sits beside the constructive refusal surface of chapter 6632 and the choice boundary of chapter 1872, and it is read by L10 completion routes such as chapter 3885, chapter 333, chapter 95, and chapter 126. The packet is only a finite refusal boundary; it is not an ultrafilter existence theorem, not a Boolean-prime-ideal theorem, and not a selected completion shortcut.

Definition 7751.1 (Ultrafilter boundary carrier)**.** *An* $\mathsf{UltrafilterBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, B, Q, L, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the inspected filter row, recording the finite base members and refinement requests exposed by a Cauchy-filter or completion-facing argument.*
2. *B is the finite Boolean-branch ledger, listing the finite subset or complement tests explicitly requested before a maximality claim would be needed.*
3. *Q is the quotient-refusal row, recording that no quotient Boolean algebra representative or host equality of filters is exported.*
4. *L is the L10 handoff row, tying any completion-facing read to* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*, and* $\mathsf{StreamName}^{\uparrow}$ *windows before the boundary is consumed.*
5. *R is the ultrafilter-refusal row. It records that the packet does not produce a maximal filter, an ultrafilter extension, a prime ideal, a countable-choice schedule, or a host-side selector.*
6. *H records componentwise* hsame *transport for F, B, Q, L, R, P, N.*
7. *C records displayed* Cont *replay from finite filter and completion rows to the refusal boundary.*
8. *P is the* Pkg *provenance over* $\mathsf{UltrafilterBoundary}^{\uparrow}$*,* $\mathsf{ConstructiveUltrafilterBoundary}^{\uparrow}$*,* $\mathsf{CountableChoiceBoundary}^{\uparrow}$*,* $\mathsf{CauchyFilter}^{\uparrow}$*,* $\mathsf{Completion}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UltrafilterBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, B, Q, L, R, H, C, P, N$. It has no coordinate for maximality, quotient completion equality, ultrafilter existence, or hidden choice.

Theorem 7751.2 (Finite boundary route)**.** *For every accepted* $\mathsf{UltrafilterBoundary}^{\uparrow}$ *carrier* $U = (F, B, Q, L, R, H, C, P, N)$*, every completion-facing filter read is routed through the displayed filter row* F*, finite Boolean-branch ledger* B*, quotient-refusal row* Q*, L10 handoff row* L*, refusal row* R*, and structural rows* H, C, P, N*. The packet exports no maximal-filter extension, no ultrafilter selector, no quotient-filter equality, and no host completion theorem.*

Proof. Project the carrier of Definition 7751.1. The only positive filter data are the finite inspected row F, the finite branch ledger B, and the L10 handoff row L.

The refusal rows Q and R record the missing endpoints. They prevent a consumer from rereading finite branch data as quotient Boolean equality, maximality, an ultrafilter extension, or a selected completion object.

Finally H, C, P, N preserve the same displayed rows as transport, replay, provenance, and local naming. Since the carrier has no further coordinate, every completion-facing filter read stays inside the finite boundary route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UltrafilterBoundary}^{\uparrow}}$**.**

Constructive story: An $\mathsf{UltrafilterBoundary}^{\uparrow}$ packet is generated from inspected filter rows, finite Boolean-branch ledgers, quotient-refusal rows, L10 CauchyFilter/Completion/StreamName handoff rows, ultrafilter-refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UltrafilterBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 7751.1 and Definition 7751.2 seed the finite no-choice boundary around L10 filter and completion arguments.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UltrafilterBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ultrafilter existence, maximal-filter selection, Boolean-prime-ideal transfer, quotient completion equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-ledger stability, quotient refusal, L10 handoff exactness, transport, replay, provenance, and local naming for BEDC.Derived.UltrafilterBoundaryUp.

Chapter 7752

A Concrete Naming Certificate for FiniteResidualConfluenceWindow$^{\uparrow}$

The FiniteResidualConfluenceWindow$^{\uparrow}$ packet realizes the MetaCIC confluence audit map as bounded residual-join evidence. It sits beside the parallel-diamond frontier of chapter 4238, the local-join ledger of chapter 4126, the residual critical-pair budget of chapter 7709, the residual-join determinacy packet of chapter 5970, and the bounded normal-equality checker of chapter 752. The chapter records a finite inspection window for local residual joins; it does not claim global confluence, unrestricted residual-substitution compatibility, subject reduction, quotient syntax equality, evaluator soundness, or kernel consistency.

Definition 7752.1 (Finite residual confluence window carrier)**.** *A* FiniteResidualConfluenceWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, R, K, J, B, O, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, naming the finite MetaCIC source and target fragments inspected before residual data are read.*
2. *R is the residual-frontier row, listing the bounded redex and residual branches visible inside the window.*
3. *K is the finite budget row, recording the depth, branch, and critical-pair bounds consumed by the window.*
4. *J is the candidate local-join row, carrying the displayed common-reduct candidates for the bounded residual branches.*
5. *B is the bounded checker row, routed through the bounded normal-equality checker before a candidate join is accepted.*
6. *O is the obstruction-retention row, recording that residual-substitution compatibility and arbitrary parallel diamond remain named premises outside the packet.*
7. *G is the TasteGate preparation row for future* Nontrivial *and* FieldFaithful *instances over the displayed carrier fields.*
8. *H records componentwise* hsame *transport for $T, R, K, J, B, O, G, P, N$.*

9. *C records displayed* Cont *replay through the typed window, residual frontier, finite budget, candidate join, bounded checker, obstruction, TasteGate preparation, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$, $\mathsf{MetaCICResidualCriticalPairBudget}^{\uparrow}$, $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, K, J, B, O, G, H, C, P, N$. It has no coordinate for a global Church–Rosser theorem, unrestricted substitution compatibility, subject reduction, quotient conversion equality, or a host evaluator.

Theorem 7752.2 (Finite residual confluence window obligations)**.** *For every accepted* FiniteResidualConfluenceWin *carrier $W = (T, R, K, J, B, O, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}}$ *surface consists exactly of typed-window exposure through T, residual-frontier exposure through R, finite budget exposure through K, candidate local-join exposure through J, bounded checker exposure through B, obstruction retention through O, TasteGate preparation through G, transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7752.1. The confluence-facing rows are T, R, K, J, B, O, and the structural rows are G, H, C, P, N.

Read the bounded evidence in order. The typed window T and residual frontier R identify the inspected peak, the budget row K bounds the branch search, and the candidate local-join row J names the common-reduct candidates that survive that finite window.

The bounded checker row B verifies only the displayed candidate comparison. The obstruction row O keeps residual-substitution compatibility and arbitrary parallel diamond outside the packet, while G, H, C, P, N preserve the same finite carrier fields for future TasteGate, transport, replay, provenance, and local naming obligations. □

Theorem 7752.3 (Finite residual confluence window non-escape)**.** *Every confluence-audit consumer of an accepted* $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$ *packet receives only bounded local join evidence through $T, R, K, J, B, O, G, H, C, P, N$. The packet may certify that a displayed residual peak has a bounded candidate join, but it cannot erase O, manufacture residual-substitution compatibility, prove a full parallel diamond, export arbitrary closed-term confluence, or supply subject reduction.*

Proof. Start with the typed window and residual frontier. They name only the finite source, target, redex, and residual branches inspected by the packet.

Use the budget and candidate rows next. The rows K and J restrict candidate common reducts to the displayed window, and the bounded checker row B compares only those candidates.

Finally read the obstruction and structural rows. The obstruction row O records the missing global inputs, while G, H, C, P, N prepare field-faithful TasteGate checking, transport, replay, source, and name the same finite surface. Thus the consumer receives bounded residual-join evidence and nothing stronger. □

Falsifiable prediction: A confluence-audit read that accepts $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$ while omitting any of $T, R, K, J, B, O, G, H, C, P, N$ refutes the carrier surface.

Independence witness: metacic-parallel-diamond-frontier, metacic-local-join-ledger, metacic-residual-critical-pair-budget, metacic-residual-join-determinacy, bounded-normal-equality-checker:

$\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a typed window, residual frontier, finite budget, candidate local join, bounded checker, obstruction retention, TasteGate preparation, transport, replay, provenance, and local NameCert row.

The Lean follow-up for $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$ must provide Nontrivial and FieldFaithful instances over the displayed carrier fields before the packet can be consumed as checked confluence evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$ packet is generated from typed-window rows, residual-frontier rows, finite budget rows, candidate local joins, bounded checker rows, obstruction-retention rows, TasteGate preparation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7752.1, Definition 7752.2, and Definition 7752.3 seed the bounded residual-join evidence surface for the MetaCIC confluence audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, unrestricted residual-substitution compatibility, parallel diamond, subject reduction, quotient syntax equality, Lean verification, or bridge checking for $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-frontier exposure, finite budget exactness, candidate local-join exactness, bounded checker exactness, obstruction retention, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.FiniteResidualConfluenceWindowUp.

Chapter 7753

A Concrete Naming Certificate for $\mathsf{NeighbourhoodSystem}^{\uparrow}$

Following Kelley and Bourbaki, a neighbourhood system is the pointwise local presentation of topology by neighbourhood rows and local bases. The $\mathsf{NeighbourhoodSystem}^{\uparrow}$ packet records that standard presentation as finite BEDC NameCert data: it sits beside the topology carrier of chapter 88, the filter-basis interface of chapter 1601, the local filter route of chapter 4133, the countable-base surface of chapter 1901, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is a finite local-system interface for topology and completion consumers; it is not a host powerset of neighbourhoods, a quotient filter, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7753.1 (Neighbourhood system carrier)**.** *A* $\mathsf{NeighbourhoodSystem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, N, B, T, L, W, R, E, H, C, P, Q)$$

with the following displayed rows:

1. *X is the point row, naming the displayed source point or finite point-window at which the local system is read.*
2. *N is the neighbourhood-window row, listing finite neighbourhood tokens around X together with their displayed containment and refinement requests.*
3. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row generated by the finite neighbourhood windows and their meet/refinement witnesses.*
4. *T is the topology-compatibility row, routing the neighbourhood windows through the open-set carrier and topology provenance of chapter 88.*
5. *L is the local-basis row, recording the basis tokens that refine each displayed neighbourhood window and the second-countable handoff when a countable-base consumer is present.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when local neighbourhood reads are sampled by completion-facing consumers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the point, neighbourhood, basis, topology, window, and readback rows have been displayed.*

9. *H records componentwise* hsame *transport for the point, neighbourhood-window, filter-base, topology, local-basis, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a local neighbourhood request through X, N, B, T, L, W, R, E.*
11. *P is the* Pkg *provenance over* $\mathsf{NeighbourhoodSystem}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{NeighborhoodFilter}^{\uparrow}$, $\mathsf{SecondCountable}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *Q is the local* $\mathsf{NameCert}_{\mathsf{NeighbourhoodSystem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, N, B, T, L, W, R, E, H, C, P, Q$. It has no coordinate for host powersets of neighbourhoods, quotient filters, selected limits, countable choice, host equality of topology structures, or ambient Real completeness.

Theorem 7753.2 (Neighbourhood system NameCert obligations)**.** *For every accepted* $\mathsf{NeighbourhoodSystem}^{\uparrow}$ *carrier $S = (X, N, B, T, L, W, R, E, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{NeighbourhoodSystem}^{\uparrow}}$ *surface consists exactly of point exposure, neighbourhood-window exposure, filter-base generation, topology compatibility, local-basis refinement, finite-window exposure, RegSeqRat readback, Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must display*

$$X, N, B, T, L \longmapsto W, R, E, H, C, P, Q$$

before a Real or topology consumer can inspect the route.

Proof. Project the carrier of Definition 7753.1. The accepted packet exposes exactly the rows $X, N, B, T, L, W, R, E, H, C, P, Q$.

The local-topology rows are upstream. The point row X, neighbourhood-window row N, filter-base row B, topology-compatibility row T, and local-basis row L jointly present the neighbourhood system as finite data tied to the sibling topology, filter-base, neighbourhood-filter, and second-countable routes.

The completion-facing rows are downstream. StreamName windows, RegSeqRat readback, and the terminal Real seal are read only after the local system rows have been displayed. Transport, replay, provenance, and local naming preserve that same order, so no host powerset, quotient filter, selected limit, countable choice, or ambient Real-completeness coordinate is introduced. □

Theorem 7753.3 (Neighbourhood system filter-basis route)**.** *Every local-filter or completion-facing consumer of an accepted* $\mathsf{NeighbourhoodSystem}^{\uparrow}$ *carrier reads the neighbourhood system through the route*

$$\mathsf{Topology}^{\uparrow}, \mathsf{NeighbourhoodSystem}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow}, \mathsf{NeighborhoodFilter}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The route exports finite neighbourhood-window and local-basis data only. It does not export a host powerset of all neighbourhoods, a quotient filter object, a chosen limit, countable choice, or ambient Real completeness.

Proof. Begin with the NameCert obligations of Definition 7753.2. They force every accepted consumer to expose the point row, neighbourhood windows, generated filter-base row, topology compatibility, and local-basis refinement before any downstream read.

The local filter route is horizontal. The generated base is consumed by chapter 1601 and then by chapter 4133; a second-countable consumer may additionally read the displayed local-basis row through chapter 1901.

Finally the completion route passes through chapter 126, chapter 301, and chapter 38. These siblings receive finite windows, regular rational readbacks, and a terminal Real seal only after the neighbourhood-system rows are public, so the route cannot supply host neighbourhood powersets, quotient filters, selected limits, choice schedules, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{NeighbourhoodSystem}^{\uparrow}$ completion-facing read exposes a point row, neighbourhood-window row, generated FilterBase row, topology-compatibility row, local-basis row, StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row before it can serve a topology, local-filter, or completion consumer.

Independence witness: topology, filterbase, neighborhood-filter, second-countable, streamname, regseqrat, real: none is bijective with $\mathsf{NeighbourhoodSystem}^{\uparrow}$ because this packet jointly carries pointwise neighbourhood windows, generated filter-base data, topology compatibility, local-basis refinement, finite completion windows, readback, Real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{NeighbourhoodSystem}^{\uparrow}}$.

Constructive story: A $\mathsf{NeighbourhoodSystem}^{\uparrow}$ packet is generated from a point row, neighbourhood-window row, FilterBase row, topology-compatibility row, local-basis row, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NeighbourhoodSystem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7753.1, Definition 7753.2, and Definition 7753.3 seed the finite neighbourhood-system route from topology and local bases through FilterBase, NeighborhoodFilter, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NeighbourhoodSystem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets of neighbourhoods, quotient filters, selected limits, countable choice, host equality of topology structures, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked point exposure, neighbourhood-window exposure, filter-base generation, topology compatibility, local-basis refinement, finite-window exposure, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NeighbourhoodSystemUp.

Chapter 7754

A Concrete Naming Certificate for $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$

Following Bishop and Bridges on nested closed intervals and regular Cauchy completion, the $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ packet records the finite route by which a descending located interval family, dyadic diameter ledger, regular rational midpoint readback, finite stream windows, and terminal real seal are offered to Real and Completion consumers. It sits on the completion spine of chapter 38, chapter 301, chapter 126, and chapter 291. The packet names the choice-free Cantor intersection handoff visible to regular Cauchy readers; it is not a quotient real, an arbitrary closed-set intersection theorem, countable choice, trichotomy, open-cover compactness, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7754.1 (Cantor intersection principle carrier)**.** *A* $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, W, R, E, J, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter ledger, recording the inspected dyadic precision, the nested interval endpoints visible at that precision, and the finite proof that the displayed diameters are below the requested tolerance.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing only the bounded interval indices and endpoint windows read by the consumer.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *midpoint readback row obtained from D and W; it records the regular rational name determined by the displayed nested windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic ledger, stream windows, and regular rational readback have been replayed.*
5. *J is the intersection-claim row, recording that every displayed interval window contains the same readback route and that later windows refine earlier ones.*
6. *H records componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, Real seal, intersection row, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion request through D, W, R, E, J, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CantorIntersectionPrinciple}^{\uparrow}}$ *row.*

The carrier predicate compares accepted packets only through $D, W, R, E, J, H, C, P, N$. It has no coordinate for a selected point by countable choice, quotient stream equality, host real equality, arbitrary closed subsets, open-cover compactness, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7754.2 (Cantor intersection principle NameCert obligations)**.** *For every accepted* CantorIntersectionPrinc *carrier $I = (D, W, R, E, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionPrinciple}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed dyadic diameter ledger, finite stream-window row, regular rational midpoint readback, terminal Real seal, intersection row, transport, replay, provenance, and local naming;*
2. *nested-window exactness, requiring every Real or Completion read to inspect the same finite D, W interval window before it reaches R;*
3. *regular-readback stability, requiring the midpoint route to be consumed as a* $\mathsf{RegSeqRat}^{\uparrow}$ *name before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is visible;*
4. *intersection nonescape, requiring J to record refinement of displayed windows without adding an arbitrary closed-set carrier;*
5. *ledger refusal, excluding countable choice, quotient streams, host equality, trichotomy, open-cover compactness, selected representatives, and ambient Real completeness.*

Proof. Carrier admission is projection from Definition 7754.1. The projected rows are exactly the dyadic diameter ledger D, stream windows W, regular midpoint readback R, terminal Real seal E, intersection row J, and structural rows H, C, P, N.

Nested-window exactness is read through D and W. The consumer sees only the bounded endpoint windows and the dyadic diameter comparison stored in the packet, so there is no separate source from which a point could be chosen.

The regular-readback row R repacks the displayed midpoint route as the $\mathsf{RegSeqRat}^{\uparrow}$ handoff used by chapter 301. The terminal seal E is therefore downstream of the same finite route and cannot be detached from it.

The intersection and refusal rows follow from the remaining coordinates. Row J records refinement of the displayed windows, while H, C, P, N transport, replay, source, and name that route; none of these rows stores countable choice, quotient equality, host equality, trichotomy, open-cover compactness, selected representatives, or ambient completeness. □

Theorem 7754.3 (Cantor intersection principle completion route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ *carrier $I = (D, W, R, E, J, H, C, P, N)$ must factor through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes a nested located interval family by dyadic diameter windows, then reads the regular rational midpoint name, and only then reaches the terminal Real seal. It exports no quotient-real construction, selected representative, countable-choice schedule, arbitrary closed-set intersection principle, trichotomy, open-cover compactness, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the displayed rows D and W. They bind the inspected precision, endpoint windows, and diameter comparison before any completion-facing name can be read.

The row R consumes exactly those displayed windows as a regular rational readback. Thus the completion-facing handoff has already passed through the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ surfaces before the Real seal is available.

Finally use the intersection row J together with H, C, P, N. These rows record refinement, transport, replay, provenance, and local naming for the same finite route. Since the carrier has no row for quotient reals, selected representatives, countable choice, arbitrary closed sets, trichotomy, open-cover compactness, host equality, or ambient completeness, every consumer remains inside the stated completion route. □

Falsifiable prediction: Every $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ Real-completion read factors through one DyadicRatCore diameter ledger, one StreamName finite-window row, one RegSeqRat midpoint readback row, one terminal $\mathsf{Real}^{\uparrow}$ seal, one intersection-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real: $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the nested diameter ledger, finite interval windows, regular midpoint readback, Real seal, refinement row, transport, replay, provenance, and local NameCert rows as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorIntersectionPrinciple}^{\uparrow}$ packet is generated from a DyadicRatCore diameter ledger, StreamName finite interval windows, RegSeqRat midpoint readback, a terminal RealUp seal, an intersection-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorIntersectionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7754.1, Definition 7754.2, and Definition 7754.3 seed the finite Cantor-intersection completion route from dyadic interval diameters through StreamName, RegSeqRat, and the terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorIntersectionPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, selected representatives, countable choice, arbitrary closed-set intersections, trichotomy, open-cover compactness, host equality, full $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window exactness, regular-readback stability, Real-seal nonescape, intersection refinement, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionPrinci

Chapter 7755

A Concrete Naming Certificate for $\mathsf{BirkhoffContraction}^{\uparrow}$

Following Birkhoff's Hilbert projective metric contraction theorem, the $\mathsf{BirkhoffContraction}^{\uparrow}$ packet records the finite positive-cone route by which a contraction coefficient is read before any fixed-point or Perron–Frobenius conclusion is available. It sits over the metric carrier of chapter 57, the vector-space source of chapter 47, the positive-radius ledger of chapter 1587, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite Hilbert-projective contraction budget; it is not a host fixed-point theorem, an eigenvector selection principle, a completed cone quotient, or an ambient compactness argument.

Definition 7755.1 (Birkhoff contraction carrier)**.** *A* $\mathsf{BirkhoffContraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (V, K, M, \Delta, T, \tau, R, E, H, C, P, N)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *source row carrying the finite linear operations inspected by the positive cone request.*
2. *K is the positive cone row, represented only by displayed positive-radius and order-comparison data over* $\mathsf{PositiveReal}^{\uparrow}$*.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row naming the Hilbert projective metric observations used by the packet.*
4. *Δ is the finite diameter ledger for the image of the displayed positive cone under the operator row.*
5. *T is the positive operator row, recording only the displayed cone-preserving action on the rows already exposed.*
6. *τ is the contraction-budget row, a* $\mathsf{PositiveReal}^{\uparrow}$ *or regular rational readback witness below the unit bound.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used to compare the displayed diameter and contraction budget.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the Hilbert-metric contraction estimate.*
9. *H records componentwise* hsame *transport of all displayed rows.*
10. *C records displayed* Cont *replay through $V, K, M, \Delta, T, \tau, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{BirkhoffContraction}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffContraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, K, M, \Delta, T, \tau, R, E, H, C, P, N$. There is no coordinate for a selected eigenvector, quotient projective point, host compactness theorem, fixed-point conclusion, or ambient completed cone.

Lean4 ✓ `BEDC.Derived.BirkhoffContractionUp.BirkhoffContractionTasteGate single carrier alignment`

Theorem 7755.2 (Birkhoff contraction NameCert obligations)**.** *For every accepted* $\mathsf{BirkhoffContraction}^{\uparrow}$ *carrier $B = (V, K, M, \Delta, T, \tau, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BirkhoffContraction}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the vector source, positive cone, Hilbert projective metric row, finite image-diameter ledger, positive operator row, contraction-budget row, rational readback, terminal real seal, transport, replay, provenance, and local naming row;*
2. *common-cone discipline, requiring K, M, Δ, T, τ to be read over the same displayed positive cone and vector-space source;*
3. *budget exactness, requiring the contraction estimate to pass through the diameter ledger Δ, the budget row τ, the regular readback R, and the real seal E;*
4. *replay stability, requiring transport and continuation rows H, C to preserve the same budget route before P, N name the packet;*
5. *ledger refusal, excluding selected fixed points, eigenvectors, projective quotient representatives, host compactness, completed cones, and Perron–Frobenius conclusions.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 7755.1. Its displayed rows are exactly $V, K, M, \Delta, T, \tau, R, E, H, C, P, N$, so carrier admission exposes only the finite vector, cone, metric, diameter, operator, budget, readback, seal, transport, replay, provenance, and naming data.

The common-cone and budget rows force every contraction read to start from V, K, M, pass through Δ, T, τ, and then read R before the terminal real seal E. The structural rows H, C, P, N transport and name that same route without creating an additional object.

Since the carrier has no coordinate for a selected eigenvector, projective quotient representative, host fixed point, compactness theorem, completed cone, or Perron–Frobenius conclusion, the listed rows exhaust the local NameCert surface. □

Theorem 7755.3 (Birkhoff Hilbert-metric budget)**.** *Every Hilbert-projective contraction read exported by an accepted* $\mathsf{BirkhoffContraction}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{VecSpace}^{\uparrow}, \mathsf{PositiveReal}^{\uparrow}, \mathsf{Met}^{\uparrow} \longmapsto \Delta, T, \tau \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N.$$

Thus a downstream metric or completion-facing consumer receives only the displayed vector-space source, positive-cone ledger, Hilbert projective metric observations, finite image-diameter budget, positive operator row, contraction coefficient readback, terminal real seal, componentwise transport, continuation replay, provenance, and local naming. It receives no fixed point, selected eigenline, quotient projective representative, completed cone, host compactness theorem, or ambient Perron–Frobenius principle.

Proof. Start with the carrier rows of Definition 7755.1. The only metric-facing coordinates are M, Δ, τ, R, E, and the only source rows for them are V, K, T.

Apply the obligation surface of Definition 7755.2. The common-cone row keeps the Hilbert projective metric observations attached to the displayed vector source and positive cone, while budget exactness routes the contraction coefficient through Δ, τ, R, E.

Finally transport through H and replay through C. Since P and N only record provenance and local naming for the same finite packet, the contraction budget remains a finite Hilbert-metric read and cannot export a host fixed-point or eigenvector conclusion. □

Falsifiable prediction: An accepted $\mathsf{BirkhoffContraction}^{\uparrow}$ read is refuted if it exports a Hilbert-projective contraction estimate without displaying the vector-space source, positive-cone ledger, Hilbert metric row, finite image-diameter ledger, positive operator row, contraction-budget row, regular rational readback, terminal real seal, transport, replay, provenance, and local naming.

Independence witness: vecspace, metric, positivereal, regseqrat, real: none alone is bijective with $\mathsf{BirkhoffContraction}^{\uparrow}$ because the packet jointly records positive-cone source data, Hilbert projective metric observations, finite image-diameter budgeting, positive operator action, contraction readback, terminal real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffContraction}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffContraction}^{\uparrow}$ packet is generated from a VecSpaceUp row, a positive-cone row over PositiveRealUp data, a MetricSpaceUp Hilbert-projective metric row, a finite image-diameter ledger, a positive operator row, a contraction-budget row, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffContraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7755.1, Definition 7755.2, and Definition 7755.3 seed the finite Hilbert-projective contraction route from displayed positive-cone metric data to a Real contraction-budget seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffContraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close fixed-point existence, selected eigenvectors, projective quotient representatives, completed cone compactness, Perron–Frobenius conclusions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-cone discipline, Hilbert-metric budget exactness, replay stability, refusal exactness, provenance accounting, and local naming for BEDC.Derived.BirkhoffContractionUp.

Chapter 7756

A Concrete Naming Certificate for $\mathsf{CauchyModulusCertificate}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names with explicit moduli, the $\mathsf{CauchyModulusCertificate}^{\uparrow}$ packet records the finite threshold data by which a convergence modulus is displayed before a regular rational readback or terminal real-name seal is consumed. It sits after the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal $\mathsf{Real}^{\uparrow}$ boundary of chapter 38, and the convergence-modulus ledger of chapter 2074. The packet names a finite certificate route for L10 Real and Completion consumers; it is not a selected limit, quotient Cauchy name, countable-choice schedule, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7756.1 (Cauchy modulus certificate carrier)**.** *A* $\mathsf{CauchyModulusCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, W, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance request row.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite tail-window row selected for the tolerance request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed window.*
4. *M is the convergence-modulus certificate row, recording that every later window accepted by the packet satisfies the request named by D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after D, W, Q, M have been displayed.*
6. *H records componentwise* hsame *transport for tolerance requests, finite windows, regular readback, modulus certificate rows, Real seals, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a tolerance request through the window, readback, modulus certificate, and Real seal route.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusCertificate}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealModulusOfConvergence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, W, Q, M, E, H, C, P, N$. No coordinate stores quotient stream equality, selected representatives, selected limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyModulusCertificateUp.CauchyModulusCertificateTasteGate single carrier alignment`

Theorem 7756.2 (Cauchy modulus certificate NameCert obligations)**.** *For every accepted* CauchyModulusCertificat *carrier* $K = (D, W, Q, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusCertificate}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission, finite window admission, regular rational readback, convergence-modulus certificate exposure, Real seal handoff, componentwise stability transport, displayed replay, provenance, local naming, and ledger refusal for quotient streams, selected representatives, selected limits, countable choice, host real equality, and ambient Real completeness.*

Proof. Project the carrier of Definition 7756.1. The displayed route begins with the dyadic tolerance request D, then exposes the finite window W, the regular readback Q, and the convergence-modulus certificate row M before the terminal seal E can be consumed.

Componentwise transport through H and replay through C preserve that order. The provenance and naming rows P, N source and name the same finite route, rather than adding analytic data outside the carrier.

The refusal ledger is the complement of the displayed coordinates. Since the carrier has no row for quotient stream equality, selected representatives, selected limits, countable choice, host real equality, or ambient completeness, no local NameCert obligation can export those objects. □

Theorem 7756.3 (Cauchy modulus certificate regular-Cauchy and Real route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{RealModulusOfConvergence}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusCertificate}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RealModulusOfConvergence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $D, W, Q, M, E, H, C, P, N$*. Thus the certificate supplies a named regular-Cauchy and Real handoff without asserting Real completeness, quotient Cauchy-name equality, selected limits, or countable-choice schedules.*

Proof. Start from an accepted carrier $K = (D, W, Q, M, E, H, C, P, N)$. The tolerance row D and finite window row W must be displayed before any regular rational readback is available.

The readback row Q is then the only route into $\mathsf{RegSeqRat}^{\uparrow}$. The modulus row M records the convergence certificate consumed by chapter 2074, and the terminal seal E is downstream of that certificate row.

Finally inspect H, C, P, N. They transport, replay, source, and name the same finite route, so any Real or Completion consumer receives only the displayed regular-Cauchy handoff. The carrier inventory contains no completeness, quotient, selected-limit, choice, or host-equality coordinate, and therefore cannot export such a principle. □

Falsifiable prediction: A $\mathsf{CauchyModulusCertificate}^{\uparrow}$ read is refuted whenever a Real or Completion consumer uses a convergence-modulus certificate without displaying the DyadicRatCore tolerance request, StreamName finite window, RegSeqRat readback, RealModulusOfConvergence certificate row, Real seal, componentwise transport, replay, provenance, and local naming rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, realmodulusofconvergence: none alone is bijective with $\mathsf{CauchyModulusCertificate}^{\uparrow}$ because the certificate jointly records a tolerance request, a finite tail window, a regular rational readback, a convergence-modulus row, a Real seal, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusCertificate}^{\uparrow}}$**.**

Constructive story: A CauchyModulusCertificate$^{\uparrow}$ packet is generated from a DyadicRatCore tolerance request, a StreamName finite tail window, a RegSeqRat readback row, a RealModulusOfConvergence certificate row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: TheoryGate(NameCert$_{\text{CauchyModulusCertificate}\uparrow}$, seed)

Scope closed: Definition 7756.1, Definition 7756.2, and Definition 7756.3 seed the finite certificate route from dyadic tolerance requests to regular Cauchy readback and Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{CauchyModulusCertificate}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient Cauchy-name equality, selected limits, selected representatives, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked tolerance admission, window admission, regular readback, convergence-modulus certificate exposure, Real-seal handoff, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.CauchyModulusCertificateUp.

Chapter 7757

A Concrete Naming Certificate for $\mathsf{InducedCharacter}^{\uparrow}$

Following Serre on finite-group characters and Fulton–Harris on induction and restriction, the $\mathsf{InducedCharacter}^{\uparrow}$ packet records the character-level coset-sum construction as finite NameCert data. It consumes the finite group source of chapter 41, the subgroup source of chapter 80, the coset ledger of chapter 3976, the finite action rows of chapter 3662, the trace and class-function surface of chapter 245, the value-row consumer of chapter 3574, the induction–restriction packet of chapter 247, and the reciprocity provenance of chapter 5806. The packet names only the displayed coset-sum character row, its transport, its class-function stability, and its handoff to induction and reciprocity consumers; it does not assert irreducible decomposition, Schur orthogonality, a completed character table, or a host category of representations.

Definition 7757.1 (InducedCharacter carrier)**.** *An* $\mathsf{InducedCharacter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{C} = (G, H, Q, V, \chi, \iota, \sigma, \kappa, \rho, \lambda, P, N)$$

with the following displayed rows:

1. *G is the consumed finite* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *source row.*
2. *H is the consumed* $\mathsf{NameCert}_{\mathsf{Subgroup}^{\uparrow}}$ *row naming the subgroup inclusion inside the same finite group source.*
3. *Q is the consumed* $\mathsf{NameCert}_{\mathsf{CosetSpace}^{\uparrow}}$ *row listing the finite left-coset representatives used only as display indices.*
4. *V is the consumed* $\mathsf{NameCert}_{\mathsf{FiniteGroupRepresentation}^{\uparrow}}$ *row whose restricted trace row supplies the source character on H.*
5. *χ is the consumed* $\mathsf{NameCert}_{\mathsf{CharacterTheory}^{\uparrow}}$ *row naming the source class-function and trace surface.*
6. *ι is the displayed* $\mathsf{NameCert}_{\mathsf{InducedRep}^{\uparrow}}$ *induction row.*
7. *σ is the finite coset-sum ledger assigning to each displayed group row the finite sum of the source-character values over the accepted representative rows of Q.*
8. *κ is the class-function stability row, recording conjugation transport of σ through G, H, Q, and χ.*

9. *ρ is the* $\mathsf{NameCert}_{\mathsf{FrobeniusReciprocity}^{\uparrow}}$ *provenance row tying the character-level handoff to the induction–restriction comparison.*

10. *λ is the downstream consumer ledger for* $\mathsf{CharacterTable}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, *and* $\mathsf{FrobeniusReciprocity}^{\uparrow}$ *reads.*

11. *P is the* Pkg *provenance over the consumed rows,* BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}$ *row.*

The carrier contains no host induced representation, no selected representative object beyond the displayed coset ledger, no irreducible-character decomposition, and no ambient character algebra outside these rows.

Lean4 (definition) `BEDC.Derived.InducedCharacterUp.InducedCharacterUp`

Theorem 7757.2 (InducedCharacter NameCert obligations)**.** *For every accepted* $\mathsf{InducedCharacter}^{\uparrow}$ *packet*

$$\mathcal{C} = (G, H, Q, V, \chi, \iota, \sigma, \kappa, \rho, \lambda, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission exposes the displayed group, subgroup, coset-space, finite-representation, character-theory, induced-representation, coset-sum, class-stability, reciprocity, consumer, provenance, and local naming rows of Definition 7757.1;*

2. *coset-representative invariance requires the value of σ to be unchanged under* hsame *transport of the displayed representative rows in Q, with every replacement read still sourced by H and G;*

3. *class-function stability requires the conjugation transport row κ to preserve the induced value row through the trace and class-function surface χ;*

4. *restriction/induction handoff requires every* $\mathsf{InducedRep}^{\uparrow}$ *read to pass through the displayed induction row ι and the same subgroup, representation, and coset ledgers used by σ;*

5. *reciprocity provenance requires every Frobenius comparison read to pass through ρ and the character-pairing boundary of* $\mathsf{FrobeniusReciprocity}^{\uparrow}$, *with no bypass through a host adjunction or semisimple decomposition.*

Proof. Project the carrier rows of Definition 7757.1. Carrier admission is the displayed tuple $\mathcal{C}$ itself, so every source and consumer row is already visible in finite BHist form.

For coset-representative invariance, compare two accepted representative ledgers in Q. The transport is componentwise hsame over the consumed group and subgroup rows, and each summand is still read through the source character row χ. Reindexing the finite ledger therefore changes only the display of the summation, not the named character row.

Class-function stability is the row κ. It transports the coset-sum value along conjugation in G and checks that the source trace row remains inside the class-function surface named by $\mathsf{CharacterTheory}^{\uparrow}$.

For the induction handoff, route every representation-level read through ι and the public boundary of chapter 247. For reciprocity provenance, route every comparison read through ρ and the finite character-pairing boundary of chapter 5806. Repacking these projected rows with λ, P, and N gives exactly the five listed obligations. □

Theorem 7757.3 (InducedCharacter table consumer boundary)**.** *Any* $\mathsf{CharacterTable}^{\uparrow}$ *consumer of an accepted* $\mathsf{InducedCharacter}^{\uparrow}$ *packet may read only the finite group row* G*, subgroup row* H*, coset ledger* Q*, source character row* χ*, coset-sum row* σ*, class-stability row* κ*, and consumer ledger* λ*. It may not import an irreducible decomposition, Schur orthogonality row, completed character table, host representative selector, or ambient representation category unless that row is already present in the displayed packet.*

Proof. Project the consumer request through the displayed carrier. The character-table consumer receives the group and class-function rows only through G and χ, and it receives coset indexing only through Q.

The induced value row is σ, while its class-function stability is κ. The consumer ledger λ records exactly the downstream reads exposed to $\mathsf{CharacterTable}^{\uparrow}$ together with the representation-induction and reciprocity handoff rows.

No remaining coordinate of $\mathcal{C}$ names an irreducible decomposition, a Schur row, a completed table, a representative selector, or a host representation category. Hence the table-facing boundary is precisely the finite packet described above. □

Closure status for $\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7757.1, Definition 7757.2, and Definition 7757.3 seed the finite coset-sum character carrier, its five NameCert obligations, and its character-table consumer boundary over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{CosetSpace}^{\uparrow}$, $\mathsf{FiniteGroupRepresentation}^{\uparrow}$, $\mathsf{CharacterTheory}^{\uparrow}$, $\mathsf{CharacterTable}^{\uparrow}$, $\mathsf{InducedRep}^{\uparrow}$, and $\mathsf{FrobeniusReciprocity}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InducedCharacter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close irreducible decomposition, Schur orthogonality, completed character-table computation, host representative selection, host representation categories, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coset-representative invariance, class-function stability, restriction/induction handoff, and reciprocity provenance for the same finite packet.

Constructive story: An $\mathsf{InducedCharacter}^{\uparrow}$ packet is generated from finite group and subgroup sources, a finite coset-space ledger, a represented source character, an induced-representation handoff, a finite coset-sum ledger, class-function transport, Frobenius reciprocity provenance, downstream consumer rows, package provenance, and a local NameCert row.

Chapter 7758

A Concrete Naming Certificate for $\mathsf{CompletionModulusExtractor}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CompletionModulusExtractor}^{\uparrow}$ packet records the finite extraction surface by which completion-facing data exposes a modulus row before any completed object is consumed. It sits beside chapter 1506, chapter 1501, chapter 301, chapter 291, chapter 126, and chapter 38: those chapters supply the metric-completion, filter-basis, regular rational, dyadic tolerance, finite-window, and real-seal rows, while this chapter names the extractor that keeps the modulus route finite and inspectable.

Definition 7758.1 (Completion modulus extractor carrier)**.** *A* $\mathsf{CompletionModulusExtractor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, B, S, R, D, W, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{MetricCompletion}^{\uparrow}$ *row naming the completion-facing request.*
2. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row that records the finite basis through which the source is inspected.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule opened by the extractor.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the extracted regular observations.*
6. *W is the extracted modulus row, recording for each admitted precision a finite window and dyadic tolerance witness.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after B, S, R, D, W have been displayed.*
8. *H records componentwise* hsame *transport for source, basis, window, readback, dyadic, modulus, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a completion request through the same finite extractor rows.*
10. *P is the* Pkg *provenance over* $\mathsf{CompletionModulusExtractor}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusExtractor}^{\uparrow}}$ *row.*

The classifier accepts exactly packets carrying these rows. It exports no quotient completion, selected limit, countable-choice selector, host real equality, hidden completeness principle, or modulus not displayed in W.

Lean4 (definition) `BEDC.Derived.CompletionModulusExtractorUp`

Theorem 7758.2 (Completion modulus extractor NameCert obligations)**.** *For every accepted* $\mathsf{CompletionModulusExtractor}^{\uparrow}$ *carrier*

$$E = (M, B, S, R, D, W, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionModulusExtractor}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-request readback, basis readback, finite-window admission, regular rational readback, dyadic tolerance visibility, extracted-modulus visibility, terminal real sealing, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing consumer must read the extracted modulus row W through*

$$M, B, S, R, D, W, L, H, C, P, N$$

and through no hidden completion or choice coordinate.

Proof. Project the carrier of Definition 7758.1. The source row M names the completion-facing request, while B, S, R, D expose the finite basis, window, regular readback, and dyadic tolerance data from which a modulus can be read.

Inspect the extracted row W. It is the only coordinate whose role is to present the precision-to-window and precision-to-tolerance schedule, so any consumer asking for modulus data must pass through that displayed row.

Finally read L, H, C, P, N. The terminal real seal is downstream of the modulus display, and the structural rows transport, replay, source, and locally name the same finite route. Since no coordinate of E stores a quotient completion, selected limit, countable-choice selector, host equality, or hidden completeness principle, the listed rows exhaust the local NameCert obligation surface. □

Theorem 7758.3 (Completion modulus extractor finite route)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompletionModulusExtractor}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{CauchyFilterBasis}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto W \longmapsto \mathsf{Real}^{\uparrow}$$

implemented by the displayed rows $M, B, S, R, D, W, L, H, C, P, N$. The route exposes modulus data as finite NameCert evidence; it does not select a completed point, quotient Cauchy names, invoke countable choice, prove host real equality, or assert ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with M and B. The completion request is admitted only through the displayed metric-completion row, and the Cauchy-filter basis row fixes the finite observations the extractor may open.

Next inspect S, R, D, W. The stream windows determine the finite observations, the regular rational row records the readback, the dyadic ledger supplies tolerance comparison, and W packages those data as the visible modulus row.

The final rows L, H, C, P, N preserve the same route for Real-facing consumers. They seal the terminal real row, transport displayed components, replay the finite request, record provenance, and name the local packet. None of these rows adds quotient data, a selected point, choice, host equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionModulusExtractor}^{\uparrow}$ packet is generated from MetricCompletion requests, CauchyFilterBasis rows, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, an extracted modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7758.1, Definition 7758.2, and Definition 7758.3 seed the finite extraction route from completion requests through basis windows, regular readback, dyadic tolerance, displayed modulus data, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionModulusExtractor}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CompletionModulusExtractorUp`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-source readback, basis-window exactness, RegSeqRat readback, DyadicRatCore tolerance exactness, extracted-modulus visibility, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompletionModulusExtractorUp.

Chapter 7759

A Concrete Naming Certificate for $\mathsf{SchauderTychonoff}^{\uparrow}$

Following Schauder and Tychonoff, the $\mathsf{SchauderTychonoff}^{\uparrow}$ packet records the finite handoff surface used when a compact convex source, a continuous self-map, and an approximate fixed-point mesh are displayed together. It sits after the Schauder fixed-point route of chapter 1923, the finite approximate fixed-point packet of chapter 6087, the compact-metric source of chapter 129, the convex membership surface of chapter 208, the locally convex ambient source of chapter 3386, and the continuous-map graph row of chapter 130. The chapter names a compact-convex fixed-point handoff as finite NameCert data; it does not claim arbitrary product compactness, choice-selected fixed points, quotient equality, or a host Schauder–Tychonoff theorem.

Definition 7759.1 (Schauder–Tychonoff handoff carrier)**.** *A* $\mathsf{SchauderTychonoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, V, X, f, M, A, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *or compact-source row that supplies the finite inspection windows for the domain.*
2. *V is the* $\mathsf{LocallyConvexSpace}^{\uparrow}$ *ambient row carrying the finite seminorm or weak-neighborhood windows available to the packet.*
3. *X is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the same displayed subset, including the affine-combination and membership reads used by fixed-point consumers.*
4. *f is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row whose graph reads stay inside the displayed compact convex source.*
5. *M is the finite mesh and radius ledger consumed from chapter 6087.*
6. *A is the approximate fixed-point displacement row, recording the inspected points and tolerance windows through which $f(x)$ is compared with x.*
7. *R is the fixed-point handoff row to chapter 1923, naming only the finite compact-convex route exposed by the packet.*
8. *H records componentwise* hsame *transport for the compact source, locally convex source, convex-set membership, continuous-map graph, mesh, displacement, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact and convex source reads through f, M, A, R to the structural rows.*
10. *P is the* Pkg *provenance over* $\mathsf{SchauderTychonoff}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{LocallyConvexSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, *finite approximate fixed-point rows,* BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchauderTychonoff}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $K, V, X, f, M, A, R, H, C, P, N$. It has no coordinate for arbitrary product compactness, a choice-selected exact fixed point, quotient equality of maps or points, a completed locally convex dual, or a host Schauder–Tychonoff theorem.

Theorem 7759.2 (Schauder–Tychonoff NameCert obligations)**.** *For every accepted* $\mathsf{SchauderTychonoff}^{\uparrow}$ *carrier*

$$S = (K, V, X, f, M, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchauderTychonoff}^{\uparrow}}$ *surface consists exactly of compact-source admission for K, locally convex ambient admission for V, convex-set admission for X, continuous self-map visibility for f, finite mesh and radius admission for M, approximate displacement readback for A, fixed-point handoff through R, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Every compact-convex fixed-point consumer must read the dependency route

$$K, V, X, f \longmapsto M, A \longmapsto R \longmapsto H, C, P, N$$

before using the packet as a Schauder–Tychonoff handoff. The route exports finite certificate rows only; it exports no arbitrary product compactness theorem, no selected fixed point, no quotient equality, and no host theorem beyond the displayed compact-convex fixed-point handoff.

Proof. Project the carrier of Definition 7759.1. The compact source is K, the locally convex ambient source is V, the convex subset source is X, and the self-map graph is f.

Read the finite approximation data next. The mesh and radius row M is supplied by chapter 6087, and the displacement row A records only the inspected point and tolerance comparisons needed for the handoff.

Route the fixed-point-facing read through R and chapter 1923. Transport and replay through H and C preserve the same displayed rows, while P and N name the resulting packet.

Since the carrier has no coordinate for product compactness, an exact selected fixed point, quotient equality, a completed dual, or a host Schauder–Tychonoff theorem, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderTychonoff}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderTychonoff}^{\uparrow}$ packet is generated from compact-source, locally convex, convex-set, continuous-map, finite mesh, displacement, fixed-point handoff, transport, replay, provenance, and local naming rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchauderTychonoff}^{\uparrow}}$, seed)

Scope closed: Definition 7759.1 and Definition 7759.2 seed the finite compact-convex fixed-point handoff over compact-metric, convex-set, locally convex, continuous-map, finite approximate fixed-point, and Schauder fixed-point rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchauderTychonoff}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary product compactness, choice-selected fixed points, quotient equality, completed locally convex duality, a host Schauder–Tychonoff theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-convex source routing, continuous-map visibility, finite mesh and displacement readback, fixed-point handoff, transport, replay, provenance, and local naming for the same packet.

Chapter 7760

A Concrete Naming Certificate for $\mathsf{BishopLocatedSpace}^{\uparrow}$

Following Bishop and Bridges, a Bishop-style located space is a metric object whose topology-facing and set-facing locatedness reads are exposed by finite means before completion or real-name consumers can inspect them. The $\mathsf{BishopLocatedSpace}^{\uparrow}$ packet records this interface on the L10 topology, metric, completion, and Real route of section 9467.12. It sits over the metric source of chapter 57, the topology source of chapter 88, the located-subset sibling chapter 1541, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The certificate names only the displayed finite locatedness route; it does not add quotient completion, selected nearest points, open-cover compactness, real trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7760.1 (Bishop located-space carrier)**.** *A* $\mathsf{BishopLocatedSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, T, L, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the point classifier, distance witness, and finite point-observation histories from which locatedness requests are opened.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, recording the displayed open-neighbourhood interface consumed by topology-facing readers of the same point observations.*
3. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *locatedness row. It ties each admitted set or source family to the finite distance interface of chapter 1541.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, packaging the rational comparison windows for metric distances, located-set distances, and topology-neighbourhood radii.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the metric, topology, located-set, and regular-rational rows have all been displayed.*
6. *H stores componentwise* hsame *transport for M, T, L, Q, E and for the structural certificate rows.*
7. *C stores displayed* Cont *replay from metric point observations to topology neighbourhoods, located-set requests, regular rational readback, and the terminal Real seal.*

8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, L, Q, E, H, C, P, N$. It has no coordinate for quotient completion, selected nearest points, open-cover compactness, real trichotomy, countable choice, host equality of points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7760.2 (BishopLocatedSpace NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedSpace}^{\uparrow}$ *carrier*

$$B = (M, T, L, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedSpace}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *metric-source admission for the displayed* $\mathsf{Met}^{\uparrow}$ *point classifier, distance witness, and finite observation histories in M;*
2. *topology compatibility for the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row T, requiring each topology-facing read to remain attached to the same metric observations;*
3. *located-set exactness for L, requiring every locatedness request to pass through the* $\mathsf{LocatedSet}^{\uparrow}$ *distance interface before a set-facing distance is exported;*
4. *regular-rational and Real readback for Q and E, requiring every rational comparison window to be sealed as* $\mathsf{Real}^{\uparrow}$ *only after* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is visible;*
5. *structural replay for H, C, P, N, requiring componentwise transport, displayed continuation, package provenance, and local naming to preserve exactly the same rows.*

No obligation row may call on quotient completion, selected nearest points, open-cover compactness, trichotomy, countable choice, host point equality, or ambient Real completeness.

Proof. Carrier admission is projection from Definition 7760.1. The metric row M, topology row T, located-set row L, regular rational row Q, Real seal row E, and structural rows H, C, P, N are the only rows in the packet.

The first three obligations bind the analytic source. A topology-facing read must use the neighbourhood interface T over the same metric observations in M, and a set-facing locatedness read must use L before any distance-to-set data are exported.

The fourth obligation routes numerical data through Q and E. Rational comparison windows become public only as regular rational readback, and the Real seal is exposed only after that readback is displayed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the excluded completion, selection, compactness, trichotomy, choice, host-equality, and ambient-completeness principles have no coordinate in the carrier, the five rows exhaust the local NameCert surface. □

Theorem 7760.3 (BishopLocatedSpace metric-topology handoff)**.** *Every topology-facing or located-set-facing consumer of an accepted* $\mathsf{BishopLocatedSpace}^{\uparrow}$ *carrier first reads the* $\mathsf{Met}^{\uparrow}$ *row M, then the* $\mathsf{Topology}^{\uparrow}$ *row T or the* $\mathsf{LocatedSet}^{\uparrow}$ *row L, then the* $\mathsf{RegSeqRat}^{\uparrow}$ *row Q, and only then the* $\mathsf{Real}^{\uparrow}$ *seal row E. Thus the public handoff is the finite route*

$$M, T, L, Q \longmapsto E$$

together with H, C, P, N.

Proof. Start with an accepted carrier $B = (M, T, L, Q, E, H, C, P, N)$. The carrier definition gives no direct route from a topology or set consumer to E; every read begins with the metric observations in M.

If the consumer asks for a neighbourhood read, the route uses T over the same point observations. If it asks for a located-set distance, the route uses L, whose sibling interface is fixed by chapter 1541.

Both cases then pass through Q. The regular rational row is the only row that packages the finite comparison windows used by the metric, topology, and located-set reads.

The Real seal E is therefore downstream of M, T, L, Q, and H, C, P, N preserve this order under transport, replay, provenance, and naming. No host equality, quotient completion, or selected endpoint can bypass the displayed handoff. □

Theorem 7760.4 (BishopLocatedSpace Real readback nonescape)**.** *The* $\mathsf{Real}^{\uparrow}$ *readback exported by an accepted* $\mathsf{BishopLocatedSpace}^{\uparrow}$ *packet is reachable only through* $M, T, L, Q, E, H, C, P, N$*. A Real-facing consumer receives the displayed metric source, topology interface, located-set distance route, regular rational readback, terminal Real seal, componentwise transport, displayed continuation, package provenance, and local NameCert row; it receives no quotient completion, selected nearest point, open-cover compactness, real trichotomy, countable choice, host point equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The only Real-facing coordinate is E. By Definition 7760.1, E is paired with Q, and Q is paired with the metric row M, topology row T, and located-set row L.

Apply Definition 7760.2. The five local obligation rows require metric-source admission, topology compatibility, located-set exactness, regular-rational and Real readback, and structural replay before the Real seal is public.

Apply Definition 7760.3. It identifies M, T, L, Q as the displayed handoff route to E.

Thus every Real readback remains inside the finite carrier. Since the packet contains no excluded quotient, selection, compactness, trichotomy, choice, host-equality, or ambient-completeness coordinate, none of those principles can escape through the Real seal. □

Falsifiable prediction: Any accepted $\mathsf{BishopLocatedSpace}^{\uparrow}$ consumer that reaches a Real-facing locatedness read while bypassing the metric source, topology row, located-set row, RegSeqRat readback, Real seal, transport, replay, provenance, or local NameCert row refutes the carrier surface.

Independence witness: metric, topology, locatedset, regseqrat, real: $\mathsf{BishopLocatedSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a metric source, topology interface, located-set distance route, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local NameCert registration as one Bishop-style located-space packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedSpace}^{\uparrow}$ packet is generated from a Metric source, Topology neighbourhood interface, LocatedSet distance route, RegSeqRat readback, RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7760.1, Definition 7760.2, Definition 7760.3, and Definition 7760.4 seed the Bishop-style finite locatedness route over Metric, Topology, LocatedSet, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected nearest points, open-cover compactness, real trichotomy, countable choice, host point equality, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, topology compatibility, located-set exactness, regular rational readback, Real-seal nonescape, transport replay, and local NameCert coverage for BEDC.Derived.BishopLocatedSpaceUp.

Chapter 7761

A Concrete Naming Certificate for $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$

Following Bishop and Bridges on finite metric constructions and Kelley on metric projection neighbourhoods, the $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ packet records the finite selector boundary used when a displayed finite projection table is already available. It sits after the projection carrier of chapter 2356, the finite projection table of chapter 7348, and the ambient metric source of chapter 57. The packet names a consumer-side selector row for already displayed finite candidates; it exports no nearest-point choice, quotient metric equality, or ambient completeness.

Definition 7761.1 (Finite metric projection selector carrier)**.** *A* $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, Q, E, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the consumed* $\mathsf{Met}^{\uparrow}$ *source row for the displayed finite metric data.*
2. *F is the consumed* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *table row naming the finite candidate distances and endpoint evidence already admitted by the parent finite projection packet.*
3. *Q is the finite selector ledger, recording the displayed index or candidate row selected from the table F.*
4. *E is the endpoint handoff row, read only as the finite endpoint evidence already exposed by F.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *distance seal attached to the selected candidate through the finite projection table.*
6. *H records componentwise* hsame *transport for the metric source, finite projection table, selector ledger, endpoint handoff, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a projection request through the finite table, selector ledger, endpoint handoff, and terminal seal.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$, $\mathsf{FiniteMetricProjection}^{\uparrow}$, $\mathsf{MetricProjection}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricProjectionSelector}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a host nearest-point function, quotient metric equality, hidden endpoint choice, countable selection schedule, or ambient completeness theorem.

Theorem 7761.2 (Finite metric projection selector NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ *carrier* $S = (M, F, Q, E, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteMetricProjectionSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, finite projection table exposure, selector-ledger admission, endpoint handoff, terminal distance sealing, componentwise stability transport, displayed replay, provenance, local naming, and refusal of nearest-point choice, quotient metric equality, hidden endpoint selection, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 7761.1. Its public data are exactly $M, F, Q, E, R, H, C, P, N$, with the selector ledger Q downstream of the finite projection table F.

The endpoint handoff is inherited from the table row. By Definition 7348.3, the endpoint evidence in F is already a finite table read through the displayed metric and comparison rows, so Q can only point into that displayed table.

Transport, replay, provenance, and local naming preserve the same finite route. Since no coordinate stores a host nearest-point function, quotient metric equality, hidden endpoint selector, countable schedule, or ambient completeness theorem, the NameCert surface cannot export any of those objects. □

Theorem 7761.3 (Finite metric projection selector nonescape)**.** *Every consumer of an accepted* $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ *packet must read the parent* $\mathsf{Met}^{\uparrow}$ *row* M*, the* $\mathsf{FiniteMetricProjection}^{\uparrow}$ *table row* F*, the selector ledger* Q*, the endpoint handoff* E*, the terminal seal* R*, and the structural rows* H, C, P, N *before using the selected projection candidate. The packet supplies a finite selector boundary for displayed candidates only; it exports no nearest-point choice, quotient metric equality, hidden endpoint selection, countable-choice schedule, or ambient completeness.*

Proof. Begin with the consumed metric source and finite projection table. The row M supplies the metric context, while F supplies the finite candidate-distance and endpoint evidence route of chapter 7348.

Read the selector ledger Q next. It chooses only among the displayed candidate rows of F, and the endpoint handoff E remains the endpoint evidence carried by the same finite table rather than a new projection principle.

Finally replay the terminal seal and structural rows. The route through R, H, C, P, N exposes the selected candidate as finite BEDC data and has no coordinate for a host nearest-point choice, quotient metric equality, hidden endpoint selection, countable-choice schedule, or ambient completeness. □

Falsifiable prediction: A $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ read is refuted whenever a projection consumer uses a selected candidate without displaying the MetricUp source, FiniteMetricProjectionUp table, selector ledger, endpoint handoff, RealUp seal, componentwise transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMetricProjectionSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMetricProjectionSelector}^{\uparrow}$ packet is generated from a Metric source row, a FiniteMetricProjection table row, a finite selector ledger, an endpoint handoff, a terminal Real distance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMetricProjectionSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7761.1, Definition 7761.2, and Definition 7761.3 seed the finite selector boundary from displayed metric projection tables to selected candidate reads.

Formal verification: FormalStatus(NameCert$_{\text{FiniteMetricProjectionSelector}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close nearest-point choice, quotient metric equality, hidden endpoint selection, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite projection table exposure, selector-ledger admission, endpoint handoff, terminal distance sealing, transport, replay, provenance, local naming, and refusal of choice principles for BEDC.Derived.FiniteMetricProjectionSelectorUp.

Chapter 7762

A Concrete Naming Certificate for $\mathsf{CompletionModulusFunctor}^{\uparrow}$

Following Bishop and Bridges on constructive completion and modulus data, the $\mathsf{CompletionModulusFunctor}^{\uparrow}$ packet records the finite handoff by which a completion witness is transported through displayed Cauchy-modulus evidence before a regular rational or Real consumer reads it. It sits over the finite completion window of chapter 1559, the directed-net completion route of chapter 3794, the uniform completion surface of chapter 1473, the explicit modulus row of chapter 292, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a functorial L10 handoff surface; it is not quotient completion equality, a representative selector, countable choice, host equality, open-cover compactness, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7762.1 (CompletionModulusFunctor carrier)**.** *A* $\mathsf{CompletionModulusFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, N, U, Q, R, E, H, C, P, L)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *finite-window completion row.*
2. *N is the* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *directed-net completion row read from the same displayed source.*
3. *U is the* $\mathsf{UniformCompletion}^{\uparrow}$ *uniform-structure completion row.*
4. *Q is the* $\mathsf{CauchyModulus}^{\uparrow}$ *refinement row that names the visible modulus transport.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the completion rows and modulus row are displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read from the regular rational handoff.*
7. *H records componentwise* hsame *transport for completion rows, modulus rows, regular readback, Real sealing, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the finite completion source through the modulus, readback, and Real-seal route.*
9. *P is* Pkg *provenance over* $\mathsf{CompletionModulusFunctor}^{\uparrow}$, $\mathsf{MetricCompletionFinite}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, N, U, Q, R, E, H, C, P, L$. No coordinate stores quotient completion equality, selected representatives, countable-choice schedules, host equality, open-cover compactness, or ambient complete metric spaces.

Theorem 7762.2 (CompletionModulusFunctor NameCert obligations)**.** *For every accepted* CompletionModulusFun *carrier $F = (M, N, U, Q, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{CompletionModulusFunctor}^{\uparrow}}$ *surface consists exactly of finite metric-completion admission, Cauchy-net completion admission, uniform-completion admission, Cauchy-modulus refinement exposure, regular rational readback, Real seal handoff, componentwise stability transport, displayed replay, provenance, local naming, and ledger refusal for quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, and ambient complete metric spaces.*

Proof. Project the carrier of Definition 7762.1. The completion-facing rows M, N, U supply the finite metric, directed-net, and uniform completion witnesses, while Q is the only displayed modulus-refinement row.

The readback row R and terminal seal E are downstream of those rows. Componentwise transport through H and replay through C keep the same route visible under hsame without adding hidden completion data.

The provenance and local naming rows P, L source and name that finite route. Since the carrier has no quotient, representative, choice, host-equality, compactness, or ambient-completeness coordinate, the local obligations cannot export those objects. □

Theorem 7762.3 (CompletionModulusFunctor L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{CompletionModulusFunctor}^{\uparrow}$ *packet must read the displayed route*

$$\mathsf{MetricCompletionFinite}^{\uparrow}, \mathsf{CauchyNetCompletion}^{\uparrow}, \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Rea}$$

through $M, N, U, Q, R, E, H, C, P, L$. Thus the functorial handoff preserves the same downstream $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal after componentwise* hsame *transport, while refusing quotient completion equality, representative selection, countable choice, host equality, open-cover compactness, and ambient complete metric spaces.*

Proof. Start with an accepted packet $F = (M, N, U, Q, R, E, H, C, P, L)$. The completion rows M, N, U are displayed before the modulus row Q, so a downstream consumer cannot read a modulus-refined completion without naming its finite, net, and uniform completion sources.

Replay the route through C and transport it through H. The regular rational readback R and terminal Real seal E remain attached to the same displayed completion-modulus path after componentwise hsame transport.

Finally inspect the ledger recorded by the carrier. The route contains no coordinate for quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, or ambient complete metric spaces, so the L10 handoff is exactly the finite certificate surface named by $M, N, U, Q, R, E, H, C, P, L$. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionModulusFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionModulusFunctor}^{\uparrow}$ packet is generated from MetricCompletionFinite, CauchyNetCompletion, UniformCompletion, CauchyModulus, RegSeqRat, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompletionModulusFunctor}^{\uparrow}}$, seed)

Scope closed: Definition 7762.1, Definition 7762.2, and Definition 7762.3 seed the finite functorial handoff from completion witnesses through modulus rows to regular rational and Real consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompletionModulusFunctor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, host equality, open-cover compactness, ambient complete metric spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-row admission, modulus refinement exposure, regular readback, Real-seal handoff, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.CompletionModulusFunctorUp.

Chapter 7763

A Concrete Naming Certificate for FiniteProofDagFrontier$^{\uparrow}$

The FiniteProofDagFrontier$^{\uparrow}$ packet realizes a MetaCIC open-problem route as finite proof-DAG bookkeeping. It sits beside the critical-path surface of chapter 765, the public residual frontier of chapter 4238, and the normal-form consistency seal of chapter 740. The packet is a finite frontier carrier for nodes, edges, checker rows, normalization-frontier rows, obstructions, transport, replay, provenance, and local naming; it does not export subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, or kernel consistency.

Definition 7763.1 (Finite proof-DAG frontier carrier)**.** *A* FiniteProofDagFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (V, A, K, F, O, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite node row, recording the proof objects, typing windows, and local source names inspected by the packet.*
2. *A is the finite edge row, recording premise-to-conclusion dependencies and residual links between displayed proof-DAG nodes.*
3. *K is the checker row, recording the bounded local verifier that reads only the displayed nodes and edges.*
4. *F is the normalization-frontier row, recording candidate normal endpoints, unfinished normalization windows, and the boundary between them.*
5. *O is the obstruction row, retaining absent subject-reduction, residual-substitution, global-normalization, evaluator-equality, quotient-proof-equality, and kernel-consistency endpoints.*
6. *H records componentwise* hsame *transport for nodes, edges, checker rows, normalization frontiers, obstructions, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay through the proof-DAG node, edge, checker, frontier, and obstruction route.*
8. *P is* Pkg *provenance over* FiniteProofDagFrontier$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteProofDagFrontier}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $V, A, K, F, O, H, C, P, N$. No coordinate stores subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, or kernel consistency.

Theorem 7763.2 (Finite proof-DAG frontier NameCert obligations)**.** *For every accepted* $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ *carrier $D = (V, A, K, F, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteProofDagFrontier}^{\uparrow}}$ *surface consists exactly of finite node admission, finite edge admission, bounded checker exposure, normalization-frontier exposure, obstruction retention, componentwise transport, displayed replay, provenance, local naming, and ledger refusal for subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, and kernel consistency.*

Proof. Project the carrier of Definition 7763.1. The node and edge rows V, A are the only proof-DAG shape data available to the packet, while K is the only checker row and F is the only normalization-frontier row.

The obstruction row O records the endpoints that remain absent. Transport through H and replay through C preserve the displayed DAG route without adding subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, or kernel consistency.

The provenance and local naming rows P, N source and name the same finite route. Hence the local obligations are exactly the displayed node, edge, checker, frontier, obstruction, transport, replay, provenance, and naming rows. □

Theorem 7763.3 (Finite proof-DAG frontier non-escape)**.** *An accepted* $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ *packet exports no subject reduction, no unrestricted confluence, no evaluator equality, no quotient proof equality, no global normalization, no residual-substitution discharge, and no kernel consistency. Every MetaCIC consumer of the packet must read only the displayed route*

$$V, A \longmapsto K, F, O \longmapsto H, C, P, N.$$

Proof. Begin with the carrier inventory. The packet lists finite nodes, finite edges, a bounded checker, a normalization frontier, an obstruction row, transport, replay, provenance, and local naming.

Now inspect the consumer route. Any downstream read must pass through V, A before reaching the checker and frontier rows K, F, and the obstruction row O remains attached to the same route.

Since the carrier has no additional coordinate beyond $V, A, K, F, O, H, C, P, N$, none of subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, or kernel consistency can be projected from an accepted packet. □

Falsifiable prediction: A $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ read is refuted whenever a MetaCIC consumer treats a finite proof-DAG frontier as subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, or kernel consistency without displaying the node, edge, checker, normalization-frontier, obstruction, transport, replay, provenance, and local naming rows.

Independence witness: metaciccriticalpath, metacic-parallel-diamond-frontier, metacicnormalizationfrontier, normalformconsistencyseal: none is bijective with $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ because

the packet jointly records finite nodes, finite edges, a bounded checker, a normalization frontier, obstruction retention, transport, replay, provenance, and local naming.

The Lean follow-up path is `lean4/BEDC/Derived/FiniteProofDagFrontierUp/TasteGate.lean`. It must provide explicit Nontrivial $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ and FieldFaithful $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ instances preserving node, edge, checker, normalization-frontier, obstruction, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteProofDagFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteProofDagFrontier}^{\uparrow}$ packet is generated from finite proof-DAG nodes, finite edges, bounded checker rows, normalization-frontier rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteProofDagFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7763.1, Definition 7763.2, and Definition 7763.3 seed the finite proof-DAG frontier route for MetaCIC bookkeeping consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteProofDagFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, unrestricted confluence, evaluator equality, quotient proof equality, global normalization, residual-substitution discharge, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked node admission, edge admission, bounded checker exposure, normalization-frontier exposure, obstruction retention, transport, replay, provenance, local naming, and ledger non-escape for BEDC.Derived.FiniteProofDagFrontierUp.

Chapter 7764

A Concrete Naming Certificate for $\mathsf{HyperbolicLimitSet}^{\uparrow}$

Following Beardon and Bridson–Haefliger, the $\mathsf{HyperbolicLimitSet}^{\uparrow}$ packet records the finite boundary accumulation surface of a displayed hyperbolic action. It sits after the visual boundary route of chapter 4181, the boundary-shadow route of chapter 3813, the Busemann boundary route of chapter 3732, the visual metric route of chapter 3866, the geodesic-flow route of chapter 3856, the Patterson–Sullivan shadow route of chapter 6070, the axis-shadow route of chapter 6122, and the terminal disk and real seals of chapter 377 and chapter 38. The packet names a finite limit-set read; it does not complete the ideal boundary, quotient geodesic rays, select orbit representatives, or import host compactness.

Definition 7764.1 (Hyperbolic limit set carrier)**.** *A* $\mathsf{HyperbolicLimitSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, S, U, V, G, P, A, D, R, H, C, Q, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *boundary readback row.*
2. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *shadow row recording the finite orbit-shadow observations.*
3. *U is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row attaching the boundary read to Busemann-level comparison data.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row comparing boundary observations by displayed visual metric windows.*
5. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row naming the finite orbit or geodesic-flow observations whose accumulation is being read.*
6. *P is the Patterson–Sullivan shadow row, used only as a displayed weighting and shadow-support surface.*
7. *A is the* $\mathsf{HyperbolicAxisShadow}^{\uparrow}$ *row for axial shadow support when the orbit read comes from a displayed axis route.*
8. *D is the* $\mathsf{UnitDisk}^{\uparrow}$ *source row for disk-coordinate admission.*
9. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the finite visual-radius and shadow-size reads.*

10. *H records componentwise* hsame *transport for boundary, shadow, Busemann, visual-metric, flow, Patterson–Sullivan, axis, disk, real-seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay through the same boundary and shadow route.*
12. *Q is the* Pkg *provenance over* $\mathsf{HyperbolicLimitSet}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{HyperbolicAxisShadow}^{\uparrow}$, $\mathsf{UnitDisk}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed boundary compactification, quotient boundary equality, selected orbit representative, global group action, host compactness theorem, or ambient hyperbolic space.

Theorem 7764.2 (Hyperbolic limit set NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicLimitSet}^{\uparrow}$ *carrier*

$$L = (B, S, U, V, G, P, A, D, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$ *surface consists exactly of visual-boundary readback, boundary-shadow exposure, Busemann-boundary attachment, visual-metric comparison, geodesic-flow observation, Patterson–Sullivan shadow support, axis-shadow support, disk-coordinate admission, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7764.1. Rows B, S, U, V are the boundary-facing rows, while G, P, A, D, R record the displayed source observations, shadow support, disk admission, and finite real-valued reads.

The boundary route is read first. The visual boundary row supplies the boundary token, the boundary-shadow row supplies finite orbit-shadow observations, the Busemann row attaches the read to boundary comparison data, and the visual metric row supplies the displayed comparison window.

The source and support rows then constrain the accumulation read. Geodesic-flow observations, Patterson–Sullivan shadow support, axis-shadow support, disk-coordinate admission, and the terminal Real seal remain finite fields of the same packet rather than a completed boundary object.

Finally H, C, Q, N transport, replay, source, and name exactly that packet. Since no completed compactification, quotient equality, selected representative, global action, host compactness theorem, or ambient hyperbolic space coordinate appears in L, the listed rows exhaust the NameCert obligation surface. □

Theorem 7764.3 (Hyperbolic limit set boundary non-escape)**.** *Every accepted* $\mathsf{HyperbolicLimitSet}^{\uparrow}$ *read factors through*

$$\mathsf{HyperbolicVisualBoundary}^{\uparrow},\ \mathsf{HyperbolicBoundaryShadow}^{\uparrow},\ \mathsf{HyperbolicBusemannBoundary}^{\uparrow},\ \mathsf{HyperbolicVisualMetric}^{\uparrow},$$

before it exports a limit-set boundary token. The read may use Patterson–Sullivan shadow support as a displayed finite weighting row, but it cannot replace the packet by a completed ideal boundary, quotient of geodesic rays, selected orbit representative, global group action, host compactness theorem, or ambient hyperbolic space.

Proof. Start with Definition 7764.2. It orders the accepted read through the boundary, shadow, Busemann, visual-metric, flow, support, disk, real-seal, transport, replay, provenance, and local naming rows.

The boundary rows B, S, U, V keep the limit-set token attached to displayed finite boundary observations. The source rows G, A, D keep the orbit or axis read tied to finite geodesic-flow, axis-shadow, and disk-coordinate data.

The Patterson–Sullivan row P and Real seal R are downstream support rows. They can weight and seal the displayed shadow data, but they do not add quotient boundary equality, selected representatives, global action data, compactness, or ambient geometry.

Thus the only exported token is the local $\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$ boundary read named by N over the same packet. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicLimitSet}^{\uparrow}$ read exposes visual-boundary, boundary-shadow, Busemann-boundary, visual-metric, geodesic-flow, Patterson–Sullivan support, axis-shadow, disk, Real-seal, transport, replay, provenance, and local NameCert rows before any limit-set boundary token is exported.

Independence witness: Nearest siblings: hyperbolic-visual-boundary, hyperbolic-boundary-shadow, hyperbolic-busemann-boundary, hyperbolic-visual-metric, hyperbolic-geodesic-flow, hyperbolic-patterson-sullivan-shadow, and hyperbolic-axis-shadow. None is bijective to $\mathsf{HyperbolicLimitSet}^{\uparrow}$ because this packet jointly carries boundary readback, orbit-shadow support, Busemann comparison, visual metric comparison, flow observation, weighting support, axis support, disk admission, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{HyperbolicLimitSet}^{\uparrow}$ packet is generated from visual-boundary rows, boundary-shadow rows, Busemann-boundary rows, visual-metric rows, geodesic-flow observations, Patterson–Sullivan shadow support, axis-shadow support, UnitDisk admission, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$, seed)

Scope closed: Definition 7764.1, Definition 7764.2, and Definition 7764.3 seed the finite limit-set boundary read over visual-boundary, shadow, Busemann, visual-metric, flow, support, disk, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicLimitSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed boundary compactification, quotient boundary equality, selected orbit representatives, global group actions, host compactness, ambient hyperbolic spaces, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary readback, shadow exposure, Busemann attachment, visual-metric comparison, geodesic-flow observation, support rows, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicLimitSetUp.

Chapter 7765

A Concrete Naming Certificate for $\mathsf{ProperMetricGroupAction}^{\uparrow}$

Following Bourbaki and Bridson–Haefliger on group actions on proper metric spaces, the $\mathsf{ProperMetricGroupAction}^{\uparrow}$ packet records a displayed group action by isometries on a proper metric carrier as finite BEDC NameCert data. It consumes the group source of chapter 41, the metric source of chapter 57, and the closed-ball compactness discipline of **??**. The packet names only action rows, orbit-window rows, compact ball witnesses, transport, replay, provenance, and local naming; it does not assert a host quotient orbit space, a global choice of representatives, or a full geometric group theory package.

Definition 7765.1 (Proper metric group action carrier)**.** *A* $\mathsf{ProperMetricGroupAction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (G, M, P, \alpha, I, O, W, H, C, Q, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{Group}^{\uparrow}$ *source row, including the displayed carrier, multiplication, unit, inverse, and classifier rows used to index action words.*
2. *M is the consumed* $\mathsf{Met}^{\uparrow}$ *source row for the acted-on points, distance observations, and metric-law ledger.*
3. *P is the consumed* $\mathsf{ProperMetric}^{\uparrow}$ *row, exposing compact closed-ball witnesses for the finite center-radius windows read by the action packet.*
4. *α is the action endpoint ledger. For each displayed group row g and point row x, it records the endpoint row $\alpha(g, x)$ as a carried metric point.*
5. *I is the isometry ledger, recording that each displayed action endpoint preserves the metric-distance rows inspected by the packet.*
6. *O is the finite orbit-window ledger, listing the displayed group words and point rows inspected by a downstream consumer.*
7. *W is the properness and cocompactness window ledger. It records compact closed-ball witnesses from P and finite orbit-window coverage rows for the displayed windows only.*
8. *H records componentwise* hsame *transport for the group, metric, proper-metric, action, isometry, orbit-window, coverage-window, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from group multiplication and inverse rows through action endpoints, isometry comparisons, compact closed-ball witnesses, and finite coverage windows.*
10. *Q is the* Pkg *provenance over* $\mathsf{ProperMetricGroupAction}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProperMetricGroupAction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $G, M, P, \alpha, I, O, W, H, C, Q, N$. It has no coordinate for quotient orbit-space equality, selected orbit representatives, an ambient isometry group, open-cover compactness, or a global geometric group theory structure.

Theorem 7765.2 (Proper metric group action NameCert obligations)**.** *For every accepted* ProperMetricGroupActio *carrier $A = (G, M, P, \alpha, I, O, W, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProperMetricGroupAction}^{\uparrow}}$ *surface consists exactly of carrier admission, group-source exposure, metric-source exposure, proper-metric closed-ball exposure, action endpoint admission, isometry-ledger admission, finite orbit-window admission, properness and cocompactness window admission, componentwise transport, displayed replay, provenance, local naming, and refusal of quotient orbit spaces, global representative choice, and full geometric group theory.*

Proof. Project the carrier of Definition 7765.1. Its public rows are exactly $G, M, P, \alpha, I, O, W, H, C, Q, N$, with the group and metric inputs read before any action endpoint is accepted.

The action endpoint and isometry ledgers are finite rows. The endpoint row $\alpha(g, x)$ is inspected only for displayed group rows and point rows, and I compares only the metric-distance observations already exposed by M.

The properness and cocompactness boundary is the window ledger W. It may read compact closed-ball witnesses from P and the displayed orbit-window rows from O, but it has no field that selects orbit representatives or forms a host quotient space.

Transport, replay, provenance, and local naming preserve the same finite surface. Since no other row is present in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 7765.3 (Proper and cocompact finite-window handoff)**.** *Every properness-facing or cocompactness-facing consumer of an accepted* $\mathsf{ProperMetricGroupAction}^{\uparrow}$ *packet factors through*

$$G, \quad M, \quad P, \quad \alpha, \quad I, \quad O, \quad W, \quad H, \quad C, \quad Q, \quad N.$$

For each displayed orbit window, the consumer first reads the $\mathsf{Group}^{\uparrow}$ *word rows, the* $\mathsf{Met}^{\uparrow}$ *point and distance rows, the* $\mathsf{ProperMetric}^{\uparrow}$ *closed-ball compactness witness, the action endpoint ledger, and the isometry ledger; only then may it read the finite coverage row in W. The handoff therefore supplies finite window data for proper and cocompact action reads, not a quotient orbit space, a selected representative system, or a general geometric group theory theorem.*

Proof. Fix a displayed orbit window. The group rows in G supply the finite words being tested, and the metric rows in M supply the point and distance observations for the same window.

Read the proper-metric row P next. The compact closed-ball witness used by the window is one of the displayed proper-metric witnesses, so the route is inherited from **??** and not from an open-cover compactness principle.

The action ledger α and isometry ledger I then attach the group words to the metric rows. The orbit-window ledger O records which endpoint rows are inspected, and W records the finite properness or cocompactness coverage row attached to that window.

Finally use H, C, Q, N to transport, replay, source, and name the same finite packet. None of these rows contains a quotient orbit-space carrier, a representative selector, or a global geometric group theory structure, so the consumer receives only the displayed finite-window handoff. □

Falsifiable prediction: A $\mathsf{ProperMetricGroupAction}^{\uparrow}$ read is refuted whenever a properness-facing or cocompactness-facing consumer uses orbit coverage without first displaying the GroupUp source, MetricUp source, ProperMetricUp closed-ball witness, action endpoint ledger, isometry ledger, finite orbit-window ledger, componentwise transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ProperMetricGroupAction}^{\uparrow}}$.

Constructive story: A $\mathsf{ProperMetricGroupAction}^{\uparrow}$ packet is generated from a Group source row, a Metric source row, a ProperMetric closed-ball compactness row, an action endpoint ledger, an isometry ledger, a finite orbit-window ledger, a properness and cocompactness window ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProperMetricGroupAction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7765.1, Definition 7765.2, and Definition 7765.3 seed the finite action carrier, its NameCert obligation surface, and the properness and cocompactness finite-window handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProperMetricGroupAction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host quotient orbit space, global representative choice, full geometric group theory, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, group and metric source exposure, proper-metric closed-ball exposure, action endpoint admission, isometry admission, orbit-window admission, coverage-window admission, transport, replay, provenance, local naming, and refusal of quotient-space and representative-choice principles for BEDC.Derived.ProperMetricGroupActionUp.

Chapter 7766

A Concrete Naming Certificate for $\mathsf{BishopLocatedSequence}^{\uparrow}$

Following Bishop–Bridges constructive analysis, a located sequence is a displayed real-name sequence whose finite windows, locatedness moduli, and regular rational readback are visible before any completion-facing consumer may inspect a limiting claim. The $\mathsf{BishopLocatedSequence}^{\uparrow}$ packet records this L10 neighbour of constructive Real and Completion objects. It sits beside the finite stream windows of chapter 126, the regular rational readback route of chapter 301, the terminal Real seal of chapter 38, and the located-space route of chapter 7760. The certificate names only the finite sequence surface; it does not select a limit, quotient streams, invoke countable choice, compare by trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7766.1 (Bishop located sequence carrier)**.** *A* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *carrier is a finite* BHist *tuple*

$$X = (S, L, R, E, H, C, P, N)$$

with the following rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of finite sequence windows. Each consumer request names a displayed prefix or tolerance-indexed observation window before reading any Real-facing data.*
2. *L is the locatedness-modulus row. It records the finite modulus by which the requested window is witnessed as located in the source sequence surface.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It packages the rational comparison data extracted from the sequence windows and locatedness modulus.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is exposed only after S, L, R have been displayed.*
5. *H stores componentwise* hsame *transport for S, L, R, E and for the structural certificate rows.*
6. *C stores displayed* Cont *replay from stream windows through locatedness moduli, regular rational readback, and the terminal Real seal.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedSequence}^{\uparrow}}$ *row.*

The classifier compares packets only through S, L, R, E, H, C, P, N. It has no coordinate for a selected limit, quotient stream equality, countable choice, real trichotomy, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopLocatedSequenceUp.BishopLocatedSequenceTasteGate single carrier alignment`

Theorem 7766.2 (BishopLocatedSequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *carrier*

$$X = (S, L, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedSequence}^{\uparrow}}$ *surface is exhausted by four obligation rows:*

1. *stream-window admission, requiring every sequence read to begin at the displayed* $\mathsf{StreamName}^{\uparrow}$ *row* S*;*
2. *locatedness-modulus visibility, requiring the row* L *to be visible before any located-sequence or* $\mathsf{LocatedSpace}^{\uparrow}$ *consumer reads the sequence as located data;*
3. *regular rational and Real readback, requiring* R *to expose the rational comparison windows before* E *seals the read as* $\mathsf{Real}^{\uparrow}$ *data;*
4. *structural replay, requiring* H, C, P, N *to preserve the same finite route under transport, continuation replay, provenance, and local naming.*

No obligation row may call on a selected limit, quotient stream map, countable choice, trichotomy, host equality of sequences, or ambient Real completeness.

Proof. Carrier admission is projection from Definition 7766.1. The only analytic rows are S, L, R, E, and the only structural rows are H, C, P, N.

The first two obligations bind the sequence source. A consumer starts at finite $\mathsf{StreamName}^{\uparrow}$ windows and can treat the sequence as located data only after the modulus row L is displayed.

The third obligation routes numerical data through R and E. Regular rational readback supplies the finite comparisons, and the Real seal is downstream of those comparisons.

Finally, H, C, P, N transport, replay, source, and name the same packet. Since the excluded principles have no carrier coordinate, these four rows exhaust the local NameCert surface. □

Theorem 7766.3 (BishopLocatedSequence window stability)**.** *Every accepted* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *packet keeps finite window reads stable under componentwise* hsame *transport: if a consumer reads the row* S *and then uses the locatedness modulus* L*, regular rational readback* R*, and Real seal* E*, the transported read must expose the same route*

$$S, L, R, E, H, C, P, N.$$

The transported consumer receives a finite located sequence surface and not a quotient stream, selected limit, countable-choice witness, trichotomy decision, or ambient Real-completeness theorem.

Proof. Read H in Definition 7766.1. It is componentwise transport for the stream windows, locatedness modulus, regular rational readback, and Real seal.

Replay the consumer route through C. The replay row can inspect S before L, then R, then E, so transport preserves the displayed order of the sequence read.

The provenance and local name rows P, N keep the transported read attached to the same packet. Since no quotient, selected-limit, choice, trichotomy, or completeness coordinate is present, window stability remains a finite NameCert statement. □

Theorem 7766.4 (BishopLocatedSequence L10 route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *carrier must traverse the L10 route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow L \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

as displayed by S, L, R, E, H, C, P, N. The same route may be compared with the located-space sibling chapter 7760, but it does not supply selected limits, quotient streams, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7766.2. They force every public read through stream-window admission, locatedness-modulus visibility, regular rational readback, and the Real seal.

Use window stability from Definition 7766.3. Transport and replay preserve the same displayed rows, so a downstream Real or Completion consumer cannot bypass the finite sequence windows.

The sibling comparison with $\mathsf{LocatedSpace}^{\uparrow}$ uses only the locatedness row L and the shared structural rows H, C, P, N. It is therefore a finite L10 route over StreamName, RegSeqRat, Real, and LocatedSpace data, not a claim of selected convergence or ambient completeness. □

Falsifiable prediction: Any accepted $\mathsf{BishopLocatedSequence}^{\uparrow}$ consumer that reaches a Real-facing sequence read while bypassing the StreamName row, locatedness modulus, RegSeqRat readback, Real seal, transport, replay, provenance, or local NameCert row refutes the carrier surface.

Independence witness: streamname, regseqrat, real, locatedspace: $\mathsf{BishopLocatedSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite sequence windows, a locatedness-modulus row, regular rational readback, Real seal, componentwise transport, continuation replay, package provenance, and local NameCert registration as one Bishop-style located-sequence packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedSequence}^{\uparrow}$ packet is generated from StreamName windows, a locatedness-modulus row, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7766.1, Definition 7766.2, Definition 7766.3, and Definition 7766.4 seed the finite located-sequence route over StreamName, RegSeqRat, Real, and LocatedSpace rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedSequence}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BishopLocatedSequenceUp.BishopLocatedSequenceTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, countable choice, trichotomy, ambient Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, locatedness-modulus visibility, regular rational readback, Real-seal nonescape, transport replay, and local NameCert coverage for BEDC.Derived.BishopLocatedSequenceUp.

Chapter 7767

A Concrete Naming Certificate for $\mathsf{CylinderObject}^{\uparrow}$

Following Quillen's model-category cylinder objects, the $\mathsf{CylinderObject}^{\uparrow}$ packet records the finite BEDC row that factors the fold map from two displayed copies of one object through a weak-equivalence face. It sits after the model-category carrier of chapter 158, the category dependency of chapter 61, the cofibrant-replacement witness of chapter 308, and the homotopy ledger of chapter 156. The packet names one displayed cylinder for one object; it does not export functorial cylinders, mapping cylinders, homotopy-category quotients, derived mapping spaces, or a global replacement choice.

Definition 7767.1 (Cylinder object carrier)**.** *A* $\mathsf{CylinderObject}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M, X, I_0, I_1, C, W, F, H, R, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{ModelCat}^{\uparrow}$ *row supplying the category, cofibration, fibration, weak-equivalence, lifting, and factorization surfaces.*
2. *X is the displayed object row over the* $\mathsf{Cat}^{\uparrow}$ *surface of M.*
3. *I_0 and I_1 are the two endpoint inclusion rows from X into the candidate cylinder row.*
4. *C is the cylinder-object row through which the fold request on the two copies of X factors.*
5. *W is the weak-equivalence ledger marking the projection from C back to the displayed object row.*
6. *F is the finite factorization row read from the* $\mathsf{ModelCat}^{\uparrow}$ *factorization surface.*
7. *H is the* $\mathsf{Homotopy}^{\uparrow}$ *ledger that records the homotopy-facing interpretation of the displayed weak-equivalence row.*
8. *R is the* $\mathsf{CofibrantReplacement}^{\uparrow}$ *dependency row when the object is read through a displayed cofibrant witness.*
9. *P is the* Pkg *provenance over* $\mathsf{CylinderObject}^{\uparrow}$, $\mathsf{ModelCat}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{CofibrantReplacement}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CylinderObject}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, X, I_0, I_1, C, W, F, H, R, P, N$. It has no coordinate for a functorial cylinder assignment, mapping-cylinder construction, host homotopy category, derived mapping space, quotient weak-equivalence calculus, or global replacement choice.

Lean4 (statement) `BEDC.Derived.CylinderObjectUp`

Theorem 7767.2 (Cylinder object NameCert obligations)**.** *For every accepted* $\mathsf{CylinderObject}^{\uparrow}$ *carrier* $Z = (M, X, I_0, I_1, C, W, F, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CylinderObject}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *endpoint admission, requiring I_0 and I_1 to be displayed as the two copies of X entering the cylinder row C;*
2. *model-category factorization, requiring F to read the factorization surface supplied by M before C can be consumed;*
3. *weak-equivalence projection, requiring W to mark the projection from C back to X inside the weak-equivalence row of M;*
4. *homotopy and cofibrant-replacement compatibility, requiring H and R to be read only as the displayed homotopy and cofibrant-witness dependencies of the same packet;*
5. *ledger non-escape, requiring P and N to source and name only the displayed rows, with no functorial cylinder assignment, mapping-cylinder construction, homotopy-category quotient, derived mapping space, quotient weak-equivalence calculus, or global replacement choice.*

Proof. Project the carrier of Definition 7767.1. The endpoint rows I_0 and I_1 are stored as displayed inputs to C, so a cylinder read starts from the two named copies of X rather than from an ambient coproduct or host fold map.

Next read the model-category row M and its factorization row F. These rows supply the finite factorization surface on which C is admitted and prevent the certificate from importing an external weak-equivalence calculus.

The weak-equivalence ledger W and homotopy ledger H are consumed only after the cylinder row is visible. The cofibrant-replacement row R is a dependency row for the displayed object witness, not a global replacement operator.

Finally inspect P and N. They source and name the same finite packet, and none of the refused objects appears as a carrier coordinate. The five displayed obligation families therefore exhaust the local NameCert surface. □

Theorem 7767.3 (Cylinder object factorization route)**.** *Every downstream homotopy or cofibrant-replacement consumer citing an accepted* $\mathsf{CylinderObject}^{\uparrow}$ *carrier must factor its read through*

$$M, X, I_0, I_1, C, W, F, H, R, P, N.$$

The route exports one displayed cylinder object for one displayed object and does not export a functorial cylinder construction, mapping-cylinder construction, homotopy-category quotient, derived mapping space, quotient weak-equivalence calculus, or global replacement choice.

Proof. Begin with the endpoint and cylinder rows of Definition 7767.1. A consumer reaches the cylinder row C only after the object row X and the two endpoint inclusions I_0, I_1 have been displayed.

Use the obligation surface of Definition 7767.2. The model-category factorization row F and weak-equivalence ledger W bind the cylinder read to M, while the homotopy and cofibrant-replacement rows H and R keep the homotopy-facing and cofibrant-facing uses inside the same finite packet.

The provenance and local naming rows P, N preserve that route for downstream consumers. Since the carrier lacks every refused coordinate, the consumer receives only the displayed cylinder route and cannot promote it to a functorial, quotient, derived, or global-choice construction. □

Closure status for $\mathsf{NameCert}_{\mathsf{CylinderObject}^{\uparrow}}$.

Constructive story: A $\mathsf{CylinderObject}^{\uparrow}$ packet is generated from ModelCat, Category, endpoint inclusion, cylinder, weak-equivalence, factorization, Homotopy, CofibrantReplacement, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CylinderObject}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7767.1, Definition 7767.2, and Definition 7767.3 seed the finite cylinder-object route over ModelCat, Category, CofibrantReplacement, and Homotopy rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CylinderObject}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CylinderObjectUp`

Bridge status: none

Not claimed: This chapter does not close functorial cylinders, mapping cylinders, homotopy-category quotients, derived mapping spaces, global replacement choices, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, model-category factorization, weak-equivalence projection, homotopy and cofibrant-replacement compatibility, ledger non-escape, provenance, and local naming for BEDC.Derived.CylinderObjectUp.

Chapter 7768

A Concrete Naming Certificate for $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ packet records the constructive Banach fixed-point route as finite located-completion data. It sits after the compact interval fixed-point packet of chapter 1437, the located metric surface of chapter 1533, the finite stream-window boundary of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a contraction row and a finite Picard-window handoff inside a displayed complete metric source; it does not claim general Brouwer fixed points, trichotomy of constructive reals, quotient stream equality, a choice-selected limit, or host completeness.

Definition 7768.1 (Bishop located Banach fixed-point carrier)**.** *A* $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, L, K, X, W, S, Q, Cm, E, H, R, P, N)$$

with the following displayed rows:

1. *M is the consumed* $\mathsf{LocatedMetric}^{\uparrow}$ *row naming the distance reads, located comparison windows, and metric transport surface for the source.*
2. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *boundary row used only as a displayed regular-Cauchy landing discipline, not as host completeness.*
3. *K is the contraction row, containing the map graph, a rational Lipschitz bound below one, and the finite contraction-read ledger.*
4. *X is the displayed initial seed row for the Picard iteration.*
5. *W is the finite Picard-window row listing the iterates inspected at the requested dyadic tolerance.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that exposes those Picard windows to downstream consumers.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the window schedule into regular rational approximants.*
8. *Cm is the contraction-Cauchy modulus row, tying the rational contraction bound to the Picard-window tail estimate.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the named fixed-point value, exposed only after W, S, Q, Cm have been displayed.*

10. *H records componentwise* hsame *transport for $M, L, K, X, W, S, Q, Cm, E$ and the local certificate row.*
11. *R records displayed* Cont *replay from a fixed-point request through the contraction, Picard windows, stream schedule, regular readback, modulus, and terminal seal.*
12. *P is the* Pkg *provenance over* $\mathsf{LocatedMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}}$ *registration row.*

The carrier predicate says that these rows form one finite contraction-and-Picard certificate. It has no coordinate for a host fixed point, selected completed limit, quotient equality of Cauchy streams, countable choice, real trichotomy, or ambient completeness.

Theorem 7768.2 (Bishop located Banach fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ *carrier $T = (M, L, K, X, W, S, Q, Cm, E, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}}$ *obligations are exhausted by carrier admission, located-metric distance exposure, displayed completeness-boundary admission, contraction-row exactness, initial-seed exposure, finite Picard-window construction, stream scheduling, regular-rational readback, contraction-Cauchy modulus sealing, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming. No obligation may call on general Brouwer fixed points, trichotomy, quotient stream equality, countable choice, a selected host limit, or host completeness.*

Proof. Project the carrier of Definition 7768.1. The only analytic rows are the located metric source M, the displayed completion boundary L, the contraction row K, the seed row X, the Picard windows W, the stream schedule S, the regular readback Q, and the contraction-Cauchy modulus Cm.

The Picard route is finite at every read. The contraction row supplies the rational contraction ledger, the seed row starts the displayed iteration, and the window row lists the iterates inspected before any readback is possible.

The completion-facing handoff then passes through S, Q, Cm, E in order. Transport, replay, provenance, and local naming preserve the same rows, so no excluded host fixed-point, selected-limit, quotient, trichotomy, choice, or ambient-completeness principle can enter the NameCert surface. □

Theorem 7768.3 (Bishop located Banach fixed-point Picard-window handoff)**.** *Every consumer of an accepted* $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ *packet must read the contraction row K, the initial seed X, the finite Picard-window row W, the* $\mathsf{StreamName}^{\uparrow}$ *schedule S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, the contraction-Cauchy modulus Cm, and the* $\mathsf{Real}^{\uparrow}$ *seal E before treating the output as a fixed-point value. The packet therefore exports a Picard-window handoff for a displayed located complete metric source, not a host-level fixed-point operator.*

Proof. Begin with the fixed-point request. The route first consumes the located metric row M and displayed completion boundary L, then reads the contraction row K and initial seed X before any Picard data are available.

The row W exposes the finite Picard windows requested by the tolerance. These windows are scheduled by S and translated by Q into regular rational readback, while Cm records the contraction tail estimate that licenses the terminal seal.

Only after that chain is displayed may the consumer read E. Since H, R, P, N merely transport, replay, record provenance, and name the same route, the packet has no bypass through a selected limit, host completeness theorem, or general Brouwer fixed-point principle. □

Falsifiable prediction: A $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ consumer is refuted whenever it reaches a fixed-point seal without displaying the contraction row, seed row, Picard windows, StreamName schedule, RegSeqRat readback, contraction-Cauchy modulus, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}$ packet is generated from located metric data, a displayed complete-metric boundary, a contraction row, an initial seed, finite Picard windows, StreamName scheduling, RegSeqRat readback, a contraction-Cauchy modulus, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7768.1, Definition 7768.2, and Definition 7768.3 seed the constructive contraction fixed-point route as finite located-completion data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedBanachFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general Brouwer fixed points, real trichotomy, quotient stream equality, countable choice, selected host limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-row exactness, finite Picard-window construction, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedBanachFixedPoi

Chapter 7769

A Concrete Naming Certificate for $\mathsf{FiniteCoverMeshChain}^{\uparrow}$

Following Bishop and Bridges on finite-cover proofs of Heine–Cantor, the $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ packet records the mesh-chain route from compact finite-cover data to a tolerance-only uniform-modulus handoff. It sits over the compact source of chapter 60, continuous-map rows of chapter 130, the metric source of chapter 57, rational lower-bound reads from chapter 37, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet names only finite cover rows, dyadic mesh bounds, star-refinement transport, rational lower-bound folds, and uniform-modulus handoff data.

Definition 7769.1 (Finite cover mesh-chain carrier)**.** *A* $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, G, B, D, S, L, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the consumed* $\mathsf{Compact}^{\uparrow}$ *finite-cover source row, exposed as finite* $\mathsf{ProbeBundle}^{\uparrow}$ *cover data.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source row used for mesh-radius comparisons and triangle transport.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the displayed compact source.*
4. *B is the dyadic mesh-bound row, recording the finite mesh scale and cover-radius comparisons.*
5. *D is the finite cover-chain ledger connecting each mesh cell to a displayed cover member.*
6. *S is the star-refinement transport row, carrying local pointwise moduli along neighbouring mesh cells.*
7. *L is the* $\mathsf{Rat}^{\uparrow}$ *rational lower-bound fold over the finitely many displayed radii.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed only after B, D, S, L have been read.*
9. *H records componentwise* hsame *transport for K, M, G, B, D, S, L, U and the local certificate row.*
10. *C records displayed* Cont *replay from compact-cover reads through mesh bounds, refinement transport, rational folding, and uniform-modulus handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{Compact}^{\uparrow}$, $\mathsf{ProbeBundle}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverMeshChain}^{\uparrow}}$ *registration row.*

The classifier compares accepted carriers only through these finite rows. It has no coordinate for open-cover compactness, a host Lebesgue number, semantic continuity, quotient metric equality, selected centres outside the displayed cover, or an external modulus oracle.

Theorem 7769.2 (Finite cover mesh-chain NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ *carrier* $F = (K, M, G, B, D, S, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverMeshChain}^{\uparrow}}$ *obligations are exactly compact cover exposure, metric source exposure, continuous-map row admission, dyadic mesh-bound admission, finite cover-chain routing, star-refinement transport, rational lower-bound folding, UniformModulus handoff, componentwise stability transport, displayed replay, provenance, and local naming. The obligations do not include open-cover compactness, a host Lebesgue number, semantic continuity, quotient metric equality, hidden centre selection, or an external modulus oracle.*

Proof. Project the carrier of Definition 7769.1. Its compact-uniform data are the finite cover row K, metric source M, continuous-map row G, mesh bound B, cover chain D, star-refinement row S, rational fold L, and uniform-modulus handoff U.

The finite-cover route is ordered. Mesh bounds are inspected before cover-chain transport, star refinement moves only along the displayed finite chain, and the rational lower-bound fold reads only the finitely many radii exposed by that chain.

The UniformModulus handoff is downstream of those rows. Transport, replay, provenance, and local naming preserve the same displayed route, so none of the excluded host compactness, semantic-continuity, quotient, hidden-selection, or oracle principles can enter the NameCert surface. □

Theorem 7769.3 (Finite cover mesh-chain UniformModulus handoff)**.** *Every consumer of an accepted* $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ *packet must read the compact finite-cover row* K*, metric row* M*, continuous-map row* G*, dyadic mesh bound* B*, cover-chain ledger* D*, star-refinement transport* S*, rational lower-bound fold* L*, and* $\mathsf{UniformModulus}^{\uparrow}$ *handoff* U *before using the exported modulus. Thus the packet realizes the finite-cover mesh route as concrete NameCert data rather than as a host compactness theorem.*

Proof. Start with the compact and metric sources. The row K supplies finite cover data, M supplies mesh comparisons, and G supplies the pointwise-modulus rows that will be transported.

The mesh chain is then read through B, D, S. These rows expose the dyadic mesh scale, the finite cover member attached to each mesh cell, and the star-refinement transport that keeps local moduli valid along neighbouring cells.

Finally the rational lower-bound fold L produces the tolerance-only value consumed by U. The rows H, C, P, N preserve and name this same finite path, so the exported modulus has no bypass through open-cover compactness, a host Lebesgue number, hidden centre selection, quotient metric equality, or an external oracle. □

Falsifiable prediction: A $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ consumer is refuted whenever a uniform-modulus read bypasses the compact cover row, metric source, continuous-map row, dyadic mesh bound, cover-chain ledger, star-refinement transport, rational lower-bound fold, UniformModulus handoff, transport, replay, provenance, or local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverMeshChain}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteCoverMeshChain}^{\uparrow}$ packet is generated from compact finite-cover data, metric source rows, continuous-map pointwise moduli, dyadic mesh bounds, finite cover-chain routing, star-refinement transport, rational lower-bound folding, UniformModulus handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteCoverMeshChain}\uparrow}$, seed)

Scope closed: Definition 7769.1, Definition 7769.2, and Definition 7769.3 seed the compact-uniform-continuity finite-cover mesh route as concrete NameCert data.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteCoverMeshChain}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host Lebesgue-number existence, semantic continuity, quotient metric equality, hidden centre selection, external modulus oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover exposure, dyadic mesh bounds, star-refinement transport, rational lower-bound folding, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverMeshChainUp.

Chapter 7770

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailDifference}^{\uparrow}$

Following Bishop and Bridges' constructive-analysis treatment of regular Cauchy names, the $\mathsf{RegularCauchyTailDifference}^{\uparrow}$ packet records the finite two-tail comparison surface visible before a $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the one-tail estimate route of chapter 1487, the dyadic tolerance surface of chapter 291, the finite stream window of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet compares two displayed regular Cauchy tails; it is not a quotient stream equality, a selected limit, a countable-choice schedule, host real equality, or an ambient completeness theorem.

Definition 7770.1 (Regular Cauchy tail difference carrier)**.** *A* $\mathsf{RegularCauchyTailDifference}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Delta = (M_0, M_1, W_0, W_1, D, R_0, R_1, E, H, C, P, N)$$

with the following displayed rows:

1. M_0 *and* M_1 *are the two tail-threshold rows, one for each accepted regular Cauchy tail estimate.*
2. W_0 *and* W_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows inspected at and beyond the displayed thresholds.*
3. D *is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row against which the two tail windows are compared.*
4. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows reached from* W_0, D *and* W_1, D.
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal boundary that may be consumed only after both threshold, window, tolerance, and readback routes have been replayed.*
6. H *records componentwise* hsame *transport for the two threshold rows, the two windows, the shared dyadic tolerance, the two readbacks, the seal boundary, continuation, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from a two-tail comparison request through* $M_0, M_1, W_0, W_1, D, R_0, R_1$ *and then* E.
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailDifference}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these displayed rows to a common finite two-tail surface. It has no coordinate for quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, or ambient completeness.

Theorem 7770.2 (Regular Cauchy tail difference NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailDifference}^{\uparrow}$ *carrier* $\Delta = (M_0, M_1, W_0, W_1, D, R_0, R_1, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauch}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the two thresholds, two stream windows, shared dyadic tolerance, two regular readbacks, real seal boundary, transport, continuation, provenance, and local name;*
2. *classifier transport to a common finite surface over* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*;*
3. *stability of* $M_0, M_1, W_0, W_1, D, R_0, R_1, E$ *under the componentwise* hsame *rows recorded in* H*;*
4. *seal-route exactness requiring every Real-facing two-tail comparison to pass through both displayed threshold-window-readback routes before* E *is public;*
5. *refusal rows excluding quotient streams, selected limits, host real equality, countable choice, trichotomy, open-cover compactness, and ambient completeness.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 7770.1. The projection exposes exactly the two threshold rows, two finite windows, shared dyadic tolerance, two regular readbacks, real seal boundary, transport, continuation, provenance, and local naming rows.

Use Definition 1487.9. The sibling theorem in the one-tail estimate chapter says that two accepted tail-estimate packets sharing transported threshold and dyadic rows compare through their displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ seal rows.

The structural rows do not create another comparison surface. The row H transports only the displayed coordinates, C replays the same two-tail route, and P, N record provenance and local naming for the finite packet.

Since no quotient stream, selected limit, host equality, countable-choice schedule, trichotomy, open-cover compactness, or ambient completeness coordinate occurs in the carrier, none can appear as a local obligation. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailDifference}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyTailDifference}^{\uparrow}$ packet is generated from two regular Cauchy tail-threshold rows, two StreamName windows, one shared DyadicRatCore tolerance row, two RegSeqRat readbacks, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailDifference}^{\uparrow}}$, seed)

Scope closed: Definition 7770.1, Definition 7770.2, and Definition 1487.9 seed the finite two-tail comparison surface over regular Cauchy tail estimates.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailDifference}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, host equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, stability, seal-route exactness, and ledger non-escape for the same two-tail packet.

Chapter 7771

A Concrete Naming Certificate for $\mathsf{CaratheodoryExtension}^{\uparrow}$

Following Caratheodory and Halmos, the $\mathsf{CaratheodoryExtension}^{\uparrow}$ packet records the finite boundary by which a displayed premeasure read can be carried toward a measurable-hull value seal inside BEDC NameCert data. It sits beside the event-row discipline of chapter 92, the set-presentation boundary of chapter 3668, the distance-facing examples of chapter 57, and the terminal value seal of chapter 38. The packet names only the finite rows inspected by a downstream measure consumer; it does not assume the full sigma-algebra extension theorem as a primitive.

Definition 7771.1 (Caratheodory finite premeasure carrier)**.** *A* $\mathsf{CaratheodoryExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (M, S, \mu, U, V, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the consumed* $\mathsf{Measure}^{\uparrow}$ *source row exposing the event boundary, finite additivity rows, and downstream measure-facing ledger already admitted by the measure packet.*
2. *S is the* $\mathsf{SetLike}^{\uparrow}$ *source row naming the finite set presentation on which the inspected event rows are read.*
3. *μ is the premeasure row. It assigns the displayed source events to value rows before any hull or value-seal request is accepted.*
4. *U is the finite cover ledger. It lists only the finite covers and finite refinements inspected by the packet.*
5. *V is the measurable-hull row. It records the displayed hull candidate generated from the source event rows and finite cover ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *value seal for the inspected hull value, exposed only after M, S, μ, U, V have been displayed.*
7. *H records componentwise* hsame *transport for the measure source, setlike source, premeasure row, finite cover ledger, measurable-hull row, real value seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through finite event inclusion, finite cover comparison, premeasure value reads, hull formation, and terminal value sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{CaratheodoryExtension}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $M, S, \mu, U, V, R, H, C, P, N$. It has no coordinate for a completed sigma-algebra, countable choice over covers, ambient measure completion, host set equality, or quotient equality of event presentations.

Theorem 7771.2 (Caratheodory finite premeasure NameCert obligations)**.** *For every accepted* $\mathsf{CaratheodoryExtension}^{\uparrow}$ *carrier $E = (M, S, \mu, U, V, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CaratheodoryExtension}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{Measure}^{\uparrow}$ *source exposure,* $\mathsf{SetLike}^{\uparrow}$ *source exposure, premeasure-row admission, finite cover-ledger admission, measurable-hull row admission,* $\mathsf{Real}^{\uparrow}$ *value sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and refusal of full sigma-algebra extension, countable choice over covers, ambient measure completion, and host set equality.*

Proof. Project the carrier of Definition 7771.1. Its public rows are exactly $M, S, \mu, U, V, R, H, C, P, N$, with the measure and setlike source rows read before any premeasure or hull value can be consumed.

The premeasure row μ and the cover ledger U are finite ledgers. They expose only displayed event-value assignments and displayed finite cover comparisons, so no countable cover selector or completed sigma-algebra can be recovered from them.

The measurable-hull row V and the value seal R are downstream rows over the same displayed data. The value seal is a $\mathsf{Real}^{\uparrow}$ row reached after the finite cover ledger has been inspected, not an ambient measure-completion theorem.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no other coordinate exists in the carrier, the listed rows exhaust the NameCert surface and the stated refusals are forced by absence of fields. □

Falsifiable prediction: A $\mathsf{CaratheodoryExtension}^{\uparrow}$ read is refuted whenever a consumer reaches a measurable-hull RealUp value without first displaying the MeasureUp source, SetLikeUp source, premeasure row, finite cover ledger, measurable-hull row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CaratheodoryExtension}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CaratheodoryExtension}^{\uparrow}$ packet is generated from a Measure source row, a SetLike source row, a premeasure row, a finite cover ledger, a measurable-hull row, a RealUp value seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CaratheodoryExtension}^{\uparrow}}$, seed)

Scope closed: Definition 7771.1 and Definition 7771.2 seed the finite premeasure carrier and its local NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CaratheodoryExtension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim the full sigma-algebra extension theorem, countable choice over covers, ambient measure completion, host set equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Measure and SetLike source exposure, premeasure admission, finite cover admission, measurable-hull admission, Real value sealing, transport, replay, provenance, local naming, and refusal of full extension principles for BEDC.Derived.CaratheodoryExtensionUp.

Chapter 7772

A Concrete Naming Certificate for $\mathsf{StreamRegularCompleteness}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{StreamRegularCompleteness}^{\uparrow}$ packet records the finite ledger by which certified stream names are read as regular rational Cauchy data before a terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the finite stream-window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name carrier of chapter 38. The packet names a constructive completeness route for displayed regular data; it is not a quotient of Cauchy streams, a selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7772.1 (Stream regular completeness ledger)**.** *A* $\mathsf{StreamRegularCompleteness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, R, D, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing the finite name windows and requested precisions inspected by the completion consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row translating those windows into a regular rational Cauchy readback.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording dyadic radii, refinement cells, and comparison budgets used by R.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after S, R, D have been displayed.*
5. *H records componentwise* hsame *transport for the stream, regular readback, dyadic ledger, Real seal, replay, provenance, and local naming rows.*
6. *T records displayed* Cont *replay from a completion request through S, R, D, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{StreamRegularCompleteness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamRegularCompleteness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, R, D, E, H, T, P, N. It has no coordinate for quotient stream equality, a chosen Cauchy representative, a selected limit, countable choice, trichotomy, host real equality, or ambient completeness.

Theorem 7772.2 (Stream regular completeness NameCert obligations)**.** *For every accepted* $\mathsf{StreamRegularComplete}$ *carrier* $C = (S, R, D, E, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StreamRegularCompleteness}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, transport, replay, provenance, and local naming rows;*
2. *window coverage, requiring each completion request to expose the* $\mathsf{StreamName}^{\uparrow}$ *finite observations in* S *before any rational readback is consumed;*
3. *regularity coverage, requiring* R *to exhibit the regular rational Cauchy route over the same windows;*
4. *dyadic tolerance coverage, requiring* D *to account for the precision and refinement cells used by the regular readback;*
5. *Real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to read* E *only after* S, R, D *and the structural rows* H, T, P, N *have been displayed.*

No local obligation supplies quotient representatives, selected limits, countable-choice schedules, trichotomy, host equality, or ambient completeness.

Proof. Project the carrier of Definition 7772.1. The visible rows are exactly S, R, D, E, H, T, P, N, so each obligation must be read from one of those rows.

The first three substantive rows expose the constructive completion data. S supplies finite stream windows, R reads them as regular rational Cauchy data, and D records the dyadic budgets used to compare those readings.

The terminal row E is downstream of that route. Transport through H, replay through T, provenance through P, and naming through N preserve the same displayed packet and do not add a quotient, selected representative, choice schedule, trichotomy, host equality, or ambient completeness principle. □

Theorem 7772.3 (Stream regular completeness Real handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{StreamRegularCompleteness}^{\uparrow}$ *packet reaches terminal* $\mathsf{Real}^{\uparrow}$ *evidence only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto H, T, P, N.$$

Thus a certified stream name becomes a regular Cauchy real seal only after its finite windows, regular rational readback, and dyadic tolerance ledger are visible, and no consumer receives quotient-stream equality, a selected Cauchy representative, a selected limit, countable choice, trichotomy, host real equality, or ambient completeness from the packet.

Proof. Use the obligation surface of Definition 7772.2. Window coverage exposes S, regularity coverage exposes R, and dyadic tolerance coverage exposes D before the Real-seal nonescape row may be read.

The carrier definition then identifies the only terminal Real coordinate as E. Since E is downstream of S, R, D, every Real or Completion read factors through the displayed stream, regular-rational, and dyadic-tolerance route before the seal is available.

Finally inspect H, T, P, N. These rows transport, replay, source, and name the same finite packet. They do not contain quotient representatives, selected limits, choice schedules, trichotomy decisions, host equalities, or an ambient completeness theorem, so the handoff remains internal to the displayed NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{StreamRegularCompleteness}^{\uparrow}$ read is refuted if a Real or Completion consumer reaches terminal $\mathsf{Real}^{\uparrow}$ evidence without first exposing StreamName finite windows, RegSeqRat regular readback, DyadicRatCore tolerance cells, componentwise transport, displayed replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{StreamRegularCompleteness}^{\uparrow}$ because the packet binds finite stream windows, regular rational Cauchy readback, dyadic tolerance accounting, terminal Real sealing, transport, replay, provenance, and local NameCert rows in one completeness ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamRegularCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamRegularCompleteness}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat regular rational readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamRegularCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7772.1, Definition 7772.2, and Definition 7772.3 seed the finite completeness route from certified stream names to regular Cauchy Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamRegularCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy streams, selected representatives, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window coverage, regularity coverage, dyadic tolerance coverage, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.StreamRegularCompletenessUp.

Chapter 7773

A Concrete Naming Certificate for $\mathsf{BishopLocatedDerivative}^{\uparrow}$

Following Bishop and Bridges on constructive differentiation, the $\mathsf{BishopLocatedDerivative}^{\uparrow}$ packet records a located finite derivative window before any host derivative or completed real-function equality is available. It sits over the finite $\mathsf{StreamName}^{\uparrow}$ surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name boundary of chapter 38, the finite-difference handoff of chapter 5135, and the derivative-facing carrier of chapter 122. The packet supplies the Real and Completion route with a finite located derivative window, not quotient real equality, selected limits, a host differentiability theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7773.1 (Bishop located derivative carrier)**.** *A* $\mathsf{BishopLocatedDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (W, X, M, D, Q, R, F, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the located source-window row, listing the inspected* $\mathsf{StreamName}^{\uparrow}$ *input windows around the displayed base point.*
2. *X is the location row, naming the base point, neighbourhood tag, and finite radius requests used to keep the derivative window local.*
3. *M is the mesh row, recording the finite step choices, sidedness tags, endpoint reuse schedule, and exclusion of the zero step.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for step size, coefficient, denominator, and local-radius budgeting.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed difference quotients and their finite error ledger.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q has been read.*
7. *F is the* $\mathsf{FiniteDifference}^{\uparrow}$ *handoff row, exposing the finite quotient packet consumed before any derivative-facing read.*
8. *E is the* $\mathsf{Derivative}^{\uparrow}$ *boundary row, publishing only the located finite-window route.*

9. *H records componentwise* hsame *transport for source windows, location data, mesh choices, dyadic budgeting, regular readback, Real sealing, finite-difference handoff, derivative boundary, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay of the route*

$$W, X, M \longmapsto D \longmapsto Q \longmapsto R \longmapsto F \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedDerivative}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDerivative}^{\uparrow}}$ *row.*

The classifier has no coordinate for an ambient function space, quotient real equality, selected limiting derivative, host differentiability theorem, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7773.2 (BishopLocatedDerivativeUp NameCert obligations)**.** *For every accepted* BishopLocatedDerivativ *carrier*

$$B = (W, X, M, D, Q, R, F, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedDerivative}^{\uparrow}}$ *surface consists exactly of carrier admission for the located source windows, local base-point and radius data, finite mesh schedule, dyadic tolerance budgeting, regular rational readback, terminal Real seal, finite-difference handoff, derivative boundary exposure, transport, replay, provenance, and local naming. No obligation is stored in a host derivative, a quotient real equality proof, a selected limit, or an ambient completeness theorem.*

Proof. Project the carrier of Definition 7773.1. The rows W, X, M are the only coordinates containing source windows, location data, and finite mesh choices.

The numerical rows then force the Real-facing read through D, Q, R. The dyadic row D supplies the finite tolerance budget, the regular row Q reads the difference quotients, and the Real row R seals only that readback.

The consumer rows F, E expose the same finite route to chapter 5135 and chapter 122. The structural rows H, C, P, N transport, replay, source, and name the displayed packet without adding hidden data.

Since the carrier contains no ambient function-space, quotient-equality, selected-limit, host-differentiability, or completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 7773.3 (BishopLocatedDerivativeUp finite-difference handoff)**.** *Every* $\mathsf{Derivative}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopLocatedDerivative}^{\uparrow}$ *packet reads the finite-difference boundary F before it can inspect the derivative-facing row E. The handoff reaches F only through the source-window, location, mesh,* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows displayed in the carrier, so it does not export host differentiability, quotient real equality, selected limits, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 7773.2. It places every accepted read on $W, X, M, D, Q, R, F, E, H, C, P, N$.

The finite-difference row F is downstream of the source-window and mesh rows and downstream of the regular-real chain D, Q, R. Thus it receives a finite displayed quotient packet rather than a host derivative.

The derivative boundary E is downstream of F. Componentwise hsame transport and displayed Cont replay preserve that order, while provenance and local naming identify the same finite packet.

The absent host differentiability, quotient equality, selected-limit, and completeness claims are not coordinates of the carrier, so no derivative consumer can bypass F. □

Theorem 7773.4 (BishopLocatedDerivativeUp Real seal nonescape)**.** *For every accepted* BishopLocatedDerivative$^{\uparrow}$ *packet, the Real-facing value exposed by the located derivative window is exactly the value sealed by the row R after* StreamName$^{\uparrow}$ *windows,* DyadicRatCore$^{\uparrow}$ *tolerances, and* RegSeqRat$^{\uparrow}$ *readback have been displayed. The packet cannot re-expose that value as quotient real equality, a selected derivative limit, a host real function, or an ambient* Real$^{\uparrow}$ *completeness witness.*

Proof. Read R from the carrier in Definition 7773.1. By construction it is downstream of the finite source windows W, the local data X, M, the dyadic tolerance row D, and the regular readback row Q.

Apply Definition 7773.2. Its Real seal exposure clause identifies R as the only terminal Real-facing row in the local certificate.

The finite-difference and derivative rows F, E may consume that seal, but they do not replace it with a quotient equality or selected limiting object. The structural rows H, C, P, N only preserve and name the same displayed route.

Because no other carrier coordinate can hold a Real-facing witness, coordinate exhaustion prevents escape from the D, Q, R route. □

Closure status for NameCert$_{\text{BishopLocatedDerivative}^{\uparrow}}$**.**

Constructive story: A BishopLocatedDerivative$^{\uparrow}$ packet is generated from StreamName source windows, located base-point and mesh rows, DyadicRatCore tolerance budgeting, RegSeqRat readback, a RealUp seal, FiniteDifference and Derivative consumer boundaries, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopLocatedDerivative}^{\uparrow}}$, seed)

Scope closed: Definition 7773.1, Definition 7773.2, Definition 7773.3, and Definition 7773.4 seed the located finite derivative-window surface over StreamName, DyadicRatCore, RegSeqRat, Real, FiniteDifference, Derivative, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopLocatedDerivative}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host differentiability, quotient real equality, selected derivative limits, host real function equality, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked source-window admission, location admission, mesh admission, dyadic budgeting, regular readback, Real sealing, finite-difference handoff, derivative-boundary exposure, and transport/provenance/name exhaustion for BEDC.Derived.BishopLocatedDerivativeUp.

Chapter 7774

A Concrete Naming Certificate for $\mathsf{NormedGroup}^{\uparrow}$

Following Bourbaki, *General Topology*, the $\mathsf{NormedGroup}^{\uparrow}$ packet records the traditional normed-group interface as finite BEDC NameCert data. It consumes the algebraic operation rows of $\mathsf{Group}^{\uparrow}$ from chapter 41, the distance row of $\mathsf{Met}^{\uparrow}$ from chapter 57, and the value row of $\mathsf{Norm}^{\uparrow}$ from chapter 89. The carrier binds these three siblings as one displayed packet; it does not import quotient groups, host equality, selected representatives, or choice of completions.

Definition 7774.1 (Normed group carrier)**.** *A* $\mathsf{NormedGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, M, I, E, N, D, T, H, C, P, L)$$

with the following displayed rows:

1. *A is the consumed* $\mathsf{Group}^{\uparrow}$ *row, including carrier admission, multiplication, unit, inverse, and group-law evidence.*
2. *M is the consumed* $\mathsf{Met}^{\uparrow}$ *row on the same displayed carrier.*
3. *I is the displayed identity row inherited from the group packet.*
4. *E is the displayed inverse row inherited from the group packet.*
5. *N is the consumed* $\mathsf{Norm}^{\uparrow}$ *value row, read only on displayed group endpoints.*
6. *D is the norm-distance row recording $d(x, y) = N(x^{-1}y)$ inside the packet.*
7. *T is the translation-stability row recording that left and right multiplication preserve the displayed distance readback.*
8. *H is the componentwise* hsame *transport row for A, M, I, E, N, D, T.*
9. *C is the displayed* Cont *replay row for the same fields.*
10. *P is the* Pkg *provenance over* $\mathsf{NormedGroup}^{\uparrow}$*,* $\mathsf{Group}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
11. *L is the local* $\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, M, I, E, N, D, T, H, C, P, L$. It has no coordinate for host group equality, quotient completion, an ambient topological group, a chosen dense subgroup, or an external real-valued norm object outside the displayed $\mathsf{Norm}^{\uparrow}$ *row.*

Theorem 7774.2 (Normed group NameCert obligations)**.** *For every accepted* $\mathsf{NormedGroup}^{\uparrow}$ *carrier* $G = (A, M, I, E, N, D, T, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}$ *surface consists exactly of group-source admission, metric-source admission, norm-source admission, the identity and inverse readback rows, the norm-distance equation row* D*, translation stability* T*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, package provenance* P*, and local naming* L*.*

Proof. Project the carrier of Definition 7774.1. The algebraic source is the consumed $\mathsf{Group}^{\uparrow}$ row A, and the metric and norm sources are the consumed $\mathsf{Met}^{\uparrow}$ and $\mathsf{Norm}^{\uparrow}$ rows M and N.

The identity and inverse rows I and E are inherited from the same group packet. The distance row D is not an additional metric carrier; it is the displayed equation reading the metric value through the norm of $x^{-1}y$.

Translation stability is the row T. Transport, continuation, provenance, and local naming preserve exactly the displayed rows, so the obligation surface is exhausted by the listed finite packet. □

Theorem 7774.3 (Normed group metric translation stability)**.** *Every accepted* $\mathsf{NormedGroup}^{\uparrow}$ *consumer that reads a translated pair must expose the same* $\mathsf{Group}^{\uparrow}$ *multiplication row, inverse row,* $\mathsf{Met}^{\uparrow}$ *distance row, and* $\mathsf{Norm}^{\uparrow}$ *value row before reading the translated distance. Thus left and right translation are certificate-preserving routes through* T*, not host-level isometries imported from outside the packet.*

Proof. Read the translated pair through the group row A. Multiplication and inverse endpoints are visible only as rows of the consumed $\mathsf{Group}^{\uparrow}$ packet.

Next read M and N. The metric value and norm value are available only through those two source rows, and D ties the distance comparison to the norm of the displayed group difference.

The row T records the translation-stability replay. Since H, C, P, L preserve the same packet and no host isometry coordinate appears in the carrier, translated reads remain inside the accepted NameCert route. □

Theorem 7774.4 (Normed group norm-distance compatibility)**.** *For an accepted* $\mathsf{NormedGroup}^{\uparrow}$ *carrier, a metric read* $d(x, y)$ *and a norm read* $N(x^{-1}y)$ *are compatible only through the displayed row* D*. A consumer cannot replace* D *by host equality of group elements, quotient equality of representatives, or an unrecorded real-valued norm while retaining the local* $\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}$ *read.*

Proof. Project the distance and norm rows from Definition 7774.1. The metric row M supplies the displayed distance read, and the norm row N supplies the displayed value read.

The group row A supplies the inverse and multiplication endpoints used to form the displayed difference. The compatibility assertion is exactly row D, so the route has no independent equality or quotient coordinate.

Transport and continuation replay the same row data. Hence any replacement by host equality, quotient equality, or an unrecorded norm leaves the accepted packet. □

Theorem 7774.5 (Normed group ledger nonescape)**.** *Every downstream completion, topological-group, or Banach-facing consumer citing* $\mathsf{NormedGroup}^{\uparrow}$ *must first expose* $A, M, I, E, N, D, T, H, C, P, L$*. Dropping the group row, the metric row, the norm row, the norm-distance row, or the translation-stability row exits the accepted normed-group ledger and cannot be repaired by provenance or local naming alone.*

Proof. Apply the obligation surface of Definition 7774.2. The group, metric, and norm rows are independent consumed siblings, while D and T are the local rows that bind them into one normed-group packet.

Completion and topological consumers may inspect the metric-facing and translation-facing rows only after those local rows are displayed. Banach-facing consumers may inspect norm values only through N and the compatibility row D.

The support rows H, C, P, L preserve an admitted packet. They do not synthesize a missing algebraic source, metric source, norm source, compatibility row, or translation-stability row, so dropping any of those rows leaves the accepted ledger. □

Falsifiable prediction: Removing D permits a metric row and norm row that no longer determine the same displayed group-difference distance.

Independence witness: group, metric, norm: none is bijective to $\mathsf{NormedGroup}^{\uparrow}$. The group packet lacks distance and norm values; the metric packet lacks multiplication and inverse rows; the norm packet lacks the metric translation-stability ledger and cannot by itself expose the displayed group operation route.

Closure status for $\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}$.

Constructive story: A $\mathsf{NormedGroup}^{\uparrow}$ packet is generated from displayed GroupUp, MetricUp, NormUp, identity, inverse, norm-distance, translation-stability, transport, continuation, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7774.1, Definition 7774.2, Definition 7774.3, Definition 7774.4, and Definition 7774.5 seed the finite normed-group route over displayed $\mathsf{Group}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, and $\mathsf{Norm}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormedGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient groups, group completions, Banach-space structure, topological-group bridge checking, host equality, selected representatives, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, metric translation stability, norm-distance compatibility, ledger nonescape, provenance, and local naming for BEDC.Derived.NormedGroupUp.

Chapter 7775

A Concrete Naming Certificate for $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$

Following Moore and Smith on nets, the $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ packet records the finite cofinal net window that an L10 completion route may inspect before it reads a completion-facing boundary. It sits over the directed-index carrier of chapter 1607, refines the net rows of chapter 3403, feeds the Cauchy-net completion corridor of chapter 3794, and presents the same finite readback style consumed by chapter 126, chapter 301, and chapter 38. The packet is a displayed finite window and handoff object; it is not a subnet selector, quotient net, cofinal-choice functional, selected limit, host equality assertion, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 7775.1 (Finite directed net window carrier)**.** *A* $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, M, \Omega, U, T, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DirectedSet}^{\uparrow}$ *index substrate, exposing the inspected addresses, preorder comparisons, finite request windows, and upper-window witnesses.*
2. *M is the* $\mathsf{MooreSmithNet}^{\uparrow}$ *source row whose tail ledger is being inspected.*
3. *Ω is the finite retained window of directed addresses used by the completion request.*
4. *U records, for every displayed finite subwindow of Ω, an upper witness still visible through D and the Moore–Smith tail ledger.*
5. *T is the cofinal touch row, stating that every completion-facing tail request named by the route has a displayed successor request meeting Ω through the same directed substrate.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row obtained by listing the retained finite window as an explicit schedule.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled window.*
8. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, M, Ω, U, T, S, R have been displayed.*
9. *H records componentwise* hsame *transport for the directed substrate, Moore–Smith source, retained window, upper witnesses, cofinal touch row, schedule, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a completion request through the finite route*

$$D, M, \Omega, U, T \longmapsto S \longmapsto R \longmapsto A, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$, $\mathsf{DirectedSet}^{\uparrow}$, $\mathsf{MooreSmithNet}^{\uparrow}$, $\mathsf{CauchyNetCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDirectedNetWindow}^{\uparrow}}$ *row.*

The carrier exports only this finite completion-facing window. It has no coordinate for an infinite cofinal family, a selected subnet, quotient-net equality, a selected limit, countable choice, host real equality, or ambient completeness.

Theorem 7775.2 (Finite directed net window NameCert obligations)**.** *For an accepted* $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ *carrier $W = (D, M, \Omega, U, T, S, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteDirectedNetWindow}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the directed substrate, Moore–Smith source, retained finite window, upper witnesses, cofinal touch row, StreamName schedule, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming row;*
2. *directed-window readability, requiring every retained address in Ω and every comparison used by U to be read through the displayed* $\mathsf{DirectedSet}^{\uparrow}$ *row D;*
3. *Moore–Smith tail compatibility, requiring the retained window and its upper witnesses to be visible in the* $\mathsf{MooreSmithNet}^{\uparrow}$ *tail ledger M;*
4. *finite cofinal touch, requiring each completion-facing tail request to pass through the displayed touch row T before any scheduled observation or readback is consumed;*
5. *completion readback order, requiring the route D, M, Ω, U, T to be displayed before the* $\mathsf{StreamName}^{\uparrow}$ *row S, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal A;*
6. *ledger refusal for infinite cofinal families, selected subnets, quotient-net equality, selected limits, countable choice, host real equality, and ambient completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7775.1. The displayed packet exposes $D, M, \Omega, U, T, S, R, A$ as analytic rows and H, C, P, N as structural rows.

Directed-window readability follows from the role of D. A retained address in Ω is usable only as an inspected directed address, and each upper witness in U is certified by the displayed comparison rows already present in the directed substrate.

Moore–Smith tail compatibility is the role of M. The retained finite window is not an external subnet; it is the finite part of the Moore–Smith tail ledger being handed to the completion route.

The cofinal touch row T is then read before any numerical schedule. It records the finite successor request that meets the retained window for the particular completion-facing demand under inspection, without selecting a global cofinal family.

Finally the scheduled exit is ordered through S, R, A. Transport and replay preserve the same rows through H and C, while P and N source and name the packet. Since none of the refused objects appears as a carrier coordinate, the listed rows exhaust the local obligation surface. □

Theorem 7775.3 (Finite directed net window completion handoff)**.** *Every* $\mathsf{CauchyNetCompletion}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{DirectedSet}^{\uparrow},\ \mathsf{MooreSmithNet}^{\uparrow},\ \Omega,\ U,\ T \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus an L10 completion route may inspect a finite cofinal net window as displayed BEDC data before the completion boundary is consumed, while quotient nets, selected subnets, selected limits, countable choice, host equality, and ambient $\mathsf{Real}^{\uparrow}$ *completeness remain outside the packet.*

Proof. Apply the obligation surface of Definition 7775.2. It first forces the consumer to read the directed substrate D, Moore–Smith source M, retained window Ω, upper witnesses U, and cofinal touch row T.

The completion-facing route of chapter 3794 can then consume the same finite directed data as a boundary request. The packet supplies a displayed window and touch row, not a selected subnet or quotient of nets.

The numerical handoff is downstream of the directed window. The finite schedule S is read as a $\mathsf{StreamName}^{\uparrow}$ row, the regular rational readback R follows that schedule, and the terminal $\mathsf{Real}^{\uparrow}$ seal A is inspected only afterward.

Componentwise transport, continuation replay, provenance, and local naming remain H, C, P, N. Since the carrier has no coordinate for choice, selected limits, quotient equality, host equality, or ambient completeness, no such object can bypass the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ read exposes one DirectedSet row, one MooreSmithNet source row, one retained finite window, one upper-witness ledger, one cofinal touch row, one StreamName schedule, one RegSeqRat readback, one RealUp seal, componentwise hsame, Cont replay, Pkg provenance, and a local NameCert row before a CauchyNetCompletion consumer receives the packet.

Independence witness: directedset, moore-smith-net, cauchynetcompletion, streamname, regseqrat, real: $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds retained directed windows, upper witnesses, a finite cofinal touch row, scheduled observation, regular readback, terminal Real sealing, transport, replay, provenance, and local naming as one L10 completion handoff packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDirectedNetWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDirectedNetWindow}^{\uparrow}$ packet is generated from DirectedSet rows, MooreSmithNet source rows, retained finite directed windows, upper-witness ledgers, cofinal touch rows, StreamName schedules, RegSeqRat readback, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDirectedNetWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7775.1, Definition 7775.2, and Definition 7775.3 seed the finite cofinal net-window handoff used by L10 completion routes over DirectedSetUp, MooreSmithNetUp, CauchyNetCompletionUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDirectedNetWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subnets, quotient nets, infinite cofinal families, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, directed-window readability, Moore–Smith tail compatibility, finite cofinal touch, completion readback order, transport preservation, and ledger refusal for the same finite packet.

Chapter 7776

A Concrete Naming Certificate for $\mathsf{UlmInvariant}^{\uparrow}$

Following Kaplansky and Fuchs, the $\mathsf{UlmInvariant}^{\uparrow}$ packet records the classical height-filtration invariant for countable reduced p-primary abelian groups as finite BEDC NameCert data. It sits over the commutative operation surface of chapter 42, the filtered scalar bookkeeping of chapter 46, and the torsion-window route of chapter 6880. The packet names finite height slices, quotient multiplicity rows, transport, replay, provenance, and local naming evidence; it does not assert the full Ulm classification theorem, choose representatives of quotient slices, construct an ambient Prüfer envelope, or compare external groups by an isomorphism selector.

Definition 7776.1 (Ulm invariant carrier)**.** *An* $\mathsf{UlmInvariant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (p, A, H, F, Q, M, T, C, P, N)$$

with the following displayed rows:

1. *p is the prime row naming the fixed p-primary torsion coordinate and its visible arithmetic ledger.*
2. *A is the* $\mathsf{AbGroup}^{\uparrow}$ *source row, exposing the abelian operation, unit, inverse, commutativity, and classifier rows read by the invariant.*
3. *H is the height-filtration row, listing the displayed finite height stages and the rowwise membership tests used at each stage.*
4. *F is the successor-filtration row, recording the displayed passage from a height stage to its next p-multiple boundary.*
5. *Q is the quotient-slice row, naming the finite comparison surface for height-stage elements modulo the next displayed boundary.*
6. *M is the multiplicity row, recording the finite cardinal ledger of independent quotient-slice generators inspected by the packet.*
7. *T records componentwise* hsame *transport for the prime, abelian source, height filtration, successor filtration, quotient slices, multiplicities, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a torsion-height query through $p, A, H, F, Q, M, T, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UlmInvariant}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{PrueferGroup}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{UlmInvariant}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a full external abelian group classification, a selected basis of quotient slices, a hidden completion of the height filtration, or an ambient Prüfer-group embedding.

Theorem 7776.2 (Ulm invariant height-filtration obligation)**.** *For every accepted* $\mathsf{UlmInvariant}^{\uparrow}$ *carrier*

$$U = (p, A, H, F, Q, M, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UlmInvariant}^{\uparrow}}$ *surface first reads the* $\mathsf{AbGroup}^{\uparrow}$ *source row A, then the displayed height-filtration row H, then the successor-filtration row F, and only then the quotient-slice and multiplicity rows Q, M. Thus every invariant-facing consumer receives height data as a finite* BHist *filtration route rather than as an ambient ordinal-indexed subgroup lattice or a choice-selected basis.*

Proof. Project the carrier of Definition 7776.1. The only algebraic source row is A, and the only height-facing rows are H, F, Q, M.

The abelian source is read first. It supplies the operation, inverse, unit, commutativity, and classifier surface needed to speak about p-multiples and torsion-height comparisons.

The height filtration is then exposed through H and F. Row H lists the displayed stages, while F records the successor boundary used to compare a height stage with its next p-multiple layer.

Finally Q and M read quotient slices and multiplicities only after those boundaries are visible. The transport, replay, provenance, and local naming rows T, C, P, N preserve this order, so no hidden subgroup lattice or selected quotient basis enters the NameCert surface. □

Theorem 7776.3 (Ulm invariant Pruefer dependency route)**.** *Every Prüfer-facing or classification-facing consumer of an accepted* $\mathsf{UlmInvariant}^{\uparrow}$ *packet must retain the displayed route through chapter 42, chapter 46, and chapter 6880. The* $\mathsf{PrueferGroup}^{\uparrow}$ *dependency is read only as a torsion-window comparison surface for p-primary height behavior; it is not a construction of an ambient divisible hull, a selected compatible root chain, or the full Ulm classification isomorphism.*

Proof. Start with the provenance row P of Definition 7776.1. It lists the abelian-group, module-style filtration, and Prüfer torsion-window surfaces as named dependencies of the same packet.

The abelian-group row supplies the operation and classifier. The module-style row supplies filtered scalar bookkeeping for the p-multiple boundary, and the Prüfer-group row supplies the finite torsion-window comparison surface used to keep height behavior visible.

The quotient-slice and multiplicity rows remain downstream of those dependencies. Because T, C, P, N only transport, replay, source, and name the same finite route, no consumer can replace it by a divisible hull, a compatible root selector, or an external classification isomorphism. □

Closure status for $\mathsf{NameCert}_{\mathsf{UlmInvariant}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UlmInvariant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7776.1, Definition 7776.2, and Definition 7776.3 seed the finite prime, abelian-source, height-filtration, successor-filtration, quotient-slice, multiplicity, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UlmInvariant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim the full Ulm classification theorem, selected quotient representatives, ambient Prüfer envelopes, external group isomorphism, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, height-filtration stability, quotient-slice multiplicity, Prüfer torsion-window dependency, transport, replay, provenance, and local naming for BEDC.Derived.UlmInvariantUp.

Constructive story: A $\mathsf{UlmInvariant}^{\uparrow}$ packet is generated from a fixed prime row, AbGroup source row, height-filtration row, successor-filtration boundary, quotient-slice row, multiplicity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7777

A Concrete Naming Certificate for $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$

Following Cauchy and Hardy, the $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ packet records the finite estimate surface needed before a product of regular Cauchy names can expose a Real-facing tail bound. It refines the product-tail budget route of chapter 6606, consumes the regular rational readback of chapter 301, and remains attached to the dyadic tolerance core of chapter 291, the product convergence and metric routes of chapter 3608 and chapter 3551, and the terminal real-name seal of chapter 38. The packet is a finite NameCert surface for product-tail estimates; it does not assert a selected infinite product, quotient equality of series, choice, trichotomy, host completed multiplication, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7777.1 (Regular Cauchy product-tail estimate carrier)**.** *A* $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, B, J, L, R, M, D, Q, Z, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose finite rational windows are inspected.*
2. *J is the* $\mathsf{CauchyProductTailBudget}^{\uparrow}$ *schedule naming the left tail, right tail, and mixed finite convolution windows allowed for the requested precision.*
3. *L and R are the left and right regular-tail ledgers read from A and B under the schedule J.*
4. *M is the mixed-window convolution ledger, containing only finitely many rational products and finite partial sums.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger assigning dyadic radii to L, R, and M.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed tail estimate.*
7. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after A, B, J, L, R, M, D, Q are visible.*
8. *H records componentwise* hsame *transport for the source rows, schedule, tail ledgers, mixed window, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same finite product-tail estimate route.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$, $\mathsf{CauchyProductTailBudget}^{\uparrow}$, $\mathsf{CauchyProduct}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}}$ *row.*
The classifier reads only these rows. It has no coordinate for a chosen infinite product, quotient equality of regular names, countable choice, trichotomy, host multiplication on completed reals, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7777.2 (Regular Cauchy product-tail estimate NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ *carrier* $E = (A, B, J, L, R, M, D, Q, Z, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}}$ *surface consists exactly of carrier admission, two* $\mathsf{RegSeqRat}^{\uparrow}$ *source exposures, product-tail budget scheduling, left-tail and right-tail ledger exposure, mixed finite-window convolution,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7777.1. The two source rows A, B, the budget row J, the tail ledgers L, R, the mixed window M, and the dyadic ledger D are the only numerical rows available before readback.

The readback row Q is downstream of those finite rows. It repacks the displayed source windows and product-tail estimate as regular rational data rather than as quotient equality of regular names or a chosen infinite product.

Finally inspect Z, H, C, P, N. The Real seal Z is reached only after the source, schedule, tail-ledger, mixed-window, dyadic, and readback rows have been displayed, while the structural rows preserve the same packet. Hence the listed rows exhaust the local NameCert obligation surface. □

Theorem 7777.3 (Regular Cauchy product-tail estimate Real-seal route)**.** *Every Real-facing read of an accepted* $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyProductTailBudget}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the displayed left-tail ledger, right-tail ledger, mixed finite convolution window, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *rows still attached. The route exports no selected infinite product, quotient equality of regular names, countable choice, trichotomy row, host completed multiplication, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Begin with Definition 7777.2. It makes the two regular Cauchy sources, product-tail schedule, left and right tail ledgers, mixed finite convolution row, dyadic tolerance ledger, and regular readback mandatory before the Real seal can be consumed.

The finite route through J, L, R, M, D, Q controls the estimate request. A consumer may inspect only the displayed source windows, tail rows, mixed products, and dyadic tolerances assigned to the requested precision; no coordinate supplies an external selector or host infinite product.

The structural rows H, C, P, N preserve this same route under transport, replay, provenance, and naming. Therefore any Real-facing read reaches Z only through the displayed BEDC rows and cannot escape to quotient equality, choice, trichotomy, host multiplication, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ endpoint read exposes two RegSeqRat source rows, a CauchyProductTailBudget schedule, left and right finite tail ledgers, a mixed finite convolution window, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert evidence before any product-tail estimate is public.

Independence witness: cauchy-product-tail-budget, regseqrat, dyadicratcore, real: RegularCauchyProductTailEst is not bijective to any listed sibling because it jointly carries two regular Cauchy sources, a product-tail schedule, two tail ledgers, a mixed finite convolution row, dyadic tolerance accounting, regular readback, terminal Real sealing, transport, replay, provenance, and local naming in one estimate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a CauchyProductTailBudget schedule, finite tail ledgers, a mixed convolution window, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7777.1, Definition 7777.2, and Definition 7777.3 seed the finite Cauchy-product tail-estimate route over displayed regular sources, product-tail budgets, dyadic tolerance ledgers, readback, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductTailEstimate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected infinite products, quotient equality of regular names, countable choice, trichotomy, host completed multiplication, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, product-tail scheduling, left and right tail-ledger exposure, mixed finite-window convolution, dyadic tolerance accounting, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyProductTailEstimateUp.

Chapter 7778

A Concrete Naming Certificate for $\mathsf{SequentialCompletionCriterion}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{SequentialCompletionCriterion}^{\uparrow}$ packet records the finite sequential criterion that an L10 completion route may read before treating a regular Cauchy stream as completion-facing data. It sits after the metric substrate of chapter 57, the stream windows of chapter 126, the regular rational readback of chapter 301, the Real seal of chapter 38, the complete-metric row of chapter 128, and the completion-existence route of chapter 5721. The packet is a displayed criterion and handoff object; it is not a quotient completion, selected representative functional, countable-choice principle, trichotomy oracle, open-cover compactness argument, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7778.1 (Sequential completion criterion carrier)**.** *A* $\mathsf{SequentialCompletionCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, S, R, D, E, U, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the named distance comparisons and the separated metric source inspected by the criterion.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite stream observations that the completion route is allowed to read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row attached to the displayed stream windows.*
4. *D is the dyadic tolerance ledger, recording the finite tolerance requests and regularity bounds used by the readback.*
5. *E is the completion-seal row, stating that the displayed source, stream windows, readback, and tolerance ledger are accepted as completion-facing data for the named route.*
6. *U is the separated uniqueness row, comparing two displayed readbacks only through metric separation, regular tolerances, and the same completion seal.*
7. *H records componentwise* hsame *transport for the metric source, stream windows, readback, tolerance ledger, completion seal, separated uniqueness row, replay, provenance, and local naming row.*

8. *C records displayed* Cont *replay from a sequential completion request through*

$$M, S, R, D \longmapsto E, U, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{SequentialCompletionCriterion}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletionExistence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletionCriterion}^{\uparrow}}$ *row.*

The carrier exports only this finite sequential criterion. It has no coordinate for a quotient completion, selected representative, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or unlogged equality of limits.*

Theorem 7778.2 (Sequential completion criterion NameCert obligations)**.** *For an accepted* SequentialCompletionC *carrier $Q = (M, S, R, D, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletionCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the metric source, stream-name windows, regular Cauchy readback, dyadic tolerance ledger, completion-seal row, separated uniqueness row, transport, replay, provenance, and local naming row;*

2. *source readability, requiring every distance comparison and separatedness use to pass through the displayed* $\mathsf{Met}^{\uparrow}$ *row M;*

3. *sequential observation, requiring the completion-facing stream requests to be named by the finite* $\mathsf{StreamName}^{\uparrow}$ *window row S before any rational readback is consumed;*

4. *regular readback, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R and dyadic tolerance ledger D to witness the finite Cauchy bounds used by the criterion;*

5. *completion sealing and uniqueness, requiring E and U to bind the displayed readback to the completion route and to compare candidate readings only through separated metric data;*

6. *ledger refusal for quotient representatives, selected limits, countable choice, trichotomy, open-cover compactness, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and any equality assertion not displayed in $M, S, R, D, E, U, H, C, P, N$.*

No local NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 7778.1. The rows M, S, R, D, E, U are the analytic part of the criterion, while H, C, P, N transport, replay, source, and name the same finite packet.

Source readability is forced by M. Any metric comparison used by the completion route is read as displayed metric data, so the criterion cannot appeal to a hidden equality of points or an ambient complete space.

The sequential part is then ordered through S, R, D. The stream windows name the observations, the regular rational readback supplies the Cauchy data attached to those observations, and the dyadic ledger records the tolerance requests that are actually inspected.

The completion seal E and separated uniqueness row U close the finite criterion. They certify that the displayed readback is completion-facing and that two displayed readings are compared only by the separated metric rows and the same tolerance ledger.

Finally H and C replay these rows componentwise, while P and N record provenance and local naming. Since none of the refused objects appears as a carrier coordinate, quotient representatives, selected limits, countable choice, trichotomy, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness cannot be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{SequentialCompletionCriterion}^{\uparrow}$ read exposes one Metric row, one StreamName window row, one RegSeqRat readback row, one dyadic tolerance ledger, one completion-seal row, one separated uniqueness row, componentwise hsame, Cont replay, Pkg provenance, and a local NameCert row before an L10 completion consumer receives the criterion.

Independence witness: metric, streamname, regseqrat, real, completemetric, metric-completion-existence: $\mathsf{SequentialCompletionCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds metric source readability, finite stream windows, regular Cauchy readback, dyadic tolerance inspection, completion sealing, separated uniqueness, transport, replay, provenance, and local naming as one L10 completion criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompletionCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCompletionCriterion}^{\uparrow}$ packet is generated from Metric rows, StreamName windows, RegSeqRat regular Cauchy readback, dyadic tolerance ledgers, completion-seal rows, separated uniqueness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialCompletionCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7778.1 and Definition 7778.2 seed the finite sequential completion criterion route over MetricUp, StreamNameUp, RegSeqRatUp, RealUp, CompleteMetricUp, MetricCompletionExistenceUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialCompletionCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric source readability, sequential observation, regular readback, dyadic tolerance inspection, completion sealing, separated uniqueness, transport preservation, and ledger refusal for the same finite packet.

Chapter 7779

A Concrete Naming Certificate for $\mathsf{LocatedCompactnessModulus}^{\uparrow}$

Following Bishop–Bridges constructive compactness and Kelley's finite-cover viewpoint, the LocatedCompactnessMo packet records the finite-net route by which a compact metric source exports a usable lower-bound modulus. It sits after the compact metric surface of chapter 129, the finite Lebesgue-number route of chapter 452, and the regular rational readback route of chapter 126, chapter 301, chapter 291, and chapter 38. The packet names finite located-net evidence; it does not claim open-cover compactness, choose an external subcover, complete $\mathsf{Real}^{\uparrow}$, or identify compactness with a host-space theorem.

Definition 7779.1 (Located compactness modulus carrier)**.** *A* $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, Q, B, S, G, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the accepted compact metric carrier and the finite metric windows read by the packet.*
2. *F is the located finite-net cover row, listing the displayed centers, membership tests, and cover evidence used for the modulus.*
3. *Q is the positive rational radius ledger, recording the finite radius candidates and their comparison data.*
4. *B is the finite lower-bound fold, producing the displayed positive rational lower bound from the nonempty radius ledger.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row for the stream-facing name of the selected finite radius data.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, presenting the regular rational sequence visible to downstream modulus consumers.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, packaging the regular rational readback as the real-valued modulus output without using a completeness theorem.*
8. *H records componentwise* hsame *transport for the compact metric source, located finite-net cover, rational-radius ledger, lower-bound fold, stream name, regular rational readback, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compact-source tolerance query through* $K, F, Q, B, S, G, R, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactnessModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, choice-selected subcovers, unbounded radius searches, hidden Cauchy completion, or external compactness principles.

Theorem 7779.2 (Located compactness modulus NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ *carrier*

$$L = (K, F, Q, B, S, G, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompactnessModulus}^{\uparrow}}$ *surface consists exactly of compact metric source admission, located finite-net cover exposure, positive rational radius ledgering, finite lower-bound folding,* $\mathsf{StreamName}^{\uparrow}$ *readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7779.1. Row K is the only compact source row, rows F, Q, B are the finite-net and lower-bound rows, and rows S, G, R are the readback and real-seal rows.

The compact source is read first. It supplies the metric windows and compact carrier evidence, but it does not export an arbitrary open-cover compactness theorem.

The located finite-net cover row then exposes exactly the displayed centers, membership tests, and cover certificates used by the modulus. The rational ledger Q lists the candidate radii, and the finite fold B returns the positive lower bound by inspecting that finite list.

Finally S, G, R present the bound to stream, regular-rational, and real-valued consumers. Rows H, C, P, N transport, replay, source, and name the same packet, so the listed rows exhaust the NameCert obligation surface. □

Theorem 7779.3 (Located compactness modulus finite-net extraction)**.** *Every accepted* LocatedCompactnessModu *packet extracts its modulus through a displayed finite net*

$$\mathsf{CompactMetric}^{\uparrow} \longrightarrow F \longrightarrow Q \longrightarrow B$$

before any readback row is exported. Thus a compact-uniform-continuity consumer may read a positive rational lower bound only after the located cover evidence and finite fold have appeared in the packet.

Proof. Start from Definition 7779.2. The rows are ordered so that K precedes the finite-net row F, the finite-net row precedes the rational ledger Q, and the ledger precedes the fold B.

The extraction is therefore finite at the point where the lower bound is formed. The fold B has access only to the displayed candidates in Q and the located cover evidence in F; it has no access to an external cover selector or an infinite search.

Since S, G, R, H, C, P, N occur downstream of B, every exported modulus readback factors through the same finite-net extraction route. □

Theorem 7779.4 (Located compactness modulus real handoff)**.** *The* $\mathsf{Real}^{\uparrow}$ *output of an accepted* $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ *carrier is a seal on the displayed* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows. It is not a proof of* $\mathsf{Real}^{\uparrow}$ *completeness, not an external located-real construction, and not a replacement for the finite lower-bound fold.*

Proof. Inspect the readback rows in Definition 7779.1. The stream row S names the selected finite radius data, the regular rational row G presents it as a visible regular sequence, and the real row R seals that presentation for consumers expecting a real-valued modulus.

This handoff is downstream of K, F, Q, B. The lower bound has already been produced by the finite fold before the stream and regular-rational rows are read.

Thus R carries only the terminal seal for the displayed readback route. It does not add a completeness proof, an external located-real selector, or a new source for the modulus. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ packet exposes compact metric source, located finite-net cover, positive rational radius ledger, finite lower-bound fold, StreamName readback, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows before a modulus is exported.

Independence witness: Nearest siblings: CompactMetric, FiniteLebesgueNumber, StreamName, RegSeqRat, DyadicRatCore, and Real. None is bijective to $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ because this packet jointly carries the finite located-net cover, rational-radius ledger, lower-bound fold, readback, sealing, transport, replay, provenance, and local naming route for compact-uniform modulus consumers.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactnessModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactnessModulus}^{\uparrow}$ packet is generated from a CompactMetric source row, located finite-net cover row, positive rational radius ledger, finite lower-bound fold, StreamName readback, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactnessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7779.1, Definition 7779.2, Definition 7779.3, and Definition 7779.4 seed the finite compact-source, located-net, rational-radius, lower-bound, readback, Real-seal, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactnessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected subcovers, Real completeness, external located-real construction, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located finite-net extraction, rational-radius ledgering, finite lower-bound folding, StreamName and RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactnessModulusUp.

Chapter 7780

A Concrete Naming Certificate for $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ packet records the constructive uniform Cauchy criterion for a displayed sequence of functions before a ContinuousMap or completion consumer may read a terminal Real seal. It sits after the stream-name schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name carrier of chapter 38, the continuous-map route of chapter 130, and the metric-space carrier discipline of chapter 57. The packet supplies a finite-window criterion for function sequences; it is not pointwise convergence by host functions, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness.

Definition 7780.1 (Uniform Cauchy criterion function carrier)**.** *A* $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, R, X, F, W, T, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule for the function sequence and the finite family of inspected arguments.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distance stream produced by the inspected function values.*
3. *X is the displayed domain-window row whose metric comparisons are read through* $\mathsf{Met}^{\uparrow}$*.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row certifying that each inspected function value is read through the same displayed continuity route.*
5. *W is the finite uniform tail window, listing the indices and argument windows needed for one requested tolerance.*
6. *T is the dyadic tolerance ledger comparing the requested uniform bound with the distances generated by S, R, X, F, W.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed uniform Cauchy bound.*
8. *M is the target* $\mathsf{Met}^{\uparrow}$ *distance row, consumed only after S, R, X, F, W, T, E are visible.*

9. *H records componentwise* hsame *transport for the stream schedule, regular readback, domain window, continuous-map row, uniform tail window, tolerance ledger, Real seal, metric row, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a uniform tolerance request through $S, R, X, F, W, T, E, M, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterionFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host function equality, pointwise-only convergence, quotient stream equality, selected representatives, countable-choice schedules, trichotomy, or ambient completeness.

Theorem 7780.2 (Uniform Cauchy criterion function obligations)**.** *For every accepted* UniformCauchyCriterionFunc *carrier $U = (S, R, X, F, W, T, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterionFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed stream schedule, regular readback, domain metric window, continuous-map row, finite uniform tail window, dyadic tolerance ledger, Real seal, metric row, componentwise transport, continuation replay, provenance, and local naming; uniform-tail exposure through W; Real-seal handoff through T, E; and ledger refusal for pointwise-only convergence, host function equality, quotient streams, selected representatives, countable choice, trichotomy, and ambient completeness.*

Proof. Project the carrier of Definition 7780.1. The rows S, R, X, F, W, T, E, M are the only analytic rows available to a uniform Cauchy read, and H, C, P, N are the only structural rows that may transport, replay, source, and name the packet.

Uniform-tail exposure is the role of W. It records one finite window for the requested tolerance, with the function-sequence schedule in S, the regular readback in R, the domain metric window in X, and the continuous-map row F already displayed.

The tolerance ledger T compares the requested bound with the distances generated by that finite window. The terminal Real row E and metric row M are therefore downstream of the finite uniform route, not detached pointwise evidence.

Since no carrier coordinate stores host function equality, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7780.3 (Uniform Cauchy criterion function finite-window induction)**.** *Let $U = (S, R, X, F, W, T, E, M, H$ be an accepted* $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ *carrier. Induction over the displayed finite uniform tail window preserves the route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{Met}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Strengthening or extending a finite prefix keeps the uniform Cauchy read inside $S, R, X, F, W, T, E, M, H, C, P, N$ and cannot introduce pointwise-only convergence, host function equality, quotient stream equality, selected representatives, countable choice, trichotomy, or ambient completeness.

Proof. The base window is the carrier projection of Definition 7780.1. The displayed rows already expose the function-sequence schedule, regular rational readback, domain metric window, continuous-map row, finite tail window, dyadic tolerance ledger, terminal Real seal, and metric row.

For the induction step, extend the finite prefix by one accepted argument window or one accepted tail-index comparison. The obligation surface of Definition 7780.2 forces the extension to pass through S, R, X, F, W before the tolerance ledger T and Real seal E are consumed.

If the prefix is strengthened without adding a new argument window, the same obligation surface keeps the readback and continuous-map rows fixed while only the displayed finite tolerance ledger is refined. The route therefore remains a uniform window route rather than a host-level pointwise convergence claim.

Finally inspect H, C, P, N. These structural rows transport, replay, source, and name only the same displayed packet, so the induction cannot acquire quotient stream equality, selected representatives, countable choice, trichotomy, host equality, or ambient completeness from outside the carrier. □

Falsifiable prediction: An accepted $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ read is refuted if a ContinuousMap or completion consumer obtains a uniform Cauchy bound without displaying the StreamName schedule, RegSeqRat readback, ContinuousMap row, MetricSpace distance row, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, real, continuous-map, metric-space: none alone is bijective with $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ because the packet binds a function-sequence schedule, regular readback, domain windows, continuous-map rows, finite uniform tail windows, dyadic tolerance accounting, terminal Real sealing, metric rows, transport, replay, provenance, and local NameCert rows in one uniform criterion surface.

Lean4 (statement) `BEDC.Derived.UniformCauchyCriterionFunctionUp`

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyCriterionFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyCriterionFunction}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readbacks, displayed metric windows, ContinuousMap rows, finite uniform tail windows, dyadic tolerance ledgers, RealUp seals, MetricSpace rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyCriterionFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7780.1, Definition 7780.2, and Definition 7780.3 seed the finite-window uniform Cauchy criterion for displayed function sequences over StreamNameUp, RegSeqRatUp, RealUp, ContinuousMapUp, MetricSpaceUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyCriterionFunction}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close pointwise-only convergence, host function equality, quotient stream equality, selected representatives, countable choice, trichotomy, ambient completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-tail exposure, Real-seal handoff, finite-window induction, transport, replay, provenance, and ledger refusal for BEDC.Derived.UniformCauchyCriterionFunctionUp.

Chapter 7781

A Concrete Naming Certificate for $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ packet records the finite compact-net diagonal data needed to read compact equicontinuous families without importing a choice-selected subsequence or an ambient completeness theorem. It sits between the compact metric source of chapter 129, the family-radius ledger of chapter 413, the bounded-family rows of chapter 3522, the Arzela–Ascoli handoff of chapter 412, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed diagonal schedule over finite windows only; it does not assert countable choice, selected subsequences outside the displayed schedule, quotient function equality, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7781.1 (Bishop equicontinuity diagonal carrier)**.** *A* $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, B, \Delta, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *packet and its displayed finite probes.*
2. *F is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *source row recording the family-radius ledger visible at the inspected compact-net scales.*
3. *B is the* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *ledger that bounds the same displayed family windows before any diagonal readback is accepted.*
4. *Δ is the finite diagonal schedule: it lists the inspected net scale, family index window, source window, and target tolerance window in the order in which the diagonal reader may consume them.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the scheduled family values and candidate limit reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after K, F, B, Δ, W, R have been displayed.*

8. *H records componentwise* hsame *transport for the compact-net, equicontinuity, bounded-family, diagonal-schedule, stream-window, rational-readback, real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from compact finite-net exposure through equicontinuity-family rows, bounded-family ledgers, the diagonal schedule, finite stream windows, regular rational readback, and terminal Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{BoundedFunctionFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}}$ *row.*

Accepted packets are compared only through the displayed finite compact-net, equicontinuity, boundedness, diagonal schedule, finite-window, readback, seal, transport, replay, provenance, and naming rows.

Theorem 7781.2 (Bishop equicontinuity diagonal NameCert obligations)**.** *For every accepted* $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ *carrier* $E = (K, F, B, \Delta, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityDiago}}$ *surface consists exactly of compact finite-net source exposure, equicontinuity-family source exposure, bounded-family ledger exposure, displayed diagonal scheduling, StreamName finite windows, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7781.1. The compact finite-net source is K, the family-radius source is F, and the bounded-family ledger is B; these are precisely the rows whose sibling chapters are chapter 129, chapter 413, and chapter 3522.

The diagonal information is finite. The schedule Δ displays the net scale, family-index window, source window, and target tolerance window before any readback is public. Thus a consumer may not replace the schedule by countable choice or by a selected subsequence outside the packet.

The readback route remains visible. Rows W, R, S expose the StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the Real seal of chapter 38; the seal is reached only after the compact, family, boundedness, and schedule rows are displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores quotient function equality, host compactness, a choice-selected subsequence, countable choice, or ambient Real completeness, the local NameCert surface cannot export those objects. □

Theorem 7781.3 (Bishop equicontinuity diagonal finite-net route)**.** *Every* $\mathsf{ArzelaAscoli}^{\uparrow}$ *or compact-uniform-continuity consumer of an accepted* $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ *packet must read the compact finite-net row, the equicontinuity-family source row, the bounded-family ledger, the displayed diagonal schedule, StreamName finite windows, RegSeqRat readback, and the terminal Real seal before it consumes any diagonal handoff. The handoff is a finite schedule route, not countable choice, a subsequence selector outside Δ, quotient equality of functions, host compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted carrier $E = (K, F, B, \Delta, W, R, S, H, C, P, N)$. The only compact source visible to a consumer is K, and the only family-radius and boundedness data visible before the diagonal read are F and B.

Next read the schedule Δ. It lists exactly the finite net scales, family-index windows, source windows, and target tolerance windows consumed by the diagonal route, so no unstated subsequence or external selector is available.

The readback rows W, R, S then force the same route through chapter 126, chapter 301, and chapter 38. The $\mathsf{ArzelaAscoli}^{\uparrow}$ consumer of chapter 412 therefore receives a displayed finite diagonal packet, not a quotient function equality or a host compactness theorem.

The structural rows H, C, P, N preserve this route componentwise. They add provenance and local naming but no countable-choice coordinate, no subsequence outside Δ, and no ambient completeness principle. □

Theorem 7781.4 (Bishop equicontinuity diagonal Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ *packet factors through*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{EquicontinuityFamily}^{\uparrow},\quad \mathsf{BoundedFunctionFamily}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

together with the displayed diagonal schedule, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The seal is not an ambient completeness theorem and cannot be read before the displayed schedule and finite windows have been exposed.*

Proof. Project the Real-facing row S. By Definition 7781.2, S is exposed only after K, F, B, Δ, W, R have already been displayed.

The finite-net route theorem Definition 7781.3 identifies this same order as the only diagonal handoff available to Arzela–Ascoli and compact-uniform-continuity consumers. Hence a Real-facing read receives the scheduled finite windows and regular rational readbacks before the seal.

The rows H, C, P, N then preserve the displayed route under classifier transport and replay. None of them contains countable choice, a subsequence outside the displayed schedule, quotient function equality, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the Real seal remains local to the packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ reader that claims a diagonal Real-facing handoff while omitting compact finite-net exposure, EquicontinuityFamily source rows, BoundedFunctionFamily ledgers, the displayed diagonal schedule, StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, or local naming refutes the packet.

Independence witness: compactmetric, equicontinuityfamily, bounded-function-family, arzelaascoli, streamname, regseqrat, real: $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ is not bijective with any listed sibling because it joins compact finite-net source data, family equicontinuity rows, bounded-family ledgers, a displayed diagonal schedule, finite stream windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}$ packet is generated from compact finite-net source rows, EquicontinuityFamilyUp source rows, BoundedFunctionFamilyUp ledgers, a displayed diagonal schedule, StreamName windows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7781.1, Definition 7781.2, Definition 7781.3, and Definition 7781.4 seed the finite compact-net diagonal route for compact equicontinuous families.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopEquicontinuityDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, selected subsequences outside the displayed schedule, quotient function equality, host compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, equicontinuity-family exposure, bounded-family ledger exposure, diagonal scheduling, finite-window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopEquicontinuityDiagonalUp.

Chapter 7782

A Concrete Naming Certificate for $\mathsf{CalibratedMetricFamily}^{\uparrow}$

Following Dudley and van der Vaart–Wellner, the $\mathsf{CalibratedMetricFamily}^{\uparrow}$ packet records a finite metric-family calibration surface for bracketing, covering, packing, entropy, and uniform-modulus handoff data. It sits beside the metric source of chapter 57, the compact-metric source of chapter 129, the finite entropy ledger of chapter 5209, the covering row of chapter 2187, the packing row of chapter 3761, and the modulus consumer of chapter 369. The packet names only displayed finite calibration rows and does not import host function-space compactness, measurable envelopes, selected brackets, or choice.

Definition 7782.1 (Calibrated metric-family carrier)**.** *A* $\mathsf{CalibratedMetricFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, K, B, C, Pc, E, U, H, T, Q, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row naming the common metric classifier, distance observations, and finite tolerance comparisons used by the family.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row for the displayed compact-metric domain or finite compact-metric witness consumed by calibration readers.*
3. *B is the finite bracket row. It records a displayed list of lower and upper metric-family brackets and the finite tolerance at which the list is admitted.*
4. *C is the* $\mathsf{MetricCoveringNumber}^{\uparrow}$ *row read at the same tolerance and metric source as B.*
5. *Pc is the* $\mathsf{PackingNumber}^{\uparrow}$ *row read against the same metric source and tolerance ledger.*
6. *E is the* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *row comparing the displayed bracket count, covering number, and packing lower bound as one finite entropy budget.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row. It exposes the calibration tolerance, entropy budget, and finite bracket envelope before any uniform-modulus consumer may inspect the family.*
8. *H records componentwise* hsame *transport for the metric, compact-metric, bracket, covering, packing, entropy, uniform-modulus, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from any calibration request through M, K, B, C, Pc, E, U, H.*

10. *Q is the* Pkg *provenance over* $\mathsf{CalibratedMetricFamily}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{MetricCoveringNumber}^{\uparrow}$, $\mathsf{PackingNumber}^{\uparrow}$, $\mathsf{FiniteMetricEntropy}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CalibratedMetricFamily}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host function spaces, open-cover compactness, measurable envelope selection, countable bracket families, quotient maps, selected limits, or choice.

Theorem 7782.2 (Calibrated metric-family NameCert obligations)**.** *For every accepted* $\mathsf{CalibratedMetricFamily}^{\uparrow}$ *carrier*

$$F = (M, K, B, C, Pc, E, U, H, T, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CalibratedMetricFamily}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, compact-metric source, finite bracket list, covering row, packing row, entropy budget, uniform-modulus handoff, transport, replay, provenance, and local naming rows;*
2. *bracket visibility, requiring every calibration read to inspect the finite bracket row B and its tolerance before it reads an entropy or modulus consequence;*
3. *covering and packing exactness, requiring C and Pc to be read against the same M, K, B tolerance surface;*
4. *entropy compatibility, requiring E to compare only the displayed bracket count, covering upper bound, and packing lower-bound rows;*
5. *uniform-modulus handoff, requiring U to consume the finite entropy and bracket envelope before exporting any modulus-facing data;*
6. *ledger nonescape, excluding host function-space compactness, selected brackets, quotient families, measurable envelopes, countable choice, selected limits, and ambient completeness as local certificate data.*

No calibrated metric-family obligation is stored outside $M, K, B, C, Pc, E, U, H, T, Q, N$.

Proof. Carrier admission is projection from Definition 7782.1. The packet displays the metric source, compact-metric source, finite bracket list, covering and packing rows, entropy ledger, modulus handoff, transport, replay, provenance, and local naming rows.

Bracket visibility comes next. A calibration reader reaches neither E nor U until it has inspected the finite bracket row B and the tolerance shared with the metric and compact-metric sources.

The covering and packing rows are rowwise comparisons. They are read against the same M, K, B surface, so their budgets cannot be replaced by a host covering argument, a selected packing, or a compactness principle outside the packet.

Finally E and U account for entropy and modulus-facing consumption, while H, T, Q, N transport, replay, source, and name the same finite route. Since the carrier contains none of the excluded host or choice coordinates, the listed rows exhaust the local NameCert surface. □

Theorem 7782.3 (Calibrated metric-family entropy handoff)**.** *Every* $\mathsf{FiniteMetricEntropy}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CalibratedMetricFamily}^{\uparrow}$ *carrier factors through*

$$M, K, B \longmapsto C, Pc, E \longmapsto U, H, T, Q, N.$$

The consumer receives a finite bracketing and entropy calibration ledger before any uniform-modulus read is exposed. It receives no host function-space compactness theorem, no selected bracket family,

no quotient-family equality, no measurable envelope, no selected limit, and no countable-choice schedule.

Proof. Begin with the carrier projection. The metric and compact-metric rows M, K supply the only source surface, and the bracket row B is the only place where a family envelope can be read.

The entropy-facing rows then open in order. The covering row C and packing row Pc are read at the displayed tolerance, and the finite entropy row E compares those budgets with the finite bracket list.

Only after this entropy route is visible may the handoff row U be consumed by a $\mathsf{UniformModulus}^{\uparrow}$ reader. The transport, replay, provenance, and local naming rows keep the same route attached under hsame and Cont.

The refused host principles have no carrier coordinate. Therefore every entropy or modulus-facing consumer factors through the displayed finite route and cannot replace it by function-space compactness, selected brackets, quotient families, measurable envelopes, selected limits, or countable choice. □

Falsifiable prediction: An accepted $\mathsf{CalibratedMetricFamily}^{\uparrow}$ consumer that exports a uniform-modulus read without first displaying the metric source, compact-metric source, finite bracket row, covering row, packing row, and entropy budget refutes the carrier surface.

Independence witness: metric, compactmetric, finite-metric-entropy, metric-covering-number, packing-number, uniformmodulus: no listed sibling is bijective with $\mathsf{CalibratedMetricFamily}^{\uparrow}$ because this packet jointly carries metric-family source data, finite brackets, covering and packing budgets, entropy calibration, uniform-modulus handoff, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CalibratedMetricFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CalibratedMetricFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7782.1, Definition 7782.2, and Definition 7782.3 seed the finite bracketing, covering, packing, entropy, and uniform-modulus handoff surface for displayed metric-family calibration data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CalibratedMetricFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close empirical-process convergence, measurable envelopes, host function-space compactness, countable bracket families, selected limits, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, bracket visibility, covering and packing exactness, entropy compatibility, uniform-modulus handoff, and ledger nonescape for BEDC.Derived.CalibratedMetricFamilyUp.

Constructive story: A $\mathsf{CalibratedMetricFamily}^{\uparrow}$ packet is generated from MetricUp source data, CompactMetricUp source data, finite bracket rows, MetricCoveringNumberUp and PackingNumberUp budgets, FiniteMetricEntropyUp calibration, UniformModulusUp handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7783

Zero-Dimensional Compact Space NameCert Construction

Following Engelking and Stone, the $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ packet records the compact zero-dimensional interface as a finite clopen-basis carrier rather than as a host point-set primitive. It consumes the Stone-space route of chapter 7424, the topology rows of chapter 88, and the clopen algebra ledger of chapter 7214. The compact Hausdorff readback is the displayed $\mathsf{CompactHausdorff}^{\uparrow}$ row already exposed by the Stone-space carrier, so the packet is a compact zero-dimensional surface over existing BEDC rows, not a duplicate Stone-space construction.

Definition 7783.1 (Zero-dimensional compact space carrier)**.** *A* $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, T, K, L, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StoneSpace}^{\uparrow}$ *source row. It supplies the Boolean-to-clopen route and the compact Hausdorff readback already certified by the Stone-space packet.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *public-open row read from the same source. It exposes only the indexed opens generated by the displayed clopen ledger.*
3. *K is the* $\mathsf{CompactHausdorff}^{\uparrow}$ *compact separation row. It is consumed as a readback obligation over S and T, not as a host compactification theorem.*
4. *L is the* $\mathsf{ClopenAlgebra}^{\uparrow}$ *ledger of clopen rows whose finite Boolean operations generate the public-open basis.*
5. *B is the zero-dimensional basis row. It records that every accepted public neighbourhood request is answered by a displayed clopen row from L before it reaches T or K.*
6. *H records componentwise* hsame *transport for the Stone source, topology row, compact Hausdorff row, clopen ledger, basis row, replay, provenance, and local name.*
7. *C records displayed* Cont *replay for the route*

$$S, L, B \longmapsto T, K.$$

8. *P is the* Pkg *provenance over* $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$, $\mathsf{StoneSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{CompactHausdorff}^{\uparrow}$, $\mathsf{ClopenAlgebra}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, T, K, L, B, H, C, P, N$. It has no coordinate for selected ultrafilters, arbitrary host opens, quotient topology equality, open-cover compactness, selected clopen refinements, or bridge checking.

Theorem 7783.2 (Zero-dimensional compact space NameCert obligations)**.** *For every accepted* $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ *carrier*

$$Z = (S, T, K, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}}$ *surface consists exactly of Stone-space source exposure through S, topology public-open exposure through T, compact Hausdorff readback through K, clopen-algebra ledger exposure through L, clopen-basis response through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every compact-topology consumer receives the zero-dimensional compact interface only through those rows.*

Proof. Project the carrier of Definition 7783.1. The packet exposes exactly the Stone source, topology row, compact Hausdorff readback, clopen ledger, basis row, transport, replay, provenance, and local naming row.

The Stone-space source supplies the Boolean-to-clopen route, while L and B keep the clopen generator visible before any public topology read is exported. Thus a consumer cannot replace the basis row by a host open set or by an unrecorded clopen selector.

The compact Hausdorff row is read only as K over the same displayed topology row T. Since the carrier has no selected ultrafilter, arbitrary-open completion, quotient topology equality, selected refinement, or bridge witness coordinate, those objects remain outside the local NameCert surface. □

Theorem 7783.3 (Zero-dimensional compact space clopen-basis stability)**.** *Every transported or replayed* $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ *public-open request preserves the same clopen-basis route*

$$\mathsf{StoneSpace}^{\uparrow} \longmapsto \mathsf{ClopenAlgebra}^{\uparrow} \longmapsto \mathsf{Topology}^{\uparrow}.$$

If two accepted packets are compared by H or replayed by C, the basis row B still answers each public neighbourhood request through the same clopen ledger L before the compact Hausdorff row K is consumed.

Proof. Start with a public-open request in an accepted carrier. The carrier forces the request to pass through B, and B names only clopen rows from L as its basis responses.

Componentwise hsame transport preserves the displayed rows S, T, K, L, B. Displayed Cont replay uses the same route $S, L, B \longmapsto T, K$, so replay cannot insert an arbitrary open, a selected refinement, or a quotient-topology witness.

Therefore every transported or replayed request still has the displayed clopen-basis origin before it is consumed by the compact Hausdorff readback. □

Theorem 7783.4 (Zero-dimensional compact space compact Hausdorff route)**.** *Every compact-facing read of an accepted* $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StoneSpace}^{\uparrow},\ \mathsf{ClopenAlgebra}^{\uparrow},\ \mathsf{Topology}^{\uparrow},\ \mathsf{CompactHausdorff}^{\uparrow},\ H, C, P, N.$$

The route exports compact zero-dimensional structure as displayed clopen-basis and compact Hausdorff rows; it exports no host compact space, open-cover compactness proof, selected subcover, ultrafilter choice, quotient topology equality, or checked standard bridge.

Proof. The compact-facing read first exposes the Stone-space source row S. The clopen algebra ledger L and basis row B then determine the public topology row T before any compact Hausdorff readback is available.

The compact readback is exactly K. It is tied to the same S, T, L, B rows by componentwise transport and displayed replay, and P, N record only that finite package and local name.

Since the accepted carrier has no field for host compact spaces, open-cover compactness, selected subcovers, ultrafilter choice, quotient topology equality, or a standard bridge, the displayed route exhausts the compact Hausdorff handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}$ packet is generated from StoneSpace source rows, Topology public-open rows, CompactHausdorff readback rows, a ClopenAlgebra ledger, clopen-basis responses, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7783.1, Definition 7783.2, Definition 7783.3, and Definition 7783.4 seed the compact zero-dimensional interface over StoneSpaceUp, TopologyUp, CompactHausdorffUp, ClopenAlgebraUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ZeroDimensionalCompactSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected ultrafilters, arbitrary host opens, quotient topology equality, open-cover compactness, selected subcovers, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, clopen-basis stability, compact Hausdorff route exposure, transport, replay, provenance, and local naming for BEDC.Derived.ZeroDimensionalCompactSpaceUp.

Chapter 7784

Dyadic Cantor Window NameCert Construction

Following Cantor-space prefix practice and the finite-cover proof of Heine–Cantor, the $\mathsf{DyadicCantorWindow}^{\uparrow}$ packet records finite Boolean prefix windows with dyadic refinement rows. It sits beside the Boolean constructor surface of chapter 32, the finite spine discipline of chapter 36, the dyadic tolerance ledger of chapter 291, the compact metric source of chapter 129, and the uniform-modulus consumer of chapter 369. The packet is a finite prefix-window carrier; it is not a completed Cantor space, a host product space, or a selected infinite branch.

Definition 7784.1 (Dyadic Cantor window carrier)**.** *A* $\mathsf{DyadicCantorWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, L, D, M, U, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *digit row used to discriminate the two Cantor-prefix branches.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *finite prefix row. It stores only finite Boolean words and their prefix extension relation.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger. It records the dyadic cell, depth, radius, and comparison budget attached to each finite prefix window.*
4. *M is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row for the compact finite-window source.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that may consume the finite window after dyadic refinement has been exposed.*
6. *R is the prefix refinement row tying B, L, D together. It records how successor windows split by Boolean digit and how their dyadic cells sit inside the parent cell.*
7. *H records componentwise* hsame *transport for Boolean digits, list prefixes, dyadic rows, compact-metric support, uniform-modulus handoff, refinement, replay, provenance, and local name.*
8. *C records displayed* Cont *replay for the finite route*

$$B, L, D, R \longmapsto M, U.$$

9. *P is the* Pkg *provenance over* $\mathsf{DyadicCantorWindow}^{\uparrow}$, $\mathsf{Bool}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicCantorWindow}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, L, D, M, U, R, H, C, P, N$. It has no coordinate for an infinite branch, completed Cantor space, host product topology, selected subcover, global fan functional, countable choice, quotient stream equality, or bridge checking.

Lean4 ✓ `BEDC.Derived.DyadicCantorWindowUp.DyadicCantorWindowTasteGate single carrier alignment`

Theorem 7784.2 (Dyadic Cantor window NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCantorWindow}^{\uparrow}$ *carrier*

$$W = (B, L, D, M, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCantorWindow}^{\uparrow}}$ *surface consists exactly of Boolean digit exposure through B, finite prefix exposure through L, dyadic refinement exposure through D, compact-metric support through M, uniform-modulus handoff through U, prefix-refinement stability through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No window obligation is stored outside those rows.*

Proof. Projection from Definition 7784.1 gives exactly the displayed Boolean, finite-list, dyadic, compact-metric, uniform-modulus, refinement, transport, replay, provenance, and local naming rows.

The finite prefix discipline is carried by L, and the only branch split available to the packet is the displayed Boolean digit row B. The dyadic ledger D attaches a finite cell and tolerance budget to those prefixes before compact or uniform consumers can read the packet.

The rows H, C, P, N preserve and name the same finite route. Since there is no field for infinite branches, completed Cantor space, selected subcovers, countable choice, quotient stream equality, or a bridge witness, the listed rows exhaust the local NameCert obligations. □

Theorem 7784.3 (Dyadic Cantor window vision handoff)**.** *Every compact-uniform-continuity consumer reading a* $\mathsf{DyadicCantorWindow}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{Bool}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ H, C, P, N.$$

The handoff realizes a finite prefix-window cover with dyadic refinement rows before the uniform-modulus ledger is consumed; it exports no completed Cantor space, selected infinite branch, global fan functional, selected subcover, host product topology, quotient stream equality, or countable choice.

Proof. Begin with the prefix rows. The Boolean digit row B and finite list row L determine the inspected prefix window, while the refinement row R records the immediate successor windows without selecting an infinite branch.

The dyadic ledger D gives the cell and tolerance budget for that finite prefix. Only after B, L, D, R are displayed may the compact-metric support row M and uniform-modulus handoff row U be read.

Componentwise transport, replay, provenance, and local naming preserve this finite order. Therefore the compact-uniform-continuity consumer receives a finite prefix-window carrier rather than any completed or choice-based Cantor object. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCantorWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCantorWindow}^{\uparrow}$ packet is generated from Bool digit rows, List finite prefix rows, DyadicRatCore refinement ledgers, CompactMetric support, UniformModulus handoff rows, prefix-refinement stability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicCantorWindow}\uparrow}$, seed)

Scope closed: Definition 7784.1, Definition 7784.2, and Definition 7784.3 seed the finite dyadic Cantor prefix-window route over BoolUp, ListUp, DyadicRatCoreUp, CompactMetricUp, UniformModulusUp, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicCantorWindow}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.DyadicCantorWindowUp.DyadicCantorWindowTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close completed Cantor space, selected infinite branches, global fan functionals, selected subcovers, host product topology, quotient stream equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix refinement stability, dyadic compact-window handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCantorWindowUp.

Chapter 7785

A Concrete Naming Certificate for $\mathsf{AscoliLTenCompactFamily}^{\uparrow}$

Following Arzela, Ascoli, and Bishop–Bridges constructive analysis, the $\mathsf{AscoliLTenCompactFamily}^{\uparrow}$ packet records the reusable compact-uniform family carrier used before any selection theorem is invoked. It sits after the compact metric source of chapter 129, the bounded-family ledger of chapter 3522, the equicontinuity family surface of chapter 413, the finite diagonal schedule of chapter 2219, and the terminal readback rows of chapter 301 and chapter 38. The chapter names the compact family carrier only; it does not assert a host function-space compactness theorem, a selected subsequence outside the displayed schedule, quotient equality of functions, or ambient completeness.

Definition 7785.1 (Ascoli L10 uniform compact-family carrier)**.** *An* $\mathsf{AscoliLTenCompactFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{A}_{10} = (K, B, E, F, U, W, Q, R, H, C, P, N),$$

where K is the compact source row read through $\mathsf{CompactMetric}^{\uparrow}$*, B is the bounded-family row read through* $\mathsf{BoundedFunctionFamily}^{\uparrow}$*, E is the equicontinuity row read through* $\mathsf{EquicontinuityFamily}^{\uparrow}$*, F is the displayed compact finite-net row, U is the uniform-modulus handoff row, W is the finite window schedule read through* $\mathsf{StreamName}^{\uparrow}$*, Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise* hsame *transport across source, family, net, window, readback, and seal rows, C is displayed* Cont *replay for the same finite route, P is* Pkg *provenance over the listed sibling packets, and N is the local* $\mathsf{NameCert}_{\mathsf{AscoliLTenCompactFamily}^{\uparrow}}$ *row.*

Theorem 7785.2 (Ascoli L10 finite-net subsequence obligation)**.** *Every accepted* $\mathsf{AscoliLTenCompactFamily}^{\uparrow}$ *consumer that later reads a compact-family or subsequence-facing conclusion must first display the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{BoundedFunctionFamily}^{\uparrow},\ \mathsf{EquicontinuityFamily}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route exposes the compact finite-net row F, the uniform modulus row U, the window schedule W, the regular rational readback Q, and the Real seal R before any downstream compact-uniform argument may consume the packet. It exports no host function-space compactness theorem, no selected representative outside W, no quotient stream equality, and no ambient completeness principle.

Proof. Start from the carrier of Definition 7785.1. The compact source, bounded family, equicontinuity family, finite-net, uniform-modulus, window, readback, and seal coordinates are all explicit rows of the tuple.

The finite-net and window rows determine the only subsequence-facing schedule available to later Ascoli consumers. The $\mathsf{RegSeqRat}^{\uparrow}$ row reads that schedule as regular rational data, and the $\mathsf{Real}^{\uparrow}$ row seals only the displayed readback.

Transport and replay are componentwise through H and C, while provenance and local naming are carried by P and N. Since the tuple contains no coordinate for host compactness, selected representatives outside W, quotient stream equality, or ambient completeness, every downstream read factors through the listed finite route. □

Theorem 7785.3 (Ascoli L10 NameCert ledger)**.** *The local* $\mathsf{NameCert}_{\mathsf{AscoliLTenCompactFamily}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-family row, equicontinuity row, compact finite-net row, uniform-modulus row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local NameCert row* N*. The ledger is a reusable compact-uniform family carrier for downstream Ascoli and completion arguments, not a replacement for the selection theorem of chapter 3930 or the diagonal packet of chapter 2219.*

Proof. Read the accepted packet coordinate by coordinate. The rows B, E, F, U, Q, R supply the bounded-family, equicontinuity, compact finite-net, uniform modulus, regular rational readback, and terminal seal obligations.

The rows H, C, P, N then record transport, replay, provenance, and local naming for exactly those obligations. No further NameCert clause can be read, because no further row occurs in the carrier.

Thus the ledger exposes a reusable compact-uniform family surface. Selection, diagonal extraction, quotient equality, and host compactness remain outside the local packet unless a downstream chapter supplies its own displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliLTenCompactFamily}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AscoliLTenCompactFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7785.1, Definition 7785.2, and Definition 7785.3 seed the finite compact-uniform family carrier over bounded-family, equicontinuity, compact finite-net, uniform-modulus, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliLTenCompactFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function-space compactness, selected subsequences outside the displayed schedule, quotient function equality, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net route, readback exactness, transport, replay, provenance, and local naming for BEDC.Derived.AscoliLTenCompactFamilyUp.

Constructive story: An $\mathsf{AscoliLTenCompactFamily}^{\uparrow}$ packet is generated from a compact source row, bounded-family row, equicontinuity-family row, compact finite-net row, uniform-modulus handoff, finite StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7786

A Concrete Naming Certificate for $\mathsf{WhitneyDecomposition}^{\uparrow}$

Following Whitney on decompositions of open sets, the $\mathsf{WhitneyDecomposition}^{\uparrow}$ packet records the finite-window NameCert surface for covering a displayed metric-open region by dyadic cells whose sizes are controlled by their distance to the displayed boundary. It sits over the dyadic grid and tolerance rows of chapter 1658, chapter 291, and chapter 1877, the metric and ball rows of chapter 4230 and chapter 1450, the finite-cover route of chapter 6105, and the located-real comparison surface of chapter 1730. The packet names only a finite decomposition window; it does not assert an infinite locally finite family, selected nearest boundary points, open-cover compactness, quotient cubes, or ambient completeness.

Definition 7786.1 (Whitney decomposition carrier)**.** *A* $\mathsf{WhitneyDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (X, U, D, Q, A, L, B, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row with the metric ball and located-distance reads available to the decomposition window;*
2. *U is the displayed open-region row, naming the finite membership tests whose admitted points may be covered;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *and dyadic-grid ledger, recording the dyadic scales and coordinate cells used by the window;*
4. *Q is the finite cell inventory, listing the displayed dyadic cells and their parent-child refinement relations;*
5. *A is the admission row, requiring each listed cell to lie inside U through metric-ball certificates;*
6. *L is the local-finiteness ledger, recording finite overlap checks for the displayed cell inventory;*
7. *B is the boundary-distance comparison row, relating each admitted cell diameter to the located distance from that cell to the displayed complement boundary;*
8. *H records componentwise* hsame *transport for the metric, dyadic, cover, overlap, and boundary-distance rows;*
9. *C records displayed* Cont *replay for cell admission, finite-overlap reads, and boundary-distance comparisons;*

10. *P is the* Pkg *provenance over* $\mathsf{WhitneyDecomposition}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *dyadic cover rows, finite metric covers, located-real comparison rows,* BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, U, D, Q, A, L, B, H, C, P, N$.

Theorem 7786.2 (Whitney decomposition NameCert obligations)**.** *Every accepted* $\mathsf{WhitneyDecomposition}^{\uparrow}$ *packet binds exactly the finite NameCert obligation surface of Definition 7786.1: metric-source exposure through X, open-region membership through U, dyadic scale and cell data through D, Q, cell admission through A, finite local-overlap checks through L, boundary-distance control through B, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $W = (X, U, D, Q, A, L, B, H, C, P, N)$. The metric and region rows supply the source carrier and the displayed open-region membership tests, while the dyadic rows supply only the finite cell inventory named by the packet.

The admission, overlap, and boundary rows then own the analytic checks. Cell containment is read through A, local finiteness is read through the finite overlap ledger L, and boundary-distance control is read through B.

Finally H, C, P, N transport, replay, cite, and name the same displayed rows. Since the carrier has no additional coordinate, the NameCert surface cannot expose an infinite decomposition, selected boundary points, open-cover compactness, quotient cubes, or ambient completeness. □

Theorem 7786.3 (Whitney decomposition local finite cover)**.** *For every accepted* $\mathsf{WhitneyDecomposition}^{\uparrow}$ *carrier $W = (X, U, D, Q, A, L, B, H, C, P, N)$, every covered point of the displayed open row U is read through a finite subinventory of Q, and every local-overlap query is answered by the finite ledger L. Thus the public cover read is a finite dyadic-window cover over X and U, not an infinite locally finite family, selected enumeration, open-cover compactness proof, or host topological cover.*

Proof. Begin with a point admitted by U. The cover read must inspect the metric source X, the dyadic scale ledger D, and the finite cell inventory Q before it can name a cell containing the point.

Use the admission row A to keep every selected displayed cell inside the open-region row. The local-overlap ledger L then answers neighbourhood and overlap queries by finite inspection of the same inventory Q.

Transport through H and replay through C preserve the displayed finite inventory. The provenance and local naming rows record no additional cells, so the read remains a finite dyadic cover window and cannot become a global host cover principle. □

Theorem 7786.4 (Whitney decomposition boundary-distance control)**.** *For every accepted* $\mathsf{WhitneyDecomposition}^{\uparrow}$ *carrier $W = (X, U, D, Q, A, L, B, H, C, P, N)$, each public cell read from Q exposes a dyadic diameter estimate and a located-real comparison in B relating that diameter to the displayed distance from the cell to the complement boundary of U. The estimate is read only through* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *dyadic cover rows, and located-real comparison rows; it exports no selected nearest boundary point, no quotient cube equality, no ambient real completeness theorem, and no global Whitney decomposition theorem.*

Proof. Read a cell through the finite inventory Q and its dyadic scale data in D. The dyadic ledger supplies the diameter window, while the metric and ball rows in X supply the distance reads available to the packet.

The boundary-distance comparison is the row B. It compares the displayed dyadic diameter with the located boundary-distance window and records the comparison as part of the finite carrier, not as a selected nearest-boundary construction.

The structural rows H, C, P, N do not add an analytic endpoint. They preserve, replay, source, and name the same metric, dyadic, cover, and comparison rows, so quotient cube equality, ambient completeness, and a global Whitney theorem remain outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{WhitneyDecomposition}^{\uparrow}$ read exposes a MetricSpace source row, an open-region membership row, DyadicRatCore scale data, a finite dyadic cell inventory, cell-admission witnesses, finite local-overlap checks, boundary-distance comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any cover or boundary-control consumer receives the packet.

Independence witness: whitney-covering-finite, finite-metric-cover, dyadic-cover-refinement, located-real-comparison: no listed sibling supplies the full eleven-row packet $W = (X, U, D, Q, A, L, B, H, C, P, N)$, because each sibling contributes only a finite cover route, a dyadic refinement ledger, or a located comparison surface while this chapter binds the Whitney decomposition window into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{WhitneyDecomposition}^{\uparrow}$ packet is generated from a MetricSpace source row, an open-region row, DyadicRatCore scale data, finite dyadic cell inventory, admission witnesses, finite local-overlap ledger, boundary-distance comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WhitneyDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7786.1, Definition 7786.2, Definition 7786.3, and Definition 7786.4 seed the finite Whitney decomposition window over displayed metric, dyadic, cover, overlap, comparison, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WhitneyDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close infinite locally finite decompositions, selected nearest boundary points, open-cover compactness, quotient cube equality, ambient completeness, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, dyadic cell inventory, local finite cover readback, boundary-distance control, transport, replay, provenance, and local naming for BEDC.Derived.WhitneyDecompositionUp.

Chapter 7787

A Concrete Naming Certificate for $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$

Following Heine–Cantor in Bishop–Bridges constructive analysis, the $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$ packet records the finite oscillation-window carrier that turns compact finite-net data and pointwise continuous-map moduli into a tolerance-only uniform-modulus read. It realizes the compact-uniform-continuity route of chapter 9237 and sits over the compact metric source of chapter 129, the compact certificate of chapter 60, the continuous-map rows of chapter 130, the rational fold of chapter 37, the finite minimum surface of Definition 9237.5, the uniform-modulus target of chapter 369, and the terminal real-name seal of chapter 38. The packet names a finite oscillation ledger; it does not assert open-cover compactness, selected global moduli, function-space quotient equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7787.1 (Compact finite oscillation modulus carrier)**.** *A* $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, K, F, E, R, M, U, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the metric carrier and compact finite-net data;*
2. *K is the compact finite-net bundle, naming the centers, coverage rows, and finite* $\mathsf{ProbeBundle}$ *spine used at a tolerance;*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed map whose oscillation is being controlled;*
4. *E is the positive* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tolerance row requested by the consumer;*
5. *R is the pointwise radius ledger over the centers of K, read through the continuous-map certificate;*
6. *M is the finite rational lower-bound fold over the pointwise radii, using only* $\mathsf{Rat}^{\uparrow}$ *order readback;*
7. *U is the resulting* $\mathsf{UniformModulus}^{\uparrow}$ *ledger from the tolerance row E to the folded precision row;*
8. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *comparison seal used when the oscillation statement is read in real-valued form;*
9. *H records componentwise* hsame *transport for compact, continuous-map, rational-fold, uniform-modulus, and real-seal rows;*

10. *C records displayed* Cont *replay for finite-net coverage, pointwise-radius reads, rational folds, and uniform-modulus readback;*
11. *P is the* Pkg *provenance over* $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactFiniteOscillationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, K, F, E, R, M, U, T, H, C, P, N$.

Theorem 7787.2 (Compact finite oscillation NameCert obligations)**.** *Every accepted* CompactFiniteOscillationMod *packet binds exactly the finite NameCert obligation surface of Definition 7787.1: compact metric source exposure through X, finite-net coverage through K, continuous-map pointwise modulus exposure through F, R, tolerance readback through E, rational lower-bound folding through M, uniform-modulus output through U, real-valued oscillation sealing through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier $O = (X, K, F, E, R, M, U, T, H, C, P, N)$. The compact source and finite-net rows are X, K, while the displayed continuous map and tolerance request are F, E.

The pointwise oscillation data are read through R. The finite rational fold M then consumes the finite radius ledger and produces the precision row used by the uniform-modulus ledger U.

The real-valued read is sealed only through T, and the structural rows H, C, P, N preserve the same finite route. No coordinate supplies open-cover compactness, a selected global modulus, quotient function equality, countable choice, or ambient real completeness. □

Theorem 7787.3 (Compact finite oscillation uniform readback)**.** *For every accepted* CompactFiniteOscillationModu *carrier $O = (X, K, F, E, R, M, U, T, H, C, P, N)$, a consumer requesting oscillation at tolerance E must first read the compact finite-net row K, the continuous-map pointwise radius ledger R, and the rational lower-bound fold M. The public output is the* $\mathsf{UniformModulus}^{\uparrow}$ *row U, optionally sealed by the* $\mathsf{Real}^{\uparrow}$ *comparison row T, and it is not a selected modulus function, open-cover compactness theorem, quotient function-space equality, or ambient completeness claim.*

Proof. Start with the tolerance request E. The compact source row X and finite-net bundle K determine the finite list of center-radius obligations that the continuous-map row must answer.

Read the pointwise radius ledger through F and R. The fold row M performs only finite $\mathsf{Rat}^{\uparrow}$ lower-bound comparison over that ledger, so the resulting precision depends on the displayed tolerance and finite bundle rather than on a selected global modulus.

The uniform readback is the row U. The optional real-valued seal T records the oscillation comparison after the uniform-modulus row is available, and H, C, P, N add no independent analytic endpoint. Thus the packet exports exactly the finite uniform-modulus readback. □

Falsifiable prediction: Every accepted $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$ read exposes CompactMetric source data, a compact finite-net ProbeBundle row, ContinuousMap pointwise modulus rows, RatUp tolerance and lower-bound folds, a UniformModulus output ledger, a RealUp comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any uniform-oscillation consumer receives the packet.

Independence witness: compactuniformcontinuity, compact-uniform-modulus, finitenetminimumfold, subordinatemoduluscover: no listed sibling supplies the full twelve-row packet $O = (X, K, F, E, R, M, U, T, H, C, P, N)$, because each sibling contributes only a finite-net construction, a pointwise-modulus cover, a rational fold, or a uniform-modulus target while this chapter binds the oscillation window into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactFiniteOscillationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactFiniteOscillationModulus}^{\uparrow}$ packet is generated from a CompactMetric source row, compact finite-net ProbeBundle data, ContinuousMap pointwise-radius rows, RatUp tolerance and lower-bound folds, a UniformModulus output ledger, a RealUp comparison seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactFiniteOscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7787.1, Definition 7787.2, and Definition 7787.3 seed the compact finite oscillation modulus packet over displayed compact, continuous-map, rational-fold, uniform-modulus, real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactFiniteOscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected global moduli, quotient function-space equality, countable choice, ambient RealUp completeness, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, compact finite-net exposure, pointwise-radius reads, rational lower-bound fold, uniform readback, transport, replay, provenance, and local naming for BEDC.Derived.CompactFiniteOscillatio

Chapter 7788

A Concrete Naming Certificate for $\mathsf{MetricUniformity}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures generated by metrics, the $\mathsf{MetricUniformity}^{\uparrow}$ packet records the finite BEDC handoff from displayed metric balls to uniform entourages. It sits between the metric carrier of chapter 57, the uniform-space surface of chapter 339, the complete-metric route of chapter 128, the compact-metric row of chapter 129, the stream-name windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only the entourage basis generated by positive Real radii and its completion-facing readers; it does not add host uniform-space primitives, quotient filters, selected limits, open-cover compactness, or ambient Real completeness.

Definition 7788.1 (Metric uniformity carrier)**.** *A* $\mathsf{MetricUniformity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, E, B, C, F, H, T, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *row whose distance observations and named balls are the source of every entourage request.*
2. *E is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage family generated by positive* $\mathsf{Real}^{\uparrow}$ *radii from M.*
3. *B is the finite ball-basis row, listing the inspected centers, positive radius names, and inclusion witnesses used to cover one requested entourage.*
4. *C is the Cauchy-filter handoff row for completion-facing consumers that read Cauchy data through the generated entourages.*
5. *F is the completion-facing row that exposes the same generated uniformity to* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *stream-window, and regular-readback consumers.*
6. *H stores componentwise* hsame *transports for M, E, B, C, F and the local naming row.*
7. *T stores displayed* Cont *replay from a metric-ball request through positive-radius generation, entourage exposure, Cauchy-filter handoff, and completion-facing readback.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricUniformity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricUniformity}^{\uparrow}}$ *registration row.*

The classifier compares accepted packets only through these rows. There is no coordinate for primitive uniformity independent of the metric row, quotient Cauchy-filter equality, a selected completion point, open-cover compactness, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7788.2 (MetricUniformity NameCert obligations)**.** *For every accepted* $\mathsf{MetricUniformity}^{\uparrow}$ *carrier* $U = (M, E, B, C, F, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricUniformity}^{\uparrow}}$ *obligations are exhausted by carrier admission for the displayed metric row, generated entourage family, finite ball-basis row, Cauchy-filter handoff, completion-facing row, componentwise transport, continuation replay, provenance, and local naming; by positive-radius generation of each entourage from* M *through* B*; by completion-facing consumption through* C *and* F*; and by ledger refusal for host uniform-space primitives, quotient filters, selected completion points, open-cover compactness, countable choice, trichotomy, and ambient Real completeness.*

Proof. Project the carrier of Definition 7788.1. The analytic rows are M, E, B, C, F, and the structural rows are H, T, P, N.

The generated-entourage obligation first reads a positive $\mathsf{Real}^{\uparrow}$ radius and a metric ball from M. The finite basis row B records the inspected centers and inclusions needed to present that ball request as an entourage in E.

Completion-facing consumers are downstream of the generated row. A Cauchy-filter read uses C, and the complete-metric or compact-metric read uses F, only after E and the finite basis data have been exposed.

Transport, replay, provenance, and local naming preserve exactly this route. Since the packet has no independent coordinate for host uniformity, quotient filters, selected completion points, open-cover compactness, countable choice, trichotomy, or ambient Real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7788.3 (MetricUniformity entourage basis)**.** *Every entourage exposed by an accepted* $\mathsf{MetricUniformity}^{\uparrow}$ *packet factors through a finite metric-ball basis row. More precisely, a consumer of* E *must display the metric row* M*, a positive* $\mathsf{Real}^{\uparrow}$ *radius, and the finite basis row* B *before the entourage can be read as a* $\mathsf{UniformSpace}^{\uparrow}$ *surface. The read cannot replace that finite route by a primitive host entourage family or by quotient equality of filters.*

Proof. Start with an accepted packet $U = (M, E, B, C, F, H, T, P, N)$. The carrier definition makes E generated data rather than a primitive uniformity row.

To read an entourage, the continuation replay T first exposes the metric observation in M and the positive radius name. The row B then supplies the finite ball-basis evidence for the requested scale and center data.

Only after those rows are displayed may the consumer read E as a $\mathsf{UniformSpace}^{\uparrow}$ surface. Componentwise transport in H preserves the same M, B, E route, while P and N record no independent host entourage source. □

Theorem 7788.4 (MetricUniformity Cauchy-filter handoff)**.** *Every* $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *completion-facing read of an accepted* $\mathsf{MetricUniformity}^{\uparrow}$ *packet must pass through the generated entourage row* E*, the finite basis row* B*, the Cauchy-filter handoff* C*, and the completion-facing row* F*. Thus metric completion consumers see a finite Metric-to-UniformSpace route, not a host completion object, selected Cauchy limit, quotient filter, or ambient completeness principle.*

Proof. Begin with a completion-facing consumer. Carrier admission gives access only to $M, E, B, C, F, H, T, P, N$.

The entourage read is forced by Definition 7788.3. Hence M and B are visible before any uniform-space consumer can inspect E.

The Cauchy-filter handoff C is the next available completion row, and F is the row through which complete-metric, compact-metric, stream-window, regular-readback, and Real-seal consumers read the generated uniformity.

The structural rows preserve and name the same finite route. Because no carrier row stores a host completion object, selected limit, quotient filter, countable-choice schedule, open-cover compactness, trichotomy, or ambient Real completeness, none of those objects can be exported by the handoff. □

Falsifiable prediction: An accepted $\mathsf{MetricUniformity}^{\uparrow}$ read is refuted if a completion-facing consumer obtains a $\mathsf{UniformSpace}^{\uparrow}$ entourage or Cauchy-filter handoff without displaying the metric row, a positive Real radius, the finite ball-basis row, generated entourage row, transport, replay, provenance, and local NameCert rows.

Independence witness: metric, uniformspace, completemetric, compactmetric, streamname, regseqrat, real: none alone is bijective to $\mathsf{MetricUniformity}^{\uparrow}$ because this packet binds metric balls, positive Real radius generation, finite basis evidence, generated entourages, Cauchy-filter handoff, completion-facing readback, transport, replay, provenance, and local naming as one bridge.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricUniformity}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricUniformity}^{\uparrow}$ packet is generated from MetricUp distance rows, positive RealUp radius requests, finite ball-basis evidence, UniformSpaceUp entourage rows, Cauchy-filter handoff rows, completion-facing rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricUniformity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7788.1, Definition 7788.2, Definition 7788.3, and Definition 7788.4 seed the finite Metric-to-UniformSpace bridge for completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricUniformity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host uniform-space primitives, quotient Cauchy-filter equality, selected completion points, open-cover compactness, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius generation, finite entourage-basis coverage, Cauchy-filter handoff, completion-facing readback, transport, replay, provenance, and local NameCert coverage for the displayed packet.

Chapter 7789

A Concrete Naming Certificate for $\mathsf{MengerCurve}^{\uparrow}$

Following Menger and continuum theory, the $\mathsf{MengerCurve}^{\uparrow}$ packet records the universal one-dimensional compact metric continuum by finite cube-refinement obligations rather than by an ambient subset of Euclidean space. It sits between the compactum surface of chapter 7046, the continuum boundary of chapter 2160, the planar comparison surface of chapter 3960, the compact metric carrier of chapter 129, and the metric source of chapter 57. The packet gives L10 compact and metric consumers a finite refinement ledger for the curve; it does not import open-cover compactness, host hyperspace equality, selected points, quotient continua, or ambient completeness.

Definition 7789.1 (Menger curve carrier)**.** *A* $\mathsf{MengerCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, K, L, S, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the displayed distance comparisons read by every cube-refinement request;*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, exposing compact metric coverage before any continuum or cube row is consumed;*
3. *L is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, recording connected locally connected compact-continuum data as a finite NameCert dependency;*
4. *S is the* $\mathsf{SierpinskiCarpet}^{\uparrow}$ *comparison row, recording the planar hole-boundary sibling used only as a contrast surface;*
5. *Q is the* $\mathsf{MengerCompactum}^{\uparrow}$ *row, carrying the compactum and covering-dimension surface already named for Menger compacta;*
6. *R is the finite cube-refinement ledger, whose entries name stage, retained subcubes, face-incidence tests, and adjacency witnesses;*
7. *E is the* $\mathsf{MengerCoverCompactness}^{\uparrow}$ *row, recording finite cover requests and finite subcover witnesses for the inspected refinement stage;*
8. *H records componentwise* hsame *transport for $M, K, L, S, Q, R, E, P, N$;*
9. *C records displayed* Cont *replay through the metric, compact, continuum, compactum, cube-refinement, cover, provenance, and local naming rows;*

10. *P is the* Pkg *provenance over* $\mathsf{MengerCurve}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{SierpinskiCarpet}^{\uparrow}$, $\mathsf{MengerCompactum}^{\uparrow}$, $\mathsf{MengerCoverCompactness}^{\uparrow}$, $\mathsf{MengerNobelingEmbedding}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerCurve}^{\uparrow}}$ *row.*

The carrier has no coordinate for an arbitrary open cover, a host continuum object, a quotient of compact subsets, a selected point sequence, or an ambient Euclidean equality oracle.

Theorem 7789.2 (Menger curve NameCert obligations)**.** *For every accepted* $\mathsf{MengerCurve}^{\uparrow}$ *carrier $U = (M, K, L, S, Q, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MengerCurve}^{\uparrow}}$ *surface consists exactly of metric exposure through M; compact metric finite-net exposure through K; Peano-continuum exposure through L; planar comparison exposure through S; Menger compactum exposure through Q; finite cube-refinement exposure through R; finite cover-compactness exposure through E; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Theorem 7789.3 (Menger curve finite cube refinement)**.** *Every compact, metric, continuum, or embedding-facing consumer of an accepted* $\mathsf{MengerCurve}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{PeanoContinuum}^{\uparrow},\ \mathsf{SierpinskiCarpet}^{\uparrow},\ \mathsf{MengerCompactum}^{\uparrow},\ R,\ \mathsf{MengerCoverCompactness}^{\uparrow},$$

through the displayed rows $M, K, L, S, Q, R, E, H, C, P, N$ before treating the packet as the Menger curve. The cube-refinement ledger R is consumed as finite subcube incidence and adjacency data; it cannot be replaced by open-cover compactness, a host universal-curve theorem, quotient compactum equality, or an ambient Euclidean subset.

Falsifiable prediction: An accepted $\mathsf{MengerCurve}^{\uparrow}$ consumer that reaches compact, metric, continuum, or embedding-facing data while omitting the finite cube-refinement ledger R refutes the carrier of Definition 7789.1.

Independence witness: menger-compactum, peano-continuum, sierpinski-carpet, compactmetric, metric: $\mathsf{MengerCurve}^{\uparrow}$ is not bijective to any listed sibling because this packet binds metric source rows, compact finite-net rows, continuum rows, planar comparison rows, Menger compactum rows, finite cube-refinement rows, finite cover-compactness rows, transport, replay, provenance, and local naming into one curve certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerCurve}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MengerCurve}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite-net row, a PeanoContinuumUp row, a SierpinskiCarpetUp comparison row, a MengerCompactumUp row, a finite cube-refinement ledger, a MengerCoverCompactnessUp row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MengerCurve}^{\uparrow}}$, seed)

Scope closed: Definition 7789.1, Definition 7789.2, and Definition 7789.3 seed the finite cube-refinement NameCert surface for the displayed Menger curve packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MengerCurve}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, open-cover compactness, host universal-curve uniqueness, quotient compactum equality, ambient Euclidean subset equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cube-refinement exposure, compact metric exposure, continuum exposure, Menger compactum exposure, cover-compactness exposure, transport, replay, provenance, and local naming for BEDC.Derived.MengerCurveUp.

Chapter 7790

A Concrete Naming Certificate for $\mathsf{ChannelTerminationBoundary}^{\uparrow}$

The $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ packet realizes the local delimiter boundary of chapter 9369 as finite NameCert data. It isolates the active-channel fact that a legal event ends at the first displayed 11 while refusing any conversion of that local boundary into a global halting classifier. The packet sits beside the channel/halting separator of chapter 3996, the type-checking classifier membership surface of chapter 3911, the MetaCIC parallel-diamond frontier of chapter 4238, the subject-reduction boundary of chapter 483, and the classifier boundary of chapter 595.

Definition 7790.1 (Channel termination boundary carrier)**.** *A* $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, E, T, D, R, F, H, C, P, N)$$

with the following displayed rows:

1. *A is the active binary alphabet row, recording the source fragments $0, 1$ and channel fragments $0, 10, 11$;*
2. *E is the legal channel-event row, recording membership in $(0 \mid 10)^*11$ for the inspected finite event;*
3. *T is the terminator row, recording that the first adjacent 11 is the local endpoint;*
4. *D is the decoder-state row, recording the finite scan state before and after the local endpoint;*
5. *R is the refusal row separating local delimiter termination from certificate-level halting;*
6. *F is the finite trace row, recording the inspected event prefix and the endpoint witness;*
7. *H records componentwise* hsame *transport for A, E, T, D, R, F, P, N;*
8. *C records displayed* Cont *replay through the active alphabet, legal-event, terminator, decoder, refusal, finite trace, provenance, and local naming rows;*
9. *P is the* Pkg *provenance over* $\mathsf{ChannelTerminationBoundary}^{\uparrow}$, $\mathsf{ChannelTerminationHaltingBoundary}^{\uparrow}$, $\mathsf{TypeCheckingClassifierMembership}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{SubjectReduction}^{\uparrow}$, $\mathsf{ClassifierBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ChannelTerminationBoundary}^{\uparrow}}$ *row.*

The carrier has no coordinate for a total halting oracle, evaluator equality, subject-reduction discharge, residual-substitution discharge, quotient equality, or kernel consistency.

Theorem 7790.2 (Channel termination boundary NameCert obligations)**.** *For every accepted* $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ *carrier* $B = (A, E, T, D, R, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ChannelTerminationBoundary}^{\uparrow}}$ *surface consists exactly of active alphabet exposure through* A*; legal event exposure through* E*; first-terminator exposure through* T*; decoder-state exposure through* D*; local/global refusal exposure through* R*; finite trace exposure through* F*; componentwise transport through* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Theorem 7790.3 (Channel termination boundary local delimiter)**.** *Every accepted* $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ *packet factors local event completion through the finite route*

$$A,\ E,\ T,\ D,\ F,\ H,\ C,\ P,\ N$$

and factors refusal of global halting through R*. A consumer may use the first displayed* 11 *as the endpoint of the current legal channel event, but it may not treat that endpoint as type-checking classifier membership, MetaCIC parallel-diamond closure, subject reduction, classifier-boundary collapse, evaluator equality, quotient equality, or kernel consistency.*

Falsifiable prediction: A claimed $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ consumer that decides certificate-level halting while displaying only the local legal-event row E and terminator row T refutes the carrier of Definition 7790.1.

Independence witness: type-checking-classifier-membership, metacic-parallel-diamond-frontier, subjectreduction, classifierboundary: $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ is not bijective to any listed sibling because it carries active alphabet, legal event, terminator, decoder-state, local/global refusal, finite trace, transport, replay, provenance, and local NameCert rows. Type-checking classifier membership lacks the local delimiter trace; the MetaCIC parallel-diamond frontier lacks the active-channel endpoint; subject reduction lacks the delimiter/refusal split; classifier boundary lacks the concrete first-11 event row.

The Lean follow-up must provide $\mathsf{Nontrivial}\ \mathsf{ChannelTerminationBoundary}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{ChannelTerminationB}$ TasteGate instances. Those instances must preserve $A, E, T, D, R, F, H, C, P, N$ as distinct displayed fields before any checked theorem may cite $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ as a field-faithful local delimiter boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{ChannelTerminationBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChannelTerminationBoundary}^{\uparrow}$ packet is generated from active alphabet rows, legal event rows, first-terminator rows, decoder-state rows, local/global refusal rows, finite trace rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChannelTerminationBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7790.1, Definition 7790.2, and Definition 7790.3 seed the finite local delimiter boundary separating channel-event termination from global halting claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChannelTerminationBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, global halting decidability, subject reduction, full parallel diamond, evaluator equality, quotient equality, kernel consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, legal-event exposure, first-terminator exposure, decoder-state exposure, local/global refusal, finite trace exposure, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.ChannelTerminationBoundaryUp.

Chapter 7791

A Concrete Naming Certificate for $\mathsf{MetricCoveringDimension}^{\uparrow}$

Following Hurewicz and Wallman on covering dimension and Bishop–Bridges finite metric compactness, the $\mathsf{MetricCoveringDimension}^{\uparrow}$ packet records finite-order metric covers over an explicit L10 compact-metric substrate. It sits after the metric source of chapter 57, the compact finite-net rows of chapter 129, the finite refinement route of chapter 4205, and the dyadic mesh ledger of chapter 358. The packet names only finite cover rows, order ledgers, star-refinement or mesh handoff rows, transport, replay, provenance, and local naming; it is not an arbitrary open-cover compactness theorem, a choice-selected refinement principle, a paracompactness assertion, or an ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7791.1 (Metric covering dimension carrier)**.** *A* $\mathsf{MetricCoveringDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, K, U, O, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the metric source row, exposing the accepted* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *distance interface used by the cover cells.*
2. *K is the compact-metric substrate row, exposing the finite-net and finite-cover boundary over the same metric source.*
3. *U is the finite metric-cover row, listing named center-radius cells or named finite cover cells over M, K.*
4. *O is the finite order-bound row, recording that every displayed point-history inspection meets at most the chosen number of cover cells.*
5. *S is the star-refinement or mesh row, routing the finite cover through the dyadic mesh handoff and the sibling covering-dimension refinement surface.*
6. *H records componentwise* hsame *transport for M, K, U, O, S and the certificate rows.*
7. *C records displayed* Cont *replay from metric source and compact finite-net data through finite cover inspection, order checking, star-refinement or mesh handoff, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricCoveringDimension}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{LebesgueCoveringDimensi}$ $\mathsf{DyadicMesh}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetricCoveringDimension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by transporting these rows. It has no coordinate for arbitrary open covers, host paracompactness, selected subcovers outside the displayed finite bundle, quotient compacta, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7791.2 (Metric covering dimension NameCert obligations)**.** *For every accepted* MetricCoveringDimension *carrier*

$$D = (M, K, U, O, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCoveringDimension}^{\uparrow}}$ *surface consists exactly of metric source exposure through M, compact-metric finite-net exposure through K, finite cover admission through U, order-bound checking through O, star-refinement or dyadic-mesh handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7791.1. The coordinates M, K, U, O, S are the only rows that expose metric source data, compact finite-net data, finite cover cells, overlap order, and mesh or star-refinement handoff.

The structural coordinates H, C, P, N preserve that route. Transport is componentwise, replay follows the displayed finite cover inspection, provenance names the same upstream packets, and the local naming row certifies no additional object.

Since arbitrary open covers, selected refinements, paracompactness data, quotient compacta, and ambient completeness are absent from the carrier, no local NameCert obligation can export them. The listed rows therefore exhaust the certificate surface. □

Theorem 7791.3 (Metric covering dimension refinement stability)**.** *Let $D = (M, K, U, O, S, H, C, P, N)$ and $D' = (M', K', U', O', S', H', C', P', N')$ be accepted* $\mathsf{MetricCoveringDimension}^{\uparrow}$ *carriers. If the displayed* hsame *transport identifies the metric source rows, compact-metric rows, finite cover rows, order ledgers, and star-refinement or mesh rows componentwise, then every finite-order metric-cover consumer of D replays as a finite-order metric-cover consumer of D' through the same bound and the same mesh handoff route.*

Proof. Read the consumer through the NameCert obligations of Definition 7791.2. The consumer may inspect only M, K, U, O, S before structural replay and provenance.

Apply the assumed componentwise hsame transport to those rows. The metric source, compact substrate, finite cover, order ledger, and star-refinement or mesh handoff are carried to the corresponding rows of D' without adding a new cover selector.

Replay through C' and source the result through P', N'. The order bound remains the displayed bound carried by the transported order ledger, and the mesh handoff remains the displayed handoff carried by S'. Thus refinement stability is internal to the finite packet. □

Theorem 7791.4 (Metric covering dimension finite mesh handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, LebesgueCoveringDimen $\mathsf{DyadicMesh}^{\uparrow}$, *or* $\mathsf{Met}^{\uparrow}$ *consumer of an accepted* $\mathsf{MetricCoveringDimension}^{\uparrow}$ *packet must traverse the finite route*

$$M, K, U, O, S, H, C, P, N$$

before it can use a dimension bound. In particular, the dimension read is a finite metric-cover and mesh handoff over the compact substrate, not a general open-cover compactness principle, an arbitrary paracompactness result, a choice-selected cover refinement, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the accepted carrier. The source metric row M and compact-metric row K must be exposed before any finite cover cell in U can be read.

The order ledger O and the handoff row S then place the cover inside the finite covering-dimension and dyadic-mesh interfaces. A consumer that omits those rows has not displayed the finite order bound or the mesh route.

Finally H, C, P, N transport, replay, source, and name the same finite route. Because the carrier has no coordinate for arbitrary open-cover compactness, choice, paracompactness, quotient compacta, or ambient Real completeness, the finite mesh handoff is the entire exported surface. □

Falsifiable prediction: An accepted $\mathsf{MetricCoveringDimension}^{\uparrow}$ read is refuted if a consumer exports a covering-dimension bound without displaying the metric source row, compact-metric finite-net row, finite metric-cover row, finite order-bound row, star-refinement or dyadic-mesh handoff row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: metric, compactmetric, lebesgue-covering-dimension, dyadicmesh: MetricCoveringDimen is not bijective to any listed sibling because it binds finite metric-cover cells, compact finite-net support, overlap order, mesh handoff, transport, replay, provenance, and local naming into one finite certificate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCoveringDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCoveringDimension}^{\uparrow}$ packet is generated from a MetricUp source row, a CompactMetricUp finite-net row, finite metric-cover rows, finite order-bound rows, a star-refinement or dyadic-mesh handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCoveringDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7791.1, Definition 7791.2, Definition 7791.3, and Definition 7791.4 seed the finite metric-cover dimension route over MetricUp, CompactMetricUp, LebesgueCoveringDimensionUp, and DyadicMeshUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCoveringDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general open-cover compactness, choice-selected subcovers, arbitrary paracompactness, quotient compacta, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover admission, order-bound exactness, star-refinement or mesh handoff, compact-metric substrate compatibility, transport, replay, provenance, and local naming for BEDC.Derived.MetricCoveringDimensionUp.

Chapter 7792

A Concrete Naming Certificate for $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's order-theoretic treatment of envelopes, the $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$ packet records the finite lower-envelope regularization surface read by Real and Completion consumers. It sits after the lower-semicontinuity route of chapter 1536, the epigraph route of chapter 6224, the regular-rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names displayed envelope data only: it does not form a host infimum or supremum, quotient functions, choose minimizing representatives, or import $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7792.1 (Lower-envelope regularization carrier)**.** *A* $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, F, E, O, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the domain-window row naming the finite points, neighbourhood probes, or compact subwindows on which the lower envelope is inspected.*
2. *F is the source-function observation row, exposing only the displayed value windows relevant to the regularization request.*
3. *E is the* $\mathsf{Epigraph}^{\uparrow}$ *row that packages the value and lower-bound comparison surface.*
4. *O is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *obligation row, recording the closed lower-envelope condition read from the epigraph surface.*
5. *Q is the finite lower-envelope ledger, listing candidate lower bounds, tolerance cells, and the accepted comparison witnesses for the inspected windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite ledger Q.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the regularized value read through R.*
8. *H records componentwise* hsame *transport for the domain window, source observations, epigraph row, lower-semicontinuity row, lower-envelope ledger, readback row, real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from each lower-envelope request through D, F, E, O, Q, R, S, H.*

10. *P is the* Pkg *provenance over* $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Epigraph}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerEnvelopeRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, F, E, O, Q, R, S, H, C, P, N$. It has no coordinate for a host supremum or infimum, quotient equality of functions, a choice-selected minimizer, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7792.2 (Lower-envelope regularization NameCert obligations)**.** *For every accepted* LowerEnvelopeRegula *carrier*

$$L = (D, F, E, O, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerEnvelopeRegularization}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; domain-window exposure for D; source-function observation for F; epigraph comparison for E; lower-semicontinuity obligation exposure for O; finite lower-envelope ledger exactness for Q;* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal nonescape for R, S; componentwise transport, replay, provenance, and local naming for H, C, P, N. No local obligation is stored in host suprema, quotient functions, selected minimizers, countable choice, or ambient real completeness.*

Proof. Project the accepted carrier $L = (D, F, E, O, Q, R, S, H, C, P, N)$. The projection exposes exactly the domain window, source observation row, epigraph row, lower-semicontinuity row, finite envelope ledger, regular-rational readback, Real seal, transport, replay, provenance, and local naming.

Read an envelope request through D and F. The row E supplies the epigraph comparison, and O ties that comparison to the lower-semicontinuity surface before the lower-envelope ledger Q is available.

The rows R and S remain downstream of Q. Thus a Real-facing consumer obtains a regular-rational readback and a terminal seal only from the displayed finite lower-envelope ledger.

The structural rows H, C, P, N transport, replay, source, and name that route. Since the carrier contains no host supremum, quotient-function equality, selected minimizer, choice principle, or completeness coordinate, the listed rows exhaust the local certificate. □

Theorem 7792.3 (Lower-envelope regularization L10 handoff)**.** *Every Real-facing or calculus-facing consumer of an accepted* $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$ *packet must first read the finite route*

$$D, F \longmapsto E, O \longmapsto Q \longmapsto R, S, H, C, P, N.$$

In particular, the lower-envelope value reaches a $\mathsf{Real}^{\uparrow}$ *seal only after the consumer has passed through the sibling surfaces* $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Epigraph}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *in that order. The handoff exports no host supremum, quotient function, selected minimizer, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier and a Real-facing request. The request first exposes the domain-window and source-observation rows D, F; no lower-envelope ledger can be read before those rows are present.

Next pass through the epigraph and lower-semicontinuity rows. The row E supplies the value/lower-bound comparison surface, and O records the lower-semicontinuity obligation that lets the finite lower-envelope ledger Q be read as regularization data.

Finally read R and S. The regular-rational readback R is produced from Q, and the terminal seal S receives only that readback together with the structural rows H, C, P, N.

Because the packet has no coordinate for host suprema, quotient functions, selected minimizers, countable choice, or ambient completeness, the displayed route is the whole L10 handoff. □

Falsifiable prediction: An accepted $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the epigraph comparison, lower-semicontinuity row, finite lower-envelope ledger, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: lowersemicontinuous, epigraph, regseqrat, real: no listed sibling supplies the whole eleven-row packet $L = (D, F, E, O, Q, R, S, H, C, P, N)$, because each sibling contributes only the lower-semicontinuity, epigraph, regular-rational, or real-seal face while this chapter binds them into one finite lower-envelope regularization route.

Closure status for $\mathsf{NameCert}_{\mathsf{LowerEnvelopeRegularization}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerEnvelopeRegularization}^{\uparrow}$ packet is generated from domain windows, source-function observations, an Epigraph row, a LowerSemicontinuous row, a finite lower-envelope ledger, a RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerEnvelopeRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7792.1, Definition 7792.2, and Definition 7792.3 seed the finite lower-envelope regularization route over $\mathsf{LowerSemicontinuous}^{\uparrow}$, $\mathsf{Epigraph}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerEnvelopeRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host suprema or infima, quotient functions, choice-selected minimizers, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, epigraph comparison, lower-semicontinuity exposure, finite lower-envelope ledger exactness, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LowerEnvelopeRegularizationUp.

Chapter 7793

A Concrete Naming Certificate for $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$

Following Bishop and Bridges on regulated functions and one-sided limits, the $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ packet records the paired side-limit surface carried by a regulated real function. It sits over the source route of chapter 1906, the one-sided limit interface of chapter 5841, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance rows of chapter 291, the terminal real seal of chapter 38, the cadlag path carrier of chapter 5968, and the path-topology consumer of chapter 6693. The packet packages left and right side data as finite BEDC rows; it does not import host function quotients, selected limiting values outside the displayed rows, path-space completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7793.1 (Regulated left–right limit carrier)**.** *A* $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, A, W^-, W^+, R^-, R^+, D, E^-, E^+, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row, read through the regulated-function route of chapter 1906.*
2. *A is the finite anchor ledger naming the endpoint, jump site, or interior cell at which the paired side read is taken.*
3. *W^- and W^+ are the left and right* $\mathsf{StreamName}^{\uparrow}$ *approach-window rows.*
4. *R^- and R^+ are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from those windows.*
5. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the two side windows and their real seals.*
6. *E^- and E^+ are the terminal* $\mathsf{Real}^{\uparrow}$ *seals for the displayed left and right side limits.*
7. *H records componentwise* hsame *transport for the regulated source, anchor ledger, side windows, regular readbacks, dyadic tolerance ledger, real seals, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a regulated-function request through the anchor, the two side-window rows, the readback rows, the dyadic comparison ledger, and the two real seals.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CadlagRealFunction}^{\uparrow}$, $\mathsf{SkorokhodTopology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedLeftRightLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the rows $F, A, W^-, W^+, R^-, R^+, D, E^-, E^+, H, C, P, N$. No coordinate stores a host quotient of functions, a path-space completion theorem, a selected limit outside the displayed side seals, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7793.2 (Regulated left–right limit NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ *carrier*

$$L = (F, A, W^-, W^+, R^-, R^+, D, E^-, E^+, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedLeftRightLimit}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated source, anchor ledger, left and right StreamName windows, regular rational readbacks, dyadic tolerance row, left and right Real seals, componentwise transport, displayed replay, provenance, and local naming. The side-window exactness clause requires W^- and W^+ to be consumed as paired* $\mathsf{OneSidedLimit}^{\uparrow}$ *rows over the same source row F and anchor ledger A. The nonescape clause requires every cadlag or path-topology consumer to remain downstream from $F, A, W^-, W^+, R^-, R^+, D, E^-, E^+, H, C, P, N$.*

Proof. Project the carrier of Definition 7793.1. Its displayed inventory is exactly the regulated source row, anchor ledger, two side-window rows, two readback rows, the shared dyadic tolerance ledger, two real seals, and the structural rows H, C, P, N.

The side-window clause is read from A, W^-, W^+, R^-, R^+, D. Both windows are attached to the same anchor and source row before either regular-rational readback or dyadic comparison row is available.

The terminal seals E^- and E^+ are downstream of those rows. Transport and replay preserve the same paired route, while provenance and local naming record only the listed dependencies.

Since the carrier contains no host function quotient, selected external limit, path-space completion theorem, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, the local NameCert cannot export any of those principles. □

Theorem 7793.3 (Regulated left–right limit regulated handoff)**.** *Every accepted* $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ *packet exposes its paired side limits only after the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source route has been displayed. The public handoff factors through*

$$F, A \longmapsto W^-, W^+ \longmapsto R^-, R^+ \longmapsto D \longmapsto E^-, E^+ \longmapsto H, C, P, N,$$

with F read through Definition 1906.8. Thus the packet supplies a finite paired side-limit interface for regulated functions, not a host-level function object or a selected path value outside the displayed seals.

Proof. Start with the source row F of Definition 7793.1. By Definition 1906.8, any consumer of paired one-sided limits must keep the regulated-function route visible before one-sided limit rows or terminal Real seals are consumed.

The anchor ledger A then fixes the endpoint, jump site, or interior cell for the paired read. The two StreamName windows W^- and W^+ are therefore side-tagged observations over the same source and anchor.

Regular rational readback and dyadic comparison are downstream. The rows R^-, R^+ and D are read before the Real seals E^-, E^+, while H, C, P, N preserve, replay, source, and name that finite route. □

Theorem 7793.4 (Regulated left–right limit Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CadlagRealFunction}^{\uparrow}$*, or* $\mathsf{SkorokhodTopology}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ *packet receives the left and right seals only through the displayed route*

$$F, A, W^-, W^+, R^-, R^+, D, E^-, E^+, H, C, P, N.$$

The route may be consumed as cadlag side-window data or as path-topology jump data, but it exports no quotient of functions, no path-space completeness theorem, no selected limit outside E^-, E^+*, no open-cover compactness principle, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 7793.3. It places the two Real seals behind the regulated source, anchor ledger, side-window rows, readback rows, and dyadic comparison row.

A cadlag consumer reads the same paired seals as left and right path limits, while a Skorokhod-topology consumer reads them as finite jump-window data. In both cases the source route remains the displayed regulated-function packet and the side data remains the paired $\mathsf{OneSidedLimit}^{\uparrow}$ hand-off.

The carrier has no coordinate for a host function quotient, a completed path space, an external selected value, open-cover compactness, or ambient Real completeness. Therefore any Real, cadlag, or topology-facing read remains inside the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ read is refuted if it reaches a $\mathsf{OneSidedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CadlagRealFunction}^{\uparrow}$, or $\mathsf{SkorokhodTopology}^{\uparrow}$ consumer without displaying the regulated source, anchor ledger, paired StreamName windows, paired RegSeqRat readbacks, shared DyadicRatCore tolerance row, paired Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regulated-function, one-sided-limit, streamname, regseqrat, dyadicrat-core, real, cadlag-real-function, skorokhod-topology: $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ is not bijective to any listed sibling because it binds a regulated source, a shared anchor, paired side windows, paired regular-rational readbacks, one dyadic comparison ledger, paired Real seals, transport, replay, provenance, and local naming as one finite side-limit packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedLeftRightLimit}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegulatedLeftRightLimit}^{\uparrow}$ packet is generated from a RegulatedFunction source row, an anchor ledger, paired StreamName side windows, paired RegSeqRat readbacks, a DyadicRatCore tolerance row, paired RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegulatedLeftRightLimit}^{\uparrow}}$, seed)

Scope closed: Definition 7793.1, Definition 7793.2, Definition 7793.3, and Definition 7793.4 seed the paired side-limit route between regulated functions, one-sided limits, cadlag paths, and Skorokhod topology consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegulatedLeftRightLimit}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function quotients, path-space completeness, selected external limits, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.RegulatedLeftRightLimitUp covering carrier admission, side-window exactness, dyadic comparison, paired Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 7794

A Concrete Naming Certificate for $\mathsf{CauchyCondensationPacket}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationPacket}^{\uparrow}$ packet records Cauchy's condensation test for positive decreasing real series as finite BEDC rows. It sits after the finite partial-sum surface of $\mathsf{RealSeries}^{\uparrow}$ in chapter 1581, the series-tail criterion of chapter 2015, the positive comparison route of chapter 7665, the dyadic arithmetic core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite condensation route; it is not a quotient of term streams, a selected infinite sum, countable choice, order trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7794.1 (Cauchy condensation packet carrier)**.** *A* $\mathsf{CauchyCondensationPacket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, S, L, M, R, E, H, Q, P, N)$$

with the following displayed rows:

1. *A is the positive decreasing source-series row. It records a* $\mathsf{RealSeries}^{\uparrow}$ *term surface whose inspected terms are nonnegative and monotone decreasing on the accepted finite windows.*
2. *S is the dyadic block schedule. It names the finite powers-of-two cut points and the requested block windows as* $\mathsf{DyadicRatCore}^{\uparrow}$ *data rather than as a host exponentiation oracle.*
3. *L is the block-sum ledger. It records the displayed comparison between each source block and its condensed representative block sum.*
4. *M is the monotone comparison row. It exposes the finite inequalities that bound every term in a displayed dyadic block by the appropriate endpoint terms.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff reached from the source windows, block schedule, ledger, and comparison row.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after A, S, L, M, R have been displayed.*
7. *H records componentwise* hsame *transport for the source series, dyadic schedule, block ledger, monotone comparison, regular handoff, real seal, replay, provenance, and local naming rows.*
8. *Q records displayed* Cont *replay from a requested series-tail read through the dyadic block schedule, block-sum ledger, monotone comparison row, regular handoff, and real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationPacket}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchySeriesCriterion}^{\uparrow}$, $\mathsf{PositiveSeriesComparison}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationPacket}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, S, L, M, R, E, H, Q, P, N$. It has no coordinate for a host convergence theorem, quotient stream equality, a selected sum, countable choice, order trichotomy, or ambient completeness.

Theorem 7794.2 (Cauchy condensation packet NameCert obligations)**.** *For every accepted* CauchyCondensationPa *carrier $K = (A, S, L, M, R, E, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationPacket}^{\uparrow}}$ *surface consists exactly of carrier admission for the positive decreasing source series, dyadic block schedule, block-sum ledger, monotone comparison row,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. No local obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7794.1. Its analytic inventory is exactly the source series row A, the dyadic block schedule S, the block ledger L, the monotone comparison row M, the regular readback R, and the real seal E.

The condensation obligations are finite. The source series is inspected only through displayed windows, while S and L record the finite powers-of-two blocks and their block sums as $\mathsf{DyadicRatCore}^{\uparrow}$ data.

The monotone comparison row M supplies the only route from source terms to block bounds. The handoff R and seal E are therefore available only after the source windows, schedule, ledger, and comparison rows have been displayed.

Finally H, Q, P, N transport, replay, source, and name the same route. Since the carrier has no row for quotient streams, selected sums, countable choice, order trichotomy, host convergence, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7794.3 (Cauchy condensation packet real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or completion-facing read from an accepted* $\mathsf{CauchyCondensationPacket}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the condensation read reaches the terminal real seal only by displaying the positive decreasing source-series windows, the dyadic block schedule, the block-sum ledger, the monotone comparison row, and the regular rational handoff.

Proof. Start with a real-facing read of an accepted carrier. The source series row A exposes only finite term windows, so the read begins at the $\mathsf{StreamName}^{\uparrow}$ surface.

Next read S, L, M. These rows provide the dyadic block schedule, block-sum ledger, and monotone comparison evidence as $\mathsf{DyadicRatCore}^{\uparrow}$ data before any regular rational handoff may be consumed.

The row R is the unique $\mathsf{RegSeqRat}^{\uparrow}$ handoff for the displayed condensation route. Once R is present, the terminal seal E may be read, and H, Q, P, N preserve and name the same route.

Thus every real- or completion-facing condensation read factors through the displayed stream windows, dyadic block evidence, regular rational handoff, and real seal. No bypass supplies quotient stream equality, selected sums, countable choice, order trichotomy, host convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCondensationPacket}^{\uparrow}$ read displays one positive decreasing RealSeries source row, one dyadic block schedule, one block-sum ledger, one monotone comparison row, one RegSeqRat handoff, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a condensation conclusion is consumed.

Independence witness: realseries, cauchy-series-criterion, positive-series-comparison, dyadicrat-core, streamname, regseqrat, real: $\mathsf{CauchyCondensationPacket}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a positive decreasing source series, dyadic block scheduling, block-sum comparison, monotone endpoint control, regular rational handoff, and real sealing in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationPacket}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationPacket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7794.1, Definition 7794.2, and Definition 7794.3 seed the finite Cauchy condensation route over positive decreasing source series, dyadic block schedules, block-sum ledgers, monotone comparison rows, regular handoff, real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationPacket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host infinite-sum theorems, quotient stream equality, selected sums, order trichotomy, countable choice, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, block schedule admission, block-sum ledger exactness, monotone comparison stability, regular handoff nonescape, real-seal nonescape, transport stability, replay stability, and local naming for BEDC.Derived.CauchyCondensationPacketUp.

Constructive story: A $\mathsf{CauchyCondensationPacket}^{\uparrow}$ packet is generated from a positive decreasing source series, a dyadic block schedule, a block-sum ledger, a monotone comparison row, a $\mathsf{RegSeqRat}^{\uparrow}$ handoff, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7795

A Concrete Naming Certificate for $\mathsf{NagumoViability}^{\uparrow}$

Following Nagumo's invariance theorem and the constructive ODE tradition, the $\mathsf{NagumoViability}^{\uparrow}$ packet records the finite boundary-viability surface by which a displayed vector field is read as staying inside a named closed constraint set. It consumes the ODE source of chapter 193, the local interval and vector-field rows of chapter 3530, the initial-data packet of chapter 3979, the continuous-map handoff of chapter 130, and the compact interval fixed-point boundary route of chapter 1437. The packet names a finite viability-boundary certificate; it does not select a maximal flow, assert uniqueness, impose host compactness, choose a solution representative, or provide a standard bridge.

Definition 7795.1 (Nagumo viability carrier)**.** *A* $\mathsf{NagumoViability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (O, I, F, K, B, T, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *source row carrying the time-state interface and vector-field request.*
2. *I is the* $\mathsf{InitialValueProblem}^{\uparrow}$ *row naming the initial time, initial state, local window, and solution-read surface.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *vector-field graph and modulus row used for all boundary-facing reads.*
4. *K is the closed constraint row, read through the existing closed-set and Real boundary surfaces and exposing only the displayed membership and complement-neighborhood tests.*
5. *B is the Nagumo boundary row, recording the finite tangent or inward-pointing comparison data inspected at the displayed boundary cells of K.*
6. *T is the interval trap row inherited from the Peano local-existence route, keeping Euler polygon and local solution reads inside the certified Real time-state window.*
7. *E is the* $\mathsf{PeanoExistence}^{\uparrow}$ *existence row that exports a local solution read only after O, I, F, K, B, T have been displayed.*
8. *Q is the compact interval fixed-point comparison row used when a finite interval boundary or residual trap is needed to certify the viability step.*
9. *H stores componentwise* hsame *transports for the ODE, initial-data, continuous-map, closed-set, boundary, trap, existence, fixed-point, and local certificate rows.*

10. *C stores displayed* Cont *replay from the ODE request through the finite viability-boundary route.*
11. *P is the* Pkg *provenance over* NagumoViability$^{\uparrow}$, Ode$^{\uparrow}$, InitialValueProblem$^{\uparrow}$, PeanoExistence$^{\uparrow}$, ContinuousMap$^{\uparrow}$, ClosedSet$^{\uparrow}$, CompactIntervalFixedPoint$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{NagumoViability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no coordinate for uniqueness, maximal-flow selection, host compactness, a choice-selected solution, quotient trajectory equality, or a standard bridge.

Theorem 7795.2 (Nagumo viability NameCert obligations)**.** *For every accepted* NagumoViability$^{\uparrow}$ *carrier*

$$V = (O, I, F, K, B, T, E, Q, H, C, P, N),$$

the local NameCert$_{\text{NagumoViability}^{\uparrow}}$ *obligations are exactly carrier admission for the ODE source, initial-data row, continuous vector-field row, closed constraint row, finite boundary comparison row, Peano interval trap, local existence row, compact interval fixed-point comparison row, componentwise transport, displayed replay, package provenance, and local naming. Any viability read must therefore pass through $O, I, F, K, B, T, E, Q, H, C, P, N$ before it can expose an invariant local solution segment.*

Proof. Project the accepted carrier of Definition 7795.1. The rows O, I, F fix the displayed ODE request, initial data, and continuous vector-field read before any boundary comparison is inspected.

The constraint-facing rows then supply the finite viability data. The closed-set row K exposes the displayed boundary surface, B records the Nagumo comparison at that boundary, and T keeps the Peano polygon and solution reads inside the certified Real time-state window.

The consumer-facing rows E and Q provide only the local existence and compact interval comparison data already routed through the previous rows. Finally H, C, P, N transport, replay, package, and name the same finite route. Since no carrier coordinate stores uniqueness, maximal-flow selection, host compactness, a choice-selected solution, quotient trajectory equality, or a bridge schema, none of those objects belongs to the local NameCert obligations. □

Closure status for NameCert$_{\text{NagumoViability}^{\uparrow}}$**.**

Constructive story: A NagumoViability$^{\uparrow}$ packet is generated from an ODE source row, an initial-value row, a continuous vector-field row, a closed constraint row, a finite Nagumo boundary comparison row, a Peano interval trap, a local existence row, a compact interval fixed-point comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{NagumoViability}^{\uparrow}}$, seed)

Scope closed: Definition 7795.1 and Definition 7795.2 seed the finite viability-boundary packet over ODE, Peano existence, initial-value, continuous-map, closed-set, compact-interval, Real, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{NagumoViability}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim uniqueness, maximal flow selection, host compactness, choice-selected solutions, quotient trajectory equality, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, boundary comparison exposure, interval-trap exactness, Peano existence handoff, compact interval comparison nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NagumoViabilityUp.

Chapter 7796

A Concrete Naming Certificate for $\mathsf{DecimalExpansionUniqueness}^{\uparrow}$

Following Bishop and Bridges together with the standard convention that decimal streams are read in normalized form, the $\mathsf{DecimalExpansionUniqueness}^{\uparrow}$ packet records the finite route by which a decimal real has at most one normalized decimal stream presentation. It sits after the decimal readback carrier of chapter 2058, the dual-tail boundary of chapter 6932, the endpoint-normalization route of chapter 1429, and the real decimal normal-form route of chapter 3952. The packet names uniqueness for normalized tails only; it does not quotient all decimal streams, choose representatives at endpoints, or expose host equality of real numbers.

Definition 7796.1 (Decimal expansion uniqueness carrier)**.** *A* $\mathsf{DecimalExpansionUniqueness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (D, E, N, W, Q, R, Y, H, C, P, L)$$

with the following displayed rows:

1. *D is the* $\mathsf{DecimalReal}^{\uparrow}$ *readback row whose signed decimal prefix, ambiguity boundary, finite window, dyadic tolerance, regular rational readback, and terminal real seal are being inspected.*
2. *E is the* $\mathsf{DecimalEndpointAmbiguity}^{\uparrow}$ *boundary row, exposing whether a displayed tail is ordinary, trailing-nine-facing, or trailing-zero-facing before any uniqueness consumer proceeds.*
3. *N is the* $\mathsf{DecimalEndpointNormalization}^{\uparrow}$ *row, replacing an endpoint-facing tail by the displayed normalized tail convention without choosing a quotient representative for arbitrary streams.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the decimal cells and precision requests actually read by the comparison.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite decimal windows and tolerance requests.*
6. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare normalized decimal tails at the requested precision.*
7. *Y is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, E, N, W, Q, R have been displayed.*
8. *H records componentwise* hsame *transport for decimal readback, endpoint ambiguity, endpoint normalization, stream windows, regular readback, dyadic tolerance, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the normalized comparison route*

$$D, E, N, W, Q, R \longmapsto Y.$$

10. *P is the* Pkg *provenance over* DecimalExpansionUniqueness$^{\uparrow}$, DecimalReal$^{\uparrow}$, DecimalEndpointAmbiguity$^{\uparrow}$, DecimalEndpointNormalization$^{\uparrow}$, RealDecimalNormalForm$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* NameCert$_{\text{DecimalExpansionUniqueness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, E, N, W, Q, R, Y, H, C, P, L$. It has no coordinate for quotient stream equality, selected endpoint representatives, arbitrary decimal-stream uniqueness, trichotomy, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7796.2 (Decimal expansion uniqueness NameCert obligations)**.** *For every accepted* DecimalExpansionUniqueness$^{\uparrow}$ *carrier*

$$U = (D, E, N, W, Q, R, Y, H, C, P, L),$$

the local NameCert$_{\text{DecimalExpansionUniqueness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for decimal readback, endpoint ambiguity, endpoint normalization, finite stream windows, regular rational readback, dyadic tolerance, real seal, transport, replay, provenance, and local naming;*

2. *endpoint visibility, requiring E to be read before a trailing-nine-facing or trailing-zero-facing tail is normalized;*

3. *normalization exactness, requiring N to display the normalized tail convention consumed by the uniqueness comparison;*

4. *finite-window comparison, requiring W, Q, R to expose the inspected decimal cells, regular rational readback, and dyadic tolerance ledger before the* Real$^{\uparrow}$ *seal Y is available;*

5. *nonescape, requiring H, C, P, L to transport, replay, source, and name only the displayed normalized-tail route and to export no quotient stream equality, selected endpoint representative, arbitrary decimal-stream uniqueness, trichotomy, countable choice, or ambient completeness row.*

No DecimalExpansionUniqueness obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7796.1. The accepted packet displays the decimal readback, endpoint ambiguity, endpoint normalization, finite windows, regular readback, dyadic tolerance ledger, real seal, and structural rows.

Endpoint visibility is the row E. It is inspected before normalization, so a dual-tail boundary is not silently treated as an equality of unnormalized streams.

Normalization exactness is the row N. It records the standard normalized-tail convention as packet data, while refusing a selected representative for arbitrary decimal presentations.

The comparison then passes through W, Q, R. These rows display the finite decimal cells, the regular rational readback, and the dyadic tolerance ledger before the real seal Y can be consumed.

Finally H, C, P, L transport, replay, source, and name the same route. Since the carrier contains no quotient stream equality, endpoint choice, arbitrary uniqueness, trichotomy, choice, or ambient completeness coordinate, the listed rows exhaust the NameCert surface. □

Theorem 7796.3 (Decimal expansion uniqueness normal-form route)**.** *Every uniqueness read exported by an accepted* $\mathsf{DecimalExpansionUniqueness}^{\uparrow}$ *carrier factors through*

$\mathsf{DecimalReal}^{\uparrow}$, $\mathsf{DecimalEndpointAmbiguity}^{\uparrow}$, $\mathsf{DecimalEndpointNormalization}^{\uparrow}$, $\mathsf{RealDecimalNormalForm}^{\uparrow}$, StreamNam

as the displayed route $D, E, N, W, Q, R, Y, H, C, P, L$*. Thus the comparison concerns normalized decimal tails reaching the same terminal real seal, not quotient equality of all decimal streams and not a choice of endpoint representative.*

Proof. Start with a uniqueness consumer of the carrier. Projection from Definition 7796.1 gives the route $D, E, N, W, Q, R, Y, H, C, P, L$ and no additional stream-equality object.

Read D first. This supplies the decimal real readback route through finite prefixes, ambiguity boundary data, dyadic tolerance, regular rational readback, and a terminal real seal.

Read E and N next. The endpoint ambiguity row exposes the dual-tail boundary, and the endpoint normalization row records the normalized-tail convention used by the comparison.

The finite comparison then runs through W, Q, R. The stream windows and regular rational readback are inspected at a displayed dyadic tolerance before the real seal Y is reached.

The structural rows H, C, P, L keep the consumer on the same route. Therefore the packet exports uniqueness only for normalized decimal tails and cannot export quotient equality of all streams or selected endpoint representatives. □

Closure status for $\mathsf{NameCert}_{\mathsf{DecimalExpansionUniqueness}^{\uparrow}}$.

Constructive story: A $\mathsf{DecimalExpansionUniqueness}^{\uparrow}$ packet is generated from DecimalReal readback, endpoint ambiguity, endpoint normalization, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DecimalExpansionUniqueness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7796.1, Definition 7796.2, and Definition 7796.3 seed the normalized decimal-tail uniqueness route through decimal readback, endpoint ambiguity, endpoint normalization, normal-form reading, finite windows, regular readback, dyadic tolerance, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DecimalExpansionUniqueness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected endpoint representatives, arbitrary decimal-stream uniqueness, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, endpoint visibility, normalization exactness, finite-window comparison, nonescape, and local naming for BEDC.Derived.DecimalExpansionUniquenessUp.

Chapter 7797

A Concrete Naming Certificate for $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$

Following the standard MetaCIC proof-engineering route for substitution, residuals, and confluence boundaries, the $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$ packet records the finite socket where a residual source and a substitution window must agree before normalization or confluence audit data may be consumed. It sits beside the residual-substitution compatibility packet of chapter 4370, the residual diamond budget of chapter 7407, and the closure-substitution frontier of chapter 7682. The packet is a socket for audit surfaces; it does not claim full subject reduction, full confluence, normalization, conversion typing, or kernel consistency.

Definition 7797.1 (MetaCIC residual-substitution socket carrier)**.** *A* $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, B, J, F, V, H, C, P, N)$$

with the following displayed rows:

1. *R is the residual source row, naming the redex or residual family whose descendants are being audited.*
2. *W is the substitution-window row, listing the binder depth, occurrence window, and substitution request visible before residual transport.*
3. *B is the candidate-boundary row, exposing the candidate branch or normalization boundary that will consume the socket.*
4. *J is the confluence socket row, recording the finite join or conditional-diamond handoff available after R, W, B have been displayed.*
5. *F is the refusal row, listing the subject-reduction, full confluence, normalization, conversion-typing, quotient-syntax, and consistency claims not exported by this socket.*
6. *V is the provenance row for the MetaCIC audit-map route, retaining which normalization and confluence audit surfaces supplied the residual and substitution data.*
7. *H records componentwise* hsame *transport for residual source, substitution window, candidate boundary, confluence socket, refusal, provenance, replay, package, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$R, W, B \longmapsto J \longmapsto F, V.$$

9. *P is the* Pkg *provenance over* $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionCompatibility}^{\uparrow}$, $\mathsf{MetaCICResidualDiamondBudget}^{\uparrow}$, $\mathsf{MetaCICClosureSubstitutionFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceSubstitutionBoundar}$ BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, W, B, J, F, V, H, C, P, N$. It has no coordinate for full subject reduction, full confluence, normalization, conversion typing, quotient syntax equality, hidden substitution admissibility, or kernel consistency.

Theorem 7797.2 (MetaCIC residual-substitution socket NameCert obligations)**.** *For every accepted* $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$ *carrier*

$$S = (R, W, B, J, F, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}}$ *surface consists exactly of carrier admission for residual source, substitution-window compatibility, candidate-boundary exposure, confluence socket handoff, refusal and provenance rows, componentwise transport, displayed replay, package provenance, and local naming. Any normalization or confluence audit consumer must read*

$$R, W, B \longmapsto J$$

before it may use the socket-facing row.

Proof. Project the carrier of Definition 7797.1. The residual source, substitution window, candidate boundary, confluence socket, refusal, provenance, and structural rows are exactly the displayed coordinates.

Substitution-window compatibility is the pair R, W. The source residual data and the binder-window request are read together before a candidate branch is exposed.

The candidate-boundary row B fixes the branch that may consume the socket. The confluence socket row J can therefore be read only after R, W, B are visible.

The refusal and provenance rows F, V keep the audit boundary explicit. They record which large MetaCIC claims are absent and which normalization or confluence audit surfaces supplied the data.

Finally H, C, P, N transport, replay, source, and name only those rows. Since the carrier has no coordinate for full subject reduction, confluence, normalization, conversion typing, quotient syntax equality, hidden substitution admissibility, or consistency, the listed rows exhaust the local obligation surface. □

Theorem 7797.3 (MetaCIC residual-substitution socket audit route)**.** *Every audit consumer of an accepted* $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$ *packet must expose the residual source row R, substitution-window row W, candidate-boundary row B, confluence socket row J, refusal row F, provenance row V, and structural rows H, C, P, N. The packet connects normalization and confluence audit surfaces through finite socket data without exporting full subject reduction, full confluence, normalization, conversion typing, quotient syntax equality, hidden substitution admissibility, or kernel consistency.*

Proof. Begin with an audit consumer of the socket. Projection from Definition 7797.1 gives the rows $R, W, B, J, F, V, H, C, P, N$ and no global preservation theorem.

The consumer first reads the residual source and substitution window. This fixes the redex family, binder depth, occurrence window, and substitution request as finite packet data.

Next it reads the candidate boundary and confluence socket. These rows identify the finite branch and conditional join handoff available to the audit route.

The refusal and provenance rows are read before the socket is exported. They retain the absence of subject reduction, full confluence, normalization, conversion typing, quotient syntax equality, hidden substitution admissibility, and consistency, while naming the audit surfaces that supplied the socket data.

The structural rows preserve only that displayed route. Thus the packet connects the normalization and confluence audit surfaces without turning the socket into any of the excluded MetaCIC theorems. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}$ packet is generated from residual source rows, substitution-window rows, candidate-boundary rows, confluence socket rows, refusal and provenance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7797.1, Definition 7797.2, and Definition 7797.3 seed the finite residual-substitution socket connecting normalization and confluence audit surfaces through residual source, substitution-window, candidate-boundary, confluence socket, refusal, provenance, transport, replay, package, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicResidualSubstitutionSocket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, full confluence, normalization, conversion typing, quotient syntax equality, hidden substitution admissibility, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires carrier admission, residual source exposure, substitution-window compatibility, candidate-boundary exposure, confluence socket handoff, refusal/provenance stability, and local naming for BEDC.Derived.MetacicResidualSubstitutionSocketUp.

Chapter 7798

A Concrete Naming Certificate for $\mathsf{CotransitiveApartness}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CotransitiveApartness}^{\uparrow}$ packet records the constructive apartness layer in which a displayed apartness witness can be relayed through a finite cotransitivity ledger before it is consumed by real or completion routes. It refines the metric positive-distance packet of chapter 3505, the order-facing positive real bridge of chapter 1905, and the located metric-space route of chapter 3685. The packet supplies cotransitivity as finite NameCert data; it does not import real trichotomy, quotient apartness, host inequality, or ambient completeness.

Definition 7798.1 (CotransitiveApartness carrier)**.** *A* $\mathsf{CotransitiveApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, O, L, M, R, W, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{MetricApartness}^{\uparrow}$ *source row, exposing the positive-distance apartness read already certified by the metric apartness sibling.*
2. *O is the* $\mathsf{RealApartnessOrderBridge}^{\uparrow}$ *order-facing handoff row, used only to read the finite positive-radius comparison cell exported by the real apartness bridge.*
3. *L is the* $\mathsf{LocatedMetricSpace}^{\uparrow}$ *located-distance row that supplies the dyadic tolerance windows through which intermediate point requests are inspected.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *metric-source row shared by the endpoint and intermediate-point observations.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *real-seal row reached by the displayed positive-radius and located-distance reads.*
6. *W is the finite cotransitivity witness row. For an accepted apartness read between displayed endpoints and a displayed intermediate point request, it stores the finite branch data saying that the request is routed to the left endpoint or to the right endpoint through the rows above.*
7. *H records componentwise* hsame *transport for the apartness source, real-order bridge, located metric-space row, metric source, real seal, cotransitivity witness, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an apartness request through $A, O, L, M, R, W, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CotransitiveApartness}^{\uparrow}$, $\mathsf{MetricApartness}^{\uparrow}$, $\mathsf{RealApartnessOrderBridge}^{\uparrow}$, $\mathsf{LocatedMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CotransitiveApartness}^{\uparrow}}$ *row.*

The carrier has no coordinate for real trichotomy, quotient apartness, host inequality, selected representatives, or completeness.

Definition 7798.2 (CotransitiveApartness classifier)**.** *The* $\mathsf{CotransitiveApartness}^{\uparrow}$ *classifier compares accepted carriers only through the rows*

$$A, O, L, M, R, W, H, C, P, N.$$

Two displayed packets are classifier-compatible when their metric apartness source rows, real-order bridge rows, located metric-space rows, metric-source rows, real-seal rows, cotransitivity witness rows, componentwise hsame *transports, displayed* Cont *replays,* Pkg *provenance rows, and local* $\mathsf{NameCert}$ *rows agree through the displayed BEDC transport surface. No comparison may inspect a host inequality predicate, a quotient apartness class, a total order branch on* $\mathsf{Real}^{\uparrow}$*, or a completion principle.*

Theorem 7798.3 (CotransitiveApartness NameCert obligations)**.** *For every accepted* $\mathsf{CotransitiveApartness}^{\uparrow}$ *carrier*

$$K = (A, O, L, M, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CotransitiveApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{MetricApartness}^{\uparrow}$ *row A, order-facing positive-radius handoff through O, located-distance and tolerance-window admission through L, metric-source visibility through M, real-seal readback through R, finite cotransitivity witness admission through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7798.1. The rows A, O, L, M, R expose the positive-distance, order-facing, located-distance, metric-source, and real-seal data before any cotransitivity read is available.

The row W is therefore the only cotransitivity witness row. It records the finite branch through which an intermediate point request is routed to the left endpoint or to the right endpoint, using the displayed rows already present in the packet.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Since the carrier contains no further coordinate, these rows exhaust the local NameCert obligations and exclude real trichotomy, quotient apartness, host inequality, selected representatives, and completeness. □

Theorem 7798.4 (Cotransitivity ledger)**.** *Every cotransitivity read exported by an accepted* $\mathsf{CotransitiveApartness}^{\uparrow}$ *packet factors through the finite route*

$$A, O, L, M, R \longmapsto W \longmapsto H, C, P, N.$$

The exported ledger says only that the displayed intermediate-point request is assigned to one of the two endpoint apartness branches through the metric apartness, real-order bridge, located metric-space, metric, and real rows already visible in the carrier.

Proof. Begin with an accepted cotransitivity request. The metric apartness row A supplies the original positive-distance apartness read, while O and R expose the positive-radius real handoff available to order-facing consumers.

The intermediate request is inspected through the located metric-space row L and the shared metric source M. These rows provide finite tolerance windows and metric observations before the branch row can be read.

The cotransitivity witness W then records the displayed branch assignment. Transport and replay through H and C keep the assignment attached to the same rows, and P, N provide provenance and local naming.

Thus the ledger exports only a finite branch route. It cannot create trichotomy of $\mathsf{Real}^{\uparrow}$, quotient apartness, host inequality, selected representatives, or ambient completeness because none of those objects occurs in the carrier. □

Theorem 7798.5 (CotransitiveApartness Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{CotransitiveApartness}^{\uparrow}$ *packet may read only the finite positive-distance, located-window, and cotransitivity ledger rows displayed in*

$$K = (A, O, L, M, R, W, H, C, P, N).$$

The handoff exposes the metric apartness source, real-order positive-radius bridge, located metric-space tolerance route, metric source, real seal, finite cotransitivity branch ledger, componentwise transport, replay, provenance, and local naming. It does not expose $\mathsf{Real}^{\uparrow}$ *trichotomy, quotient apartness, host inequality, selected limits, or completeness.*

Proof. Start from a real or completion-facing apartness request. The request must first read the metric apartness source A and the real-order bridge O, because these are the only rows that expose positive-distance and positive-radius data.

Located tolerance information is then read from L over the shared metric source M, and the resulting real-facing seal is read through R. Only after those rows are displayed can the cotransitivity branch ledger W be consumed.

The handoff to downstream consumers is preserved by H and replayed by C, with P and N recording source and local naming. Therefore the downstream route is exactly the finite packet surface and not a route through trichotomy, quotient apartness, host inequality, selected limits, or completeness. □

Falsifiable prediction: Every accepted $\mathsf{CotransitiveApartness}^{\uparrow}$ cotransitivity read factors through MetricApartnessUp positive-distance data, RealApartnessOrderBridgeUp positive-radius handoff, LocatedMetricSpaceUp tolerance windows, MetricUp source rows, RealUp seals, one finite cotransitivity branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metricapartness, realapartnessorderbridge, locatedmetricspace, metric, real: $\mathsf{CotransitiveApartness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a positive-distance apartness source, order-facing positive-radius bridge, located tolerance route, metric source, real seal, finite cotransitivity branch ledger, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CotransitiveApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{CotransitiveApartness}^{\uparrow}$ packet is generated from a MetricApartnessUp positive-distance row, RealApartnessOrderBridgeUp positive-radius handoff, LocatedMetricSpaceUp tolerance route, MetricUp source row, RealUp seal row, finite cotransitivity branch ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CotransitiveApartness}^{\uparrow}}$, seed)

Scope closed: Definition 7798.1, Definition 7798.2, Definition 7798.3, Definition 7798.4, and Definition 7798.5 seed the finite cotransitive apartness interface consumed by real and completion-facing routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CotransitiveApartness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close RealUp trichotomy, quotient apartness, host inequality, selected limits, completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, finite cotransitivity branch admission, RealUp handoff stability, transport and replay stability, provenance non-escape, and local naming for BEDC.Derived.CotransitiveApa

Chapter 7799

A Concrete Naming Certificate for $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$

Following Stolz and Cesaro, and in the Bishop–Bridges treatment of regular real sequences, the $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$ packet records the finite tail-compression surface by which certified weighted-difference tails and certified denominator growth are read as a regular Cauchy quotient-tail row. It sits beside the theorem-level certificate of chapter 6137, the finite quotient-tail route of chapter 1439, the regular Cauchy Stolz transform of chapter 7551, the stream naming surface of chapter 126, the regular rational sequence handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only a finite compression route for Cauchy tails over displayed rows; it does not select a host limit, quotient carrier, ambient completeness theorem, or detached real-equality witness.

Definition 7799.1 (Stolz-Cesaro Cauchy tail-compression carrier)**.** *A* $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (W, G, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the weighted-difference tail row, displaying the inspected numerator-tail differences and their finite weights.*
2. *G is the denominator-growth row, displaying the positive growth windows used before any quotient-tail classifier is read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the inspected weighted-difference quotients and requested Cauchy moduli.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite tail windows consumed by each tolerance request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *quotient-tail compression row reached from W, G, D, S.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *compatibility row reached only after the regular rational quotient-tail row has been displayed.*
7. *H records componentwise* hsame *transport for W, G, D, S, R, E.*
8. *C records displayed* Cont *replay from weighted-difference tails through denominator growth, dyadic estimates, stream schedules, regular rational compression, and the real-name compatibility row.*

9. *P is the* Pkg *provenance over* StolzCesaroCauchyTailCompression$^{\uparrow}$, StolzCesaroTheorem$^{\uparrow}$, StolzCesaro$^{\uparrow}$, RegularCauchyStolzTransform$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{StolzCesaroCauchyTailCompression}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected host limit, quotient stream, quotient carrier, countable-choice schedule, trichotomy, or ambient Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.StolzCesaroCauchyTailCompressionUp.StolzCesaroCauchyTailCompressionTasteGate`
`single carrier alignment`

Theorem 7799.2 (Stolz-Cesaro Cauchy-tail-compression obligations)**.** *For every accepted* StolzCesaroCauchyTailCo *carrier $K = (W, G, D, S, R, E, H, C, P, N)$, a certified weighted-difference tail row together with a certified denominator-growth row induces a regular Cauchy quotient-tail compression row without selecting a host limit or quotient carrier. The local* NameCert$_{\text{StolzCesaroCauchyTailCompression}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier predicate: the accepted object is precisely the displayed packet $K = (W, G, D, S, R, E, H, C, P, N)$;*
2. *classifier: quotient-tail admission is classified only through the dyadic ledger D after the weighted-difference tail row W and denominator-growth row G have both been displayed;*
3. *tail stability: the stream schedule S preserves the admitted tail windows under requested Cauchy tolerances before R is read;*
4. *ledger compression: the regular rational row R is obtained by compressing the finite ledger W, G, D, S and has no independent quotient-carrier coordinate;*
5. *real-name compatibility: the row E reads the* Real$^{\uparrow}$ *face only through R and is preserved by H, C, P, N.*

Proof. Project the carrier $K = (W, G, D, S, R, E, H, C, P, N)$. Carrier admission gives exactly the displayed finite packet, so a consumer starts with the weighted-difference tail row W, denominator-growth row G, dyadic tolerance ledger D, stream schedule S, regular rational row R, real-name compatibility row E, and the structural rows H, C, P, N.

The classifier is then forced by the order of the rows. A quotient-tail request can be admitted only after W and G have been displayed, and its estimates are stored in D against the same dyadic tolerances. Thus the classifier has no separate source from which to select a quotient carrier or host limit.

Tail stability is supplied by S. The schedule names the finite tail windows used for each tolerance request, so the route from W, G, D to R is a finite compression of displayed windows rather than an appeal to ambient real completeness.

Finally the real-facing row E is downstream from R. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve the same displayed route, so the five listed obligation rows exhaust the accepted NameCert surface. □

Theorem 7799.3 (Stolz-Cesaro Cauchy tail nonescape)**.** *Every completion-facing read from an accepted* StolzCesaroCauchyTailCompression$^{\uparrow}$ *packet factors through the finite route*

$$W, G \longmapsto D \longmapsto S \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

In particular, no accepted consumer can reach a RegSeqRat$^{\uparrow}$ *quotient-tail compression row or a* Real$^{\uparrow}$ *compatibility row without first reading the certified weighted-difference tail row, certified denominator-growth row, dyadic quotient ledger, and stream tail schedule.*

Proof. Apply Definition 7799.2. Its carrier predicate identifies the only available rows, and its classifier and tail-stability clauses place W, G, D, S before any regular rational readback.

The ledger-compression clause then identifies R as the regular Cauchy quotient-tail compression row induced from the displayed finite ledger. Since R has no independent quotient-carrier coordinate, the route cannot branch to a host quotient stream.

The real-name compatibility clause places E after R and preserves the same packet through H, C, P, N. Hence the displayed route is mandatory for every accepted completion-facing read, and the excluded host limit, quotient carrier, countable choice, trichotomy, and ambient completeness objects remain outside the packet. □

Falsifiable prediction: An accepted $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ quotient-tail row or $\mathsf{Real}^{\uparrow}$ compatibility row without first reading weighted-difference tails, denominator growth, dyadic quotient estimates, and a stream tail schedule refutes the carrier surface.

Independence witness: stolzcesarotheorem, stolzcesaro, regularcauchystolztransform, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the full ten-row packet $K = (W, G, D, S, R, E, H, C, P, N)$, because each sibling contributes only a theorem route, quotient-tail route, regular Cauchy transform, stream schedule, regular rational readback, dyadic tolerance ledger, or real-name seal while this chapter binds the compression route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}}$.

Constructive story: A $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$ packet is generated from certified weighted-difference tails, certified denominator-growth rows, dyadic quotient ledgers, stream tail schedules, a RegSeqRat quotient-tail compression row, RealUp compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7799.1, Definition 7799.2, and Definition 7799.3 seed the finite Cauchy-tail compression route over weighted differences, denominator growth, dyadic estimates, stream schedules, RegSeqRat readback, RealUp compatibility, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Stolz-Cesaro theorem, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient carrier construction, selected limits, countable choice, trichotomy, Lean verification, or bridge checking for $\mathsf{StolzCesaroCauchyTailCompression}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, quotient-tail classifier admission, tail stability, ledger compression, real-name compatibility, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.StolzCesaroCauchyT

Chapter 7800

A Concrete Naming Certificate for $\mathsf{DedekindLocatedInterval}^{\uparrow}$

Following Dedekind's interval separation tradition and the Bishop–Bridges located-real discipline, the $\mathsf{DedekindLocatedInterval}^{\uparrow}$ packet records a finite located interval separator before any completion-facing consumer reads a Real seal. It sits beside the located interval route of chapter 394, the rational interval carrier of chapter 354, the dyadic tolerance core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal Real boundary of chapter 38, and the located-space request route of chapter 2043. The packet names a displayed separator row over finite interval data; it is not a Dedekind-cut construction of $\mathsf{Real}^{\uparrow}$, a quotient real equality principle, a trichotomy decision, countable choice, or ambient Real completeness.

Definition 7800.1 (Dedekind located interval carrier)**.** *A* $\mathsf{DedekindLocatedInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, Q, D, S, R, E, X, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedInterval}^{\uparrow}$ *source row, displaying the lower and upper interval endpoints together with the finite locatedness request.*
2. *Q is the* $\mathsf{RationalInterval}^{\uparrow}$ *rational bracket row through which endpoint comparisons are read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the requested separator scale.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row naming the finite windows inspected by the separator.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to those windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, Q, D, S, R have been displayed.*
7. *X is the* $\mathsf{LocatedSpace}^{\uparrow}$ *request row recording the ambient located-distance query consumed by interval-facing callers.*
8. *H records componentwise* hsame *transport for L, Q, D, S, R, E, X and the structural rows.*
9. *C records displayed* Cont *replay through the route*

$$L, Q, D, S, R, X \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{DedekindLocatedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{DedekindLocatedInterval}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, Q, D, S, R, E, X, H, C, P, N$. It has no coordinate for Dedekind-cut Real construction, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.DedekindLocatedIntervalUp.DedekindLocatedIntervalTasteGate single carrier alignment`

Theorem 7800.2 (Dedekind located interval NameCert obligations)**.** *For every accepted* $\mathsf{DedekindLocatedInterval}^{\uparrow}$ *carrier*

$$I = (L, Q, D, S, R, E, X, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DedekindLocatedInterval}^{\uparrow}}$ *surface consists exactly of carrier admission, located interval exposure through L, rational bracket readback through Q, dyadic separator budgeting through D, finite window inspection through S, regular-rational readback through R, Real-seal handoff through E, located-space request routing through X, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 7800.1. The located interval row L and rational bracket row Q expose the displayed endpoints before any separator read is admitted.

The dyadic ledger D, finite windows S, and regular readback R supply the finite inspection route. They determine the separator evidence only at the displayed scale and do not introduce a cut over all rational tests.

The located-space row X records the ambient request that may consume the separator, while E is reachable only after the interval, bracket, dyadic, stream, and regular rows are visible.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the refused objects do not occur as carrier coordinates, the local certificate surface cannot export them. □

Theorem 7800.3 (Dedekind located interval separator boundary)**.** *Any completion-facing consumer that reads an accepted* $\mathsf{DedekindLocatedInterval}^{\uparrow}$ *packet must pass through*

$$\mathsf{LocatedInterval}^{\uparrow}, \mathsf{RationalInterval}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{LocatedSpace}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed finite rows. The route supplies a located interval separator for downstream Real and completion-boundary arguments, but it does not construct $\mathsf{Real}^{\uparrow}$ *by Dedekind cuts, quotient real equality, trichotomy, countable choice, or ambient Real completeness.*

Proof. Use Definition 7800.2. It identifies the visible route $L, Q, D, S, R, X, E, H, C, P, N$ and forces every consumer to inspect the finite interval, bracket, tolerance, window, regular readback, located-space, and seal rows in that order.

The separator is therefore a row inside the displayed NameCert packet. It can be transported or replayed by H and C, but those structural rows preserve only the listed coordinates.

No coordinate stores a global lower cut, upper cut, quotient equality class, trichotomy decision, countable-choice schedule, or ambient completeness theorem. The separator boundary is exactly the finite route, not a construction of the real line. □

Closure status for $\mathsf{NameCert}_{\mathsf{DedekindLocatedInterval}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DedekindLocatedInterval}^{\uparrow}$ packet is generated from a LocatedInterval source row, RationalInterval bracket row, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, LocatedSpace request row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DedekindLocatedInterval}\uparrow}$, seed)

Scope closed: Definition 7800.1, Definition 7800.2, and Definition 7800.3 seed the finite located interval separator over rational brackets, dyadic budgets, stream windows, regular readback, located-space requests, and Real seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{DedekindLocatedInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut Real construction, quotient real equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located interval exposure, rational bracket readback, dyadic separator budgeting, finite window inspection, regular-rational readback, located-space request routing, Real-seal handoff, and nonescape proofs for BEDC.Derived.DedekindLocatedIntervalUp.

Chapter 7801

A Concrete Naming Certificate for $\mathsf{PoincareDiskHorocycleReturn}^{\uparrow}$

Following Poincare's disk model and the classical horocycle tradition in hyperbolic geometry, the $\mathsf{PoincareDiskHorocycleReturn}^{\uparrow}$ packet records a finite return-window surface for a displayed horocycle read inside the disk. It realizes the observer-expansion branch of chapter 9463 after the disk metric packet of chapter 6209, the horocycle carrier of chapter 6980, the geodesic-flow route of chapter 3856, the visual-boundary surface of chapter 4181, and the Busemann cocycle row of chapter 4134. The packet names boundary-shadow, disk-metric, horocycle transport, return-window, Real-seal, and provenance rows; it is not a global recurrence theorem, a quotient boundary flow, a selected complete orbit, a physical observer law, or ambient hyperbolic completeness.

Definition 7801.1 (Poincare disk horocycle-return carrier)**.** *A* $\mathsf{PoincareDiskHorocycleReturn}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, B, Hc, G, V, U, W, E, T, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric row used by the local read.*
2. *B is the boundary-shadow row naming the displayed ideal endpoint or boundary window.*
3. *Hc is the* $\mathsf{HyperbolicPhaseHorocycle}^{\uparrow}$ *horocycle carrier row.*
4. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *comparison row that keeps the return tied to the displayed flow parameter.*
5. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *visual-boundary readback row.*
6. *U is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *cocycle row that records the signed horocycle displacement ledger.*
7. *W is the return-window row, listing the finite disk and boundary observations accepted for the return read.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed return scale or displacement.*
9. *T records componentwise* hsame *transport for D, B, Hc, G, V, U, W, E and the structural rows.*
10. *C records displayed* Cont *replay through the route*

$$D, B, Hc, G, V, U, W \longmapsto E.$$

11. *P is the* Pkg *provenance over* PoincareDiskHorocycleReturn$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicPhaseHorocycle$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{PoincareDiskHorocycleReturn}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, B, Hc, G, V, U, W, E, T, C, P, N$. It has no coordinate for a global recurrence theorem, quotient boundary flow, selected complete orbit, physical observer law, ambient hyperbolic completeness, Lean verification, or bridge checking.

Theorem 7801.2 (Poincare disk horocycle-return NameCert obligations)**.** *For every accepted* PoincareDiskHorocycleReturn$^{\uparrow}$ *carrier*

$$R = (D, B, Hc, G, V, U, W, E, T, C, P, N),$$

the local NameCert$_{\text{PoincareDiskHorocycleReturn}^{\uparrow}}$ *surface consists exactly of disk-metric exposure through D, boundary-shadow readback through B, horocycle transport through Hc, geodesic-flow comparison through G, visual-boundary readback through V, Busemann-cocycle displacement through U, finite return-window admission through W, Real-seal handoff through E, and structural transport, replay, provenance, and local naming through T, C, P, N.*

Proof. Project the carrier of Definition 7801.1. The disk metric row D and boundary-shadow row B establish the displayed disk and boundary surface before the horocycle return is read.

The horocycle row Hc, geodesic-flow row G, visual-boundary row V, and Busemann-cocycle row U supply the hyperbolic transport and displacement data. The return window W is admitted only over those displayed rows.

The Real-seal row E is downstream of the finite return window. Transport, replay, provenance, and local naming through T, C, P, N preserve the same packet and add no orbit selector or quotient boundary flow. □

Theorem 7801.3 (Poincare disk horocycle-return vision realization)**.** *The hyperbolic phase geometry route of chapter 9463 is realized, at the horocycle-return site, by an accepted* PoincareDiskHorocycleReturn$^{\uparrow}$ *carrier whose finite route is*

PoincareDiskMetric$^{\uparrow}$, HyperbolicPhaseHorocycle$^{\uparrow}$, HyperbolicGeodesicFlow$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBu

The realization is a concrete NameCert packet over displayed disk, boundary, transport, return-window, Real-seal, and provenance rows, not a global recurrence theorem or a completed boundary dynamics object.

Proof. Read the vision through the concrete disk and boundary rows named by D, B, V. These rows keep the Poincare disk metric and visual boundary visible before any return claim is inspected.

The horocycle and flow data are the rows Hc, G, U, W. They record the finite horocycle carrier, geodesic-flow comparison, Busemann displacement, and accepted return window.

Finally consume E, T, C, P, N. The Real-seal row reports only the displayed return scale or displacement, while transport, replay, provenance, and local naming keep the realization inside the same finite NameCert packet. □

Closure status for NameCert$_{\text{PoincareDiskHorocycleReturn}^{\uparrow}}$.

Constructive story: A PoincareDiskHorocycleReturn$^{\uparrow}$ packet is generated from PoincareDiskMetric disk rows, boundary-shadow rows, HyperbolicPhaseHorocycle transport, HyperbolicGeodesicFlow comparison, HyperbolicVisualBoundary readback, HyperbolicBusemannCocycle displacement, a finite return window, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PoincareDiskHorocycleReturn}\uparrow}$, seed)

Scope closed: Definition 7801.1, Definition 7801.2, and Definition 7801.3 seed the finite Poincare disk horocycle-return route over disk metric, boundary shadow, horocycle transport, geodesic flow, visual boundary, Busemann cocycle, return-window, Real-seal, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{PoincareDiskHorocycleReturn}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim global recurrence, quotient boundary flow, selected complete orbit, physical observer dynamics, ambient hyperbolic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-metric exposure, boundary-shadow readback, horocycle transport, geodesic-flow comparison, visual-boundary readback, Busemann-cocycle displacement, finite return-window admission, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.PoincareDiskHorocycleReturnUp.

Chapter 7802

A Concrete Naming Certificate for $\mathsf{RegularCauchyDominatedTail}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyDominatedTail}^{\uparrow}$ packet records the finite L10 route by which a regular Cauchy source row, a displayed domination budget, and a tail row produce a regular rational readback before any real seal is consumed. It sits over the dyadic tolerance arithmetic of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the real-name boundary of chapter 38, and the comparison discipline of chapter 1459. The packet names a dominated-tail certificate only as finite NameCert data; it is not a selected limit, quotient equality of Cauchy names, countable choice, trichotomy, host real comparison, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7802.1 (Regular Cauchy dominated-tail carrier)**.** *A* $\mathsf{RegularCauchyDominatedTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, T, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source regular-Cauchy row whose inspected entries are read only through finite windows.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dominance budget, recording the dyadic tolerance and domination margin used to compare the source tail with its displayed majorant.*
3. *T is the dominated tail row, containing the tail index, the finite tail window, and the pointwise domination reads admitted for that window.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window surface that lists every source and tail coordinate inspected before a regular readback is exported.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the source windows, tail windows, and dyadic budget.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after S, D, T, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the source row, dominance budget, dominated tail row, stream windows, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, D, T, W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyDominatedTail}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDominatedTail}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, T, W, R, E, H, C, P, N$. It has no coordinate for a hidden limit selector, quotient equality of regular Cauchy names, countable choice, trichotomy on arbitrary rational tails, host real comparison, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Theorem 7802.2 (Regular Cauchy dominated-tail obligation surface)**.** *For every accepted* RegularCauchyDominate *carrier*

$$K = (S, D, T, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDominatedTail}^{\uparrow}}$ *surface consists exactly of carrier admission for the source regular-Cauchy row S, dyadic dominance budget D, dominated tail row T, stream-window surface W, regular readback R, real seal E, componentwise transport H, displayed replay C, provenance P, and local naming N. The comparison-test use is finite: every domination read must be routed through the displayed* $\mathsf{RegularCauchyComparisonTest}^{\uparrow}$ *discipline on S, D, T, W before R or E can be consumed.*

Proof. Project the accepted carrier onto its ten rows. The source data are S, the dyadic tolerance and domination margin are D, and the dominated tail is T; no tail comparison is available outside these displayed rows.

The window and readback rows then fix the observation route. The row W lists the finite stream coordinates inspected for the source and tail, while R is the only regular rational readback attached to those windows and to the dyadic budget.

The real seal E is downstream from S, D, T, W, R. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve exactly that route. Since the carrier has no extra coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 7802.3 (Regular Cauchy dominated-tail L10 handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyDominatedTail}^{\uparrow}$ *carrier receives the finite L10 handoff*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegularCauchyComparisonTest}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

implemented by the displayed route $S, D, T, W, R, E, H, C, P, N$. The handoff certifies only that the dominated tail has been read through the dyadic budget and finite stream windows before the regular rational row and real seal are exposed; it exports no selected limit, quotient equality of Cauchy names, countable choice, host real comparison, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the obligation surface of Definition 7802.2. It forces the source regular-Cauchy row, dominance budget, dominated tail row, and stream windows to be displayed before any regular rational readback can be used.

The comparison-test row is consumed on that same finite surface. Its role is to check the tail domination against the dyadic budget, not to supply a host real comparison or a selected endpoint.

After the finite comparison is displayed, R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback and E supplies the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows H, C, P, N transport, replay, source, and name the same route, so the public handoff is exactly the finite L10 certificate above. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDominatedTail}^{\uparrow}}$.

Constructive story: A RegularCauchyDominatedTail$^{\uparrow}$ packet is generated from a source regular-Cauchy row, a dyadic dominance budget, a dominated tail row, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyDominatedTail}^{\uparrow}}$, seed)

Scope closed: Definition 7802.1, Definition 7802.2, and Definition 7802.3 seed the finite dominated-tail route from dyadic domination and stream windows through regular rational readback to the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyDominatedTail}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient equality of Cauchy names, countable choice, trichotomy, host real comparison, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: A stronger status requires Lean coverage for carrier admission, dominated-tail comparison routing, regular rational readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyDominatedTailUp

Chapter 7803

A Concrete Naming Certificate for $\mathsf{CauchyTailMeet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyTailMeet}^{\uparrow}$ packet records the finite common-tail witness used when two displayed Cauchy requests must be synchronized before a regular rational or real-name consumer reads them. It sits over the one-tail estimate route of chapter 1487, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance meet of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite common threshold and its inspected windows; it is not a selected limit, quotient stream equality, countable-choice schedule, host real equality, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7803.1 (Cauchy tail meet carrier)**.** *A* $\mathsf{CauchyTailMeet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A_0, A_1, \tau, W_0, W_1, D, R_0, R_1, E, H, C, P, N)$$

with the following displayed rows:

1. *A_0 and A_1 are the two admitted tail requests, each naming a finite request into the sibling* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *surface.*
2. *τ is the common threshold row at which both requests are simultaneously inspected.*
3. *W_0 and W_1 are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows read at and beyond τ.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance meet, recording the common dyadic budget used by both tail windows.*
5. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows reached from W_0, D and W_1, D.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after the two requests, common threshold, finite windows, tolerance meet, and regular readbacks have been replayed.*
7. *H records componentwise* hsame *transport for the two requests, common threshold, windows, tolerance meet, readbacks, seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a paired tail request through $\tau, W_0, W_1, D, R_0, R_1$ and then E.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailMeet}^{\uparrow}$*,* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailMeet}^{\uparrow}}$ *row naming exactly this finite common-tail packet.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a selected infinite tail, quotient stream equality, countable choice, host real equality, trichotomy, or ambient completeness.

Theorem 7803.2 (Cauchy tail meet NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailMeet}^{\uparrow}$ *carrier*

$$T = (A_0, A_1, \tau, W_0, W_1, D, R_0, R_1, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyTailMeet}^{\uparrow}}$ *surface consists exactly of carrier admission, two tail-request reads, common-threshold visibility, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance meet, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every common-tail consumer must pass through*

$$A_0, A_1, \tau, W_0, W_1, D, R_0, R_1, E, H, C, P, N$$

and through no selected limit, quotient stream equality, countable-choice schedule, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7803.1. The rows A_0, A_1 expose the two finite tail requests, and the row τ is the single common threshold at which both requests are inspected.

Read the analytic rows after the threshold. The windows W_0, W_1 give the finite $\mathsf{StreamName}^{\uparrow}$ observations, D is the shared $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance meet, and R_0, R_1 are the only regular rational readbacks downstream of those windows.

Finally read the seal and structural rows. The row E is available only after the displayed request, threshold, window, tolerance, and readback rows have been replayed, while H, C, P, N preserve, replay, source, and name the same finite route.

Since no carrier coordinate stores a selected infinite tail, quotient stream equality, countable-choice schedule, host real equality, trichotomy, or ambient completeness witness, none of those objects can appear as a local NameCert obligation. □

Theorem 7803.3 (Cauchy tail meet finite induction)**.** *Every predicate Q on accepted* $\mathsf{CauchyTailMeet}^{\uparrow}$ *packets is established by finite induction when the following displayed cases are stable under* hsame*:*

1. *the two tail requests A_0, A_1 have been admitted;*
2. *the common threshold τ has been read;*
3. *the two finite windows W_0, W_1 have been inspected;*
4. *the shared dyadic meet D and regular readbacks R_0, R_1 have been replayed;*
5. *the real seal E, continuation row C, provenance row P, and local name N have been consumed.*

Thus common-tail arguments over $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *use only finite rows of T and do not appeal to a choice-selected threshold family.*

Proof. Induct over the displayed rows of the carrier. The base stage admits A_0, A_1 and exposes no threshold-dependent data.

The threshold stage adds the single row τ. Since both requests read the same threshold row, the induction context has one common finite index rather than two independently chosen tails.

The window and readback stages add W_0, W_1, D, R_0, R_1 in the displayed order. Stability under the componentwise hsame rows transports each finite observation and dyadic meet without changing the route.

The final stage reads E, C, P, N. The seal, continuation, provenance, and local name consume the accumulated finite route and introduce no further threshold selector, so the predicate Q is obtained by the stated finite induction. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailMeet}\uparrow}$.

Constructive story: A $\mathsf{CauchyTailMeet}^{\uparrow}$ packet is generated from two tail requests, one common threshold, finite StreamName windows, a DyadicRatCore tolerance meet, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyTailMeet}\uparrow}$, seed)

Scope closed: Definition 7803.1, Definition 7803.2, and Definition 7803.3 seed the finite common-tail witness over StreamName windows, dyadic tolerance meets, regular rational readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyTailMeet}\uparrow}$, unformalized)

Bridge status: none

Not claimed: The chapter does not close regular Cauchy completeness, quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold visibility, finite window admission, dyadic meet stability, regular rational readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailMeetUp.

Chapter 7804

A Concrete Naming Certificate for $\mathsf{FenchelYoungInequality}^{\uparrow}$

Following Rockafellar and Boyd–Vandenberghe, the $\mathsf{FenchelYoungInequality}^{\uparrow}$ packet records the finite convex-analysis surface for the inequality $f(x) + f^*(y) \geq \langle y, x\rangle$. It sits between the convex-set, vector-space, real-name, conjugate, and duality rows of chapter 208, chapter 47, chapter 38, chapter 3563, and chapter 321. The packet names the displayed inequality as BEDC carrier data; it does not import host suprema, quotient function spaces, selected minimizers, choice, or ambient completeness.

Definition 7804.1 (Fenchel–Young inequality carrier)**.** *A* $\mathsf{FenchelYoungInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, V, R, F, D, E, P, L, H, C, Q, N)$$

with the following displayed rows:

1. *X is the displayed* $\mathsf{ConvexSet}^{\uparrow}$ *row carrying the primal convex-domain boundary.*
2. *V is the displayed* $\mathsf{VecSpace}^{\uparrow}$ *row carrying the primal and dual vector-space read.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *comparison row that records the ordered scalar boundary.*
4. *F is the* $\mathsf{ConvexConjugate}^{\uparrow}$ *row carrying the finite conjugate packet for f^*.*
5. *D is the* $\mathsf{FenchelDuality}^{\uparrow}$ *row that records the surrounding primal-dual ledger.*
6. *E is the pairing-evaluation row for the finite read of $\langle y, x\rangle$.*
7. *P is the comparison ledger row displaying $f(x)$, $f^*(y)$, the sum row, the pairing row, and the inequality comparison.*
8. *L is the handoff ledger that orders the convex-set, vector-space, real, conjugate, duality, pairing, and comparison rows before any optimization consumer reads the inequality.*
9. *H stores componentwise* hsame *transport for all displayed rows.*
10. *C stores displayed* Cont *replay from primal and dual reads to pairing evaluation, from conjugate read to comparison, and from comparison to the inequality handoff.*
11. *Q is the* Pkg *provenance over* $\mathsf{FenchelYoungInequality}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FenchelYoungInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, V, R, F, D, E, P, L, H, C, Q, N$. It has no coordinate for a host supremum operator, quotient function space, selected optimizer, separating hyperplane principle, or ambient completeness theorem.

Theorem 7804.2 (Fenchel–Young inequality NameCert obligations)**.** *For every accepted* $\mathsf{FenchelYoungInequality}^{\uparrow}$ *carrier* $K = (X, V, R, F, D, E, P, L, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FenchelYoungInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows, classifier stability under componentwise* hsame *transport, pairing replay through the* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows, conjugate handoff through* $\mathsf{ConvexConjugate}^{\uparrow}$*, primal-dual ledger handoff through* $\mathsf{FenchelDuality}^{\uparrow}$*, comparison-ledger exactness through* P, L*, and local provenance through* Q, N*. Every inequality read must pass through the convex domain row, vector-space row, real comparison row, conjugate row, duality row, pairing row, and displayed comparison ledger before an optimization consumer can inspect it.*

Proof. Project the carrier of Definition 7804.1. The visible coordinates are exactly $X, V, R, F, D, E, P, L, H, C, Q, N$ so carrier admission and classifier comparison are componentwise on those rows.

The analytic sources are read only through sibling packets. The rows X, V, R provide the convex-domain, vector-space, and scalar-order boundaries, while F and D import only the displayed conjugate and primal-dual ledgers of chapter 3563 and chapter 321.

The pairing and comparison rows then determine the inequality surface. The replay row C routes primal and dual reads to E, routes the conjugate read to P, and routes the comparison ledger to L, Q, N. Since no host supremum, quotient function space, optimizer selector, or completeness row is present in the carrier, the listed rows form the whole local NameCert surface. □

Theorem 7804.3 (Fenchel–Young inequality conjugate handoff)**.** *Every* $\mathsf{FenchelDuality}^{\uparrow}$ *or optimization consumer that reads a Fenchel–Young inequality through an accepted* $\mathsf{FenchelYoungInequality}^{\uparrow}$ *carrier receives only the displayed route*

$$X, V, R, F, D, E, P, L \longmapsto H, C, Q, N.$$

The consumer reads convex-domain data, vector-space data, real comparison data, conjugate data, primal-dual ledger data, pairing evaluation, and the comparison ledger before receiving the local NameCert *row. The route exports no host supremum, quotient function space, selected minimizer, Hahn–Banach separation, strong-duality existence, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 7804.2. It places each inequality read on X, V, R, F, D, E, P, L before the transport, replay, provenance, and local naming rows can return an answer.

Now read the conjugate dependency. The $\mathsf{ConvexConjugate}^{\uparrow}$ row F supplies conjugacy only as the finite packet of chapter 3563; the $\mathsf{FenchelDuality}^{\uparrow}$ row D supplies only the surrounding primal-dual ledger of chapter 321. Thus the inequality handoff is a finite comparison route rather than an imported theorem of host convex analysis.

The refused objects are absent from Definition 7804.1. Therefore the handoff can deliver the displayed inequality surface to downstream optimization chapters, but it cannot deliver a selected optimizer, host supremum, quotient-function equality, separation theorem, strong-duality existence witness, or ambient completeness result. □

Falsifiable prediction: Every $\mathsf{FenchelYoungInequality}^{\uparrow}$ consumer reads the inequality through convex-domain, vector-space, real-comparison, convex-conjugate, Fenchel-duality, pairing-evaluation, comparison-ledger, handoff-ledger, transport, continuation replay, provenance, and local naming rows.

Independence witness: convexset, vecspace, real, convex-conjugate, fenchelduality: $\mathsf{FenchelYoungInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the conjugate comparison, pairing evaluation, primal-dual ledger, inequality ledger, transport, replay, provenance, and local naming rows as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FenchelYoungInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{FenchelYoungInequality}^{\uparrow}$ packet is generated from displayed convex-domain, vector-space, real-comparison, convex-conjugate, Fenchel-duality, pairing-evaluation, comparison-ledger, handoff-ledger, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FenchelYoungInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7804.1, Definition 7804.2, and Definition 7804.3 bind the finite Fenchel–Young inequality certificate surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FenchelYoungInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex analysis, host suprema, quotient function spaces, selected minimizers, separation theorems, strong duality, choice, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, conjugate handoff, comparison-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.FenchelYoungInequalityUp.

Chapter 7805

A Concrete Naming Certificate for $\mathsf{HamiltonJacobiBellman}^{\uparrow}$

Following Bellman, Fleming–Rishel, and Evans, the $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ packet records the finite dynamic-programming, PDE, and control interface at which a displayed value row is read through a Hamiltonian minimization surface. It sits after the finite Bellman recursion of chapter 5875, the Hamilton-Jacobi readback packet of chapter 7663, the PDE relation surface of chapter 194, the quadratic-control dependency of chapter 5103, and the finite LQR route of chapter 296. The packet names only displayed state, control, value, Hamiltonian, PDE-relation, dynamic-programming, Riccati, LQR, transport, replay, provenance, and local naming rows; it is not an existence theorem for optimal controls, not a classical viscosity-solution theorem, not a global PDE regularity theorem, and not an ambient completeness assertion for $\mathsf{Real}^{\uparrow}$.

Definition 7805.1 (Hamilton-Jacobi-Bellman carrier)**.** *A* $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, U, T, C, V, G, E, D, J, Q, L, R, A, M, K, P, N)$$

with the following displayed rows:

1. *X is the displayed state row and U is the admissible control row consumed by the finite control request.*
2. *T is the transition or dynamics row, and C is the running-cost row sealed only through displayed* $\mathsf{Real}^{\uparrow}$ *data.*
3. *V is the value-row name, G is the finite slope or gradient-read row, and E is the terminal or boundary value row.*
4. *D is the* $\mathsf{DynamicProgramming}^{\uparrow}$ *recursion row that supplies finite Bellman table readback.*
5. *J is the* $\mathsf{HamiltonJacobi}^{\uparrow}$ *Hamiltonian readback row, and Q is the* $\mathsf{Pde}^{\uparrow}$ *relation row tying the value surface to a displayed PDE request.*
6. *L is the* $\mathsf{LQR}^{\uparrow}$ *quadratic-control dependency row, and R is the* $\mathsf{ControlRiccati}^{\uparrow}$ *Riccati comparison row available for the linear-quadratic face.*
7. *A records componentwise* hsame *transport for $X, U, T, C, V, G, E, D, J, Q, L, R$.*
8. *M records displayed* Cont *replay through the route*

$$D, J, Q, L, R \longmapsto V.$$

9. *K is the* Pkg *provenance over* $\mathsf{HamiltonJacobiBellman}^{\uparrow}$, $\mathsf{DynamicProgramming}^{\uparrow}$, $\mathsf{HamiltonJacobi}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *P, N are the refusal and local* $\mathsf{NameCert}_{\mathsf{HamiltonJacobiBellman}^{\uparrow}}$ *rows.*

The classifier compares accepted packets only through $X, U, T, C, V, G, E, D, J, Q, L, R, A, M, K, P, N$. It has no coordinate for selected optimal controls, classical solution existence, viscosity uniqueness, unbounded PDE regularity, host minimizers, quotient value-function equality, or ambient real completeness.

Theorem 7805.2 (Hamilton-Jacobi-Bellman NameCert obligations)**.** *For every accepted* $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ *carrier*

$$H = (X, U, T, C, V, G, E, D, J, Q, L, R, A, M, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HamiltonJacobiBellman}^{\uparrow}}$ *surface is the following five-row obligation surface:*

1. *carrier admission exposes the displayed state, control, transition, running-cost, value, slope, and terminal rows X, U, T, C, V, G, E;*
2. *dynamic-programming exposure routes finite Bellman recursion through D and chapter 5875;*
3. *Hamilton-Jacobi and PDE exposure routes Hamiltonian and relation reads through J, Q and chapter 7663, chapter 194;*
4. *quadratic-control exposure routes the LQR and Riccati faces through L, R and chapter 296, chapter 5103;*
5. *structural exposure routes componentwise transport, replay, provenance, refusal, and local naming through A, M, K, P, N.*

No listed row exports selected optimal controls, classical solution existence, viscosity uniqueness, unbounded PDE regularity, host minimizers, quotient value-function equality, or ambient real completeness.

Proof. Project the carrier of Definition 7805.1. The rows X, U, T, C, V, G, E give the visible finite control and value surface before any Bellman or PDE request is read.

Read the sibling rows next. The dynamic-programming row D supplies finite Bellman recursion, the Hamilton-Jacobi row J supplies Hamiltonian readback, and the PDE row Q supplies the displayed relation surface.

For the quadratic-control face, the LQR row L and Riccati row R are dependency rows inside the same packet. A consumer may read them only after the finite value, Hamiltonian, and relation rows have been displayed.

Finally use A, M, K, P, N for transport, replay, provenance, refusal, and local naming. Since the carrier has no further coordinate, none of the refused analytic or choice-theoretic objects can be exported by the NameCert surface. □

Theorem 7805.3 (Hamilton-Jacobi-Bellman sibling dependency route)**.** *Every downstream consumer of an accepted* $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ *packet that asks for a control-facing PDE read must pass through*

$$\mathsf{DynamicProgramming}^{\uparrow}, \mathsf{HamiltonJacobi}^{\uparrow}, \mathsf{Pde}^{\uparrow}, \mathsf{ControlRiccati}^{\uparrow}, \mathsf{LQR}^{\uparrow} \longmapsto \mathsf{HamiltonJacobiBellman}^{\uparrow}$$

as displayed sibling rows. The route binds finite Bellman recursion, Hamiltonian readback, PDE relation data, Riccati comparison, and LQR specialization as one NameCert packet, without turning any sibling into an optimal-control existence theorem or a classical PDE regularity theorem.

Proof. Apply Definition 7805.2. The dynamic-programming, Hamilton-Jacobi, PDE, LQR, and Riccati obligations are separate displayed rows of the same accepted carrier.

The structural rows A, M, K, P, N preserve that row inventory under transport and replay. They do not add a host minimizer, a selected policy, a viscosity uniqueness theorem, or an ambient completion principle.

Thus a consumer reaches $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ only through the finite sibling route shown above, and the refused analytic objects remain outside the packet. □

Falsifiable prediction: A claimed $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ read that reaches a PDE relation or quadratic-control face without displaying the DynamicProgramming, HamiltonJacobi, Pde, ControlRiccati, and LQR rows refutes the carrier.

Independence witness: dynamic-programming, hamilton-jacobi, pde, control-riccati, lqr: no listed sibling is bijective to $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ because only this packet binds finite Bellman recursion, Hamiltonian readback, PDE relation data, Riccati comparison, LQR specialization, value rows, transport, replay, provenance, refusal, and local naming as one HJB interface.

Closure status for $\mathsf{NameCert}_{\mathsf{HamiltonJacobiBellman}^{\uparrow}}$.

Constructive story: A $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ packet is generated from displayed state, control, transition, cost, value, slope, terminal, DynamicProgramming, HamiltonJacobi, Pde, ControlRiccati, LQR, transport, replay, provenance, refusal, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HamiltonJacobiBellman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7805.1, Definition 7805.2, and Definition 7805.3 seed the finite HJB control-PDE interface over dynamic programming, Hamilton-Jacobi, PDE, Riccati, and LQR rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HamiltonJacobiBellman}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected optimal controls, classical solution existence, viscosity uniqueness, global PDE regularity, host minimizers, quotient value-function equality, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dynamic-programming exposure, Hamilton-Jacobi and PDE exposure, quadratic-control exposure, transport, replay, provenance, refusal, and local naming for BEDC.Derived.HamiltonJacobiBellmanUp.

Chapter 7806

A Concrete Naming Certificate for $\mathsf{PoincareHalfPlane}^{\uparrow}$

Following Poincare and the standard upper-half-plane model of hyperbolic geometry, the $\mathsf{PoincareHalfPlane}^{\uparrow}$ packet records finite half-plane coordinate, boundary, metric, and transport rows as BEDC NameCert data. It realizes a concrete model for the observer-expansion branch of chapter 9463 beside the disk metric packet of chapter 6209, the hyperbolic metric surface of chapter 3474, the visual-boundary route of chapter 4181, and the Mobius transport surface of chapter 5110. The packet names only displayed half-plane, boundary, metric, Mobius transport, disk-comparison, Real-seal, provenance, and local naming rows; it is not a global model equivalence theorem, a quotient boundary dynamics object, an analytic completeness theorem, or a physical observer law.

Definition 7806.1 (Poincare half-plane carrier)**.** *A* $\mathsf{PoincareHalfPlane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (H, B, M, D, V, T, E, C, R, Q, N)$$

with the following displayed rows:

1. *H is the upper-half-plane coordinate row, naming the displayed point window whose imaginary coordinate is positive.*
2. *B is the boundary row, containing the displayed real-axis and far-end boundary observations accepted by the packet.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row restricted to the displayed half-plane window.*
4. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *comparison row used only when a Cayley-style disk comparison is displayed.*
5. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *readback row attached to the same boundary window.*
6. *T is the* $\mathsf{MobiusTransform}^{\uparrow}$ *transport row recording the finite fractional-linear map data inspected by the consumer.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for metric, boundary, or distortion values read from the displayed rows.*
8. *C records componentwise* hsame *transport for H, B, M, D, V, T, E and the structural rows.*
9. *R records displayed* Cont *replay through the route*

$$H, B, M, V, T \longmapsto E.$$

10. *Q is the* Pkg *provenance over* $\mathsf{PoincareHalfPlane}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicVisualBound}$ $\mathsf{MobiusTransform}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareHalfPlane}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, B, M, D, V, T, E, C, R, Q, N$. It has no coordinate for global disk-half-plane equivalence, quotient boundary flow, selected complete geodesics, analytic hyperbolic completeness, physical observer dynamics, Lean verification, or bridge checking.

Theorem 7806.2 (Poincare half-plane NameCert obligations)**.** *For every accepted* $\mathsf{PoincareHalfPlane}^{\uparrow}$ *carrier*

$$P = (H, B, M, D, V, T, E, C, R, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareHalfPlane}^{\uparrow}}$ *surface consists exactly of half-plane coordinate exposure through H, boundary readback through B, hyperbolic metric exposure through M, optional disk comparison through D, visual-boundary readback through V, Mobius transport through T, Real-seal handoff through E, and structural transport, replay, provenance, and local naming through C, R, Q, N.*

Proof. Project the carrier of Definition 7806.1. The half-plane coordinate row H and boundary row B establish the displayed upper-half-plane window before any metric or transport read is inspected.

The metric and boundary rows are then read through M, V, E. The optional disk-comparison row D remains a comparison row inside the same packet, not a proof that every disk model object has been globally identified with a half-plane object.

Mobius transport is supplied by T and preserved by C, R, Q, N. Since the carrier has no further coordinate, the packet cannot export quotient boundary dynamics, complete geodesic selection, physical observer dynamics, analytic completeness, or bridge checking. □

Theorem 7806.3 (Poincare half-plane boundary transport)**.** *Every boundary-transport consumer of an accepted* $\mathsf{PoincareHalfPlane}^{\uparrow}$ *packet must first expose the half-plane coordinate row H, boundary row B, hyperbolic metric row M, visual-boundary row V, Mobius transport row T, Real-seal row E, and structural rows C, R, Q, N. A disk comparison may be read through D only after those half-plane rows are visible, and the read exports no global disk-half-plane equivalence, quotient boundary flow, or selected complete orbit.*

Proof. Use Definition 7806.2. It identifies the visible boundary-transport route as $H, B, M, V, T, E, C, R, Q, N$ with D as an optional comparison row.

The transport row T is finite Mobius data attached to the displayed half-plane and boundary observations. It can move the named rows under componentwise hsame transport, but it does not create a quotient boundary object or a completed orbit.

The Real-seal and provenance rows close only the displayed metric and boundary reads. Therefore the half-plane packet can be consumed by later disk, boundary, and Mobius chapters without claiming global equivalence or analytic completeness. □

Falsifiable prediction: A claimed $\mathsf{PoincareHalfPlane}^{\uparrow}$ boundary transport that omits the half-plane coordinate row, boundary row, hyperbolic metric row, visual-boundary row, Mobius transport row, Real seal, transport, replay, provenance, or local NameCert row refutes the carrier.

Independence witness: hyperbolicmetric, poincare-disk-metric, hyperbolic-visual-boundary, mobius-transform: no listed sibling is bijective to $\mathsf{PoincareHalfPlane}^{\uparrow}$ because only this packet binds upper-half-plane coordinates, boundary rows, metric reads, disk comparison, Mobius transport, Real sealing, provenance, and local naming as one half-plane model surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareHalfPlane}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareHalfPlane}^{\uparrow}$ packet is generated from upper-half-plane coordinate rows, boundary rows, HyperbolicMetric rows, optional PoincareDiskMetric comparison rows, HyperbolicVisualBoundary readback, MobiusTransform transport, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareHalfPlane}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7806.1, Definition 7806.2, and Definition 7806.3 seed the finite upper-half-plane model surface over boundary, metric, disk-comparison, Mobius transport, Real-seal, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareHalfPlane}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global disk-half-plane equivalence, quotient boundary dynamics, selected complete geodesics, physical observer laws, analytic hyperbolic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked coordinate exposure, boundary readback, hyperbolic metric exposure, disk comparison, visual-boundary readback, Mobius transport, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.PoincareHalfPlaneUp.

Chapter 7807

A Concrete Naming Certificate for $\mathsf{UniformFilterCompletion}^{\uparrow}$

Following Kelley and Bourbaki on uniform spaces and filters, the $\mathsf{UniformFilterCompletion}^{\uparrow}$ packet records the L10 completion surface where a displayed Cauchy-filter base is read through a uniform-completion handoff before any completion consumer sees a real-facing seal. It sits beside the functorial completion route of chapter 1892, the Cauchy-filter base route of chapter 1915, the Cauchy-filter completion criterion of chapter 3885, the regular rational readback of chapter 301, the finite StreamName windows of chapter 126, and the terminal Real seal of chapter 38. The packet names a filter-based completion surface without quotient completions, selected limits, choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7807.1 (Uniform filter completion carrier)**.** *A* $\mathsf{UniformFilterCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, B, Q, G, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{UniformCompletionFunctor}^{\uparrow}$ *route row, exposing the functorial completion handoff used by downstream completion consumers.*
2. *B is the* $\mathsf{CauchyFilterBase}^{\uparrow}$ *basis row, listing the finite filter-base requests and directed refinements consumed by the completion route.*
3. *Q is the* $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$ *criterion row, requiring the filter route to pass through displayed basis, window, readback, and seal data.*
4. *G is the* $\mathsf{UniformCompletion}^{\uparrow}$ *source row, binding the same uniform source to the functorial and criterion rows.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the filter-base and completion requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, readable only after F, B, Q, G, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the functorial, filter-base, criterion, uniform-source, window, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay of the same finite completion route.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformFilterCompletion}^{\uparrow}$, $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformFilterCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, B, Q, G, S, R, E, H, C, P, N$. It has no coordinate for quotient filter equality, quotient completion equality, selected representatives, selected limits, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7807.2 (Uniform filter completion NameCert obligations)**.** *For every accepted* $\mathsf{UniformFilterCompletion}^{\uparrow}$ *carrier $U = (F, B, Q, G, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformFilterCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the functorial uniform-completion route, Cauchy-filter base, Cauchy-filter completion criterion, uniform source, StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed replay, provenance, and local naming rows. Every completion-facing obligation is read through those rows before a consumer may inspect the terminal seal, and no obligation is stored in quotient filters, selected limits, choice, host equality, or ambient completion data.*

Proof. Project the carrier of Definition 7807.1. The tuple displays exactly the rows $F, B, Q, G, S, R, E, H, C, P, N$.

Read the completion source first. The uniform source row G and functorial handoff row F fix the displayed uniform-completion route, while the Cauchy-filter base row B supplies the finite basis data consumed by that route.

Read the criterion and numerical rows next. The criterion row Q requires the completion read to remain attached to the displayed basis route, the StreamName row S schedules the finite observations, the RegSeqRat row R reads back those windows, and the Real seal E is exposed only after that readback.

Finally H, C, P, N transport, replay, source, and name the same packet. Since quotient completions, selected limits, choice, host equality, and ambient completeness are absent from the carrier, the listed rows exhaust the local certificate surface. □

Theorem 7807.3 (Uniform filter completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{UniformFilterCompletion}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{UniformCompletionFunctor}^{\uparrow} \longmapsto \mathsf{CauchyFilterBase}^{\uparrow} \longmapsto \mathsf{CauchyFilterCompletionCriterion}^{\uparrow} \longmapsto \mathsf{UniformCompletion}^{\uparrow} \mapsto$$

The route exports filter-based completion data only through displayed BEDC rows. It exports no quotient completion, quotient filter, selected representative, selected limit, countable-choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Apply Definition 7807.2. It confines every accepted read to the displayed functorial, filter-base, criterion, uniform-source, window, readback, seal, and structural rows.

The filter route passes through B before the criterion row Q can be consumed. Thus a completion-facing consumer cannot replace the basis data by an unrecorded filter or a quotient-filter equality.

The completion route passes through F, G, S, R, E in the displayed order. The functorial and uniform-source rows precede the finite windows, the regular rational readback precedes the Real seal, and the structural rows preserve that same order.

Therefore the accepted handoff is exactly the finite route in the statement. The excluded quotient, selector, choice, host-equality, and ambient-completeness objects are not coordinates of the carrier. □

Falsifiable prediction: Every accepted $\mathsf{UniformFilterCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the $\mathsf{UniformCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyFilterBase}^{\uparrow}$, $\mathsf{CauchyFilterCompletionCriterion}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, componentwise hsame, displayed Cont, Pkg, and local NameCert rows is outside the packet surface.

Independence witness: uniformcompletionfunctor, cauchy-filter-base, cauchy-filter-completion-criterion, regseqrat, streamname, real: no listed sibling is bijective to $\mathsf{UniformFilterCompletion}^{\uparrow}$ because this packet jointly carries the functorial uniform-completion handoff, finite Cauchy-filter base, completion criterion, uniform source, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local naming as one filter-based completion surface.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformFilterCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformFilterCompletion}^{\uparrow}$ packet is generated from a UniformCompletionFunctorUp route row, CauchyFilterBaseUp basis row, CauchyFilterCompletionCriterionUp criterion row, UniformCompletionUp source row, StreamNameUp windows, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformFilterCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7807.1, Definition 7807.2, and Definition 7807.3 seed the L10 filter-based uniform completion route over UniformCompletionFunctorUp, CauchyFilterBaseUp, CauchyFilterCompletionCriterionUp, UniformCompletionUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformFilterCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completions, quotient filters, selected representatives, selected limits, countable choice, host equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, functorial uniform-completion handoff, Cauchy-filter base exposure, Cauchy-filter completion criterion routing, finite-window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformFilterCompletionUp.

Chapter 7808

A Concrete Naming Certificate for $\mathsf{DushnikMillerDimension}^{\uparrow}$

Following Dushnik and Miller on the dimension of partially ordered sets, the $\mathsf{DushnikMillerDimension}^{\uparrow}$ packet records the finite order-theoretic certificate by which a displayed poset is represented as the intersection of a finite family of linear extensions. It sits after the separated order surface of chapter 53, the inherited preorder route of chapter 52, the total-order comparison surface of chapter 54, and the membership discipline of chapter 3668. The packet names only finite extension rows, an intersection ledger, a minimal-cardinality witness, transport, replay, provenance, and local naming; it does not import a host powerset of orders, quotient posets, choice-selected extension families, or ambient set-theoretic dimension.

Definition 7808.1 (Dushnik–Miller dimension carrier)**.** *A* $\mathsf{DushnikMillerDimension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (P, L, I, M, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{Poset}^{\uparrow}$ *source row, including the inherited* $\mathsf{Preorder}^{\uparrow}$ *comparison ledger and antisymmetry data for the displayed carrier.*
2. *L is a finite family of* $\mathsf{TotalOrder}^{\uparrow}$ *rows on the same displayed carrier, each row carrying a linear-extension ledger for the order named by P.*
3. *I is the intersection ledger: for any displayed pair of carried elements, the* $\mathsf{Poset}^{\uparrow}$ *comparison holds exactly when every row of L compares the pair in that direction.*
4. *M is the minimal-cardinality witness, recording a displayed natural-number bound for the family L and a local refusal ledger for smaller displayed families.*
5. *H records componentwise* hsame *transport for the poset source, total-order family, intersection ledger, minimality witness, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a dimension request through the poset source, the finite linear-extension family, the intersection ledger, and the minimality witness.*
7. *Q is the* Pkg *provenance over* $\mathsf{DushnikMillerDimension}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DushnikMillerDimension}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a host powerset of all linear orders, quotient poset equality, a choice-selected extension family, or an ambient cardinal-invariant theorem.

Theorem 7808.2 (Dushnik–Miller dimension NameCert obligations)**.** *For every accepted* $\mathsf{DushnikMillerDimension}^{\uparrow}$ *carrier* $D = (P, L, I, M, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DushnikMillerDimension}^{\uparrow}}$ *surface consists exactly of source admission for* P*, finite total-order family admission for* L*, linear-extension compatibility of each row of* L *with the* $\mathsf{Poset}^{\uparrow}$ *comparison, intersection exactness through* I*, minimal-cardinality witnessing through* M*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* Q*, and local naming through* N*.*

Proof. Project the carrier of Definition 7808.1. The poset source is the displayed row P, and the only extension data are the finitely listed total-order rows in L.

Read the compatibility and intersection rows next. Each total order in L extends the comparison of P, while I records the reverse read: a comparison belongs to P precisely when all listed total orders compare the pair in that direction.

Finally inspect the minimality, transport, replay, provenance, and naming rows M, H, C, Q, N. Since the carrier has no coordinate for all host linear orders, quotient posets, selected extension families, or ambient cardinal invariants, the NameCert obligations are exactly the displayed finite rows. □

Theorem 7808.3 (Dushnik–Miller linear-extension route)**.** *Every downstream consumer of an accepted* $\mathsf{DushnikMillerDimension}^{\uparrow}$ *packet that reads order dimension must factor through*

$$P, L \longmapsto I, M \longmapsto H, C, Q, N.$$

The consumer sees a $\mathsf{Poset}^{\uparrow}$ *source, a finite family of* $\mathsf{TotalOrder}^{\uparrow}$ *linear-extension rows over the same carrier, the intersection ledger, and the minimal-cardinality witness before any dimension value is public. It receives no host powerset of orders, quotient poset, choice-selected family of extensions, or ambient set-theoretic dimension argument.*

Proof. Begin with the accepted carrier $D = (P, L, I, M, H, C, Q, N)$. A dimension consumer can inspect the source order only through P, and it can inspect linear extensions only through the finite family L.

The intersection ledger I is then load-bearing: it states both that every row of L extends P and that the common comparison induced by all rows of L recovers exactly the displayed poset comparison. The minimality row M supplies the local cardinal witness and the refusal of smaller displayed families.

The rows H, C, Q, N transport, replay, source, and name the same finite route. Because no additional coordinate is present, the route cannot be replaced by a host powerset search, quotient-poset equality, a choice-selected family of extensions, or an ambient cardinal-invariant proof. □

Falsifiable prediction: A claimed $\mathsf{DushnikMillerDimension}^{\uparrow}$ read that omits the PosetUp source row, finite TotalOrderUp extension family, intersection ledger, minimal-cardinality witness, hsame, Cont, Pkg, or local $\mathsf{NameCert}$ row refutes the carrier of Definition 7808.1.

Independence witness: poset, preorder, totalorder, setlike: $\mathsf{DushnikMillerDimension}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a PosetUp source, a finite family of TotalOrderUp linear-extension rows, an intersection ledger, minimal-cardinality data, componentwise transport, replay, provenance, and local NameCert naming. PosetUp and PreorderUp supply comparison rows without finite extension families; TotalOrderUp supplies a single comparison surface without an intersection ledger; SetLikeUp supplies membership discipline without order-dimension minimality.

Closure status for $\mathsf{NameCert}_{\mathsf{DushnikMillerDimension}^{\uparrow}}$.

Constructive story: A $\mathsf{DushnikMillerDimension}^{\uparrow}$ packet is generated from a PosetUp source, inherited PreorderUp comparison data, a finite family of TotalOrderUp linear-extension rows, an intersection ledger, a minimal-cardinality witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DushnikMillerDimension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7808.1, Definition 7808.2, and Definition 7808.3 seed the finite Dushnik–Miller order-dimension carrier over displayed poset, preorder, total-order, set-like, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DushnikMillerDimension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host powerset of orders, quotient poset equality, choice-selected extension families, ambient set-theoretic dimension, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, finite linear-extension admission, intersection exactness, minimal-cardinality witnessing, transport, replay, provenance, and local naming for BEDC.Derived.DushnikMillerDimensionUp.

Chapter 7809

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$

Following Bishop and Bridges on located metric spaces, regular Cauchy names, and completion by finite approximation, the $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$ packet records a metric source whose located-distance requests and Cauchy-readback obligations are already complete as displayed BEDC data. It sits beside the located source of chapter 2043, the complete-metric service of chapter 128, the completion boundary of chapter 1506, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a finite means route for located complete metric reads; it is not a quotient completion, a selected-limit principle, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7809.1 (Bishop located complete metric carrier)**.** *A* $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, L, C, Q, W, R, E, H, T, P, N)$$

with the following displayed rows:

1. *M is the metric source row, exposing the inspected points, distance requests, symmetry, triangle, and zero-distance comparison used by the packet.*
2. *L is the* $\mathsf{LocatedSpace}^{\uparrow}$ *row, recording the finite positive-distance and locatedness requests attached to the metric source.*
3. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, displaying the Cauchy-admission and completion-readback obligations available to accepted requests.*
4. *Q is the* $\mathsf{MetricCompletion}^{\uparrow}$ *boundary row, available only as the finite completion route attached to M, L, C and not as a quotient carrier.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for the inspected points, Cauchy approximants, tolerances, and completion-facing requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows and regular rational distance observations.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after M, L, C, Q, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the metric, locatedness, completeness, completion-boundary, window, readback, seal, replay, provenance, and naming rows.*

9. *T records displayed* Cont *replay of every located complete metric read through*

$$M, L, C, Q, W, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$, $\mathsf{LocatedSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteMetric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, C, Q, W, R, E, H, T, P, N$. It has no coordinate for quotient completion, selected limits, countable choice, open-cover compactness, host real equality, trichotomy, Lean verification, or a standard bridge.

Theorem 7809.2 (Bishop located complete metric NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$ *carrier*

$$B = (M, L, C, Q, W, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteMetric}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed metric source, locatedness requests, complete-metric service, completion boundary, stream windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *locatedness stability, requiring every transported or replayed distance-to-source request to keep the same M, L, W, R rows before it can read the terminal seal E;*
3. *completeness stability, requiring every Cauchy-facing request to pass through the displayed service row C and the completion-boundary row Q before any regular rational or real-name read is exposed;*
4. *finite readback exactness, requiring the* $\mathsf{StreamName}^{\uparrow}$ *window W and* $\mathsf{RegSeqRat}^{\uparrow}$ *row R to carry all tolerance, approximant, and distance observations used by the completion-facing route;*
5. *ledger refusal, requiring H, T, P, N to transport, replay, source, and name only the displayed rows, with no quotient completion, selected limit, countable choice, host real equality, trichotomy, Lean verification, or bridge credential.*

No Bishop located complete metric NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7809.1. The accepted packet displays the metric source, locatedness row, complete-metric service, completion boundary, stream windows, regular rational readback, real seal, and structural rows.

Locatedness stability is componentwise. Transport and replay preserve the same metric source and locatedness request before the stream window or regular readback can be inspected.

Completeness stability is read through C and Q. A Cauchy-facing request may use the complete-metric service only through the displayed completion boundary, so it receives a finite route rather than a quotient representative or selected host limit.

Finite readback exactness follows from the order of W, R, E. The stream windows expose the inspected approximants and tolerances, the regular rational row records the distance readbacks, and only then can the real seal be consumed.

Finally, H, T, P, N contain only transport, replay, provenance, and naming for the displayed rows. Since the carrier has no quotient, choice, host equality, trichotomy, Lean verification, or bridge coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7809.3 (Bishop located complete metric finite completion route)**.** *Every completion-facing read of an accepted* $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$ *carrier*

$$B = (M, L, C, Q, W, R, E, H, T, P, N)$$

factors through the finite route

$$M, L, C, Q, W, R \longmapsto E$$

with structural support H, T, P, N*. The route first exposes the metric and locatedness rows, then the complete-metric service and completion boundary, then the stream windows and regular rational readbacks, and only then the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no quotient completion, selected limit, countable choice, open-cover compactness, host real equality, trichotomy, Lean verification, or standard bridge.*

Proof. Start with the carrier projection. The metric and locatedness rows M, L are the only source-side rows available to a completion-facing request.

The read then passes through C, Q. These rows display the complete-metric service and the completion boundary as finite data, so the request cannot jump to a quotient completion or a selected limit.

Next the route opens W, R. The stream windows carry the inspected approximants and tolerances, while the regular rational row records the finite distance readbacks consumed by the completion route.

Only after those rows have been displayed can the terminal real seal E be read. The structural rows H, T, P, N preserve the same order under transport, replay, provenance, and local naming, and no excluded object is present in the accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteMetric}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7809.1, Definition 7809.2, and Definition 7809.3 seed the finite located complete metric route through metric, locatedness, complete-metric, completion-boundary, stream-window, regular-readback, real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompleteMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, countable choice, open-cover compactness, host real equality, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locatedness stability, completeness stability, finite readback exactness, completion-boundary nonescape, and provenance locality for BEDC.Derived.BishopLocatedCompleteMetricUp.

Constructive story: A $\mathsf{BishopLocatedCompleteMetric}^{\uparrow}$ packet is generated from a Metric source row, a LocatedSpace request row, a CompleteMetric service row, a MetricCompletion boundary row, StreamName windows, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7810

A Concrete Naming Certificate for $\mathsf{CompactModulusEvaluation}^{\uparrow}$

Following Heine–Cantor and Bishop's finite-net reading of compact uniform continuity, the CompactModulusEvaluat packet records how a compact metric source, a continuous-map row, and pointwise modulus data are evaluated into a finite uniform-modulus output without invoking open-cover compactness or a selected subcover theorem. It concretizes the compact uniform continuity direction of chapter 9237 beside the compact metric source of chapter 129, the continuous-map surface of chapter 130, the uniform-modulus consumer of chapter 369, the dyadic tolerance ledger of chapter 291, the finite observation interface of chapter 126, and the terminal real seal of chapter 38. The packet is a finite NameCert evaluation route, not an external compactness theorem, choice principle, host equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7810.1 (Compact modulus evaluation carrier)**.** *A* $\mathsf{CompactModulusEvaluation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, P, D, N, U, W, R, S, H, C, G, Q)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, displaying the inspected probes, mesh radius, and compact-metric provenance.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise continuity reads are being evaluated on the compact source.*
3. *P is the pointwise modulus row attached to the inspected probes and tolerance request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the requested output radius, finite mesh slack, and lower-bound comparisons.*
5. *N is the finite net and overlap row, recording which inspected probe covers each source request before the modulus is read.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced after the finite lower-bound fold.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for point observations, probe reads, and requested tolerances.*
8. *R is the regular rational readback row attached to the inspected windows and dyadic tolerance comparisons.*

9. *S is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after K, F, P, D, N, U, W, R have been displayed.*

10. *H records componentwise* hsame *transport for the compact source, continuous map, pointwise modulus, dyadic ledger, finite net, uniform handoff, window, readback, seal, replay, provenance, and naming rows.*

11. *C records displayed* Cont *replay of every compact modulus evaluation through*

$$K, F, P, D, N, W, R \longmapsto U, S.$$

12. *G is the* Pkg *provenance over* $\mathsf{CompactModulusEvaluation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *Q is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusEvaluation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, P, D, N, U, W, R, S, H, C, G, Q$. It has no coordinate for arbitrary open covers, selected subcovers, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or a standard bridge.

Theorem 7810.2 (Compact modulus evaluation NameCert obligations)**.** *For every accepted* CompactModulusEvalu *carrier*

$$E = (K, F, P, D, N, U, W, R, S, H, C, G, Q),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusEvaluation}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact metric source, continuous map, pointwise modulus data, dyadic tolerance ledger, finite net and overlap rows, uniform-modulus handoff, stream windows, regular rational readback, real seal, transport, replay, provenance, and local naming rows;*

2. *compact-source stability, requiring every transported or replayed evaluation to keep the same finite-net source K and finite net row N before any modulus handoff can be consumed;*

3. *pointwise-modulus stability, requiring the continuous-map row F and pointwise modulus row P to be read at the displayed probe windows and never as a host-level function predicate;*

4. *dyadic fold exactness, requiring the tolerance ledger D and readback row R to carry all lower-bound, slack, and radius comparisons used to produce U;*

5. *ledger refusal, requiring H, C, G, Q to transport, replay, source, and name only the displayed rows, with no arbitrary open cover, selected subcover, host function equality, quotient real equality, countable choice, trichotomy, Lean verification, or bridge credential.*

No compact modulus evaluation NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7810.1. The accepted packet displays the compact source, continuous map, pointwise modulus, dyadic ledger, finite net, uniform handoff, stream windows, regular readback, real seal, and structural rows.

Compact-source stability is componentwise. Transport and replay keep the same finite-net source and cover row, so the packet never replaces the displayed compact metric data by an arbitrary open cover.

Pointwise-modulus stability is read through F, P, W. The continuous map and its pointwise modulus are inspected only at displayed probe windows, not through a host-level function equality predicate.

Dyadic fold exactness is the shared role of D, N, R, U. The finite net supplies the inspected probes, the dyadic ledger records the lower-bound and slack comparisons, the regular rational readback records the finite observations, and the uniform-modulus row is downstream of those data.

Finally, H, C, G, Q only transport, replay, source, and name the displayed rows. Since the carrier contains no open-cover theorem, selected subcover, choice row, host equality coordinate, Lean verification, or bridge credential, the listed rows exhaust the local NameCert surface. □

Theorem 7810.3 (Compact modulus evaluation finite net route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *output exported by an accepted* $\mathsf{CompactModulusEvaluation}^{\uparrow}$ *carrier*

$$E = (K, F, P, D, N, U, W, R, S, H, C, G, Q)$$

factors through the finite route

$$K, F, P, D, N, W, R \longmapsto U, S$$

with structural support H, C, G, Q*. The route first exposes the compact metric finite-net source, then the continuous-map and pointwise-modulus reads, then the dyadic tolerance fold and regular rational readback, and only then the uniform-modulus handoff and terminal* $\mathsf{Real}^{\uparrow}$ *seal. It exports no arbitrary open-cover compactness, selected subcover, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or standard bridge.*

Proof. Start with the carrier projection. The compact metric source K and finite net row N are the only compact-facing rows available to the evaluation.

The continuous-map and pointwise-modulus data are read through F, P, W. Each inspected probe and tolerance request is attached to a displayed stream window, so no host-level function predicate is introduced.

The dyadic tolerance ledger D and regular rational readback R then perform the finite lower-bound and slack comparisons. These rows are upstream of the uniform-modulus handoff U.

Only after those rows have been displayed can the output row U and terminal seal S be consumed. Transport, replay, provenance, and naming through H, C, G, Q preserve the same order, and the excluded open-cover, selection, choice, equality, verification, and bridge data are absent from the accepted packet. □

Theorem 7810.4 (Compact modulus evaluation sibling route)**.** *Every* $\mathsf{CompactModulusEvaluation}^{\uparrow}$ *output exported by an accepted carrier*

$$E = (K, F, P, D, N, U, W, R, S, H, C, G, Q)$$

factors through the sibling route

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{UniformModulus}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

before any uniform-modulus consumer reads it. More precisely, the compact metric finite-net source, continuous-map row, pointwise modulus data, dyadic tolerance ledger, stream-window schedule, regular rational readback, and terminal Real seal are displayed before the $\mathsf{UniformModulus}^{\uparrow}$ *handoff is consumed. The route exports no arbitrary open-cover compactness, selected subcover, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or standard bridge.*

Proof. Project the accepted carrier using Definition 7810.1. The rows $K, F, P, D, N, U, W, R, S$ display the compact metric source, continuous map, pointwise modulus, dyadic ledger, finite net, uniform handoff, stream windows, regular readback, and Real seal.

Apply Definition 7810.2. Carrier admission and compact-source stability keep K and N upstream of the uniform-modulus handoff, while pointwise-modulus stability keeps F and P inside the displayed stream windows.

Now use Definition 7810.3. The finite net route reads D, W, R before U, S, so the dyadic tolerance ledger, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal are all visible before the output is consumed.

Transport, replay, provenance, and naming through H, C, G, Q preserve this sibling order. Since the accepted packet contains no open-cover theorem, selected subcover, host function equality, quotient real equality, choice row, trichotomy row, Lean verification, or bridge credential, none can be exported by a uniform-modulus consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusEvaluation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusEvaluation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7810.1, Definition 7810.2, and Definition 7810.3 seed the finite compact-modulus route through compact metric, continuous-map, pointwise-modulus, dyadic-ledger, finite-net, stream-window, regular-readback, uniform-modulus, real-seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusEvaluation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source stability, pointwise-modulus stability, dyadic fold exactness, finite-net handoff, uniform-modulus nonescape, and provenance locality for BEDC.Derived.CompactModulusEvalua

Constructive story: A $\mathsf{CompactModulusEvaluation}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise reads, pointwise modulus data, a DyadicRatCore tolerance ledger, finite net and overlap rows, StreamName windows, RegSeqRat readback, a UniformModulus handoff, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7811

A Concrete Naming Certificate for $\mathsf{CauchyModulusFusion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy convergence with explicit moduli, the $\mathsf{CauchyModulusFusion}^{\uparrow}$ packet records the finite surface that fuses two displayed Cauchy-modulus sources into one shared tail schedule before Real and Completion consumers inspect a seal. It sits beside the majorant route of chapter 4087, the dominance route of chapter 1814, the rate lattice route of chapter 1818, the dyadic modulus lattice of chapter 2386, the finite window service of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38.

Definition 7811.1 (Cauchy modulus fusion carrier)**.** *A* $\mathsf{CauchyModulusFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M_0, M_1, J, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. M_0 *and* M_1 *are the two source* $\mathsf{CauchyModulusMajorant}^{\uparrow}$ *schedules whose tail requests are to be read on one shared precision surface;*
2. J *is the fused join row, read through* $\mathsf{CauchyRateDominance}^{\uparrow}$, $\mathsf{CauchyRateLattice}^{\uparrow}$, *and* $\mathsf{DyadicCauchyModulusLatt}$ *witnessing that both source schedules are served by the same displayed tail threshold;*
3. W *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened only after* M_0, M_1, J *have been displayed;*
4. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the fused window route;*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger supporting the comparison and fused-window readback;*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the two sources, fused join, window, readback, and dyadic ledger have all been displayed;*
7. H *records componentwise* hsame *transport for the two sources, fused join, window, readback, tolerance, seal, replay, provenance, and local naming rows;*
8. C *records displayed* Cont *replay from a precision request through* M_0, M_1, J, W, Q, D, E *and then through the structural rows;*
9. P *is the* Pkg *provenance over* $\mathsf{CauchyModulusFusion}^{\uparrow}$, $\mathsf{CauchyModulusMajorant}^{\uparrow}$, $\mathsf{CauchyRateDominance}^{\uparrow}$, $\mathsf{CauchyRateLattice}^{\uparrow}$, $\mathsf{DyadicCauchyModulusLattice}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyModulusFusion}^\uparrow}$ *row.*

The classifier has no coordinate for quotient stream equality, selected limits, host real comparison, countable choice, trichotomy, independent per-source Real seals, ambient $\mathsf{Real}^\uparrow$ *completeness, Lean verification, or bridge checking.*

Theorem 7811.2 (Cauchy modulus fusion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusFusion}^\uparrow$ *carrier $F = (M_0, M_1, J, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusFusion}^\uparrow}$ *surface consists exactly of carrier admission, paired source-modulus exposure through M_0, M_1, fused join exposure through J, finite-window service through W, regular rational readback through Q, dyadic tolerance exposure through D, Real seal ordering through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7811.1. The tuple lists exactly two source schedules, one fused join row, one finite-window row, one regular readback row, one dyadic tolerance ledger, one terminal Real seal, and the structural transport, replay, provenance, and local naming rows.

The sibling routes determine the fusion surface. $\mathsf{CauchyModulusMajorant}^\uparrow$ supplies the two source schedules, while $\mathsf{CauchyRateDominance}^\uparrow$, $\mathsf{CauchyRateLattice}^\uparrow$, and $\mathsf{DyadicCauchyModulusLattice}^\uparrow$ force the join row J to dominate both sources on the same displayed dyadic precision surface.

The observation and seal rows are then downstream. $\mathsf{StreamName}^\uparrow$ opens W, $\mathsf{RegSeqRat}^\uparrow$ reads Q, $\mathsf{DyadicRatCore}^\uparrow$ supplies D, and $\mathsf{Real}^\uparrow$ consumes the terminal seal E only after the fused route is visible. The structural rows H, C, P, N preserve that same finite route and add no hidden analytic coordinate. □

Theorem 7811.3 (Cauchy modulus fusion Real and Completion route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CauchyModulusFusion}^\uparrow$ *packet must factor through*

$$M_0, M_1, J, W, Q, D, E, H, C, P, N.$$

Thus the consumer receives one shared fused-modulus surface before it reads the $\mathsf{Real}^\uparrow$ *seal, not two independent per-source tail choices, a quotient stream equality, a selected limit, a host product of schedules, or an ambient completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 7811.2. They place every accepted read behind the two source schedules M_0, M_1 and the fused join row J before any window or seal can be consumed.

Now read the finite observation route. The rows W, Q, D provide the StreamName window, regular rational readback, and dyadic tolerance ledger used by downstream Real and Completion consumers, and the Real seal E is downstream of those rows.

Finally apply the non-escape clauses of the carrier. Since no coordinate stores independent seals, quotient stream equality, selected limits, a host schedule product, or ambient completeness, replay through C, transport through H, provenance through P, and local naming through N preserve only the displayed fused route. □

Falsifiable prediction: An accepted $\mathsf{CauchyModulusFusion}^\uparrow$ Real or Completion consumer that reaches the $\mathsf{Real}^\uparrow$ seal without first displaying both source schedules, the fused join row, the finite $\mathsf{StreamName}^\uparrow$ window, the $\mathsf{RegSeqRat}^\uparrow$ readback, and the $\mathsf{DyadicRatCore}^\uparrow$ tolerance ledger refutes the carrier surface.

Independence witness: cauchy-modulus-majorant, cauchy-rate-dominance, cauchy-rate-lattice, dyadic-cauchy-modulus-lattice, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole eleven-row packet $F = (M_0, M_1, J, W, Q, D, E, H, C, P, N)$, because each sibling

contributes only source majorants, dominance, lattice comparison, windows, readback, dyadic tolerance, or Real sealing while this chapter binds the two-source fused-modulus route into one local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusFusion}\uparrow}$.

Constructive story: A $\mathsf{CauchyModulusFusion}^{\uparrow}$ packet is generated from two CauchyModulusMajorant source schedules, a fused join row over CauchyRateDominance, CauchyRateLattice, and DyadicCauchyModulusLattice, a StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusFusion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7811.1, Definition 7811.2, and Definition 7811.3 seed the two-source shared-modulus route used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusFusion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real comparison, countable choice, trichotomy, independent per-source Real seals, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fused join exposure, finite-window service, regular readback, dyadic tolerance exposure, Real seal ordering, componentwise transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusFusionUp.

Chapter 7812

A Concrete Naming Certificate for $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$

Following Bishop and Bridges' constructive analysis, the $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$ packet records the finite certificate surface for replacing a bounded window of one regular rational Cauchy name by a compatible window from another. It sits over the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite stream-surgery interface for Real and Completion consumers; it is not host sequence equality, quotient representative selection, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7812.1 (Bishop regular sequence splice carrier)**.** *A* $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, R, U, B, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *stream rows whose finite windows are candidates for the splice.*
2. *U is a unary splice-window row, recording the displayed interval of stream positions where the right row is read instead of the left row.*
3. *B is the dyadic boundary agreement ledger at the two splice edges.*
4. *W records the paired* $\mathsf{StreamName}^{\uparrow}$ *finite windows inspected before, inside, and after U.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for all comparisons in W and across B.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the spliced stream assembled from L, R, U, B, W, D.*
7. *E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after the splice window, boundary ledger, stream observations, dyadic tolerances, and regular readback have been displayed.*
8. *H records componentwise* hsame *transport for both source streams, the splice window, boundary agreement, stream windows, dyadic ledger, regular readback, seal boundary, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same finite route.*

10. *P records* Pkg *provenance over* $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularSequenceSplice}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, R, U, B, W, D, Q, E, H, C, P, N$. It has no coordinate for host sequence equality, quotient representatives, countable choice, selected limits, host real equality, or a completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 7812.2 (Bishop regular sequence splice regularity)**.** *For every accepted* $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$ *carrier*

$$S = (L, R, U, B, W, D, Q, E, H, C, P, N),$$

the spliced row Q is a regular rational Cauchy readback over the displayed finite route. Its regularity is witnessed by the left $\mathsf{RegSeqRat}^{\uparrow}$ *row before U, by the right* $\mathsf{RegSeqRat}^{\uparrow}$ *row inside U, by the left* $\mathsf{RegSeqRat}^{\uparrow}$ *row after U, and by the boundary agreement ledger*

$$B : \quad \begin{array}{c} L(a) \sim_D R(a), \\ R(b) \sim_D L(b) \end{array}$$

at the displayed endpoints a, b of the unary splice window.

Proof. Project the carrier of Definition 7812.1. The rows L and R supply the two regular rational source streams, U names the finite splice interval, W names the inspected stream windows, and D supplies the dyadic tolerances used by every comparison.

Before the splice window, the assembled row Q reads from L. Regularity there is exactly the regularity already displayed by the left $\mathsf{RegSeqRat}^{\uparrow}$ row, transported through the corresponding coordinates of H and replayed through C.

Inside the splice window, Q reads from R. Regularity there is exactly the regularity already displayed by the right $\mathsf{RegSeqRat}^{\uparrow}$ row, with the same dyadic tolerance row D and the same finite observations W.

After the splice window, Q returns to L. This is the same left-row regularity argument as before the window, again transported and replayed by the structural rows.

It remains to cross the two boundaries. The ledger B gives the displayed dyadic agreement at a and b, and D records the comparison budgets used at those edges. Combining the source regularity rows with the two boundary agreements yields the regularity of Q across the splice boundary.

No other equality source is available in the carrier. Thus the regularity proof is confined to the displayed source streams, unary window, dyadic ledger, stream observations, transport, replay, provenance, and local naming rows. □

Theorem 7812.3 (Bishop regular sequence splice Real seal)**.** *Every Real and Completion consumer of an accepted* $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$ *carrier reaches terminal* $\mathsf{Real}^{\uparrow}$ *evidence only through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The route first displays the left and right source streams, the unary splice window, the dyadic boundary agreement ledger, finite stream windows, and the spliced regular readback. It exports no host sequence equality, quotient representative, countable-choice schedule, selected limit, or $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Use Definition 7812.2. The theorem identifies Q as the regular rational readback produced from L, R, U, B, W, D and the structural rows.

The seal row E is downstream of that route in the carrier definition. A consumer therefore reaches E only after the source streams, splice window, boundary agreement, stream observations, dyadic tolerances, and regular readback have been displayed.

Inspect the remaining rows. The transport row H, continuation row C, provenance row P, and naming row N preserve the same finite packet and do not add a quotient representative, selected limit, countable-choice schedule, host sequence equality, host real equality, or ambient completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularSequenceSplice}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularSequenceSplice}^{\uparrow}$ packet is generated from left and right RegSeqRat streams, a unary splice window, a dyadic boundary agreement ledger, finite StreamName windows, DyadicRatCore tolerance accounting, a spliced RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularSequenceSplice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7812.1, Definition 7812.2, and Definition 7812.3 seed the finite regular-sequence splice route from RegSeqRat windows to Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularSequenceSplice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence equality, quotient representatives, countable choice, selected limits, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, splice-window coverage, boundary agreement, regularity preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularSequenceSpliceU

Chapter 7813

A Concrete Naming Certificate for DyadicIntervalSubdivisionTree$^{\uparrow}$

Bishop–Bridges constructive interval bisection and Moore–Kearfott–Cloud interval analysis both use finite subdivision trees before any completed interval limit is read. The DyadicIntervalSubdivisionTree$^{\uparrow}$ packet records that finite tree as NameCert data between the one-step dyadic refinement carrier of chapter 1831, the endpoint arithmetic surface of chapter 1645, the nested Cauchy interval consumer of chapter 1811, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It is a finite L10 subdivision carrier, not a selected infinite branch, a quotient stream equality principle, trichotomy, countable choice, open-cover compactness, or ambient Real$^{\uparrow}$ completeness.

Definition 7813.1 (Dyadic interval nested subdivision carrier)**.** *A* DyadicIntervalSubdivisionTree$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, D, V, E, L, S, Q, H, C, P, N)$$

with the following displayed rows:

1. *R is the root* DyadicInterval$^{\uparrow}$ *row whose lower and upper dyadic endpoints are read through* DyadicRatCore$^{\uparrow}$*.*
2. *D is the finite depth budget, naming the largest inspected level and the dyadic scale attached to each level.*
3. *V is the finite child-incidence table, recording for every displayed internal node the two displayed child interval rows supplied by* DyadicIntervalRefinement$^{\uparrow}$*.*
4. *E is the endpoint-reuse ledger, identifying each child endpoint with the parent endpoints or the displayed midpoint row through* DyadicIntervalArithmetic$^{\uparrow}$*.*
5. *L is the retained-leaf coverage row, listing the leaves that remain available to downstream interval consumers after the finite subdivision.*
6. *S is the* StreamName$^{\uparrow}$ *observation window, naming the finite node, endpoint, and leaf reads inspected by the tree consumer.*
7. *Q is the* RegSeqRat$^{\uparrow}$ *readback row attached to the scheduled dyadic endpoint observations.*
8. *H records componentwise* hsame *transport for the root, depth, incidence, endpoint-reuse, leaf-coverage, window, readback, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay of every accepted subdivision read through*

$$R, D, V, E, L, S \longmapsto Q.$$

10. *P is the* Pkg *provenance over* DyadicIntervalSubdivisionTree$^{\uparrow}$, DyadicInterval$^{\uparrow}$, DyadicIntervalRefinement$^{\uparrow}$, DyadicIntervalArithmetic$^{\uparrow}$, NestedDyadicCauchy$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{DyadicIntervalSubdivisionTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, V, E, L, S, Q, H, C, P, N$. It has no coordinate for a selected infinite branch, quotient stream equality, trichotomy, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Theorem 7813.2 (Dyadic interval nested subdivision obligations)**.** *For every accepted* DyadicIntervalSubdivisionTre *carrier*

$$T = (R, D, V, E, L, S, Q, H, C, P, N),$$

the local NameCert surface consists exactly of carrier admission for the root dyadic interval, finite depth budget, child-incidence table, endpoint-reuse ledger, retained-leaf coverage, StreamName$^{\uparrow}$ *observation window,* RegSeqRat$^{\uparrow}$ *readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. Every downstream* NestedDyadicCauchy$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *or* Real$^{\uparrow}$ *consumer of the subdivision must expose those rows before it may inspect a leaf chain or readback boundary.*

Proof. Project the carrier of Definition 7813.1. The root row, finite depth budget, child-incidence table, endpoint-reuse ledger, retained leaves, stream windows, readback, and structural rows are exactly the displayed coordinates of the packet.

The one-step refinement route is supplied by chapter 1831, while endpoint reuse and midpoint arithmetic are read through chapter 1645. Thus each internal node is certified by finite dyadic interval rows rather than by a completed path.

The observation and readback rows S, Q are the only route toward NestedDyadicCauchy$^{\uparrow}$, RegSeqRat$^{\uparrow}$, and Real$^{\uparrow}$ consumers. Since H, C, P, N only transport, replay, source, and name the same displayed rows, no selected infinite branch, quotient stream equality, trichotomy, countable-choice row, open-cover compactness proof, or ambient completeness theorem can be projected from the carrier. □

Closure status for NameCert$_{\text{DyadicIntervalSubdivisionTree}^{\uparrow}}$.

Constructive story: A DyadicIntervalSubdivisionTree$^{\uparrow}$ packet is generated from a root DyadicInterval row, finite depth budget, child-incidence table, endpoint-reuse ledger, retained-leaf coverage row, StreamName observation window, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicIntervalSubdivisionTree}^{\uparrow}}$, seed)

Scope closed: Definition 7813.1 and Definition 7813.2 seed the finite subdivision-tree carrier over dyadic interval roots, one-step refinements, endpoint arithmetic, retained leaves, stream windows, regular readback, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicIntervalSubdivisionTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, quotient stream equality, trichotomy, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, child-incidence exactness, endpoint-reuse stability, retained-leaf coverage, finite StreamName exposure, RegSeqRat readback, consumer nonescape, and local naming for BEDC.Derived.DyadicIntervalSubdivisionTreeUp.

Chapter 7814

A Concrete Naming Certificate for $\mathsf{RegularCauchyInduction}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyInduction}^{\uparrow}$ packet records the finite induction surface by which a displayed regular Cauchy real-name construction advances from a base window to a successor tail window before any $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits over the dyadic arithmetic of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the real-name boundary of chapter 38, and the regular-completion route of chapter 7398. The packet is an induction bridge for finite regular Cauchy windows; it is not countable choice, quotient equality of Cauchy names, a selected limit operator, host real arithmetic, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7814.1 (Regular Cauchy induction carrier)**.** *A* $\mathsf{RegularCauchyInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, S, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the base window row, containing the initial finite* $\mathsf{StreamName}^{\uparrow}$ *observations and the dyadic tolerance ledger visible at the first construction stage.*
2. *S is the successor and tail-step row, recording the rule that extends an accepted displayed window to the next regular Cauchy tail request.*
3. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row used by both B and S for radius comparison and tail contraction.*
4. *W is the finite request-window ledger listing every stream coordinate read by the base and successor rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback row attached to B, S, Q, W.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the finite induction route has replayed the base window, successor row, dyadic budget, request windows, and regular readback.*
7. *H records componentwise* hsame *transport for the base window, successor step, dyadic budget, request windows, regularity readback, real seal, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$B, S, Q, W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyInduction}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealRegularCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyInduction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, S, Q, W, R, E, H, C, P, N$. It has no coordinate for a hidden infinite choice sequence, quotient equality of regular Cauchy names, a selected limit point, host real arithmetic, trichotomy, or ambient completeness.

Theorem 7814.2 (Regular Cauchy induction step soundness)**.** *For every accepted* $\mathsf{RegularCauchyInduction}^{\uparrow}$ *carrier*

$$I = (B, S, Q, W, R, E, H, C, P, N),$$

the successor row S may advance a regular Cauchy construction only along request windows already displayed by W and budgeted by Q. After componentwise transport through H and replay through C, the same finite route exposes the $\mathsf{RegSeqRat}^{\uparrow}$ *readback R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. No step exports countable choice, quotient equality of names, host real comparison, or a selected limit.*

Proof. Project the accepted carrier onto its displayed rows. The only induction data are the base window B, the successor and tail-step row S, the dyadic budget Q, and the finite request ledger W.

Induct on the displayed BHist request window. In the base case, the request is already listed by B and budgeted by Q, so the route reaches R without reading any hidden tail coordinate.

For the successor case, the induction hypothesis gives the prior displayed window. The row S appends exactly the next tail request named in W, while Q supplies the dyadic comparison budget needed for the regularity readback.

Transport through H and replay through C preserve that order. The rows P and N only record provenance and local naming, and the seal E is downstream from R, so no unlisted choice sequence, quotient-equality test, host real comparison, or selected limit can enter the step. □

Theorem 7814.3 (Regular Cauchy induction finite-window coverage)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyInduction}^{\uparrow}$ *carrier receives the finite L10 handoff*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{BishopRealRegularCompletion}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed route $B, S, Q, W, R, E, H, C, P, N$. The handoff certifies only finite base-window coverage, successor-tail coverage, regularity readback, seal preservation, transport, replay, provenance, and local naming.

Proof. Run finite induction on the request windows displayed in W. The base window is supplied by B, so the initial stream observations and dyadic tolerance reads are part of the public packet.

At each successor stage, the row S extends the displayed window and consumes the same dyadic budget row Q. The induction hypothesis supplies all earlier reads, so the extended packet remains finite and visible in W.

Once the displayed window is fixed, R is the only regular rational readback and E is the only real seal boundary. Componentwise transport, continuation replay, provenance, and local naming through H, C, P, N keep the same route.

Thus a consumer sees exactly the finite handoff through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopRealRegularCompletion}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Nothing in the carrier supplies a countable-choice schedule, quotient equality of Cauchy names, a host real primitive, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyInduction}^{\uparrow}$ packet is generated from a base window, successor and tail-step row, DyadicRatCore budget, finite StreamName request windows, RegSeqRat regularity readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7814.1, Definition 7814.2, and Definition 7814.3 seed the finite induction bridge from regular Cauchy request windows through regular rational readback to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient equality of Cauchy names, selected limits, host real arithmetic, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, base-window coverage, successor-tail coverage, regularity readback, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyInductionUp.

Chapter 7815

A Concrete Naming Certificate for $\mathsf{CeaLemma}^{\uparrow}$

Following Cea and standard Galerkin error analysis, the $\mathsf{CeaLemma}^{\uparrow}$ packet records the finite quasi-optimality route that turns coercivity, continuity, variational exactness, and Galerkin residual orthogonality into a displayed best-approximation certificate. It sits after the projection row of chapter 5169, the error-estimate surface of chapter 6619, the variational solve of chapter 3419, the Hilbert comparison route of chapter 91, and the norm ledger of chapter 89. The packet names the quasi-optimal projection bound without importing a host Hilbert projection theorem, quotient function space, selected minimizer, or choice principle.

Definition 7815.1 (Cea lemma carrier)**.** *A* $\mathsf{CeaLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (V, a, u, u_h, c, M, B, E, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite trial-space row consumed from* $\mathsf{GalerkinProjection}^{\uparrow}$*.*
2. *a is the coercive bilinear-form row, read through* $\mathsf{LaxMilgram}^{\uparrow}$ *and the Hilbert comparison surface.*
3. *u is the exact variational solution row supplied by the displayed Lax–Milgram route.*
4. *u_h is the Galerkin projection row, including residual orthogonality over V.*
5. *c is the coercivity scalar row.*
6. *M is the continuity scalar row for the same bilinear-form comparison.*
7. *B is the finite best-approximation ledger comparing u to each displayed trial competitor.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *bound row recording the quasi-optimal estimate against the* $\mathsf{Norm}^{\uparrow}$ *ledger.*
9. *H records componentwise* hsame *transport for trial-space, bilinear-form, exact-solution, Galerkin, scalar, best-approximation, bound, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$V, a, u, u_h, c, M, B \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CeaLemma}^{\uparrow}$, $\mathsf{GalerkinProjection}^{\uparrow}$, $\mathsf{GalerkinErrorEstimate}^{\uparrow}$, $\mathsf{LaxMilgram}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{CeaLemma}^\uparrow}$ *row.*
The classifier compares accepted packets only through $V, a, u, u_h, c, M, B, E, H, T, P, N$. It has no coordinate for a quotient function space, selected best approximant, host projection operator, global minimizer, countable choice, or ambient Hilbert-space theorem.

Theorem 7815.2 (Cea lemma NameCert obligations)**.** *For every accepted* $\mathsf{CeaLemma}^\uparrow$ *carrier*

$$K = (V, a, u, u_h, c, M, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CeaLemma}^\uparrow}$ *surface consists exactly of carrier admission, Galerkin residual-orthogonality exposure, Lax–Milgram variational exposure, coercivity and continuity scalar exposure, finite best-approximation comparison, scalar-bound readback, componentwise transport, displayed replay, provenance, and local naming. Every row is read through the displayed siblings* $\mathsf{GalerkinProjection}^\uparrow$, $\mathsf{GalerkinErrorEstimate}^\uparrow$, $\mathsf{LaxMilgram}^\uparrow$, $\mathsf{Hilbert}^\uparrow$, *and* $\mathsf{Norm}^\uparrow$ *before the quasi-optimality seal E is consumed.*

Proof. Project the carrier of Definition 7815.1. The finite trial row, bilinear form, exact solution, Galerkin row, scalar constants, comparison ledger, bound, transport, replay, provenance, and local name are the full visible inventory.

The Galerkin side is read through chapter 5169; the exact variational side is read through chapter 3419. The scalar rows c, M are attached to the same Hilbert and norm comparison surface, so the estimate cannot switch to a host norm or a different bilinear form.

The best-approximation row B then compares only displayed trial competitors, and the error-estimate sibling of chapter 6619 supplies the route to the bound row E. Since H, C, P, N transport, replay, source, and name only these rows, the listed obligations exhaust the local certificate. □

Theorem 7815.3 (Cea quasi-optimal projection route)**.** *Every public* $\mathsf{CeaLemma}^\uparrow$ *quasi-optimality read factors through the route*

$$\mathsf{GalerkinProjection}^\uparrow \longmapsto \mathsf{GalerkinErrorEstimate}^\uparrow \longmapsto \mathsf{LaxMilgram}^\uparrow \longmapsto (\mathsf{Hilbert}^\uparrow, \mathsf{Norm}^\uparrow) \longmapsto \mathsf{Real}^\uparrow.$$

The consumer must first display the finite trial space, residual orthogonality, variational exactness, coercivity and continuity constants, and best-approximation ledger before reading the scalar quasi-optimal bound. No quotient function space, selected minimizer, host projection theorem, or choice principle is exported.

Proof. Start with the obligation surface of Definition 7815.2. It orders the finite trial row, the exact variational row, the Galerkin row, the scalar constants, and the best-approximation ledger before the bound row.

Use the Galerkin projection sibling to obtain residual orthogonality on the displayed trial space. Use the Lax–Milgram sibling for the exact variational equation and the Hilbert and norm siblings for the comparison surface on which coercivity and continuity are read.

Finally consume the Galerkin error-estimate route. Its best-approximation comparison feeds the same scalar bound row E, and the structural rows preserve the displayed path. The refused quotient, minimizer, host projection, and choice objects are absent from the carrier, so they cannot be exported by the quasi-optimality read. □

Closure status for $\mathsf{NameCert}_{\mathsf{CeaLemma}^\uparrow}$**.**

Constructive story: A $\mathsf{CeaLemma}^\uparrow$ packet is generated from finite Galerkin trial-space rows, coercive bilinear-form rows, exact variational rows, Galerkin projection rows, coercivity and continuity scalar rows, a best-approximation ledger, a RealUp bound row, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CeaLemma}\uparrow}$, seed)

Scope closed: Definition 7815.1, Definition 7815.2, and Definition 7815.3 seed the finite quasi-optimal Galerkin projection route over GalerkinProjection, GalerkinErrorEstimate, LaxMilgram, Hilbert, Norm, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CeaLemma}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient function spaces, selected minimizers, host Hilbert projection theorems, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-orthogonality exposure, variational exposure, coercivity and continuity scalar exposure, best-approximation comparison, scalar-bound readback, transport, replay, provenance, and local naming for BEDC.Derived.CeaLemmaUp.

Chapter 7816

A Concrete Naming Certificate for $\mathsf{FiniteTriggerCube}^{\uparrow}$

The $\mathsf{FiniteTriggerCube}^{\uparrow}$ packet realizes the conditional trigger ensemble of Definition 9462.1594 as finite BEDC data: cube coordinates, trigger subsets, blocker rows, energy rows, rank rows, and local naming are displayed before any probability-like read is consumed. The packet consumes the finite conditional-trigger ensemble of chapter 3870, the energy-biased trigger reliability rows of chapter 3583, the trigger-blocker duality rows of chapter 3801, and the trigger-energy partition rows of chapter 3806. The carrier is finite combinatorics over the trigger cube, but its role is BEDC-native: it turns the ensemble into a falsifiable NameCert surface rather than an ambient probability measure or an unbounded stochastic model.

Definition 7816.1 (Finite trigger-cube carrier)**.** *A* $\mathsf{FiniteTriggerCube}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, M, B, T, R, E, W, Z, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite cube row, naming the visible cube coordinates and face incidences.*
2. *M is the boundary-mask row, including the distinguished blocked mask $M^{\star}$ when the conditional trigger ensemble is read.*
3. *B is the finite subset row under inspection.*
4. *T is the trigger row, recording whether B meets the displayed full-trigger condition.*
5. *R is the blocker row, recording the complementary blocked condition used to form Z_{block}.*
6. *E is the energy row $\mathcal{E}(B)$.*
7. *W is the finite weight row $t^{|B|}y^{\mathcal{E}(B)}$.*
8. *Z is the partition-rank row, listing the finite sums used for Z_{all}, Z_{block}, and Z_{trig}.*
9. *H records componentwise* hsame *transport for cube, mask, subset, trigger, blocker, energy, weight, rank, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the finite route*

$$Q, M, B, T, R, E, W, Z \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteTriggerCube}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows, with a pointer back to the conditional trigger ensemble theorem of Definition 9462.1601.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, M, B, T, R, E, W, Z, H, C, P, N$. It has no coordinate for an infinite probability space, hidden sampler, host independence axiom, unbounded cube, selected random variable, or unstated measure.

Theorem 7816.2 (Finite trigger-cube NameCert obligations)**.** *For every accepted* $\mathsf{FiniteTriggerCube}^{\uparrow}$ *carrier*

$$F = (Q, M, B, T, R, E, W, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}$ *surface consists exactly of cube admission, boundary-mask exposure, subset exposure, trigger exposure, blocker exposure, energy exposure, finite weight exposure, partition-rank exposure, componentwise transport, displayed replay, provenance, and local naming. A conditional-trigger consumer may read the distributional expressions of Definition 9462.1594 only after those finite rows have been displayed.*

Proof. Project the carrier of Definition 7816.1. The cube, mask, subset, trigger, blocker, energy, weight, and partition-rank rows are displayed before transport, replay, provenance, and local naming.

The trigger and blocker rows are separate fields, so a full-trigger read cannot silently replace the blocker complement by an unstated event. The energy and weight rows are finite table entries, and the partition-rank row records the finite sums that support the conditional expressions.

Transport and replay preserve the same displayed fields through H and C. Since no carrier coordinate names an infinite probability space, hidden sampler, host independence axiom, unbounded cube, selected random variable, or unstated measure, the listed finite rows exhaust the NameCert obligations. □

Theorem 7816.3 (Finite trigger-cube ensemble route)**.** *Every conditional trigger-ensemble read carried by* $\mathsf{FiniteTriggerCube}^{\uparrow}$ *factors through the finite cube route*

$$Q, M, B, T, R, E, W, Z \longmapsto \mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}.$$

The route displays the trigger row, blocker row, energy row, finite weight row, and partition-rank row before any expectation, reliability, or low-energy conditional table is read. It exports finite rows only, not a host probability space, hidden sampler, independence axiom, or unbounded stochastic model.

Proof. Apply Definition 7816.2. It gives the finite inventory through which the conditional trigger expressions must be read.

The rows T and R separate full-trigger and blocked cases, while E, W, Z display the energy, monomial weight, and finite partition sums. Thus the expectation and low-energy tables consume finite rank data rather than a measure-theoretic background object.

Finally, H, C, P, N preserve and name the same route. The refused probabilistic and unbounded objects are absent from the carrier, so the ensemble route remains a finite trigger-cube NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{FiniteTriggerCube}^{\uparrow}$ conditional read displays cube coordinates, boundary mask, subset, trigger, blocker, energy, finite weight, partition-rank, transport,

replay, provenance, and local NameCert rows before any expectation or reliability expression is consumed.

Independence witness: conditional-trigger-ensemble, finite-cube, blocker-ledger, energy-rank-table: none is bijective to $\mathsf{FiniteTriggerCube}^{\uparrow}$ because this packet jointly carries cube coordinates, boundary mask, trigger rows, blocker rows, energy rows, finite weights, partition ranks, transport, replay, provenance, and local naming in one finite carrier.

Theorem 7816.4 (Finite trigger-cube TasteGate obligations)**.** *A checked TasteGate for* $\mathsf{FiniteTriggerCube}^{\uparrow}$ *must exhibit a nonempty accepted trigger-cube packet and must preserve the displayed fields* $Q, M, B, T, R, E, W, Z, P$ *separately. In particular, changing the trigger row while holding the blocker row fixed, or changing the energy row while holding the subset row fixed, must be visible to the classifier before a consumer can treat the conditional ensemble as a named packet.*

Proof. The carrier definition lists trigger, blocker, energy, and rank as separate rows. A nonempty accepted packet witnesses that the carrier is not only an empty formal shell.

Field preservation is required because the conditional ensemble reads trigger and blocker data differently, and it reads energy before forming the finite weight row. Collapsing those fields would make the displayed partition-rank table unable to distinguish full-trigger, blocked, and energy-biased reads.

Thus the TasteGate obligation is to keep the finite fields visible before classifier acceptance. This is a paper-side obligation statement and does not assert a checked Lean target. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTriggerCube}^{\uparrow}$ packet is generated from finite cube coordinates, a boundary mask, a subset row, trigger and blocker rows, an energy row, a finite weight row, partition-rank rows, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7816.1, Definition 7816.2, Definition 7816.3, and Definition 7816.4 seed the finite trigger-cube realization of the conditional trigger ensemble as displayed cube, trigger, blocker, energy, rank, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTriggerCube}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an infinite probability space, a host sampler, a measure-theoretic independence axiom, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked cube admission, trigger exposure, blocker exposure, energy exposure, weight exposure, partition-rank exposure, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTriggerCubeUp.

Chapter 7817

A Concrete Naming Certificate for $\mathsf{EuclideanSpace}^{\uparrow}$

Following Euclid, Hilbert, and Bourbaki, the $\mathsf{EuclideanSpace}^{\uparrow}$ packet records a finite-dimensional real coordinate carrier whose metric, vector-space, inner-product, and matrix-readback rows are all displayed before any geometric consumer reads a distance, norm, projection, or coordinate transform. It sits beside the real scalar seal of chapter 38, the metric source of chapter 57 read as $\mathsf{Met}^{\uparrow}$, the vector-space source of chapter 47, the inner-product surface of chapter 86, and the finite matrix row of chapter 49. The packet is a finite coordinate NameCert surface for Euclidean spaces; it is not a host theorem about all finite-dimensional normed spaces, a selected orthonormal basis, quotient linear algebra, spectral completeness, or an ambient completeness claim for $\mathsf{Real}^{\uparrow}$.

Definition 7817.1 (EuclideanSpace carrier)**.** *A* $\mathsf{EuclideanSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, M, V, I, A, D, N, H, C, P, Q)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal and finite coordinate readback row.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row for the displayed coordinate carrier.*
3. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row recording zero, addition, inverse, and real scalar multiplication on the displayed finite coordinate windows.*
4. *I is the* $\mathsf{InnerProduct}^{\uparrow}$ *row whose bilinear and positive rows compute the Euclidean norm and distance used by M.*
5. *A is the* $\mathsf{Mat}^{\uparrow}$ *coordinate-transform row, used only for displayed finite matrices between certified coordinate presentations.*
6. *D records the finite dimension tag, coordinate index window, and endpoint-radius ledger for all inspected coordinates.*
7. *N records the norm, distance, projection, and affine-combination readback rows computed from R, M, V, I, A, D.*
8. *H records componentwise* hsame *transport for the scalar, metric, vector-space, inner-product, matrix, dimension, readback, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay of every Euclidean read through*

$$R, M, V, I, A, D \longmapsto N.$$

10. *P is the* Pkg *provenance over* $\mathsf{EuclideanSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{InnerProduct}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{EuclideanSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, V, I, A, D, N, H, C, P, Q$. It has no coordinate for a hidden basis choice, host equality of coordinate functions, quotient vector spaces, spectral diagonalization, compactness, countable choice, excluded middle, Lean verification, or a standard bridge.

Theorem 7817.2 (EuclideanSpace NameCert obligations)**.** *For every accepted* $\mathsf{EuclideanSpace}^{\uparrow}$ *carrier*

$$E = (R, M, V, I, A, D, N, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{EuclideanSpace}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the real scalar seal, metric distance row, vector-space operation row, inner-product row, finite matrix row, dimension and coordinate-window ledger, norm and distance readback, transport, replay, provenance, and local naming rows;*

2. *scalar and coordinate stability, requiring every vector operation, inner-product read, and matrix transform to use the displayed* $\mathsf{Real}^{\uparrow}$ *scalar row and the same finite coordinate window D;*

3. *metric and inner-product compatibility, requiring the distance row M and norm readback N to be computed from the displayed* $\mathsf{InnerProduct}^{\uparrow}$ *row I rather than from an external metric predicate;*

4. *finite-coordinate exactness, requiring every projection, affine combination, and coordinate transform to pass through the displayed* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *rows before any downstream consumer reads it;*

5. *ledger refusal, requiring H, C, P, Q to transport, replay, source, and name only the displayed rows, with no hidden basis selector, quotient vector-space equality, host coordinate-function equality, spectral theorem, compactness, countable choice, excluded middle, Lean verification, or bridge credential.*

No EuclideanSpace NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7817.1. The accepted packet displays the real scalar seal, metric row, vector-space operations, inner-product row, finite matrix row, coordinate ledger, readback rows, and structural rows.

Scalar and coordinate stability are componentwise. The same R and D rows are read before vector addition, scalar multiplication, inner-product evaluation, distance computation, and matrix transport, so no hidden coordinate source is available.

Metric and inner-product compatibility is the role of M, I, N. The distance and norm rows are read from the displayed inner-product computation, not from a host metric predicate or an external norm theorem.

Finite-coordinate exactness follows through V, A, D, N. Projections, affine combinations, and coordinate transforms are inspected as finite rows before a consumer can read the resulting point, vector, distance, or norm.

Finally, H, C, P, Q only transport, replay, source, and name the displayed rows. Since the carrier contains no hidden basis selector, quotient equality, host coordinate-function equality, spectral theorem, compactness row, choice row, Lean verification, or bridge credential, the five listed rows exhaust the local NameCert surface. □

Theorem 7817.3 (EuclideanSpace finite-coordinate route)**.** *Every accepted* $\mathsf{EuclideanSpace}^{\uparrow}$ *carrier*

$$E = (R, M, V, I, A, D, N, H, C, P, Q)$$

exports geometric data only through the finite route

$$\mathsf{Real}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{VecSpace}^{\uparrow}, \mathsf{InnerProduct}^{\uparrow}, \mathsf{Mat}^{\uparrow} \longmapsto D, N, H, C, P, Q.$$

A downstream consumer reading a Euclidean distance, norm, projection, affine combination, or coordinate transform must first read the scalar seal, metric row, vector-space row, inner-product row, matrix row, and finite coordinate ledger displayed by the packet. No hidden basis choice, quotient vector-space equality, host coordinate-function equality, compactness theorem, spectral theorem, countable-choice schedule, Lean verification, or bridge credential is exported.

Proof. Start from the carrier projection. The scalar, metric, vector-space, inner-product, matrix, and finite coordinate rows are the only upstream rows available to a Euclidean read.

The norm and distance readback is computed through I, M, N, while projection, affine-combination, and coordinate-transform reads pass through V, A, D, N. Each read is finite because the coordinate window D is displayed before N is consumed.

Transport, replay, provenance, and naming through H, C, P, Q preserve the same route. The excluded host equality, hidden basis, quotient, compactness, spectral, choice, verification, and bridge data are absent from the accepted carrier, so no consumer can export them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{EuclideanSpace}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EuclideanSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7817.1, Definition 7817.2, and Definition 7817.3 seed the finite Euclidean coordinate route over RealUp scalars, MetricSpace distance, VecSpace operations, InnerProduct norms, Matrix coordinate transforms, finite coordinate windows, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EuclideanSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary finite-dimensional normed-space equivalence, hidden basis selection, quotient linear algebra, spectral diagonalization, compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, scalar and coordinate stability, metric and inner-product compatibility, finite-coordinate exactness, and provenance locality for BEDC.Derived.EuclideanSpaceUp.

Constructive story: A $\mathsf{EuclideanSpace}^{\uparrow}$ packet is generated from a RealUp scalar seal, MetricSpace distance row, VecSpace operation row, InnerProduct row, Matrix coordinate-transform row, finite dimension and coordinate-window ledger, norm and distance readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7818

A Concrete Naming Certificate for $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$ packet records the finite compact-net route by which pointwise bounded real-family rows become a displayed bound-modulus certificate. It sits after the compact finite-net source of chapter 129, the pointwise bounded family surface of chapter 6555, the finite supremum readback of chapter 1427, the windowed observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite compact-net bound-modulus certificate, not open-cover compactness, host suprema, countable choice, quotient family equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7818.1 (Compact pointwise bounded modulus carrier)**.** *A* $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, F, L, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the inspected probes, mesh radius, overlap witnesses, and compact-metric provenance.*
2. *F is the* $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$ *row, displaying the family entries and pointwise boundedness data read at the probes of K.*
3. *L is the finite* $\mathsf{LocatedSupremum}^{\uparrow}$ *comparison row used only over the displayed probe bounds.*
4. *S is the finite lower-bound and slack ledger converting the probe bounds into one shared bound-modulus request.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for family observations, compact-net probes, and tolerance requests.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite rational bounds and slack comparisons.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after K, F, L, S, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the compact source, pointwise family, finite supremum row, slack ledger, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of every bound-modulus read through*

$$K, F, L, S, W, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PointwiseBoundedRealFamily}$ $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, S, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, host suprema, countable-choice selections, quotient family equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or a standard bridge.*

Theorem 7818.2 (Compact pointwise bounded modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$ *carrier*

$$B = (K, F, L, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the compact finite-net source, pointwise bounded family, finite located-supremum row, slack ledger, stream windows, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *compact-net exposure, requiring K to display the inspected probes and overlap witnesses before any family bound is folded;*
3. *pointwise-bound exposure, requiring F and W to read family bounds at the displayed probes and never as quotient equality of families;*
4. *finite bound-modulus fold, requiring L, S, R to carry the finite maximum, lower-bound, slack, and rational readback comparisons used to produce the shared bound;*
5. *ledger refusal, requiring H, C, P, N to transport, replay, source, and name only the displayed rows, with no open-cover compactness, host supremum, countable-choice selector, quotient family equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge credential.*

No compact pointwise bounded modulus NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7818.1. The accepted packet displays exactly the compact source, pointwise family row, finite supremum comparison, slack ledger, stream windows, regular readback, Real seal, and structural rows.

Compact-net exposure is read through K. The inspected probes and overlaps are finite data, so the packet never replaces them by an arbitrary open cover or selected subcover.

Pointwise-bound exposure is read through F and W. Each family bound is attached to a displayed probe window, not to host equality of families or quotient real equality.

The finite bound-modulus fold is the shared role of L, S, R. The located-supremum row is used only over the finite displayed probe bounds, the slack ledger records the lower-bound comparisons, and the regular rational row records the finite readback.

Finally, H, C, P, N transport, replay, source, and name the same displayed packet. Since the carrier contains no open-cover compactness row, host supremum, countable-choice selector, quotient family equality, ambient completeness principle, verification row, or bridge credential, the five listed rows exhaust the local NameCert surface. □

Theorem 7818.3 (Compact pointwise bounded modulus finite-net bound)**.** *Every bound-modulus output exported by an accepted* $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$ *carrier*

$$B = (K, F, L, S, W, R, E, H, C, P, N)$$

factors through the finite route

$\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PointwiseBoundedRealFamily}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$

displayed by $K, F, L, S, W, R, E, H, C, P, N$*. The compact finite net is read first, pointwise family bounds are read only at its displayed probe windows, the finite located-supremum and slack rows compute the shared bound, and the regular rational readback precedes the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The route exports no open-cover compactness, host suprema, countable choice, quotient family equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier projection. The compact-facing data are exactly the finite-net row K, and the family-facing data are exactly F and the stream windows W.

Apply the NameCert obligations of Definition 7818.2. They force the compact probes to be displayed before the family bounds are folded and force every pointwise bound to remain attached to a visible probe window.

The shared bound is then computed only through L, S, R. The row L reads a finite located-supremum comparison over the displayed probe bounds, S records the lower-bound and slack budget, and R turns that finite ledger into regular rational readback.

Only after this route is visible can the Real-facing seal E be consumed. The structural rows H, C, P, N preserve the same finite route, so there is no coordinate through which open-cover compactness, a host supremum, countable choice, quotient family equality, or ambient Real completeness can enter the exported certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7818.1, Definition 7818.2, and Definition 7818.3 seed the finite compact-net route from pointwise bounded real-family rows to a displayed bound-modulus certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host suprema, countable choice, quotient family equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, pointwise-bound exposure, finite located-supremum fold, slack-ledger exactness, regular rational readback, Real seal locality, and ledger refusal for BEDC.Derived.CompactPointwiseBoundedModulusUp.

Constructive story: A $\mathsf{CompactPointwiseBoundedModulus}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, PointwiseBoundedRealFamily rows, a finite LocatedSupremum comparison row, a slack ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7819

A Concrete Naming Certificate for $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$

Following Cousin and Bishop–Bridges finite-cover practice, the $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$ packet records the finite radius-choice row that turns gauge-cover cells into compact-uniform modulus handoff data. It sits between the Cousin cover source of chapter 3426, the finite gauge-cover rows of chapter 6708, the finite subcover ledger of chapter 6125, the compact metric source of chapter 129, and the uniform-modulus consumer of chapter 369. The packet names a finite gauge-radius choice ledger only; it is not an open-cover compactness theorem, a countable-choice selector, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 7819.1 (Finite cover gauge-radius choice carrier)**.** *A* $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, Q, F, L, S, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact finite-cover or finite-net window inspected by the radius-choice construction.*
2. *Q is the* $\mathsf{CousinCover}^{\uparrow}$ *gauge source row, carrying positive local gauge radii and tagged cover-cell admission data.*
3. *F is the* $\mathsf{FiniteGaugeCover}^{\uparrow}$ *row, listing the finite gauge cells, tag witnesses, mesh-control data, and readback route through the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
4. *L is the* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *row, recording which displayed finite cells cover the compact source window and how their radius ledger is replayed for compact-uniform consumers.*
5. *S is the radius-choice row. For every cell named by F and accepted by L, it stores the chosen positive radius history as a displayed finite ledger entry, not as a countable selector or host minimum.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, consumed only after the compact source, Cousin gauge row, finite gauge-cover row, subcover ledger, and finite radius-choice row have all been exposed.*
7. *H records componentwise* hsame *transport for compact source, gauge source, finite gauge cover, subcover ledger, radius choice, uniform-modulus handoff, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a compact finite-cover request through gauge inspection, finite cover admission, radius choice, and uniform-modulus export.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{FiniteGaugeCover}^{\uparrow}$, $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, Q, F, L, S, U, H, C, P, N$. It has no coordinate for host open-cover compactness, countable choice, a detached subcover selector, quotient cover equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7819.2 (Finite cover gauge-radius choice NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$ *carrier $G = (K, Q, F, L, S, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverGaugeRadiusChoic}}$ *surface consists exactly of compact-source exposure through K, Cousin gauge-source admission through Q, finite gauge-cover admission through F, finite subcover-ledger coverage through L, displayed radius-choice exactness through S,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation is discharged by host open-cover compactness, countable choice, a detached subcover selector, quotient cover equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7819.1. The tuple displays the compact source, Cousin gauge source, finite gauge-cover row, finite subcover ledger, radius-choice ledger, uniform-modulus handoff, transport, replay, provenance, and local naming rows.

The radius-choice row is downstream of the finite cover data. The rows Q and F expose the available positive gauge radii and finite cells, while L restricts the compact read to the displayed finite coverage ledger.

The row S then records only finitely many positive radius histories, one for each displayed ledger entry that survives the finite cover route. Because this row is part of the carrier, the construction uses no external selector and no host minimum over an open cover.

Finally U, H, C, P, N export, transport, replay, source, and name exactly this route. Since the excluded compactness, choice, quotient, and completeness objects are absent from the carrier, they cannot appear in the local NameCert obligations. □

Theorem 7819.3 (Finite cover gauge-radius uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$ *packet receives its radius data only through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{CousinCover}^{\uparrow},\ \mathsf{FiniteGaugeCover}^{\uparrow},\ \mathsf{FiniteSubcoverLedger}^{\uparrow},\ S,\ \mathsf{UniformModulus}^{\uparrow}.$$

The handoff therefore turns Cousin/gauge cover rows into compact-uniform modulus data by finite carrier projection. It exports no open-cover compactness proof, countable-choice selector, detached subcover choice, quotient cover equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the compact and gauge sources. The row K exposes the compact metric window, and Q exposes the Cousin gauge-radius data attached to that window.

The finite cover route is then read through F and L. The row F lists the admitted gauge cells and tag witnesses, while L records the finite coverage ledger used by compact-uniform consumers.

The radius-choice ledger S is therefore a finite row over displayed cells. The $\mathsf{UniformModulus}^{\uparrow}$ handoff U can consume only this finite row together with the visible source and cover rows.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Thus the consumer receives compact-uniform modulus handoff data without receiving any excluded open-cover, choice, quotient, or completeness object. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}$ packet is generated from CompactMetric source windows, CousinCover gauge rows, FiniteGaugeCover cell rows, a FiniteSubcoverLedger coverage row, a displayed finite radius-choice ledger, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7819.1, Definition 7819.2, and Definition 7819.3 seed the finite gauge-radius choice route from Cousin and finite gauge-cover rows to compact-uniform modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverGaugeRadiusChoice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, countable choice, detached subcover selection, quotient cover equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, Cousin gauge-source admission, finite gauge-cover admission, subcover-ledger coverage, radius-choice exactness, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverGaugeRadiusChoiceUp.

Chapter 7820

A Concrete Naming Certificate for $\mathsf{FrechetUrysohnMetric}^{\uparrow}$

Following Frechet and Urysohn, the $\mathsf{FrechetUrysohnMetric}^{\uparrow}$ packet records the metric sequence-closure readback route as finite BEDC NameCert data. It sits over the metric carrier of chapter 57, the sequential metric packet of chapter 7680, the stream naming discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the traditional sequence-closure interface without importing a host sequence selector, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7820.1 (Frechet-Urysohn metric carrier)**.** *A* $\mathsf{FrechetUrysohnMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, M, Q, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the point carrier inherited from the underlying* $\mathsf{Met}^{\uparrow}$ *surface.*
2. *M is the metric distance ledger, including only displayed tolerance comparisons and triangle rows used by the sequential closure test.*
3. *Q is the sequence-closure query row, recording the finite neighbourhood windows whose eventual membership is being read.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the inspected sequence positions and no external sequence selector.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational distance and tolerance observations requested by M, Q, S.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback is displayed.*
7. *H records componentwise* hsame *transport for point, metric, query, stream, regular rational, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from sequence-closure queries through M, Q, S, R, E, H, P, N.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetUrysohnMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{SequentialMetricSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohnMetric}^{\uparrow}}$ *row.*

The classifier of an accepted carrier compares packets only through these rows. It has no coordinate for a host sequence selector, quotient equality of streams, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7820.2 (Frechet-Urysohn metric NameCert obligations)**.** *For every accepted* $\mathsf{FrechetUrysohnMetric}^{\uparrow}$ *carrier* $F = (X, M, Q, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohnMetric}^{\uparrow}}$ *surface consists exactly of metric carrier exposure, sequential query exposure, finite StreamName schedule readback, RegSeqRat tolerance readback, terminal Real seal discipline, componentwise transport, displayed continuation replay, package provenance, and local naming. Every sequence-closure consumer must display the metric row of chapter 57, the sequential metric row of chapter 7680, the StreamName row of chapter 126, the RegSeqRat row of chapter 301, and the Real seal row of chapter 38 before exporting a closure read.*

Proof. Project the carrier of Definition 7820.1. The rows X, M, Q give the point, metric, and sequence-closure query surface, while S, R, E are the only rows that can expose sequence-indexed observations to downstream Real-facing consumers.

The sibling chapters determine the read order. The metric carrier supplies the distance ledger, the sequential metric packet supplies the sequence-indexed observation discipline, StreamName supplies the finite schedule, RegSeqRat supplies the regular rational readback, and Real supplies only the terminal seal.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no row contains a host sequence selector, quotient stream equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, the listed rows exhaust the local obligation surface. □

Theorem 7820.3 (Frechet-Urysohn metric sequence readback)**.** *Every accepted* $\mathsf{FrechetUrysohnMetric}^{\uparrow}$ *packet that witnesses a point in the sequence closure of a displayed metric set exports its Real-facing closure value only through the finite route*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{SequentialMetricSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The readback may consume displayed metric neighbourhood rows and displayed sequence windows, but it cannot replace them by a host sequence selector, quotient stream equality, a selected representative, or an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 7820.2. It places every accepted closure query behind the carrier rows $X, M, Q, S, R, E, H, C, P, N$.

Use the sequential metric packet of chapter 7680 to read sequence-indexed metric observations. Its consumer route already requires a StreamName handoff before any RegSeqRat or Real-facing read can be consumed.

Now route the metric distance observations through chapter 57, chapter 126, chapter 301, and chapter 38. The result is a displayed schedule, a regular rational tolerance read, and a terminal Real seal.

No excluded object is introduced by the support rows. Thus the exported sequence-closure value remains a finite BEDC readback through the displayed metric, sequential, stream, regular rational, and Real rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetUrysohnMetric}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FrechetUrysohnMetric}^{\uparrow}$ packet is generated from MetricSpaceUp carrier rows, SequentialMetricSpaceUp sequence-query rows, StreamNameUp finite schedules, RegSeqRatUp tolerance readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FrechetUrysohnMetric}^{\uparrow}}$, seed)

Scope closed: Definition 7820.1, Definition 7820.2, and Definition 7820.3 seed the metric sequence-closure readback route through StreamName, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FrechetUrysohnMetric}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove host sequence selection, quotient stream equality, selected representatives, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric query exactness, StreamName schedule readback, RegSeqRat tolerance readback, Real seal discipline, transport, replay, provenance, and nonescape for BEDC.Derived.FrechetUrysohnMetricUp.

Chapter 7821

A Concrete Naming Certificate for $\mathsf{CompactMetricModulusRealizer}^{\uparrow}$

Following Heine–Cantor and Bishop's finite-net proof of uniform continuity on compact metric spaces, the $\mathsf{CompactMetricModulusRealizer}^{\uparrow}$ packet records the finite data used by the compact-uniform-continuity theorem of chapter 9237. It sits over the compact metric source of chapter 129, the continuous-map pointwise modulus rows of chapter 130, the metric carrier rows of chapter 57, the $\mathsf{Met}^{\uparrow}$ distance classifiers of chapter 57, the rational and real readback route of chapter 37 and chapter 38, and the tolerance-only handoff of chapter 369. The packet names the finite-net fold, not an external minimum selector or a host compactness theorem.

Definition 7821.1 (Compact metric modulus realizer carrier)**.** *A* $\mathsf{CompactMetricModulusRealizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, B, L, M, T, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including the displayed center bundle and located half-radius cover witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, carrying the pointwise-modulus rows attached to the centers named by K.*
3. *B is the finite* $\mathsf{ProbeBundle}$ *spine consumed by the lower-bound fold.*
4. *L is the rational lower-bound fold over the positive center radii, read through* $\mathsf{Rat}^{\uparrow}$ *order data.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *triangle ledger joining source-point, center, and target-image estimates.*
6. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for halving, positivity, and lower-bound transport.*
7. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *seal row for the rational and Real comparisons already displayed by L, M, T.*
8. *U is the resulting* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row.*
9. *H records componentwise* hsame *transport for compact metric, continuous map, bundle, fold, metric, tolerance, seal, handoff, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a requested tolerance through $K, F, B, L, M, T, E, H, P, N$ to U.*

11. *P is the* Pkg *provenance over* CompactMetricModulusRealizer$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, Rat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{CompactMetricModulusRealizer}^{\uparrow}}$ *row.*

The classifier of an accepted carrier compares packets only through these finite rows. It has no coordinate for an external compactness theorem, an open-cover choice functional, a host minimum operator, quotient equality of functions, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 7821.2 (Compact metric modulus realizer finite-net fold)**.** *For every accepted* CompactMetricModulusRea *carrier $R = (K, F, B, L, M, T, E, U, H, C, P, N)$, the exported* UniformModulus$^{\uparrow}$ *row U is consumed only after the finite-net row K, pointwise-modulus row F, ProbeBundle spine B, rational lower-bound fold L, metric-triangle ledger M, dyadic tolerance row T, and RegSeqRat-to-Real seal row E are displayed. This is the NameCert realization of the finite fold in Definition 9237.5 and the uniform-modulus theorem of Definition 9237.6; it exports no external minimum selector, host compactness theorem, quotient function equality, selected center family, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7821.1. The compact metric source K supplies the finite center bundle and located coverage witnesses, while F attaches the pointwise continuous-map radius rows to those displayed centers.

Read the finite fold through B, L, T. The ProbeBundle spine B is finite, the row L performs the rational lower-bound fold over the displayed positive radii, and the dyadic tolerance row T transports the requested tolerance through halving and lower-bound comparisons.

Use the metric ledger M before any Real-facing read. Its source and target triangle rows connect the selected displayed center to the two inspected points and their images, so the regular rational and Real seal row E can only seal comparisons already witnessed by K, F, B, L, M, T.

The handoff row U is therefore a tolerance-only UniformModulus$^{\uparrow}$ output. The support rows H, C, P, N transport, replay, source, and name the same finite route, and no excluded compactness, minimum, quotient, selection, or ambient-completeness coordinate is present. □

Closure status for NameCert$_{\text{CompactMetricModulusRealizer}^{\uparrow}}$.

Constructive story: A CompactMetricModulusRealizer$^{\uparrow}$ packet is generated from CompactMetricUp finite-net rows, ContinuousMapUp pointwise-modulus rows, ProbeBundle finite spines, RatUp lower-bound folds, MetricSpaceUp triangle ledgers, DyadicRatCoreUp tolerance rows, RegSeqRatUp and RealUp seals, UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactMetricModulusRealizer}^{\uparrow}}$, seed)

Scope closed: Definition 7821.1 and Definition 7821.2 seed the compact metric finite-net modulus realizer route from pointwise moduli to a tolerance-only UniformModulus handoff.

Formal verification: FormalStatus(NameCert$_{\text{CompactMetricModulusRealizer}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not prove external compactness, host finite minima, quotient equality of functions, selected center families, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, pointwise-modulus row coverage, ProbeBundle fold exactness, metric triangle replay, dyadic tolerance transport, RegSeqRat and Real seal discipline, UniformModulus handoff, and nonescape for BEDC.Derived.CompactMetricModulusRealizerUp.

Chapter 7822

A Concrete Naming Certificate for $\mathsf{DyadicBracketSchedule}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real approximations, the $\mathsf{DyadicBracketSchedule}^{\uparrow}$ packet records the finite inspection schedule by which dyadic brackets feed regular rational readback, stream windows, and the terminal real-name seal. It sits after the dyadic arithmetic surface of chapter 291, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet also consumes the lower-and-upper endpoint surface of chapter 7222. It is a finite constructive-analysis schedule, not a quotient real, a selected completed limit, a countable-choice selector, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7822.1 (Dyadic bracket schedule carrier)**.** *A* $\mathsf{DyadicBracketSchedule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, I, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row inspected at the requested scale.*
2. *U is the upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row inspected at the same scale.*
3. *I is the finite inspection schedule row, recording the order in which bracket widths, endpoint comparisons, and tolerance checks are replayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the inspection schedule.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after the schedule has exposed L, U, I, W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular rational readback row R has been displayed.*
7. *H records componentwise* hsame *transport for endpoint, schedule, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bracket request through L, U, I, W to R and then to E.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicBracketSchedule}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicBracketing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicBracketSchedule}^{\uparrow}}$ *row.*

The classifier compares accepted schedules only through $L, U, I, W, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable-choice schedules outside the displayed finite row, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7822.2 (Dyadic bracket schedule NameCert obligations)**.** *For every accepted* $\mathsf{DyadicBracketSchedule}^{\uparrow}$ *carrier $S = (L, U, I, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicBracketSchedule}^{\uparrow}}$ *surface consists exactly of lower endpoint exposure, upper endpoint exposure, finite inspection-schedule replay, StreamName window coverage, RegSeqRat readback, terminal Real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every Real or Completion consumer must read those rows before treating E as a real-name seal.*

Proof. Project the carrier of Definition 7822.1. The endpoint rows L, U are the only dyadic bracket endpoints available to the local classifier, and the inspection row I is the only schedule row.

Read the finite window route next. The row W opens the $\mathsf{StreamName}^{\uparrow}$ window requested by I, and R is the regular rational readback from the displayed endpoint and window data.

The Real-facing output is downstream of that readback. The seal row E appears only after R, and the structural rows H, C, P, N transport, replay, source, and name the same finite route.

Since the carrier has no coordinate for quotient stream equality, selected limits, hidden choice schedules, host real equality, ambient completeness, or bridge certificates, the displayed rows exhaust the local NameCert obligation surface. □

Theorem 7822.3 (Dyadic bracket schedule regular-Cauchy handoff)**.** *Let $S = (L, U, I, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{DyadicBracketSchedule}^{\uparrow}$ *carrier. Every regular-Cauchy or Completion-facing consumer of S factors through the finite route*

$$L, U, I, W \longmapsto R \longmapsto E$$

with H, C, P, N preserving the same route under transport, replay, provenance, and local naming. Thus the consumer receives dyadic lower and upper bracket endpoints, the inspection schedule, a finite StreamName window, RegSeqRat readback, and the terminal Real seal, but receives no quotient filter, selected limit, countable-choice selector, host equality, ambient Real completeness, or bridge certificate.

Proof. Start with the NameCert obligations of Definition 7822.2. They require endpoint exposure, schedule replay, window coverage, regular rational readback, and Real-seal handoff as displayed rows of the same packet.

The regular-Cauchy handoff is the row R. It is read only after L, U, I, W have appeared, so it cannot be detached from the displayed bracket schedule or replaced by a selected completed limit.

The terminal seal E is downstream of R. Componentwise transport through H and replay through C preserve the same order, while P and N record provenance and local naming without adding any alternate Completion-facing coordinate. □

Theorem 7822.4 (Dyadic bracket schedule Real-seal nonescape)**.** *For every accepted* $\mathsf{DyadicBracketSchedule}^{\uparrow}$ *carrier $S = (L, U, I, W, R, E, H, C, P, N)$, no Real-facing read can reach the seal row E without first displaying the dyadic lower endpoint L, dyadic upper endpoint U, finite inspection schedule I, StreamName window W, and RegSeqRat readback R. In particular, the accepted schedule cannot export quotient real equality, selected limits, countable-choice schedules, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge checking.*

Proof. Inspect the carrier definition. The only Real-facing row is E, and it is placed after the displayed dyadic, schedule, window, and regular-readback rows.

Apply Definition 7822.2. The local naming surface requires endpoint exposure, schedule replay, StreamName window coverage, and RegSeqRat readback before the Real-seal handoff is admitted.

Use Definition 7822.3 for consumers. Every regular-Cauchy or Completion-facing request follows the route $L, U, I, W \longmapsto R \longmapsto E$, and the structural rows preserve that route rather than adding a second path to $\mathsf{Real}^{\uparrow}$.

The excluded quotient, selected-limit, choice, host-equality, ambient-completeness, and bridge objects are absent from the carrier. Hence any read using them has left the accepted $\mathsf{DyadicBracketSchedule}^{\uparrow}$ packet instead of reading its Real-seal surface. □

Falsifiable prediction: Every accepted $\mathsf{DyadicBracketSchedule}^{\uparrow}$ Real-facing read must display lower and upper $\mathsf{DyadicRatCore}^{\uparrow}$ endpoints, the finite inspection schedule, a $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicbracketing, dyadicratcore, streamname, regseqrat, real: $\mathsf{DyadicBracketSchedule}^{\uparrow}$ is not bijective to any listed sibling because it binds bracket endpoints, one inspection schedule, one stream window, regular rational readback, Real seal, transport, replay, provenance, and local naming as one schedule certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBracketSchedule}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicBracketSchedule}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, a finite inspection schedule, a StreamName window, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBracketSchedule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7822.1, Definition 7822.2, Definition 7822.3, and Definition 7822.4 seed the finite dyadic bracket schedule route feeding regular-Cauchy, Real, and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBracketSchedule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected completed limits, hidden choice schedules, host equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, inspection-schedule replay, StreamName window coverage, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicBracketSche

Chapter 7823

A Concrete Naming Certificate for $\mathsf{RiemannCauchyRealName}^{\uparrow}$

Following Riemann and Bishop–Bridges, the $\mathsf{RiemannCauchyRealName}^{\uparrow}$ packet records a real name as a finite BEDC certificate around rational fundamental sequences rather than as a host real. It sits between the finite stream discipline of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational sequence route of chapter 301, the public real-name boundary of chapter 38, and the regularizing handoff of chapter 7319. The packet exposes the traditional Cauchy fundamental-sequence surface only through finite windows, rational readback, dyadic moduli, transport, replay, provenance, and a local name.

Definition 7823.1 (Riemann–Cauchy real-name carrier)**.** *A* $\mathsf{RiemannCauchyRealName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (Q, S, W, D, R, U, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational source row for the fundamental sequence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row exposing finite sequence windows.*
3. *W is the Cauchy-window schedule row for requested rational tolerances.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger bounding the window comparison.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback obtained from S, W, D.*
6. *U is the regularizer row that presents the same name at the* $\mathsf{Real}^{\uparrow}$ *boundary.*
7. *H records componentwise* hsame *transport for the source, stream, window, dyadic, readback, regularizer, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route $Q, S, W, D \longmapsto R \longmapsto U$.*
9. *P is the* Pkg *provenance over* $\mathsf{RiemannCauchyRealName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannCauchyRealName}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed host real, quotient stream equality, a selected limit, trichotomy, countable choice, or an ambient completeness theorem.

Theorem 7823.2 (Riemann–Cauchy real-name NameCert obligations)**.** *For every accepted* RiemannCauchyRealNa *carrier* $X = (Q, S, W, D, R, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RiemannCauchyRealName}^{\uparrow}}$ *surface consists exactly of carrier admission for* X*, rational fundamental-sequence exposure through* Q*, finite stream windows through* S*, Cauchy-window scheduling through* W*, dyadic tolerance accounting through* D*, regular rational readback through* R*, regularized* $\mathsf{Real}^{\uparrow}$ *boundary exposure through* U*, component-wise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 7823.1. Its first four rows expose only rational source data, finite stream windows, requested tolerances, and dyadic bounds.

The readback row R is therefore reached through the same finite route used by the $\mathsf{RegSeqRat}^{\uparrow}$ chapter, and the regularizer row U is the only public route from that readback to the $\mathsf{Real}^{\uparrow}$ boundary.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no further coordinate is present, the local certificate cannot ask for a selected host limit, quotient stream equality, countable choice, trichotomy, or ambient completeness. □

Theorem 7823.3 (Riemann–Cauchy real-name RegSeqRat factorization)**.** *Every accepted* RiemannCauchyRealNam *consumer that reads the public real-name boundary must first factor through the finite route*

$$Q, S, W, D \longmapsto R \longmapsto U$$

where R *is the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* U *is the regularized* $\mathsf{Real}^{\uparrow}$ *boundary row. The consumer receives no host real equality, quotient stream equality, selected limit, detached completion route, countable-choice schedule, or ambient completeness principle.*

Proof. Begin with the NameCert obligations of Definition 7823.2. They order the rational source, finite windows, Cauchy-window schedule, and dyadic tolerance ledger before any regular readback is available.

The row R is the unique regular rational readback inside the packet. Any consumer of the $\mathsf{Real}^{\uparrow}$ boundary must therefore pass through the $\mathsf{RegSeqRat}^{\uparrow}$ route before it can read the regularizer row U.

Finally inspect the refused coordinates. The carrier does not contain a quotient stream, selected limit, host real, choice schedule, detached completion route, or ambient completeness row, so none can replace the displayed Q, S, W, D, R, U factorization. □

Falsifiable prediction: A consumer that claims a $\mathsf{RiemannCauchyRealName}^{\uparrow}$ real-name boundary while omitting the rational source, finite stream window, Cauchy-window schedule, dyadic tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, regularizer, hsame, Cont, Pkg, or local NameCert rows refutes Definition 7823.1.

Independence witness: streamname, dyadicratcore, regseqrat, real, regular-sequence-regularizer: $\mathsf{RiemannCauchyRealName}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a rational fundamental-sequence source, finite stream windows, Cauchy-window scheduling, dyadic tolerance accounting, regular readback, and a real-boundary regularizer. StreamNameUp lacks the tolerance ledger; DyadicRatCoreUp lacks the sequence route; RegSeqRatUp lacks the raw fundamental-sequence source; RealUp lacks the displayed Cauchy-window schedule; the regularizer chapter supplies a handoff without this full source packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannCauchyRealName}^{\uparrow}}$**.**

Constructive story: A RiemannCauchyRealName$^{\uparrow}$ packet is generated from a rational source row, finite StreamName windows, a Cauchy-window schedule, a DyadicRatCore tolerance ledger, RegSeqRat readback, a Real-boundary regularizer, componentwise transport, displayed replay, provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{RiemannCauchyRealName}^{\uparrow}}$, seed)

Scope closed: Definition 7823.1, Definition 7823.2, and Definition 7823.3 seed the finite Riemann–Cauchy real-name route over rational source rows, finite windows, dyadic tolerances, regular readback, real-boundary regularization, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{RiemannCauchyRealName}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real construction, selected limits, countable choice, trichotomy, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window scheduling, dyadic tolerance accounting, RegSeqRat factorization, regularizer routing, transport, replay, provenance, and local naming for BEDC.Derived.RiemannCauchyReal

Chapter 7824

A Concrete Naming Certificate for $\mathsf{SteinerTree}^{\uparrow}$

Following Gilbert and Pollak and standard finite network optimization, the $\mathsf{SteinerTree}^{\uparrow}$ packet names the finite certificate that connects a displayed terminal family inside a weighted graph by a tree-shaped subnetwork. It sits over the graph carrier of chapter 118, the acyclic connected carrier of chapter 119, the spanning-tree surface of chapter 237, the shortest-path ledger of chapter 236, and the metric-graph route of chapter 6788. The packet is a finite optimization certificate; it does not import ambient network-flow duality, a host minimum oracle, graph isomorphism, an infinite network limit, or quotient equality of vertex sets.

Definition 7824.1 (Steiner tree carrier)**.** *A* $\mathsf{SteinerTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, W, T, R, E, A, L, B, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *row naming the finite vertex and edge incidence data.*
2. *W is the finite edge-weight ledger over G, read through the same weighted path surface used by* $\mathsf{ShortestPath}^{\uparrow}$ *and* $\mathsf{MetricGraph}^{\uparrow}$*.*
3. *T is the terminal-family row, a finite list or finite subset of vertices of G that must be connected.*
4. *R is the selected root or anchor row used only to orient the finite certificate and not to choose a canonical optimum.*
5. *E is the candidate edge-subset row, naming the displayed subgraph used by the certificate.*
6. *A is the admitted auxiliary-vertex row, naming nonterminal vertices of G that may appear in the candidate subgraph.*
7. *L is the length ledger, summing the displayed edge weights of E.*
8. *B is the bound row, comparing L with the finite competitor ledgers that the packet chooses to expose.*
9. *H records componentwise* hsame *transport for graph, weight, terminal, anchor, candidate-edge, auxiliary-vertex, length, bound, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from graph incidence and terminal rows through the candidate tree route, length ledger, and bound row.*

11. *P is the* Pkg *provenance over* $\mathsf{SteinerTree}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{ShortestPath}^{\uparrow}$, $\mathsf{MetricGraph}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{SteinerTree}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It carries no coordinate for a hidden global optimizer, unlisted terminals, quotient graph isomorphism, network-flow duality, infinite graph limits, or a host enumeration of all candidate subnetworks.

Theorem 7824.2 (Steiner tree NameCert obligations)**.** *For every accepted* $\mathsf{SteinerTree}^{\uparrow}$ *carrier* $S = (G, W, T, R, E, A, L, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SteinerTree}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed graph row, edge-weight ledger, terminal-family row, anchor row, candidate edge-subset row, auxiliary-vertex row, length ledger, bound row, componentwise transport, displayed replay, package provenance, and local naming. Every public read must keep the* $\mathsf{Graph}^{\uparrow}$, $\mathsf{Tree}^{\uparrow}$, $\mathsf{SpanningTree}^{\uparrow}$, $\mathsf{ShortestPath}^{\uparrow}$, *and* $\mathsf{MetricGraph}^{\uparrow}$ *source rows visible before it cites the Steiner certificate.*

Proof. Project the carrier of Definition 7824.1. The graph, weights, terminal family, candidate edge set, auxiliary vertices, length, and bound rows are the only optimization-facing coordinates.

Read the graph-theoretic rows first. The $\mathsf{Graph}^{\uparrow}$ row supplies finite incidence, the $\mathsf{Tree}^{\uparrow}$ row supplies connected acyclic recognition for the candidate subgraph, and the $\mathsf{SpanningTree}^{\uparrow}$ row supplies the spanning comparison surface when all graph vertices are required rather than only the displayed terminal family.

Now read the metric rows. $\mathsf{ShortestPath}^{\uparrow}$ and $\mathsf{MetricGraph}^{\uparrow}$ provide the finite path and weight ledgers used by L and B. The structural rows H, C, P, N transport, replay, source, and name the same displayed packet, so no hidden optimizer or external graph enumeration is available. □

Theorem 7824.3 (Steiner tree finite-terminal nonescape)**.** *Every accepted* $\mathsf{SteinerTree}^{\uparrow}$ *consumer must display the terminal-family row T and the candidate tree route through E, A before reading the length and bound rows L, B. A consumer that adds a terminal, removes a required terminal, or reads a bound for a different terminal family has left the accepted carrier.*

Proof. Start from the carrier inventory. The terminal-family row T is separate from the graph row G, the candidate edge-subset row E, and the auxiliary-vertex row A.

The tree certificate is downstream of the displayed terminal family. The candidate subgraph must connect every vertex named by T, while auxiliary vertices may appear only through the admitted row A and the same graph row G.

Finally read L and B. These rows sum and compare only the candidate edge rows visible through E for the terminal family visible through T. Transport and replay preserve those rows componentwise, so a different terminal family is not a read of the same $\mathsf{SteinerTree}^{\uparrow}$ packet. □

Theorem 7824.4 (Steiner tree network-flow boundary)**.** *The* $\mathsf{SteinerTree}^{\uparrow}$ *packet may be consumed by network or flow-facing arguments only through the displayed finite graph, path, tree, weight, length, and bound rows*

$$\mathsf{Graph}^{\uparrow},\ \mathsf{Tree}^{\uparrow},\ \mathsf{SpanningTree}^{\uparrow},\ \mathsf{ShortestPath}^{\uparrow},\ \mathsf{MetricGraph}^{\uparrow},\ G, W, T, E, A, L, B, H, C, P, N.$$

It does not export a max-flow min-cut theorem, a linear-programming dual, a host optimum oracle, quotient equality of graphs, or an infinite-network compactness principle.

Proof. Project the displayed route. The graph and metric rows supply finite incidence, edge weights, path ledgers, and metric reads; the tree rows supply connected acyclic recognition for the selected subnetwork.

The bound row B is a finite comparison row inside the packet. It may be read as a certificate boundary for exposed competitors, but it is not a duality theorem and not an external optimization oracle.

Since the carrier has no coordinate for max-flow min-cut data, linear programming dual variables, quotient graph equality, or infinite-network compactness, any consumer claiming those endpoints has left the displayed NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{SteinerTree}^{\uparrow}$ read is refuted if it claims a Steiner certificate without displaying the graph row, terminal-family row, candidate tree route, edge-weight ledger, finite length comparison, transport, replay, provenance, and local naming rows.

Independence witness: graph, tree, spanningtree, shortestpath, metric-graph: $\mathsf{Graph}^{\uparrow}$ supplies incidence without terminal optimization; $\mathsf{Tree}^{\uparrow}$ supplies connected acyclic recognition without weighted terminal bounds; $\mathsf{SpanningTree}^{\uparrow}$ supplies full-vertex spanning witnesses without auxiliary terminal selection; $\mathsf{ShortestPath}^{\uparrow}$ supplies path comparisons without a tree-shaped terminal subnetwork; and $\mathsf{MetricGraph}^{\uparrow}$ supplies graph metric reads without a Steiner certificate. None is bijective to $\mathsf{SteinerTree}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{SteinerTree}^{\uparrow}}$.

Constructive story: A $\mathsf{SteinerTree}^{\uparrow}$ packet is generated from a finite GraphUp row, an edge-weight ledger, a finite terminal-family row, a candidate tree-shaped edge set, admitted auxiliary vertices, a length ledger, a bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SteinerTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7824.1, Definition 7824.2, Definition 7824.3, and Definition 7824.4 seed the finite Steiner-tree certificate over GraphUp, TreeUp, SpanningTreeUp, ShortestPathUp, MetricGraphUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SteinerTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, max-flow min-cut duality, host optimality, quotient graph equality, infinite network compactness, or an exhaustive external enumeration of candidate subnetworks.

Upgrade path: Obligation closure requires checked carrier admission, terminal-family stability, candidate-tree validity, auxiliary-vertex boundary, length-ledger exactness, bound-row replay, provenance, and local naming for BEDC.Derived.SteinerTreeUp.

Chapter 7825

A Concrete Naming Certificate for MetaCICSubjectReductionResidualGap$^{\uparrow}$

The MetaCICSubjectReductionResidualGap$^{\uparrow}$ packet realizes the dependent-codomain obstruction of chapter 9377 as finite residual-gap NameCert data. It sits beside the subject-reduction discharge socket of chapter 719, the subject-reduction frontier of chapter 730, the app-argument stability ledger of chapter 6474, the normalization frontier of chapter 892, and the critical-path packet of chapter 765. The packet names the residual budget that remains after the checked independent-codomain application case; it does not prove closed subject reduction, discharge the four preservation rows, identify evaluator equality, quotient terms, or kernel consistency.

Definition 7825.1 (MetaCIC subject-reduction residual-gap carrier)**.** *A* MetaCICSubjectReductionResidualGap$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, D, A, C, O, T, E, H, Q, P, N)$$

with the following displayed rows:

1. *S is the subject-reduction socket row naming the four discharge obligations that a consumer must keep visible.*
2. *D is the dependent-codomain residual row, recording the application case in which the codomain may observe the reducing argument.*
3. *A is the app-argument stability row, consumed from the displayed argument-type ledger.*
4. *C is the candidate-normalization row, recording the normalization frontier data that may be inspected without closing subject reduction.*
5. *O is the obstruction-retention row, naming the checked dependent-codomain obstruction and the endpoints it refuses.*
6. *T is the transport row for socket, residual, app-argument, candidate-normalization, obstruction, replay, provenance, and local naming data.*
7. *E is the replay row, routing a subject-reduction request through S, D, A, C, O, T before any downstream normalization or critical-path consumer may inspect it.*
8. *H records componentwise* hsame *transport for all displayed rows.*
9. *Q records displayed* Cont *replay for the same route.*

10. *P is the* Pkg *provenance over* MetaCICSubjectReductionResidualGap$^{\uparrow}$, SubjectReduction$^{\uparrow}$, SubjectReductionDischa MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}}$ *row.*

The carrier has no coordinate for a closed subject-reduction theorem, unrestricted substitution compatibility, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.

Theorem 7825.2 (MetaCIC subject-reduction residual-gap obligations)**.** *For every accepted* MetaCICSubjectReduc *carrier $R = (S, D, A, C, O, T, E, H, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}}$ *surface consists exactly of carrier admission, socket visibility, dependent-codomain residual display, app-argument stability handoff, candidate-normalization visibility, obstruction retention, transport, replay, provenance, and local naming. Every consumer must expose the rows $S, D, A, C, O, T, E, H, Q, P, N$ before citing the residual-gap packet.*

Proof. Project the carrier of Definition 7825.1. The subject-reduction socket, dependent-codomain residual, app-argument stability, candidate-normalization, and obstruction rows are distinct visible coordinates.

Read the socket row first. It keeps the four discharge obligations in view and prevents the residual-gap packet from standing in for any missing preservation row.

Next read D, A, C, O. The dependent-codomain row records the residual case, the app-argument row keeps the argument-type ledger attached, the candidate-normalization row records the normalization-facing budget, and the obstruction row keeps the checked counterexample boundary visible.

Finally T, E, H, Q, P, N transport, replay, source, and name the same packet. Since none of those rows contains a closed subject-reduction theorem, evaluator equality, quotient syntax equality, or kernel-consistency coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7825.3 (MetaCIC subject-reduction residual-gap nonescape)**.** *Every subject-reduction, normalization, or critical-path consumer of an accepted* MetaCICSubjectReductionResidualGap$^{\uparrow}$ *packet must keep the finite route*

$$S, D, A, C, O, T, E, H, Q, P, N$$

visible. The route may expose a residual-gap budget for the dependent-codomain application case, but it cannot be reread as closed subject reduction, a discharge of the four preservation rows, unrestricted substitution compatibility, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.

Proof. Start with the obligation surface above. A consumer reaches the residual-gap row only after the subject-reduction socket S and dependent-codomain row D are displayed.

The app-argument and candidate-normalization rows then remain boundary data. They allow the consumer to inspect argument-type stability and normalization-facing candidates, while the obstruction row O records that the dependent-codomain obstruction has not been discharged.

Transport and replay preserve the same route. The rows T, E, H, Q, P, N attach the finite packet to its provenance and local name; they do not add any of the refused subject-reduction, substitution, equality, normalization, or kernel-consistency endpoints. □

Falsifiable prediction: An accepted MetaCICSubjectReductionResidualGap$^{\uparrow}$ read is refuted if it claims a subject-reduction residual without displaying the socket, dependent-codomain residual, app-argument stability, candidate-normalization, obstruction-retention, transport, replay, provenance, and local naming rows.

Independence witness: subject-reduction-discharge-socket, metacic-subject-reduction-frontier, metacic-app-argument-stability-ledger, metacicnormalizationfrontier, metaciccriticalpath: none is bijective to $\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}$ because this packet jointly carries residual-gap, socket, app-argument, candidate-normalization, obstruction, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}$ packet is generated from subject-reduction socket rows, dependent-codomain residual rows, app-argument stability rows, candidate-normalization rows, obstruction-retention rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7825.1, Definition 7825.2, and Definition 7825.3 seed the finite residual-gap route over SubjectReductionUp, SubjectReductionDischargeSocketUp, MetaCICNormalizationFrontierUp, MetaCICCriticalPathUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove closed subject reduction, discharge the four preservation obligations, close unrestricted substitution compatibility, identify evaluator equality, quotient terms, global normalization, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, socket visibility, dependent-codomain residual display, app-argument stability handoff, candidate-normalization visibility, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICSubjectReductionResidualGapUp.

Chapter 7826

A Concrete Naming Certificate for $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$

Following Moore–Osgood and Bishop–Bridges constructive analysis, the $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ packet records the finite window at which an iterated-limit handoff can be inspected before any consumer invokes the broader interchange certificate of chapter 1686. It reads the two-parameter source through the $\mathsf{CauchyDoubleSequence}^{\uparrow}$ surface of chapter 460, keeps every row inside the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ observation discipline, and reaches the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38 only after the displayed handoff rows have been exposed.

Definition 7826.1 (Moore-Osgood finite-window carrier)**.** *A* $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, F, S, U, Q, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite two-parameter* $\mathsf{CauchyDoubleSequence}^{\uparrow}$ *window, listing the row and column indices, the inspected rectangle, and the tolerance request opened by the handoff.*
2. *F is the first-direction* $\mathsf{StreamName}^{\uparrow}$ *handoff row read from the windows in W.*
3. *S is the second-direction* $\mathsf{StreamName}^{\uparrow}$ *handoff row read from the same finite window family.*
4. *U is the finite uniform-tail row binding the active tolerance to the side of the window that remains fixed while the other side is enlarged.*
5. *Q is the finite schedule row that records which rectangle enlargements are allowed before the handoff reaches regular rational readback.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row that reads the two displayed handoff streams as regular rational data.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for the tolerance budget, tail bound, rectangle enlargement, and accumulated handoff error.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after W, F, S, U, Q, R, D have all been displayed.*
9. *H records componentwise* hsame *transport for the window, two stream handoffs, uniform-tail row, schedule, regular readback, dyadic ledger, real seal, continuation, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from finite rectangle inspection to stream handoff rows, from the uniform-tail and schedule rows to the regular readback row, and from dyadic accounting to the real seal.*

11. *P is the* Pkg *provenance over* $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$, $\mathsf{CauchyDoubleSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, F, S, U, Q, R, D, E, H, C, P, N$. It has no coordinate for a completed double limit, quotient equality of arrays, countable choice, selected limiting representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7826.2 (Moore-Osgood finite-window NameCert obligations)**.** *For every accepted* MooreOsgoodFiniteWi *carrier*

$$M = (W, F, S, U, Q, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}}$ *surface consists exactly of the following finite rows:*

1. *carrier admission for the displayed* $\mathsf{CauchyDoubleSequence}^{\uparrow}$ *window, two* $\mathsf{StreamName}^{\uparrow}$ *handoff rows, uniform-tail row, finite schedule, regular readback, dyadic ledger, real seal, transport, replay, provenance, and local naming rows;*

2. *window stability, requiring every handoff consumer to read the same finite rectangle row W before either stream handoff F or S is exposed;*

3. *tail-schedule exactness, requiring U and Q to bind the active tolerance and allowed rectangle enlargements before the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R can be read;*

4. *dyadic accounting, requiring D to ledger the tolerance, tail, schedule, and handoff-error rows before the* $\mathsf{Real}^{\uparrow}$ *seal E is visible;*

5. *nonescape, requiring H, C, P, N to transport, replay, source, and name only the displayed rows, with no host double-limit theorem, quotient array equality, countable choice, selected limiting representative, or ambient Real completeness.*

No finite-window Moore-Osgood NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 7826.1. Carrier admission is the displayed inventory $W, F, S, U, Q, R, D, E, H, C, P, N$, and every row is finite BHist data.

Window stability follows from the placement of F and S after the common two-parameter window W. A consumer can inspect either handoff direction only through the same finite rectangle.

Tail-schedule exactness is the role of U and Q. The active tolerance is bound before the schedule allows rectangle enlargement, and R is read only after that finite route has been displayed.

Dyadic accounting and nonescape then follow from D, E, H, C, P, N. The dyadic row records the tolerance and handoff-error budget before the real seal is reached, while the structural rows preserve only the displayed route and contain none of the excluded host principles. □

Theorem 7826.3 (Moore-Osgood finite-window limit handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ *packet factors through the finite route*

$$W, F, S, U, Q, R, D, E, H, C, P, N.$$

Consequently the packet supplies only a finite iterated-limit handoff surface from $\mathsf{CauchyDoubleSequence}^{\uparrow}$ *windows to regular rational readback and the terminal Real seal; it does not supply a host double-limit convergence theorem, quotient equality of arrays, countable choice, selected limiting representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted packet and project its carrier rows. The only two-parameter source data are the windows in W, and the only iterated handoff rows are the two stream rows F and S.

Apply the obligation surface of Definition 7826.2. It forces any consumer to pass from W through the tail and schedule rows U, Q before reaching the regular readback row R.

The route then continues through the dyadic ledger D to the seal E. Since H, C, P, N preserve and name only those rows, every $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer factors through the displayed finite packet, and the excluded host double-limit, quotient, choice, selected-limit, and completeness data cannot be exported. □

Falsifiable prediction: Every $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ handoff read exposes a finite Cauchy-DoubleSequence window, two StreamName handoff rows, a uniform-tail row, a finite schedule, RegSeqRat readback, DyadicRatCore accounting, a RealUp seal, transport, continuation, provenance, and local naming.

Independence witness: mooreosgood, cauchydoublesequence, streamname, regseqrat, dyadicratcore, real: $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ is not bijective to any listed sibling because it isolates the finite window handoff before the broader Moore-Osgood interchange certificate, while still carrying the two handoff streams, uniform tail, schedule, regular readback, dyadic ledger, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}$ packet is generated from a finite CauchyDoubleSequence window, two StreamName handoff rows, a uniform-tail row, a finite schedule, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7826.1, Definition 7826.2, and Definition 7826.3 bind the finite-window iterated-limit handoff surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreOsgoodFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host double-limit convergence, quotient array equality, countable choice, selected limiting representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, window stability, tail-schedule exactness, dyadic accounting, real-seal nonescape, and TasteGate field faithfulness for BEDC.Derived.MooreOsgoodFiniteWindowUp.

Chapter 7827

A Concrete Naming Certificate for $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ packet records the finite closed-interval route by which a displayed continuous map receives one source tolerance for a requested target tolerance. It reads its interval endpoints from chapter 394, its graph and pointwise-radius rows from chapter 130, its finite window discipline from chapter 126, its regular rational readback from chapter 301, its terminal value boundary from chapter 38, the fixed-point consumer route of chapter 1437, and the separate modulus-object surface of chapter 2292. The packet names a displayed finite-net modulus route for one located closed interval; it does not claim general Heine–Borel compactness, sequential compactness, selected limits, quotient reals, or $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7827.1 (Compact interval uniform-continuity carrier)**.** *A* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (J, F, N_\varepsilon, M, W, Q, E, H, C, P, L)$$

with the following visible rows:

1. *J is the* $\mathsf{LocatedInterval}^{\uparrow}$ *closed-interval row, including the displayed endpoint names and the located endpoint-order evidence consumed by all later reads.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-radius row for the displayed map on J.*
3. *N_ε is the finite interval-net row at the requested target tolerance, listing the inspected subinterval centers and their covering radii.*
4. *M is the rational lower-bound fold over the pointwise source radii attached to those centers, producing the uniform source tolerance.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window surface for the interval endpoints, inspected centers, nearby input names, and output reads.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row translating the retained finite windows into regular rational comparisons.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row used only after W and Q have displayed the required input and output comparisons.*
8. *H records componentwise* hsame *transport for $J, F, N_\varepsilon, M, W, Q, E$ and the local certificate rows.*

9. *C records displayed* Cont *replay from a target tolerance request through the interval net, center-wise pointwise-continuity rows, lower-bound fold, window/readback rows, and real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$, $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *L is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalUniformContinuity}^{\uparrow}}$ *row.*

The carrier is an interval-specific uniform-continuity certificate over displayed finite rows. It has no coordinate for general Heine–Borel compactness, sequential compactness, selected limits, quotient real equality, open-cover subcover selection, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.CompactIntervalUniformContinuityUp.CompactIntervalUniformContinuityTasteGate`
`single carrier alignment`

Theorem 7827.2 (CompactIntervalUniformContinuity NameCert obligations)**.** *For an accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *carrier* $U = (J, F, N_\varepsilon, M, W, Q, E, H, C, P, L)$, *the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalUn}}$ *surface consists exactly of the following obligations:*

1. *carrier admission for the located interval, continuous-map row, finite interval-net row, lower-bound fold, finite windows, regular readback, real seal, componentwise transport, continuation replay, provenance, and local naming;*

2. *source lock, requiring J and the source of F to name the same located closed interval before any pointwise radius is read;*

3. *finite-net coverage, requiring every input comparison to pass through one displayed center of N_ε before the pointwise row in F is used;*

4. *lower-bound exactness, requiring the uniform source tolerance to be read from M and not from a host minimum or selected Lebesgue number;*

5. *window and seal nonescape, requiring each downstream value comparison to pass through W, Q, and E before it can be consumed by fixed-point or modulus-object users.*

No obligation may call on general Heine–Borel compactness, sequential compactness, selected limits, quotient reals, or $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 7827.1. The interval row J and continuous-map row F are the only sources for endpoint, graph, and pointwise-radius information.

The finite-net obligation is carried by N_ε. Each input comparison is routed to one displayed center before the corresponding pointwise radius in F is used, so no open-cover subcover selection or host compactness step is available.

The uniform source tolerance is then computed by the finite fold M. The window/readback rows W and Q expose exactly the input and output comparisons needed by the requested target tolerance, and the real seal E is read only after those rows have been displayed.

Transport, replay, provenance, and local naming preserve the same route. Since the carrier has no coordinate for the excluded compactness or completion principles, the listed obligations exhaust the local NameCert surface. □

Theorem 7827.3 (Compact interval uniform-continuity source lock)**.** *Every accepted* CompactIntervalUniformConti *carrier* $U = (J, F, N_\varepsilon, M, W, Q, E, H, C, P, L)$ *must expose the same located closed interval row J as the source of the continuous-map row F before any consumer reads N_ε, M, W, Q, or E. Thus the*

finite-net radius rows, lower-bound fold, finite windows, regular readback, and real seal all remain locked to the displayed source interval of F.

Proof. Project the carrier of Definition 7827.1. The displayed row J is the only located closed interval coordinate, and F is explicitly the continuous-map row for the displayed map on J.

Now apply the source-lock obligation in Definition 7827.2. Before any pointwise radius is read, the NameCert surface requires J and the source of F to name the same located closed interval.

The remaining rows are downstream of that obligation. The finite net N_ε, the lower-bound fold M, the window row W, the readback row Q, and the real seal E consume pointwise-radius and comparison data only after the source lock has been exposed, so none of them can be read from a different source interval. □

Theorem 7827.4 (Compact interval finite-net modulus)**.** *For every accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *carrier* $U = (J, F, N_\varepsilon, M, W, Q, E, H, C, P, L)$ *and every displayed target tolerance, the source tolerance exported by the packet is obtained by the finite route*

$$J, F, N_\varepsilon, M, W, Q, E, H, C, P, L.$$

If two input names are read within that source tolerance through W and Q, then the output comparison is accepted only through the same centerwise pointwise-continuity rows and the same real-seal row E. The route is a finite-net modulus route, not a general compactness theorem or a selected limit construction.

Proof. Begin with the target tolerance request. The continuation row C sends it to the displayed interval-net row N_ε, whose centers and covering radii are finite rows over the same located interval J.

For each listed center, the continuous-map row F supplies a pointwise source radius. The fold M computes one rational lower bound from those displayed radii, giving the source tolerance exported by the packet.

Input names and output values are then inspected through W and translated through Q. The real seal E can be consumed only after these window and readback rows have displayed the required comparisons.

Thus the modulus route is finite and internal to the packet. It neither selects a limit point nor appeals to open-cover compactness, sequential compactness, quotient real equality, or ambient completeness. □

Definition 7827.5 (Compact interval uniform-continuity modulus carrier)**.** *The modulus carrier extracted from an accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *packet is the finite* BHist *row*

$$U_{\mathrm{mod}} = (J, F, N_\varepsilon, X, W, Q, E, H, C, P, L_{\mathrm{mod}})$$

where J is the located closed-interval row, F is the $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row, N_ε is the finite interval-net row, and X is the sibling* $\mathsf{CompactModulusExtraction}^{\uparrow}$ *row that folds the displayed centerwise radii into one source tolerance. The remaining rows are the* $\mathsf{StreamName}^{\uparrow}$ *finite windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback Q, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalUniformContinuity}^{\uparrow}}$ *modulus row L_{mod}.*

This carrier is an interval-local modulus surface. It has no row for open-cover compactness, selected subcovers, sequential compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7827.6 (Compact interval uniform-continuity modulus obligations)**.** *For every accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *packet* $U = (J, F, N_\varepsilon, M, W, Q, E, H, C, P, L)$*, the modulus carrier* U_{mod} *of Definition 7827.5 exposes exactly the following obligation surface:*

1. *the located interval row* J *and the continuous-map row* F *must be read before any centerwise radius is folded;*
2. *the finite-net row* N_ε *must display the inspected centers and covering radii for the requested target tolerance;*
3. *the* $\mathsf{CompactModulusExtraction}^{\uparrow}$ *sibling row* X *must perform the finite lower-bound extraction from the displayed centerwise data;*
4. *the windows* W*, readback* Q*, and seal* E *must be displayed before a* $\mathsf{Real}^{\uparrow}$*-facing consumer reads the exported comparison;*
5. *the transport, replay, provenance, and local naming rows* $H, C, P, L_{\mathrm{mod}}$ *must preserve that same route.*

No obligation can be discharged by open-cover compactness, a selected Lebesgue-number object, sequential compactness, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted packet and read Definition 7827.4. It places the exported source tolerance behind the located interval row, the displayed continuous-map row, the finite-net row, and the rational fold already present in the packet.

Replace the fold read by the sibling extraction surface of chapter 6750. That chapter supplies only the finite-net, pointwise-modulus, lower-bound, metric, and modulus handoff rows, so the extraction remains a displayed finite route.

The remaining rows are inherited without widening the carrier. The stream windows, regular readback, real seal, transport, replay, provenance, and local name are exactly the rows already admitted by the interval packet, and none of them contains a compactness or completion principle outside the displayed finite surface. □

Theorem 7827.7 (Compact interval uniform-continuity finite-net route)**.** *Every finite-modulus consumer of an accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *packet must read the interval-specific route*

$$J, F, N_\varepsilon, \mathsf{CompactModulusExtraction}^{\uparrow}, W, Q, E, H, C, P, L_{\mathrm{mod}}.$$

In particular, the consumer receives the located interval row, continuous-map graph and pointwise-modulus rows, finite net row, sibling compact-modulus extraction row, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row before it can use the extracted source tolerance.*

Proof. Apply Definition 7827.6. The obligation surface orders the interval, graph, finite-net, and extraction rows before any consumer-facing modulus read.

Now use the finite-net modulus theorem Definition 7827.4. It shows that the source tolerance exported by the interval packet is obtained from the displayed finite route rather than from a selected limit or ambient compactness argument.

Finally replay the structural rows. The $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ readback expose the finite comparisons, the $\mathsf{Real}^{\uparrow}$ seal is read only after those comparisons, and $H, C, P, L_{\mathrm{mod}}$ transport, replay, source, and name the same packet. The route therefore reaches later uniform-continuity and compact-interval consumers only through the displayed finite modulus surface. □

Theorem 7827.8 (Compact interval uniform-continuity Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ *packet receives value comparisons only after the route*

$$\mathsf{LocatedInterval}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

has passed through the displayed finite-net and lower-bound rows N_ε *and* M*. In particular, the fixed-point consumer of chapter 1437 and the modulus-object consumer of chapter 2292 receive only this displayed seal boundary.*

Proof. Read the carrier rows in order. The located interval J fixes the endpoint surface, while the continuous-map row F fixes the graph and pointwise continuity data over that same interval.

The finite-net row N_ε and lower-bound fold M must be displayed before any uniform source tolerance is public. They are the only rows that turn centerwise pointwise data into one tolerance for the whole interval.

The remaining value comparisons pass through the stream windows W, regular readback Q, and real seal E. These are the only Real-facing rows available to consumers such as $\mathsf{CompactIntervalFixedPoint}^{\uparrow}$ and $\mathsf{CompactUniformContinuityModulus}^{\uparrow}$.

Consequently any consumer that bypasses $N_\varepsilon, M, W, Q, E$ has left the accepted packet. The chapter supplies no quotient real equality, selected limit, sequential compactness, general Heine–Borel compactness, or $\mathsf{Real}^{\uparrow}$ completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalUniformContinuity}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$ packet is generated from a $\mathsf{LocatedInterval}^{\uparrow}$ endpoint row, $\mathsf{ContinuousMap}^{\uparrow}$ pointwise-radius rows, a finite interval-net row, a rational lower-bound fold, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalUniformContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7827.1, Definition 7827.2, Definition 7827.4, Definition 7827.5, Definition 7827.6, Definition 7827.7, and Definition 7827.8 seed the interval-specific finite-net uniform-continuity route over located interval, continuous-map, stream-window, regular-readback, real-seal, compact-modulus extraction, fixed-point, and modulus-object consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalUniformContinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim general Heine–Borel compactness, sequential compactness, selected limits, quotient reals, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source lock, finite-net coverage, lower-bound exactness, window and seal nonescape, transport and replay stability, and TasteGate field faithfulness for BEDC.Derived.CompactIntervalUniformC

Chapter 7828

A Concrete Naming Certificate for $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$

Following Arzela and Ascoli, the $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ packet records the constructive finite-net route by which an equicontinuous family exposes a subsequence certificate without selecting an infinite host subsequence. It sits after the finite-net extraction boundary of chapter 7576, the equicontinuous-family carrier of chapter 4036, the compact source surface of chapter 60, the finite-window stream interface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the finite diagonal extraction certificate consumed by downstream compactness arguments; it is not open-cover compactness, a host function-space compactness theorem, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7828.1 (Ascoli equicontinuous subsequence carrier)**.** *An* $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, E, K, W, R, L, D, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$ *finite-net extraction row, exposing the finite centers, tolerance budgets, and value windows available to the diagonal read.*
2. *E is the* $\mathsf{EquicontinuousFamily}^{\uparrow}$ *row, recording one shared modulus route for the displayed family and compact source.*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row, read only through finite cover, located, or compact-metric certificates already visible to the packet.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected family indices, source centers, and target value observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the rational value windows in W.*
6. *L is the finite subsequence-ledger row: it records a displayed increasing list of selected indices for the inspected windows, not a host infinite subsequence.*
7. *D is the diagonal compatibility row, requiring each later window in L to refine the finite-net and equicontinuity data exposed by A, E, K, W, R.*

8. *H records componentwise* hsame *transport for the finite-net, equicontinuity, compact, stream, rational-readback, subsequence-ledger, diagonal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a finite compactness request through A, E, K, W, R, L, D to the downstream subsequence certificate.*
10. *P is the* Pkg *provenance over* $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$, $\mathsf{ArzelaAscoliFiniteNet}^{\uparrow}$, $\mathsf{EquicontinuousFamily}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, E, K, W, R, L, D, H, C, P, N$. It has no coordinate for a selected infinite subsequence, a host function-space limit, quotient equality of maps, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.AscoliEquicontinuousSubsequenceUp.AscoliEquicontinuousSubsequenceUp single carrier alignment`

Theorem 7828.2 (Ascoli equicontinuous subsequence obligations)**.** *For every accepted* AscoliEquicontinuousSubseq *carrier*

$$S = (A, E, K, W, R, L, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission; finite-net extraction exposure through A; equicontinuity exposure through E; compact-source exposure through K; finite-window exposure through W; regular rational readback through R; finite subsequence-ledger exposure through L; diagonal compatibility through D; componentwise transport through H; displayed replay through C; package provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 7828.1. The rows A, E, K, W, R, L, D are the only mathematical rows, and H, C, P, N are the only structural rows.

The finite-net and equicontinuity inputs are read first. The row A supplies the finite extraction windows of chapter 7576, while E supplies the shared family modulus and K supplies the compact source boundary.

The finite observation route then passes through W and R. These rows expose only displayed stream windows and regular rational readbacks before any Real-facing consumer reaches the terminal seal surface of chapter 38.

The subsequence information is the finite ledger L together with the diagonal compatibility row D. Because L records only displayed increasing finite lists, it cannot provide an infinite host subsequence or a choice-selected limit.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the excluded subsequence-choice, function-space limit, quotient equality, open-cover compactness, countable-choice, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7828.3 (Ascoli equicontinuous finite-net extraction)**.** *Every compactness-facing consumer of an accepted* $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ *carrier must read the displayed route*

$$\mathsf{ArzelaAscoliFiniteNet}^{\uparrow},\ \mathsf{EquicontinuousFamily}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow}$$

through the rows A, E, K, W, R before it may consume the finite subsequence-ledger row L and diagonal compatibility row D. The exported certificate is a finite-net subsequence surface for the inspected windows; it supplies no selected infinite subsequence, host function-space compactness theorem, quotient equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-net extraction row A. It forces the consumer to use the finite centers and tolerance budgets already named by chapter 7576.

Next read the equicontinuity and compact-source rows. The row E gives a single family modulus over the displayed compact source K, so the diagonal read cannot replace the shared modulus by memberwise radius choices.

The observation windows are then exposed through W and R. The row W names only finite stream coordinates, and R translates those observations through regular rational readback before any $\mathsf{Real}^{\uparrow}$ seal is available.

Only after those rows are fixed can L and D be consumed. They certify finite increasing-index windows and their compatibility with the same finite-net and equicontinuity data.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Because the carrier contains no infinite subsequence selector, host function-space compactness object, quotient map equality, countable-choice schedule, or ambient completeness theorem, none can be exported by the finite-net certificate. □

Falsifiable prediction: Every accepted $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ compactness-facing read factors through ArzelaAscoliFiniteNet, EquicontinuousFamily, Compact, StreamName, RegSeqRat, finite subsequence-ledger, diagonal-compatibility, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: arzela-ascoli-finite-net, equicontinuous-family, compact, streamname, regseqrat, real: $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite-net extraction, equicontinuity, compact-source, finite stream-window, regular rational readback, finite subsequence-ledger, diagonal compatibility, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}}$.

Constructive story: An $\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}$ packet is generated from an ArzelaAscoliFiniteNet row, an EquicontinuousFamily row, a Compact source row, StreamName finite windows, RegSeqRat readback, a finite subsequence ledger, diagonal compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7828.1, Definition 7828.2, and Definition 7828.3 seed the finite-net subsequence certificate consumed by compactness-facing Ascoli routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AscoliEquicontinuousSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subsequences, host function-space compactness, quotient equality of maps, open-cover compactness, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net extraction exposure, equicontinuity exposure, compact-source exposure, finite-window exposure, regular rational readback, finite subsequence-ledger exposure, diagonal compatibility, transport, replay, provenance, and local naming for BEDC.Derived.AscoliEquicontinuousSubsequenceUp.

Chapter 7829

A Concrete Naming Certificate for $\mathsf{BipolarTheorem}^{\uparrow}$

Following Bourbaki and Rockafellar on polar sets and the bipolar theorem in locally convex analysis, the $\mathsf{BipolarTheorem}^{\uparrow}$ packet records the finite BEDC surface by which a displayed convex row is compared with its polar-polar return. It sits after the convex carrier of chapter 208, the support-budget row of chapter 7505, the finite alternative boundary of chapter 6185, the separating-functional packet of chapter 7658, the vector-space source of chapter 47, and the scalar seal of chapter 38. The chapter names only finite polar handoff data; it does not assert host local convexity, a completed dual space, selected supporting functionals, quotient polar equality, or choice.

Definition 7829.1 (Bipolar theorem carrier)**.** *A* $\mathsf{BipolarTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, V, R, S, F, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{ConvexSet}^{\uparrow}$ *row naming the inspected convex set, its displayed membership tests, and the convex-combination ledger available to polar consumers.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row over which every vector, scalar, pairing, and finite affine-functional read is performed.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for all inequality levels, support comparisons, and polar-bound readbacks.*
4. *S is the* $\mathsf{SupportFunction}^{\uparrow}$ *row, supplying only the finite support-budget comparisons attached to inspected directions and witnesses.*
5. *F is the* $\mathsf{FarkasLemma}^{\uparrow}$ *row, supplying the finite alternative ledger used when a polar-bound failure is converted into a displayed multiplier obstruction.*
6. *E is the* $\mathsf{SeparatingHyperplane}^{\uparrow}$ *row, exposing the separating functional only as the finite vector, convex, scalar-level, Farkas, and witness rows already present in that sibling packet.*
7. *Q is the polar-polar handoff row. It lists the inspected point, the displayed polar tests, the finite support-budget comparisons, and the return comparison saying that the point is admitted by the carried convex row exactly through the visible certificate.*

8. *H records componentwise* hsame *transport for the convex, vector, real, support, Farkas, separation, polar-polar, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from convex membership and vector pairing through support budgets, finite alternatives, separating hyperplanes, and the terminal polar-polar return.*
10. *P is the* Pkg *provenance over* $\mathsf{BipolarTheorem}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{SupportFunction}^{\uparrow}$, $\mathsf{FarkasLemma}^{\uparrow}$, $\mathsf{SeparatingHyperplane}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BipolarTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, V, R, S, F, E, Q, H, C, P, N$. It has no coordinate for an ambient dual-space completion, an unbounded family of seminorms, quotient polar equality, selected separating functionals, host closure of convex sets, or choice.

Theorem 7829.2 (Bipolar theorem NameCert obligations)**.** *For every accepted* $\mathsf{BipolarTheorem}^{\uparrow}$ *carrier $B = (X, V, R, S, F, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BipolarTheorem}^{\uparrow}}$ *surface consists exactly of convex-set admission through X, vector-space admission through V, scalar sealing through R, finite support-budget exposure through S, finite-alternative handoff through F, separating-functional exposure through E, polar-polar return through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7829.1. The geometric source is exhausted by X, V, R, so every convex, vector, pairing, and scalar-level read is tied to the displayed rows.

Read the convex-duality siblings next. The support row S contributes only the finite budget surface of chapter 7505; the finite alternative row F contributes only the multiplier or obstruction boundary of chapter 6185; and the separation row E contributes only the displayed affine-functional witness ledger of chapter 7658.

The polar-polar row Q is therefore a handoff over already visible data. Rows H, C, P, N transport, replay, source, and name that same finite packet. Since no carrier coordinate stores host closure, a completed dual space, quotient polar equality, a selector for separating functionals, or choice, the listed rows exhaust the local NameCert obligations. □

Theorem 7829.3 (Bipolar theorem polar handoff)**.** *Every downstream convex-duality consumer of an accepted* $\mathsf{BipolarTheorem}^{\uparrow}$ *packet must read the polar-polar return through*

$$\mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{SupportFunction}^{\uparrow} \longmapsto \mathsf{FarkasLemma}^{\uparrow} \longmapsto \mathsf{SeparatingHyperplane}^{\uparrow}$$

over the shared $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *rows. The consumer receives only the finite convex row, displayed vector and scalar seals, support-budget comparisons, finite alternative boundary, separating-functional witness, polar-polar handoff row, componentwise transport, replay, provenance, and local name. It receives no detached bipolar theorem, host closure operation, quotient dual-space equality, selected support functional, or choice principle.*

Proof. Begin with the carried convex row X and the shared vector and scalar rows V, R. These rows fix the only vector, pairing, and inequality endpoints that may be inspected by a polar consumer.

The support route is then read through S. By chapter 7505, this exposes finite support-budget comparisons rather than a host supremum or a selected exposed point.

Next read the obstruction and separation rows. The $\mathsf{FarkasLemma}^{\uparrow}$ row F supplies a finite alternative boundary, and the $\mathsf{SeparatingHyperplane}^{\uparrow}$ row E packages any separating functional as displayed coefficient, scalar-level, and witness rows. Thus the polar-polar handoff Q can only cite the sibling certificate surface already visible in the packet.

Finally H, C, P, N preserve that route under transport, replay, provenance, and naming. Any consumer that replaces it by a detached closure theorem, completed dual-space equality, selected functional, or choice principle would require a carrier row absent from B. □

Closure status for $\mathsf{NameCert}_{\mathsf{BipolarTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{BipolarTheorem}^{\uparrow}$ packet is generated from a ConvexSetUp row, VecSpaceUp row, RealUp scalar seal, SupportFunctionUp support-budget row, FarkasLemmaUp finite alternative row, SeparatingHyperplaneUp witness row, polar-polar handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BipolarTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 7829.1, Definition 7829.2, and Definition 7829.3 seed the finite bipolar-theorem NameCert surface over convex-duality sibling rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BipolarTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close locally convex host closure, completed dual spaces, quotient polar equality, selected separating functionals, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support-budget exposure, finite-alternative handoff, separating-functional exactness, polar-polar return, structural transport, replay, provenance, and local naming for BEDC.Derived.BipolarTheoremUp.

Chapter 7830

A Concrete Naming Certificate for $\mathsf{ConnectedCompactInterval}^{\uparrow}$

Following Bishop and Bridges on constructive compact intervals, the $\mathsf{ConnectedCompactInterval}^{\uparrow}$ packet records the finite route by which a located compact interval supplies connectedness data without appealing to open-cover compactness. It sits after the located endpoint packet of chapter 394, the compact uniform-continuity packet of chapter 7827, the interval image-connected route of chapter 7542, the Real seal of chapter 38, the finite StreamName windows of chapter 126, and the RegSeqRat readback boundary of chapter 301. The packet names compact interval connectedness as displayed finite data; it does not assert open-cover compactness, selected subcovers, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7830.1 (Connected compact interval carrier)**.** *A* $\mathsf{ConnectedCompactInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (E, N, I, W, Q, R, H, C, P, L)$$

with the following displayed rows:

1. *E is the located interval endpoint row, recording the left endpoint, right endpoint, endpoint order, membership boundary, and located interval probes supplied by* $\mathsf{LocatedInterval}^{\uparrow}$*.*
2. *N is the compact finite-net row, recording the dyadic mesh, finite covering windows, mesh-radius certificate, and endpoint coverage consumed from* $\mathsf{CompactIntervalUniformContinuity}^{\uparrow}$*.*
3. *I is the interval image-connected route row, recording the path from interval data to connectedness reads through* $\mathsf{IntervalImageConnected}^{\uparrow}$*.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for endpoints, mesh points, bisection probes, and connectedness challenge reads.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those finite windows and rational endpoint comparisons.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint and image-value names, reached only after E, N, I, W, Q are displayed.*
7. *H records componentwise* hsame *transport for endpoints, finite nets, connectedness route, windows, readbacks, Real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay through the endpoint, finite-net, connectedness-route, window, readback, Real-seal, transport, provenance, and local certificate rows.*

9. *P is the* Pkg *provenance over* ConnectedCompactInterval$^{\uparrow}$, LocatedInterval$^{\uparrow}$, CompactIntervalUniformContinuity$^{\uparrow}$, IntervalImageConnected$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *L is the local* NameCert$_{\text{ConnectedCompactInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, N, I, W, Q, R, H, C, P, L$. It has no coordinate for open-cover compactness, selected subcovers, host image subsets, quotient real equality, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Theorem 7830.2 (Connected compact interval NameCert obligations)**.** *For every accepted* ConnectedCompactInter *carrier*

$$K = (E, N, I, W, Q, R, H, C, P, L),$$

the local NameCert$_{\text{ConnectedCompactInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for located endpoints, compact finite-net data, interval image-connected routing, finite windows, regular readbacks, Real sealing, transport, replay, provenance, and local naming;*
2. *endpoint exactness, requiring all interval-boundary reads to pass through the displayed* LocatedInterval$^{\uparrow}$ *row E;*
3. *finite-net exactness, requiring all compact interval mesh and coverage reads to pass through N rather than through an open-cover compactness principle;*
4. *connectedness-route exactness, requiring every connectedness read to pass through the interval image-connected route I;*
5. *window and readback exactness, requiring StreamName windows W and RegSeqRat readbacks Q before the terminal* Real$^{\uparrow}$ *seal R is inspected;*
6. *transport and replay locality, requiring H and C to preserve the same displayed rows componentwise;*
7. *nonescape, excluding open-cover compactness, selected subcovers, host image connectedness, quotient real equality, trichotomy, countable choice, ambient* Real$^{\uparrow}$ *completeness, Lean verification, and bridge checking.*

No connected compact interval obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7830.1. The accepted packet displays one endpoint row, one finite-net row, one connectedness-route row, finite windows, readbacks, a Real seal, and structural support.

Endpoint exactness is supplied by E. Every interval-boundary read uses the same located endpoints and membership boundary, so no separate host interval or quotient real representative is introduced.

Finite-net exactness is supplied by N. Mesh points, finite covering windows, and radius certificates are read as finite packet data, not as an open-cover compactness theorem or a selected subcover functional.

Connectedness-route exactness is supplied by I. The route delegates the connectedness read to the interval image-connected packet after the endpoint and finite-net rows are displayed.

Finally W, Q, R, H, C, P, L impose readback order and local naming. StreamName windows and RegSeqRat readbacks precede the Real seal, and the structural rows transport, replay, source, and name only the displayed carrier rows. □

Theorem 7830.3 (Connected compact interval route)**.** *Every connectedness read exported by an accepted* $\mathsf{ConnectedCompactInterval}^{\uparrow}$ *carrier factors through*

$$E, N \longmapsto I \longmapsto W, Q, R, H, C, P, L.$$

The route uses located interval endpoints, compact finite-net data, the interval image-connected handoff, finite StreamName windows, RegSeqRat readbacks, a Real seal, componentwise transport, displayed continuation replay, package provenance, and the local NameCert row. It exports no open-cover compactness claim.

Proof. Start with an accepted packet $K = (E, N, I, W, Q, R, H, C, P, L)$. The endpoint row E fixes the located interval boundary, and the finite-net row N fixes the compact mesh data available to the interval consumer.

The connectedness read must then pass through I. This row is the only connectedness coordinate in the carrier, and it points to the interval image-connected route rather than to a host connectedness theorem.

The downstream rows W, Q, R, H, C, P, L expose finite observations, rational readbacks, the terminal Real seal, transport, replay, provenance, and local naming. Since no row stores open-cover compactness or a selected subcover, the exported connectedness claim is exactly the displayed finite route. □

Theorem 7830.4 (Connected compact interval Real-seal nonescape)**.** *Every Real-facing seal read of an accepted* $\mathsf{ConnectedCompactInterval}^{\uparrow}$ *packet is downstream of the located endpoint row, compact finite-net row, interval image-connected route, finite-window row, and RegSeqRat readback row. The terminal* $\mathsf{Real}^{\uparrow}$ *row cannot be read as ambient Real completeness, quotient real equality, open-cover compactness, or a selected-subcover principle.*

Proof. The carrier places the Real seal at R after E, N, I, W, Q. Thus a Real-facing consumer first reads the located endpoints, finite compact mesh data, connectedness route, finite windows, and rational readbacks.

The structural rows preserve that order. Componentwise hsame transport and displayed Cont replay move the same packet through provenance and local naming; they add no independent completeness or compactness coordinate.

Therefore the Real seal is a downstream endpoint and image-value seal for the displayed finite route. It is not an escape hatch to open-cover compactness, quotient real equality, selected subcovers, trichotomy, choice, or ambient completeness. □

Falsifiable prediction: A $\mathsf{ConnectedCompactInterval}^{\uparrow}$ consumer that reads connectedness without the located endpoint row, compact finite-net row, interval image-connected route, StreamName windows, and RegSeqRat readbacks is not reading the accepted packet.

Independence witness: locatedinterval, compact-interval-uniform-continuity, interval-image-connected, streamname, regseqrat, real: none is bijective to $\mathsf{ConnectedCompactInterval}^{\uparrow}$ because this packet jointly carries located endpoints, compact finite-net data, connectedness routing, finite windows, rational readbacks, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ConnectedCompactInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{ConnectedCompactInterval}^{\uparrow}$ packet is generated from located interval endpoints, compact finite-net data, an interval image-connected route, StreamName windows, RegSeqRat readbacks, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConnectedCompactInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7830.1, Definition 7830.2, Definition 7830.3, and Definition 7830.4 seed the finite connected compact interval route over located endpoints, compact finite nets, interval image-connected routing, finite windows, rational readbacks, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ConnectedCompactInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, selected subcovers, host image connectedness, quotient real equality, trichotomy, countable choice, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, finite-net exactness, connectedness-route exactness, window and readback exactness, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.ConnectedCompactIntervalUp.

Chapter 7831

A Concrete Naming Certificate for $\mathsf{CanonicalLatentCompletion}^{\uparrow}$

The $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ packet realizes the selected two-state completion of Definition 9462.1838 as finite NameCert data. It refines the broader $\mathsf{LatentCompletion}^{\uparrow}$ surface of chapter 3521 by fixing the canonical latent rows L_{SS} and $L_{*|W}$, then routing the resulting target-monotone coverage through the finite trigger cube of chapter 7816 and the trigger-hypergraph reliability sibling of chapter 3657. The packet names a BEDC-selected completion witness; it is not an empirical transition model, not an unbounded latent search, and not a global graph-completion oracle.

Definition 7831.1 (Canonical latent completion carrier)**.** *A* $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{CanonicalLatentCompletion}(O, E, S, T, D, M, K, H, C, P, N)$$

with the following displayed rows:

1. *O is the observed module-state ledger inherited from the latent-completion source.*
2. *E is the exception ledger for the table-9, table-14, and table-28 target-monotone failures.*
3. *S is the selected-state row naming exactly L_{SS} and $L_{*|W}$ as the canonical latent completion.*
4. *T is the two-state target-monotone route row, recording the deep-branch and partial-boundary paths of Definition 9462.1839.*
5. *D is the directed rewrite-edge row consumed from the latent-completion packet.*
6. *M is the monotone coverage row verifying that every observed state reaches the target after the selected two states are admitted.*
7. *K is the finite trigger-cube and trigger-hypergraph reliability row, recording the sibling trigger constraints and energy-rank-table sibling reference as displayed finite support.*
8. *H records componentwise* hsame *transport for observed states, exception rows, selected states, target-monotone routes, rewrite edges, coverage, trigger support, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay through $O, E, S, T, D, M, K, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CanonicalLatentCompletion}^{\uparrow}$, $\mathsf{LatentCompletion}^{\uparrow}$, $\mathsf{FiniteTriggerCube}^{\uparrow}$, $\mathsf{TriggerHypergraphReliability}^{\uparrow}$, *the energy-rank-table sibling,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. N is the local $\mathsf{NameCert}_{\mathsf{CanonicalLatentCompletion}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, E, S, T, D, M, K, H, C, P, N$. It has no coordinate for an alternate latent pair, empirical transition dynamics, unbounded latent search, a hidden graph-completion oracle, or an equality principle outside the displayed rows.

Theorem 7831.2 (Canonical latent completion NameCert obligations)**.** *For every accepted* CanonicalLatentComple *carrier*

$$\mathsf{CanonicalLatentCompletion}(O, E, S, T, D, M, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CanonicalLatentCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for observed module states, exception rows, the selected two canonical latent states, target-monotone route rows, directed rewrite edges, monotone coverage, finite trigger support, componentwise transport, displayed replay, provenance, and local naming.*

Every accepted coverage consumer must read $S = \{L_{SS}, L_{*|W}\}$ before reading T, D, M, K, H, C, P, N. No obligation is stored in an alternate latent-pair selector, empirical transition model, unbounded latent search, hidden graph-completion oracle, or complete state-space claim.

Proof. Carrier admission is projection from Definition 7831.1. The accepted packet displays observed states, exception rows, selected latent states, target-monotone routes, rewrite edges, coverage, trigger support, and structural rows.

The selected-state row is decisive. Since S names exactly L_{SS} and $L_{*|W}$, a consumer omitting either state is not reading the accepted canonical carrier.

The route and coverage rows are T, D, M. They replay the deep-branch and partial-boundary paths, rebuild the finite rewrite-edge graph, and record coverage of every observed endpoint.

The trigger-support row K and the structural rows H, C, P, N preserve the same finite witness through sibling support, transport, replay, provenance, and local naming. None of these rows adds an alternate selector, empirical dynamics, unbounded search, graph oracle, or complete state-space claim. □

Theorem 7831.3 (Canonical latent completion selected-route coverage)**.** *Every target-monotone coverage read exported by an accepted* $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ *packet factors through*

$$O, E, S \longmapsto T, D, M \longmapsto K, H, C, P, N.$$

The selected-state row must expose both L_{SS} and $L_{*|W}$ before the coverage row is read, and the trigger-support row must keep the finite-trigger-cube, trigger-hypergraph-reliability, and energy-rank-table sibling references visible.

Proof. Start with O, E, S. The observed ledger and exception ledger identify the finite target-monotone failures, while the selected-state row supplies the two canonical latent states that answer the independent missing squares.

Next read T, D, M. The target-monotone route row records the two canonical paths, the directed rewrite-edge row rebuilds the finite graph, and the monotone coverage row records reachability for the observed endpoints.

Finally read K, H, C, P, N. The trigger-support row keeps the finite-trigger-cube, trigger-hypergraph-reliability, and energy-rank-table sibling support visible, and the structural rows transport, replay, source, and name the same finite carrier. □

Falsifiable prediction: Any canonical latent-completion consumer that omits either L_{SS} or $L_{*|W}$ fails to read the accepted $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ packet.

Independence witness: latent-completion, finite-trigger-cube, trigger-hypergraph-reliability, energy-rank-table: none is bijective to $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ because this packet fixes the selected two latent states, their target-monotone routes, rewrite coverage, trigger support, transport, replay, provenance, and local naming in one finite carrier.

The Lean follow-up must provide Nontrivial and FieldFaithful instances for $\mathsf{CanonicalLatentCompletion}^{\uparrow}$, separating the selected-state row from the route row, coverage row, trigger-support row, transport row, replay row, provenance row, and local naming row.

Closure status for $\mathsf{NameCert}_{\mathsf{CanonicalLatentCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{CanonicalLatentCompletion}^{\uparrow}$ packet is generated from observed module-state rows, exception rows, the selected states L_{SS} and $L_{*|W}$, target-monotone routes, directed rewrite edges, coverage rows, finite trigger support, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CanonicalLatentCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7831.1, Definition 7831.2, and Definition 7831.3 seed the finite canonical latent-completion witness over the selected two latent states, target-monotone routes, rewrite edges, coverage, trigger support, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CanonicalLatentCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close empirical transition dynamics, unbounded latent search, alternate latent-pair selection, complete state-space sampling, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selected-state exactness, target-monotone route exactness, rewrite-edge reachability, trigger-support exposure, Nontrivial and FieldFaithful instances, transport, replay, provenance, and local naming for BEDC.Derived.CanonicalLatentCompletionUp.

Chapter 7832

A Concrete Naming Certificate for $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$

Following Moore, Osgood, and Bishop–Bridges constructive analysis, the $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ packet records the classical limit-interchange theorem as finite NameCert data over displayed rectangular windows and uniform-tail evidence. It consumes the rectangular double-sequence carrier of chapter 6871, the uniform-tail endpoint route of chapter 463, the finite schedule discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the finite theorem handoff only; it is not a host function space, quotient limit, countable choice principle, selected two-parameter limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7832.1 (Moore-Osgood limit-interchange carrier)**.** *A* $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, U, S, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ *rectangular double-sequence row, exposing the two index schedules and the inspected finite rectangle.*
2. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *uniform-tail evidence row, binding one tail budget that is read before either iterated route reaches a limit handoff.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row, listing exactly the finite row, column, and tail requests opened by the interchange.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rectangular observations and the two iterated regular rational handoffs.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the active precision, rectangular tail budget, and dyadic slack used to compare the two routes.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal reached only after D, U, S, R, T have all been displayed.*
7. *H records componentwise* hsame *transport for the double-sequence row, uniform-tail evidence, schedule, readback, tolerance, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from rectangular requests to schedules, from schedules and uniform-tail evidence to regular readback, and from the dyadic tolerance ledger to the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$, $\mathsf{PringsheimDoubleSequence}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, U, S, R, T, E, H, C, P, N$. It has no coordinate for host function spaces, quotient equality of double sequences, countable choice, selected limiting representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.MooreOsgoodLimitInterchangeUp`

Theorem 7832.2 (Moore-Osgood limit-interchange NameCert obligations)**.** *For every accepted* $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ *carrier $M = (D, U, S, R, T, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MooreOsgoodLimitInterchan}}$ *surface consists exactly of carrier admission for the displayed* $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ *rectangle,* $\mathsf{UniformLimit}^{\uparrow}$ *tail evidence,* $\mathsf{StreamName}^{\uparrow}$ *schedules,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows; rectangular-window exactness through D; uniform-tail exactness through U; finite schedule exposure through S; regular readback through R; dyadic tolerance accounting through T; Real-seal nonescape through E; and structural preservation through H, C, P, N.*

Proof. Project the carrier in Definition 7832.1. The tuple lists every row available to a certificate consumer, so carrier admission is componentwise over the displayed rectangle, uniform tail, schedule, readback, tolerance, seal, and structural rows.

The analytic route is ordered by the finite rows. A consumer first reads D to fix the rectangular double-sequence window, then reads U and S to bind the uniform tail and the finite schedules that both iterated routes must share.

The readback and tolerance rows are downstream of that shared route. The row R records the regular rational observations, while T accounts for the precision and tail budget before E is exposed.

The structural rows preserve the same route. Componentwise transport, continuation replay, provenance, and local naming cannot introduce host function spaces, quotient limits, choice, selected representatives, or ambient completeness because no such coordinate is present in M. □

Theorem 7832.3 (Moore-Osgood Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ *packet factors through the finite route*

$$D, U, S \longmapsto R, T \longmapsto E, H, C, P, N.$$

Thus the classical Moore-Osgood interchange is exported only as a displayed rectangular-window and uniform-tail handoff from $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ *and* $\mathsf{UniformLimit}^{\uparrow}$ *data to regular rational readback and a terminal Real seal. The route exports no host function space, quotient limit, countable choice, selected two-parameter limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted packet and project its carrier rows. The Real seal E is not an entrance row: the packet first exposes the rectangular $\mathsf{PringsheimDoubleSequence}^{\uparrow}$ row D, the $\mathsf{UniformLimit}^{\uparrow}$ tail row U, and the finite schedule row S.

Apply Definition 7832.2. It forces the regular readback row R and the dyadic tolerance ledger T to be read only after the rectangle, uniform tail, and schedule rows have been displayed.

The seal and structural rows then package the same finite route. Since H, C, P, N transport, replay, source, and name only the listed rows, a completion-facing consumer receives the displayed factorization and no stronger host-level limiting principle. □

Falsifiable prediction: Every accepted $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ Real-facing read exposes a PringsheimDoubleSequence rectangle, a UniformLimit tail row, finite StreamName schedules, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, transport, continuation, provenance, and local naming before any endpoint is consumed.

Independence witness: pringsheim-double-sequence, uniformlimit, streamname, regseqrat, dyadicratcore, real: $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds rectangular double-sequence windows, one uniform-tail evidence row, finite schedules, regular readback, dyadic tolerance accounting, a terminal Real seal, transport, replay, provenance, and local naming in one theorem packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7832.1, Definition 7832.2, and Definition 7832.3 seed the finite Moore-Osgood limit-interchange route over rectangular windows, uniform tails, finite schedules, regular readback, dyadic tolerances, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MooreOsgoodLimitInterchangeUp`

Bridge status: none

Not claimed: This chapter does not close host function spaces, quotient limits, countable choice, selected two-parameter limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked NameCert obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, rectangular-window exactness, uniform-tail exactness, schedule exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, Real-seal nonescape, and structural transport for BEDC.Derived.MooreOsgoodLimitInterchangeUp.

Constructive story: A $\mathsf{MooreOsgoodLimitInterchange}^{\uparrow}$ packet is generated from a PringsheimDoubleSequence rectangle, UniformLimit tail evidence, StreamName schedules, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7833

A Concrete Naming Certificate for $\mathsf{BishopFanModulusBoundary}^{\uparrow}$

Following Brouwer and Bishop–Bridges finite fan analysis, the $\mathsf{BishopFanModulusBoundary}^{\uparrow}$ packet records the boundary object consumed when finite fan-bar data are handed to compact-uniform-continuity moduli. It sits after the finite fan-bar modulus carrier of chapter 4297, the fan theorem packet of chapter 400, and the finite fan theorem packet of chapter 5863. It realizes the compact finite-bar boundary used by chapter 9237 without adding selected infinite branches, open-cover compactness, countable choice, quotient map equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7833.1 (Bishop fan modulus boundary carrier)**.** *A* $\mathsf{BishopFanModulusBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, A, K, L, R, U, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite fan-bar source row, read through* $\mathsf{FiniteFanBarModulus}^{\uparrow}$ *and the fan theorem boundary.*
2. *A is the admitted finite-bar boundary row, recording the prefix depth, bar classifier, and coverage witness used by downstream compact consumers.*
3. *K is the compact finite-probe alignment row that matches fan prefixes with compact-source observations.*
4. *L is the local modulus ledger attached to the admitted fan leaves.*
5. *R is the positive rational lower-bound row obtained by finite recursion over the admitted leaves.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exposed after F, A, K, L, R have all been displayed.*
7. *H records componentwise* hsame *transport for the finite-bar, boundary, compact-probe, local-modulus, lower-bound, uniform-modulus, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$F, A, K, L \longmapsto R \longmapsto U.$$

9. *P is the* Pkg *provenance over* $\mathsf{BishopFanModulusBoundary}^{\uparrow}$, $\mathsf{FiniteFanBarModulus}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopFanModulusBoundary}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, A, K, L, R, U, H, C, P, N$.

Theorem 7833.2 (Bishop fan modulus boundary NameCert obligations)**.** *For every accepted* $\mathsf{BishopFanModulusBoundary}^{\uparrow}$ *carrier $B = (F, A, K, L, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopFanModulusBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission, finite fan-bar source exposure, admitted boundary coverage, compact finite-probe alignment, local modulus exposure, positive rational lower-bound extraction,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored in an open cover, selected infinite branch, countable-choice row, quotient function equality, selected limit, host compactness theorem, or ambient real-completeness principle.*

Proof. Project the carrier of Definition 7833.1. The rows $F, A, K, L, R, U, H, C, P, N$ are exactly the finite fan-bar source, boundary, compact-probe, local-modulus, lower-bound, handoff, transport, replay, provenance, and local naming coordinates.

The source and boundary obligations are forced by F and A. They expose the finite fan-bar and its admitted prefix boundary before any compact-uniform-continuity consumer can inspect a modulus row.

The rows K, L, R then align the finite boundary with compact-source observations, read the local moduli, and fold their positive rational radii into a lower-bound ledger. The handoff row U can consume only that displayed lower-bound row.

Transport, replay, provenance, and local naming preserve the same packet. Since the carrier has no coordinate for open-cover compactness, branch selection, countable choice, quotient function equality, selected limits, host compactness, or ambient real completeness, the listed rows exhaust the NameCert surface. □

Theorem 7833.3 (Bishop fan modulus boundary finite-fan handoff)**.** *Every compact-uniform-continuity read of an accepted* $\mathsf{BishopFanModulusBoundary}^{\uparrow}$ *packet must pass through the finite fan-bar modulus route of chapter 4297 before the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff is exposed. The handoff factors through*

$$\mathsf{FiniteFanBarModulus}^{\uparrow} \longmapsto \mathsf{BishopFanModulusBoundary}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}$$

with compact finite-probe alignment and positive rational lower-bound extraction displayed inside the boundary packet.

Proof. Begin with the obligations of Definition 7833.2. They require the finite fan-bar source row F and the admitted boundary row A before the local-modulus and lower-bound rows can be read.

The sibling finite fan-bar modulus chapter supplies the source route for F. The boundary packet then records the compact-probe row K, the local modulus ledger L, and the positive lower-bound row R that the compact-uniform-continuity consumer needs.

Only after those rows are displayed can U expose the uniform-modulus handoff. Thus the finite fan-bar data are consumed as a boundary object rather than as an open-cover compactness principle, branch selector, chosen limit, or quotient function equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFanModulusBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopFanModulusBoundary}^{\uparrow}$ packet is generated from finite fan-bar source rows, admitted prefix-boundary coverage, compact finite-probe alignment, local modulus ledgers, positive rational lower-bound extraction, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopFanModulusBoundary}\uparrow}$, seed)

Scope closed: Definition 7833.1, Definition 7833.2, and Definition 7833.3 seed the finite fan-bar boundary consumed by compact-uniform-continuity and UniformModulus rows.

Formal verification: FormalStatus(NameCert$_{\text{BishopFanModulusBoundary}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite branches, countable choice, quotient function equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite fan-bar source exposure, admitted boundary coverage, compact finite-probe alignment, local modulus exposure, rational lower-bound extraction, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopFanModulusBoundaryUp.

Chapter 7834

A Concrete Naming Certificate for $\mathsf{RealModulusNormalization}^{\uparrow}$

Following Bishop and Bridges on moduli of continuity and regular real names, the $\mathsf{RealModulusNormalization}^{\uparrow}$ packet records the finite normalization step that turns compact-uniform local modulus rows into Real-facing uniform-modulus ledger data. It sits over the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the regular rational readback of chapter 301, the finite schedule surface of chapter 126, the dyadic tolerance core of chapter 291, the compact source surface of chapter 129, the continuous-map pointwise modulus rows of chapter 130, and the $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369. It realizes the compact-uniform-continuity route of chapter 9237 by normalizing dyadic tolerances, regular rational readback, stream schedules, and uniform-modulus rows without selecting completed representatives or importing ambient completeness.

Definition 7834.1 (Real modulus normalization carrier)**.** *A* $\mathsf{RealModulusNormalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, D, S, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row whose local cover or finite-net observations are being normalized.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise modulus row over the same compact source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-normalization ledger, carrying dyadic requests, slack cells, and positive comparison budgets.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row for the inspected Real-facing windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after D, S, R have been displayed.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row whose tolerance-only ledger consumes the normalized Real-facing data.*
8. *H records componentwise* hsame *transport for compact-source, continuous-map, dyadic, stream, regular-readback, Real-seal, uniform-modulus, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$K, F, D, S, R \longmapsto E \longmapsto U.$$

10. *P is the* Pkg *provenance over* $\mathsf{RealModulusNormalization}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusNormalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, D, S, R, E, U, H, C, P, N$.

Theorem 7834.2 (Real modulus normalization NameCert obligations)**.** *For every accepted* RealModulusNormalizat *carrier $M = (K, F, D, S, R, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealModulusNormalization}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-source exposure, continuous-map pointwise modulus exposure, dyadic tolerance normalization, StreamName scheduling, RegSeqRat readback, Real seal exposure, UniformModulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is supplied by quotient real equality, a selected representative, countable choice, open-cover compactness, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7834.1. The rows $K, F, D, S, R, E, U, H, C, P, N$ are the only coordinates available to a compact-uniform-continuity consumer.

The compact-source and continuous-map obligations are K and F. They place every pointwise modulus read over the displayed compact metric source before any Real-facing normalization is inspected.

The normalization rows are D, S, R, E. They convert the tolerance request into dyadic comparison cells, inspect the scheduled finite windows, read regular rational data, and expose the terminal Real seal only after those rows are present.

The uniform-modulus handoff is U, preserved by H, C, P, N. Since no carrier coordinate stores quotient real equality, selected representatives, countable choice, open-cover compactness, selected limits, or ambient Real completeness, the stated rows exhaust the local NameCert surface. □

Theorem 7834.3 (Real modulus normalization tail stability)**.** *Every accepted* $\mathsf{RealModulusNormalization}^{\uparrow}$ *consumer that changes the inspected Real-facing tail must keep the same dyadic tolerance ledger, StreamName schedule, RegSeqRat readback, terminal Real seal, and UniformModulus handoff rows visible before the normalized modulus is read. Tail changes therefore factor through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow}$$

inside the displayed packet rather than through quotient stream equality, selected representatives, or ambient completeness.

Proof. Start from the carrier definition. A tail change can be observed only through the schedule row S and the dyadic tolerance row D, because the packet has no external stream or representative coordinate.

Read the regular rational row R and terminal Real seal E after the schedule and dyadic rows. These rows keep the normalized tail attached to displayed finite windows and regular readback rather than to quotient stream equality.

Finally expose U. The uniform-modulus handoff consumes the same normalized dyadic, stream, regular-readback, and Real-seal route under H, C, P, N, so the accepted consumer cannot insert selected representatives, countable choice, selected limits, open-cover compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusNormalization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealModulusNormalization}^{\uparrow}$ packet is generated from compact metric source rows, continuous-map pointwise modulus rows, dyadic tolerance normalization, StreamName schedules, RegSeqRat readback, a RealUp seal,

UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RealModulusNormalization}\uparrow}$, seed)

Scope closed: Definition 7834.1, Definition 7834.2, and Definition 7834.3 seed the Real-facing modulus normalization route consumed by compact-uniform-continuity and UniformModulus rows.

Formal verification: FormalStatus(NameCert$_{\text{RealModulusNormalization}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, countable choice, open-cover compactness, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, continuous-map modulus exposure, dyadic tolerance normalization, StreamName scheduling, RegSeqRat readback, Real seal exposure, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealModulusNormalizationUp.

Chapter 7835

A Concrete Naming Certificate for $\mathsf{FiniteDyadicMesh}^{\uparrow}$

Following Bishop and Bridges on finite partitions of compact real intervals, the $\mathsf{FiniteDyadicMesh}^{\uparrow}$ packet records the finite dyadic interval mesh used by L10 Real and Completion consumers before any compactness theorem or selected limit is available. It sits over the endpoint arithmetic of chapter 291, the located-cell surface of chapter 394, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite partition carrier, not an open-cover compactness principle, a host list equality theorem, countable choice, quotient-real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7835.1 (Finite dyadic interval mesh carrier)**.** *A* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, Z, C, W, R, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the lower endpoint ledger, a finite row of* $\mathsf{DyadicRatCore}^{\uparrow}$ *names for the left endpoints inspected by the mesh.*
2. *Z is the upper endpoint ledger, a finite row of* $\mathsf{DyadicRatCore}^{\uparrow}$ *names for the matching right endpoints, with each row read at the same dyadic scale as its lower endpoint.*
3. *C is the finite* $\mathsf{LocatedInterval}^{\uparrow}$ *cell table, assigning to each displayed adjacent endpoint pair the located interval cell consumed by later Real or Completion reads.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records the endpoint, adjacency, and cell observations requested by the consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained after W has exposed the endpoint and cell windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the finite mesh windows and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for endpoint, cell, window, readback, seal, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay of every accepted mesh read through*

$$A, Z, C, W \longmapsto R \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FiniteDyadicMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicMesh}^{\uparrow}}$ *row.*

The classifier compares accepted mesh packets only through $A, Z, C, W, R, E, H, K, P, N$. It has no coordinate for host list equality, selected refinement trees, countable choice, open-cover compactness, quotient real equality, host real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7835.2 (Finite dyadic mesh NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *carrier*

$$M = (A, Z, C, W, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDyadicMesh}^{\uparrow}}$ *surface consists exactly of lower endpoint exposure, upper endpoint exposure, finite located-cell admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window coverage,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every L10 Real or Completion consumer of the mesh must display those rows before it may read the terminal seal.*

Proof. Project the carrier of Definition 7835.1. The only endpoint data are the two finite dyadic ledgers A, Z, and the only cell data are the located interval rows C.

The finite observation row W records the requested endpoint and cell windows. The readback row R is therefore downstream of the displayed mesh observations, not an independent list selector or completed subdivision tree.

The Real-facing output is the seal row E, and it appears only after R. The structural rows H, K, P, N transport, replay, source, and name the same finite route without adding a second Real, Completion, compactness, or equality coordinate.

Thus the listed rows exhaust the local NameCert surface, and any consumer using host list equality, countable choice, open-cover compactness, quotient real equality, selected limits, or ambient completeness has left the accepted packet. □

Theorem 7835.3 (Finite dyadic mesh subdivision induction)**.** *Let $M = (A, Z, C, W, R, E, H, K, P, N)$ be an accepted* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *carrier. Suppose a displayed finite subdivision step replaces one located dyadic cell in C by its two adjacent located dyadic subcells, with the new endpoints read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and the new cells admitted through* $\mathsf{LocatedInterval}^{\uparrow}$*. Then the resulting finite mesh read still factors through the route*

$$A, Z, C, W \longmapsto R \longmapsto E$$

with the same transport, replay, provenance, and local naming rows. Induction over displayed finite subdivision steps never invokes host natural-number recursion, host list equality, selected infinite branches, countable choice, open-cover compactness, quotient real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The base case is the accepted carrier itself. By Definition 7835.2, every visible read passes through the endpoint ledgers, located cells, finite windows, regular readback, and Real seal.

For one subdivision step, the replacement cell contributes only two new endpoint reads through $\mathsf{DyadicRatCore}^{\uparrow}$ and two new located-cell rows through $\mathsf{LocatedInterval}^{\uparrow}$. The finite window row W records those displayed reads before R is available.

Now iterate over the displayed subdivision history inside the finite BHist packet. Each step rewrites only the finite endpoint and cell rows already named by A, Z, C; the downstream window, readback, and seal route remains W, R, E.

The structural rows H, K, P, N preserve that route under transport, replay, provenance, and local naming. Since the induction ranges only over displayed finite subdivision entries, no host recursion principle, list equality, infinite branch, choice selector, compactness theorem, quotient equality, selected limit, or ambient completeness coordinate is introduced. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDyadicMesh}^{\uparrow}$ Real or Completion read must expose dyadic endpoint rows, located interval cells, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the mesh is consumed.

Independence witness: dyadicratcore, locatedinterval, streamname, regseqrat, real: $\mathsf{FiniteDyadicMesh}^{\uparrow}$ is not bijective to any listed sibling because it binds two endpoint ledgers, a located-cell table, finite observation windows, regular readback, terminal Real seal, transport, replay, provenance, and local naming as one finite mesh certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDyadicMesh}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint ledgers, a finite LocatedInterval cell table, a StreamName finite-window row, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7835.1, Definition 7835.2, and Definition 7835.3 seed the finite dyadic mesh route over endpoint ledgers, located cells, finite windows, regular readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDyadicMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host list equality, selected refinement trees, countable choice, open-cover compactness, quotient real equality, host real equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint exposure, located-cell admission, finite StreamName coverage, RegSeqRat readback, Real-seal nonescape, subdivision induction, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDyadicMeshUp.

Chapter 7836

A Concrete Naming Certificate for $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$

Following Bishop and Bridges and standard functional analysis, the $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$ packet records the scalar read $f \mapsto f(x)$ as finite NameCert data over a compact displayed source and a continuous real-valued map. It reads compactness through chapter 60, continuity through chapter 130, scalar endpoints through chapter 38, metric support through chapter 4230, and dual-facing scalar-functional rows through chapter 5790 and chapter 2265. The packet names only displayed point evaluation and its boundedness ledger; it does not introduce a host function space, quotient equality of maps, selected norm-attaining witness, or bridge theorem.

Definition 7836.1 (Bounded point-evaluation functional carrier)**.** *For a displayed compact metric source row K and a continuous real-valued map row F, a* $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}(K, F)$ *carrier is a finite* BHist *packet*

$$\mathcal{E} = (K, F, X, V, B, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, including the underlying* $\mathsf{Met}^{\uparrow}$ *carrier and the finite compactness ledger consumed by uniform and dual-facing reads.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}(K, \mathsf{Real}^{\uparrow})$ *row for the real-valued input map.*
3. *X is the point row, naming the displayed element of the compact source.*
4. *V is the evaluation readback row, recording the scalar endpoint $F(X)$ as a* $\mathsf{Real}^{\uparrow}$ *row.*
5. *B is the boundedness ledger, recording that the point-evaluation read is bounded by the displayed scalar-control surface supplied by the compact source and continuous-map rows.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal for the value and bound endpoints read by V and B.*
7. *H records componentwise* hsame *transport for the compact source, continuous real-valued map, point row, evaluation readback, boundedness ledger, scalar seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point-evaluation request through $K, F, X, V, B, S, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{BanachDual}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, F, X, V, B, S, H, C, P, N$. It has no coordinate for an ambient function space, quotient equality of continuous maps, unrestricted Banach-dual object, selected representative, or checked standard bridge.

Theorem 7836.2 (Bounded point-evaluation functional NameCert obligations)**.** *For every accepted* $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}(K, F)$ *carrier*

$$\mathcal{E} = (K, F, X, V, B, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}}$ *surface consists exactly of compact-source admission, continuous real-valued map admission, point-row exposure, evaluation readback, boundedness ledger exposure, RealUp value-and-bound sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape from host function-space or quotient-dual objects. A Banach-dual or bounded-functional consumer may inspect the rows $K, F, X, V, B, S, H, C, P, N$, but it cannot replace them by an ambient evaluation operator without displaying those rows.*

Proof. Project the carrier rows. The source of the read is the compact metric row K, the scalar-valued map is the continuous row F, and the inspected source element is the point row X.

The evaluation readback row V then records the RealUp scalar endpoint $F(X)$. The boundedness ledger B records the finite control needed by a scalar-functional consumer, while the seal S keeps the value and bound endpoints inside the same RealUp surface.

Transport and replay preserve these displayed rows through H and C. The provenance row P exposes exactly the compact, continuous-map, scalar, metric, bounded-functional, and Banach-dual neighbours that may consume the packet.

No remaining carrier coordinate names a host function space, quotient equality of maps, selected representative, unrestricted dual object, or checked bridge. Hence the displayed rows exhaust the local NameCert obligations. □

Theorem 7836.3 (Bounded point-evaluation dual handoff)**.** *Every accepted* $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}(K$ *read exported to a* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *or* $\mathsf{BanachDual}^{\uparrow}$ *consumer factors through the finite route*

$$\mathsf{Compact}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BoundedPointEvaluationFunctional}^{\uparrow}.$$

The route displays the compact source, continuous real-valued map, point row, RealUp evaluation endpoint, boundedness ledger, transport, replay, provenance, and local naming before any dual-facing scalar-functional read is consumed.

Proof. Begin with an accepted packet $\mathcal{E} = (K, F, X, V, B, S, H, C, P, N)$. The compact source and metric support are read through K, while the scalar-valued continuity data are read through F.

The point row X and evaluation row V force the scalar read to be the displayed endpoint $F(X)$. The boundedness ledger B and RealUp seal S then provide the finite scalar-control surface that a bounded-functional or Banach-dual consumer may inspect.

Finally, H, C, P, N transport, replay, source, and name the same rows. Since no host evaluation operator, quotient function class, selected representative, or bridge theorem is present, the exported handoff remains the displayed point-evaluation NameCert route. □

Falsifiable prediction: Every accepted $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$ read displays a compact source, continuous real-valued map, point row, RealUp evaluation endpoint, boundedness

ledger, scalar seal, transport, replay, provenance, and local NameCert row before any bounded-functional or Banach-dual consumer reads the scalar value.

Independence witness: compact, continuousmap, real, metricspace, boundedlinearfunctional, and banachdual: no listed sibling is bijective to $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$ because this packet jointly stores the point row, evaluation readback, boundedness ledger, scalar seal, transport, replay, provenance, and local naming as one finite point-evaluation surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}$ packet is generated from a displayed compact metric source, a continuous real-valued map row, a point row, an evaluation readback row, a boundedness ledger, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7836.1, Definition 7836.2, and Definition 7836.3 seed the finite point-evaluation carrier over compact, continuous-map, RealUp, metric, bounded-functional, and Banach-dual rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedPointEvaluationFunctional}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function spaces, quotient equality of maps, selected representatives, unrestricted Banach-dual objects, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, continuous real-valued map admission, point-row exposure, evaluation readback, boundedness ledger exactness, RealUp sealing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.BoundedPointEvaluationFunctionalUp.

Chapter 7837

A Concrete Naming Certificate for $\mathsf{RegulatedPrimitive}^{\uparrow}$

Following Saks and Bishop–Bridges on regulated functions and primitive integration, the $\mathsf{RegulatedPrimitive}^{\uparrow}$ packet records a finite primitive-window object for a regulated integral source. It sits after the regulated-integral rows of chapter 1557, the gauge-integral handoff of chapter 1999, the dyadic tolerance surface of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite family of primitive windows; it is not a host antiderivative, not a quotient of functions, not a global selection of primitives, and not an ambient completeness claim for $\mathsf{Real}^{\uparrow}$.

Definition 7837.1 (Regulated primitive carrier)**.** *A* $\mathsf{RegulatedPrimitive}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{RegulatedPrimitive}(I, G, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the regulated integral source row, naming the interval, integrand window, and finite regulated-integral ledger consumed from* $\mathsf{RegulatedIntegral}^{\uparrow}$*.*
2. *G is the gauge and integral handoff row, recording the compatible* $\mathsf{GaugeIntegral}^{\uparrow}$ *route whenever the same primitive window is read through tagged subdivisions.*
3. *W is the primitive-window row, a finite ordered list of subintervals with basepoint, endpoint, orientation, and local integral-read data.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row controlling endpoint brackets, window overlap comparisons, and the local error budget for adjacent primitive reads.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the windowed step sums and gauge sums into regular rational names.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, G, W, D, R have been read.*
7. *H records componentwise* hsame *transport for the regulated source, gauge handoff, primitive windows, dyadic tolerances, regular rational readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay along the route from regulated integral source to primitive window, then through gauge handoff, dyadic tolerance, regular rational readback, and real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedPrimitive}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedPrimitive}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, G, W, D, R, E, H, C, P, N$. It has no coordinate for a host antiderivative, quotient function equality, an unrestricted primitive selector, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegulatedPrimitiveUp.RegulatedPrimitiveTasteGate single carrier alignment`

Theorem 7837.2 (Regulated primitive NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedPrimitive}^{\uparrow}$ *carrier*

$$\mathsf{RegulatedPrimitive}(I, G, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegulatedPrimitive}^{\uparrow}}$ *surface consists exactly of carrier admission for the regulated integral source, gauge/integral handoff, finite primitive windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Every accepted primitive consumer must read the finite window row W before reading D, R, E, H, C, P, N. No obligation is stored in a host antiderivative, a quotient of functions, a selected global primitive, a measure-completion object, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Proof. Carrier admission is projection from Definition 7837.1. The accepted packet displays the regulated source, gauge handoff, primitive windows, tolerance ledger, rational readback, real seal, transport, replay, provenance, and local naming rows.

The primitive-window row is decisive. It lists the basepoint, endpoint, orientation, and local integral read for each inspected subinterval, so a consumer omitting W is not reading the accepted primitive carrier.

The rows D, R, E then control the analytic handoff. The dyadic tolerance row compares adjacent windows and endpoint brackets, the regular rational row records the finite readback, and the real seal is available only after those rows have been consumed.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7837.3 (Regulated primitive integral handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{RegulatedPrimitive}^{\uparrow}$ *packet factors through*

$$I, G, W \longmapsto D, R \longmapsto E, H, C, P, N.$$

Thus the regulated integral source, gauge/integral handoff, and primitive-window row are present before any regular rational or real-facing primitive value is exposed.

Proof. Start with the carrier of Definition 7837.1. The rows I and G identify the regulated-integral and gauge-integral sources, while W binds those sources to finite primitive windows.

Next consume D and R. The dyadic tolerance row fixes endpoint brackets and overlap comparisons, and the regular rational row reads the windowed sums as rational names. These rows are the only bridge from window data toward a real-facing value.

Finally consume E, H, C, P, N. The real seal, transport, continuation replay, provenance, and local naming rows preserve the same order of inspection. Since no host antiderivative or selected global primitive appears in the carrier, every accepted real-facing primitive read factors through the displayed finite handoff. □

Falsifiable prediction: Any primitive consumer that reads a $\mathsf{Real}^{\uparrow}$ value without first reading I, G, W, D, R fails to read the accepted $\mathsf{RegulatedPrimitive}^{\uparrow}$ packet.

Independence witness: regulated-integral, gauge-integral, dyadic-rational-core, regular-rational-readback, and real seal: none is bijective to $\mathsf{RegulatedPrimitive}^{\uparrow}$ because this packet binds those source rows to finite primitive windows, overlap tolerances, readback, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedPrimitive}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulatedPrimitive}^{\uparrow}$ packet is generated from a regulated integral source row, gauge/integral handoff row, finite primitive-window row, DyadicRatCore tolerance row, RegSeqRat readback row, Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulatedPrimitive}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7837.1, Definition 7837.2, and Definition 7837.3 seed the finite primitive-window route over regulated integral source, gauge handoff, dyadic tolerance, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulatedPrimitive}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RegulatedPrimitiveUp.RegulatedPrimitiveTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close host antiderivatives, quotient function equality, selected global primitive families, measure completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, primitive-window exactness, gauge/integral handoff exactness, DyadicRatCore tolerance exposure, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedPrimitiveUp.

Chapter 7838

A Concrete Naming Certificate for $\mathsf{KnuthBendixCompletion}^{\uparrow}$

Following Knuth and Bendix, the $\mathsf{KnuthBendixCompletion}^{\uparrow}$ packet records the finite critical-pair completion route by which oriented rewrite rules, a well-founded reduction ordering, and residual join witnesses are packaged as NameCert data. It is a traditional completion-theory neighbor of the MetaCIC confluence route: the packet reads the critical-path pressure of chapter 765, the finite parallel-diamond frontier of chapter 4238, and the local critical-pair boundary of chapter 2212. The chapter names a finite completion ledger; it does not claim global termination, full Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Definition 7838.1 (Knuth–Bendix completion carrier)**.** *A* $\mathsf{KnuthBendixCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (R, O, C, S, J, U, H, T, P, N)$$

with the following displayed rows:

1. *R is the finite rewrite-rule row, listing oriented rules $l_i \to r_i$ and the finite signature cells on which the rules are admitted.*
2. *O is the well-founded reduction ordering row, recording the displayed decrease checks used to orient each accepted equation.*
3. *C is the critical-pair ledger row, listing every displayed overlap inspected by the completion packet.*
4. *S is the completion-step row, recording whether an overlap is joined, oriented into a new displayed rule, or routed to an obstruction.*
5. *J is the residual join row, listing the finite reduct witnesses consumed when a critical pair is declared locally joinable.*
6. *U is the obstruction row, naming unorientable equations, failed decrease checks, unresolved joins, and resource bounds as visible obstructions rather than hidden proof debt.*
7. *H records componentwise* hsame *transport for rewrite rules, ordering checks, critical-pair rows, completion steps, residual joins, obstructions, replay, provenance, and local naming rows.*
8. *T records displayed* Cont *replay by which a completion consumer reads*

$$R, O, C, S, J, U$$

before any confluence-facing handoff is made.

9. *P is the* Pkg *provenance over* $\mathsf{KnuthBendixCompletion}^{\uparrow}$*, finite rewrite rules, well-founded ordering rows, critical-pair ledgers, completion steps, residual joins, obstruction rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{KnuthBendixCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary term rewriting systems, external termination proofs, global Church–Rosser, quotient term equality, evaluator equality, subject reduction, MetaCIC kernel consistency, or unchecked residual-substitution discharge.

Theorem 7838.2 (Knuth–Bendix critical-pair resolution)**.** *Let $K = (R, O, C, S, J, U, H, T, P, N)$ be an accepted* $\mathsf{KnuthBendixCompletion}^{\uparrow}$ *carrier. Every critical pair consumed from K is resolved only through the displayed route*

$$C \longmapsto S \longmapsto J, U.$$

A row of S may certify a local join by pointing to J, may orient a new displayed rule by pointing back to the decrease checks in O, or may expose an obstruction in U. No consumer may read the route as full Church–Rosser, arbitrary termination, quotient term equality, evaluator equality, subject reduction, or MetaCIC kernel consistency.

Proof. Project the carrier of Definition 7838.1. The only critical-pair ledger is C, the only completion-step ledger is S, the only residual join ledger is J, and the only obstruction ledger is U.

A locally joinable pair is therefore witnessed by a row of S whose target is a displayed residual join in J. An oriented equation is witnessed by a row of S whose target is a displayed decrease check in O, and an unresolved pair is witnessed by a row of S whose target is the obstruction row U.

Rows H, T, P, N transport, replay, source, and name the same finite route. Since the carrier contains no global termination theorem, Church–Rosser theorem, quotient equality, evaluator equality, subject-reduction row, or kernel-consistency certificate, none of those claims can be exported by a critical-pair consumer. □

Theorem 7838.3 (Knuth–Bendix NameCert obligations)**.** *For every accepted* $\mathsf{KnuthBendixCompletion}^{\uparrow}$ *carrier*

$$K = (R, O, C, S, J, U, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KnuthBendixCompletion}^{\uparrow}}$ *surface consists exactly of rewrite-rule admission, well-founded ordering checks, critical-pair ledgering, completion-step ledgering, residual join exposure, obstruction exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7838.1. It exposes the ten rows $R, O, C, S, J, U, H, T, P, N$ and no hidden row.

The rule row R and ordering row O provide the only source for oriented rewrite rules. The critical-pair row C and step row S provide the only source for completion progress.

The residual join row J and obstruction row U exhaust the possible displayed outcomes for inspected overlaps. Finally, H, T, P, N carry transport, replay, provenance, and local naming for those same rows. Thus the listed obligations are exactly the local NameCert surface. □

Theorem 7838.4 (Knuth–Bendix MetaCIC frontier handoff)**.** *The* KnuthBendixCompletion$^{\uparrow}$ *packet is a finite completion neighbor for the MetaCIC confluence frontier. A MetaCIC-facing consumer may compare its critical-pair ledger to chapter 2212 and its obstruction rows to chapter 4238, but the handoff remains a local finite completion ledger controlled by the critical-path boundary of chapter 765.*

Proof. Read the packet through Definition 7838.2. Its critical-pair rows are finite ledger entries, and each inspected row is sent either to a residual join, an oriented rule backed by the displayed ordering check, or an obstruction.

The MetaCIC critical-pair boundary supplies a sibling finite ledger for confluence audit rows, while the parallel-diamond frontier supplies the residual-frontier and obstruction-facing handoff. The critical-path chapter is the upstream route that keeps these consumers from treating a local completion row as a kernel-wide confluence theorem.

Therefore the comparison is a route comparison between finite NameCert packets. It does not add global termination, full Church–Rosser, subject reduction, evaluator equality, quotient equality, residual-substitution compatibility, or kernel consistency. □

Falsifiable prediction: Every accepted KnuthBendixCompletion$^{\uparrow}$ packet exposes finite rewrite rules, well-founded ordering checks, critical-pair ledger rows, completion-step rows, residual join rows, obstruction rows, transport, replay, provenance, and local NameCert rows before a completion consumer reads the packet.

Independence witness: Nearest siblings: MetaCICCriticalPath, MetaCICParallelDiamond-Frontier, and MetaCICConfluenceCriticalPairBoundary. None is bijective to KnuthBendixCompletion$^{\uparrow}$ because this packet jointly carries traditional rewrite rules, reduction-ordering checks, completion-step outcomes, residual joins, obstructions, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{KnuthBendixCompletion}^{\uparrow}}$**.**

Constructive story: A KnuthBendixCompletion$^{\uparrow}$ packet is generated from finite rewrite-rule rows, well-founded reduction-ordering checks, critical-pair ledger rows, completion-step rows, residual join rows, obstruction rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{KnuthBendixCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7838.1, Definition 7838.2, Definition 7838.3, and Definition 7838.4 seed the finite completion route through rewrite rules, ordering checks, critical pairs, completion steps, residual joins, obstructions, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{KnuthBendixCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary termination, full Church–Rosser, subject reduction, evaluator equality, quotient term equality, residual-substitution compatibility, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, ordering decrease rows, critical-pair coverage, completion-step locality, residual join exposure, obstruction exposure, transport, replay, provenance, and local naming for BEDC.Derived.KnuthBendixCompletionUp.

Chapter 7839

A Concrete Naming Certificate for $\mathsf{FiniteModulusTransfer}^{\uparrow}$

Following Bishop's finite-net reading of compact uniform continuity, the $\mathsf{FiniteModulusTransfer}^{\uparrow}$ packet records the finite transfer by which a compact source, a continuous-map row, and local modulus witnesses are folded into one tolerance-indexed uniform-modulus handoff. It concretizes the finite modulus branch of chapter 9237 beside the compact source of chapter 129, the continuous-map carrier of chapter 130, the uniform-modulus consumer of chapter 369, and the real-seal route of chapter 38. The packet is a transfer ledger, not an open-cover theorem, selected-subcover principle, host equality of functions, or $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 7839.1 (Finite modulus transfer carrier)**.** *A* $\mathsf{FiniteModulusTransfer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, L, G, B, U, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, listing the inspected probes and their cover relation to source requests.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose local continuity data is being transferred.*
3. *L is the local modulus row, assigning displayed pointwise tolerance witnesses to the finite probe list.*
4. *G is the finite gauge-transfer row, recording the finite comparisons that move each local witness to a common tolerance request.*
5. *B is the lower-bound fold row, producing the finite candidate selected for the uniform handoff from the displayed gauge ledger.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row reached only after K, F, L, G, B have been displayed.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the transferred tolerance value, read only as a seal on the finite fold and not as a completeness theorem.*
8. *H records componentwise* hsame *transport for the compact source, continuous-map row, local modulus row, gauge-transfer row, lower-bound fold, uniform handoff, real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of every transfer query through*

$$K, F, L, G, B \longmapsto U, R.$$

10. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusTransfer}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusTransfer}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, external subcover choice, host-level function equality, quotient real equality, countable choice, trichotomy, Lean verification, or bridge credentials.

Theorem 7839.2 (Finite modulus transfer obligations)**.** *For every accepted* $\mathsf{FiniteModulusTransfer}^{\uparrow}$ *carrier*

$$M = (K, F, L, G, B, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteModulusTransfer}^{\uparrow}}$ *surface consists exactly of compact finite-net source admission, continuous-map admission, local modulus exposure, finite gauge transfer, lower-bound folding, uniform-modulus handoff, real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7839.1. The displayed rows are exactly $K, F, L, G, B, U, R, H, C, P, N$.

Rows K and F provide the source and map data. Row L exposes the local modulus witnesses on the finite probe list, and row G records the finite comparisons that transfer those witnesses to a common tolerance request.

The lower-bound fold B is the only row that selects a transfer candidate, while U and R are downstream handoffs. Rows H, C, P, N only transport, replay, source, and name the displayed route. Hence the listed rows exhaust the local NameCert surface. □

Theorem 7839.3 (Finite modulus transfer handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *output exported by an accepted* $\mathsf{FiniteModulusTransfer}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, L, G, B \longmapsto \mathsf{UniformModulus}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The output is therefore a finite transfer from compact-source probes and local modulus witnesses to a uniform-modulus handoff. It is not an arbitrary open-cover compactness theorem, selected-subcover principle, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or bridge checking.

Proof. Start with the source rows K and F from Definition 7839.1. They display the compact finite-net probes and the continuous-map row before any modulus output is available.

The local modulus row L and gauge-transfer row G are read next. They record finitely many local witnesses and the comparisons that make those witnesses comparable under the requested tolerance.

Only after the lower-bound fold B has been displayed can U and R be consumed. Since H, C, P, N merely transport, replay, source, and name this route, no excluded compactness, selection, equality, choice, verification, or bridge datum is exported. □

Falsifiable prediction: Every accepted $\mathsf{FiniteModulusTransfer}^{\uparrow}$ packet exposes compact finite-net source rows, ContinuousMap rows, local modulus rows, gauge-transfer rows, lower-bound fold rows,

UniformModulus handoff rows, Real seal rows, transport, replay, provenance, and local NameCert rows before a uniform-modulus consumer reads the packet.

Independence witness: Nearest siblings: CompactMetric, ContinuousMap, UniformModulus, Real, CompactModulusEvaluation, and CompactIntervalUniformContinuity. None is bijective to $\mathsf{FiniteModulusTransfer}^{\uparrow}$ because this packet isolates the finite transfer ledger from local modulus witnesses through gauge comparison and lower-bound folding into a uniform-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusTransfer}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusTransfer}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap rows, local modulus rows, finite gauge-transfer rows, lower-bound fold rows, UniformModulus handoff rows, Real seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusTransfer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7839.1, Definition 7839.2, and Definition 7839.3 seed the finite compact-source, continuous-map, local-modulus, gauge-transfer, lower-bound, uniform-modulus, real-seal, transport, replay, provenance, and local naming route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusTransfer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host equality of functions, quotient real equality, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source stability, continuous-map stability, local modulus exposure, gauge-transfer locality, lower-bound fold exactness, uniform-modulus handoff, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusTransferUp.

Chapter 7840

A Concrete Naming Certificate for $\mathsf{QuasiCauchySequence}^{\uparrow}$

Following Bishop and Bridges on constructive real sequences, the $\mathsf{QuasiCauchySequence}^{\uparrow}$ packet records the adjacent-difference boundary of a real sequence as finite BEDC NameCert data. It sits on the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives later Real and Completion arguments a sequence frontier where adjacent gaps vanish without asserting the full Cauchy condition, selecting limits, quotienting streams, invoking countable choice, or claiming ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7840.1 (Quasi-Cauchy sequence carrier)**.** *A* $\mathsf{QuasiCauchySequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, W, D, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the inspected real sequence by finite windows.*
2. *W is the adjacent-window schedule row exposing each displayed pair (x_n, x_{n+1}).*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare adjacent differences.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational difference stream attached to the displayed windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for each inspected adjacent distance value.*
6. *A is the adjacent-difference ledger, recording that every accepted tolerance request is eventually met by the displayed adjacent rows.*
7. *H records componentwise* hsame *transport for the stream, schedule, dyadic, regular-rational, Real-seal, adjacent-ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a quasi-Cauchy request through S, W, D, R, E, A, H.*
9. *P is the* Pkg *provenance over* $\mathsf{QuasiCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiCauchySequence}^{\uparrow}}$ *row.*

The classifier accepts a sequence read only through $S, W, D, R, E, A, H, C, P, N$. It has no coordinate for arbitrary tail-pair Cauchy comparison, selected limit, quotient stream equality, countable-choice schedule, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7840.2 (Quasi-Cauchy sequence NameCert obligations)**.** *For every accepted* $\mathsf{QuasiCauchySequence}^{\uparrow}$ *carrier*

$$Q = (S, W, D, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{QuasiCauchySequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite stream source, adjacent-window schedule, dyadic tolerance ledger, regular-rational readback, terminal Real seal, adjacent-difference ledger, componentwise transport, displayed replay, provenance, and local naming rows; adjacent-window exposure before any difference read; tolerance-readback coherence through D, R, E; eventual adjacent-smallness through A; and structural preservation through H, C, P, N. No quasi-Cauchy obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7840.1. The tuple displays the stream source, adjacent schedule, dyadic tolerance ledger, regular-rational readback, Real seal, adjacent-difference ledger, and structural rows.

The adjacent-window exposure clause is exactly the row pair S, W. It forces a consumer to inspect displayed neighbouring entries before reading any distance or tolerance datum.

The tolerance coherence clause is stored in D, R, E. The dyadic tolerance row supplies the requested precision, the regular-rational row reads the finite rational difference stream, and the Real seal records the accepted adjacent distance as a displayed real-name boundary.

Finally A, H, C, P, N record eventual adjacent-smallness, transport, replay, source, and local naming. Since no carrier coordinate compares arbitrary distant tail pairs or chooses a limit, the listed obligations exhaust the local NameCert surface without promoting the packet to a full Cauchy or completion theorem. □

Theorem 7840.3 (Quasi-Cauchy adjacent-difference ledger)**.** *Every accepted* $\mathsf{QuasiCauchySequence}^{\uparrow}$ *packet routes each Real- or Completion-facing adjacent-difference request through*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

and then through the adjacent ledger A and structural rows H, C, P, N. The route certifies only that displayed adjacent differences become small along the inspected schedule; it does not certify the full Cauchy comparison of arbitrary tail pairs, a selected limiting real, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted adjacent-difference request. The carrier forces the request to read S and W, so the compared entries are the displayed neighbours of the same finite stream schedule.

The request then passes through D, R, E. These rows expose the dyadic tolerance, the regular rational readback of the difference stream, and the terminal Real seal before any completion-facing consumer can inspect the ledger.

The row A records the eventual adjacent-smallness claim for exactly those displayed neighbouring entries. The structural rows H, C, P, N preserve and name the same packet.

Because the route never adds a coordinate comparing arbitrary x_m and x_n in the tail, it remains the quasi-Cauchy adjacent-difference ledger and cannot be reread as full Cauchy convergence, selected completion, quotient stream equality, countable choice, or ambient Real completeness. □

Falsifiable prediction: An accepted $\mathsf{QuasiCauchySequence}^{\uparrow}$ consumer is refuted if it treats adjacent-smallness as a full Cauchy tail comparison without displaying a separate arbitrary-tail Cauchy ledger.

Independence witness: streamname, regseqrat, dyadicratcore, real: $\mathsf{QuasiCauchySequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the adjacent-window schedule, dyadic tolerance ledger, regular-rational difference readback, Real seal, adjacent-smallness ledger, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiCauchySequence}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasiCauchySequence}^{\uparrow}$ packet is generated from finite StreamName windows, adjacent-pair schedules, DyadicRatCore tolerance rows, RegSeqRat difference readback, Real seal rows, adjacent-smallness ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasiCauchySequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7840.1, Definition 7840.2, and Definition 7840.3 seed the finite adjacent-difference packet over StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasiCauchySequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, full Cauchy convergence, selected limits, quotient stream equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, adjacent-window exposure, dyadic and regular readback coherence, Real-seal preservation, adjacent-smallness exactness, transport stability, and replay stability for BEDC.Derived.QuasiCauchySequenceUp.

Chapter 7841

A Concrete Naming Certificate for $\mathsf{FiniteRankDeficiency}^{\uparrow}$

The $\mathsf{FiniteRankDeficiency}^{\uparrow}$ packet realizes the local support-rank prototype of Definition 9462.1756 and Definition 9462.1760 as finite NameCert data. It generalizes the stop/Trp face packet of chapter 4090 by making the support universe, proper-support classifier, witness ledger, and non-escape boundary explicit. It also reads the finite coverage-rank algebra of chapter 3734 and the rank-nullity accounting surface of chapter 3438 as sibling ledgers. The packet is a finite support-rank certificate; it is not a host rank oracle, a biological semantics claim, quotient support equality, an infinite support lattice, or a basis-selection theorem.

Definition 7841.1 (Finite rank-deficiency carrier)**.** *A* $\mathsf{FiniteRankDeficiency}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, S, R, P, L, K, T, C, G, N)$$

with the following displayed rows:

1. *U is the finite support-universe row naming the inspected support coordinates.*
2. *S is the finite support-family row whose members are compared with U.*
3. *R is the support-rank row, recording the visible size or rank token of each displayed support.*
4. *P is the proper-support classifier row, accepting exactly the displayed supports that remain below the full support named by U.*
5. *L is the deficiency ledger separating proper-support rows from the full-support corner.*
6. *K is the consumed* $\mathsf{CoverageRankAlgebra}^{\uparrow}$ *sibling row when the support family comes from a coverage or trigger algebra.*
7. *T is the consumed* $\mathsf{RankNullity}^{\uparrow}$ *sibling row when the support-rank read is compared with a kernel-image accounting surface.*
8. *C records componentwise* hsame *transport for support universes, support rows, rank rows, proper-support classifiers, ledgers, sibling algebra rows, replay, provenance, and local naming.*
9. *G records displayed* Cont *replay from a finite rank-deficiency request through U, S, R, P, L, K, T, C.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRankDeficiency}^{\uparrow}}$ *row, with* Pkg *provenance over the displayed rows, Definition 9462.1760,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

The classifier accepts a finite rank-deficiency read only through $U, S, R, P, L, K, T, C, G, N$. It has no coordinate for hidden full-support escape, host rank completion, quotient support equality, biological interpretation, stochastic dynamics, infinite support search, or selected bases.

Theorem 7841.2 (Finite rank-deficiency NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRankDeficiency}^{\uparrow}$ *carrier*

$$F = (U, S, R, P, L, K, T, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRankDeficiency}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite support universe, support family, rank row, proper-support classifier, deficiency ledger, optional coverage-rank sibling row, optional rank-nullity sibling row, componentwise transport, displayed replay, provenance, and local naming; proper-support exactness for P against the full support named by U; ledger separation of proper-support rows from the full-support corner; sibling preservation through K and T whenever those rows are present; and structural preservation through C, G, N. No finite rank-deficiency obligation is stored outside these rows.*

Proof. Project the carrier of Definition 7841.1. The rows U, S, R, P, L display the finite support universe, support family, rank read, proper-support classifier, and deficiency ledger before any sibling algebra is consumed.

Proper-support exactness is the finite law of Definition 9462.1760: accepted deficient rows are those whose displayed support remains below the full support named by U. The ledger row L keeps the full-support corner visible as a refused escape rather than erasing it.

The sibling rows K and T do not add hidden rank data. They only route already displayed coverage-rank and rank-nullity surfaces into the same finite support-rank packet.

Finally C, G, N transport, replay, source, and name the same rows. Since hidden support completion, quotient support equality, biological interpretation, infinite search, and selected bases are absent from the carrier, the listed obligations exhaust the NameCert surface. □

Theorem 7841.3 (Finite rank-deficiency proper-support nonescape)**.** *Every accepted* $\mathsf{FiniteRankDeficiency}^{\uparrow}$ *packet that reads a proper-support row must keep the route*

$$U, S, R, P, L, K, T, C, G, N$$

visible until the local $\mathsf{NameCert}$ *row is consumed. In particular, a consumer cannot promote the proper-support classifier P to the full-support corner of U, cannot replace the displayed rank row R by a host rank oracle, and cannot identify two support packets by quotient support equality unless the required transport is already displayed in C.*

Proof. Start from an accepted proper-support read. Carrier projection exposes U, S, R, P, L, so the support universe, inspected support family, rank token, classifier, and deficiency ledger are all visible.

The nonescape claim follows from the separation row L. It records the full-support corner as a boundary distinct from the accepted proper-support rows, so a downstream consumer cannot collapse the boundary into the classifier without adding a row not present in the packet.

The coverage-rank and rank-nullity siblings are read only through K and T. These rows preserve the same support-rank evidence and do not supply a host rank oracle or selected basis.

The structural rows C, G, N then transport, replay, source, and name the displayed packet. Therefore any read that leaves $U, S, R, P, L, K, T, C, G, N$ has left the finite rank-deficiency NameCert route. □

Falsifiable prediction: A $\mathsf{FiniteRankDeficiency}^{\uparrow}$ consumer is refuted if it treats a proper-support classifier as a full-support conclusion without displaying the deficiency ledger L and the transport row C.

Independence witness: stop-trp-face-rank-deficiency, coverage-rank-algebra, rank-nullity: $\mathsf{FiniteRankDeficiency}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite support universe, support-family row, support-rank row, proper-support classifier, nonescape ledger, sibling algebra rows, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRankDeficiency}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRankDeficiency}^{\uparrow}$ packet is generated from finite support universes, displayed support-family rows, support-rank rows, proper-support classifiers, deficiency ledgers, CoverageRankAlgebra sibling rows, RankNullity sibling rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRankDeficiency}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7841.1, Definition 7841.2, and Definition 7841.3 seed the finite support-rank deficiency packet over the rank-deficiency prototype.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRankDeficiency}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host rank completion, quotient support equality, biological semantics, stochastic dynamics, infinite support search, or selected bases.

Upgrade path: Obligation closure requires checked carrier admission, proper-support exactness, deficiency-ledger separation, coverage-rank sibling preservation, rank-nullity sibling preservation, transport stability, and replay stability for BEDC.Derived.FiniteRankDeficiencyUp.

Chapter 7842

A Concrete Naming Certificate for $\mathsf{RearrangementInequality}^{\uparrow}$

Following Hardy, Littlewood, and Polya, the $\mathsf{RearrangementInequality}^{\uparrow}$ packet records the finite sorted-sum certificate for two equally indexed real rows. It consumes finite sequence structure from chapter 36, order comparison from the $\mathsf{TotalOrder}^{\uparrow}$ surface, rational readback through $\mathsf{Rat}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal real seal of chapter 38. It is adjacent to the convex inequality route of $\mathsf{JensenInequality}^{\uparrow}$ and the majorization route of $\mathsf{KaramataInequality}^{\uparrow}$, but it does not duplicate either packet: rearrangement names the finite permutation ledger and sorted pairwise-product comparison.

Definition 7842.1 (Rearrangement inequality carrier)**.** *A* $\mathsf{RearrangementInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathcal{R} = (A, B, O, L, \Pi, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are finite* $\mathsf{List}^{\uparrow}$ *rows of equal displayed length whose entries are sealed as* $\mathsf{Real}^{\uparrow}$ *names.*
2. *O is the* $\mathsf{TotalOrder}^{\uparrow}$ *comparison ledger certifying that both rows are read in nondecreasing order.*
3. *L is the length and index ledger tying the two rows to the same finite index set.*
4. *Π is the permutation ledger, recording how any compared arrangement is obtained from the sorted row by a finite list permutation.*
5. *S is the finite sorted-sum comparison row for the two product sums.*
6. *Q is the* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational windows used to inspect the real products and sums.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for the sum endpoints after the finite comparison has been displayed.*
8. *H records componentwise* hsame *transport for the list, order, index, permutation, sum, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from a rearrangement request through $A, B, O, L, \Pi, S, Q, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RearrangementInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{JensenInequality}^{\uparrow}$, $\mathsf{KaramataInequality}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RearrangementInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for ambient completeness of $\mathsf{Real}^{\uparrow}$*, host real ordering, quotient equality of real names, selected extrema, infinite series, or a hidden optimization principle.*

Theorem 7842.2 (Rearrangement inequality NameCert obligations)**.** *For every accepted* $\mathsf{RearrangementInequality}^{\uparrow}$ *carrier*

$$\mathcal{R} = (A, B, O, L, \Pi, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RearrangementInequality}^{\uparrow}}$ *surface consists exactly of sorted finite RealUp rows, the order comparison ledger, equal-length and index alignment, finite permutation provenance, finite product-sum comparison, RatUp and RegSeqRat readback, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape from ambient completeness, host order, quotient equality, selected extrema, or infinite-series assertions.*

Proof. Project the carrier. The finite rows A and B supply the displayed list spines and RealUp entries, while O and L bind the sortedness and common index surface.

The permutation and comparison data are the rows Π and S. They record only finite rearrangements of the displayed list spines and the corresponding finite product-sum comparison.

The readback and endpoint rows are Q and E. They route rational windows through $\mathsf{Rat}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ before sealing the compared sums as $\mathsf{Real}^{\uparrow}$ endpoints.

Transport, replay, provenance, and naming are carried by H, C, P, N. Since no remaining row stores completeness, host order, quotient equality, selected extrema, or infinite series, the listed rows exhaust the local NameCert obligations. □

Theorem 7842.3 (Rearrangement inequality sorted-sum handoff)**.** *Every accepted* $\mathsf{RearrangementInequality}^{\uparrow}$ *packet exports its finite sorted-sum comparison only through the route*

$$\mathsf{List}^{\uparrow},\ \mathsf{TotalOrder}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RearrangementInequality}^{\uparrow}.$$

A Jensen or Karamata consumer may inspect this handoff as a finite inequality certificate only after the sorted rows, common index ledger, permutation ledger, rational readback, RealUp seals, transport, replay, provenance, and local naming rows have been displayed.

Proof. Begin with an accepted carrier $\mathcal{R} = (A, B, O, L, \Pi, S, Q, E, H, C, P, N)$. The finite list rows and common index ledger determine the product positions that can be compared.

The order row O and permutation row Π force every admissible arrangement to be read as a finite permutation of the displayed sorted rows. The comparison row S then records the sorted product-sum inequality for that finite index set.

The rational readback row Q and RealUp seal E keep the numerical comparison inside the displayed BEDC real surface. The rows H, C, P, N transport, replay, source, and name the same data.

Thus the handoff can be consumed by $\mathsf{JensenInequality}^{\uparrow}$ or $\mathsf{KaramataInequality}^{\uparrow}$ only as a finite sorted-sum certificate. It exports no ambient completeness theorem, host real-order theorem, quotient equality, selected extremum, or infinite-series claim. □

Falsifiable prediction: Every accepted $\mathsf{RearrangementInequality}^{\uparrow}$ packet displays sorted finite $\mathsf{Real}^{\uparrow}$ rows, common finite indices, an order ledger, a permutation ledger, finite sum comparison, $\mathsf{Rat}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, transport, replay, provenance, and local $\mathsf{NameCert}$ rows before any inequality consumer reads the sorted-sum comparison.

Independence witness: real, rat, regseqrat, totalorder, list, jenseninequality, and karamatainequality: no listed sibling is bijective to $\mathsf{RearrangementInequality}^{\uparrow}$ because this packet jointly stores the finite sorted-row ledger, permutation provenance, and sorted product-sum comparison as one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RearrangementInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{RearrangementInequality}^{\uparrow}$ packet is generated from sorted finite RealUp list rows, a TotalOrder comparison ledger, common finite index data, permutation provenance, finite product-sum comparison, RatUp and RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RearrangementInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7842.1, Definition 7842.2, and Definition 7842.3 seed the finite rearrangement-inequality carrier over RealUp, RatUp, RegSeqRat, TotalOrder, List, Jensen, and Karamata rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RearrangementInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient completeness of RealUp, host real ordering, quotient equality of real names, selected extrema, infinite series, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked sorted finite RealUp rows, order and permutation ledgers, finite sum comparison, RatUp and RegSeqRat readback, RealUp sealing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RearrangementInequalityUp.

Chapter 7843

A Concrete Naming Certificate for $\mathsf{HyperbolicHoroball}^{\uparrow}$

Following Gromov and Bridson–Haefliger on hyperbolic spaces, the $\mathsf{HyperbolicHoroball}^{\uparrow}$ packet records a horoball by finite boundary-point, Busemann-threshold, and visual-shadow rows. It sits after the metric-read surface of chapter 3474, the Busemann-boundary packet of chapter 3732, the boundary-shadow packet of chapter 3813, the visual-metric packet of chapter 3866, and the terminal real-name seal of chapter 38. The packet names a finite horoball carrier; it is not a completed ideal-boundary quotient, not a global geodesic selection, not a measure class at infinity, and not an ambient hyperbolic space.

Definition 7843.1 (Hyperbolic horoball carrier)**.** *A* $\mathsf{HyperbolicHoroball}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{HyperbolicHoroball}(B, U, S, M, V, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the boundary-point row consumed from* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$*, naming the finite boundary end and its Busemann-level read.*
2. *U is the Busemann-threshold row, a displayed* $\mathsf{Real}^{\uparrow}$*-sealed level used to decide the local horoball side.*
3. *S is the visual-shadow row consumed from* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$*, recording the finite boundary-shadow window seen by downstream observer-expansion reads.*
4. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row over the same disk or hyperbolic source observations.*
5. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row comparing the shadow window with the visual metric read at the same boundary end.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for Busemann levels, threshold comparisons, shadow radii, and metric-read tolerances.*
7. *H records componentwise* hsame *transport for boundary point, threshold, visual shadow, hyperbolic metric, visual metric, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through boundary-point admission, Busemann-threshold comparison, visual-shadow exposure, hyperbolic-metric readback, visual-metric comparison, and real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHoroball}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicHoroball}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, U, S, M, V, R, H, C, P, N$. It has no coordinate for quotient ideal-boundary equality, a selected global geodesic ray, a Patterson–Sullivan measure class, a completed hyperbolic space, or physical horizon geometry.

Theorem 7843.2 (Hyperbolic horoball NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHoroball}^{\uparrow}$ *carrier*

$$\mathsf{HyperbolicHoroball}(B, U, S, M, V, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicHoroball}^{\uparrow}}$ *surface consists exactly of carrier admission for the boundary-point row, Busemann-threshold row, visual-shadow row,* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row,* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *comparison row,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming.*

Every accepted horoball consumer must read B and U before reading the shadow, metric, visual-metric, real-seal, transport, replay, provenance, and naming rows. No obligation is stored in quotient boundary equality, selected geodesic representatives, measure classes at infinity, completed hyperbolic spaces, or physical horizon geometry.

Proof. Carrier admission is projection from Definition 7843.1. The accepted packet displays the boundary point, threshold, shadow, metric, visual metric, real seal, transport, replay, provenance, and naming rows.

The boundary and threshold rows determine the horoball side. A consumer that omits either B or U has not read the displayed Busemann boundary end and level comparison, so it is outside the accepted carrier.

The rows S, M, V, R then expose the visible geometry. The boundary-shadow row records the finite visual shadow, the metric row supplies distance readback, the visual-metric row compares the shadow at the same boundary end, and the real row seals the threshold and tolerance data.

The structural rows H, C, P, N only transport, replay, source, and name this finite route. Since the excluded global objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7843.3 (Hyperbolic horoball shadow route)**.** *Every visual-shadow read exported by an accepted* $\mathsf{HyperbolicHoroball}^{\uparrow}$ *packet factors through*

$$B, U \longmapsto S, M, V \longmapsto R, H, C, P, N.$$

Thus the boundary-point and Busemann-threshold rows are present before the horoball can expose a boundary shadow, hyperbolic metric read, visual metric comparison, or real-sealed radius.

Proof. Start with the carrier of Definition 7843.1. The row B names the Busemann boundary end and U names the real-sealed threshold level, so these rows are the only source of horoball membership data.

Next consume S, M, V. The visual-shadow row is read from the same boundary end, the hyperbolic-metric row supplies the metric readback, and the visual-metric row compares the resulting shadow window with the displayed visual metric surface.

Finally consume R, H, C, P, N. The real seal records the threshold and tolerance data, while transport, replay, provenance, and local naming preserve the same order. Since no selected geodesic ray or completed boundary quotient appears in the carrier, every accepted visual-shadow read follows the displayed finite route. □

Falsifiable prediction: Any horoball consumer that exposes a visual shadow without first reading B, U, S, M, V fails to read the accepted $\mathsf{HyperbolicHoroball}^{\uparrow}$ packet.

Independence witness: hyperbolic-metric, hyperbolic-busemann-boundary, hyperbolic-boundary-shadow, hyperbolic-visual-metric, real seal: none is bijective to $\mathsf{HyperbolicHoroball}^{\uparrow}$ because this packet binds boundary end, Busemann threshold, visual shadow, metric read, visual metric comparison, Real sealing, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHoroball}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHoroball}^{\uparrow}$ packet is generated from a boundary-point row, Busemann-threshold row, visual-shadow row, HyperbolicMetric row, HyperbolicVisualMetric row, Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroball}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7843.1, Definition 7843.2, and Definition 7843.3 seed the finite horoball route over boundary point, Busemann threshold, visual shadow, hyperbolic metric, visual metric, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHoroball}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ideal-boundary equality, selected geodesic representatives, measure classes at infinity, completed hyperbolic spaces, physical horizon geometry, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-point exactness, Busemann-threshold exactness, shadow-route exactness, HyperbolicMetric and HyperbolicVisualMetric handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicHoroballUp.

Chapter 7844

A Concrete Naming Certificate for $\mathsf{HamiltonJacobiAction}^{\uparrow}$

Following Evans and Arnold, the $\mathsf{HamiltonJacobiAction}^{\uparrow}$ packet records the finite action-functional surface that sits between variational mechanics and Hamilton-Jacobi readback. It reads the Lagrangian action row of chapter 337, the Hamilton-Jacobi row of chapter 7663, the Hamilton-Jacobi-Bellman row of chapter 7805, the routed dynamics rows of chapter 195 and chapter 193, the scalar readback of chapter 38, and the linear state displays of chapter 49 and chapter 47. The packet names action data for a displayed trajectory window; it is not a viscosity-solution theorem, not a global minimizer existence result, not a selected optimal-control policy, and not an ambient completeness assertion for $\mathsf{Real}^{\uparrow}$.

Definition 7844.1 (Hamilton-Jacobi action carrier)**.** *A* $\mathsf{HamiltonJacobiAction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, T, Q, V, L, S, G, J, B, D, O, M, R, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{VecSpace}^{\uparrow}$ *state row and T is the finite time-window row for the displayed path segment.*
2. *Q is the path or configuration row exposed by* $\mathsf{LagrangianMechanics}^{\uparrow}$*, and V is the velocity or tangent readback row.*
3. *L is the displayed Lagrangian row and S is the action-accumulation row sealed only through finite* $\mathsf{Real}^{\uparrow}$ *data.*
4. *G is the endpoint-gradient or momentum readback row consumed by the Hamilton-Jacobi interface.*
5. *J is the* $\mathsf{HamiltonJacobi}^{\uparrow}$ *Hamiltonian-readback row and B is the* $\mathsf{HamiltonJacobiBellman}^{\uparrow}$ *control-facing sibling row.*
6. *D and O are the* $\mathsf{DynSystem}^{\uparrow}$ *and* $\mathsf{Ode}^{\uparrow}$ *route rows that tie the path segment to displayed dynamics.*
7. *M is the* $\mathsf{Mat}^{\uparrow}$ *coefficient row used when the action request is specialized to a finite linear or quadratic display.*
8. *R is the componentwise* hsame *transport row for $X, T, Q, V, L, S, G, J, B, D, O, M$.*

9. *C records displayed* Cont *replay through the route*

$$Q, V, L, D, O \longmapsto S.$$

10. *P is the* Pkg *provenance over* HamiltonJacobiAction$^{\uparrow}$, HamiltonJacobi$^{\uparrow}$, HamiltonJacobiBellman$^{\uparrow}$, LagrangianMechanics$^{\uparrow}$, DynSystem$^{\uparrow}$, Ode$^{\uparrow}$, Real$^{\uparrow}$, Mat$^{\uparrow}$, VecSpace$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{HamiltonJacobiAction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, Q, V, L, S, G, J, B, D, O, M, R, C, P, N$. It has no coordinate for a selected minimizer, a host path space, classical differentiability of all trajectories, viscosity uniqueness, PDE regularity, quotient equality of actions, or ambient real completeness.

Theorem 7844.2 (Hamilton-Jacobi action NameCert obligations)**.** *For every accepted* HamiltonJacobiAction$^{\uparrow}$ *carrier*

$$A = (X, T, Q, V, L, S, G, J, B, D, O, M, R, C, P, N),$$

the local NameCert$_{\text{HamiltonJacobiAction}^{\uparrow}}$ *surface consists exactly of carrier admission, path-window exposure, Lagrangian action exposure, Hamilton-Jacobi readback, Hamilton-Jacobi-Bellman sibling exposure, routed dynamics exposure, linear coefficient exposure, componentwise transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7844.1. The rows X, T, Q, V, L, S, G expose the finite state, path-window, Lagrangian, action, and endpoint-gradient data before any Hamilton-Jacobi read is available.

Read the sibling rows next. The Hamilton-Jacobi row J supplies Hamiltonian readback, while the Hamilton-Jacobi-Bellman row B supplies the control-facing sibling surface. The dynamics rows D, O keep the path segment tied to displayed DynSystem and Ode data.

The matrix row M is only a finite coefficient display for specialized linear or quadratic requests. Transport, replay, provenance, and local naming then pass through R, C, P, N.

Since no carrier coordinate contains a selected minimizer, host path space, global differentiability theorem, viscosity uniqueness theorem, PDE regularity theorem, quotient action equality, or real-completeness principle, none of those objects can be exported by the local NameCert surface. □

Theorem 7844.3 (Hamilton-Jacobi action HJB route)**.** *Every downstream consumer of an accepted* HamiltonJacobiAction$^{\uparrow}$ *packet that asks for a control-facing action read must pass through the displayed sibling route*

$$\text{LagrangianMechanics}^{\uparrow}, \text{DynSystem}^{\uparrow}, \text{Ode}^{\uparrow}, \text{HamiltonJacobi}^{\uparrow}, \text{HamiltonJacobiBellman}^{\uparrow} \longmapsto \text{HamiltonJacobiAction}^{\uparrow}.$$

The route binds finite Lagrangian action data, dynamics rows, Hamiltonian readback, and HJB-facing control rows without converting the packet into an optimal-control existence theorem or a global PDE regularity theorem.

Proof. Apply Definition 7844.2. The Lagrangian action rows Q, V, L, S, the dynamics rows D, O, the Hamilton-Jacobi row J, and the HJB row B are separate displayed rows of the same accepted carrier.

Use R, C, P, N to preserve that row inventory under transport, replay, provenance, and local naming. These structural rows do not add a host minimizer, a selected policy, a viscosity uniqueness theorem, or an ambient completion principle.

Thus a consumer reaches the control-facing action read only through the displayed finite route, and the refused analytic objects remain outside the packet. □

Falsifiable prediction: A claimed $\mathsf{HamiltonJacobiAction}^{\uparrow}$ read that reaches a control-facing action row without displaying the LagrangianMechanics, DynSystem, Ode, HamiltonJacobi, and HamiltonJacobiBellman sibling rows refutes the carrier.

Independence witness: hamilton-jacobi, hamilton-jacobi-bellman, lagrangianmechanics, dynsystem, ode, real, matrix, vecspace: no listed sibling is bijective to $\mathsf{HamiltonJacobiAction}^{\uparrow}$ because only this packet binds finite action accumulation, endpoint-gradient readback, Hamilton-Jacobi readback, HJB-facing control exposure, dynamics routes, coefficient display, transport, replay, provenance, and local naming as one action-functional packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HamiltonJacobiAction}^{\uparrow}}$.

Constructive story: A $\mathsf{HamiltonJacobiAction}^{\uparrow}$ packet is generated from finite state, time-window, path, velocity, Lagrangian, action, endpoint-gradient, HamiltonJacobi, HamiltonJacobiBellman, DynSystem, Ode, Matrix, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HamiltonJacobiAction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7844.1, Definition 7844.2, and Definition 7844.3 seed the finite Hamilton-Jacobi action surface over Lagrangian mechanics, dynamics, Hamilton-Jacobi, and HJB rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HamiltonJacobiAction}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.HamiltonJacobiActionUp`

Bridge status: none

Not claimed: This chapter does not claim selected minimizers, optimal-control existence, viscosity uniqueness, global PDE regularity, classical differentiability of all paths, quotient equality of actions, ambient real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Lagrangian action exposure, Hamilton-Jacobi and HJB exposure, dynamics exposure, coefficient exposure, transport, replay, provenance, and local naming for BEDC.Derived.HamiltonJacobi

Chapter 7845

A Concrete Naming Certificate for $\mathsf{EilenbergMooreCategory}^{\uparrow}$

Following Mac Lane's categorical account of monads and the Eilenberg–Moore construction, the $\mathsf{EilenbergMooreCategory}^{\uparrow}$ packet names the category of displayed algebra objects for a displayed monad. It sits after the categorical carrier of chapter 61, the functorial transport surface of chapter 62, the monad packet of chapter 108, the Kleisli completion category of chapter 3826, and the completion-algebra surface of chapter 2139. The chapter records the finite NameCert rows by which monad algebras and their homomorphisms become a category-level consumer interface.

The packet is the algebra-object companion to the Kleisli category route. It does not identify algebras by quotient equality, select representatives, construct a host category of algebras, or import ambient equality of algebra maps.

Definition 7845.1 (Eilenberg–Moore category carrier)**.** *An* $\mathsf{EilenbergMooreCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (B, T, A, S, U, M, H, C, R, P, N)$$

with the following displayed rows:

1. *B is the base* $\mathsf{Cat}^{\uparrow}$ *row, exposing object and hom histories before any algebra row is read.*
2. *T is the* $\mathsf{Monad}^{\uparrow}$ *row on the base category, with its endofunctor, unit, and multiplication data displayed as finite BEDC carrier rows.*
3. *A is the algebra-object row, listing the displayed object on which the monad acts.*
4. *S is the structure-map row from the monad-applied object back to the algebra object.*
5. *U is the unit-law row, comparing the unit route followed by S with the displayed identity route on the algebra object.*
6. *M is the multiplication-law row, comparing the multiplication route followed by S with the route that first applies the monad to S and then applies S.*
7. *H is the algebra-homomorphism row, recording maps between displayed algebra objects whose square with the two structure maps is certified by the same finite carrier route.*
8. *C is the composition ledger for algebra homomorphisms, including identity homomorphisms and associative composition as displayed* $\mathsf{Cat}^{\uparrow}$ *and* $\mathsf{Monad}^{\uparrow}$ *route comparisons.*
9. *R records componentwise* hsame *transport and displayed* Cont *replay for B, T, A, S, U, M, H, C.*

10. *P is the* Pkg *provenance over* $\mathsf{EilenbergMooreCategory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{Monad}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{CauchyCompletionKleisliCategory}^{\uparrow}$, $\mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{EilenbergMooreCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, T, A, S, U, M, H, C, R, P, N$. It has no coordinate for quotient algebras, selected representatives, host equality of algebra maps, ambient category objects, or a collapse of the Eilenberg–Moore route into the Kleisli route.

Theorem 7845.2 (Eilenberg–Moore category NameCert obligations)**.** *For every accepted* $\mathsf{EilenbergMooreCategory}^{\uparrow}$ *carrier*

$$E = (B, T, A, S, U, M, H, C, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EilenbergMooreCategory}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the base category, monad, algebra object, structure map, unit law, multiplication law, algebra homomorphism, composition ledger, transport, provenance, and local naming rows;*
2. *monad-source exposure, requiring the base category and monad rows B, T before any algebra object or homomorphism can be inspected;*
3. *algebra-object exposure, requiring A and S to display the object and its structure map before either law row is public;*
4. *law exactness, requiring U and M to compare only the displayed unit and multiplication routes of the same monad row;*
5. *homomorphism and composition exactness, requiring H and C to keep algebra maps, identities, and composites inside the displayed algebra rows;*
6. *structural exhaustion, requiring R, P, N to transport, replay, source, and name the listed rows without adding quotient algebras, selected representatives, host equality of algebra maps, ambient category objects, or a Kleisli-category identification.*

No obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7845.1. The accepted packet exposes exactly the base category, monad, algebra-object, structure-map, law, homomorphism, composition, transport, provenance, and local naming rows.

Monad-source exposure is read from B and T. Since the monad is displayed over the same base category row, an algebra consumer cannot begin from a separate host category or from an unrecorded endofunctor.

Algebra-object exposure is read from A and S. The object row is available before the structure-map row, and the structure map is the only coordinate that turns the monad-applied object back into the algebra object.

Law exactness is read from U and M. The unit law compares the displayed unit route with the identity route, while the multiplication law compares the displayed multiplication route with the two-step action route; both comparisons use the same B, T, A, S rows.

Finally H, C, R, P, N bind maps, composites, transport, provenance, and local naming to the same finite packet. Because no other coordinate occurs in the carrier, the listed rows exhaust the NameCert obligation surface. □

Theorem 7845.3 (Eilenberg–Moore category algebra route)**.** *Every consumer that reads an accepted* $\mathsf{EilenbergMooreCategory}^{\uparrow}$ *packet as a category of algebra objects factors through the route*

$$\mathsf{Cat}^{\uparrow},\ \mathsf{Functor}^{\uparrow},\ \mathsf{Monad}^{\uparrow},\ \mathsf{NatTrans}^{\uparrow},\ \mathsf{EilenbergMooreCompletionAlgebra}^{\uparrow},\ \mathsf{CauchyCompletionKleisliCategory}^{\uparrow}.$$

The object side reads B, T, A, S, U, M *before any algebra homomorphism is public, and the arrow side reads* H, C, R, P, N *before identities or composites can be exported. Thus the packet gives a finite category-level algebra interface without quotient categories, selected algebra representatives, host equality of algebra maps, ambient category equality, or identification with the Kleisli category.*

Proof. Start with the object side. Projection of the carrier supplies B and T as the base category and monad rows, then A and S as the displayed algebra object and structure map.

The law rows are then forced in order. The unit row U compares the unit action against the displayed identity route, and the multiplication row M compares the two monad-action schedules against the same structure map.

Turn to arrows. The homomorphism row H reads maps only after their source and target algebra rows have exposed the same B, T, A, S, U, M data, and the composition ledger C records identities and composites as displayed category and monad route comparisons.

The dependency route is therefore the advertised sibling route: the base categorical rows come from $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{Monad}^{\uparrow}$, and $\mathsf{NatTrans}^{\uparrow}$, while the completion-facing algebra and Kleisli consumers cite chapter 2139 and chapter 3826. The structural rows R, P, N add transport, replay, provenance, and local naming only, so no quotient or host equality coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{EilenbergMooreCategory}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EilenbergMooreCategory}^{\uparrow}$ packet is generated from a base category row, a monad row, an algebra-object row, a structure-map row, unit and multiplication law rows, an algebra-homomorphism row, a composition ledger, componentwise hsame and Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EilenbergMooreCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7845.1, Definition 7845.2, and Definition 7845.3 seed the finite category-level Eilenberg–Moore algebra interface for monad and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EilenbergMooreCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient categories of algebras, selected representatives, host equality of algebra maps, ambient category equality, Lean verification, bridge checking, or an identification with the Kleisli category.

Upgrade path: Obligation closure requires checked carrier admission, monad-source exposure, algebra-object exposure, unit-law exactness, multiplication-law exactness, homomorphism and composition exactness, structural replay, and ledger non-escape for BEDC.Derived.EilenbergMooreCategoryUp.

Chapter 7846

A Concrete Naming Certificate for BishopRegularCauchyTailCommonRefinement$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopRegularCauchyTailCommonRefinement$^{\uparrow}$ packet records the finite common-refinement surface used when two regular Cauchy rational names must be read through one late tail before a real-name consumer can compare or transport them. It sits over the regular rational source rows of chapter 301, the finite observation schedules of chapter 126, the dyadic tolerance ledger of chapter 291, the common-tail filter basis of chapter 2129, the tail-comparison route of chapter 2146, the tail-functor handoff of chapter 3602, and the terminal real-name seal of chapter 38. The packet names a displayed late-tail refinement for two Bishop regular Cauchy names; it is not quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Definition 7846.1 (Bishop regular Cauchy tail common-refinement carrier)**.** *A* BishopRegularCauchyTailCommonR *carrier is a finite* BHist *packet*

$$K = (X, Y, S, T, R, D, F, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* RegSeqRat$^{\uparrow}$ *source-name rows. Each source is exposed only through its displayed regular rational reads.*
2. *S is the shared* StreamName$^{\uparrow}$ *schedule. It records the finite observation windows, inspected indices, and synchronized late-window requests used for both sources.*
3. *T is the common tail-cut row. It records the late cut, cofinal refinement requests, and membership witnesses saying that both sources are read beyond the same displayed tail.*
4. *R is the regular readback row. It records the rational observations of X and Y at the windows specified by S and T.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger. It records the requested radius, tail slack, enclosure budget, and finite-window exhaustion consumed by the refinement.*
6. *F is the* RegularCauchyCommonTailFilter$^{\uparrow}$ *row. It reads T as a finite common-tail basis and exports only displayed basis and cofinality data.*
7. *Q is the* RegularCauchyTailComparison$^{\uparrow}$ *row. It records the comparison-facing late-window route obtained after X, Y, S, T, R, D, F have been displayed.*

8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the shared schedule, common tail, readback, dyadic ledger, filter row, and comparison row have been displayed.*

9. *H records componentwise* hsame *transport for the two source rows, shared schedule, common tail, readback, dyadic ledger, filter row, comparison row, real seal, replay, provenance, and local naming row.*

10. *C records displayed* Cont *replay of the route*

$$X, Y, S, T, D \longmapsto R \longmapsto F \longmapsto Q \longmapsto E.$$

11. *P is the* Pkg *provenance over* $\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyCommonTailFilter}^{\uparrow}$, $\mathsf{RegularCauchyTailComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these thirteen rows. Its classifier compares accepted packets only through $X, Y, S, T, R, D, F, Q, E, H, C, P, N$ and has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7846.2 (Bishop regular Cauchy tail common-refinement NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}$ *carrier*

$$K = (X, Y, S, T, R, D, F, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two regular Cauchy source rows, shared stream schedule, common tail cut, regular readback, dyadic tolerance ledger, common-tail filter row, comparison row, terminal real seal, transport, replay, provenance, and local naming row;*

2. *shared-schedule discipline, requiring both source rows to be inspected through the same S row before either a comparison route or real seal is available;*

3. *common-tail discipline, requiring T to display the late cut, cofinal refinement requests, and membership witnesses consumed by both sources;*

4. *tolerance and readback exactness, requiring R and D to expose only the rational observations and dyadic budgets read from the displayed source rows, schedule, and common tail;*

5. *filter and comparison non-escape, requiring F and Q to remain downstream of X, Y, S, T, R, D and to export no quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness;*

6. *real-seal discipline, requiring E to be read only after the common-tail filter and comparison rows have both been displayed;*

7. *transport, replay, provenance, and naming stability, requiring H, C, P, N to preserve and source exactly the displayed rows componentwise.*

No Bishop regular Cauchy tail common-refinement obligation is stored outside these rows.

Proof. Project the accepted packet $K = (X, Y, S, T, R, D, F, Q, E, H, C, P, N)$. The carrier exposes exactly the two source rows, shared schedule, common tail, regular readback, dyadic ledger, filter row, comparison row, terminal real seal, and structural rows.

The shared schedule and common tail are finite. The row S fixes the inspected windows for both source names, while T fixes the late cut and cofinal refinement requests through which both sources must be read.

The readback and tolerance rows are tied to that same tail. The row R supplies only the regular rational observations visible at the displayed windows, and D supplies only the dyadic radius, slack, enclosure budget, and finite-window exhaustion attached to those observations.

The filter and comparison rows remain downstream. The row F reads the common tail as a finite common-tail filter basis, and Q reads the resulting late-window route as the comparison-facing surface.

Finally E, H, C, P, N seal, transport, replay, source, and name the same displayed route. Since none of the excluded host objects has a carrier coordinate, replay edge, provenance entry, or local naming row, the listed obligations exhaust the local NameCert surface. □

Theorem 7846.3 (Bishop regular Cauchy tail common-refinement stability)**.** *Let $K = (X, Y, S, T, R, D, F, Q, E, H$ be an accepted* $\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}$ *carrier. Under componentwise* hsame *transport of the displayed rows $X, Y, S, T, R, D, F, Q, E, C, P, N$, the accepted common-refinement packet remains accepted with the same shared schedule, common tail, tolerance ledger, filter row, comparison row, and real-seal boundary. The transported packet still has no coordinate for quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the transport row H. It is componentwise: it identifies the two source rows, shared schedule, common tail, readback, dyadic ledger, filter row, comparison row, seal row, replay, provenance, and local naming row with their transported copies.

Replay the carrier predicate after transport. Each accepted coordinate is replaced by the corresponding hsame coordinate, so the shared schedule S, tail cut T, tolerance ledger D, filter row F, comparison row Q, and seal boundary E retain the same displayed dependency order.

The structural rows C, P, N are transported along the same route. Therefore the local NameCert reads the transported packet through exactly the same finite coordinates.

Because transport only moves existing displayed rows and does not add a new coordinate, the refused quotient, selection, choice, host-equality, trichotomy, and completeness objects remain absent. □

Theorem 7846.4 (Bishop regular Cauchy tail common-refinement L10 handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing equality, comparison, or completion consumer of an accepted* $\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}$ *carrier factors through the finite route*

$$X, Y, S, T, D \longmapsto R \longmapsto F \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives two displayed regular Cauchy source names, one shared StreamName schedule, one common tail cut, regular rational readback, DyadicRatCore tolerance accounting, a common-tail filter row, a comparison row, the terminal RealUp seal, componentwise transport, continuation replay, package provenance, and local naming. It receives no quotient stream equality, selected limit, countable-choice schedule, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted Real-facing consumer read. The source rows are X and Y, and the carrier requires both rows to be observed through the common schedule S and late tail T.

The dyadic ledger D fixes the precision budget attached to that shared observation. The regular readback row R then supplies the rational observations of the two source names at the displayed windows.

The common-tail filter row F reads the same late cut as a finite basis, and the comparison row Q reads the resulting route as the late-window comparison surface. Only after both rows are displayed can the terminal seal row E be reached.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Induction over the displayed route order proves that a consumer cannot skip from the source rows to the seal: the base stage reads X, Y, S, T, D, the readback stage reads R, the filter stage reads F, the comparison stage reads Q, and the terminal stage reads E, H, C, P, N.

Since the carrier has no coordinate outside this route, the consumer cannot obtain quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}$ packet is generated from two RegSeqRat source rows, one shared StreamName schedule, one common tail cut, regular readback, a DyadicRatCore tolerance ledger, a RegularCauchyCommonTailFilter row, a RegularCauchyTailComparison row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7846.1, Definition 7846.2, Definition 7846.3, and Definition 7846.4 seed the finite Bishop regular Cauchy tail common-refinement route over shared StreamName schedules, RegSeqRat source rows, DyadicRatCore tolerances, common-tail filters, tail comparisons, RealUp seals, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyTailCommonRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-schedule discipline, common-tail discipline, tolerance and readback exactness, filter and comparison non-escape, real-seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyTailCommonRefinementUp.

Chapter 7847

A Concrete Naming Certificate for $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$

Following Bourbaki and Kelley on local compactness in metric spaces, the $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ packet records the finite certificate surface for a pointwise compact-neighbourhood witness around a displayed metric source. It sits between the metric source of chapter 57 and the compact metric surface of chapter 129: the packet names a local compact ball handoff, not an open-cover compactness theorem, a choice-selected neighbourhood family, a host topology, or ambient completeness.

Definition 7847.1 (Locally compact metric space carrier)**.** *A* $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, K, r, B, J, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the points, distance requests, symmetry, triangle, and zero-distance comparison used by the local certificate.*
2. *K is the compact-neighbourhood witness row, naming the local* $\mathsf{CompactMetric}^{\uparrow}$ *packet that contains the displayed point after the radius and containment rows have been checked.*
3. *r is the* $\mathsf{PositiveReal}^{\uparrow}$ *radius row, recording that the inspected point has a positive metric radius available to the local packet.*
4. *B is the local ball-containment row, displaying that the metric ball determined by M and r is contained in the compact-neighbourhood witness K.*
5. *J is the compact-ball handoff row from the metric source and positive-radius request into the local compact metric certificate.*
6. *H records componentwise* hsame *transport for the metric source, compact-neighbourhood witness, radius, containment, handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of every local compactness read through*

$$M, r, B, K \longmapsto J.$$

8. *P is the* Pkg *provenance over* $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, K, r, B, J, H, C, P, N$. It has no coordinate for open-cover compactness, choice-selected neighbourhoods, host topological interiors, ambient completion, quotient metric equality, Lean verification, or a standard bridge.

Theorem 7847.2 (Locally compact metric space compact-ball handoff)**.** *For every accepted* $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ *carrier*

$$L = (M, K, r, B, J, H, C, P, N),$$

each local compactness read first exposes the $\mathsf{Met}^{\uparrow}$ *source M, the* $\mathsf{PositiveReal}^{\uparrow}$ *radius row r, and the local ball-containment row B, and only then hands the request to the* $\mathsf{CompactMetric}^{\uparrow}$ *witness K through J. The handoff preserves componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}$ *row. It exports no open-cover compactness, choice-selected neighbourhood family, host topology, quotient metric equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 7847.1. The metric source M, positive radius r, ball-containment row B, compact-neighbourhood witness K, and handoff row J are the only mathematical rows available to a local compactness consumer.

The read order is forced by the rows themselves. A compact witness can be consumed only after the point and radius have been displayed in the metric source and the containment row has placed the resulting ball inside the compact neighbourhood.

Transport and replay are componentwise. The hsame row H keeps the same metric source, radius, containment, and compact witness, while the displayed Cont row C repeats the same route for later consumers.

Finally, P and N source and name only the displayed packet. Since no excluded coordinate appears in the carrier, the compact-ball handoff is the whole local compactness surface. □

Theorem 7847.3 (Locally compact metric space NameCert obligations)**.** *For every accepted* $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ *carrier $L = (M, K, r, B, J, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}$ *surface consists exactly of metric-source admission, compact-neighbourhood witness exposure, positive-radius admission, local ball containment, compact-ball handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7847.1. The accepted packet displays the metric source, compact-neighbourhood witness, radius, containment, handoff, transport, replay, provenance, and naming rows.

The compactness obligation is local. It is read only through K after M, r, B have been displayed, so the packet does not assert a global open-cover compactness theorem or select a neighbourhood family by choice.

The structural rows H, C, P, N preserve and name the same finite route. No remaining row stores host topology, quotient metric equality, ambient completion, Lean verification, or a bridge credential, so the listed rows exhaust the NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ packet displays a $\mathsf{Met}^{\uparrow}$ source, a $\mathsf{PositiveReal}^{\uparrow}$ radius row, a local ball-containment row, a $\mathsf{CompactMetric}^{\uparrow}$ witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local $\mathsf{NameCert}$ row before any compact-neighbourhood read is public.

Independence witness: metric and compactmetric: neither sibling is bijective to $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ because this packet jointly stores the pointwise positive-radius row and the local ball-containment handoff from chapter 57 into chapter 129.

Closure status for $\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{LocallyCompactMetricSpace}^{\uparrow}$ packet is generated from a MetricSpace source row, a CompactMetric witness row, a positive-radius row, local ball containment, a compact-ball handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7847.1, Definition 7847.2, and Definition 7847.3 seed the finite local compactness route from MetricSpace rows to compact metric witnesses.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocallyCompactMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected neighbourhoods, host topology, quotient metric equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius admission, ball-containment exactness, compact-neighbourhood exposure, handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocallyCompactMetricSpaceUp.

Chapter 7848

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailPasting}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and tail-equivalent representatives, the $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ packet records the finite shared-tail pasting surface used before a real-name seal is read. It sits beside the finite observation surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names a finite tail-pasting route; it is not quotient sequence equality, a selected limit, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7848.1 (Regular Cauchy tail pasting carrier)**.** *A* $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, R, \tau, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right* $\mathsf{RegSeqRat}^{\uparrow}$ *rows whose late observations are pasted along a shared tail.*
2. *τ is the finite tail threshold row, naming the stage after which the two rows are compared through the same observed tail window.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *shared-tail window row containing the inspected rational observations after τ.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for every tail comparison and pasted readback.*
5. *Q is the pasted* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from L, R, τ, W, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after the shared-tail window, dyadic ledger, and pasted regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the source rows, tail threshold, shared window, tolerance ledger, pasted readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the tail-pasting route*

$$L, R, \tau, W, D \longmapsto Q \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailPasting}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $L, R, \tau, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, host sequence equality, host real equality, countable choice, ambient completeness, Lean verification, or a standard bridge.

Theorem 7848.2 (Regular Cauchy tail pasting shared-tail handoff)**.** *For every accepted* $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ *carrier*

$$T = (L, R, \tau, W, D, Q, E, H, C, P, N),$$

each Real-completion consumer reads the shared-tail route in the order

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer first displays the tail threshold τ and shared $\mathsf{StreamName}^{\uparrow}$ *window W, then the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows L, R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, the pasted readback Q, and finally the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The handoff preserves componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}$ *row, and it exports no quotient stream equality, selected limit, host sequence equality, countable-choice schedule, or ambient Real completeness coordinate.*

Proof. Project the carrier of Definition 7848.1. The mathematical rows are exactly the two source readbacks, the tail threshold, the shared window, the dyadic tolerance ledger, the pasted readback, and the terminal real seal.

The shared-tail route begins with τ and W. These rows state which finite tail is visible and which rational observations are inspected before any pasted readback can be consumed.

Next read L, R, D, Q. The two regular rational rows supply the source observations, the dyadic ledger records the comparison budgets on the shared tail, and the pasted row Q is assembled only from those displayed rows.

Only after Q is public can the terminal seal E be read. The structural rows H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming.

Since the carrier has no quotient-stream, selected-limit, host-sequence, choice, or ambient-completeness coordinate, the handoff is confined to the listed StreamName, RegSeqRat, DyadicRatCore, RealUp, and structural rows. □

Theorem 7848.3 (Regular Cauchy tail pasting NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailPasti}$ *carrier $T = (L, R, \tau, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}$ *surface consists exactly of left and right RegSeqRat source admission, finite tail-threshold exposure, shared StreamName window exposure, DyadicRatCore tolerance exactness, pasted RegSeqRat readback, RealUp seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7848.1. The accepted packet displays the two regular rational source rows, the finite tail threshold, the shared window, the tolerance ledger, the pasted readback, the Real seal, and the structural rows.

The tail-pasting obligation is finite. The threshold and window rows determine the only observations available to the pasted readback, while the dyadic ledger supplies all comparison budgets used on that tail.

The Real seal is downstream of the pasted readback. Thus a consumer reaches $\mathsf{Real}^{\uparrow}$ only after the StreamName, RegSeqRat, and DyadicRatCore rows have been displayed.

Finally, H, C, P, N transport, replay, source, and name only these rows. Because the carrier contains no quotient equality, selected representative, selected limit, host equality, countable-choice schedule, ambient completeness, Lean verification, or bridge coordinate, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ packet displays two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, a finite tail threshold, a shared $\mathsf{StreamName}^{\uparrow}$ window, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a pasted readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any Real seal read is public.

Independence witness: streamname, regseqrat, dyadicratcore, and real: no listed sibling is bijective to $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ because this packet jointly stores the shared-tail threshold, pasted readback, and terminal RealUp seal route as one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailPasting}^{\uparrow}$ packet is generated from left and right RegSeqRat rows, a finite tail threshold, a shared StreamName window, a DyadicRatCore tolerance ledger, a pasted RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7848.1, Definition 7848.2, and Definition 7848.3 seed the finite shared-tail pasting route before terminal RealUp seal reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailPasting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, host sequence equality, host real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, tail-threshold exposure, shared-window exactness, dyadic tolerance exactness, pasted readback stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailPastingUp.

Chapter 7849

A Concrete Naming Certificate for $\mathsf{LebesgueConstant}^{\uparrow}$

Following Lebesgue and Zygmund on Fourier partial sums, the $\mathsf{LebesgueConstant}^{\uparrow}$ packet records the finite norm-growth data of trigonometric partial-sum operators as BEDC NameCert rows. It sits over the Fourier coefficient windows of chapter 124, the Dirichlet-kernel row of chapter 2311, the circle phase samples of chapter 58, the integral normalization route of chapter 123, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the downstream approximation boundary of chapter 463. The packet names a finite harmonic-analysis growth surface, not a host L^1 operator norm, not Haar measure, and not a quotient function-space object.

Definition 7849.1 (LebesgueConstant carrier)**.** *A* $\mathsf{LebesgueConstant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, D, S, I, N, W, R, E, H, C, P, L)$$

with the following displayed rows:

1. *F is the Fourier coefficient-window row naming the finite frequency interval whose partial sum is inspected.*
2. *D is the Dirichlet-kernel row supplying the finite convolution kernel for that window.*
3. *S is the* $\mathsf{S}^{1\uparrow}$ *phase-sample row used to evaluate the displayed kernel and partial-sum reads.*
4. *I is the* $\mathsf{Integral}^{\uparrow}$ *normalization row for the finite absolute-kernel read.*
5. *N is the finite norm-growth ledger recording the inspected Lebesgue-constant value window.*
6. *W is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance window bounding the displayed norm read.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite rational approximations.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed norm-growth datum.*
9. *H records componentwise* hsame *transport for $F, D, S, I, N, W, R, E, C, P, L$.*
10. *C records displayed* Cont *replay from a partial-sum request through the Dirichlet-kernel and integral rows to the norm ledger.*
11. *P is the* Pkg *provenance over the Fourier, Dirichlet-kernel, circle, integral, dyadic, regular-rational, Real, transport, replay, and NameCert rows.*

12. *L is the local* $\mathsf{NameCert}_{\mathsf{LebesgueConstant}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying all twelve rows. It has no coordinate for Haar measure, host L^1 spaces, quotient function equality, selected Fourier representatives, ambient completeness, or an unrestricted Fourier-convergence theorem.

Lean4 (statement) `BEDC.Derived.LebesgueConstantUp`

Theorem 7849.2 (LebesgueConstant NameCert obligations)**.** *For the carrier of Definition 7849.1, the local* $\mathsf{NameCert}_{\mathsf{LebesgueConstant}^{\uparrow}}$ *surface is exhausted by five obligation rows:*

1. *carrier admission for $K = (F, D, S, I, N, W, R, E, H, C, P, L)$;*
2. *Fourier-window and Dirichlet-kernel exposure through F and D;*
3. *phase-sample and integral-normalization exposure through S and I;*
4. *norm-growth, dyadic tolerance, regular rational readback, and Real sealing through N, W, R, E;*
5. *componentwise transport, replay, provenance, and local naming through H, C, P, L.*

Every accepted norm-growth read must display these rows before a downstream approximation consumer may cite a Lebesgue-constant datum.

Proof. Project the carrier of Definition 7849.1. The displayed tuple contains exactly the Fourier window, Dirichlet kernel, phase samples, integral normalization, norm ledger, dyadic tolerance, regular rational readback, Real seal, transport, replay, provenance, and local NameCert rows.

The first two obligations bind the source of the partial-sum read. The Fourier window F names the finite frequency interval, and the Dirichlet row D supplies the only kernel through which the partial-sum norm can be inspected.

The phase and normalization rows S, I then make the finite absolute-kernel read visible before any norm-growth entry is accepted. Rows N, W, R, E keep the numeric read inside the dyadic, regular-rational, and Real sealing route.

Finally H, C, P, L preserve, replay, source, and name the same packet. Since the carrier has no row for Haar measure, host L^1 spaces, quotient function equality, selected Fourier representatives, or ambient completeness, the five listed obligations exhaust the local NameCert surface. □

Theorem 7849.3 (LebesgueConstant Dirichlet norm handoff)**.** *Every Fourier partial-sum norm read exported by an accepted* $\mathsf{LebesgueConstant}^{\uparrow}$ *packet factors through the Dirichlet-kernel and integral rows*

$$F, D, S, I \longmapsto N, W, R, E$$

before any $\mathsf{UniformLimit}^{\uparrow}$ *handoff can consume the norm-growth datum. The handoff does not export Haar measure, host L^1 spaces, quotient function equality, selected Fourier representatives, or ambient completeness.*

Proof. Begin with a consumer of the norm ledger N. Carrier admission places N downstream of the Fourier window F, Dirichlet kernel D, circle phase samples S, and integral normalization I.

The replay row C records the only displayed route from a partial-sum request to the norm-growth read. Thus the request must first expose the finite coefficient window, then read the Dirichlet-kernel row and the integral-normalization row before the dyadic tolerance window W and regular-rational readback R are available.

The Real seal E is reached only after N, W, R have been displayed. Transport and provenance through H and P keep that same route attached to the local name L, so a $\mathsf{UniformLimit}^{\uparrow}$ consumer receives only the finite norm-growth datum produced by the Dirichlet-kernel and integral rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueConstant}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueConstant}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7849.1, Definition 7849.2, and Definition 7849.3 seed the finite Fourier partial-sum norm-growth packet through Dirichlet-kernel, integral, dyadic, regular-rational, Real, and uniform-limit-facing rows.

Constructive story: A $\mathsf{LebesgueConstant}^{\uparrow}$ packet is generated from Fourier coefficient-window data, Dirichlet-kernel rows, circle phase samples, integral-normalization rows, a finite norm-growth ledger, dyadic tolerance data, RegSeqRat readback, a Real seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueConstant}\uparrow}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.LebesgueConstantUp`

Bridge status: none

Not claimed: This chapter does not claim Haar measure, host L^1 spaces, quotient function equality, selected Fourier representatives, ambient completeness, Lean-checked obligations, or a standard bridge.

Upgrade path: Obligation closure requires Lean-checked carrier admission, NameCert surface, Dirichlet norm handoff, and ledger non-escape rows for $F, D, S, I, N, W, R, E, H, C, P, L$.

Chapter 7850

A Concrete Naming Certificate for $\mathsf{RichmanCompletion}^{\uparrow}$

Following Bishop and Richman, the $\mathsf{RichmanCompletion}^{\uparrow}$ packet records a constructive completion neighbour for the L10 Real and Completion corridor as finite BEDC NameCert data. It consumes the dyadic arithmetic core of chapter 291, finite stream windows from chapter 126, regular rational readback from chapter 301, the terminal real-name seal of chapter 38, and the completion-functor handoff of chapter 7003. The packet names the inspected regular-Cauchy completion route; it does not quotient names, select limits, use countable choice, assert ambient $\mathsf{Real}^{\uparrow}$ completeness, choose finite subcovers, or import open-cover compactness.

Definition 7850.1 (Richman completion carrier)**.** *A* $\mathsf{RichmanCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (D, S, Q, E, L, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, recording dyadic endpoints, comparisons, and rational tolerance arithmetic used by the completion read.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing exactly the inspected rational-name windows visible to a consumer.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row obtained from the displayed stream windows and dyadic tolerance data.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after D, S, Q and the local comparison data have been displayed.*
5. *L is the located comparison row, answering each admitted rational cut request by finite inspection of D, S, Q before any terminal seal is consumed.*
6. *B is the dyadic radius-budget row, recording the finite radii and contraction budgets used to pass from regular-Cauchy data to the completion handoff.*
7. *H records componentwise* hsame *transport for the dyadic arithmetic, stream windows, regular readback, real seal, located comparison, radius budget, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same finite completion route.*

9. *P is the* Pkg *provenance over* $\mathsf{RichmanCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RichmanCompletion}^{\uparrow}}$ *row naming exactly this packet.*

The classifier compares accepted carriers only through $D, S, Q, E, L, B, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, selected limits, countable choice, host equality of real names, ambient $\mathsf{Real}^{\uparrow}$ *completeness, open-cover compactness, or selected finite subcovers.*

Lean4 ✓ `BEDC.Derived.RichmanCompletionUp.RichmanCompletionTasteGate single carrier alignment`

Theorem 7850.2 (Richman completion NameCert obligations)**.** *For every accepted* $\mathsf{RichmanCompletion}^{\uparrow}$ *carrier*

$$R = (D, S, Q, E, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RichmanCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic visibility, finite* $\mathsf{StreamName}^{\uparrow}$ *window admission,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback,* $\mathsf{Real}^{\uparrow}$ *seal discipline, located comparison, dyadic radius-budget exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must pass through those rows before the terminal seal is available.*

Proof. Project the carrier of Definition 7850.1. The analytic rows D, S, Q, E, L, B expose the dyadic arithmetic, finite windows, regular-Cauchy readback, terminal Real seal, located comparison, and radius-budget data in the order named by the tuple.

Read the constructive route through the sibling chapters. The dyadic row D is the arithmetic source, the stream row S fixes the finite observations, and the regular row Q provides the Cauchy readback before E can be consumed.

The comparison and budget rows L, B keep the Richman-facing completion read local: each cut response and radius request is answered by visible finite data rather than by a quotient object or selected limiting representative.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for quotient completion equality, selected limits, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, open-cover compactness, or selected finite subcovers, the listed rows exhaust the local NameCert surface. □

Theorem 7850.3 (Richman completion regular-Cauchy handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or completion-functor-facing consumer of an accepted* $\mathsf{RichmanCompletion}^{\uparrow}$ *packet receives the finite handoff*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BishopRegularCompletionFunctor}^{\uparrow}$$

through the displayed rows $D, S, Q, E, L, B, H, C, P, N$. The handoff is a regular-Cauchy completion route with located comparison and dyadic radius budgets; it is not a quotient completion, selected limit, countable-choice schedule, host real equality theorem, ambient $\mathsf{Real}^{\uparrow}$ *completeness claim, selected finite subcover, or open-cover compactness principle.*

Proof. Start with the source side. The rows D and S determine the dyadic tolerance cells and the finite rational-name windows available to the read.

Next pass through Q, E. The $\mathsf{RegSeqRat}^{\uparrow}$ row reads the displayed windows as regular-Cauchy data, and the terminal $\mathsf{Real}^{\uparrow}$ seal is exposed only after that readback.

Then use L, B to route the Richman completion interface. The located comparison row answers admitted cut requests from the same finite data, while the dyadic radius-budget row records the radius schedule consumed by the completion-functor handoff.

The structural rows H, C, P, N preserve the sibling route and attach the local name. Thus any completion-facing consumer receives the displayed regular-Cauchy handoff and no quotient, selector, choice, host-equality, ambient-completeness, finite-subcover, or open-cover compactness coordinate. □

Falsifiable prediction: Any accepted $\mathsf{RichmanCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or a $\mathsf{BishopRegularCompletionFunctor}^{\uparrow}$ handoff without first reading the displayed $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, located comparison, dyadic radius-budget, hsame, Cont, Pkg, and local NameCert rows is outside the packet surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, bishop-regular-completion-functor: no listed sibling is bijective to $\mathsf{RichmanCompletion}^{\uparrow}$ because this packet binds dyadic arithmetic, finite windows, regular-Cauchy readback, terminal Real sealing, located comparison, radius budgets, transport, replay, provenance, and local naming as one constructive completion surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RichmanCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RichmanCompletion}^{\uparrow}$ packet is generated from DyadicRatCore arithmetic rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, located comparison, dyadic radius budgets, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RichmanCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7850.1, Definition 7850.2, and Definition 7850.3 seed the Richman constructive completion route over dyadic arithmetic, finite windows, regular-Cauchy readback, Real sealing, located comparison, radius budgets, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RichmanCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none
