Not claimed: This chapter does not claim RealUp completeness, quotient completion, quotient stream equality, selected limits, countable choice, selected finite subcovers, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic arithmetic coverage, finite-window readback, regular-Cauchy handoff, located comparison exactness, radius-budget stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RichmanCompletionUp.

Chapter 7851

A Concrete Naming Certificate for $\mathsf{RegularCauchyPruning}^{\uparrow}$

Following Bishop and Bridges on subsequences and regular Cauchy sequences, the $\mathsf{RegularCauchyPruning}^{\uparrow}$ packet records the finite certificate surface for deleting redundant observation requests from a regular Cauchy rational stream while preserving the terminal real-name seal. It sits after the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the tail restriction route of chapter 2084, the cofinal-subsequence surface of chapter 1998, and the terminal boundary of chapter 38. The packet is a non-quotient, choice-free pruning certificate for L10 Real and Completion consumers; it does not select a hidden subsequence, quotient streams, compare host real equality, or invoke ambient completeness.

Definition 7851.1 (Regular-Cauchy pruning carrier)**.** *A* $\mathsf{RegularCauchyPruning}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, W, \rho, T, Q, D, R, E, H, C, G, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row whose regular Cauchy rational observations are being pruned.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger listing the inspected source requests and the retained requests after pruning.*
3. *ρ is the pruning schedule row. It records, for each displayed retained request, the source request that survives; it is finite on the inspected window and cofinal on the displayed thresholds.*
4. *T is the* $\mathsf{RegularCauchyTailSubsequence}^{\uparrow}$ *tail row exposing the initial cutoff before any retained window is read.*
5. *Q is the* $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$ *cofinal row exposing the monotone retained schedule after the tail cutoff.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger shared by the source, retained windows, tail row, cofinal row, and real seal.*
7. *R is the retained* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W, ρ, T, Q, D.*
8. *E is the inherited* $\mathsf{Real}^{\uparrow}$ *seal, exposed only after the retained readback row has been displayed.*
9. *H records componentwise* hsame *transport for the source, windows, pruning schedule, tail row, cofinal row, tolerance ledger, retained readback, real seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a pruning request through the same finite rows.*
11. *G is the* Pkg *provenance over* $\mathsf{RegularCauchyPruning}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailSubsequence}$ $\mathsf{RegularCauchyCofinalSubsequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyPruning}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, \rho, T, Q, D, R, E, H, C, G, N$. It has no coordinate for quotient stream equality, a hidden infinite selector, selected ambient limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 7851.2 (Regular-Cauchy pruning tail stability)**.** *Let*

$$P = (S, W, \rho, T, Q, D, R, E, H, C, G, N)$$

be an accepted $\mathsf{RegularCauchyPruning}^{\uparrow}$ *carrier. Every tail-facing or cofinal-subsequence consumer of P reads the same terminal* $\mathsf{Real}^{\uparrow}$ *seal E through the finite route*

$$S, W, \rho, T, Q, D, R, E, H, C, G, N.$$

Consequently pruning redundant observed requests preserves the displayed real-name boundary and supplies no quotient stream equality, selected limit, host real equality, countable choice, or ambient completeness principle.

Proof. Project the carrier of Definition 7851.1. The tail row T and cofinal row Q are displayed coordinates of the same packet as the source row S, window ledger W, pruning schedule ρ, dyadic ledger D, retained readback R, and seal E.

Read the tail route first. The row T exposes the initial cutoff through chapter 2084, so retained requests are not read until the tail window has been displayed.

Read the cofinal route next. The row Q exposes the retained monotone cofinal schedule through chapter 1998. The schedule row ρ is therefore a finite pruning ledger on the inspected windows, not an external choice function.

Finally read D, R, E. The dyadic tolerance ledger is shared by the source, tail, cofinal, and retained readback rows, and R is the only regular rational readback available before the real seal. Since H, C, G, N transport, replay, source, and name only these rows, a consumer cannot extract quotient stream equality, selected limits, host equality, countable choice, or ambient completeness from the pruning packet. □

Theorem 7851.3 (Regular-Cauchy pruning NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyPruning}^{\uparrow}$ *carrier*

$$P = (S, W, \rho, T, Q, D, R, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPruning}^{\uparrow}}$ *surface consists exactly of carrier admission for the source regular rational row, finite window ledger, pruning schedule, tail row, cofinal retained schedule, dyadic tolerance ledger, retained regular rational readback, real seal, componentwise transport, continuation replay, provenance, and local naming rows; tail stability through T; cofinal stability through Q; retained readback exactness through R; and ledger nonescape through H, C, G, N. No NameCert obligation is stored outside those displayed rows.*

Proof. Carrier admission is projection from Definition 7851.1. The packet displays exactly the source row, inspected and retained windows, pruning schedule, tail and cofinal routes, dyadic ledger, retained readback, Real seal, and structural rows.

Tail stability is Definition 7851.2. It ensures that the tail and cofinal consumers read the same seal through the retained finite route.

Retained readback exactness is read from R. The retained $\mathsf{RegSeqRat}^{\uparrow}$ row consumes the displayed windows, pruning schedule, tail row, cofinal row, and dyadic ledger before E is visible.

The structural rows exhaust the route. Componentwise transport, continuation replay, provenance, and local naming preserve only the displayed packet, so no hidden selector, quotient stream, selected limit, host equality, countable choice, ambient completeness, Lean verification, or bridge credential can serve as a local obligation. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyPruning}^{\uparrow}$ completion-facing read exposes the source StreamName windows, pruning schedule, tail row, cofinal row, dyadic tolerance ledger, retained RegSeqRat readback, and inherited RealUp seal before any consumer can inspect the pruned stream.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyPruning}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyPruning}^{\uparrow}$ packet is generated from a source RegSeqRat row, StreamName window ledger, pruning schedule, tail-subsequence row, cofinal-subsequence row, DyadicRatCore tolerance ledger, retained RegSeqRat readback, inherited RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyPruning}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7851.1, Definition 7851.2, and Definition 7851.3 seed the finite pruning route for regular Cauchy rational streams over displayed StreamName windows, tail and cofinal subsequence rows, dyadic tolerance ledgers, retained RegSeqRat readback, and the inherited RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyPruning}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, hidden infinite selectors, selected ambient limits, countable choice, host real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pruning schedule stability, tail stability, cofinal retained-schedule stability, retained readback exactness, RealUp seal compatibility, and ledger nonescape for BEDC.Derived.RegularCauchyPrur

Chapter 7852

A Concrete Naming Certificate for $\mathsf{DyadicMidpointCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion by finite approximation data, the $\mathsf{DyadicMidpointCompletion}^{\uparrow}$ packet records the midpoint-refinement route by which dyadic bracket approximants are turned into regular rational reads and then into a Real name. It sits over the dyadic arithmetic core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the constructive completion neighbour of chapter 7850. The packet names a finite midpoint-refinement completion surface; it is not Dedekind completeness, open-cover compactness, quotient real equality, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7852.1 (Dyadic midpoint completion carrier)**.** *A* $\mathsf{DyadicMidpointCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, E, J, W, S, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row, recording the admitted dyadic endpoints, midpoint operation, interval inclusion comparisons, and tolerance cells used by the refinement.*
2. *E is the endpoint row. It lists the finite left and right dyadic endpoints inspected at each refinement stage and records their displayed nesting order.*
3. *J is the midpoint-refinement schedule. It records which midpoint bisections are performed, which half-interval survives each displayed comparison, and the finite dependency of every later bracket on earlier endpoint rows.*
4. *W is the finite window budget. It records the number of endpoint and midpoint observations needed for each admitted precision request before any regular rational readback is exposed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row obtained from the finite endpoint and midpoint windows E, J, W.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity witness. It certifies that the stream windows read through S satisfy the displayed dyadic Cauchy bounds supplied by D and W.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, readable only after the dyadic endpoints, midpoint schedule, finite window budget, StreamName row, and RegSeqRat witness have been displayed.*

8. *H records componentwise* hsame *transport for the dyadic arithmetic, endpoint row, midpoint schedule, window budget, StreamName readback, RegSeqRat witness, Real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the route*

$$D, E, J, W \longmapsto S \longmapsto Q \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{DyadicMidpointCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMidpointCompletion}^{\uparrow}}$ *row naming exactly this finite midpoint-refinement packet.*

The classifier compares accepted carriers only through $D, E, J, W, S, Q, R, H, C, P, N$. It has no coordinate for Dedekind completeness, open-cover compactness, quotient reals, host equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7852.2 (Dyadic midpoint completion NameCert obligations)**.** *For every accepted* DyadicMidpointComple *carrier*

$$M = (D, E, J, W, S, Q, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicMidpointCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for dyadic endpoints, the midpoint refinement schedule, the finite window budget, StreamName readback, RegSeqRat regularity, Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real-name consumer of the packet must read the finite route*

$$D, E, J, W \longmapsto S \longmapsto Q \longmapsto R$$

before it can consume the terminal seal.

Proof. Project the accepted packet $M = (D, E, J, W, S, Q, R, H, C, P, N)$. The carrier exposes dyadic arithmetic, endpoint brackets, midpoint choices, precision windows, stream readback, regular rational bounds, the Real seal, and the four structural rows in the displayed order.

The endpoint and midpoint data are finite. The row D supplies dyadic arithmetic and comparisons, while E lists the endpoint brackets and J lists the midpoint bisections that refine them. The window row W fixes, for each admitted precision request, the finite prefix of those rows that must be inspected.

Readback then proceeds through S and Q. The $\mathsf{StreamName}^{\uparrow}$ row is obtained only from the displayed finite windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row records the regular Cauchy bounds witnessed by the dyadic tolerance ledger and midpoint schedule.

Finally R, H, C, P, N seal, transport, replay, source, and name the same finite route. Since no carrier row stores Dedekind completeness, open-cover compactness, quotient real equality, host equality, a selected limiting representative, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Any accepted $\mathsf{DyadicMidpointCompletion}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the displayed dyadic endpoint, midpoint-refinement schedule, finite window, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows is outside the packet surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, richman-completion: no listed sibling is bijective to $\mathsf{DyadicMidpointCompletion}^{\uparrow}$ because this packet binds dyadic endpoints,

midpoint refinement, finite precision windows, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one constructive completion surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMidpointCompletion}\uparrow}$.

Constructive story: A $\mathsf{DyadicMidpointCompletion}^{\uparrow}$ packet is generated from dyadic endpoint rows, midpoint refinement schedules, finite window budgets, StreamName readback, RegSeqRat regularity witnesses, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMidpointCompletion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7852.1 and Definition 7852.2 seed the finite midpoint-refinement completion route over dyadic endpoints, midpoint schedules, finite windows, StreamName readback, RegSeqRat regularity, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMidpointCompletion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, open-cover compactness, quotient reals, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint nesting, midpoint-refinement exactness, finite-window budgeting, StreamName readback, RegSeqRat regularity, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMidpointCompletionUp.

Chapter 7853

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ packet records the finite basis object that sits between regular Cauchy schedules and completion-facing filter reads. It is grounded in the finite stream windows of chapter 126, the regular-rational readback surface of chapter 301, the basis-completion handoff of chapter 4050, and the terminal real-name seal of chapter 38. The packet makes the basis row first-class before completion consumers inspect it; it does not add quotient filters, selected limits, host real equality, countable choice, or ambient completeness.

Definition 7853.1 (RegularCauchyFilterBasis carrier)**.** *A* $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, R, D, B, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the regular Cauchy tail observations that may be inspected.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the same windows and regular-rational reads.*
4. *B is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row whose basic observations are exactly the displayed windows in S with tolerances supplied by D.*
5. *M is the finite meet row: every pair of displayed basis observations has a later displayed observation refining both and preserving the same tolerance ledger.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D, B, M have been displayed.*
7. *H records componentwise* hsame *transport for windows, readback, tolerance, basis, meet, seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from basis refinements through $S, R, D, B, M, E, H, P, N$.*
9. *P records* Pkg *provenance over* $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasis}^{\uparrow}}$ *row.*

The classifier accepts packets only through the ten displayed rows $S, R, D, B, M, E, H, C, P, N$. No coordinate stores a quotient filter, hidden cofinal family, selected completion point, host real equality, countable-choice selector, or ambient completeness witness.

Lean4 ✓ `BEDC.Derived.RegularCauchyFilterBasisUp.RegularCauchyFilterBasisTasteGate single carrier alignment`

Theorem 7853.2 (RegularCauchyFilterBasis NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterBasis}$ *carrier*

$$Q = (S, R, D, B, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasis}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite window schedule, regular-rational readback, dyadic tolerance ledger, basis row, finite meet row, terminal real seal, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing or Real-facing consumer must first read S, then R and D, then the basis and meet rows B, M, and only then the seal and structural rows E, H, C, P, N.*

Proof. Project the carrier of Definition 7853.1. The visible source of the packet is the finite window schedule S together with its regular-rational readback R and dyadic tolerance ledger D.

Read the basis row next. The row B contains exactly the observations listed by S and the tolerance information listed by D, while M supplies the finite common-refinement row needed to keep the basis directed.

Finally consume the seal and structural rows. The row E is downstream from S, R, D, B, M, and H, C, P, N only transport, replay, source, and name that same route. Since no excluded quotient, selector, host-equality, choice, or completeness coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 7853.3 (RegularCauchyFilterBasis stability scope)**.** *Let $Q = (S, R, D, B, M, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ *carrier. Any finite refinement of displayed basis observations stays inside the same route*

$$S, R, D \longmapsto B, M \longmapsto E, H, C, P, N.$$

The refinement preserves the $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E under componentwise* hsame *transport and displayed* Cont *replay. The stability scope is a finite basis certificate; it is not quotient filter equality, a selected limit, host real equality, countable choice, or ambient completeness.*

Proof. Begin with the displayed basis observations in B. By carrier admission, each observation is named by the finite window schedule S and carries its tolerance data in D.

Use the meet row M for refinement. For a pair of displayed observations, M names a later displayed observation refining both; induction over a finite list repeats this same row without introducing any hidden cofinal family.

The regular-rational and Real-facing rows remain fixed. The readback row is R, the seal row is E, and H, C, P, N preserve the route by transport, replay, provenance, and local naming. Hence every stable refinement remains inside the displayed packet and cannot be reread as one of the excluded completion or equality principles. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ consumer preserving the same displayed basis windows factors through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, finite meet, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: `regularcauchyfilter`, `cauchyfilterbasiscompletion`, `regseqrat`, `real`: the RegularCauchyFilter packet carries a source CauchyFilter row; the CauchyFilterBasis-Completion packet carries the completion-facing basis route; the RegSeqRat packet carries regular rational readback without a basis meet; and the Real packet carries the terminal seal. None is bijective to $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasis}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyFilterBasis row, a finite meet row, a RealUp seal, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasis}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7853.1, Definition 7853.2, and Definition 7853.3 seed the finite regular Cauchy basis route between schedules and completion-facing filters.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasis}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected completion points, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite meet stability, readback preservation, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFilterBasisUp.

Chapter 7854

A Concrete Naming Certificate for $\mathsf{RegularRealGauge}^{\uparrow}$

Following Bishop and Bridges on regular real names with explicit moduli, the $\mathsf{RegularRealGauge}^{\uparrow}$ packet records finite modulus-gauge control for a regular real name before any completion consumer treats the name as a completed real. It sits over the $\mathsf{StreamName}^{\uparrow}$ finite stream windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ regular rational readback of chapter 301, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the $\mathsf{IntervalDomain}^{\uparrow}$ boundary of chapter 1543. The packet exposes a finite gauge route for later completion and interval consumers; it does not assert quotient real equality, trichotomy, selected limits, or ambient completeness.

Definition 7854.1 (RegularRealGauge carrier)**.** *A* $\mathsf{RegularRealGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (W, R, D, G, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected from the regular real name;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row obtained from the window W;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the displayed dyadic precision request and its admissible refinements;*
4. *G is the gauge and modulus row, recording the finite precision-to-window control visible to consumers;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row by which the readback is treated as a real-name boundary after the gauge has been displayed;*
6. *H stores componentwise* hsame *transport for the window, readback, tolerance ledger, gauge row, real seal, replay, provenance, and local naming;*
7. *C stores the displayed* Cont *replay from W through R, D, G into the sealed* $\mathsf{Real}^{\uparrow}$ *readback;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularRealGauge}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{IntervalDomain}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRealGauge}^{\uparrow}}$ *row.*

The accepted packet stores only this finite gauge surface. It has no coordinate for host completeness, quotient real equality, trichotomy, selected limits, or an unbounded external modulus function.

Theorem 7854.2 (RegularRealGauge NameCert obligations)**.** *For the carrier of Definition 7854.1, the local* $\mathsf{NameCert}_{\mathsf{RegularRealGauge}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier admission for the displayed packet* $J = (W, R, D, G, E, H, C, P, N)$*;*
2. *gauge visibility: every accepted consumer sees the gauge and modulus row* G *before reading the real seal* E*;*
3. *tolerance monotonicity: refinements recorded by* D *preserve the same stream window and regular-rational readback route;*
4. *real-seal nonescape: the* $\mathsf{Real}^{\uparrow}$ *row* E *is reached only through* W, R, D, G *and the displayed replay row* C*;*
5. *ledger refusal of host completeness: the packet exports no quotient equality of real names, no trichotomy principle, no selected limit, and no ambient completeness witness.*

Proof. Carrier admission is projection from Definition 7854.1. The rows $W, R, D, G, E, H, C, P, N$ are displayed coordinates of one finite BHist packet.

Gauge visibility is forced by the row order. A consumer reaches the real seal E only after the finite window W, readback R, tolerance ledger D, and gauge row G have been read.

For tolerance monotonicity, the ledger D is the only displayed dyadic budget. Refining a precision request therefore preserves the same route through W and R rather than selecting a detached real representative.

The replay row C and transport row H carry exactly this finite route into the seal E. Since no row contains host completeness, quotient equality, trichotomy, or a selected limit operator, the local NameCert refuses those readings. □

Theorem 7854.3 (RegularRealGauge modulus readback)**.** *Every accepted modulus-gauge read for a* $\mathsf{RegularRealGauge}^{\uparrow}$ *packet factors through* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *in the carrier order of Definition 7854.1. The interval-facing consumer may read* $\mathsf{IntervalDomain}^{\uparrow}$ *provenance from* P*, but the only tolerance budget available to that consumer is the displayed dyadic ledger* D *together with the gauge row* G*.*

In particular, the readback route exports no host function space of moduli, quotient real equality, trichotomy, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier $J = (W, R, D, G, E, H, C, P, N)$. The stream window W is read first, and the regular rational row R is the only readback obtained from that window.

Next read the dyadic ledger D and the gauge row G. These rows jointly record the finite precision-to-window control, so the consumer sees a displayed modulus route rather than a host function space of moduli.

The real seal E is then reached through the replay row C, while H transports the same rows componentwise and P records the sibling provenance, including $\mathsf{IntervalDomain}^{\uparrow}$. Thus the readback factors through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ without exporting quotient equality, trichotomy, selected limits, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealGauge}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularRealGauge}^{\uparrow}$ packet is generated from a StreamName finite window, a RegSeqRat readback, one DyadicRatCore tolerance ledger, a finite gauge and modulus row, a Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularRealGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7854.1, Definition 7854.2, and Definition 7854.3 seed the finite gauge route for regular real names over displayed dyadic tolerance data.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularRealGauge}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completeness, trichotomy, quotient real equality, selected limits, host modulus functions, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, gauge visibility, tolerance monotonicity, Realseal nonescape, and ledger refusal for the displayed packet.

Chapter 7855

A Concrete Naming Certificate for $\mathsf{BuchbergerCriterion}^{\uparrow}$

Following Buchberger's critical-pair criterion, the $\mathsf{BuchbergerCriterion}^{\uparrow}$ packet records the finite sufficiency surface by which displayed S-polynomial reductions certify that a finite generator list is already a Groebner basis. It sits after the polynomial carrier of chapter 50, the ideal source of chapter 81, the coefficient algebra rows of chapter 43 and chapter 44, and the finite reduction packet of chapter 2197. The chapter names the traditional finite critical-pair test as BEDC NameCert data; it does not import quotient ideal equality, an ambient term-order oracle, algebraic closure, selected normal forms outside the displayed rows, or a global ideal-membership decision procedure.

Definition 7855.1 (Buchberger criterion carrier)**.** *A* $\mathsf{BuchbergerCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (P, I, O, L, A, S, R, Z, H, C, K, N)$$

with the following displayed rows:

1. *P is the finite* $\mathsf{Poly}^{\uparrow}$ *source row, including the coefficient operations and polynomial syntax inspected by the packet.*
2. *I is the* $\mathsf{Ideal}^{\uparrow}$ *generator row naming the displayed generator list and its ambient ideal-membership surface.*
3. *O is the finite monomial-order row used only for the inspected leading-term comparisons and descent witnesses.*
4. *L is the leading-term ledger for the displayed generators and intermediate reduction rows.*
5. *A is the finite critical-pair index row, listing exactly the generator pairs inspected by the criterion.*
6. *S is the S-polynomial construction row, displaying common multiples, multiplier rows, and subtraction rows for every pair in A.*
7. *R is the reduction-trace row, listing reducer choices, multiplier rows, subtraction steps, and descent evidence for each displayed S-polynomial.*
8. *Z is the zero-remainder row, recording that each inspected S-polynomial reduction terminates at the displayed zero normal form.*
9. *H records componentwise* hsame *transport for polynomial, ideal, ordering, leading-term, critical-pair, S-polynomial, reduction, zero-remainder, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a Buchberger-criterion request through P, I, O, L, A, S, R, Z before any Groebner-basis handoff is consumed.*
11. *K is the* Pkg *provenance over* BuchbergerCriterion$^{\uparrow}$, Poly$^{\uparrow}$, Ideal$^{\uparrow}$, Ring$^{\uparrow}$, CommRing$^{\uparrow}$, GroebnerBasis$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BuchbergerCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient polynomial-ring equality, a hidden global term order, algebraic closure, a selected infinite basis, or a normal-form oracle outside R and Z.

Theorem 7855.2 (Buchberger criterion obligation surface)**.** *For every accepted* BuchbergerCriterion$^{\uparrow}$ *carrier*

$$B = (P, I, O, L, A, S, R, Z, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{BuchbergerCriterion}^{\uparrow}}$ *surface consists exactly of polynomial-source admission, ideal-generator admission, inspected monomial-order and leading-term exposure, critical-pair coverage through A, S-polynomial construction through S, reduction-trace exactness through R, zero-remainder exposure through Z, componentwise transport through H, displayed replay through C, provenance through K, and local naming through N. A downstream* GroebnerBasis$^{\uparrow}$ *consumer may read the packet only as this finite criterion surface.*

Proof. Project the carrier of Definition 7855.1. The algebraic source rows are P and I, and the inspected comparison rows are O and L.

Read the finite critical-pair row A. Each listed pair is expanded by S into the displayed common multiple, multiplier rows, and subtraction row that form the corresponding S-polynomial.

Induct over the reduction trace R for each listed pair. The base step is the S-polynomial row supplied by S; each later step names a reducer from the displayed generator surface, a multiplier row over P, a subtraction row, and a descent witness from O and L.

At the terminal step, Z records the zero remainder for every inspected pair. Thus the criterion exports only the finite zero-reduction surface consumed by the Groebner-basis route of chapter 2197.

Finally H, C, K, N transport, replay, source, and name the same rows. Since no carrier coordinate stores quotient ideal equality, a hidden term-order oracle, algebraic closure, selected infinite bases, or external normal forms, the listed rows exhaust the local obligation surface. □

Theorem 7855.3 (Buchberger criterion Groebner handoff)**.** *Every accepted* BuchbergerCriterion$^{\uparrow}$ *read handed to a* GroebnerBasis$^{\uparrow}$ *consumer factors through the finite route*

$$P, I, O, L, A, S, R, Z \longmapsto H, C, K, N.$$

The handoff supplies the critical-pair sufficiency rows required by the Groebner-basis finite reduction surface, but it does not supply quotient ideal equality, completed ideal membership, a selected normal-form function, an infinite basis, or a host proof of global algebraic closure.

Proof. Start with the obligation surface above. A Groebner-facing consumer first sees the polynomial and ideal source rows, then the inspected monomial-order and leading-term rows.

The critical-pair index row A determines the finite scope of the criterion. The S-polynomial row S and reduction trace R show how each pair is reduced, while Z records that the displayed terminal row is zero.

Transport and replay preserve that same finite handoff through H and C, with provenance and local naming supplied by K and N. No other row is available, so the consumer cannot reinterpret the criterion as a quotient-ring theorem, a hidden normal-form oracle, or a complete ideal-membership decision procedure. □

Falsifiable prediction: Every accepted $\mathsf{BuchbergerCriterion}^{\uparrow}$ consumer must display the polynomial source, ideal source, inspected monomial-order and leading-term rows, critical-pair index row, S-polynomial construction row, reduction trace, zero-remainder row, transport, replay, provenance, and local naming before using the Buchberger criterion as a Groebner-basis handoff.

Independence witness: polynomial, ideal, groebner-basis: $\mathsf{BuchbergerCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite critical-pair coverage, S-polynomial construction, zero-reduction traces, criterion-specific transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BuchbergerCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BuchbergerCriterion}^{\uparrow}$ packet is generated from polynomial rows, ideal-generator rows, finite monomial-order and leading-term rows, critical-pair index rows, S-polynomial rows, reduction traces, zero-remainder rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BuchbergerCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7855.1, Definition 7855.2, and Definition 7855.3 seed the finite Buchberger critical-pair criterion over PolynomialUp, IdealUp, RingUp, CommRingUp, GroebnerBasisUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BuchbergerCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ideal equality, a completed ideal-membership decision procedure, algebraic closure, a hidden term-order oracle, selected infinite bases, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, critical-pair coverage, S-polynomial exactness, reduction-trace exactness, zero-remainder exposure, Groebner handoff, transport, replay, provenance, and local naming for BEDC.Derived.BuchbergerCriterionUp.

Chapter 7856

A Concrete Naming Certificate for MetaCICSubstitutionResidualSpine$^{\uparrow}$

The MetaCICSubstitutionResidualSpine$^{\uparrow}$ packet realizes the residual boundary of chapter 9380 as finite substitution-audit spine data. It sits beside the closed substitution spine of chapter 6103, the typed substitution window of chapter 7519, the residual substitution boundary of chapter 2181, and the subject-reduction discharge route of chapter 719. The packet names the residual window that must remain visible before confluence or subject-reduction consumers use substitution data; it does not prove unrestricted substitution commutation, closed subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 7856.1 (MetaCIC substitution residual-spine carrier)**.** *A* MetaCICSubstitutionResidualSpine$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, W, B, O, T, E, P, H, C, K, N)$$

with the following displayed rows:

1. *S is the substitution-audit source row, naming the closed shift, closed substitution, closed composition, and generator-closure facts available from the audit map.*
2. *W is the residual-window row, recording the finite binder depths, payload positions, and open residual cells that must be displayed before a consumer reads the packet.*
3. *B is the binder-seal row, separating closed-boundary cases from residual cases under lambda and Pi binders.*
4. *O is the obstruction row, naming missing unrestricted commutation, beta-substitution preservation, dependent-codomain preservation, and subject-reduction discharge boundaries.*
5. *T is the transport row for substitution source, residual windows, binder seals, obstructions, typed-window handoff, replay, provenance, and local naming data.*
6. *E is the confluence and subject-reduction exposure row, specifying which residual-window entries must be visible before any handoff to the confluence or subject-reduction frontier is consumed.*
7. *P is the provenance row over the substitution audit map, the typed substitution window, the residual substitution boundary, the subject-reduction discharge route,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
8. *H records componentwise* hsame *transport for all displayed rows.*

9. *C records displayed* Cont *replay from a residual-spine request through S, W, B, O, T, E before any downstream handoff is used.*
10. *K is the* Pkg *source row over* $\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}$, $\mathsf{MetaCICSubstitutionSpine}^{\uparrow}$, $\mathsf{MetaCICTypedSubstitutionWindow}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{SubjectReductionDischargeSocket}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for unrestricted substitution calculus, closed subject reduction, confluence closure, evaluator equality, quotient syntax equality, or kernel consistency. Future Lean `TasteGate.lean` *coverage for this packet must include both* `Nontrivial` *and* `FieldFaithful` *instances for the residual-window classifier.*

Theorem 7856.2 (MetaCIC substitution residual-spine obligations)**.** *For every accepted* MetaCICSubstitutionResid *carrier*

$$R = (S, W, B, O, T, E, P, H, C, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}}$ *surface consists exactly of substitution-audit source admission through S, residual-window exposure through W, binder-seal exposure through B, obstruction exposure through O, transport through T and H, confluence and subject-reduction exposure through E, displayed replay through C, provenance through P and K, and local naming through N. Every confluence or subject-reduction consumer must keep the residual-window row visible before using the packet.*

Proof. Project the carrier of Definition 7856.1. The substitution-audit source is S, while W and B separate the visible residual windows from binder-sealed closed cases.

Read the obstruction row O. It keeps unrestricted substitution commutation, beta-substitution preservation, dependent-codomain preservation, and subject-reduction discharge as explicit boundaries rather than hidden consequences of the spine.

The exposure row E then governs downstream handoff. A confluence or subject-reduction consumer may inspect the packet only after the relevant entries of W have been displayed and transported through T and H.

Finally C, P, K, N replay, source, and name the same finite route. Since no carrier coordinate stores closed subject reduction, full confluence, evaluator equality, quotient syntax equality, or kernel consistency, the listed rows exhaust the local obligation surface. □

Theorem 7856.3 (MetaCIC residual-window handoff)**.** *Every accepted* $\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}$ *read sent to a confluence or subject-reduction consumer factors through the finite route*

$$S, W, B, O, T, E \longmapsto H, C, P, K, N.$$

The handoff may expose residual substitution windows, binder seals, and obstruction rows for downstream audit. It cannot be reread as unrestricted substitution compatibility, closed subject reduction, evaluator equality, quotient syntax equality, confluence closure, or kernel consistency.

Proof. Begin with the residual-spine obligation surface. The source row S supplies only the closed substitution-audit facts, so any open residual demand must pass through W.

The binder-seal row B distinguishes closed-boundary cases from residual cases, while O records the endpoints that remain unavailable. The handoff row E therefore exposes a residual window before a confluence or subject-reduction consumer may proceed.

Transport and replay through T, H, C preserve the same route, and P, K, N attach provenance and local naming. Because no hidden row discharges the obstruction endpoints, the packet remains a residual spine rather than a closed substitution or subject-reduction theorem. □

Falsifiable prediction: Every accepted read exposes the residual-window row before any subject-reduction or confluence handoff is consumed.

Independence witness: metacic-substitution-spine, metacic-typed-substitution-window, metacic-residual-substitution-boundary, subjectreductiondischarge: none is bijective to $\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}$ because this packet jointly carries residual-window, binder-seal, obstruction, transport, replay, provenance, and local NameCert rows for the substitution audit boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}$ packet is generated from substitution-audit source rows, residual-window rows, binder-seal rows, obstruction rows, confluence and subject-reduction exposure rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7856.1, Definition 7856.2, and Definition 7856.3 seed the finite residual-substitution spine over MetaCIC substitution audit rows, residual windows, binder seals, obstructions, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubstitutionResidualSpine}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution commutation, closed subject reduction, confluence closure, evaluator equality, quotient syntax equality, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, residual-window exposure, binder-seal exposure, obstruction exposure, handoff exposure, transport, replay, provenance, local naming, and TasteGate nontriviality and field-faithfulness for BEDC.Derived.MetaCICSubstitutionResidualSpineUp.

Chapter 7857

A Concrete Naming Certificate for $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$

Following Banach and Mazur on invariant means and the later finite-window summability tradition, the $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ packet records the bounded-sequence shift-average rows that may be inspected before any Banach-limit boundary is discussed. It sits between the finite shift-average route of chapter 7251, the Hardy–Cesaro mean surface of chapter 1765, the Toeplitz matrix-window route of chapter 1682, the Silverman–Toeplitz regularity packet of chapter 2126, and the boundary chapter for chapter 6697. The chapter names only finite windows, local shift rows, displayed averages, boundedness ledgers, real-name seals, transport, replay, provenance, and local naming; it does not assert a Hahn–Banach extension, an ultrafilter, a choice-selected Banach limit, quotient equality of bounded sequences, or an ambient dual-space element.

Definition 7857.1 (Banach limit finite-window carrier)**.** *A* $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, S, A, H, T, V, E, M, C, P, N)$$

with the following displayed rows:

1. *B is the bounded-sequence window row, listing the finite scalar entries and the displayed bound available to the consumer.*
2. *S is the shift schedule row, recording the finite offsets by which the same bounded sequence is re-indexed.*
3. *A is the finite average row supplied by* $\mathsf{FiniteShiftAverage}^{\uparrow}$ *for each displayed shift window.*
4. *H is the Hardy–Cesaro comparison row supplied by* $\mathsf{HardyCesaroMean}^{\uparrow}$ *for the same finite prefix data.*
5. *T is the Toeplitz matrix-window row, and V is the Silverman–Toeplitz regularity row, recording the finite transform checks that remain visible to summability consumers.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal obtained only after the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback of the inspected averages.*
7. *M records componentwise* hsame *transport for B, S, A, H, T, V, E.*
8. *C records displayed* Cont *replay from a finite-window request through shift scheduling, averaging, Cesaro comparison, Toeplitz windows, Silverman–Toeplitz regularity, and real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$, $\mathsf{FiniteShiftAverage}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{ToeplitzLemma}^{\uparrow}$, $\mathsf{SilvermanToeplitz}^{\uparrow}$, $\mathsf{BanachLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachLimitFiniteWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a full invariant mean, a Hahn–Banach extension theorem, an ultrafilter, a choice-selected functional, quotient equality of bounded sequences, or equality inside an ambient dual space.

Lean4 ✓ `BEDC.Derived.BanachLimitFiniteWindowUp.BanachLimitFiniteWindowTasteGate single carrier alignment`

Theorem 7857.2 (Banach limit finite-window NameCert obligations)**.** *For every accepted* BanachLimitFiniteWindo *carrier $W = (B, S, A, H, T, V, E, M, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachLimitFiniteWindow}^{\uparrow}}$ *surface contains exactly the following finite obligation blocks:*

1. *bounded-window admission through B, including the displayed scalar entries and bound ledger;*
2. *shift-schedule admission through S, including every inspected offset and its finite source window;*
3. *finite averaging through A and Hardy–Cesaro comparison through H;*
4. *Toeplitz and Silverman–Toeplitz summability-window visibility through T, V;*
5. $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *sealing through E;*
6. *componentwise transport, displayed replay, provenance, and local naming through M, C, P, N.*

No other block is exported by the carrier.

Proof. Project the carrier of Definition 7857.1. The rows $B, S, A, H, T, V, E, M, C, P, N$ are the complete finite packet, so each obligation must be read from one of those rows.

The source and shift data are exhausted by B and S. The averaging rows A, H then expose the finite shift average and Hardy–Cesaro comparison before any summability endpoint is visible.

The matrix-facing route is exhausted by T, V. These rows record only finite Toeplitz and Silverman–Toeplitz windows, and E seals only the displayed regular-rational readback of the inspected averages.

Finally M, C, P, N transport, replay, source, and name the same rows. Since the tuple has no coordinate for a Hahn–Banach extension, ultrafilter, selected invariant mean, quotient equality, or ambient dual-space equality, those objects cannot be exported from the local certificate. □

Theorem 7857.3 (Banach limit finite-window summability boundary)**.** *Every summability-facing consumer of an accepted* $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ *packet must pass through the sibling route*

$$\mathsf{FiniteShiftAverage}^{\uparrow} \longmapsto \mathsf{HardyCesaroMean}^{\uparrow} \longmapsto \mathsf{ToeplitzLemma}^{\uparrow} \longmapsto \mathsf{SilvermanToeplitz}^{\uparrow} \longmapsto \mathsf{BanachLimit}^{\uparrow}$$

as a finite BHist *ledger over $B, S, A, H, T, V, E, M, C, P, N$. The consumer may cite the packet as a finite shift-average boundary for bounded-sequence reads, but it may not retype that boundary as a full Banach-limit existence theorem, a Hahn–Banach extension, an ultrafilter construction, a choice-selected invariant mean, quotient equality of bounded sequences, or equality in an ambient dual carrier.*

Proof. Apply the obligation theorem Definition 7857.2. It forces bounded windows, shifts, finite averages, Hardy–Cesaro comparison, Toeplitz windows, Silverman–Toeplitz regularity, regular-rational readback, and real sealing to be displayed before a summability consumer receives any token.

The displayed sibling route records the order in which those rows are consumed. $\mathsf{FiniteShiftAverage}^{\uparrow}$ supplies A, $\mathsf{HardyCesaroMean}^{\uparrow}$ supplies H, $\mathsf{ToeplitzLemma}^{\uparrow}$ supplies T, $\mathsf{SilvermanToeplitz}^{\uparrow}$ supplies V, and $\mathsf{BanachLimit}^{\uparrow}$ is present only as the boundary chapter named in provenance.

Transport, replay, provenance, and local naming through M, C, P, N keep the handoff finite. Because the carrier does not contain a full extension functional, an ultrafilter, a choice selector, quotient sequence equality, or ambient dual equality, a consumer that claims one of those endpoints has left the displayed $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ packet. □

Falsifiable prediction: Every accepted $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ consumer must display bounded-sequence windows, shift schedules, finite shift averages, Hardy–Cesaro comparison, Toeplitz windows, Silverman–Toeplitz regularity, RegSeqRat readback, Real sealing, transport, replay, provenance, and local NameCert evidence before any Banach-limit-facing boundary token is public.

Independence witness: finite-shift-average, hardy-cesaro-mean, toeplitz-lemma, silverman-toeplitz, banach-limit: $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds bounded windows, shifts, finite averages, Cesaro comparison, matrix windows, regularity rows, Real sealing, transport, replay, provenance, and local naming into one finite packet while refusing full Banach-limit existence.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachLimitFiniteWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachLimitFiniteWindow}^{\uparrow}$ packet is generated from bounded-sequence windows, finite shift schedules, finite average rows, Hardy–Cesaro comparison rows, Toeplitz matrix windows, Silverman–Toeplitz regularity rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachLimitFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7857.1, Definition 7857.2, and Definition 7857.3 seed the finite bounded-sequence shift-average boundary for Banach-limit-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachLimitFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Hahn–Banach, ultrafilter, choice-based Banach-limit existence, ambient quotient equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked bounded-window admission, shift-schedule stability, finite-average exactness, Hardy–Cesaro comparison, Toeplitz and Silverman–Toeplitz window visibility, real-name sealing, transport, replay, provenance, and local naming for BEDC.Derived.BanachLimitFiniteWindowUp.

Chapter 7858

A Concrete Naming Certificate for $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley filter terminology, the $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ packet records the functorial handoff by which a displayed regular Cauchy filter-basis route is transported between completion-facing sources without choosing a completed limit. It sits after the basis carrier of chapter 7853, the filter surface of chapter 333, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed basis-to-filter route and its structural preservation; it does not assert $\mathsf{Real}^{\uparrow}$ completeness, selected limits, quotient filters, host equality of completions, or countable choice.

Definition 7858.1 (RegularCauchyFilterBasisFunctor carrier)**.** *A* $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, R, D, B, M, \Phi, G, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule inherited from the source regular Cauchy basis.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger transported with the same windows.*
4. B *is the source* $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ *basis row, including its finite meet surface.*
5. M *records preservation of the finite meet row under the handoff.*
6. Φ *is the displayed map row sending each accepted source basis observation to a target basis observation.*
7. G *is the* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer row exposed only after* S, R, D, B, M, Φ *have been read.*
8. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached by the target filter-basis handoff.*
9. H *records componentwise* hsame *transport for the schedule, readback, tolerance, basis, meet, map, filter, seal, replay, provenance, and local naming rows.*
10. C *records displayed* Cont *replay of the same handoff route.*
11. P *records* Pkg *provenance over* $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$, $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}}$ *row.*
The carrier stores no quotient filter, no chosen limit point, no external completion object, no countable-choice selector, and no ambient proof that every Cauchy filter converges.

Theorem 7858.2 (RegularCauchyFilterBasisFunctor NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ *carrier*

$$F = (S, R, D, B, M, \Phi, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite schedule, regular-rational readback, dyadic tolerance ledger, source basis row, meet-preservation row, displayed handoff map, target* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. Every Real-facing or Completion-facing consumer must first read the finite route*

$$S, R, D, B, M, \Phi \longmapsto G, E, H, C, P, N.$$

Proof. Project the carrier of Definition 7858.1. The source side is the finite window schedule S, the regular-rational readback R, the dyadic tolerance ledger D, the source basis row B, and the meet-preservation row M inherited from chapter 7853.

Read the functorial handoff through Φ. It sends accepted source basis observations to target basis observations while preserving the finite meet and tolerance rows, so the target filter row G is exposed only after the displayed basis data have already been read.

Finally consume the seal and structural rows. The real-name seal E and the transport, replay, provenance, and local naming rows H, C, P, N preserve the same route. Since the carrier has no coordinate for quotient filters, selected limits, countable choice, host completion equality, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7858.3 (RegularCauchyFilterBasisFunctor finite handoff scope)**.** *Every accepted* RegularCauchyFilterBas *handoff from a* $\mathsf{RegularCauchyFilterBasis}^{\uparrow}$ *source to a* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer factors through* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerances, the source basis and meet rows, the displayed handoff map, the target filter row, the* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows H, C, P, N. The handoff is a finite functorial route; it is not quotient-filter equality, selected convergence, countable choice, or ambient completeness of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Begin with the source basis carrier. The rows S, R, D, B, M provide all source observations and finite common-refinement data before a target filter consumer can read the packet.

Apply the displayed map row Φ. It preserves the basis observations and the meet row at the level of the carried BHist data, so the consumer row G is reached by a finite handoff rather than by quotienting filters.

The remaining rows E, H, C, P, N only seal, transport, replay, source, and name the same handoff. Therefore no selected limit, countable-choice selector, host equality of completions, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available from the packet. □

Falsifiable prediction: A $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ consumer that exposes a target $\mathsf{CauchyFilter}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ row while omitting the finite schedule, regular-rational readback, dyadic tolerance ledger, source basis, meet-preservation, displayed handoff map, transport, replay, provenance, or local $\mathsf{NameCert}$ rows refutes Definition 7858.1.

Independence witness: regular-cauchy-filter-basis, cauchyfilter, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ is not bijective to any listed sibling because it

carries a displayed preservation map from a regular Cauchy basis into a filter consumer. The basis sibling has the source meet row without the handoff map; CauchyFilterUp has filter consumption without the source basis functor; StreamNameUp, RegSeqRatUp, and DyadicRatCoreUp provide schedule, readback, and tolerance rows without filter functoriality; RealUp supplies the terminal seal without the basis-to-filter route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RegularCauchyFilterBasis source row, meet preservation, a displayed handoff map, a CauchyFilter consumer row, a RealUp seal, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7858.1, Definition 7858.2, and Definition 7858.3 seed the functorial handoff from regular Cauchy filter bases to completion-facing filter and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyFilterBasisFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, selected limits, quotient filters, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, meet preservation, displayed handoff stability, filter consumer nonescape, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyFilterBasisFunctor

Chapter 7859

A Concrete Naming Certificate for $\mathsf{MacLanePentagonCoherence}^{\uparrow}$

Following Mac Lane's coherence theorem for monoidal categories, the $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ packet records the finite pentagon route by which fourfold tensor reassociation is read as one BEDC NameCert surface. It sits after the categorical carrier of chapter 61, the functorial tensor surface of chapter 62, the natural-transformation comparison surface of chapter 63, and the monoidal-category carrier of chapter 181. The packet names only displayed object rows, tensor-functor rows, associator rows, the two pentagon boundary composites, transport, replay, provenance, and local naming; it is not a host coherence theorem, not a quotient of parenthesized tensor words, and not an ambient category-library appeal.

Definition 7859.1 (Mac Lane pentagon coherence carrier)**.** *A* $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (C, T, A, W, L, R, H, Q, K, N)$$

with the following displayed rows:

1. *C is the source* $\mathsf{Cat}^{\uparrow}$ *row naming the object and morphism carrier on which the monoidal structure is inspected.*
2. *T is the* $\mathsf{Functor}^{\uparrow}$ *tensor row, recording the displayed binary tensor action used in each reassociation step.*
3. *A is the* $\mathsf{NatTrans}^{\uparrow}$ *associator row, recording the natural isomorphism component read for each adjacent reassociation.*
4. *W is the four-object word row naming the inspected quadruple and its five parenthesized tensor shapes.*
5. *L is the left pentagon boundary row, recording the two-step reassociation route from $(((w \otimes x) \otimes y) \otimes z)$ to $w \otimes (x \otimes (y \otimes z))$.*
6. *R is the right pentagon boundary row, recording the three-step reassociation route through the remaining pentagon edges.*
7. *H records componentwise* hsame *transport for category, tensor, associator, word, left-boundary, right-boundary, replay, provenance, and local naming rows.*

8. *Q records displayed* Cont *replay from a pentagon request through C, T, A, W, L, R before any monoidal consumer is allowed to read the coherence row.*
9. *K is the* Pkg *provenance over* $\mathsf{MacLanePentagonCoherence}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{MonoidalCat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MacLanePentagonCoherence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an external category object, quotient equality of parenthesized tensor expressions, a hidden naturality square, or a host proof of monoidal coherence.

Theorem 7859.2 (Mac Lane pentagon coherence NameCert obligations)**.** *For every accepted* $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ *carrier*

$$P = (C, T, A, W, L, R, H, Q, K, N),$$

the local $\mathsf{NameCert}_{\mathsf{MacLanePentagonCoherence}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed* $\mathsf{Cat}^{\uparrow}$ *row C, tensor* $\mathsf{Functor}^{\uparrow}$ *row T, associator* $\mathsf{NatTrans}^{\uparrow}$ *row A, four-object word row W, and pentagon boundary rows L, R;*
2. *tensor typing, requiring every edge of the pentagon to read the same category and tensor rows before any reassociation is consumed;*
3. *associator exposure, requiring each pentagon edge to be one displayed component of the associator row A;*
4. *boundary comparison, requiring L and R to name the two Mac Lane pentagon composites over the same word row W;*
5. *ledger exhaustion through H, Q, K, N, excluding external category carriers, quotient parenthesization equality, hidden naturality squares, and host coherence imports.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7859.1. The packet exposes only the category row, tensor row, associator row, four-object word row, the two boundary composites, and the structural rows.

Tensor typing is read before any associator edge. Each edge of the pentagon is a tensor expression over the same displayed category carrier and the same tensor functor row, so no second monoidal carrier can enter the route.

Associator exposure is then read from A. The five pentagon edges are not arbitrary morphisms; each is the displayed associator component or tensoring of such a component required by the word row W.

The boundary comparison is local to L and R. These rows name the two Mac Lane composites over the same four-object word, so the packet records coherence as a comparison of displayed histories rather than as an ambient theorem about all parenthesizations.

Finally, H, Q, K, N transport, replay, source, and name the same finite packet. Since the carrier contains no quotient parenthesization equality, hidden naturality square, external category object, or host coherence import, the five rows exhaust the local NameCert surface. □

Theorem 7859.3 (Mac Lane pentagon coherence sibling handoff)**.** *Every accepted* $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ *read factors through the sibling surfaces*

$$\mathsf{Cat}^{\uparrow}, \quad \mathsf{Functor}^{\uparrow}, \quad \mathsf{NatTrans}^{\uparrow}, \quad \mathsf{MonoidalCat}^{\uparrow}$$

before it exports a pentagon comparison. The handoff supplies a finite reassociation ledger for monoidal consumers, but it does not supply a host monoidal category, quotient equality of tensor words, a global coherence theorem, or an unrestricted naturality oracle.

Proof. Start with the obligation surface above. The category row C supplies the object and morphism carrier, the tensor row T supplies the binary functorial action, and the associator row A supplies the natural-transformation components.

Read the word row W next. It fixes the four displayed objects and the five parenthesized tensor shapes inspected by the packet.

The boundary rows L and R then expose the two pentagon routes over that same word. Transport and replay through H and Q preserve the displayed rows, while K and N record provenance and local naming.

Thus a $\mathsf{MonoidalCat}^{\uparrow}$ consumer receives only the finite BEDC pentagon ledger. No host monoidal category, quotient tensor-word equality, global coherence theorem, or unrestricted naturality oracle is available from the packet. □

Falsifiable prediction: Every accepted $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ consumer must display the category row, tensor functor row, associator natural-transformation row, four-object word row, both pentagon boundary rows, transport, replay, provenance, and local naming before reading the pentagon comparison.

Independence witness: category, functor, nattrans, monoidalcat: $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the four-object word, both pentagon boundary composites, pentagon-specific transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MacLanePentagonCoherence}^{\uparrow}}$.

Constructive story: A $\mathsf{MacLanePentagonCoherence}^{\uparrow}$ packet is generated from category rows, tensor functor rows, associator natural-transformation rows, four-object word rows, two pentagon boundary composites, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MacLanePentagonCoherence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7859.1, Definition 7859.2, and Definition 7859.3 seed the finite Mac Lane pentagon coherence ledger over CategoryUp, FunctorUp, NatTransUp, MonoidalCatUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MacLanePentagonCoherence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host coherence theorem, quotient equality of parenthesized tensor words, ambient monoidal-category semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tensor typing, associator exposure, boundary comparison, transport, replay, provenance, and local naming for BEDC.Derived.MacLanePentagonCoherenceUp.

Chapter 7860

A Concrete Naming Certificate for $\mathsf{CZeroSpace}^{\uparrow}$

Following Banach-space treatments of c_0, the $\mathsf{CZeroSpace}^{\uparrow}$ packet presents a real-valued sequence with an explicit tail-to-zero modulus as finite NameCert data rather than as a quotient subspace of a completed sequence algebra. It is grounded in the sequence carrier of chapter 3641, the bounded-sequence surface of chapter 3451, the regular-rate route of chapter 3541, the finite stream naming of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the complete-metric boundary of chapter 3424.

Definition 7860.1 (CZeroSpace carrier)**.** *A* $\mathsf{CZeroSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (S, R, B, T, K, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSequenceSpace}^{\uparrow}$ *source row, read only through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule naming inspected sequence windows.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *real-coordinate seal, supplying regular rational readback for every coordinate requested by S.*
3. *B is the* $\mathsf{RealBoundedSequence}^{\uparrow}$ *boundedness witness, displayed before any norm-facing or complete-metric consumer may read the packet.*
4. *T is the dyadic tail modulus: for each displayed tolerance request, T gives a finite tail window after which the inspected coordinates are forced inside that tolerance.*
5. *K is the* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *readback row, carrying the same tail ledger as a regular-rate sequence-space route.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the coordinate readback, boundedness witness, and tail modulus.*
7. *H records componentwise* hsame *transport for the sequence source, real-coordinate seal, boundedness witness, tail modulus, regular Cauchy readback, dyadic ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each finite coordinate, boundedness, tail, and complete-metric request through S, R, B, T, K, D.*

9. *P is the* Pkg *provenance over* $\mathsf{CZeroSpace}^{\uparrow}$, $\mathsf{RealSequenceSpace}^{\uparrow}$, $\mathsf{RealBoundedSequence}^{\uparrow}$, $\mathsf{RegularCauchySequence}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{BishopCompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CZeroSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for arbitrary choice of subsequences, quotient stream equality, trichotomy, host real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7860.2 (CZeroSpace tail-modulus obligation)**.** *For every accepted* $\mathsf{CZeroSpace}^{\uparrow}$ *carrier* $Z = (S, R, B, T, K, D, H, C, P, N)$*, the tail-to-zero claim is exhausted by the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *coordinate readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RealBoundedSequence}^{\uparrow}$ *boundedness witness, and* $\mathsf{RegularCauchySequenceSpace}^{\uparrow}$ *rate row. In particular, every tail-zero consumer must first read the finite route*

$$S \longrightarrow R \longrightarrow D \longrightarrow T \longrightarrow K$$

with B displayed as the boundedness side condition, and no consumer may replace that route by arbitrary choice of subsequences, quotient stream equality, trichotomy, selected limits, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7860.1. The sequence source is the $\mathsf{RealSequenceSpace}^{\uparrow}$ row S, the coordinate readback is the $\mathsf{RegSeqRat}^{\uparrow}$ row R, and the tolerance information for each coordinate and each tail request is the $\mathsf{DyadicRatCore}^{\uparrow}$ row D.

The displayed tail modulus T is then read over those same finite windows. The boundedness witness B records the norm-facing side condition, while the regular Cauchy readback K exposes the tail ledger to the regular-rate route described in Definition 3541.5.

Finally use the sequence-space subspace route of Definition 3641.6. It identifies the tail-zero surface as an extra displayed ledger over the existing real-sequence route, so the excluded host-side objects never become classifier coordinates of Z. □

Theorem 7860.3 (CZeroSpace metric seal)**.** *Every* $\mathsf{BishopCompleteMetric}^{\uparrow}$ *or norm-facing consumer of an accepted* $\mathsf{CZeroSpace}^{\uparrow}$ *carrier reads the packet through the bounded real sequence row B, the tail modulus T, and the regular Cauchy route K after the sequence source, coordinate seal, and dyadic ledger have been displayed. The exported metric surface is therefore the finite packet*

$$S, R, B, T, K, D, H, C, P, N$$

rather than an ambient complete subspace obtained from quotient stream equality, trichotomy, selected limits, arbitrary subsequence choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a complete-metric or norm-facing read. The carrier exposes no such read before S, R, D name the inspected real-valued coordinates and before B supplies the boundedness witness.

The tail-to-zero data are supplied by T and replayed through K. By Definition 7860.2, the tail read is a dyadic ledger obligation over the displayed real-sequence route, and by Definition 3541.5 the same obligation remains visible to regular-rate consumers.

The complete-metric boundary can therefore inspect only the rows $S, R, B, T, K, D, H, C, P, N$. Since neither the definition nor the preceding obligation theorem contains quotient stream equality, trichotomy, selected limits, arbitrary subsequence choice, host real equality, or ambient Real completeness, the metric seal exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CZeroSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CZeroSpace}^{\uparrow}$ packet is generated from a RealSequenceSpace source, regular rational coordinate readback, a bounded real sequence witness, a displayed dyadic tail-to-zero modulus, a RegularCauchySequenceSpace rate row, DyadicRatCore tolerance data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CZeroSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7860.1, Definition 7860.2, and Definition 7860.3 seed the constructive tail-zero real sequence space over displayed real-sequence, boundedness, regular-rate, dyadic tolerance, and complete-metric rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CZeroSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary choice of subsequences, quotient stream equality, trichotomy, selected limits, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundedness routing, tail-modulus exactness, regular Cauchy readback, dyadic tolerance stability, metric-seal non-escape, and transport stability for BEDC.Derived.CZeroSpaceUp.

Chapter 7861

A Concrete Naming Certificate for $\mathsf{CantorIntersectionWindow}^{\uparrow}$

Following Cantor and Bishop–Bridges on nested interval principles, the $\mathsf{CantorIntersectionWindow}^{\uparrow}$ packet records finite nested closed-window data at the point where a Real and Completion consumer asks for a displayed handoff. It sits after the nested-chain surface of chapter 320, the dyadic tolerance ledger of chapter 291, the finite observation route of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The route is the finite-window counterpart of the real-completeness vision in section 9238.1: it names inspected nested windows and their regular readback, not an ambient completeness theorem.

Definition 7861.1 (Cantor intersection window carrier)**.** *A* $\mathsf{CantorIntersectionWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{NestedInterval}^{\uparrow}$ *row naming the finite nested closed-window chain under inspection.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint, width, and tolerance ledger for those same windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation row listing the stages read by the handoff.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name extracted from the displayed windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, D, S, R have been exposed.*
6. *H records componentwise* hsame *transport for the nested-window, dyadic-ledger, stream-window, readback, seal, provenance, replay, and local naming rows.*
7. *C records displayed* Cont *replay from a finite window request through I, D, S, R, E and back to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{CantorIntersectionWindow}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for interval compactness, countable choice, selected completed endpoints, quotient stream equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7861.2 (Cantor intersection window NameCert obligations)**.** *For every accepted* CantorIntersectionWindo *carrier* $W = (I, D, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CantorIntersectionWindow}^{\uparrow}}$ *surface consists exactly of the nested closed-window row* I*, dyadic endpoint and tolerance ledger* D*, finite stream window* S*, regular rational readback* R*, terminal Real seal* E*, componentwise transport* H*, displayed replay* C*, provenance* P*, and local naming* N*. A Real or Completion consumer must expose these rows before reading the finite nested-window handoff.*

Proof. Project the carrier of Definition 7861.1. The analytic rows I, D, S, R, E list the only route from the displayed nested windows to a Real-facing seal.

The nested interval row I is read first, and the dyadic ledger D records the endpoint and width data for that same finite chain. The stream row S then identifies the inspected stages, while R supplies the regular rational readback available at those stages.

The seal row E is downstream of this finite display. The structural rows H, C, P, N transport, replay, source, and name the same packet, so no extra coordinate can introduce compactness, choice, quotient equality, host real equality, or ambient completeness. □

Theorem 7861.3 (Cantor intersection window Real and Completion handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{CantorIntersectionWindow}^{\uparrow}$ *packet factors through*

$$\mathsf{NestedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $I, D, S, R, E, H, C, P, N$*. The handoff may transport and replay the finite nested-window route, but it cannot export interval compactness, countable choice, quotient stream equality, selected completed endpoints, a chosen limit real, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert-obligation theorem. It forces the consumer to expose the nested closed-window row, dyadic endpoint and tolerance ledger, finite stream window, and regular rational readback before the terminal Real seal is read.

Read the sibling route in order. The $\mathsf{NestedInterval}^{\uparrow}$ chapter supplies the retained finite chain, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the endpoint and tolerance arithmetic, $\mathsf{StreamName}^{\uparrow}$ supplies the inspected stages, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal reached after those rows.

The same route is the Completion-facing handoff: a completion consumer receives the finite window and regular readback rows before it can inspect a Real-facing seal. Since the packet contains no selector for an infinite branch, no quotient stream equality, no countable-choice schedule, no chosen limit real, and no ambient completeness theorem, the handoff remains finite NameCert data. □

Closure status for $\mathsf{NameCert}_{\mathsf{CantorIntersectionWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorIntersectionWindow}^{\uparrow}$ packet is generated from displayed NestedIntervalUp finite closed-window rows, a DyadicRatCoreUp endpoint and tolerance ledger, StreamNameUp finite observations, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CantorIntersectionWindow}^{\uparrow}}$, seed)

Scope closed: Definition 7861.1, Definition 7861.2, and Definition 7861.3 seed the finite nested-window Real and Completion handoff route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CantorIntersectionWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close interval compactness, countable choice, quotient stream equality, selected completed endpoints, chosen limit reals, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested-window exposure, dyadic tolerance exposure, finite-window readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CantorIntersectionWindowU

Chapter 7862

A Concrete Naming Certificate for $\mathsf{BohrCompactification}^{\uparrow}$

Following Bohr and Weil on compactification of topological groups, read through the finite-window discipline of BEDC naming, the $\mathsf{BohrCompactification}^{\uparrow}$ packet records the compactification-facing data exposed by almost-periodic observables without taking a host compact group as primitive. It sits beside the translation ledger of chapter 5969, the topological-group source of chapter 204, the compact target interface of chapter 60, the uniform handoff of chapter 339, the continuous-map carrier of chapter 130, and the terminal real-name seal of chapter 38. The packet names only the finite compactification boundary visible through displayed translation and character rows; it does not assert host compactification, quotient hull equality, selected limits, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7862.1 (Bohr compactification carrier)**.** *A* $\mathsf{BohrCompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (G, A, K, U, M, S, R, H, C, P, N)$$

with the following visible rows:

1. *G is the* $\mathsf{TopGroup}^{\uparrow}$ *source row, naming the displayed topological-group multiplication, inverse, identity, neighbourhood, and translation windows consumed by the compactification-facing read.*
2. *A is the* $\mathsf{AlmostPeriodic}^{\uparrow}$ *translation ledger row, recording the finite almost-periodic translation budgets and relative-density witnesses inspected before any compact target is exposed.*
3. *K is the compact target row, read through* $\mathsf{Compact}^{\uparrow}$ *as a displayed finite-cover and finite-net target interface rather than as an external compact group.*
4. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *handoff row, carrying entourages and uniform-comparison data needed by character and translation consumers.*
5. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *handoff row for continuous real-valued character windows from the source side to the compact target side.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *readback row, used when real-valued characters are inspected through finite observation windows and regular rational seals.*
7. *R is the refusal row, recording the absent quotient hull, host function extensionality, selected-limit operator, open-cover compactness theorem, and ambient real-completeness principle.*
8. *H records componentwise* hsame *transport for $G, A, K, U, M, S, R, P, N$.*

9. *C records displayed* Cont *replay of the route from topological-group source rows through almost-periodic translation data, uniform and continuous-map handoffs, finite real readback, refusal rows, provenance, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{BohrCompactification}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{AlmostPeriodic}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BohrCompactification}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed quotient hull, host equality of almost-periodic functions, an unrestricted character dual, a selected compactification limit, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7862.2 (Bohr compactification NameCert obligations)**.** *For every accepted* $\mathsf{BohrCompactification}^{\uparrow}$ *carrier $B = (G, A, K, U, M, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BohrCompactification}^{\uparrow}}$ *surface consists exactly of carrier admission through the displayed packet; compact target exposure through K; translation-ledger exactness through A; uniform-continuous character handoff through U, M; finite real-valued character readback through S; refusal exactness through R; componentwise* hsame *transport through H; displayed* Cont *replay through C;* Pkg *provenance through P; and local naming through N. Every compactification-facing consumer must pass through those rows before inspecting a Bohr-style boundary.*

Proof. Project the carrier of Definition 7862.1. The topological-group source row G and almost-periodic ledger row A are displayed before the compact target row K, so the target cannot be read without the source translations that make it visible.

Next use the uniform and continuous-map handoffs. Rows U and M expose the uniform-continuous character route, while S forces every real-valued character inspection through finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the $\mathsf{Real}^{\uparrow}$ seal.

Finally attach the refusal, transport, replay, provenance, and local naming rows. The refusal row records that quotient hulls, host function extensionality, selected limits, open-cover compactness, and ambient real completeness are not exported, while H, C, P, N preserve the same finite route under transport and public replay. □

Falsifiable prediction: A consumer that reads a compact target for $\mathsf{BohrCompactification}^{\uparrow}$ without first exposing the $\mathsf{AlmostPeriodic}^{\uparrow}$ translation ledger and the $\mathsf{UniformSpace}^{\uparrow}$ handoff is outside the accepted carrier.

Independence witness: almostperiodic, topgroup, compact, uniformspace, continuousmap, real: $\mathsf{BohrCompactification}^{\uparrow}$ is not bijective to any listed sibling because it binds topological-group source rows, almost-periodic translation rows, compact target rows, uniform and continuous-map handoffs, finite real-valued character readback, refusal rows, transport, replay, provenance, and local NameCert into one compactification-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BohrCompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{BohrCompactification}^{\uparrow}$ packet is generated from topological-group source rows, almost-periodic translation rows, compact target rows, uniform and continuous-map handoffs, finite real-valued character readback, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BohrCompactification}^{\uparrow}}$, seed)

Scope closed: Definition 7862.1 and Definition 7862.2 specify the compactification-facing seed surface visible from the AlmostPeriodic boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BohrCompactification}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not prove Lean verification, bridge checking, host Bohr compactification, quotient hull equality, host function extensionality, selected limits, open-cover compactness, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact target exposure, translation-ledger exactness, uniform-continuous character handoff, finite real readback, refusal exactness, transport stability, and TasteGate evidence for BEDC.Derived.BohrCompactificationUp.

Chapter 7863

A Concrete Naming Certificate for $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ packet records nested dyadic interval threads as finite regular-Cauchy readback data. It sits after the dyadic arithmetic surface of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing finite-window boundary of chapter 1559. The packet is a displayed thread-to-real seal route, not a quotient completion, selected representative, trichotomy branch, or ambient completeness principle.

Definition 7863.1 (Cantor thread regular-Cauchy carrier)**.** *A* $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, W, D, R, E, F, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested dyadic interval thread row, storing a finite initial segment of dyadic left and right endpoints.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records the displayed observations of the thread.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger proving that each displayed interval width is bounded by the requested dyadic precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the interval midpoints or tagged endpoints over the same windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, W, D, R have been replayed.*
6. *F is the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *handoff row for completion-facing consumers of the finite thread.*
7. *H records componentwise* hsame *transport for the interval thread, window, tolerance, readback, seal, completion handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite precision request through $I, W, D, R, E, F, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletionFinite}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorThreadRegularCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a selected limit point, quotient stream equality, countable-choice schedule, host real equality, open-cover compactness, or ambient completion theorem.

Theorem 7863.2 (Cantor thread regular-Cauchy real seal)**.** *For every accepted* $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ *carrier*

$$T = (I, W, D, R, E, F, H, C, P, N),$$

any $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer must first expose the nested dyadic interval thread* I*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{MetricCompletionFinite}^{\uparrow}$ *handoff row* F *before the terminal seal* E *is public. The route exports only finite regular-Cauchy readback data.*

No quotient completion, selected representative, trichotomy branch, countable-choice schedule, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle can replace the displayed thread route.*

Proof. Project the carrier of Definition 7863.1. The rows $I, W, D, R, E, F, H, C, P, N$ are the whole accepted packet, and the terminal Real seal appears only after the thread, window, dyadic tolerance, regular readback, and finite-completion rows.

Run finite induction on the displayed interval windows. The base window exposes one dyadic interval row, and the tolerance ledger D records its width at the requested precision. In the induction step, append one displayed nested interval; the new row refines the previous one through the same W and D rows, so the carrier is not replaced.

Read the regular-Cauchy data through R. The induction supplies a compatible finite chain of dyadic windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row repacks that chain as the readback consumed by E and F.

Finally use the inventory refusal. Since the carrier contains no quotient stream, selected representative, trichotomy branch, choice schedule, open-cover row, or ambient completion coordinate, every Real or completion consumer must use the displayed finite thread route. □

Falsifiable prediction: An accepted $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the nested dyadic thread, StreamName window, DyadicRatCore tolerance ledger, RegSeqRat readback, and MetricCompletionFinite handoff refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, metriccompletionfinite: none is bijective to $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ because only this packet binds nested dyadic interval threads, finite windows, regular-Cauchy readback, Real sealing, completion handoff, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorThreadRegularCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CantorThreadRegularCauchy}^{\uparrow}$ packet is generated from nested dyadic interval rows, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, a MetricCompletionFinite handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorThreadRegularCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7863.1 and Definition 7863.2 seed the finite nested-thread route from dyadic intervals to regular-Cauchy Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorThreadRegularCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked nested-thread admission, dyadic width dominance, StreamName window stability, RegSeqRat readback, Real seal, MetricCompletionFinite handoff, transport, replay, provenance, and local naming for BEDC.Derived.CantorThreadRegularCauchyUp.

Chapter 7864

A Concrete Naming Certificate for $\mathsf{FiniteUniformTailVision}^{\uparrow}$

The $\mathsf{FiniteUniformTailVision}^{\uparrow}$ packet realizes the observer-expansion tail route of chapter 9463 as finite NameCert data. It binds finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, $\mathsf{UniformModulus}^{\uparrow}$ tail control, and terminal $\mathsf{Real}^{\uparrow}$ seals over the compact finite-net surface of chapter 129. The packet is a finite uniform-tail readback carrier; it is not a hidden hyperbolic boundary object, not an open-cover compactness theorem, not a selected limit, and not an ambient real-completeness principle.

Definition 7864.1 (Finite uniform-tail vision carrier)**.** *A* $\mathsf{FiniteUniformTailVision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (K, W, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row that bounds the observer-expansion tail surface.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row storing the displayed tail observations.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from those windows.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row that gives one finite tail bound for the displayed compact source.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after K, W, R, U have been replayed.*
6. *H records componentwise* hsame *transport for compact source, window, readback, modulus, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an observer-tail request through K, W, R, U, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteUniformTailVision}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteUniformTailVision}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for open-cover compactness, a selected tail point, a quotient stream, a host convergence predicate, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7864.2 (Finite uniform-tail vision readback)**.** *For every accepted* $\mathsf{FiniteUniformTailVision}^{\uparrow}$ *carrier*

$$V = (K, W, R, U, E, H, C, P, N),$$

any observer-expansion tail consumer that reaches the $\mathsf{Real}^{\uparrow}$ *seal* E *must first expose the compact finite-net row* K*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{UniformModulus}^{\uparrow}$ *tail-control row* U*. The readback is therefore a finite uniform-tail packet over displayed NameCert rows.*

No hidden boundary center, selected limit, quotient stream, open-cover compactness row, choice schedule, or ambient completeness theorem may replace this route.

Proof. Project the carrier of Definition 7864.1. The only analytic rows are K, W, R, U, E, followed by transport, replay, provenance, and local naming rows.

Read the finite source first. The compact metric row K supplies the finite-net surface, while W records the visible tail observations and R repacks them as regular rational readback data.

Apply the uniform-modulus row U. It provides one displayed tail bound for the same K, W, R surface, so the terminal seal E cannot be detached from the finite uniform-tail route.

Finally inspect the refusal ledger. Since the carrier contains no hidden boundary center, selected limit, quotient stream, open-cover compactness row, choice schedule, or ambient completeness coordinate, every observer-expansion consumer must use the displayed route. □

Falsifiable prediction: An accepted $\mathsf{FiniteUniformTailVision}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying CompactMetric finite-net data, StreamName windows, RegSeqRat readback, and UniformModulus tail control refutes the packet surface.

Independence witness: streamname, regseqrat, real, uniformmodulus, compactmetric: no listed sibling is bijective to $\mathsf{FiniteUniformTailVision}^{\uparrow}$ because only this packet binds the compact finite-net source, finite observer-tail windows, regular readback, uniform modulus, Real seal, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteUniformTailVision}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteUniformTailVision}^{\uparrow}$ packet is generated from a CompactMetric finite-net source, StreamName tail windows, RegSeqRat readback, UniformModulus tail control, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteUniformTailVision}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7864.1 and Definition 7864.2 seed the finite uniform-tail readback route for the observer-expansion vision.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteUniformTailVision}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close hyperbolic boundary semantics, open-cover compactness, selected limits, quotient streams, host convergence, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net exposure, StreamName window stability, RegSeqRat readback, UniformModulus tail control, Real seal, transport, replay, provenance, and local naming for BEDC.Derived.FiniteUniformT

Chapter 7865

A Concrete Naming Certificate for $\mathsf{CauchyRegularComparisonSeal}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{CauchyRegularComparisonSeal}^{\uparrow}$ packet names the finite comparison surface used when two regular Cauchy rows are inspected against one tolerance ledger. It sits after the observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance carrier of chapter 291, and the terminal real-name seal of chapter 38. The packet records comparison by displayed rows; it is not a quotient stream equality, a selected limit, countable choice, apartness trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7865.1 (Cauchy regular comparison seal carrier)**.** *A* $\mathsf{CauchyRegularComparisonSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (A, B, D, W_A, W_B, R_A, R_B, Q, E_A, E_B, H, K, P, N)$$

with the following displayed rows:

1. *A and B are the two regular Cauchy rows being compared, each read as* $\mathsf{RegSeqRat}^{\uparrow}$ *data.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that fixes the same precision request for both rows.*
3. *W_A and W_B are the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule windows opened for the two rows after D is displayed.*
4. *R_A and R_B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed by those windows.*
5. *Q is the finite comparison ledger recording which readback entries have been inspected under the common dyadic tolerance request.*
6. *E_A and E_B are the two* $\mathsf{Real}^{\uparrow}$ *seal rows reached only after $A, B, D, W_A, W_B, R_A, R_B, Q$ have been consumed.*
7. *H records componentwise* hsame *transport for the regular rows, tolerance ledger, schedule windows, readbacks, comparison ledger, Real seals, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay from each finite comparison request through*

$$A, B, D, W_A, W_B, R_A, R_B, Q \longmapsto E_A, E_B, H, P, N.$$

9. *P is the* Pkg *provenance over* CauchyRegularComparisonSeal$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{CauchyRegularComparisonSeal}^{\uparrow}}$ *row.*

The classifier accepts only packets in which the two regular rows are compared through the same dyadic tolerance ledger and the same finite schedule discipline before either terminal Real seal is public.

Lean4 ✓ `BEDC.Derived.CauchyRegularComparisonSealUp.CauchyRegularComparisonSealTasteGate single carrier alignment`

Theorem 7865.2 (Cauchy regular comparison seal obligations)**.** *For every accepted* CauchyRegularComparisonSeal$^{\uparrow}$ *carrier*

$$C = (A, B, D, W_A, W_B, R_A, R_B, Q, E_A, E_B, H, K, P, N),$$

the local NameCert$_{\text{CauchyRegularComparisonSeal}^{\uparrow}}$ *surface consists exactly of exposure of the two regular Cauchy rows, the shared dyadic tolerance ledger, the two StreamName windows, the two RegSeqRat readbacks, the finite comparison ledger, the two terminal Real seals, componentwise transport, continuation replay, package provenance, and local naming through N.*

Proof. Project the carrier in Definition 7865.1. The two compared rows are displayed as A and B, and the only tolerance coordinate available to either side is the shared row D.

The schedule windows W_A, W_B and readbacks R_A, R_B are opened after that shared ledger is visible. The comparison row Q therefore records finite inspected readbacks under one tolerance request, rather than under unrelated representatives.

The seals E_A, E_B occur downstream of the same comparison route. The rows H, K, P, N transport, replay, source, and name that displayed packet, and no excluded quotient, choice, trichotomy, or ambient-completeness coordinate occurs in the carrier. □

Theorem 7865.3 (Cauchy regular comparison seal stability)**.** *Every comparison-facing consumer of an accepted* CauchyRegularComparisonSeal$^{\uparrow}$ *carrier reads the route*

$$A, B, D \longmapsto W_A, W_B \longmapsto R_A, R_B \longmapsto Q \longmapsto E_A, E_B, H, P, N.$$

Componentwise hsame *transport preserves this route: replacing any displayed row by an* hsame*-transported row changes neither the shared tolerance ledger nor the order in which the schedule windows, readbacks, comparison ledger, and terminal Real seals become available.*

Proof. Start with a comparison request. By the carrier definition the request first meets the two regular rows and the common dyadic tolerance ledger D.

The StreamName windows and RegSeqRat readbacks are then attached to that same ledger. The comparison ledger Q can only inspect readback entries already exposed by those windows, so it cannot introduce quotient equality or a selected representative.

Finally, hsame transport is recorded componentwise by H and continuation replay by K. These rows preserve the displayed order of access before E_A and E_B are read, which gives the stated stability boundary. □

Closure status for NameCert$_{\text{CauchyRegularComparisonSeal}^{\uparrow}}$**.**

Constructive story: A CauchyRegularComparisonSeal$^{\uparrow}$ packet is generated from two regular Cauchy rows, one shared DyadicRatCore tolerance ledger, two StreamName windows, two RegSeqRat readbacks, a finite comparison ledger, two terminal RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRegularComparisonSeal}\uparrow}$, seed)

Scope closed: Definition 7865.1, Definition 7865.2, and Definition 7865.3 seed the finite regular-Cauchy comparison route over StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRegularComparisonSeal}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, countable choice, apartness trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared dyadic tolerance accounting, two-sided StreamName window routing, RegSeqRat readback, finite comparison stability, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRegularComparisonSealUp.

Chapter 7866

A Concrete Naming Certificate for $\mathsf{EulerPhi}^{\uparrow}$

Following Hardy and Wright on elementary number theory, the $\mathsf{EulerPhi}^{\uparrow}$ packet records Euler's totient function as a finite coprime-count certificate rather than as an ambient arithmetic oracle. It sits over the natural-number divisor rows of $\mathsf{Nat}^{\uparrow}$, the prime and coprimality surface of chapter 64, the rational denominator route of chapter 37, and the dyadic exponent and denominator ledgers of chapter 291. The packet is intended for rational normalization, dyadic denominator accounting, Real-facing denominator handoffs, and later cyclotomic degree consumers that require a displayed totient row instead of reading totient data from chapter 174.

Definition 7866.1 (EulerPhi carrier)**.** *An* $\mathsf{EulerPhi}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (N, D, C, Q, R, H, T, P, L)$$

with the following displayed rows:

1. *N is the* $\mathsf{Nat}^{\uparrow}$ *source row naming the inspected natural number and the finite divisor schedule.*
2. *D is the divisor ledger: for every displayed candidate d, it records the bounded Nat divisor test, the complementary quotient row when the divisor test succeeds, and the finite exclusion row when it fails.*
3. *C is the* $\mathsf{Prime}^{\uparrow}$ *and coprime classifier row, read only through the finite prime-factor and gcd witnesses supplied by the prime certificate surface of chapter 64.*
4. *Q is the coprime-count row. It counts exactly the displayed residues whose entries in C certify coprimality with the source row N.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *denominator-normalization handoff row. It exposes the same coprime count to rational denominator consumers after the rational source route of chapter 37 has displayed the denominator row.*
6. *H records componentwise* hsame *transport for the Nat source, divisor ledger, coprime classifier, coprime count, rational denominator handoff, dyadic ledger, replay, provenance, and local naming rows.*
7. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *exponent and denominator ledger used when a denominator consumer restricts the totient row to powers of two or dyadic denominator refinements.*

8. *P is the* Pkg *provenance over* $\mathsf{EulerPhi}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{EulerPhi}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for unbounded search over residues, host integer factorization, selected primitive roots, cyclotomic minimal polynomials, host real equality, or an ambient arithmetic oracle.

Lean4 (statement) `BEDC.Derived.EulerPhiUp`

Theorem 7866.2 (EulerPhi NameCert obligations)**.** *For every accepted* $\mathsf{EulerPhi}^{\uparrow}$ *carrier* $E = (N, D, C, Q, R, H, T, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{EulerPhi}^{\uparrow}}$ *obligation surface consists exactly of the Nat source, finite divisor ledger, Prime coprime classifier, coprime-count row, Rat denominator-normalization handoff, DyadicRatCore exponent and denominator ledger, componentwise transport, displayed replay, provenance, and local naming rows. Every consumer must read the finite route*

$$N \longrightarrow D \longrightarrow C \longrightarrow Q$$

before it may use the rational or dyadic handoff rows, and no consumer may replace that route by unbounded residue search, host integer factorization, selected primitive roots, cyclotomic minimal-polynomial data, host real equality, or an ambient arithmetic oracle.

Proof. Project the carrier of Definition 7866.1. The source row is N, the divisor schedule is D, the coprime classifier is C, and the displayed count is Q.

The prime and coprime information is then read through chapter 64. The carrier does not expose a separate factorization oracle; it exposes only the finite prime and gcd witnesses already recorded in C.

Finally inspect the handoff rows. The rational denominator row R and the dyadic ledger T occur after the count row Q, while H, replay, provenance, and L only transport or repack the same displayed route. Thus every downstream use is forced through the finite Nat, divisor, coprime, and count rows named above. □

Theorem 7866.3 (EulerPhi coprime-denominator handoff)**.** *Every* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$*, or Real-facing denominator consumer of an accepted* $\mathsf{EulerPhi}^{\uparrow}$ *carrier receives the totient data only through the packet*

$$N, D, C, Q, R, H, T, P, L.$$

In particular, a rational denominator normalization may read R only after N, D, C, Q have displayed the finite coprime-count route, and a dyadic exponent or denominator refinement may read T only as the same route repacked for chapter 291. The handoff exports no primitive-root selector, cyclotomic minimal polynomial, host factorization theorem, host real equality, or infinite residue enumeration.

Proof. Begin with a denominator-facing read. The rational route of chapter 37 can use only the displayed denominator row, so the $\mathsf{EulerPhi}^{\uparrow}$ packet supplies R as a handoff after the Nat source, divisor ledger, coprime classifier, and count row have been opened.

For dyadic consumers, use the dyadic denominator and exponent discipline of chapter 291. The row T is not a new arithmetic source; it is the same finite coprime-count route repacked for powers-of-two and denominator-refinement ledgers.

The remaining rows H, P, L and the displayed replay data preserve provenance and local naming. Since neither the carrier nor the preceding NameCert obligation includes primitive roots,

minimal polynomials, host factorization theorems, host real equality, or infinite residue enumeration, no denominator consumer receives those objects from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{EulerPhi}\uparrow}$**.**

Constructive story: An $\mathsf{EulerPhi}^{\uparrow}$ packet is generated from a Nat source row, finite divisor ledger, Prime coprime classifier, coprime-count row, Rat denominator-normalization handoff, DyadicRatCore exponent and denominator ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EulerPhi}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7866.1, Definition 7866.2, and Definition 7866.3 seed the finite coprime-count and denominator-handoff packet over displayed Nat, Prime, Rat, and DyadicRatCore rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EulerPhi}\uparrow}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim host integer factorization, primitive-root selection, cyclotomic minimal-polynomial data, host real equality, complete Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, divisor-ledger exactness, coprime-count stability, rational denominator handoff, dyadic denominator handoff, and transport stability for BEDC.Derived.EulerPhiUp.

Chapter 7867

A Concrete Naming Certificate for $\mathsf{KhalimskyLine}^{\uparrow}$

Following Khalimsky and digital topology, the $\mathsf{KhalimskyLine}^{\uparrow}$ packet records the integer line with its alternating finite-open topology as NameCert data rather than as a host topological space. It sits after the topology carrier of chapter 88, the observable-open classifier of chapter 1860, and the specialization-order carrier of chapter 1378. The packet exposes the finite local stars around integer rows, their Sierpinski truth reads, and the induced specialization comparison as one displayed surface.

Definition 7867.1 (Khalimsky line carrier)**.** *A* $\mathsf{KhalimskyLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Z, T, S, O, H, C, P, N)$$

with the following displayed rows:

1. *Z is the integer-site row, read as finite named windows of adjacent sites rather than as an external set of integers.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row whose basic opens are the Khalimsky stars: odd sites are open singletons, while even sites are read through the three-site window consisting of the site and its two neighbours.*
3. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row recording membership of a displayed site in a displayed basic open.*
4. *O is the* $\mathsf{Order}^{\uparrow}$ *specialization row generated by the finite rule that an even site specializes to its adjacent odd sites and every site specializes to itself.*
5. *H records componentwise* hsame *transport for the site, topology, Sierpinski, specialization-order, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from each local-open or specialization request through Z, T, S, O, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{KhalimskyLine}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{KhalimskyLine}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient integer topology, host subset equality, excluded middle over arbitrary opens, selected neighbourhood filters, quotient specialization equality, or Lean verification.

Theorem 7867.2 (Khalimsky line NameCert obligations)**.** *For every accepted* $\mathsf{KhalimskyLine}^{\uparrow}$ *carrier*

$$K = (Z, T, S, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KhalimskyLine}^{\uparrow}}$ *surface consists exactly of carrier admission for the integer-site row, the Khalimsky-star topology row, the Sierpinski observable-open row, the specialization-order row, componentwise transport, displayed replay, provenance, and local naming; local-star exactness for odd and even sites; Sierpinski membership exactness for displayed basic opens; specialization exactness for the reflexive and adjacent even-to-odd comparisons; and non-escape of all topology and order reads through the same finite packet.*

Proof. Project the carrier of Definition 7867.1. The accepted packet displays exactly the site row, topology row, observable-open row, specialization-order row, and structural rows.

The local-star clauses are finite. Odd sites expose a singleton basic open, while even sites expose the three-site adjacent window. The Sierpinski row reads only those displayed opens, so open membership is a truth row in the packet rather than a host proposition.

The specialization row is then read from the same local stars. Reflexivity is supplied at every displayed site, and the nontrivial comparisons are precisely the adjacent even-to-odd incidences forced by containment of observable neighbourhoods.

Finally H, C, P, N preserve the site, topology, Sierpinski, and order rows together. Since no carrier coordinate stores arbitrary open subsets, selected neighbourhood filters, host subset equality, quotient specialization equality, or excluded middle, none becomes a NameCert obligation. □

Theorem 7867.3 (Khalimsky line specialization handoff)**.** *Every* $\mathsf{Order}^{\uparrow}$ *or digital-topology consumer of an accepted* $\mathsf{KhalimskyLine}^{\uparrow}$ *carrier reads specialization through the displayed route*

$$Z \longrightarrow T \longrightarrow S \longrightarrow O.$$

Thus the exported order surface is the finite Khalimsky specialization ledger generated by local stars and Sierpinski membership rows, not an ambient order on integers, an arbitrary Alexandrov topology, a selected neighbourhood filter, host subset equality, or quotient specialization equality.

Proof. Begin with an order-facing read. The carrier exposes no specialization comparison before the site row Z and topology row T display the relevant local stars.

Read the Sierpinski row S next. It turns membership in each displayed basic open into observable truth data, so the consumer can test only the finite local-star rows carried by the packet.

The specialization row O is downstream of those observable-open reads. It records reflexive comparisons and adjacent even-to-odd comparisons exactly when every displayed open observation around the upper site is respected by the lower site.

Therefore any order or digital-topology consumer receives the route Z, T, S, O, H, C, P, N. The absent host objects are never coordinates of the packet and cannot be exported by transport, replay, provenance, or local naming. □

Closure status for $\mathsf{NameCert}_{\mathsf{KhalimskyLine}^{\uparrow}}$.

Constructive story: A $\mathsf{KhalimskyLine}^{\uparrow}$ packet is generated from integer-site windows, Khalimsky-star topology rows, Sierpinski observable-open rows, specialization-order rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{KhalimskyLine}^{\uparrow}}$, seed)

Scope closed: Definition 7867.1, Definition 7867.2, and Definition 7867.3 seed the finite Khalimsky-line topology and specialization-order route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{KhalimskyLine}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close an ambient integer topology, arbitrary open-set equality, selected neighbourhood filters, quotient specialization equality, excluded middle over opens, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-star exactness, Sierpinski membership exactness, specialization-order exactness, topology-order nonescape, and transport stability for BEDC.Derived.KhalimskyLineUp.

Chapter 7868

A Concrete Naming Certificate for $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$

Following Arzela and Ascoli, the $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ packet records the finite compact-family closure data needed before an equicontinuous family may be read as closed under compact-source limit operations. It sits after the Arzela–Ascoli surface of chapter 412, the compact-metric source rows of chapter 129, the equicontinuity packet of chapter 4076, the uniform-modulus consumer of chapter 369, the continuous-map rows of chapter 130, and the terminal real-name seal of chapter 38. The packet names a compact-family closure route for later calculus and compactness consumers; it does not claim full function-space compactness, selected subsequences, quotient map equality, or ambient completeness.

Definition 7868.1 (Equicontinuous compact closure carrier)**.** *An* $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, A, Q, U, F, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the finite compact windows and metric comparison data through which source points are read;*
2. *A is the Arzela–Ascoli dependency row, read through the finite selection and compact-family surfaces already named by chapter 412;*
3. *Q is the* $\mathsf{Equicontinuity}^{\uparrow}$ *row for the family, exposing shared tolerance and source-radius data rather than separate moduli for each downstream read;*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row consumed by closure consumers after the compact-source and equicontinuity rows have been displayed;*
5. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *ledger for the displayed family members and their pointwise graph rows;*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for target-side values, endpoint comparisons, and real-valued tolerance reads;*
7. *H records componentwise* hsame *transport for compact source data, Arzela–Ascoli rows, equicontinuity rows, uniform-modulus data, continuous-map rows, Real seals, and local naming;*
8. *C records displayed* Cont *replay for the same dependency route;*

9. *P is the* Pkg *provenance over* $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{EquicontinuousCompactClosure}^{\uparrow}}$ *row.*

The carrier has no coordinate for host function-space compactness, selected convergent subsequences, quotient equality of maps, choice-selected limits, detached Real values, or ambient compactness and completeness.

Theorem 7868.2 (Equicontinuous compact closure NameCert obligations)**.** *For every accepted* $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ *carrier*

$$E = (K, A, Q, U, F, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EquicontinuousCompactClosure}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *compact-source exposure, requiring every closure read to display the* $\mathsf{CompactMetric}^{\uparrow}$ *row K before any family or Real-facing conclusion is exported;*
2. *Arzela–Ascoli route exposure, requiring the row A to remain tied to the finite Arzela–Ascoli packet rather than to a host function-space theorem;*
3. *equicontinuity and uniform-modulus binding, requiring Q and U to be read as one shared compact-family modulus route;*
4. *continuous-map and Real sealing, requiring F and R to expose the displayed graph rows and terminal Real seals before target-side closure data are read;*
5. *transport, replay, provenance, and local naming through H, C, P, N;*
6. *ledger non-escape, excluding full function-space compactness, selected subsequences, quotient map equality, choice-selected limits, detached Real pairs, Lean verification, bridge checking, and ambient completeness.*

Proof. Project the carrier of Definition 7868.1. Its only rows are the compact source, Arzela–Ascoli dependency, equicontinuity surface, uniform-modulus handoff, continuous-map ledger, Real seal, transport, replay, provenance, and local naming.

The compact-family closure read first consumes K, A, Q, U, F, R. The compact source row supplies finite source windows, the Arzela–Ascoli row supplies the family-compactness route, the equicontinuity and uniform-modulus rows provide the shared tolerance control, and the continuous-map and Real rows expose only displayed graph and target-value data.

Finally replay H, C, P, N. These rows preserve the same finite route under transport and provenance. Since the carrier contains no host function-space compactness, selected subsequence, quotient map equality, choice-selected limit, detached Real row, Lean verification, bridge-checking row, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Any consumer that exports an $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ closure read while omitting $K, A, Q, U, F, R, H, C, P$, or the local NameCert row refutes the carrier of Definition 7868.1.

Independence witness: arzelaascoli, compactmetric, equicontinuity, uniformmodulus, continuousmap, real: none alone is bijective with $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ because the packet

jointly carries compact-source windows, Arzela–Ascoli family rows, shared equicontinuity data, a uniform-modulus handoff, continuous-map graph rows, Real seals, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{EquicontinuousCompactClosure}\uparrow}$.

Constructive story: An $\mathsf{EquicontinuousCompactClosure}^{\uparrow}$ packet is generated from CompactMetric source rows, Arzela–Ascoli dependency rows, Equicontinuity rows, UniformModulus handoff rows, ContinuousMap graph rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompactClosure}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7868.1 and Definition 7868.2 seed the finite compact-family closure surface over CompactMetric, ArzelaAscoli, Equicontinuity, UniformModulus, ContinuousMap, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EquicontinuousCompactClosure}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full function-space compactness, selected subsequences, quotient map equality, choice-selected limits, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, Arzela–Ascoli route exposure, equicontinuity and uniform-modulus binding, continuous-map and Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.EquicontinuousCompactClosureUp.

Chapter 7869

A Concrete Naming Certificate for $\mathsf{CompactUniformCoverMembership}^{\uparrow}$

Following the finite-cover reading of chapter 9237, the $\mathsf{CompactUniformCoverMembership}^{\uparrow}$ packet records the cover-membership ledger that must be displayed before a compact-uniform-continuity proof folds local radii into a uniform modulus. It sits between the compact metric source of chapter 129, the pointwise-modulus surface of chapter 130, the finite subcover ledger of chapter 6125, and the cover-read consumer of chapter 6409. The packet isolates the finite membership test for a source point against a bundled compact-net center; it does not export the final lower-bound fold or the completed $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Definition 7869.1 (Compact-uniform cover-membership carrier)**.** *A* $\mathsf{CompactUniformCoverMembership}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, L, B, x, c, \rho, Q, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the finite compact-net data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to the displayed map at compact-net centers.*
3. *L is the* $\mathsf{FiniteSubcoverLedger}^{\uparrow}$ *row that records which bundled cover entries are available.*
4. *B is the* $\mathsf{ProbeBundle}$ *index row naming the finite cover entry that is inspected.*
5. *x is the source-point history being routed through the compact cover.*
6. *c is the displayed center row attached to the bundled cover entry.*
7. *ρ is the positive radius row attached to c by the pointwise-modulus data.*
8. *Q is the* $\mathsf{Rat}^{\uparrow}$ *comparison row recording that the inspected source point lies inside the displayed radius window.*
9. *H records componentwise* hsame *transport for compact-net, pointwise-modulus, finite-subcover, ProbeBundle, point, center, radius, comparison, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from compact-net coverage through the bundled center and radius membership test.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformCoverMembership}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteSubcoverLedger}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformCoverMembership}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an external point-set cover, a selected subcover, a global modulus, quotient point equality, countable choice, or ambient compactness.

Theorem 7869.2 (Compact-uniform cover-membership obligations)**.** *For every accepted* CompactUniformCoverMe *carrier*

$$M = (K, F, L, B, x, c, \rho, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformCoverMembership}^{\uparrow}}$ *surface consists exactly of compact-net admission through K, pointwise-modulus admission through F, finite-subcover ledger admission through L, bundled cover-entry admission through B, source point and center exposure through x, c, radius exposure through ρ, rational membership comparison through Q, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7869.1. The accepted packet displays exactly the compact-net row, pointwise-modulus row, finite-subcover ledger, bundled cover entry, inspected point, center, radius, rational comparison, and structural rows.

The membership test is local to B, x, c, ρ, Q. The bundle row names the finite cover entry, the source-point and center rows name the comparison endpoints, the radius row supplies the local modulus window, and the rational comparison row records that the inspected point is inside that window.

The compact and continuous rows are dependency rows, not hidden selectors. The compact row supplies only the finite-net source for the bundle, and the continuous row supplies only the radius attached to the displayed center.

Finally H, C, P, N preserve the same finite membership packet. Since no row stores an external point-set cover, selected subcover, global modulus, quotient point equality, countable choice, or ambient compactness theorem, none can be exported by the local NameCert. □

Theorem 7869.3 (Cover membership before uniform-modulus cover read)**.** *Every* $\mathsf{CompactUniformCoverRead}^{\uparrow}$ *or* $\mathsf{UniformModulus}^{\uparrow}$ *consumer using an accepted* $\mathsf{CompactUniformCoverMembership}^{\uparrow}$ *packet must first display the route*

$$K, L, B, x, c, \rho, Q$$

before it may fold radii or consume a tolerance-only modulus. The handoff supplies only a finite membership row for one bundled compact-net center, not an external subcover selector, a completed lower-bound fold, quotient point equality, countable choice, or an ambient compactness theorem.

Proof. Start with the compact source K and finite-subcover ledger L. They determine the finite cover entries that may be inspected by the compact-uniform route.

Choose only a displayed bundle entry B. The packet then exposes the inspected source point x, the bundled center c, and the radius row ρ attached to that center by the pointwise-modulus row F.

Read the rational comparison Q. This row is the membership evidence needed before the cover-read chapter can fold radii across the finite bundle.

The packet stops at membership. The lower-bound fold and final tolerance-only consumer remain downstream in chapter 6409, so this chapter exports no selected subcover, global modulus, quotient point equality, countable choice, or ambient compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformCoverMembership}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformCoverMembership}^{\uparrow}$ packet is generated from compact-net rows, pointwise-modulus rows, finite-subcover ledger rows, ProbeBundle entries, inspected source points, center rows, radius rows, rational comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformCoverMembership}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7869.1, Definition 7869.2, and Definition 7869.3 seed the finite cover-membership route before compact-uniform cover reads fold local radii.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformCoverMembership}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subcovers, completed lower-bound folds, global modulus selection, quotient point equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net source exactness, pointwise-radius exposure, finite-subcover ledger admission, bundle membership comparison, cover-read handoff, and transport stability for BEDC.Derived.CompactUniformCoverMembershipUp.

Chapter 7870

A Concrete Naming Certificate for $\mathsf{CurvedSpacetime}^{\uparrow}$

Following Wald and Choquet-Bruhat on Lorentzian geometry, the $\mathsf{CurvedSpacetime}^{\uparrow}$ packet records the finite BEDC route by which local Lorentz-rate charts, chart transitions, curvature witnesses, and transport rows may be read as a curved-spacetime interface. It realizes the curved-gluing step of the Inter-Hist Locality chain of Definition 9419.25 by sitting over the multi-Hist configuration surface of chapter 474, the causal rows of chapter 478, the maximum-rate boundary of chapter 594, the frame-rate packet of chapter 617, and the symmetric distance-shape ledger of chapter 911. The packet names finite chart and transition data; it does not import a host smooth manifold, global frame, metric tensor primitive, selected atlas, coordinate equality, or ambient spacetime object.

Definition 7870.1 (Curved spacetime carrier)**.** *A* $\mathsf{CurvedSpacetime}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, C, R, L, G, K, T, H, Q, P, N)$$

where:

- M *is the displayed* $\mathrm{MultiHistConfig}^{\uparrow}$ *source row.*
- C *is the* $\mathsf{CrossHistCausal}^{\uparrow}$ *causal-dependence family over the displayed histories.*
- R *is the* $\mathsf{MaxCausalRate}^{\uparrow}$ *maximum-rate boundary row.*
- L *is the local* $\mathsf{LorentzFrameRate}^{\uparrow}$ *chart-rate row.*
- G *is the* $\mathsf{MinkowskiRateGeometry}^{\uparrow}$ *local distance-shape row.*
- K *is the finite curvature ledger, recording which chart overlaps have non-trivial transition curvature data.*
- T *is the finite transition ledger between chart rows.*
- H *is componentwise* hsame *transport for the multi-Hist, causal, rate, Lorentz, geometry, curvature, and transition rows.*
- Q *is the displayed* Cont *replay route for chart and overlap inspections.*
- P *is the* Pkg *provenance over* $\mathsf{CurvedSpacetime}^{\uparrow}$, $\mathrm{MultiHistConfig}^{\uparrow}$, $\mathsf{CrossHistCausal}^{\uparrow}$, $\mathsf{MaxCausalRate}^{\uparrow}$, $\mathsf{LorentzFrameRate}^{\uparrow}$, $\mathsf{MinkowskiRateGeometry}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
- N *is the local* $\mathsf{NameCert}_{\mathsf{CurvedSpacetime}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite curved-spacetime packet. It has no coordinate for a host manifold, global inertial frame, metric tensor primitive, atlas choice, point equality across charts, or ambient Lorentzian completion.

Theorem 7870.2 (Curved spacetime NameCert obligations)**.** *For every accepted* $\mathsf{CurvedSpacetime}^{\uparrow}$ *carrier* $S = (M, C, R, L, G, K, T, H, Q, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CurvedSpacetime}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed multi-Hist source, causal family, maximum-rate boundary, local Lorentz-rate chart rows, Minkowski-rate geometry rows, finite curvature ledger, finite transition ledger, componentwise transport, continuation replay, package provenance, and local naming row. Every accepted curved-spacetime read is classified only by those finite rows.*

Proof. Project the carrier of Definition 7870.1. The displayed tuple already exposes the only rows available to a consumer.

The local naming row N can certify exactly the rows named by the carrier: $M, C, R, L, G, K, T, H, Q, P$. Thus carrier admission, chart-rate exposure, transition exposure, curvature exposure, transport, replay, provenance, and local naming are the complete obligation surface.

Since no coordinate in the packet names a host manifold, global frame, primitive metric tensor, selected atlas, cross-chart point equality, or ambient Lorentzian object, no such object can be exported by the local certificate. □

Theorem 7870.3 (Curved spacetime local Lorentz stability)**.** *Every local chart read of an accepted* $\mathsf{CurvedSpacetime}^{\uparrow}$ *packet factors through the route*

$$M, C, R, L, G, H, Q, P, N.$$

In particular, local Lorentz-rate stability is read only through the displayed multi-Hist source, causal-dependence family, maximum-rate row, local Lorentz-frame-rate row, Minkowski-rate geometry row, componentwise hsame *transport, continuation replay, provenance, and local naming. It exports no global frame, synchronized clock, host real-valued coordinate system, or detached metric tensor.*

Proof. Start from the carrier route. The local Lorentz chart row L is not standalone: it is paired with the displayed multi-Hist source, causal rows, and maximum-rate boundary before any geometry row G can be read.

Componentwise transport through H keeps the same route stable under hsame comparison of the visible rows. Replay through Q and provenance through P preserve the local chart inspection as a finite continuation path named by N.

Therefore every local Lorentz-rate read is confined to the displayed route, with no coordinate for a global inertial frame, synchronized clock, host coordinate system, or primitive metric tensor. □

Theorem 7870.4 (Curved spacetime no global frame boundary)**.** *Every transition, curvature, or transport read exported by an accepted* $\mathsf{CurvedSpacetime}^{\uparrow}$ *packet must pass through the finite overlap route*

$$M, C, R, L, G, K, T, H, Q, P, N$$

before it can serve as a curved-spacetime interface. The overlap route may expose non-trivial chart gluing and curvature ledgers, but it never exports a single global frame, selected atlas, quotient point equality across charts, host manifold equality, metric tensor primitive, countable-choice chart schedule, or ambient Lorentzian spacetime.

Proof. The transition ledger T and curvature ledger K are rows of the same accepted carrier, so every overlap read begins with the displayed multi-Hist, causal, rate, Lorentz, and local geometry rows.

Apply the NameCert obligation theorem Definition 7870.2. It forces the transition and curvature rows to remain inside the finite carrier, transported by H, replayed by Q, sourced by P, and named by N.

The carrier has no field for a global frame, selected atlas, quotient point equality, host manifold equality, metric tensor primitive, countable-choice chart schedule, or ambient Lorentzian spacetime. Hence the public boundary is exactly the finite curved-gluing route. □

Falsifiable prediction: Every accepted $\mathsf{CurvedSpacetime}^{\uparrow}$ read factors through finite multi-Hist chart rows, causal rows, maximum-rate rows, local Lorentz-frame-rate rows, Minkowski-rate geometry rows, curvature and transition ledgers, hsame transport, Cont replay, Pkg provenance, and local naming before any curved-spacetime consumer receives the interface.

Independence witness: multihistconfig, crosshistcausal, maxcausalrate, lorentz-frame-rate, minkowski-rate-geometry: $\mathsf{CurvedSpacetime}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries local chart rows, non-trivial transition data, curvature ledgers, transport, replay, provenance, and local naming while refusing a global frame, selected atlas, host manifold equality, metric tensor primitive, and ambient spacetime object.

Closure status for $\mathsf{NameCert}_{\mathsf{CurvedSpacetime}^{\uparrow}}$.

Constructive story: A $\mathsf{CurvedSpacetime}^{\uparrow}$ packet is generated from finite multi-Hist chart rows, cross-Hist causal rows, maximum-rate boundaries, local Lorentz-frame-rate rows, Minkowski-rate geometry rows, curvature and transition ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CurvedSpacetime}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7870.1, Definition 7870.2, Definition 7870.3, and Definition 7870.4 bind the finite curved-gluing carrier and its no-global-frame boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CurvedSpacetime}^{\uparrow}}, \mathsf{unformalized})$

Lean target:

Bridge status: none

Not claimed: This chapter does not close a host smooth manifold, global frame, selected atlas, quotient point equality, metric tensor primitive, ambient Lorentzian spacetime, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local Lorentz stability, transition and curvature readback, transport, replay, provenance, and local naming for the $\mathsf{CurvedSpacetime}^{\uparrow}$ packet.

Chapter 7871

A Concrete Naming Certificate for $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$

Following Bishop-style constructive nested interval reasoning, the $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ packet records the finite dyadic window route by which nested located intervals yield regular rational readback and a terminal real-name handoff. It sits after the dyadic arithmetic surface of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, the interval nesting route of chapter 320, and the located endpoint discipline of chapter 394. The packet names a displayed nested-interval-to-real carrier; it is not a selected limit, quotient real equality, countable-choice branch, trichotomy principle, or ambient completeness theorem.

Definition 7871.1 (Dyadic nested interval carrier)**.** *A* $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, U, J, K, S, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the finite row of dyadic left endpoints, classified through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *U is the finite row of dyadic right endpoints, over the same endpoint window as L.*
3. *J is the nesting row asserting that each displayed successor interval lies inside its predecessor.*
4. *K is the located nonempty-window row, recording that each displayed interval has a certified dyadic inhabitance witness or overlap certificate internal to the packet.*
5. *S is the shrink schedule row that assigns a displayed precision request to a finite interval stage.*
6. *A is the diameter ledger, proving that the displayed dyadic width at the scheduled stage is bounded by the requested tolerance.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *read window that records the inspected finite stages.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the scheduled dyadic endpoints or midpoints over W.*
9. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row exposed only after L, U, J, K, S, A, W, R have been replayed.*
10. *H records componentwise* hsame *transport for endpoint, nesting, located-window, shrink, diameter, StreamName, RegSeqRat, Real handoff, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from a precision request through* $L, U, J, K, S, A, W, R, E, H, P, N$.
12. *P is the* Pkg *provenance over* $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a selected limit point, quotient real equality, countable-choice subsequence, external interval oracle, trichotomy split, or ambient completeness principle.

Theorem 7871.2 (Dyadic nested interval NameCert obligations)**.** *For every accepted* DyadicNestedIntervalChoiceFr *carrier $D = (L, U, J, K, S, A, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}}$ *obligation surface is exactly endpoint admission through L, U, nesting through J, located nonempty-window exposure through K, shrink scheduling through S, diameter control through A,* $\mathsf{StreamName}^{\uparrow}$ *windowing through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

No downstream consumer may replace this surface by selected limits, quotient-real equality, a countable-choice branch, host interval completeness, trichotomy, or an external locatedness predicate.

Proof. Project the carrier of Definition 7871.1. The endpoint rows L, U are the only dyadic data, while J, K, S, A are the displayed interval, locatedness, schedule, and diameter rows attached to them.

Read the analytic handoff through W, R, E. The StreamName row exposes only inspected finite stages, the RegSeqRat row repacks those stages as regular rational readback, and the Real handoff appears only after those rows have been replayed.

Finally inspect H, C, P, N. Transport, replay, provenance, and local naming preserve the same finite route, so the NameCert surface has no coordinate for selected limits, quotient-real equality, countable choice, host completeness, trichotomy, or external locatedness. □

Theorem 7871.3 (Dyadic nested interval window induction)**.** *For every accepted* $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ *carrier, finite induction on the displayed* $\mathsf{StreamName}^{\uparrow}$ *window preserves the route*

$$L, U, J, K, S, A, W, R, E, H, C, P, N.$$

The base window exposes one located dyadic interval with its diameter ledger, and the successor step refines the previous interval through the nesting row J while keeping the same shrink schedule, readback, transport, replay, provenance, and local naming rows.

Proof. Use induction on the finite window row W. In the base case, the first displayed interval is certified by L, U, K, and its width is bounded by the corresponding diameter row A.

For the successor step, append one inspected stage. The nesting row J places the new dyadic interval inside the previous displayed interval, and the located row K keeps the successor window nonempty inside the packet.

The schedule and readback rows are unchanged in kind. The row S chooses the displayed stage for the requested tolerance, A supplies the width bound at that stage, and R records the same finite chain as regular rational readback.

The structural rows H, C, P, N transport, replay, source, and name the whole route. Hence the induction never introduces a selected limit, quotient equality, external branch, or ambient completeness coordinate. □

Theorem 7871.4 (Dyadic nested interval Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ *packet must first expose the dyadic endpoint rows* L, U*, nesting row* J*, located nonempty-window row* K*, shrink schedule* S*, diameter ledger* A*,* $\mathsf{StreamName}^{\uparrow}$ *window* W*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*. The terminal handoff* E *is therefore a displayed regular-rational route to* $\mathsf{Real}^{\uparrow}$*, not a selected point of the intersection and not quotient-real equality.*

Proof. Apply Definition 7871.2. It makes E downstream of the endpoint, nesting, located-window, schedule, diameter, StreamName, and RegSeqRat rows.

Use Definition 7871.3. The finite windows used by R are preserved across displayed stages, so the Real handoff reads a regular rational route rather than an external intersection selector.

Finally use the refusal part of the carrier definition. Since the accepted packet has no selected limit, quotient-real equality, countable-choice branch, trichotomy split, external interval oracle, or ambient completeness row, every $\mathsf{Real}^{\uparrow}$ consumer must take the displayed handoff E through the finite route. □

Falsifiable prediction: An accepted $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ handoff without displaying dyadic endpoints, nesting, located nonempty windows, shrink schedule, diameter ledger, StreamName windows, and RegSeqRat readback refutes the packet surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, nestedinterval, locatedinterval: no listed sibling is bijective to $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ because only this packet binds dyadic endpoints, nesting, located windows, shrink scheduling, diameter control, finite observation, regular rational readback, Real handoff, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}$ packet is generated from dyadic endpoint rows, nesting rows, located nonempty-window rows, a shrink schedule, a diameter ledger, StreamName windows, RegSeqRat readback, a RealUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7871.1, Definition 7871.2, Definition 7871.3, and Definition 7871.4 seed the finite dyadic nested-interval route from displayed windows to a Real handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalChoiceFree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected intersection points, quotient Real equality, countable choice, trichotomy, host interval completeness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, nesting, located-window exposure, shrink scheduling, diameter control, StreamName window stability, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicNestedIntervalChoiceFreeUp.

Chapter 7872

A Concrete Naming Certificate for $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ packet records the finite rate-envelope surface by which a regular Cauchy read answers dyadic precision requests before a terminal real-name seal is consumed. It sits over the dyadic tolerance arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the tail-control handoff of chapter 1487, and the terminal real-name boundary of chapter 38. The packet names a finite envelope for rate requests; it is not quotient stream equality, a selected host limit, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7872.1 (Regular Cauchy rate-envelope carrier)**.** *A* $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, W, R, T, S, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *rate-request ledger, recording the dyadic precision asked of the regular Cauchy name and the tolerance cells used by the envelope.*
2. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened for that dyadic request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window W under the same tolerance ledger D.*
4. *T is the* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *handoff row, asserting that the inspected window dominates every later read at the requested dyadic rate.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, public only after D, W, R, T have been replayed.*
6. *H records componentwise* hsame *transport for the dyadic request ledger, stream window, regular readback, tail handoff, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite rate request through*

$$D, W, R, T \longmapsto S, H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient equality of streams, a selected representative, countable-choice tail selection, host real equality, or an ambient completeness field for $\mathsf{Real}^{\uparrow}$.

Theorem 7872.2 (Regular Cauchy rate-envelope NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ *carrier*

$$E = (D, W, R, T, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRateEnvelope}^{\uparrow}}$ *surface consists exactly of dyadic rate-request admission, finite StreamName window exposure, RegSeqRat readback, RegularCauchyTailEstimate handoff, terminal Real sealing, componentwise transport, displayed continuation replay, package provenance, and local naming through* N.

Proof. Project the carrier of Definition 7872.1. The dyadic request row D is the only rate coordinate, and the finite window row W is opened under that request.

Read the regular rational data through R. The tail handoff T is attached to the same D, W, R surface, so it records domination of later reads at the displayed rate rather than a detached convergence predicate.

The terminal Real seal S occurs after the rate ledger, window, readback, and tail handoff. The rows H, C, P, N transport, replay, source, and name this displayed packet, and no excluded quotient, selected limit, choice, trichotomy, host equality, or ambient-completeness row appears in the carrier. □

Theorem 7872.3 (Regular Cauchy rate-envelope finite-window induction)**.** *Let*

$$E = (D, W, R, T, S, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ *carrier. Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of* E *factors through a finite induction on the displayed window* W*: the base window exposes the first inspected rational read under* D*, and each extension appends one displayed StreamName entry whose RegSeqRat readback remains controlled by the same RegularCauchyTailEstimate handoff* T*. Therefore the terminal seal* S *can be reached only through the finite rate-envelope route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RegularCauchyTailEstimate}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Proof. Induct on the finite window row W. In the base case the carrier exposes one inspected StreamName entry, the dyadic request ledger D, and the corresponding RegSeqRat readback R.

For the extension step, append one displayed window entry. The carrier keeps the same request ledger D and the same tail handoff T, so the appended read is still part of the finite rate envelope rather than a separate representative or choice schedule.

After the induction, the consumer reaches S only through D, W, R, T. Componentwise transport H and replay C preserve that order, while P and N only record provenance and naming. Hence no Real-facing read bypasses the finite envelope route. □

Falsifiable prediction: A $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ read is refuted whenever a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal without displaying the dyadic rate request, finite StreamName window, RegSeqRat readback, RegularCauchyTailEstimate handoff, componentwise transport, continuation replay, package provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, regularcauchytailestimate, real: none alone is bijective with $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ because only this packet binds dyadic rate requests, finite StreamName windows, RegSeqRat readback, tail-estimate handoff, Real sealing, transport, replay, provenance, and local naming as one NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRateEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRateEnvelope}^{\uparrow}$ packet is generated from a dyadic rate-request ledger, finite StreamName windows, RegSeqRat readback, a RegularCauchyTailEstimate handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7872.1, Definition 7872.2, and Definition 7872.3 seed the finite rate-envelope route over dyadic requests, StreamName windows, RegSeqRat readback, tail estimates, Real seals, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic rate-request admission, StreamName window stability, RegSeqRat readback, RegularCauchyTailEstimate handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyRateEnvelopeUp.

Chapter 7873

A Concrete Naming Certificate for $\mathsf{HaarMeasure}^{\uparrow}$

Following Haar and Weil, the $\mathsf{HaarMeasure}^{\uparrow}$ packet records the finite NameCert surface for an invariant measure on a displayed locally compact group without taking the host existence theorem as a primitive. It sits after the topological-group rows of chapter 204, the measure carrier of chapter 92, the Radon–Nikodym comparison surface of chapter 3448, the character-duality boundary of chapter 263, and the finite-group averaging packet of chapter 7640. The chapter names only the local rows that an invariant-measure consumer may inspect; it does not construct the ambient Haar existence theorem, quotient measure equality, selected representatives, modular-function theory, or completed locally compact group analysis.

Definition 7873.1 (HaarMeasure carrier)**.** *A* $\mathsf{HaarMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, T, M, L, R, W, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{TopGroup}^{\uparrow}$ *source row, naming the group operation, identity, inverse, neighbourhood, compact-window, and translation data read before an invariant-measure row may be consumed.*
2. *T is the local compactness and regularity window row, exposing the compact-test and open-neighbourhood data through which measure values are inspected.*
3. *M is the* $\mathsf{Measure}^{\uparrow}$ *row, recording the displayed event family and measure-value readback available to the packet.*
4. *L and R are the left- and right-translation invariance rows, recording how translated compact or measurable windows replay the same measure read.*
5. *W is the comparison and refusal row, tying Radon–Nikodym and Pontryagin-duality consumers to the displayed invariant-measure surface while excluding quotient measure equality, selected representatives, modular-function claims, and host existence theorems.*
6. *H records componentwise* hsame *transport for the topological-group, local-compactness, measure, invariance, comparison, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route from group rows through local compactness, measure readback, translation invariance, comparison, refusal, provenance, and local naming.*

8. *P is the* Pkg *provenance over* $\mathsf{HaarMeasure}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonNikodym}^{\uparrow}$, $\mathsf{PontryaginDuality}^{\uparrow}$, $\mathsf{HaarIntegralFiniteGroup}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{HaarMeasure}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host proof of Haar-measure existence, quotient equality of measures, selected compact approximants, an unrestricted modular function, or an ambient completed locally compact group.

Theorem 7873.2 (HaarMeasure NameCert obligations)**.** *For every accepted* $\mathsf{HaarMeasure}^{\uparrow}$ *carrier* $K = (G, T, M, L, R, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HaarMeasure}^{\uparrow}}$ *surface consists exactly of these five obligation rows:*

1. *carrier admission for the displayed topological-group, local-compactness, measure, translation-invariance, comparison, refusal, transport, replay, provenance, and local naming rows;*

2. *locally compact measure exposure, requiring G, T, M to be visible before any invariant-measure consumer reads a value;*

3. *left and right invariance, requiring L and R to replay the same displayed measure row under translated windows;*

4. *sibling comparison, requiring Radon–Nikodym, Pontryagin-duality, and finite-group averaging consumers to enter through the displayed comparison row W;*

5. *ledger non-escape, excluding ambient Haar existence, quotient measure equality, selected representatives, unrestricted modular-function claims, and completed locally compact group analysis.*

Proof. Project the carrier of Definition 7873.1. The only group, compactness, and measure data available to a consumer are the displayed rows G, T, M, so invariant-measure reading cannot bypass the local compactness and event-value windows.

Next inspect the translation rows. Rows L and R replay measure values through displayed left and right translates of the same group source row, while H and C preserve this replay componentwise and publicly.

Finally use the comparison and refusal row W together with provenance P and local naming N. The Radon–Nikodym, Pontryagin-duality, and finite-group averaging siblings can consume only the displayed comparison route, and no row supplies host existence, quotient equality, selected representatives, modular-function theory, or completed locally compact group analysis. □

Closure status for $\mathsf{NameCert}_{\mathsf{HaarMeasure}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HaarMeasure}^{\uparrow}$ packet is generated from topological-group source rows, local compactness and regularity windows, measure readback rows, left and right translation-invariance rows, comparison and refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HaarMeasure}^{\uparrow}}$, seed)

Scope closed: Definition 7873.1 and Definition 7873.2 seed the locally compact invariant-measure surface over displayed topological-group and measure rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HaarMeasure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, ambient Haar-measure existence, quotient measure equality, selected representatives, unrestricted modular-function theory, or completed locally compact group analysis.

Upgrade path: Obligation closure requires checked carrier admission, locally compact measure exposure, left and right invariance, sibling comparison, transport, replay, provenance, local NameCert coverage, and ledger non-escape for the same packet.

Chapter 7874

A Concrete Naming Certificate for $\mathsf{WeilPetersson}^{\uparrow}$

Following Weil, Petersson, Ahlfors, and Wolpert, the $\mathsf{WeilPetersson}^{\uparrow}$ packet records the finite metric-geometry surface obtained from the L^2 Hermitian pairing on Teichmuller tangent data. It sits next to the marked-surface packet of chapter 6372, the metric carrier of chapter 57, the symplectic carrier of chapter 138, and the complex-structure carrier of chapter 39. The packet is a finite NameCert surface over $\mathsf{TeichmullerSpace}^{\uparrow}$, Riemann-surface coordinate windows, $\mathsf{Met}^{\uparrow}$, $\mathsf{Symplectic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert; it is not a host construction of moduli space, a quotient complex structure, a selected geodesic family, or an ambient completeness theorem.

Definition 7874.1 (Weil–Petersson carrier)**.** *A* $\mathsf{WeilPetersson}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (T, R, Q, \Omega, D, S, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{TeichmullerSpace}^{\uparrow}$ *source row, including the marked-surface, complex-structure, hyperbolic-metric, deformation, and classifier rows that the metric read may inspect.*
2. *R is the Riemann-surface coordinate-window row, recording the finite chart, quadratic-differential, or Beltrami-window data used by the pairing route.*
3. *Q is the Hermitian pairing row. It records the finite L^2 pairing witness as* $\mathsf{Complex}^{\uparrow}$*-linear data with* $\mathsf{Real}^{\uparrow}$ *readback for the positive metric part.*
4. *Ω is the symplectic and Kahler-form row, read through* $\mathsf{Symplectic}^{\uparrow}$ *and the complex row of T without adding a separate host quotient structure.*
5. *D is the metric-distance readback row. It exposes the local* $\mathsf{Met}^{\uparrow}$ *distance interface obtained from Q, Ω and the displayed* $\mathsf{Real}^{\uparrow}$ *seal.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Complex}^{\uparrow}$ *seal row, ensuring that scalar reads pass through the visible real and complex carriers before any metric or symplectic consumer receives them.*
7. *H records componentwise* hsame *transport for $T, R, Q, \Omega, D, S, C, P, N$.*
8. *C records displayed* Cont *replay from Teichmuller source rows through coordinate windows, Hermitian pairing, symplectic/Kahler form, and metric-distance readback.*

9. *P is the* Pkg *provenance over* $\mathsf{WeilPetersson}^{\uparrow}$, $\mathsf{TeichmullerSpace}^{\uparrow}$, *Riemann-surface windows,* $\mathsf{Met}^{\uparrow}$, $\mathsf{Symplectic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{WeilPetersson}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, Q, \Omega, D, S, H, C, P, N$. It has no coordinate for host moduli-space construction, quotient complex-structure equality, selected geodesics, metric completion, curvature formulae, or global analytic compactification.

Theorem 7874.2 (Weil–Petersson NameCert obligations)**.** *For every accepted* $\mathsf{WeilPetersson}^{\uparrow}$ *carrier $W = (T, R, Q, \Omega, D, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{WeilPetersson}^{\uparrow}}$ *obligation surface consists exactly of Teichmuller-source exposure through T; Riemann-surface coordinate-window exposure through R; Hermitian pairing admission through Q; symplectic and Kahler-form readback through Ω; metric-distance readback through D;* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{Complex}^{\uparrow}$ *scalar sealing through S; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Every consumer of the packet must therefore read the route

$$\mathsf{TeichmullerSpace}^{\uparrow},\quad \mathsf{Met}^{\uparrow},\quad \mathsf{Symplectic}^{\uparrow},\quad \mathsf{Complex}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}$$

through $T, R, Q, \Omega, D, S, H, C, P, N$, and no consumer receives host moduli space, quotient complex structure, selected geodesics, ambient completeness, global curvature identities, or analytic compactification data.

Proof. Project the carrier of Definition 7874.1. The rows T, R, Q, Ω, D, S display the only mathematical data visible to the local certificate: marked Teichmuller input, finite Riemann-surface windows, Hermitian pairing, symplectic/Kahler form, metric readback, and scalar seals.

The transport and replay rows H, C move only these displayed coordinates. Thus a metric or symplectic consumer can compare packets only by componentwise hsame transport and the recorded Cont route; it cannot introduce a host quotient of moduli points or select geodesics outside the packet.

Finally P names the provenance of the cited sibling packets and N names the local $\mathsf{WeilPetersson}^{\uparrow}$ surface. Since the carrier contains no coordinate for the excluded analytic structures, the listed rows exhaust the NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{WeilPetersson}^{\uparrow}$ packet displays a TeichmullerSpaceUp source row, Riemann-surface coordinate windows, Hermitian pairing, symplectic/Kahler form, MetricSpaceUp distance readback, RealUp and ComplexUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any metric-geometry consumer reads it.

Independence witness: teichmuller-space, metric, symplectic, complex: $\mathsf{WeilPetersson}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries Teichmuller source data, Riemann-surface coordinate windows, Hermitian pairing, symplectic/Kahler form, metric readback, scalar seals, transport, replay, provenance, and local naming in one finite metric-geometry packet.

Closure status for $\mathsf{NameCert}_{\mathsf{WeilPetersson}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WeilPetersson}^{\uparrow}}$, seed)

Scope closed: Definition 7874.1 and Definition 7874.2 seed the finite Weil–Petersson NameCert surface over Teichmuller source rows, Riemann-surface coordinate windows, Hermitian pairing, symplectic/Kahler form, metric readback, scalar seals, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WeilPetersson}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: Host moduli-space construction, quotient complex-structure equality, selected geodesics, ambient completeness, global curvature identities, analytic compactification, Lean verification, and bridge checking are not claimed.

Upgrade path: Obligation closure requires checked carrier admission, coordinate-window stability, Hermitian pairing exactness, symplectic/Kahler readback, metric-distance readback, scalar seals, transport, replay, provenance, and local NameCert rows.

Constructive story: A WeilPetersson$^{\uparrow}$ packet is generated from a TeichmullerSpaceUp source row, Riemann-surface coordinate windows, a Hermitian pairing row, a symplectic/Kahler-form row, a MetricSpaceUp distance readback row, RealUp and ComplexUp scalar seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7875

A Concrete Naming Certificate for $\mathsf{NormedAlgebra}^{\uparrow}$

Following Bourbaki and Rudin on normed algebras, the $\mathsf{NormedAlgebra}^{\uparrow}$ packet records a constructive algebra-over-analysis interface in which multiplication is compatible with a displayed norm. It sits after the normed-space carrier of chapter 1950, the ring multiplication surface of chapter 43, the ordered real algebra rows of chapter 766, the terminal real-name seal of chapter 38, and the complete normed-space consumer boundary of chapter 90. The packet names submultiplicative multiplication and continuous scalar multiplication as finite NameCert data; it is not a quotient algebra, a host topological algebra, a Hahn–Banach principle, or an ambient completeness theorem.

Definition 7875.1 (Normed algebra NameCert surface)**.** *A* $\mathsf{NormedAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (V, +, 0, -, \cdot, 1, \nu, \alpha, \mu, \sigma, H, C, P, N)$$

with the following displayed rows:

1. $V, +, 0, -$ *are the additive and scalar rows read from the* $\mathsf{NormedSpace}^{\uparrow}$ *source.*
2. $\cdot, 1$ *are the multiplication and unit rows read through the* $\mathsf{Ring}^{\uparrow}$ *source and transported over the same carrier classifier.*
3. ν *is the* $\mathsf{Real}^{\uparrow}$*-valued norm row of the normed-space carrier.*
4. α *is the ordered-real algebra row tying scalar multiplication to chapter 766.*
5. μ *is the submultiplicative product ledger, displaying* $\nu(x \cdot y) \leq \nu(x)\nu(y)$ *as a finite ordered-real comparison row.*
6. σ *is the scalar-continuity ledger, displaying the finite norm estimate for scalar multiplication before any Banach or bounded-operator consumer reads it.*
7. H *records componentwise* hsame *transport for carrier, additive, scalar, multiplicative, norm, product-ledger, scalar-continuity, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a normed-algebra request through* $V, +, 0, -, \cdot, 1, \nu, \alpha, \mu, \sigma, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{NormedAlgebra}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{RealAlgOrder}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{NormedAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient algebra equality, a host topological algebra, a selected completion, Hahn–Banach separation, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7875.2 (Normed algebra submultiplicative product)**.** *Every accepted* $\mathsf{NormedAlgebra}^{\uparrow}$ *multiplication read factors through the shared* $\mathsf{NormedSpace}^{\uparrow}$*,* $\mathsf{Ring}^{\uparrow}$*,* $\mathsf{RealAlgOrder}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *rows before a product norm estimate is public. The only product estimate exposed by the packet is the finite ledger* μ *in Definition 7875.1; it states that the norm of the displayed product is bounded by the displayed ordered-real product of the two input norms. No consumer may replace* μ *by a host algebra norm, quotient equality of products, a selected completion, or ambient completeness.*

Proof. Read the carrier of Definition 7875.1. The rows $V, +, 0, -, \nu$ supply the normed-space source, while $\cdot, 1$ supply the ring multiplication over the same displayed carrier.

The ordered comparison is carried by α and μ. The row α supplies the ordered-real algebra context, and μ records the single finite submultiplicative ledger tying the product row to the two input norm rows.

The structural rows H, C, P, N preserve only the displayed packet. Since no row stores quotient algebra equality, host topological algebra data, a selected completion, Hahn–Banach separation, or ambient completeness, the product estimate is exactly the ledger μ. □

Theorem 7875.3 (Normed algebra continuous scalar multiplication)**.** *Every accepted* $\mathsf{NormedAlgebra}^{\uparrow}$ *scalar-multiplication read factors through the* $\mathsf{NormedSpace}^{\uparrow}$ *scalar rows, the* $\mathsf{RealAlgOrder}^{\uparrow}$ *ordered-scalar row, and the terminal* $\mathsf{Real}^{\uparrow}$ *norm comparison before it reaches a* $\mathsf{Banach}^{\uparrow}$ *or bounded-operator consumer. The handoff is the finite scalar-continuity ledger* σ *together with* H, C, P, N*, not a host continuity theorem or a completed function-space object.*

Proof. Start with the normed-space part of the carrier. The scalar action and norm rows are displayed before any algebra-specific multiplication row is inspected.

Next use the ordered-real algebra row α. It places scalar multiplication in the same ordered $\mathsf{Real}^{\uparrow}$ comparison language as the norm and product ledgers.

The scalar-continuity estimate is then the row σ. It is replayed by C, transported by H, sourced by P, and named by N, so a Banach or bounded-operator consumer receives only the displayed finite estimate.

No excluded analytic object is generated by this route. Host continuity, quotient function equality, selected completion, Hahn–Banach separation, and ambient completeness have no coordinate in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{NormedAlgebra}^{\uparrow}}$**.**

Constructive story: A $\mathsf{NormedAlgebra}^{\uparrow}$ packet is generated from normed-space rows, ring multiplication rows, ordered-real algebra rows, Real norm comparisons, a submultiplicative product ledger, a scalar-continuity ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NormedAlgebra}^{\uparrow}}$, seed)

Scope closed: Definition 7875.1, Definition 7875.2, and Definition 7875.3 seed the constructive normed-algebra interface over normed-space, ring, ordered-real, Real, and Banach-facing rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NormedAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Banach algebra completeness, Hahn–Banach separation, spectrum theory, quotient algebra equality, host topological algebra structure, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, additive and scalar row exposure, ring multiplication exposure, ordered-real comparison, submultiplicative product exactness, scalar-continuity handoff, transport, replay, provenance, and local naming for BEDC.Derived.NormedAlgebraUp.

Chapter 7876

A Concrete Naming Certificate for $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ packet records finite regular-subsequence cluster evidence downstream of the StreamName certificate of chapter 126, the regular rational sequence certificate of chapter 301, the dyadic rational core of chapter 291, the Real certificate of chapter 38, and the regular Cauchy tail estimate of chapter 1487. The packet names a finite cluster-window surface for a displayed regular subsequence; it does not assert a Bolzano-Weierstrass theorem, choose a cluster point, or import an ambient completeness principle.

Definition 7876.1 (Real regular-subsequence cluster carrier)**.** *A* $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, T, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the subsequence schedule row: a finite* $\mathsf{StreamName}^{\uparrow}$*-indexed list of selected positions, monotone schedule comparisons, and source-window names.*
2. *R is the regular rational readback row: the* $\mathsf{RegSeqRat}^{\uparrow}$ *endpoint data read at the scheduled positions, with the source classifier and regular readback ledger still visible.*
3. *D is the dyadic tolerance ledger: a* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row recording the tolerances used to compare scheduled readbacks inside a finite cluster window.*
4. *T is the tail-estimate row: a* $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$ *packet certifying that the scheduled window is read through displayed finite tail data before any Real-facing seal is consumed.*
5. *W is the cluster-window witness row: a finite family of scheduled positions whose regular rational readbacks are pairwise inside the displayed dyadic tolerance ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row: the Real-facing endpoint exposed only after S, R, D, T, W have been displayed.*
7. *H records componentwise* hsame *transport for the schedule, readback, tolerance, tail, window, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, R, D, T, W \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyTailEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealRegularSubsequenceCluster}^{\uparrow}}$ *row.*

The carrier contains no coordinate for selecting a cluster point, quotienting streams, invoking countable choice, deciding trichotomy, or replacing the finite tail route by ambient Real completeness.

Theorem 7876.2 (Real regular-subsequence cluster NameCert obligations)**.** *For every accepted* $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ *carrier* $K = (S, R, D, T, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealRegularSubsequenceClu}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the subsequence schedule S, regular rational readback R, dyadic tolerance ledger D, tail-estimate row T, cluster-window witness W, terminal Real seal E, transport row H, replay row C, provenance row P, and local naming row N;*

2. *schedule-readback compatibility, requiring every selected position in S to be read through the same displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*

3. *dyadic-window stability, requiring the cluster-window comparisons in W to use only the tolerance ledger D and the finite tail surface T;*

4. *seal-route exactness, requiring the* $\mathsf{Real}^{\uparrow}$ *row E to be consumed only after the schedule, readback, dyadic tolerance, tail estimate, and cluster window have been displayed;*

5. *ledger non-escape, requiring P and N to source no Bolzano-Weierstrass theorem, selected cluster point, quotient stream equality, countable choice, trichotomy, or ambient Real completeness.*

No cluster obligation is stored outside these rows.

Proof. Project the carrier $K = (S, R, D, T, W, E, H, C, P, N)$. The analytic data available to a consumer are the subsequence schedule, regular rational readback, dyadic tolerance ledger, regular Cauchy tail estimate, finite cluster window, and terminal Real seal.

The schedule-readback clause follows by reading S through the StreamName route and then through the $\mathsf{RegSeqRat}^{\uparrow}$ row R. A selected position has no independent value row unless the corresponding regular rational readback is displayed.

The dyadic-window clause uses D, T, W together. The dyadic ledger records the tolerance, the tail-estimate row records the finite Real-facing route, and the cluster-window witness records only pairwise comparisons inside that displayed tolerance.

The seal-route clause places E after S, R, D, T, W. Componentwise hsame transport and displayed Cont replay preserve the same finite packet, while Pkg provenance and the local NameCert name only those rows.

Finally inspect the non-escape clause. Since the carrier has no row for a selected cluster point, quotient stream equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: A compactness consumer that reads a chosen cluster point or a Bolzano-Weierstrass theorem from $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ refutes this packet.

Independence witness: streamname, regseqrat, dyadicratcore, real, regularcauchytailestimate: $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ is not bijective to any listed sibling because it carries the subsequence schedule, regular readback, dyadic tolerance ledger, tail estimate, cluster-window witness, terminal Real seal, transport, replay, provenance, and local naming rows in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealRegularSubsequenceCluster}^{\uparrow}}$.

Constructive story: A $\mathsf{RealRegularSubsequenceCluster}^{\uparrow}$ packet is generated from a finite subsequence schedule, regular rational readback, dyadic tolerance ledger, regular Cauchy tail estimate, cluster-window witness, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealRegularSubsequenceCluster}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 7876.1 and Definition 7876.2 bind the finite cluster-window packet over StreamName, RegSeqRat, DyadicRatCore, RegularCauchyTailEstimate, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealRegularSubsequenceCluster}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Bolzano-Weierstrass, selected cluster points, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: To reach scopedClosure, a scope theorem must bind the schedule, readback, tolerance, tail, cluster-window, seal, transport, replay, provenance, and local naming rows as the only accepted packet surface.

Chapter 7877

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailMesh}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy reals, the $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ packet records the finite shared-tail mesh read when several regular rational names are compared before a $\mathsf{Real}^{\uparrow}$ handoff. It sits over the finite stream schedules of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the cofinal shared-window route of chapter 7532. The packet names a regular Cauchy tail mesh; it does not quotient streams, select limits, invoke trichotomy, import choice, or assert ambient completeness.

Definition 7877.1 (Regular Cauchy tail mesh carrier)**.** *A* $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, R, D, Q, T, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used by every participating regular name.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for every mesh comparison.*
4. *Q is the cofinal shared-tail row read through* $\mathsf{CofinalTailMesh}^{\uparrow}$*.*
5. *T is the regular Cauchy tail row recording the common precision tail on which the readbacks are compared.*
6. *W is the Real-facing window row exposed after S, R, D, Q, T have been displayed.*
7. *H records componentwise* hsame *transport for S, R, D, Q, T, W and for the structural rows.*
8. *C records displayed* Cont *replay from each finite precision request through the stream windows, regular readbacks, dyadic ledger, cofinal tail row, regular tail row, and Real-facing window.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailMesh}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{CofinalTailMesh}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $S, R, D, Q, T, W, H, C, P, N$. It has no coordinate for quotient stream equality, a selected regular Cauchy representative, a trichotomy decision, countable choice, a host cofinal subsequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7877.2 (Regular Cauchy tail mesh NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ *carrier* $M = (S, R, D, Q, T, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMesh}^{\uparrow}}$ *surface consists exactly of carrier admission, StreamName window scheduling, RegSeqRat readback, DyadicRatCore tolerance accounting, CofinalTailMesh shared-tail admission, regular Cauchy tail comparison, Real-facing window handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7877.1. The visible inventory is $S, R, D, Q, T, W, H, C, P, N$, and every row has a fixed role in the finite mesh.

The stream and rational rows are read first. Row S opens the inspected finite windows, while R supplies the regular rational readback for those same windows. The row D records the dyadic tolerance ledger against which the participating readbacks are compared.

Next the shared-tail data is displayed. Row Q imports only the cofinal tail-mesh route of chapter 7532, and row T records the regular Cauchy tail comparison used by this packet. The window W is downstream of those rows, so a Real-facing consumer cannot read it before the finite mesh has been exposed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient stream equality, selected representative, trichotomy decision, countable choice, host cofinal subsequence, or ambient completeness coordinate, those objects are not local obligations of the packet. □

Theorem 7877.3 (Regular Cauchy tail mesh Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ *carrier receives the finite route*

$$S \longrightarrow R \longrightarrow D \longrightarrow Q \longrightarrow T \longrightarrow W \longrightarrow H, C, P, N.$$

Thus the consumer reads StreamName windows, RegSeqRat tails, a DyadicRatCore tolerance ledger, the CofinalTailMesh shared-tail row, and the regular Cauchy tail comparison before any terminal Real seal may be consumed.

Proof. Start from the carrier definition. The Real-facing row is W, and it appears only after the stream schedule, regular rational readback, dyadic ledger, cofinal shared-tail row, and regular Cauchy tail row have been displayed.

Apply Definition 7877.2. It makes the route through S, R, D, Q, T part of the local NameCert surface, so a Real consumer cannot replace the route by an external representative, a chosen limit, or a host completeness proof.

The transport and replay rows preserve the same finite order for downstream consumers, while P and N name the provenance and local certificate. The handoff is therefore the displayed mesh route rather than a quotient completion or a choice-based selection of a tail. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ read factors through displayed StreamName schedules, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CofinalTailMesh shared-tail row, a regular Cauchy tail comparison, a Real-facing window, componentwise transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, cofinal-tail-mesh: $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the regular tail comparison and cofinal shared-tail mesh consumed before a Real handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailMesh}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyTailMesh}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CofinalTailMesh shared-tail row, a regular Cauchy tail comparison row, a Real-facing window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularCauchyTailMesh}\uparrow}$, seed)

Scope closed: Definition 7877.1, Definition 7877.2, and Definition 7877.3 seed the finite regular Cauchy shared-tail mesh for Real and Completion-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularCauchyTailMesh}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, trichotomy, countable choice, host cofinal subsequences, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-tail admission, dyadic tolerance accounting, regular tail comparison, Real handoff routing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.RegularCauchyTailMeshUp.

Chapter 7878

A Concrete Naming Certificate for $\mathsf{DiniUniformModulus}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{DiniUniformModulus}^{\uparrow}$ packet records the finite route by which monotone pointwise continuity data on a compact metric source become an explicit uniform-modulus certificate. It sits beside the monotone Dini route of chapter 5154, the uniformly continuous sequence surface of chapter 4287, the uniform-modulus packet of chapter 369, the continuous-map rows of chapter 130, the compact-metric source of chapter 129, and the real-name seal of chapter 38. The packet names the constructive finite modulus handoff; it does not assert open-cover compactness, countable choice, a host supremum principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7878.1 (Dini uniform-modulus carrier)**.** *A* $\mathsf{DiniUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, S, M, U, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing only the finite metric observations and compact-source identifiers used by the packet.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-continuity row for the inspected family over the compact source.*
3. *S is the* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *sequence row, recording the displayed monotone approximation schedule before any terminal modulus is read.*
4. *M is the* $\mathsf{DiniUniformMonotone}^{\uparrow}$ *monotone-convergence row that binds pointwise convergence to the finite compact route.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *output row reached only after K, F, S, M have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance and value-readback row used by the monotone comparison; it is terminal and does not export real completeness.*
7. *H records componentwise* hsame *transport for the compact source, continuous-map rows, sequence schedule, monotone route, uniform-modulus output, real readback, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through compact finite inspection, pointwise continuity, monotone schedule, and final uniform-modulus output.*

9. *P is the* Pkg *provenance over* $\mathsf{DiniUniformModulus}^{\uparrow}$, $\mathsf{DiniUniformMonotone}^{\uparrow}$, $\mathsf{UniformlyContinuousSequence}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DiniUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected infinite subcover, countable choice, quotient real equality, a host supremum, full compactness outside the displayed finite source, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7878.2 (Dini uniform-modulus NameCert obligations)**.** *For every accepted* $\mathsf{DiniUniformModulus}^{\uparrow}$ *carrier $D = (K, F, S, M, U, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DiniUniformModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, continuous-map pointwise rows, uniformly continuous sequence schedule, monotone Dini route, terminal uniform-modulus output, real tolerance readback, componentwise transport, displayed continuation replay, provenance, and local naming. Every uniform-modulus read must pass through $K, F, S, M, U, R, H, C, P, N$, and no obligation is stored outside those finite rows.*

Proof. Project the accepted carrier. The analytic rows are precisely the compact source K, pointwise continuous-map data F, the uniformly continuous sequence schedule S, the monotone Dini route M, the uniform-modulus output U, and the real tolerance readback R.

The NameCert obligations follow that order. A tolerance request first enters the compact finite source, then the pointwise continuity row, then the sequence schedule, and only then the monotone Dini row that licenses the uniform-modulus output.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no excluded object appears in the carrier, the local certificate cannot export a selected infinite subcover, countable choice, quotient real equality, a host supremum, open-cover compactness, or ambient real completeness. □

Theorem 7878.3 (Dini monotone uniform route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{DiniUniformModulus}^{\uparrow}$ *carrier receives exactly the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{UniformlyContinuousSequence}^{\uparrow},\quad \mathsf{DiniUniformMonotone}^{\uparrow},\quad \mathsf{UniformModulus}$$

through the displayed rows $K, F, S, M, U, R, H, C, P, N$. A consumer cannot bypass the monotone schedule, replace it by a host supremum argument, or import open-cover compactness, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the compact source and pointwise-continuity rows. They fix the finite metric observations and the continuous-map requests that the later sequence and modulus rows may read.

Next use the uniformly continuous sequence schedule and the $\mathsf{DiniUniformMonotone}^{\uparrow}$ row. These rows bind monotone pointwise convergence to the displayed compact route before the terminal $\mathsf{UniformModulus}^{\uparrow}$ row is visible.

Finally inspect the real readback and structural rows. The $\mathsf{Real}^{\uparrow}$ row supplies only the tolerance read needed by the displayed route, while H, C, P, N preserve the same route under transport, replay, provenance, and local naming. The absent host supremum, selected subcover, quotient equality, choice, and ambient-completeness objects therefore cannot be recovered from the accepted packet. □

Falsifiable prediction: An accepted $\mathsf{DiniUniformModulus}^{\uparrow}$ consumer that reaches a $\mathsf{UniformModulus}^{\uparrow}$ output without displaying the compact source row K, continuous-map row F, sequence schedule S, monotone Dini row M, and real tolerance row R refutes the carrier surface.

Independence witness: dini-uniform-monotone, uniformly-continuous-sequence, uniformmodulus, continuousmap, compactmetric, real: no listed sibling supplies the whole ten-row packet $D = (K, F, S, M, U, R, H, C, P, N)$, because each sibling contributes only monotone convergence, sequence scheduling, modulus output, pointwise continuity, compact metric source, or real readback while this chapter binds the route through transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniUniformModulus}\uparrow}$.

Constructive story: A $\mathsf{DiniUniformModulus}^{\uparrow}$ packet is generated from a compact metric source row, ContinuousMap pointwise rows, a UniformlyContinuousSequence schedule, a DiniUniformMonotone route, a UniformModulus output, Real tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniUniformModulus}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7878.1, Definition 7878.2, and Definition 7878.3 seed the finite Dini route from compact metric source rows, continuous-map pointwise data, uniformly continuous sequence schedules, monotone Dini rows, uniform-modulus output, real tolerance readback, transport, replay, provenance, and naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniUniformModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite subcovers, countable choice, quotient real equality, host supremum arguments, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal closure requires Lean coverage for carrier admission, pointwise-continuity exposure, sequence-schedule exactness, monotone Dini handoff, uniform-modulus output, real-readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DiniUniformModulusUp.

Chapter 7879

A Concrete Naming Certificate for MetaCICResidualPairLattice$^{\uparrow}$

The MetaCICResidualPairLattice$^{\uparrow}$ packet realizes the confluence audit route of chapter 9378 as finite local-pair and candidate-join data. It sits beside the residual substitution comparison of chapter 7405, the residual substitution boundary of chapter 2181, the local join ledger of chapter 4126, and the parallel diamond residual route of chapter 5126. The packet keeps local diamond candidates finite and obstruction-visible; it is not global confluence, subject reduction, evaluator equality, quotient syntax equality, or MetaCIC kernel consistency.

Definition 7879.1 (MetaCIC residual-pair lattice carrier)**.** *A* MetaCICResidualPairLattice$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, J, B, O, T, R, V, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite residual-pair row, listing the local peak source, left residual target, right residual target, and inspected binder window.*
2. *J is the candidate-join row, recording the bounded common-target attempts for the displayed pair.*
3. *B is the bounded-checker row, recording the finite search budget and the local tests performed inside that budget.*
4. *O is the obstruction row, retaining substitution-compatibility, closed-diamond, subject-reduction, evaluator-equality, and kernel-consistency boundaries when a candidate join is not certified.*
5. *T is the transport row for local pairs, candidate joins, bounded checks, obstructions, replay, provenance, and local naming.*
6. *R is the replay row specifying how a confluence audit consumer may inspect Q, J, B, O, T before using a conditional parallel-diamond handoff.*
7. *V is the visible candidate lattice row, ordering accepted local pairs by inspected source shape, residual frontier, bounded checker outcome, and obstruction status.*
8. *H records componentwise* hsame *transport for every displayed row.*
9. *C records displayed* Cont *replay from a local diamond request through $Q, J, B, O, T, R, V, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$*, residual-substitution comparison rows, residual-substitution boundary rows, local-join ledger rows, parallel-diamond residual rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualPairLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for global confluence, subject reduction, evaluator equality, quotient syntax equality, unrestricted substitution compatibility, or kernel consistency. Future Lean `TasteGate.lean` *coverage for this packet must include both* `Nontrivial` *and* `FieldFaithful` *instances preserving $Q, J, B, O, T, R, V, H, C, P, N$ as separate fields.*

Theorem 7879.2 (MetaCIC residual-pair lattice obligations)**.** *For every accepted* $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$ *carrier*

$$L = (Q, J, B, O, T, R, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualPairLattice}^{\uparrow}}$ *surface consists exactly of local-pair admission through Q, candidate-join exposure through J, bounded-checker exposure through B, obstruction visibility through O, transport through T and H, replay through R and C, finite lattice ordering through V, provenance through P, and local naming through N. Every conditional confluence consumer must display the residual-pair row and the bounded-checker row before it cites a candidate local diamond.*

Proof. Project the carrier of Definition 7879.1. The row Q is the only source of local peak and residual-target data, while J names candidate joins for that displayed pair.

The row B records the finite budget under which the candidate is checked. If that budget does not certify the candidate, the obstruction row O remains visible instead of disappearing behind the confluence audit map.

The lattice row V orders the accepted local pairs by exactly these displayed fields. Transport and replay through T, H, R, C preserve the same rows, and P, N source and name them.

No endpoint theorem is hidden in the packet. Global confluence, subject reduction, evaluator equality, quotient syntax equality, unrestricted substitution compatibility, and kernel consistency are absent from the carrier, so the listed rows exhaust the obligation surface. □

Theorem 7879.3 (MetaCIC residual-pair lattice local-diamond budget)**.** *Every local-diamond read exported by an accepted* $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$ *packet is budgeted by the finite route*

$$Q, J, B, O, T, R, V, H, C, P, N.$$

The packet may certify a bounded local candidate join or expose the obstruction row for the same residual pair. It cannot be promoted to arbitrary closed-term confluence, subject reduction, evaluator equality, quotient syntax equality, unrestricted substitution compatibility, or MetaCIC kernel consistency.

Proof. Start with the residual-pair row Q. It fixes the local peak, the residual targets, and the inspected binder window before any candidate join is considered.

Next inspect the candidate and budget rows J and B. A certified local candidate join is public only if the bounded checker row records the displayed success for the same pair.

If the bounded checker does not certify the pair, the obstruction row O is retained. Replay and transport through T, R, V, H, C keep this success-or-obstruction distinction visible to the confluence audit consumer.

The provenance and naming rows P, N close only the finite packet. Since the excluded endpoint theorems have no row in the packet, the local-diamond read remains a bounded candidate handoff rather than a global confluence or consistency theorem. □

Falsifiable prediction: An accepted $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$ confluence-audit read is refuted if it reaches a local-diamond candidate without displaying the residual pair row, candidate-join row, bounded-checker row, obstruction row, transport, replay, provenance, and local naming rows.

Independence witness: metacic-residual-substitution-comparison, metacic-residual-substitution-boundary, metacic-local-join-ledger, parallel-diamond-residual: none is bijective to $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$ because this packet jointly carries residual local pairs, candidate joins, bounded checker outcomes, retained obstructions, finite lattice ordering, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualPairLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualPairLattice}^{\uparrow}$ packet is generated from finite residual-pair rows, candidate-join rows, bounded-checker rows, obstruction rows, a visible candidate lattice row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualPairLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7879.1, Definition 7879.2, and Definition 7879.3 seed the finite residual-pair lattice over local confluence candidates, bounded checks, retained obstructions, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualPairLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, subject reduction, evaluator equality, quotient syntax equality, unrestricted substitution compatibility, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, local-pair exposure, candidate-join exposure, bounded-checker exactness, obstruction retention, lattice ordering, transport, replay, provenance, local naming, and TasteGate nontriviality and field-faithfulness for BEDC.Derived.MetaCICResidualPairLatticeUp.

Chapter 7880

A Concrete Naming Certificate for $\mathsf{CayleyGraph}^{\uparrow}$

Following Cayley and standard algebraic graph theory, the $\mathsf{CayleyGraph}^{\uparrow}$ packet names the finite graph generated by a displayed group row and a finite generator list as BEDC NameCert data. It sits after the finite graph surface of chapter 118, the algebraic group surface of chapter 41, and the list spine of chapter 36. The packet records vertices, directed generator-labelled edges, finite walk replay, transport, provenance, and local naming; it does not import quotient graph equality, a selected group presentation, ambient connectedness, or an unbounded word problem oracle.

Definition 7880.1 (CayleyGraph carrier)**.** *A* $\mathsf{CayleyGraph}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Gamma = (G, S, V, E, L, W, H, C, P, N)$$

with the following displayed rows:

1. *G is the consumed* $\mathsf{NameCert}_{\mathsf{Group}^{\uparrow}}$ *row, retaining the multiplication, unit, inverse, and finite support rows visible to graph construction.*
2. *S is the finite generator-list row, read through the* $\mathsf{List}^{\uparrow}$ *spine and carrying the displayed generator entries and membership tags.*
3. *V is the vertex row, naming exactly the group elements admitted from G as graph vertices.*
4. *E is the edge-incidence row, recording triples $(g, s, g \cdot s)$ for visible g in V and visible s in S.*
5. *L is the generator-label ledger, attaching each edge in E to its unique displayed generator row from S.*
6. *W is the walk and replay row, storing finite generator words, their successive vertex rows, and the displayed endpoint replay.*
7. *H records componentwise* hsame *transport for the group, generator list, vertices, edges, labels, walks, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from any graph request through G, S, V, E, L, W, H.*
9. *P is the* Pkg *provenance over* $\mathsf{CayleyGraph}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CayleyGraph}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, S, V, E, L, W, H, C, P, N$. It has no coordinate for quotienting group elements, unlabelled host graph equality, selected presentations, Cayley-complex cells, ambient connectedness, or an unbounded word problem solver.

Theorem 7880.2 (CayleyGraph NameCert obligations)**.** *For every accepted* $\mathsf{CayleyGraph}^{\uparrow}$ *carrier*

$$\Gamma = (G, S, V, E, L, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CayleyGraph}^{\uparrow}}$ *surface consists exactly of group-row admission, finite generator-list admission, vertex exposure, edge-incidence exposure, generator-label exactness, finite walk replay, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every graph-facing consumer must expose G, S, V, E, L, W before the structural rows H, C, P, N can be consumed.*

Proof. Project the carrier of Definition 7880.1. The rows G, S, V, E, L, W are the only graph-building coordinates, and the structural rows H, C, P, N preserve and name those coordinates.

The group row G supplies the multiplication, unit, inverse, and visible element rows. The finite list row S supplies the only generator entries available to edge construction.

The graph rows are then forced: vertices come from V, edge incidences from E, generator labels from L, and finite walks from W. Since no other coordinate appears in the carrier, a consumer cannot obtain quotient graph equality, a hidden presentation, or ambient connectedness from the packet. □

Theorem 7880.3 (CayleyGraph edge-label exactness)**.** *Let $\Gamma = (G, S, V, E, L, W, H, C, P, N)$ be an accepted* $\mathsf{CayleyGraph}^{\uparrow}$ *carrier. Every public edge read factors through one visible vertex row from V, one visible generator row from S, one multiplication read from G, and the edge-incidence row E before the label ledger L is consumed. Thus an accepted edge cannot be relabelled by a generator outside S or detached from the group multiplication row that produced its endpoint.*

Proof. Start with the edge-incidence row E. By Definition 7880.1, each displayed edge is a triple $(g, s, g \cdot s)$ over the vertex row V, generator list S, and multiplication row of G.

Read the label ledger L only after this incidence row is visible. The ledger attaches the edge to the same generator row s, so it cannot substitute a generator outside the finite list.

Finally apply Definition 7880.2. Transport and replay preserve the displayed incidence and label rows componentwise, so an accepted public edge retains both its group multiplication endpoint and its generator label. □

Theorem 7880.4 (CayleyGraph graph-group route)**.** *Every accepted* $\mathsf{CayleyGraph}^{\uparrow}$ *graph consumer factors through the route*

$$\mathsf{Group}^{\uparrow}, \quad \mathsf{List}^{\uparrow}, \quad \mathsf{Graph}^{\uparrow}, \quad \mathsf{BHist}, \quad \mathsf{NameCert}.$$

The $\mathsf{Graph}^{\uparrow}$ *surface sees only vertices, labelled edge incidences, and finite walk replay generated from the consumed group row and finite generator list. It does not receive quotient group equality, an unlabelled host graph, an infinite presentation, a selected normal form, or an ambient connectedness theorem.*

Proof. Project G and S from the carrier. These rows provide the algebraic source and finite generator list before any graph row is read.

Next expose V, E, L, W. This is the graph-facing surface: vertices are admitted group elements, edges are multiplication incidences by listed generators, labels retain generator identity, and walks replay finite generator words.

The route ends with H, C, P, N. These rows transport, replay, source, and name the same finite packet. Because the carrier has no row for quotient group equality, unlabelled graph equality, infinite presentations, selected normal forms, or connectedness, no accepted graph consumer can read such data from Γ. □

Falsifiable prediction: Every accepted $\mathsf{CayleyGraph}^{\uparrow}$ edge read exposes a group row, a finite generator-list row, a vertex row, an edge-incidence row, a generator-label row, transport, replay, provenance, and local naming.

Independence witness: graph, group, list: $\mathsf{CayleyGraph}^{\uparrow}$ is not bijective to any one sibling because it jointly carries group multiplication, finite generator-list membership, labelled edge incidences, finite walk replay, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CayleyGraph}^{\uparrow}}$.

Constructive story: A $\mathsf{CayleyGraph}^{\uparrow}$ packet is generated from a consumed GroupUp row, a finite ListUp generator row, vertex rows, directed generator-labelled edge-incidence rows, finite walk replay rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CayleyGraph}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7880.1, Definition 7880.2, Definition 7880.3, and Definition 7880.4 seed the finite Cayley graph NameCert surface over group, generator-list, graph, walk, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CayleyGraph}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient graph equality, selected group presentations, normal forms, ambient connectedness, Cayley complexes, word-problem decidability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, generator-list admission, vertex exposure, edge-incidence exactness, label exactness, finite walk replay, transport, provenance, and local naming for BEDC.Derived.CayleyGraphUp.

Chapter 7881

A Concrete Naming Certificate for $\mathsf{AlexandrovSpace}^{\uparrow}$

Following Alexandrov and Burago–Burago–Ivanov, the $\mathsf{AlexandrovSpace}^{\uparrow}$ packet records curvature-bounded metric geometry as a finite BEDC comparison-triangle surface. It sits over the metric source of chapter 57, the path-length ledger of chapter 2082, the displayed segment witness of chapter 2213, the CAT(0) comparison surface of chapter 6336, and the terminal scalar readback of chapter 38. The packet names a local comparison-triangle carrier for curvature-bounded consumers; it does not assert global Toponogov comparison, selected geodesics, quotient path equality, smooth structure, local compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7881.1 (Alexandrov space carrier)**.** *An* $\mathsf{AlexandrovSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, L, G, Z, R, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the distance observations and endpoint identifiers inspected by the packet.*
2. *L is the* $\mathsf{LengthSpace}^{\uparrow}$ *row, recording the finite path-length ledger that makes comparison requests length-facing.*
3. *G is the* $\mathsf{GeodesicMetric}^{\uparrow}$ *segment row, displaying the inspected geodesic windows used by the comparison triangle.*
4. *Z is the* $\mathsf{CATZeroMetric}^{\uparrow}$ *or curvature-comparison row, carrying the signed comparison orientation and the finite triangle inequalities read by the packet.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-readback row for comparison distances, angle surrogates, and tolerance budgets; it is terminal and exports no real-completeness principle.*
6. *T records the displayed triangle vertex, side, and comparison-side incidence data visible before any Alexandrov consumer may read the curvature bound.*
7. *H records componentwise* hsame *transport for the metric, length, geodesic, comparison, scalar, triangle, continuation, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a local comparison request through the metric source, length ledger, geodesic segment rows, comparison ledger, scalar readback, and triangle incidence rows.*

9. *P is the* Pkg *provenance over* $\mathsf{AlexandrovSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LengthSpace}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexandrovSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, G, Z, R, T, H, C, P, N$. It has no coordinate for a host path space, a selected global geodesic, quotient equality of paths, smooth tangent cones, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7881.2 (Alexandrov space NameCert obligations)**.** *For every accepted* $\mathsf{AlexandrovSpace}^{\uparrow}$ *carrier $A = (M, L, G, Z, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexandrovSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, length-space ledger, geodesic segment windows, comparison ledger, scalar readback, displayed triangle incidence, componentwise transport, displayed continuation replay, provenance, and local naming. Every curvature-bounded read must pass through $M, L, G, Z, R, T, H, C, P, N$, and no obligation is stored outside those finite rows.*

Proof. Project the accepted carrier. The analytic route is precisely the metric source M, the path-length ledger L, the geodesic segment rows G, the comparison row Z, the scalar readback R, and the triangle-incidence row T.

The structural route is then forced. Transport through H and replay through C preserve the same displayed rows, while P and N only record provenance and local naming for the accepted packet.

Since the carrier has no row for a host path space, selected global geodesic, quotient path equality, smooth tangent cone, open-cover compactness, or ambient real completeness, the local NameCert cannot export any of those objects. □

Theorem 7881.3 (Alexandrov comparison-triangle scope)**.** *Every* $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{LengthSpace}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{AlexandrovSpace}^{\uparrow}$ *carrier receives a comparison-triangle route only through*

$$\mathsf{Met}^{\uparrow}, \quad \mathsf{LengthSpace}^{\uparrow}, \quad \mathsf{GeodesicMetric}^{\uparrow}, \quad \mathsf{CATZeroMetric}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

and the displayed rows $M, L, G, Z, R, T, H, C, P, N$. The handoff may expose finite curvature-bound comparison data, but it cannot be read as global confluence of geodesics, a selected-geodesic operator, quotient path equality, smooth manifold structure, local compactness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the metric and length rows. They make endpoint distances and path-length requests visible before any comparison triangle can be inspected.

Next use the geodesic and comparison rows. The segment windows in G and the comparison ledger in Z bind the curvature-bounded read to displayed triangle data T before scalar readback through R is available.

Finally inspect the structural rows. The rows H, C, P, N transport, replay, source, and name the same finite comparison route, so a downstream consumer cannot replace it by a host path object, selected geodesic, quotient equality, smooth structure, compactness theorem, or real-completeness principle. □

Falsifiable prediction: An accepted $\mathsf{AlexandrovSpace}^{\uparrow}$ consumer that exports comparison-triangle data without displaying the metric row M, length row L, geodesic row G, comparison row Z, scalar row R, and triangle-incidence row T refutes the carrier surface.

Independence witness: metric, length-space, geodesic-metric, cat-zero-metric, real: no listed sibling supplies the whole ten-row packet $A = (M, L, G, Z, R, T, H, C, P, N)$, because each sibling contributes only metric source data, path-length ledgers, segment windows, comparison inequalities, or scalar readback while this chapter binds them through triangle incidence, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexandrovSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{AlexandrovSpace}^{\uparrow}$ packet is generated from a Metric source row, a LengthSpace path-length row, a GeodesicMetric segment row, a CatZeroMetric comparison row, Real scalar readback, displayed comparison-triangle incidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexandrovSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7881.1, Definition 7881.2, and Definition 7881.3 seed the finite comparison-triangle route from metric, length, geodesic, comparison, scalar, triangle-incidence, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexandrovSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global Toponogov comparison, selected geodesics, quotient path equality, smooth tangent cones, local compactness, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formal closure requires Lean coverage for carrier admission, length-ledger exposure, geodesic-window exactness, comparison-triangle ledger scope, scalar-readback nonescape, triangle incidence, transport, replay, provenance, and local naming for BEDC.Derived.AlexandrovSpaceUp.

Chapter 7882

A Concrete Naming Certificate for CompletionDenseExtensionModulus$^{\uparrow}$

Following Bishop and Bridges constructive completion and Mac Lane universal mapping language, the CompletionDenseExtensionModulus$^{\uparrow}$ packet records the finite modulus data needed when a dense-source uniformly continuous map is read through an L10 completion route. It sits beside the dense-extension packet of chapter 6382, the universal-property surface of chapter 397, the metric dense-embedding route of chapter 3351, the finite StreamName$^{\uparrow}$ windows of chapter 126, the RegSeqRat$^{\uparrow}$ readback of chapter 301, the DyadicRatCore$^{\uparrow}$ tolerance ledger of chapter 291, and the terminal Real$^{\uparrow}$ seal of chapter 38. The packet names only displayed dense-source, modulus, window, readback, tolerance, transport, replay, provenance, and local NameCert rows; it does not import quotient completions, selected limits, function extensionality, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 7882.1 (CompletionDenseExtensionModulus carrier)**.** *A* CompletionDenseExtensionModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, U, B, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the dense source row, read through the* MetricCompletionDenseEmbedding$^{\uparrow}$ *surface before a completion-facing value is exposed.*
2. *U is the uniformly continuous modulus row for the source map on the displayed dense source.*
3. *B is the completion boundary row, aligned with* CompletionDenseExtension$^{\uparrow}$ *and* CompletionUniversalProperty$^{\uparrow}$.
4. *W is the* StreamName$^{\uparrow}$ *finite-window row scheduling dense-source observations, target observations, and precision requests.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the windows in W.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row carrying the finite comparison budget used by the modulus and readback routes.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after S, U, B, W, R, D have been displayed.*
8. *H is componentwise* hsame *transport for the source, modulus, boundary, window, readback, tolerance, seal, replay, provenance, and local naming rows.*

9. *C is displayed* Cont *replay from a dense-source precision request through modulus accounting, completion boundary exposure, finite-window readback, dyadic tolerance comparison, and terminal Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$, $\mathsf{CompletionDenseExtension}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseExtensionModulus}^{\uparrow}}$ *row.*

Accepted packets are compared only through these displayed rows and their replay paths.

Lean4 (statement) `BEDC.Derived.CompletionDenseExtensionModulusUp`

Theorem 7882.2 (CompletionDenseExtensionModulus NameCert obligations)**.** *For every accepted* $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$ *carrier* $M = (S, U, B, W, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompletionDenseExtensionModulus}^{\uparrow}}$ *surface consists exactly of dense source exposure, uniformly continuous modulus exposure, completion boundary exposure, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, Real sealing, componentwise transport, displayed replay, provenance, and local naming. Every dense-extension consumer must read* S, U, B, D *before it can consume the window, readback, and seal rows* W, R, E, H, C, P, N*.*

Proof. Project the carrier of Definition 7882.1. The rows S, U, B expose the dense source, uniformly continuous modulus, and completion boundary, while D records the finite dyadic tolerance budget attached to those reads.

The finite readback rows are downstream of that analytic surface. The $\mathsf{StreamName}^{\uparrow}$ row W schedules only the displayed dense-source and target observations, the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads those windows, and the $\mathsf{Real}^{\uparrow}$ seal E is exposed only after the dyadic tolerance budget has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row stores quotient completion equality, a selected limit, function extensionality, countable choice, or ambient Real completeness, the listed finite rows exhaust the local NameCert obligations. □

Theorem 7882.3 (CompletionDenseExtensionModulus route)**.** *Every* $\mathsf{CompletionDenseExtension}^{\uparrow}$ *or* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *consumer that reads a dense-extension modulus from an accepted* $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$ *packet factors through*

$\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{CompletionDenseExtension}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, Reg

The exported route is the displayed finite modulus and tolerance surface for dense-extension reads, not a quotient completion, a selected representative, a host function equality theorem, countable choice, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start from an accepted carrier $M = (S, U, B, W, R, D, E, H, C, P, N)$. By Definition 7882.2, the consumer first reads the dense source row S, the modulus row U, the completion boundary row B, and the dyadic tolerance row D.

The sibling route then fixes the public dependency surface. The dense source is interpreted through chapter 3351; the boundary and universal handoff are interpreted through chapter 6382 and chapter 397; and the finite observations pass through chapter 126, chapter 301, chapter 291, and chapter 38.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Since the carrier has no row for quotient completions, selected limits, function

extensionality, countable choice, host equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every accepted read remains inside the displayed finite modulus surface. □

Falsifiable prediction: Every accepted $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$ reader that claims a dense-extension modulus while omitting dense source exposure, uniformly continuous modulus data, completion boundary data, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, Real sealing, hsame transport, Cont replay, Pkg provenance, or local NameCert data refutes the packet.

Independence witness: completion-dense-extension, completionuniversalproperty, metric-completion-dense-embedding, streamname, regseqrat, dyadicratcore, real: $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dense source, modulus, completion boundary, finite windows, readback, tolerance, Real seal, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionDenseExtensionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompletionDenseExtensionModulus}^{\uparrow}$ packet is generated from a dense source row, uniformly continuous modulus row, completion boundary row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionDenseExtensionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7882.1, Definition 7882.2, and Definition 7882.3 seed the dense-extension modulus route for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionDenseExtensionModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, function extensionality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense source exposure, modulus exactness, completion boundary exposure, finite readback, dyadic tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionDenseExtensionModulusUp.

Chapter 7883

A Concrete Naming Certificate for $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$

Following Bourbaki and Rudin, the $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ packet records the standard analysis object of a real-valued continuous function whose nonzero region is controlled by a displayed compact row. It sits over the compact carrier of chapter 60, the continuous-map surface of chapter 130, the topology carrier of chapter 88, the metric-space source of chapter 4230, and the terminal real-value seal of chapter 38. The packet is finite NameCert data for compactly supported real observables; it is not an ambient function space, quotient equality of maps, a selected norm-attaining point, a measure theorem, or a bridge theorem.

Definition 7883.1 (Compact-support continuous-function carrier)**.** *A* $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, T, M, K, U, f, Z, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source carrier row, read through the displayed* $\mathsf{Topology}^{\uparrow}$ *surface.*
2. *T is the topology row controlling open-neighbourhood and closed-set reads on X.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row used by metric consumers of the same source carrier.*
4. *K is the compact support row, read through* $\mathsf{Compact}^{\uparrow}$ *and naming the finite compact witness that contains every public nonzero read of the function.*
5. *U is the support-membership ledger: it records that all value reads outside the displayed compact row are forced through the zero-value branch.*
6. *f is the* $\mathsf{ContinuousMap}^{\uparrow}(X, \mathsf{Real}^{\uparrow})$ *row for the real-valued continuous map.*
7. *Z is the zero-value and exterior-vanishing row, sealing the outside-support value as a* $\mathsf{Real}^{\uparrow}$ *zero read.*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for value, zero, and comparison endpoints read by f and Z.*
9. *H records componentwise* hsame *transport for source, topology, metric, compact support, support-membership, continuous-map, zero-value, scalar-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a compact-support continuous-function request through* $X, T, M, K, U, f, Z, S, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactSupportContinuousFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an ambient function space, quotient equality of maps, selected representatives, support closure taken in a host topology, integration, measure representation, or checked standard bridge.

Theorem 7883.2 (Compact-support continuous-function NameCert obligations)**.** *For every accepted* $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ *carrier*

$$F = (X, T, M, K, U, f, Z, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactSupportContinuousFunction}^{\uparrow}}$ *surface consists exactly of source-carrier admission, topology exposure, metric-source exposure, compact-support admission, support-membership ledger exposure, continuous real-valued map admission, zero-value and exterior-vanishing exposure,* $\mathsf{Real}^{\uparrow}$ *scalar sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and nonescape from ambient function-space or host-support objects.*

Proof. Project the carrier of Definition 7883.1. The rows X, T, M display the source, topology, and metric data that a consumer may inspect, while K displays the compact support row.

The rows U, f, Z, S provide the functional data. The continuous-map row f supplies the real-valued read, U records the support-membership ledger, Z records the exterior zero branch, and S keeps all scalar endpoints inside the $\mathsf{Real}^{\uparrow}$ surface.

The structural rows H, C, P, N transport, replay, source, and name exactly the displayed packet. Since the carrier has no coordinate for host support closure, quotient equality of maps, selected representatives, integration, measure representation, or a checked bridge, the listed rows exhaust the local NameCert obligations. □

Theorem 7883.3 (Compact-support continuous-function finite support exhaustion)**.** *Every public read of an accepted* $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Topology}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Compact}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompactSupportContinuousFunction}^{\uparrow}.$$

If the read asks for a nonzero value, it must expose the compact support row K and the support-membership ledger U before reading the continuous map row f. If the read lies outside the displayed support ledger, it receives only the $\mathsf{Real}^{\uparrow}$ *zero branch Z. No public consumer receives an infinite support set, host support closure, quotient function equality, selected norm-attaining point, measure representation, or ambient completeness theorem from the packet.*

Proof. Start with the source and scalar boundaries. The topology, metric, compact, continuous-map, and real-value rows are all explicit coordinates of the carrier, so a public read cannot bypass X, T, M, K, f, S.

For a nonzero read, the support-membership ledger U must be displayed before the value row is consumed. This forces the read through the compact row K and keeps the support evidence finite.

For an exterior read, the only available value coordinate is Z, the displayed zero branch sealed by S. The transport, replay, provenance, and naming rows H, C, P, N preserve the same finite packet and introduce no additional support object.

Thus the public surface is exhausted by $X, T, M, K, U, f, Z, S, H, C, P, N$. The excluded host-side objects have no carrier coordinate and cannot be exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ packet displays topology, metric, compact-support, support-membership, continuous-map, zero-value, RealUp scalar-seal, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows before any compactly supported observable consumer reads it.

Independence witness: compact, continuousmap, topology, metricspace, and real: no listed sibling is bijective to $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ because this packet jointly carries compact support, exterior-vanishing, continuous real-valued map, scalar seal, transport, replay, provenance, and local naming as one finite compactly supported function surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactSupportContinuousFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactSupportContinuousFunction}^{\uparrow}$ packet is generated from displayed topology and metric source rows, a compact support row, a support-membership ledger, a continuous real-valued map row, an exterior zero-value row, a $\mathsf{Real}^{\uparrow}$ scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactSupportContinuousFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7883.1, Definition 7883.2, and Definition 7883.3 seed the compactly supported continuous-function surface over compact, continuous-map, topology, metric-space, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactSupportContinuousFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient function spaces, quotient equality of maps, selected representatives, host support closure, integration, measure representation, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, topology exposure, metric-source exposure, compact-support admission, support-membership exactness, continuous-map admission, exterior zero-branch exactness, RealUp sealing, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.CompactSupportContinuousFunctionUp.

Chapter 7884

A Concrete Naming Certificate for $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$ packet records a finite ladder of dyadic interval refinements before any Real or Completion consumer reads a limit-facing seal. It sits after the endpoint core of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the compact interval boundary of chapter 5553. The packet is a displayed finite refinement surface, not an infinite branch selector, quotient stream equality, compactness proof, choice principle, or ambient real-completeness assertion.

Definition 7884.1 (Dyadic interval refinement ladder carrier)**.** *A* $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, J, d, E, S, R, A, H, C, P, N)$$

with the following displayed rows:

1. *I is the parent interval row. Its lower and upper endpoints are exposed through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and are the only outer endpoints available to the ladder.*
2. *J is the child interval row retained at the last displayed rung. Its endpoints are dyadic rows produced from the parent by the finite refinement trace.*
3. *d is the dyadic mesh depth. It records the finite number of bisection or refinement steps whose mesh scale bounds J inside I.*
4. *E is the endpoint-containment ledger. It records that the child endpoints lie inside the parent endpoints and that every intermediate endpoint is a displayed dyadic mesh point.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the parent endpoints, child endpoints, mesh depth, endpoint-containment checks, and retained-rung flag.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It repacks exactly the scheduled dyadic observations from S as regular rational data for completion-facing consumers.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal. It is terminal after the dyadic endpoint rows, mesh-depth row, endpoint-containment ledger, StreamName windows, and RegSeqRat readback.*
8. *H records componentwise* hsame *transport for the parent interval, child interval, mesh depth, endpoint-containment ledger, StreamName windows, RegSeqRat readback, Real seal, replay rows, provenance, and local naming row.*

9. *C records displayed* Cont *replay from a refinement-ladder request through $I, J, d, E, S, R, A, H, P, N$ without adding a selected infinite branch or quotient stream.*
10. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven displayed rows. The carrier has no coordinate for a selected infinite refinement path, quotient stream equality, open-cover compactness, trichotomy, countable choice, host interval equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

```
Lean4 ✓  BEDC.Derived.DyadicIntervalRefinementLadderUp.DyadicIntervalRefinementLadderTasteGate
single carrier alignment
```

Theorem 7884.2 (Dyadic interval refinement ladder NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$ *carrier*

$$L = (I, J, d, E, S, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}}$ *surface consists exactly of carrier admission, parent interval exposure, child interval exposure, finite dyadic mesh-depth exposure, endpoint-containment exactness, finite StreamName window exposure, RegSeqRat readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local naming row. No local NameCert obligation is stored outside those rows.*

Proof. Project the carrier of Definition 7884.1. The projection exposes one parent interval row, one retained child interval row, one mesh-depth row, one endpoint-containment ledger, one StreamName window, one regular rational readback, one Real seal, and the structural rows.

The parent and child exposure obligations are forced by I and J. The mesh-depth obligation is forced by d, while endpoint containment and intermediate dyadic mesh membership are forced by E.

The readback route is forced by S, R, A. The StreamName row fixes the finite observations opened by the ladder, the RegSeqRat row repacks only those observations, and the Real seal is terminal after that readback.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Since the carrier has no extra coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7884.3 (Dyadic interval refinement ladder Real-seal nonescape)**.** *Let $L = (I, J, d, E, S, R, A, H, C, P, N)$ be an accepted* $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$ *carrier. Every* $\mathsf{CompactRealInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of the ladder must first read the finite route*

$$I, J, d, E \longmapsto S \longmapsto R \longmapsto A \longmapsto H, C, P, N.$$

Thus the consumer receives a parent interval, a retained child interval, a displayed mesh depth, endpoint containment, finite StreamName windows, regular rational readback, and a terminal Real seal, but receives no selected infinite branch, quotient stream equality, open-cover compactness proof, countable-choice schedule, host interval equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with the interval and mesh rows. The only parent interval is I, the only retained child interval is J, and the only mesh-scale record is d.

Use E to read endpoint containment and intermediate dyadic mesh membership. This keeps the child interval inside the parent through displayed dyadic endpoint rows before any stream or real-facing consumer can inspect the ladder.

Now read S, R, A. The StreamName window fixes the finite observations, the RegSeqRat row repacks those observations as regular rational data, and the Real seal is terminal after the readback row.

The structural rows H, C, P, N only transport, replay, source, and name this route. They do not add a branch selector, quotient stream, compactness proof, choice schedule, host interval equality, or ambient completeness row, so none of those objects can escape through the Real seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinementLadder}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinementLadder}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7884.1, Definition 7884.2, and Definition 7884.3 seed the finite dyadic refinement ladder route from parent and child intervals through mesh depth, endpoint containment, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalRefinementLadder}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, quotient stream equality, open-cover compactness, trichotomy, countable choice, host interval equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh-depth exposure, endpoint-containment exactness, finite window exposure, RegSeqRat readback, Real-seal nonescape, provenance exhaustion, and local naming for BEDC.Derived.DyadicIntervalRefinementLadderUp.

Constructive story: A $\mathsf{DyadicIntervalRefinementLadder}^{\uparrow}$ packet is generated from a parent interval row, a retained child interval row, a dyadic mesh-depth row, endpoint containment, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7885

A Concrete Naming Certificate for $\mathsf{DifferenceQuotient}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DifferenceQuotient}^{\uparrow}$ packet records the finite secant-window surface by which a displayed real-valued map is inspected before a derivative-facing consumer reads any local-linear approximation. It sits over the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the finite observation schedule of chapter 126, and the calculus carrier of chapter 3632. The packet names a finite secant slope window; it does not assert differentiability, a selected derivative, quotient equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Falsifiable prediction: Every accepted $\mathsf{DifferenceQuotient}^{\uparrow}$ packet must expose two nearby $\mathsf{Real}^{\uparrow}$ endpoint rows, a secant numerator row, a nonzero denominator row, and a dyadic tolerance ledger before any secant slope read is public.

Independence witness: real, regseqrat, dyadicratcore, streamname, calculus: the difference-quotient carrier is not bijective to any sibling because it binds endpoint Real rows, secant numerator and denominator data, dyadic tolerance, regular rational readback, Real sealing, transport, replay, provenance, and local naming as one finite secant-window packet.

Definition 7885.1 (Difference quotient carrier)**.** *A* $\mathsf{DifferenceQuotient}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, Y, A, B, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Real}^{\uparrow}$ *row for the base point of the secant window;*
2. *Y is the target* $\mathsf{Real}^{\uparrow}$ *row for the displayed function value read at the base point;*
3. *A is the nearby source* $\mathsf{Real}^{\uparrow}$ *endpoint row, displayed through a finite observation window;*
4. *B is the nearby target* $\mathsf{Real}^{\uparrow}$ *endpoint row, displaying the matching function value;*
5. *S is the secant numerator row, naming the finite difference between B and Y through regular rational readback;*
6. *D is the nonzero denominator row, naming the finite difference between A and X together with the visible nonzero-step boundary;*
7. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested endpoint and quotient comparisons;*

8. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the numerator, denominator, and quotient window inspected at the requested precision;*
9. *H records componentwise* hsame *transport for the endpoint, numerator, denominator, tolerance, readback, seal, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay from endpoint observations to numerator and denominator rows, from those rows to regular readback, and from readback to the Real-facing seal;*
11. *P is the* Pkg *provenance over* BHist, hsame, Cont, Pkg, NameCert, *and the real, regular, dyadic, stream, and calculus sibling chapters listed above;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DifferenceQuotient}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through $X, Y, A, B, S, D, R, E, H, C, P, N$. It has no coordinate for a host function-space quotient, an infinitesimal step, a completed derivative value, or a global differentiability claim.

Lean4 ✓ `BEDC.Derived.DifferenceQuotientUp.DifferenceQuotientTasteGate single carrier alignment`

Theorem 7885.2 (DifferenceQuotient NameCert obligations)**.** *For the carrier of Definition 7885.1, the local* $\mathsf{NameCert}_{\mathsf{DifferenceQuotient}^{\uparrow}}$ *surface consists exactly of carrier admission for $Q = (X, Y, A, B, S, D, R, E, H, C$ source and target endpoint exposure, secant numerator exposure, nonzero denominator exposure, dyadic tolerance accounting, regular rational readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every accepted secant-slope read must pass through the route*

$$(X, Y, A, B) \longmapsto (S, D) \longmapsto (R, E) \longmapsto C$$

with H, P, N attached as transport, provenance, and naming rows.

Proof. Carrier admission is projection from Definition 7885.1. The displayed tuple gives exactly the base source row, base target row, nearby endpoint rows, numerator row, denominator row, dyadic tolerance ledger, regular rational readback, transport, replay, provenance, and local naming coordinate.

The analytic source is the constructive secant-window reading of Bishop–Bridges analysis. The rows X, Y, A, B expose only two finite endpoint observations; S and D package the visible numerator and denominator; R and E control the requested tolerance and rational readback before any Real-facing seal is consumed.

The sibling chapters supply the boundary discipline. The Real chapter supplies the terminal seal, the RegSeqRat chapter supplies rational readback, the DyadicRatCore chapter supplies tolerance accounting, the StreamName chapter supplies the finite observation schedule, and the Calculus chapter records how derivative-facing consumers may later read finite difference-quotient rows without importing a host derivative operator.

Since no row of Q is a completed derivative, a quotient equality of functions, an infinitesimal, or an ambient completeness principle, the NameCert obligations are exhausted by the displayed secant-window route. □

Theorem 7885.3 (DifferenceQuotient finite-window scope)**.** *For every accepted* $\mathsf{DifferenceQuotient}^{\uparrow}$ *carrier $Q = (X, Y, A, B, S, D, R, E, H, C, P, N)$, a consumer may read only the finite secant-window rows displayed in Definition 7885.1. In particular, the packet supplies a finite route from two endpoint observations to a tolerance-controlled secant quotient, but it does not supply a differentiability witness, a limit over all steps, a quotient of functions, or a completed* $\mathsf{Real}^{\uparrow}$ *derivative.*

Proof. Read Definition 7885.2. It identifies the public surface with endpoint exposure, numerator and denominator exposure, dyadic tolerance accounting, regular rational readback, Real sealing, transport, replay, provenance, and naming.

Every allowed read must therefore pass through the finite route from (X, Y, A, B) to (S, D) and then through R, E, C, H, P, N. The carrier contains no additional row that ranges over all nonzero steps, selects a limiting value, or compares host functions extensionally.

Thus the packet is exactly a secant-window interface. It can be consumed by later $\mathsf{Calculus}^{\uparrow}$ derivative rows as finite difference-quotient data, while the differentiability, limit, and completeness claims remain outside this chapter. □

Closure status for $\mathsf{NameCert}_{\mathsf{DifferenceQuotient}^{\uparrow}}$.

Constructive story: A $\mathsf{DifferenceQuotient}^{\uparrow}$ packet is generated from source and target $\mathsf{Real}^{\uparrow}$ endpoint rows, a secant numerator row, a nonzero denominator row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DifferenceQuotient}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7885.1, Definition 7885.2, and Definition 7885.3 define the finite secant-window carrier and its local NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DifferenceQuotient}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close differentiability, a derivative limit, quotient equality of functions, Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires binding the endpoint, numerator, denominator, tolerance, readback, seal, transport, replay, provenance, and local naming rows to a formal DifferenceQuotient carrier.

Chapter 7886

A Concrete Naming Certificate for $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley-style completion, the $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ packet records the unit row of the Cauchy-completion adjunction as finite BEDC certificate data. It sits after the metric completion carrier of chapter 1506, the dense embedding surface of chapter 3617, the $\mathsf{StreamName}^{\uparrow}$ finite-window route of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names only a source metric, unit map, dense row, finite stream windows, regular rational readback, transport, replay, provenance, and local NameCert row; it does not import quotient completion equality, selected limits, countable choice, or ambient real completeness.

Definition 7886.1 (CauchyCompletionAdjointUnit carrier)**.** *A* $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, J, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source metric row, read through the same metric source used by* $\mathsf{MetricCompletion}^{\uparrow}$ *and its dense-completion consumers.*
2. *J is the unit map row, sending displayed source points into the completion-facing readout without selecting completed representatives.*
3. *D is the dense row, recording that every accepted completion-side finite observation is reached through the displayed source image before a terminal seal is exposed.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for source observations, completion observations, and requested tolerances.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the windows in S.*
6. *H records componentwise* hsame *transport for the source metric, unit map, dense row, window row, readback row, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from source metric reads through the unit map, dense exposure, StreamName windows, RegSeqRat readback, and the terminal* $\mathsf{Real}^{\uparrow}$*-facing seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{DenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}}$ *row.*

Accepted packets are compared only through $X, J, D, S, R, H, C, P, N$ and their displayed replay paths.

Theorem 7886.2 (CauchyCompletionAdjointUnit NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ *carrier $U = (X, J, D, S, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}}$ *surface consists exactly of source metric exposure, unit-map exposure, dense-row exposure, StreamName finite windows, RegSeqRat readback, componentwise transport, displayed replay, provenance, and local naming. Every unit consumer must read X, J, D before it can consume the finite windows, readback, transport, replay, provenance, and naming rows.*

Proof. Project the carrier of Definition 7886.1. The rows X, J, D expose the source metric, the unit map, and the dense row that makes completion-side observations source-facing.

The finite readback surface is downstream of those rows. The $\mathsf{StreamName}^{\uparrow}$ row S schedules only displayed source and completion observations, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R reads those windows before any $\mathsf{Real}^{\uparrow}$-facing seal is consumed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row stores quotient equality, a selected completed representative, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7886.3 (CauchyCompletionAdjointUnit handoff)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or completion-adjoint consumer that reads the unit of a source metric from an accepted* $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ *packet factors through*

$$\mathsf{DenseEmbedding}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The exported handoff is the displayed finite unit-row surface for source-to-completion reads, not a quotient completion, selected representative, host equality theorem, countable-choice schedule, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$*.*

Proof. Start from an accepted carrier $U = (X, J, D, S, R, H, C, P, N)$. By Definition 7886.2, the consumer first reads the source metric row X, unit map row J, and dense row D.

The sibling route then fixes the public dependency surface. The unit read is interpreted through chapter 1506 and chapter 3617; the finite observations pass through chapter 126; the regular rational readback is supplied by chapter 301; and the terminal real-facing boundary is sealed only through chapter 38.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Since the carrier has no row for quotient completions, selected limits, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, every accepted read remains inside the displayed finite unit-row surface. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ reader that claims a completion unit while omitting the source metric, unit map, dense row, StreamName windows, RegSeqRat readback, hsame transport, Cont replay, Pkg provenance, or local NameCert data refutes the packet.

Independence witness: metriccompletion, dense-embedding, streamname, regseqrat, and real: $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source metric, unit map, dense row, finite windows, regular rational readback, transport, replay, provenance, and local NameCert rows in one unit packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}$ packet is generated from a source metric row, unit map row, dense row, StreamName finite windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7886.1, Definition 7886.2, and Definition 7886.3 seed the finite completion-unit route over MetricCompletionUp, DenseEmbeddingUp, StreamNameUp, RegSeqRatUp, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionAdjointUnit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source metric exposure, unit-map exactness, dense-row exactness, finite readback, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionAdjointUnitUp.

Chapter 7887

A Concrete Naming Certificate for HyperbolicOperatorCayley$^{\uparrow}$

The HyperbolicOperatorCayley$^{\uparrow}$ packet realizes the hyperbolic phase/operator bridge as a finite Cayley disk-transport certificate. It sits beside the hyperbolic metric route of chapter 3474, the Poincare disk metric packet of chapter 6209, the reversible transport surface of chapter 219, the bounded operator-boundary discipline of chapter 213, and the spectral boundary warning of chapter 214. The packet names finite disk transport and operator-boundary rows; it is not a global spectral theorem, not an unbounded functional calculus, not a host Hilbert-space construction, and not a completed analytic model of the observer.

Definition 7887.1 (HyperbolicOperatorCayley carrier)**.** *A* HyperbolicOperatorCayley$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, M, O, Y, B, T, F, H, C, P, N)$$

with the following displayed rows:

1. *D is the disk-coordinate row, read through* PoincareDiskMetric$^{\uparrow}$ *before any operator boundary is exposed.*
2. *M is the* HyperbolicMetric$^{\uparrow}$ *metric row on the displayed disk observations.*
3. *O is the operator-window row, recording the finite operator input accepted by the packet.*
4. *Y is the Cayley-transform row, recording the displayed disk transport induced by the operator window without invoking a global spectrum.*
5. *B is the operator-boundary row, aligned with* OperatorIdeal$^{\uparrow}$ *and recording boundedness, compactness, or ideal-facing refusal data as finite rows.*
6. *T is the reversible phase-transport row, consumed through* UnitaryGroup$^{\uparrow}$*-style classifier preservation when such a reversible read is present.*
7. *F is the local refusal row excluding global spectral measures, host functional calculus, unbounded operator domains, and observer-substance readings.*
8. *H records componentwise* hsame *transport for disk, metric, operator, Cayley, boundary, reversible transport, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through disk readout, metric comparison, operator-window admission, Cayley disk transport, operator-boundary exposure, reversible transport, refusal, and local naming.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, $\mathsf{SpectralTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorCayley}^{\uparrow}}$ *row.*

The Lean-side follow-up for this carrier must provide `Nontrivial HyperbolicOperatorCayleyUp` *and* `FieldFaithful HyperbolicOperatorCayleyUp` *TasteGate instances for the same displayed packet.*

Theorem 7887.2 (HyperbolicOperatorCayley NameCert obligations)**.** *For every accepted* HyperbolicOperatorCayle *carrier $K = (D, M, O, Y, B, T, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorCayley}^{\uparrow}}$ *surface consists exactly of disk-coordinate exposure, hyperbolic metric readback, finite operator-window admission, Cayley disk-transport exposure, operator-boundary exposure, reversible phase-transport exposure, global spectral refusal, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7887.1. The rows D, M, O, Y, B, T, F expose the disk, metric, operator window, Cayley transport, operator boundary, reversible phase route, and refusal surface.

The Cayley row Y is local to the displayed disk and operator window. It may move disk observations through a finite transport row, but it does not supply a global spectral decomposition, a spectral measure, an unbounded functional calculus, or a host Hilbert-space theorem.

Finally H, C, P, N transport, replay, source, and name the same packet. Since every excluded analytic object is named only by the refusal row F and has no carrier coordinate, the listed finite rows exhaust the local NameCert obligations. □

Theorem 7887.3 (HyperbolicOperatorCayley vision handoff)**.** *Every hyperbolic phase/operator read exported by an accepted* $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$ *packet factors through*

$$\mathsf{PoincareDiskMetric}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{UnitaryGroup}^{\uparrow},\ \mathsf{OperatorIdeal}^{\uparrow}.$$

The handoff is the finite Cayley disk-transport and operator-boundary row. It cannot be strengthened into a global spectral theorem, host functional calculus, spectral-measure classifier, unbounded-domain theorem, or observer-substance model.

Proof. Start from an accepted carrier $K = (D, M, O, Y, B, T, F, H, C, P, N)$. The disk rows D, M identify the Poincare-disk and hyperbolic metric surface before any operator row is consumed.

The operator rows O, Y, B, T then expose only a finite window. The Cayley row Y records the disk transport, the boundary row B records the operator-side refusal and boundedness surface, and the reversible row T is consumed only through classifier-preserving transport.

Use the refusal row F together with transport and replay. The structural rows H, C, P, N keep the same displayed dependency route, while F blocks global spectral measures, unbounded functional calculus, host Hilbert-space carriers, and observer-substance readings. Thus the vision handoff is finite NameCert data and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$ packet exposes a finite Cayley disk-transport row and an operator-boundary row, and no accepted packet exports a global spectral theorem, spectral measure, unbounded functional calculus, host Hilbert-space construction, or observer-substance model.

Independence witness: hyperbolic-metric, poincare-disk-metric, unitarygroup, operatorideal, and spectraltheorem: none is bijective to $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$ because this packet jointly

carries disk coordinates, hyperbolic metric readback, an operator window, Cayley disk transport, operator-boundary rows, reversible transport, refusal, hsame transport, Cont replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorCayley}\uparrow}$.

Constructive story: A $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$ packet is generated from a disk-coordinate row, HyperbolicMetric row, finite operator-window row, Cayley disk-transport row, operator-boundary row, reversible phase-transport row, global spectral refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicOperatorCayley}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7887.1, Definition 7887.2, and Definition 7887.3 seed the finite Cayley operator route over PoincareDiskMetricUp, HyperbolicMetricUp, UnitaryGroupUp, OperatorIdealUp, and SpectralTheoremUp refusal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicOperatorCayley}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global spectral theorems, spectral measures, unbounded functional calculus, host Hilbert-space models, observer-substance readings, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Cayley disk-transport exactness, operator-boundary exactness, reversible transport, spectral refusal, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicOperatorCayleyUp.

Chapter 7888

A Concrete Naming Certificate for $\mathsf{CauchyModulusRegularization}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyModulusRegularization}^{\uparrow}$ packet records the finite route by which an ordinary modulus-controlled Cauchy window is read as a regular sequence interface. It sits between the Cauchy modulus surface of chapter 292, the finite observations of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet exposes only displayed modulus, window, tolerance, readback, seal, transport, replay, provenance, and local NameCert rows; it does not choose a limit, identify quotient streams, invoke countable choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7888.1 (CauchyModulusRegularization carrier)**.** *A* $\mathsf{CauchyModulusRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row recording the ordinary Cauchy threshold request and its cofinal-window response.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened from the named stream after the threshold in M has been displayed.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the requested precision with the window rows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the threshold, window, and dyadic tolerance data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, W, D, R have been exposed.*
6. *H is componentwise* hsame *transport for the modulus, window, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C is displayed* Cont *replay from a Cauchy precision request through the modulus threshold, finite-window inspection, dyadic tolerance comparison, regular rational readback, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusRegularization}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{CauchyModulusRegularization}^{\uparrow}}$ *row.*

Accepted packets are compared only through these displayed rows and the replay paths they name.

Theorem 7888.2 (CauchyModulusRegularization NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusRegularization}^{\uparrow}$ *carrier* $Q = (M, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusRegularization}^{\uparrow}}$ *surface consists exactly of CauchyModulus threshold exposure, StreamName finite-window exposure, DyadicRatCore tolerance accounting, RegSeqRat readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming. A completion-facing consumer must read* M, W, D *before it can consume* R, E, H, C, P, N*.*

Proof. Project the carrier of Definition 7888.1. The rows M, W, D expose the Cauchy threshold, finite observation window, and dyadic tolerance ledger before any regular readback is available.

The readback and seal rows are downstream of that finite route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is assembled only from the displayed threshold, window, and tolerance data, and the $\mathsf{Real}^{\uparrow}$ seal E is exposed only after R has been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row stores a selected limit, quotient stream equality, countable-choice schedule, host real equality, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 7888.3 (CauchyModulusRegularization RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyModulusRegularization}^{\uparrow}$ *carrier* $Q = (M, W, D, R, E, H, C, P, N)$ *must first read the finite route*

$$M, W, D, R, H, C, P, N.$$

Thus the regular rational sequence interface is exported only through the displayed Cauchy modulus row, finite StreamName windows, dyadic tolerance ledger, regular readback, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert*.*

The handoff exports no quotient stream, selected subsequence, countable-choice schedule, trichotomy branch, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Begin with the obligation surface of Definition 7888.2. It places every accepted readback behind the displayed threshold, window, and dyadic tolerance rows.

Now read the sibling route through chapter 292, chapter 126, chapter 291, and chapter 301. These chapters supply the named rows M, W, D, R but do not add a hidden quotient stream or selected representative to the packet.

The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming. Therefore every RegSeqRat-facing consumer receives only the displayed handoff. □

Theorem 7888.4 (CauchyModulusRegularization Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{CauchyModulusRegularization}^{\uparrow}$ *carrier* $Q = (M, W, D, R, E, H, C, P, N)$ *factors through the regularization route*

$$\mathsf{CauchyModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The seal row E is visible only after the threshold, finite-window, tolerance, and regular readback rows M, W, D, R have been displayed.

The boundary exports no Real completeness theorem, quotient stream equality, selected limit, countable-choice schedule, open-cover compactness row, or host equality of completed real values.

Proof. Apply the RegSeqRat handoff of Definition 7888.3. It exposes R only through M, W, D and the structural rows of the same packet.

The terminal seal is then read through chapter 38. Since the carrier contains no additional coordinate between R and E, the Real-facing read cannot bypass the displayed regularization route.

The refused endpoints are absent from the carrier inventory and from the sibling route just named. Hence the seal boundary is exactly the finite route stated above. □

Theorem 7888.5 (CauchyModulusRegularization completion consumer)**.** *Every completion-facing consumer that uses an accepted* $\mathsf{CauchyModulusRegularization}^{\uparrow}$ *packet must read the route* $M, W, D, R, E, H, C, P, N$ *through* $\mathsf{CauchyModulus}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *before any completion seal is visible. The route is a finite regularization handoff from ordinary modulus-controlled Cauchy windows to regular rational sequence data, not a proof of quotient completion equality, selected limits, countable choice, or ambient completeness.*

Proof. Use the NameCert obligations of Definition 7888.2. They force every accepted packet to expose the threshold, window, tolerance, readback, seal, transport, replay, provenance, and local naming rows as one finite surface.

Next combine the RegSeqRat handoff and Real seal boundary, Definition 7888.3 and Definition 7888.4. Together they place the completion-facing read behind $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Since the packet has no row for quotient completion equality, selected limits, countable choice, or ambient completeness, a completion consumer can only receive the displayed regularization handoff. □

Falsifiable prediction: Every accepted $\mathsf{CauchyModulusRegularization}^{\uparrow}$ reader that claims a completion-facing regular sequence while omitting CauchyModulus threshold exposure, StreamName windows, DyadicRatCore tolerance accounting, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, or local NameCert data refutes the packet.

Independence witness: cauchymodulus, streamname, dyadicratcore, regseqrat, real: CauchyModulusRegularizati is not bijective to any listed sibling because it jointly carries threshold, window, tolerance, readback, seal, transport, replay, provenance, and local NameCert rows in one completion-facing handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusRegularization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusRegularization}^{\uparrow}$ packet is generated from a CauchyModulus threshold row, StreamName finite windows, DyadicRatCore tolerance accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyModulusRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7888.1, Definition 7888.2, Definition 7888.3, Definition 7888.4, and Definition 7888.5 seed the finite regularization handoff from ordinary Cauchy modulus windows to RegSeqRat and Real completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyModulusRegularization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, threshold exposure, finite-window exactness, dyadic tolerance accounting, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusRegularizationUp.

Chapter 7889

Compact Open Lipschitz Modulus NameCert Construction

Following Kelley and the Arzela–Ascoli compact-open tradition, the $\mathsf{CompactOpenLipschitzModulus}^{\uparrow}$ packet records the finite BEDC surface for reading Lipschitz control through compact-open tests. It sits between the compact-open topology carrier of chapter 4138, the extension boundary of chapter 3650, the continuous-map row of chapter 130, and the metric-space carrier of chapter 57. The packet names compact tests, displayed Lipschitz bounds, and a replayable modulus ledger without assuming open-cover compactness or a host function space.

Definition 7889.1 (Compact-open Lipschitz modulus carrier)**.** *A* $\mathsf{CompactOpenLipschitzModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, B, M, T, R, P, N)$$

with the following displayed rows:

1. *K is the compact-test row, listing the compact-open test neighborhoods read from* $\mathsf{CompactOpenTopology}^{\uparrow}$ *and the source* $\mathsf{Met}^{\uparrow}$ *rows on which they are evaluated.*
2. *B is the Lipschitz-bound row, recording the displayed constants and metric-distance comparisons used by the* $\mathsf{LipschitzExtension}^{\uparrow}$ *boundary.*
3. *M is the modulus row, assigning to each admitted compact test a finite tolerance request and its displayed response.*
4. *T is the transport row, preserving K, B, M under componentwise* hsame *for the compact tests, metric observations, continuous-map graph rows, and Lipschitz-bound rows.*
5. *R is the replay row, recording displayed* Cont *reads from compact-open requests through the bound and modulus rows.*
6. *P is the provenance row over* $\mathsf{CompactOpenLipschitzModulus}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenLipschitzModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through K, B, M, T, R, P, N. It has no coordinate for open-cover compactness, quotient equality of maps, an ambient compact-open function space, selected global moduli, or completeness of a host target space.

Theorem 7889.2 (Compact-open Lipschitz modulus obligations)**.** *For the carrier of Definition 7889.1, the local* $\mathsf{NameCert}_{\mathsf{CompactOpenLipschitzModulus}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for compact tests, Lipschitz bounds, modulus data, transport, replay, provenance, and local naming;*
2. *compact-test exposure, requiring every compact-open read to pass through* K *and the cited* $\mathsf{CompactOpenTopology}^{\uparrow}$ *source rows;*
3. *Lipschitz-bound exposure, requiring every extension-facing read to expose* B *before a modulus value in* M *can be consumed;*
4. *modulus replay stability, requiring* T *and* R *to preserve the same compact-test and bound rows under componentwise transport and displayed continuation;*
5. *provenance and local naming, requiring* P *and* N *to record the packet as the sole NameCert source for the compact-open Lipschitz modulus.*

No obligation is stored outside K, B, M, T, R, P, N*.*

Proof. Project the carrier of Definition 7889.1. The displayed data are exactly the compact tests, Lipschitz-bound rows, modulus rows, transport rows, replay rows, provenance, and local naming.

The compact-open side reads only through K. The Lipschitz side reads only through B, and the modulus row M is consumed after those two rows have been displayed.

Finally T, R, P, N preserve, replay, source, and name the same finite route. Since the carrier has no coordinate for open-cover compactness, quotient map equality, host function spaces, selected global moduli, or target completeness, the listed rows exhaust the local NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOpenLipschitzModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CompactOpenLipschitzModulus}^{\uparrow}$ packet is generated from compact-open test rows, displayed Lipschitz-bound rows, a finite modulus ledger, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactOpenLipschitzModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7889.1 and Definition 7889.2 seed the finite compact-open Lipschitz modulus carrier and its five-row obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactOpenLipschitzModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host compact-open function spaces, quotient function equality, selected global moduli, target completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-test exposure, Lipschitz-bound exposure, modulus replay stability, provenance, and local naming for BEDC.Derived.CompactOpenLipschitzModulusUp.

Chapter 7890

A Concrete Naming Certificate for $\mathsf{ErdosSpace}^{\uparrow}$

Following Erdős and Engelking's classical zero-dimensional topology, the $\mathsf{ErdosSpace}^{\uparrow}$ packet records the rational-coordinate model as finite BEDC schedule rows before any topology consumer reads the named subspace. It sits after the Real-name surface of chapter 38, the regular rational readback of chapter 301, the finite observation surface of chapter 126, the metric source of chapter 57, and the topology handoff of chapter 88. The packet names a displayed rational-coordinate schedule and its induced metric/topology route; it does not supply a host subspace of Hilbert space, quotient sequence equality, a selected infinite point, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7890.1 (Erdos space carrier)**.** *An* $\mathsf{ErdosSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, S, R, A, M, O, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational-coordinate schedule row. It lists the finite coordinate requests, rational entries, support flags, and denominator guards that the packet exposes.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened for the coordinate schedule, support flags, metric requests, topology basic-neighbourhood requests, and terminal Real seals.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It repacks exactly the scheduled rational observations from S as regular rational sequence data.*
4. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row for coordinate values and distance budgets. It is terminal after Q, S, R and exports no independent completeness principle.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *handoff row. It records the finite paired-coordinate distance checks consumed by metric readers of the Erdos-space packet.*
6. *O is the* $\mathsf{Topology}^{\uparrow}$ *handoff row. It records the basic-neighbourhood and finite-cover membership requests that may be read after the metric route is displayed.*
7. *H records componentwise* hsame *transport for the coordinate schedule, StreamName windows, RegSeqRat readback, Real seals, Metric handoff, Topology handoff, replay rows, provenance, and local naming row.*

8. *C records displayed* Cont *replay from a local Erdos-space request through $Q, S, R, A, M, O, H, P, N$ without adding a selected infinite coordinate sequence or quotient sequence equality.*
9. *P is the* Pkg *provenance over* $\mathsf{ErdosSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ErdosSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, S, R, A, M, O, H, C, P, N$. It has no coordinate for a host Hilbert subspace, quotient sequence equality, selected infinite coordinate family, open-cover compactness theorem, classical separability argument, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7890.2 (Erdos space NameCert obligations)**.** *For every accepted* $\mathsf{ErdosSpace}^{\uparrow}$ *carrier $E = (Q, S, R, A, M, O, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ErdosSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the rational-coordinate schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seals, induced* $\mathsf{Met}^{\uparrow}$ *handoff, induced* $\mathsf{Topology}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every metric or topology read of the packet must pass through $Q, S, R, A, M, O, H, C, P, N$, and no obligation is stored outside those finite rows.*

Proof. Project the accepted carrier. The analytic rows are precisely the rational-coordinate schedule Q, finite window row S, regular rational readback R, Real seal A, metric handoff M, and topology handoff O.

The structural rows are then forced. Transport through H and replay through C preserve the same displayed schedule, readback, metric, and topology rows, while P and N only source and name the accepted packet.

Since the carrier has no row for a host Hilbert subspace, quotient sequence equality, selected infinite coordinate family, open-cover compactness theorem, classical separability argument, or ambient real completeness, the local NameCert cannot export any of those objects. □

Theorem 7890.3 (Erdos space rational-sequence handoff)**.** *Every* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Topology}^{\uparrow}$ *consumer of an accepted* $\mathsf{ErdosSpace}^{\uparrow}$ *packet must first read the rational-coordinate route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{Topology}^{\uparrow}$$

through the displayed rows $Q, S, R, A, M, O, H, C, P, N$. The consumer receives only finite coordinate windows, regular rational readbacks, terminal Real seals, paired-coordinate metric checks, and topology basic-neighbourhood handoffs. It receives no host product metric, quotient sequence equality, selected coordinate limit, open-cover compactness proof, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the coordinate route in Definition 7890.1. The only coordinate data are the rational schedule row Q and the finite windows S opened for that schedule.

Next use the readback and Real rows. The row R repacks exactly the scheduled observations as regular rational data, and A seals the coordinate and distance budgets as terminal $\mathsf{Real}^{\uparrow}$ rows.

Finally read the consumer handoff. The metric row M and topology row O are downstream of Q, S, R, A, while H, C, P, N transport, replay, source, and name that same finite route. Thus a metric or topology consumer cannot replace the displayed rational-sequence handoff by a host product metric, quotient sequence equality, selected coordinate limit, open-cover compactness proof, or ambient completeness principle. □

Falsifiable prediction: An accepted $\mathsf{ErdosSpace}^{\uparrow}$ consumer that exports a $\mathsf{Met}^{\uparrow}$ or $\mathsf{Topology}^{\uparrow}$ read without first displaying the rows $Q, S, R, A, M, O, H, C, P, N$ refutes the carrier surface.

Independence witness: real, regseqrat, streamname, metric, topology: no listed sibling supplies the whole packet $E = (Q, S, R, A, M, O, H, C, P, N)$, because each sibling contributes only Real seals, regular rational readback, finite stream windows, metric distance rows, or topology handoffs while this chapter binds the rational-coordinate schedule through transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ErdosSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{ErdosSpace}^{\uparrow}$ packet is generated from a rational-coordinate schedule row, finite StreamName windows, RegSeqRat readback, Real coordinate seals, induced Metric handoff, induced Topology handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ErdosSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7890.1, Definition 7890.2, and Definition 7890.3 seed the finite rational-coordinate route from schedule rows through StreamName, RegSeqRat, Real, Metric, Topology, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ErdosSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Hilbert subspaces, quotient sequence equality, selected coordinate limits, open-cover compactness, classical separability arguments, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-coordinate schedule exposure, StreamName window exactness, RegSeqRat readback, Real-seal nonescape, Metric handoff, Topology handoff, provenance exhaustion, and local naming for BEDC.Derived.ErdosSpaceUp.

Chapter 7891

A Concrete Naming Certificate for PoincareDiskGeodesicTriangle$^{\uparrow}$

The PoincareDiskGeodesicTriangle$^{\uparrow}$ packet realizes the disk-geodesic triangle branch of the hyperbolic observer-expansion reading as finite BEDC data. It sits after the disk carrier of chapter 377, the hyperbolic metric route of chapter 3474, the boundary-geodesic route of chapter 3491, the phase-transport packet of chapter 3455, and the dynamic replay surface of chapter 195. The packet names three disk points, three geodesic sides, metric and phase rows, and local provenance; it does not assert global hyperbolic completeness, selected geodesic endpoints, quotient curve equality, smooth manifold structure, or ambient field completeness.

Definition 7891.1 (Poincare disk geodesic triangle carrier)**.** *A* PoincareDiskGeodesicTriangle$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, V, G, M, B, \Phi, Y, H, C, P, N)$$

with the following displayed rows:

1. *D is the* UnitDisk$^{\uparrow}$ *source row, exposing exactly the disk-coordinate windows inspected by the packet.*
2. *V is the vertex row. It records three named disk points and the finite distinctness checks visible to the triangle carrier.*
3. *G is the side row. It records the three* HyperbolicGeodesicBoundary$^{\uparrow}$ *side windows joining the displayed vertices.*
4. *M is the* HyperbolicMetric$^{\uparrow}$ *row, carrying the finite side-length, comparison, and incidence reads consumed by metric-facing readers.*
5. *B is the boundary-incidence row. It records which boundary endpoints or limiting boundary guards are inspected by the side rows, without selecting a global boundary parametrization.*
6. *Φ is the* PoincareDiskPhaseTransport$^{\uparrow}$ *row, carrying the reversible phase transport used to compare the displayed sides inside the disk model.*
7. *Y is the* DynSystem$^{\uparrow}$ *replay row for the finite phase-geodesic observation route.*
8. *H records componentwise* hsame *transport for disk points, vertices, sides, metric reads, boundary guards, phase transport, dynamic replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a triangle request through $D, V, G, M, B, \Phi, Y, H, P, N$ without adding selected geodesic endpoints or quotient curve equality.*
10. *P is the* Pkg *provenance over* PoincareDiskGeodesicTriangle$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBo PoincareDiskPhaseTransport$^{\uparrow}$, DynSystem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{PoincareDiskGeodesicTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, V, G, M, B, \Phi, Y, H, C, P, N$. It has no coordinate for a host disk model, selected complete geodesic, quotient curve equality, smooth tangent object, measure completion, global hyperbolic completion, Nontrivial instance, or FieldFaithful instance.

Theorem 7891.2 (Poincare disk geodesic triangle NameCert obligations)**.** *For every accepted* PoincareDiskGeodesicTriangle$^{\uparrow}$ *carrier $T = (D, V, G, M, B, \Phi, Y, H, C, P, N)$, the local* NameCert$_{\text{PoincareDiskGeodesicTrian}}$ *surface consists exactly of carrier admission for the disk source, three-vertex row, three geodesic-side rows, hyperbolic-metric row, boundary-incidence guards, phase-transport row, dynamic replay row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every triangle read must pass through $D, V, G, M, B, \Phi, Y, H, C, P, N$, and no obligation is stored outside those finite rows.*

Proof. Project the accepted carrier. The geometric rows are the disk source D, vertices V, geodesic sides G, metric reads M, boundary guards B, phase transport Φ, and dynamic replay Y.

The structural rows then preserve that route. Transport through H and replay through C act componentwise on the same displayed disk, side, metric, boundary, phase, and dynamic rows, while P and N source and name the packet.

Since the carrier has no row for a host disk model, selected complete geodesic, quotient curve equality, smooth tangent object, measure completion, global completion, Nontrivial instance, or FieldFaithful instance, the local NameCert cannot export any of those objects. □

Theorem 7891.3 (Poincare disk geodesic triangle phase route)**.** *Every hyperbolic-metric, phase-transport, or dynamic consumer of an accepted* PoincareDiskGeodesicTriangle$^{\uparrow}$ *packet must first read*

UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBoundary$^{\uparrow}$, PoincareDiskPhaseTransport$^{\uparrow}$, DynSystem$^{\uparrow}$

through the displayed rows $D, V, G, M, B, \Phi, Y, H, C, P, N$. The consumer receives only finite disk-point, geodesic-side, hyperbolic-metric, boundary-guard, phase-transport, dynamic-replay, transport, provenance, and local naming rows. It receives no host disk metric, selected geodesic boundary parametrization, quotient curve equality, smooth geodesic flow, measure completion, global hyperbolic completion, Nontrivial instance, or FieldFaithful instance.

Proof. Start with the disk and side data of Definition 7891.1. The row D exposes disk coordinates, V names the three inspected vertices, and G records the three side windows.

Next read the metric and boundary guards. The row M supplies only the hyperbolic-metric reads attached to those displayed sides, and B records the finite boundary-incidence checks without selecting a boundary parametrization.

Finally apply the phase and dynamic rows. The phase-transport row Φ and dynamic replay row Y are transported by H, replayed by C, sourced by P, and named by N. Because no row contains a host disk metric, quotient curve equality, selected complete geodesic, smooth flow, measure completion, global completion, Nontrivial instance, or FieldFaithful instance, none can be read by the consumer. □

Falsifiable prediction: An accepted $\mathsf{PoincareDiskGeodesicTriangle}^{\uparrow}$ consumer that reaches a hyperbolic-metric, phase-transport, or dynamic read without first displaying $D, V, G, M, B, \Phi, Y, H, C, P, N$ refutes the carrier surface.

Independence witness: unitdisk, hyperbolic-metric, hyperbolic-geodesic-boundary, poincare-disk-phase-transport, dynsystem: no listed sibling supplies the whole packet $T = (D, V, G, M, B, \Phi, Y, H, C, P, N)$, because each sibling contributes only disk coordinates, metric reads, boundary-geodesic guards, phase transport, or dynamic replay while this chapter binds the finite geodesic triangle through local transport, provenance, and naming.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskGeodesicTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareDiskGeodesicTriangle}^{\uparrow}$ packet is generated from a UnitDisk source row, a three-vertex row, geodesic-side rows, a HyperbolicMetric row, boundary-incidence guards, PoincareDiskPhaseTransport, DynSystem replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskGeodesicTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7891.1, Definition 7891.2, and Definition 7891.3 seed the finite disk-geodesic triangle route from disk points through geodesic sides, hyperbolic metric, boundary guards, phase transport, dynamic replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskGeodesicTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host disk metrics, selected geodesic boundary parametrizations, quotient curve equality, smooth geodesic flow, measure completion, global hyperbolic completion, Nontrivial instances, FieldFaithful instances, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk-point exposure, geodesic-side exactness, hyperbolic-metric handoff, boundary-guard scope, phase-transport compatibility, dynamic replay, Nontrivial and FieldFaithful instance supply, provenance exhaustion, and local naming for BEDC.Derived.PoincareDiskGeodesicTriangleUp.

Chapter 7892

A Concrete Naming Certificate for $\mathsf{PolishZeroDimensional}^{\uparrow}$

Following Kechris and Engelking, the $\mathsf{PolishZeroDimensional}^{\uparrow}$ packet records the finite BEDC surface for a separable completely metrizable space whose usable topology is read through a clopen basis. It sits after the Polish carrier of chapter 1490, the Baire prefix surface of chapter 334, the Cantor coding surface of chapter 1530, the topological neighbourhood route of chapter 88, the metric row of chapter 57, the finite stream windows of chapter 126, and the regular rational readback of chapter 301. The packet names zero-dimensionality as finite clopen-basis data; it is not a host powerset, an arbitrary Boolean algebra of subsets, a choice of all open covers, or an ambient descriptive-set-theoretic universe.

Definition 7892.1 (Polish zero-dimensional carrier)**.** *A* $\mathsf{PolishZeroDimensional}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (P, T, M, B, C, W, R, H, E, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{PolishSpace}^{\uparrow}$ *source row, exposing the separable complete metric name that the packet refines.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *neighbourhood row read from the source topology.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *observation row used to compare finite neighbourhood requests.*
4. *B is the finite clopen-basis ledger. Each admitted basic neighbourhood request names a clopen row below the requested open row, and finite intersections are recorded by displayed ledger entries.*
5. *C is the Cantor/Baire coding boundary, tying basic clopen rows to* $\mathsf{BaireSpace}^{\uparrow}$ *and* $\mathsf{CantorSet}^{\uparrow}$ *cylinder reads without selecting infinite branches.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when a consumer probes the basis by names.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite metric and cylinder windows.*
8. *H records componentwise* hsame *transport for the Polish source, topology row, metric row, clopen ledger, coding boundary, window row, readback row, replay, provenance, and local name.*
9. *E records displayed* Cont *replay of the route*

$$P, T, M \longmapsto B \longmapsto C \longmapsto W, R.$$

10. *Q is the* Pkg *provenance over* PolishZeroDimensional$^\uparrow$, PolishSpace$^\uparrow$, Topology$^\uparrow$, Met$^\uparrow$, BaireSpace$^\uparrow$, CantorSet$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{PolishZeroDimensional}^\uparrow}$ *row.*

The classifier compares accepted packets only through these rows, the finite clopen refinement ledger, and their displayed transport and replay. It has no coordinate for host powersets, arbitrary subset equality, global choice of bases, open-cover compactness, selected infinite branches, quotient stream equality, or ambient classical descriptive set theory.

Theorem 7892.2 (Polish zero-dimensional NameCert obligations)**.** *For every accepted* PolishZeroDimensional$^\uparrow$ *carrier $Z = (P, T, M, B, C, W, R, H, E, Q, N)$, the local* NameCert$_{\text{PolishZeroDimensional}^\uparrow}$ *surface consists exactly of source admission for the Polish row, topology row, metric observations, finite clopen-basis ledger, Baire/Cantor cylinder boundary, finite stream windows, regular rational readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The certificate refuses host powersets, arbitrary subset equality, global choice of bases, open-cover compactness, selected infinite branches, quotient stream equality, and ambient classical descriptive set theory.*

Proof. Project the carrier of Definition 7892.1. Its rows expose exactly the Polish source, topology and metric observations, clopen-basis ledger, Baire/Cantor boundary, finite windows, rational readback, transport, replay, provenance, and local name.

The zero-dimensional obligation is the ledger row B. For each admitted neighbourhood request, B names a displayed clopen refinement and records the finite intersection rows needed by downstream basis consumers. The route reads P, T, M before B, so the clopen row is tied to the displayed Polish topology rather than to a host subset universe.

The coding boundary C and the observation rows W, R keep later Baire or Cantor consumers inside finite cylinder and rational-readback evidence. Transport H and replay E repeat only those rows, while Q and N source and name the same packet.

Since the carrier contains no row for host powersets, arbitrary subset equality, global basis choice, open-cover compactness, selected infinite branches, quotient stream equality, or ambient classical descriptive set theory, the listed rows exhaust the local NameCert surface. □

Theorem 7892.3 (Polish zero-dimensional clopen-basis route)**.** *Every topology-facing or coding-facing consumer of an accepted* PolishZeroDimensional$^\uparrow$ *carrier $Z = (P, T, M, B, C, W, R, H, E, Q, N)$ must read the* PolishSpace$^\uparrow$ *source row,* Topology$^\uparrow$ *neighbourhood row,* Met$^\uparrow$ *observation row, finite clopen-basis ledger, Baire/Cantor cylinder boundary,* StreamName$^\uparrow$ *windows, and* RegSeqRat$^\uparrow$ *readback before using the zero-dimensional seal. The route is a finite clopen-basis NameCert route and does not export host powersets, arbitrary subset equality, global choice of bases, open-cover compactness, selected infinite branches, quotient stream equality, or ambient classical descriptive set theory.*

Proof. Start from Definition 7892.2. It orders the source rows P, T, M before the clopen-basis ledger B and then routes coding-facing reads through C, W, R.

The consumer therefore obtains a clopen basis only as displayed finite ledger data. The Baire and Cantor rows are read as cylinder boundaries attached to the same ledger, and the stream and rational rows expose only the finite observations used by that read.

Finally, componentwise transport, replay, provenance, and local naming preserve the same packet. Because no listed carrier row contains a host powerset, arbitrary subset equality, global basis choice, open-cover compactness, selected infinite branch, quotient stream equality, or ambient

descriptive-set-theoretic universe, the zero-dimensional seal cannot be replaced by any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{PolishZeroDimensional}\uparrow}$.

Constructive story: A PolishZeroDimensional$^{\uparrow}$ packet is generated from a Polish source row, topology and metric observations, a finite clopen-basis ledger, Baire/Cantor cylinder boundary, finite StreamName windows, RegSeqRat readback, transport, replay, provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PolishZeroDimensional}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7892.1, Definition 7892.2, and Definition 7892.3 seed the finite clopen-basis packet over PolishSpace, Topology, Metric, BaireSpace, CantorSet, StreamName, RegSeqRat, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PolishZeroDimensional}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host powersets, arbitrary subset equality, global choice of bases, open-cover compactness, selected infinite branches, quotient stream equality, ambient descriptive set theory, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, clopen-basis refinement, finite-intersection stability, Baire/Cantor cylinder routing, finite-window readback, transport, replay, provenance, and local naming for BEDC.Derived.PolishZeroDimensionalUp.

Chapter 7893

A Concrete Naming Certificate for $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$

The $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ packet realizes the residual-diamond readback branch of chapter 9378 as finite candidate-mediated NameCert data. It sits beside the critical-path carrier of chapter 765, the parallel-diamond frontier of chapter 4238, the residual-pair lattice of chapter 7879, the residual-substitution compatibility packet of chapter 4370, and the local diamond witness of chapter 3595. The packet names the finite route by which a candidate-mediated residual diamond can be read back to normalization-facing or confluence-facing consumers without becoming Church–Rosser, subject reduction, quotient syntax equality, selected limits, Real completeness, or MetaCIC kernel consistency.

Definition 7893.1 (MetaCIC residual-diamond readback carrier)**.** *A* $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, S, B, J, R, L, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *source packet whose candidate-mediated SN frontier and L10 source ledger are being read.*
2. *F is the candidate frontier row, displaying Candidate, ClosedCandidate, or CandidateSet evidence before any normalization-facing readback.*
3. *S is the residual substitution budget row, recording the finite substitution and residual windows consumed by the diamond request.*
4. *B is the bounded checker row for the two residual branches and their candidate common target.*
5. *J is the local diamond witness row, displaying the bounded join or the retained local obstruction for the inspected peak.*
6. *R is the readback row, specifying how the candidate frontier, residual budget, bounded checker, and local witness are read by confluence-facing or normalization-facing consumers.*
7. *L is the L10 four-object source ledger for* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$.
8. *O is the obstruction row for subject reduction, global Church–Rosser, host confluence equality, quotient syntax equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and kernel consistency.*

9. *H records componentwise* hsame *transport for the critical-path packet, candidate frontier, residual budget, checker, local witness, readback row, L10 ledger, obstruction row, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay of the route*

$$K, F, S, B, J, L \longmapsto R \longmapsto O.$$

11. *P is the* Pkg *provenance over* MetacicResidualDiamondReadback$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICParallelDiamond MetaCICResidualPairLattice$^{\uparrow}$, MetaCICResidualSubstitutionCompatibility$^{\uparrow}$, MetaCICLocalDiamondWitness$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{MetacicResidualDiamondReadback}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for evidence-free strong normalization, global Church–Rosser, subject reduction, host confluence equality, quotient syntax equality, selected limits, ambient Real$^{\uparrow}$ *completeness, or MetaCIC kernel consistency.*

Theorem 7893.2 (MetaCIC residual-diamond readback obligations)**.** *For every accepted* MetacicResidualDiamondR *carrier $D = (K, F, S, B, J, R, L, O, H, C, P, N)$, the local* NameCert$_{\text{MetacicResidualDiamondReadback}^{\uparrow}}$ *surface consists exactly of critical-path source admission through K, candidate frontier exposure through F, residual substitution budget exposure through S, bounded-checker exposure through B, local diamond witness exposure through J, readback order through R, L10 source-ledger exposure through L, obstruction retention through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7893.1. The source row K supplies only the critical-path packet, while F exposes the candidate-mediated frontier that a normalization-facing consumer must read.

The residual-diamond data are the rows S, B, J. The residual substitution budget fixes the inspected windows, the bounded checker records the finite branch comparison, and the local diamond witness either displays the bounded join or keeps the local obstruction visible.

The readback row R can be used only after those rows and the L10 ledger L have been displayed. Transport H and replay C preserve the same order, while P and N source and name the packet.

Since O is the only row mentioning the excluded endpoints, and it records them as unavailable boundaries, the listed rows exhaust the NameCert surface. No row supplies evidence-free strong normalization, global Church–Rosser, subject reduction, host confluence equality, quotient syntax equality, selected limits, ambient Real$^{\uparrow}$ completeness, or MetaCIC kernel consistency. □

Theorem 7893.3 (MetaCIC residual-diamond candidate readback route)**.** *Every confluence-facing or normalization-facing read of an accepted* MetacicResidualDiamondReadback$^{\uparrow}$ *carrier $D = (K, F, S, B, J, R, L, O, H, C, P, N)$ must expose the candidate frontier F, residual substitution budget S, bounded checker row B, local diamond witness J, and L10 source ledger L before consuming the readback row R. The resulting route is candidate-mediated residual-diamond readback, not subject reduction, global Church–Rosser, host confluence equality, quotient syntax equality, selected limits, ambient* Real$^{\uparrow}$ *completeness, or MetaCIC kernel consistency.*

Proof. Start with the obligation surface of Definition 7893.2. It places F, S, B, J, L before any readback consumer can use R.

The candidate row F prevents the read from becoming evidence-free strong normalization. The residual budget and checker rows S, B keep the read inside a finite branch comparison, while J records the local join or the local obstruction for that same peak.

The ledger row L keeps the critical-path read attached to $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ source data before any completion-facing or normalization-facing consumer can use it. The structural rows H, C, P, N preserve only this displayed route.

Thus the readback is exactly the finite candidate-mediated route through the displayed rows. The excluded endpoints remain in the obstruction row O and are not exported as theorems. □

Falsifiable prediction: A purported $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ consumer is refuted if it reaches confluence-facing or normalization-facing readback without displaying the candidate frontier, residual substitution budget, bounded checker, local diamond witness, L10 four-object source ledger, transport, replay, provenance, and local naming rows.

Independence witness: metaciccriticalpath, metacic-parallel-diamond-frontier, metacic-residual-pair-lattice, metacic-residual-substitution-compatibility, metacic-local-diamond-witness: none is bijective to $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ because this packet jointly carries candidate frontier exposure, residual substitution budget, bounded branch checking, local diamond witness readback, L10 source ledger, obstruction retention, transport, replay, provenance, and local NameCert rows.

The Lean TasteGate follow-up for $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ instances. These instances must preserve the rows $K, F, S, B, J, R, L, O, H, C, P, N$ as separate fields before any checked carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondReadback}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$ packet is generated from a MetaCIC critical-path source, candidate frontier, residual substitution budget, bounded checker row, local diamond witness, readback row, L10 four-object source ledger, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondReadback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7893.1, Definition 7893.2, and Definition 7893.3 seed the finite candidate-mediated residual-diamond readback packet over critical-path, residual budget, bounded checker, local witness, L10 ledger, obstruction, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicResidualDiamondReadback}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, global Church–Rosser, host confluence equality, quotient syntax equality, selected limits, ambient Real completeness, evidence-free strong normalization, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, candidate-frontier exposure, residual-budget exposure, bounded-checker exactness, local-witness exposure, readback order, L10 ledger routing, obstruction retention, transport, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.MetacicResidualDiamondRead

Chapter 7894

A Concrete Naming Certificate for $\mathsf{CompactApartnessModulus}^{\uparrow}$

Bishop–Bridges-style constructive compactness reads compact information through finite approximating data rather than through an arbitrary subcover principle. The $\mathsf{CompactApartnessModulus}^{\uparrow}$ packet names the modulus row that tells an apartness-sensitive consumer how fine a finite net must be before a positive separation request is stable. It sits between the compact finite profile of chapter 5850 and the located separation route of chapter 7647, while retaining the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback rows needed by numerical consumers.

Definition 7894.1 (Compact apartness modulus carrier)**.** *A* $\mathsf{CompactApartnessModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, T, A, M, D, R, E, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compact reads are exposed by finite windows or finite-net data.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row naming the selected mesh scale, centers, and coverage ledger.*
3. *A is the apartness request row, recording the positive separation test that the modulus is asked to preserve.*
4. *M is the modulus row: it sends an apartness request and a compact finite-net scale to a displayed dyadic tolerance.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing the mesh and lower-bound comparisons.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational modulus values generated by M, D.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the numerical separation bound read from R.*
8. *S is the separated or located-separation handoff row consumed by* $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$.
9. *H records componentwise* hsame *transport for compact rows, finite-net rows, apartness requests, modulus rows, dyadic ledgers, readback rows, Real seals, separation handoff rows, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a consumer request through $K, T, A, M, D, R, E, S, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompactApartnessProfile}^{\uparrow}$, $\mathsf{CompactApartnessLocatedSeparation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactApartnessModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It contains no arbitrary open-cover compactness principle, selected subcover, apartness trichotomy, quotient completion equality, selected limit point, host equality, or ambient Real completeness assertion.

Theorem 7894.2 (Compact apartness modulus NameCert obligations)**.** *For every accepted* CompactApartnessMod *carrier*

$$U = (K, T, A, M, D, R, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactApartnessModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net exposure, apartness-request exposure, modulus-to-tolerance exposure, dyadic ledger readout,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, separated handoff, componentwise transport, displayed replay, provenance, and local naming. A consumer may use the modulus only after K, T, A, M, D, R, E, S have been displayed in the same finite packet.*

Proof. Project the carrier of Definition 7894.1. The rows $K, T, A, M, D, R, E, S, H, C, P, N$ are the complete public inventory of the packet.

The compact and apartness rows are read first. The finite-net row T supplies the mesh data for the compact source K, and the apartness row A names the positive separation request that the modulus must control.

The numerical route is then forced through M, D, R, E. The modulus row produces only a displayed dyadic tolerance, the dyadic ledger checks it, the regular rational row reads it back, and the Real row seals the terminal numerical bound.

Finally S, H, C, P, N hand the same finite route to separated consumers, transport it componentwise, replay it, record provenance, and name it locally. Since no row stores an arbitrary subcover, trichotomy, quotient equality, selected limit point, host equality, or ambient completeness theorem, those objects cannot become NameCert obligations. □

Theorem 7894.3 (Compact apartness modulus finite-net separation)**.** *Every accepted* $\mathsf{CompactApartnessModulus}^{\uparrow}$ *finite-net separation read factors through*

$$K, T, A, M, D, R, E, S, H, C, P, N.$$

The row T supplies the finite net, A supplies the apartness request, M supplies the modulus-to-tolerance map, D checks the dyadic tolerance, R and E provide the $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *numerical readback, and S is the only separation-facing handoff. Thus the modulus row is a finite compact-apartness coordinate, not an open-cover compactness theorem, an apartness trichotomy, quotient completion equality, selected limit data, host equality, countable choice, or ambient Real completeness.*

Proof. Start with the finite-net row T over the compact source K. A separation-facing consumer must first read the displayed centers, mesh scale, and coverage ledger rather than an arbitrary cover.

Read the apartness request through A and the modulus through M. The modulus is only accepted as a row that turns the displayed apartness request and finite-net scale into a dyadic tolerance governed by D.

The numerical value remains internal to the finite route until R and E read it back as a regular rational name and terminal Real seal. Only after those rows are visible may S pass the result to the located separation surface named in chapter 7647.

The exclusions are coordinate exhaustion. The carrier has no row for open-cover compactness, trichotomy, quotient completion equality, selected limits, host equality, choice schedules, or ambient Real completeness, so the finite-net separation read cannot export them. □

Falsifiable prediction: A compact-apartness consumer that claims a numerical separation modulus without displaying finite-net data, apartness request data, dyadic tolerance, RegSeqRat readback, Real sealing, and the separated handoff row is not a $\mathsf{CompactApartnessModulus}^{\uparrow}$ packet.

Independence witness: compactapartnessprofile, compactapartnesslocatedseparation, totallybounded, dyadicratcore, regseqrat, real: the packet is not bijective to these siblings because it singles out the modulus-to-tolerance row M and binds it to compact finite-net data, apartness requests, dyadic checking, numerical readback, Real sealing, separation handoff, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactApartnessModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactApartnessModulus}^{\uparrow}$ packet is generated from compact finite-net data, apartness request rows, a modulus-to-tolerance row, dyadic tolerance ledgers, RegSeqRat readback, Real sealing, separated handoff data, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactApartnessModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7894.1, Definition 7894.2, and Definition 7894.3 seed the finite compact-apartness modulus carrier and its NameCert obligation surface over displayed compact, finite-net, apartness, dyadic, RegSeqRat, Real, and separated handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactApartnessModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, open-cover compactness, selected subcover existence, apartness trichotomy, quotient completion equality, selected limit data, host equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exposure, apartness-request exposure, modulus-to-tolerance exposure, dyadic tolerance readout, RegSeqRat readback, Real sealing, separated handoff, transport, replay, provenance, and local naming for the same packet.

Chapter 7895

A Concrete Naming Certificate for $\mathsf{LelekFan}^{\uparrow}$

Following Lelek on endpoint-dense fans, the $\mathsf{LelekFan}^{\uparrow}$ packet records the finite BEDC surface of the classical smooth-fan continuum whose endpoints are dense. It sits beside the pseudo-arc reconstruction of chapter 6905, the compact-metric source of chapter 129, the path-connected carrier of chapter 6885, the Peano-continuum route of chapter 2160, and the observable-open classifier of chapter 1860. The packet names finite branch windows, endpoint-density rows, compact metric support, and local fan-root coherence before any compact-continuum neighbour may read it.

Definition 7895.1 (Lelek fan carrier)**.** *A* $\mathsf{LelekFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, P, A, B, E, D, H, C, G, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing finite metric covers, diameter bounds, and compact-metric provenance for the current fan window.*
2. *P is the* $\mathsf{PathConnectedSpace}^{\uparrow}$ *row, recording finite arc-chain data from the root window to each displayed branch point.*
3. *A is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row, supplying the compact, connected, locally connected continuum surface inspected by branch consumers.*
4. *B is the branch ledger, listing the root row, finite branch-prefix rows, attachment rows, and branch-order compatibility data.*
5. *E is the endpoint row, marking branch endpoints as finite named boundary records rather than as a completed endpoint set.*
6. *D is the endpoint-density row, recording for each inspected basic branch neighbourhood a finite endpoint witness whose carrier route remains inside that neighbourhood.*
7. *H records componentwise* hsame *transport for compact metric, path-connected, Peano-continuum, branch, endpoint, density, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from finite fan-window requests through $K, P, A, B, E, D, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{LelekFan}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PathConnectedSpace}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{PseudoArc}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LelekFan}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these ten rows form one finite endpoint-dense fan packet. It has no coordinate for a host continuum, a completed endpoint set, quotient equality of continua, open-cover compactness, selected branches outside the displayed ledger, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7895.2 (Lelek fan NameCert obligations)**.** *For every accepted* $\mathsf{LelekFan}^{\uparrow}$ *carrier* $L = (K, P, A, B, E, D, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LelekFan}^{\uparrow}}$ *surface consists exactly of compact-metric admission through* K*, path-connected route admission through* P*, Peano-continuum support through* A*, branch-ledger readback through* B*, endpoint exposure through* E*, endpoint-density exposure through* D*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* G*, and local naming through* N*.*

Proof. Project the carrier of Definition 7895.1. The compact source K, path-connected route P, and Peano-continuum support A are read before the branch rows, so every continuum-facing consumer begins from displayed finite metric covers, finite root-to-branch chains, and the local continuum support.

The rows B, E, D supply the fan-specific content. The branch ledger B records root and branch-prefix windows, the endpoint row E names the boundary records, and the density row D gives a finite endpoint witness inside each inspected branch neighbourhood.

Transport and replay keep the same packet visible. The rows H and C preserve the compact, path, continuum, branch, endpoint, and density rows under hsame and Cont, while G and N record provenance and local naming.

Since the carrier has no host continuum coordinate, completed endpoint set, quotient equality row, open-cover compactness proof, selected branch outside B, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness, the listed rows exhaust the local NameCert obligations. □

Theorem 7895.3 (Lelek fan endpoint-density handoff)**.** *Every accepted* $\mathsf{LelekFan}^{\uparrow}$ *carrier hands endpoint density to compact-continuum neighbours through the finite route*

$$K, P, A, B, E, D \longmapsto H, C, G, N.$$

In particular, a $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{PathConnectedSpace}^{\uparrow}$*,* $\mathsf{PeanoContinuum}^{\uparrow}$*, or* $\mathsf{SierpinskiSpace}^{\uparrow}$ *consumer first reads the compact fan window, the root-to-branch route, the continuum support, the branch ledger, the endpoint row, and the endpoint-density row before it may classify the packet as an endpoint-dense fan surface.*

Proof. Begin with the obligation surface of Definition 7895.2. The compact metric and continuum rows K, P, A determine the finite neighbourhood and path data available to a downstream consumer.

The endpoint-density handoff is the row D read together with B and E. For each inspected neighbourhood, B fixes the branch window, E names the endpoint candidate, and D records that the candidate lies in the displayed neighbourhood. The $\mathsf{SierpinskiSpace}^{\uparrow}$ classifier may observe the neighbourhood row only after these finite branch and endpoint rows have been exposed.

Finally H, C, G, N transport, replay, package, and name the same dependency route. Thus the handoff remains a displayed compact-continuum certificate, not a hidden host theorem about a completed endpoint set. □

Falsifiable prediction: An accepted $\mathsf{LelekFan}^{\uparrow}$ consumer that classifies endpoint density without reading the branch ledger B, endpoint row E, and density row D refutes the carrier surface.

Independence witness: pseudo-arc, compactmetric, path-connected-space, peano-continuum, sierpinski-space: none is bijective to $\mathsf{LelekFan}^{\uparrow}$ because this packet jointly carries compact metric support, root-to-branch path data, Peano-continuum support, branch windows, endpoint rows, endpoint-density witnesses, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LelekFan}\uparrow}$**.**

Constructive story: A $\mathsf{LelekFan}^{\uparrow}$ packet is generated from CompactMetricUp, PathConnectedSpaceUp, PeanoContinuumUp, branch-ledger, endpoint, endpoint-density, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LelekFan}\uparrow}$, seed)

Scope closed: Definition 7895.1, Definition 7895.2, and Definition 7895.3 seed the finite endpoint-dense fan surface over compact metric, path-connected, Peano-continuum, branch, endpoint, density, and observable-open rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LelekFan}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host Lelek fan theorem, a completed endpoint set, quotient continuum equality, open-cover compactness, selected branches outside the displayed ledger, countable choice, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric support, path and continuum support, branch-ledger readback, endpoint-density exposure, transport, replay, provenance, and local naming for BEDC.Derived.LelekFanUp.

Chapter 7896

A Concrete Naming Certificate for $\mathsf{RealArchimedeanFloor}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealArchimedeanFloor}^{\uparrow}$ packet records the finite Archimedean floor readback by which a displayed $\mathsf{Real}^{\uparrow}$ name yields an integer bracket only through inspected rational and dyadic rows. It sits over the terminal real seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the integer carrier of chapter 31, and the rational carrier of chapter 37. The packet names a finite floor-readback surface; it is not a host floor operator, a trichotomy principle, a quotient-real representative selector, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7896.1 (RealArchimedeanFloor carrier)**.** *A* $\mathsf{RealArchimedeanFloor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (R, Q, D, Z, A, L, U, H, C, P, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row whose inspected name is being read.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback attached to the same displayed Real name.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the floor comparison windows.*
4. *Z is the* $\mathsf{Int}^{\uparrow}$ *candidate bracket row.*
5. *A is the* $\mathsf{Rat}^{\uparrow}$ *Archimedean comparison row relating the integer candidate to rational windows.*
6. *L records the displayed lower bound $Z \leq R$ through the rational readback route.*
7. *U records the displayed upper bound $R < Z + 1$ through the same route.*
8. *H records componentwise* hsame *transport for the Real seal, rational readback, dyadic tolerance ledger, integer bracket, rational comparison row, displayed bounds, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for the same finite floor-readback route.*
10. *P is the* Pkg *provenance over* $\mathsf{RealArchimedeanFloor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanFloor}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. No coordinate stores a host floor function, a trichotomy decision for arbitrary Real names, a quotient-real representative, a selected regular sequence, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RealArchimedeanFloorUp.RealArchimedeanFloorTasteGate single carrier alignment`

Theorem 7896.2 (RealArchimedeanFloor NameCert obligations)**.** *For an accepted* $\mathsf{RealArchimedeanFloor}^{\uparrow}$ *carrier* $F = (R, Q, D, Z, A, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealArchimedeanFloor}^{\uparrow}}$ *surface consists exactly of carrier admission, sealed* $\mathsf{Real}^{\uparrow}$ *exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Int}^{\uparrow}$ *candidate exposure,* $\mathsf{Rat}^{\uparrow}$ *Archimedean comparison, displayed lower and upper floor bounds, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 7896.1. The only visible rows are $R, Q, D, Z, A, L, U, H, C, P, N$, so every floor-facing consumer must read the Real seal through the rational readback, dyadic tolerance ledger, integer candidate, and rational comparison rows before it can inspect the displayed bounds.

The lower and upper rows are tied to the same finite route. Row L records the lower comparison, while row U records the successor-side comparison; both use Q, D, Z, A rather than an external order oracle.

Finally read H, C, P, N. These rows transport, replay, source, and locally name exactly the displayed packet. Since the carrier has no coordinate for host floor, trichotomy, quotient-real representatives, selected representatives, countable choice, or ambient completeness, the local NameCert obligations cannot export any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealArchimedeanFloor}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealArchimedeanFloor}^{\uparrow}}$, seed)

Scope closed: Definition 7896.1 and Definition 7896.2 seed the finite floor-readback carrier over Real, RegSeqRat, DyadicRatCore, Int, and Rat rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealArchimedeanFloor}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, host floor, quotient reals, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational readback, dyadic tolerance accounting, integer bracket exposure, Archimedean comparison, displayed lower and upper bound exactness, transport, replay, provenance, and local naming for BEDC.Derived.RealArchimedeanFloorUp.

Constructive story: A $\mathsf{RealArchimedeanFloor}^{\uparrow}$ packet is generated from a sealed Real row, RegSeqRat rational readback, DyadicRatCore tolerance ledger, Int candidate bracket, Rat Archimedean comparison row, displayed lower and upper bounds, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7897

A Concrete Naming Certificate for $\mathsf{IsoperimetricInequality}^{\uparrow}$

Following Federer–Fleming finite-perimeter geometry, the $\mathsf{IsoperimetricInequality}^{\uparrow}$ packet records the finite polygonal route by which a displayed planar region exposes area, perimeter, convex comparison, and compact containment rows before any inequality consumer may read the classical isoperimetric boundary. It sits over the scalar seal of chapter 38, the metric carrier of chapter 4230, the compact containment surface of chapter 60, the convex membership row of chapter 208, and the finite face ledger of chapter 209. The packet names only polygonal and perimeter ledgers; it does not import measure completion, selected minimizing domains, quotient sets, host Euclidean equality, or classical compactness.

Definition 7897.1 (Isoperimetric inequality carrier)**.** *An* $\mathsf{IsoperimetricInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, M, K, V, Q, A, L, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *scalar surface through which all area, perimeter, and squared-perimeter comparisons are read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row for the displayed planar distance comparisons used by edge lengths and compact containment.*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *row naming the finite containment window for the inspected polygonal region.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *comparison row used for convex hull and support-line checks.*
5. *Q is the* $\mathsf{Polytope}^{\uparrow}$ *row carrying the finite vertex, edge, face, and orientation ledger.*
6. *A is the polygonal area ledger, read as a finite signed triangle sum through R.*
7. *L is the finite perimeter ledger, read as the displayed edge-length sum through M and R.*
8. *B is the isoperimetric budget row comparing the displayed inequality surface L^2 against the area ledger A through finite real comparisons.*
9. *H records componentwise* hsame *transport for the scalar, metric, compact, convex, polytope, area, perimeter, budget, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from vertex and edge rows through area and perimeter ledgers to the budget row.*

11. *P is the* Pkg *provenance over* $\mathsf{IsoperimetricInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{IsoperimetricInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transports. It has no coordinate for completed perimeter measure, selected minimizers, quotient regions, host-set equality, open-cover compactness, or ambient Euclidean integration.

Theorem 7897.2 (Isoperimetric inequality NameCert obligations)**.** *For every accepted* $\mathsf{IsoperimetricInequality}^{\uparrow}$ *carrier* $I = (R, M, K, V, Q, A, L, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IsoperimetricInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real scalar, metric, compact, convex, polytope, polygonal area, finite perimeter, isoperimetric budget, componentwise transport, replay, provenance, and local naming rows. A certificate may replay the finite inequality route, but it cannot read measure completion, a selected minimizing region, quotient equality of domains, host Euclidean equality, open-cover compactness, or an ambient compactness theorem.*

Proof. Project the carrier of Definition 7897.1. The only analytic rows available to a consumer are the scalar row R, metric row M, compact window K, convex comparison row V, polytope ledger Q, area row A, perimeter row L, and budget row B.

Read the polygonal rows first. The polytope ledger supplies the finite vertices, oriented edges, and faces; the compact row bounds the inspected region; the convex row supplies only the displayed comparison checks; and the metric and real rows turn the same edge data into length and scalar comparisons.

Transport and replay then preserve the finite route. The rows H and C move and replay the same polygonal area, perimeter, and budget ledgers, while P and N source and name the packet. Since the forbidden objects have no carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7897.3 (Isoperimetric inequality finite perimeter route)**.** *Every inequality read from an accepted* $\mathsf{IsoperimetricInequality}^{\uparrow}$ *carrier factors through the finite perimeter ledger L and polygonal area ledger A before the budget row B is visible. In particular, the consumer first reads the* $\mathsf{Polytope}^{\uparrow}$ *vertex-edge-face row, the* $\mathsf{Met}^{\uparrow}$ *edge-length row, the* $\mathsf{Real}^{\uparrow}$ *scalar comparison row, the* $\mathsf{Compact}^{\uparrow}$ *containment row, and the* $\mathsf{ConvexSet}^{\uparrow}$ *comparison row; only then may it inspect the displayed isoperimetric budget. The route exports no completed perimeter measure, selected optimizer, quotient region, host plane equality, or classical minimizer principle.*

Proof. Start with the carrier. The row B is downstream of Q, A, L and therefore cannot be read until the finite polytope, area, and perimeter ledgers have been displayed.

The sibling rows supply exactly the required inputs. $\mathsf{Polytope}^{\uparrow}$ gives the finite boundary ledger, $\mathsf{Met}^{\uparrow}$ supplies the edge-length comparisons, $\mathsf{Real}^{\uparrow}$ seals the scalar area and perimeter reads, $\mathsf{Compact}^{\uparrow}$ bounds the inspected region, and $\mathsf{ConvexSet}^{\uparrow}$ records the displayed convex comparison surface.

Finally replay the route through H, C, P, N. These rows preserve and name the same finite data, so the inequality read remains a polygonal finite-perimeter route rather than a measure-completion theorem, a selected minimizer, or an ambient Euclidean principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{IsoperimetricInequality}^{\uparrow}}$**.**

Constructive story: An $\mathsf{IsoperimetricInequality}^{\uparrow}$ packet is generated from real scalar rows, metric edge-length rows, compact containment windows, convex comparison rows, polytope vertex-edge-face ledgers, polygonal area ledgers, finite perimeter ledgers, isoperimetric budget comparisons, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{IsoperimetricInequality}\uparrow}$, seed)

Scope closed: Definition 7897.1, Definition 7897.2, and Definition 7897.3 seed the finite polygonal-perimeter certificate surface over Real, MetricSpace, Compact, ConvexSet, Polytope, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{IsoperimetricInequality}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure completion, selected minimizing domains, quotient regions, host Euclidean equality, open-cover compactness, Lean verification, axiom-purity certification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polygonal area exactness, finite perimeter routing, convex and compact dependency transport, budget replay, provenance, and local naming for BEDC.Derived.IsoperimetricInequalityUp.

Chapter 7898

A Concrete Naming Certificate for EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$ packet records the finite bridge from local epsilon-delta data to Cauchy sequential image data. It sits between the local continuity packet of chapter 3760, the Cauchy image route of chapter 4045, the uniform sequential handoff of chapter 2261, the limit boundary of chapter 3759, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a continuous-map graph, a local radius ledger, source stream windows, image readback, transport, replay, provenance, and local naming; it does not assert host sequential continuity or identify quotient representatives.

Definition 7898.1 (Epsilon-delta sequential continuity bridge carrier)**.** *An* EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, E, S, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* ContinuousMap$^{\uparrow}$ *graph row whose local epsilon-delta reads are consumed.*
2. *E is the epsilon-delta local radius ledger, pairing each displayed target tolerance with the finite source-radius data supplied by* EpsilonDeltaContinuity$^{\uparrow}$*.*
3. *S is the source* StreamName$^{\uparrow}$ *row for the regular Cauchy input stream.*
4. *W is the finite stream-window row that compares source-window entries against the local radius ledger before any image claim is read.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for source and image windows.*
6. *R is the terminal* Real$^{\uparrow}$ *seal row reached only after the image regular-Cauchy readback is displayed.*
7. *H records componentwise* hsame *transport for the graph, radius ledger, source stream, finite windows, readback, Real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from local radius requests through source-window exactness and image readback.*

9. *P is the* Pkg *provenance over* EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$, EpsilonDeltaContinuity$^{\uparrow}$, CauchySequentialContinuity$^{\uparrow}$, UniformSequentialContinuity$^{\uparrow}$, EpsilonDeltaLimit$^{\uparrow}$, ContinuousMap$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{EpsilonDeltaSequentialContinuityBridge}^{\uparrow}}$ *row.*

The classifier accepts the packet only when the same tuple $F, E, S, W, Q, R, H, C, P, N$ supplies the local epsilon-delta read and the Cauchy sequential image handoff.

Theorem 7898.2 (Epsilon-delta sequential continuity bridge obligations)**.** *For the carrier of Definition 7898.1, the local* NameCert$_{\text{EpsilonDeltaSequentialContinuityBridge}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed packet $K = (F, E, S, W, Q, R, H, C, P, N)$;*
2. *radius-window exactness, requiring the local radius ledger E and stream-window row W to be read before any image-window claim is made;*
3. *Cauchy image handoff, requiring the* RegSeqRat$^{\uparrow}$ *readback Q to feed the* CauchySequentialContinuity$^{\uparrow}$ *preservation surface before the* Real$^{\uparrow}$ *seal R is inspected;*
4. *transport and replay through the same componentwise* hsame *row H and displayed* Cont *row C;*
5. *provenance and local naming through P and N.*

No accepted packet contains a row for host function extensionality, selected subsequences, quotient real equality, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7898.1. The graph row F, local radius ledger E, source stream S, finite windows W, readback Q, and Real seal R are explicit coordinates, so a consumer cannot begin from an ambient theorem of sequential continuity.

The bridge order is forced by the rows. The radius ledger E is read against the source windows W before image readback is available. Then Q supplies the regular-rational source and image rows consumed by the Cauchy sequential preservation surface, and R is inspected only after that handoff.

The structural rows keep the same packet throughout the read. Transport H and replay C preserve the graph, ledger, stream, windows, readback, and seal coordinates, while P and N identify the provenance and local name. Since no excluded row is present, the five listed rows exhaust the NameCert surface. □

Falsifiable prediction: Every EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$ read factors a local epsilon-delta radius ledger through finite StreamName windows and RegSeqRat image readback before the terminal Real seal is inspected.

Independence witness: epsilon-delta-continuity, cauchy-sequential-continuity, uniform-sequential-continuity, epsilon-delta-limit, streamname, regseqrat, real: EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a local radius ledger, a source stream, finite bridge windows, image readback, Real seal ordering, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{EpsilonDeltaSequentialContinuityBridge}^{\uparrow}}$.

Constructive story: An EpsilonDeltaSequentialContinuityBridge$^{\uparrow}$ packet is generated from a ContinuousMap graph row, an epsilon-delta local radius ledger, a source StreamName row, finite stream windows, RegSeqRat readback, a Real seal, hsame transport, Cont replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{EpsilonDeltaSequentialContinuityBridge}^{\uparrow}}$, seed)

Scope closed: Definition 7898.1 and Definition 7898.2 seed the finite bridge from local epsilon-delta continuity data to Cauchy sequential image data.

Formal verification: FormalStatus(NameCert$_{\mathsf{EpsilonDeltaSequentialContinuityBridge}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, selected subsequences, quotient real equality, countable choice, trichotomy, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-window exactness, Cauchy image handoff, transport, replay, provenance, and local naming for BEDC.Derived.EpsilonDeltaSequentialContinuityBridgeUp.

Chapter 7899

A Concrete Naming Certificate for $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$

Following Bridson–Haefliger and Burago–Burago–Ivanov on geodesic metric spaces and convex subsets, the $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ packet records the finite BEDC surface on which a displayed geodesic segment remains inside a displayed convex target. It sits over the metric source of chapter 57, the segment witness of chapter 2213, the convex membership carrier of chapter 208, the CAT(0) comparison packet of chapter 6336, and the terminal scalar readback of chapter 38. The packet names only endpoint, segment, convex-target, comparison, transport, replay, provenance, and local naming rows; it does not select global geodesics, quotient paths, ambient closed convex subsets, or real-completeness data.

Definition 7899.1 (Finite geodesic convexity carrier)**.** *A* $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, E, G, V, Z, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the distance observations and endpoint identifiers inspected by the packet.*
2. *E is the endpoint row, recording the two displayed endpoints and their admitted membership in the target convex carrier.*
3. *G is the finite* $\mathsf{GeodesicMetric}^{\uparrow}$ *segment-witness row joining the endpoints through named segment parameters and metric-distance ledgers.*
4. *V is the* $\mathsf{ConvexSet}^{\uparrow}$ *target row, exposing the membership and convex-combination obligations that the inspected segment must respect.*
5. *Z is the comparison ledger, optionally read through* $\mathsf{CATZeroMetric}^{\uparrow}$ *or a sibling metric-convexity packet when a downstream route needs curvature-facing convexity.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for segment parameters, distance budgets, and comparison tolerances; it is terminal and exports no ambient real-completeness principle.*
7. *H records componentwise* hsame *transport for the metric source, endpoints, geodesic witness, convex target, comparison ledger, scalar readback, continuation, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a convexity request through $M, E, G, V, Z, R, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{GeodesicMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CATZeroMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteGeodesicConvexity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, G, V, Z, R, H, C, P, N$. It has no coordinate for a host path space, selected geodesic family, quotient path equality, global convex hull operator, projection selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7899.2 (Finite geodesic convexity NameCert obligations)**.** *For every accepted* $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ *carrier $F = (M, E, G, V, Z, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteGeodesicConvexity}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source, endpoint membership, finite geodesic segment witness, convex target row, comparison ledger, terminal real readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every CAT(0), Hadamard, projection, or Alexandrov consumer must read the finite segment-inside-target route through those rows before using the packet as metric-convexity data.*

Proof. Project the carrier of Definition 7899.1. The metric and endpoint data are exactly M and E, so the packet fixes the inspected source and target endpoints before a segment can be read.

Read the geodesic and convex rows next. The row G supplies the finite segment witness, while V supplies the convex target and membership obligations. The comparison row Z and scalar row R only annotate this same finite segment route with downstream comparison and tolerance data.

Finally inspect the structural rows. Transport through H and replay through C preserve the same metric, endpoint, segment, convex-target, comparison, and scalar rows, while P and N source and name the accepted packet. Since no row stores a host path space, selected geodesic family, quotient path equality, global convex hull operator, projection selector, or ambient real-completeness principle, the displayed rows exhaust the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ consumer that exports a segment-inside-convex-target read without displaying $M, E, G, V, Z, R, H, C, P, N$ refutes the carrier surface.

Independence witness: metric, geodesic-metric, convex-set, cat-zero-metric, real: no listed sibling supplies the whole packet $F = (M, E, G, V, Z, R, H, C, P, N)$, because the siblings contribute only distance observations, segment witnesses, convex membership rows, comparison ledgers, or scalar readback while this chapter binds them into one finite metric-convexity carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteGeodesicConvexity}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteGeodesicConvexity}^{\uparrow}$ packet is generated from a Metric source row, endpoint membership rows, a finite GeodesicMetric segment witness, a ConvexSet target row, a comparison ledger, terminal Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteGeodesicConvexity}^{\uparrow}}$, seed)

Scope closed: Definition 7899.1 and Definition 7899.2 seed the finite segment-inside-convex-target carrier over metric, geodesic, convex, comparison, scalar, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteGeodesicConvexity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected global geodesics, quotient path equality, global convex hull operators, projection existence, CAT(0) comparison theorems, Hadamard projection theorems, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint membership, geodesic segment exactness, convex target exposure, comparison-ledger scope, scalar-readback nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteGeodesicConvexityUp.

Chapter 7900

A Concrete Naming Certificate for $\mathsf{ClaimAuditWitness}^{\uparrow}$

The $\mathsf{ClaimAuditWitness}^{\uparrow}$ packet realizes the witness side of the legitimate-claim audit of chapter 9456 as finite BEDC NameCert data. It sits beside the two-axis closure discipline of chapter 9201, the gap boundary of chapter 1006, the legitimate-claim ledger of chapter 5122, and the claim-audit boundary of chapter 7318. Those siblings classify claim status and refusal boundaries; this packet records the particular witness row that lets a reader audit one claim without promoting missing support into theorem content.

Definition 7900.1 (Claim audit witness carrier)**.** *A* $\mathsf{ClaimAuditWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (Q, O, T, F, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the claim-text row, recording the finite statement being audited.*
2. *O is the cited-object row, naming the theorem, definition, closure block, carrier, or refusal boundary that the claim cites.*
3. *T is the closure-axis token row, recording the displayed theory-closure token attached to the cited object.*
4. *F is the formal-status token row, recording the displayed verification token attached to the cited object.*
5. *R is the off-table refusal row, recording the boundary exposed when Q asks for a closure or verification status not displayed by T and F.*
6. *H records componentwise* hsame *transport for claim text, cited object, closure token, formal token, refusal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from claim admission through cited-object lookup, two-axis token readback, refusal exposure, and permitted witness publication.*
8. *P is the* Pkg *provenance over* $\mathsf{ClaimAuditWitness}^{\uparrow}$, $\mathsf{LegitimateClaimAuditLedger}^{\uparrow}$, $\mathsf{ClaimAuditBoundary}^{\uparrow}$, $\mathsf{GapClosureBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ClaimAuditWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, O, T, F, R, H, C, P, N$. It has no coordinate for a global truth predicate, hidden marker resolution, off-table verification, or claim strength beyond the displayed theory and formal tokens.

Theorem 7900.2 (Claim audit witness NameCert obligations)**.** *For every accepted* $\mathsf{ClaimAuditWitness}^{\uparrow}$ *carrier* $W = (Q, O, T, F, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ClaimAuditWitness}^{\uparrow}}$ *surface consists exactly of claim-text admission, cited-object readback, closure-axis token readback, formal-status token readback, off-table refusal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7900.1. The rows Q, O, T, F display the claim, the cited object, and the two tokens that license what may be said about the object.

If the claim asks for a status not displayed by T and F, the row R is exposed before publication. Thus a missing bridge, missing Lean theorem, or missing closure grade remains a refusal row rather than becoming theorem content.

The rows H, C, P, N preserve the witness under transport, replay, provenance, and local naming. Since the carrier has no hidden truth predicate, marker resolver, off-table verification row, or stronger claim coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7900.3 (Claim audit witness two-axis nonescape)**.** *Every accepted* $\mathsf{ClaimAuditWitness}^{\uparrow}$ *read factors a claim through the displayed route*

$$Q, O, T, F, R, H, C, P, N.$$

Consequently a consumer may publish only the closure and verification strength displayed by T and F; if stronger support is requested, the consumer must expose R as a refusal row before the claim can be read.

Proof. Start from Definition 7900.2. The cited object O is not read alone: it is paired with the theory token T and the formal token F inside the same finite packet.

The refusal row R handles off-table requests. When Q asks for public closure, bridge checking, theorem status, or object truth not displayed by the two tokens, the replay route C sends the request to R rather than to a hidden proof source.

Finally H, P, N transport, package, and name the same distinction. They cannot raise either axis, discharge a missing bridge, or resolve a marker not displayed by the packet. □

Falsifiable prediction: If a claim-audit read publishes a stronger closure or verification status than the displayed rows T and F while omitting the refusal row R, it is not a $\mathsf{ClaimAuditWitness}^{\uparrow}$ packet.

Independence witness: legitimate-claim-audit-ledger, claim-audit-boundary, gapclosureboundary: none is bijective to $\mathsf{ClaimAuditWitness}^{\uparrow}$ because the ledger records claim status, the boundary records permitted publication, and the gap boundary records refusal routes, while this packet jointly carries one claim text, one cited object, two-axis tokens, an off-table refusal row, transport, replay, provenance, and local naming.

The future TasteGate file for lean4/BEDC/Derived/ClaimAuditWitnessUp must supply explicit Nontrivial $\mathsf{ClaimAuditWitness}^{\uparrow}$ and FieldFaithful $\mathsf{ClaimAuditWitness}^{\uparrow}$ instances. The field-faithfulness witness must keep $Q, O, T, F, R, H, C, P, N$ distinct, so claim text, cited object, theory token, formal token, and refusal exposure cannot collapse.

Closure status for $\mathsf{NameCert}_{\mathsf{ClaimAuditWitness}^{\uparrow}}$**.**

Constructive story: A ClaimAuditWitness$^{\uparrow}$ packet is generated from claim text, cited object, theory-closure token, formal-status token, off-table refusal, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{ClaimAuditWitness}\uparrow}$, seed)

Scope closed: Definition 7900.1, Definition 7900.2, and Definition 7900.3 seed the finite witness surface for two-axis legitimate-claim audits.

Formal verification: FormalStatus(NameCert$_{\text{ClaimAuditWitness}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global truth, registry-wide claim correctness, Lean marker resolution, bridge checking, or any closure or verification status beyond the displayed packet rows.

Upgrade path: Obligation closure requires checked carrier admission, cited-object readback, two-axis token readback, refusal exposure, transport, replay, provenance, local naming, and TasteGate field faithfulness for BEDC.Derived.ClaimAuditWitnessUp.

Chapter 7901

A Concrete Naming Certificate for $\mathsf{PretopologicalSpace}^{\uparrow}$

Following Bourbaki and Kelley, a pretopological space is the neighbourhood-interface presentation obtained before open-set closure laws are imposed as a full topology. The $\mathsf{PretopologicalSpace}^{\uparrow}$ packet sits between the indexed open carrier of chapter 88, the pointwise neighbourhood rows of chapter 7753, and the prefix-sensitive neighbourhood read of chapter 2336. It records finite local neighbourhood, closure, interior, transport, replay, provenance, and naming rows without forcing a host powerset of opens, quotient equality of neighbourhood filters, selected limits, or ambient topological equivalence.

Definition 7901.1 (PretopologicalSpace carrier)**.** *A* $\mathsf{PretopologicalSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (X, N, C, I, H, R, Q, L)$$

with the following displayed rows:

1. *X is the point row, naming the displayed carrier points and the classifier used to compare point observations.*
2. *N is the neighbourhood-system row, recording the finite neighbourhood tokens around each displayed point and their pointwise containment requests.*
3. *C is the closure readback row, recording which displayed point lies in the closure of a displayed finite neighbourhood observation.*
4. *I is the interior readback row, recording which displayed point is accepted by a finite interior observation.*
5. *H records componentwise* hsame *transport for point rows, neighbourhood tokens, closure readbacks, interior readbacks, replay rows, provenance rows, and local naming rows.*
6. *R records displayed* Cont *replay from a local neighbourhood request through X, N, C, I.*
7. *Q is the* Pkg *provenance over* $\mathsf{PretopologicalSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{NeighbourhoodSystem}^{\uparrow}$, $\mathsf{NeighborhoodFunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{PretopologicalSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, N, C, I, H, R, Q, L. It has no coordinate for full open-set topology laws, host powersets of opens or neighbourhoods, quotient equality of filters, selected limit points, countable choice, or ambient equality of topology structures.

Theorem 7901.2 (PretopologicalSpace NameCert obligations)**.** *For every accepted* $\mathsf{PretopologicalSpace}^{\uparrow}$ *carrier* $P = (X, N, C, I, H, R, Q, L)$*, the local* $\mathsf{NameCert}_{\mathsf{PretopologicalSpace}^{\uparrow}}$ *surface consists exactly of point-row exposure, neighbourhood-system exposure, closure readback, interior readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every topology-facing or neighbourhood-facing consumer must display*

$$X, N \longmapsto C, I, H, R, Q, L$$

before it may inspect closure, interior, or local neighbourhood data.

Proof. Project the carrier of Definition 7901.1. The accepted packet exposes exactly the rows X, N, C, I, H, R, Q, L, with no separate row for a host topology, powerset of opens, quotient filter, selected limit, or countable-choice schedule.

The local rows are read first. The point row X fixes the displayed classifier, and the neighbourhood-system row N supplies the finite pointwise neighbourhood tokens inherited from the neighbourhood presentation.

The readback rows are then confined to the same finite surface. Closure and interior observations are recorded by C and I, while H, R, Q, L transport, replay, source, and name the packet. Hence the local certificate obligations are exhausted by the displayed rows. □

Theorem 7901.3 (PretopologicalSpace neighbourhood transport)**.** *Every neighbourhood, closure, or interior read of an accepted* $\mathsf{PretopologicalSpace}^{\uparrow}$ *packet transports only through the route*

$$\mathsf{Topology}^{\uparrow}, \mathsf{NeighbourhoodSystem}^{\uparrow}, \mathsf{NeighborhoodFunction}^{\uparrow} \longmapsto \mathsf{PretopologicalSpace}^{\uparrow}.$$

The route preserves point-row identity, finite neighbourhood tokens, closure readback, interior readback, displayed hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. It does not export full topology laws, host powersets of opens, quotient neighbourhood filters, selected limits, countable choice, or ambient topological equality.*

Proof. Start with the topology side. The indexed-open interface of chapter 88 supplies open-index membership and classifier transport, but the pretopological packet reads only the neighbourhood-facing consequences needed for N, C, I.

Read the pointwise neighbourhood surface next. The finite neighbourhood rows of chapter 7753 provide the local tokens, and the finite-observation discipline of chapter 2336 supplies the prefix-sensitive replay pattern for neighbourhood requests.

Finally apply the carrier inventory. Transport by H, replay by R, provenance by Q, and naming by L preserve the same rows and add no coordinate for full open-set topology laws, host powersets, quotient filters, selected limits, choice, or ambient topology equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{PretopologicalSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PretopologicalSpace}^{\uparrow}$ packet is generated from a point row, neighbourhood-system row, closure readback row, interior readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PretopologicalSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7901.1, Definition 7901.2, and Definition 7901.3 seed the neighbourhood-interface carrier between Topology, NeighbourhoodSystem, and NeighborhoodFunction rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PretopologicalSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full open-set topology laws, quotient equality of neighbourhood filters, selected limits, countable choice, ambient topology equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked point exposure, neighbourhood-system exposure, closure and interior readback, neighbourhood transport, replay, provenance, and local naming for BEDC.Derived.PretopologicalSpaceUp.

Chapter 7902

A Concrete Naming Certificate for $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$

Following Bishop and Bridges' constructive diagonal arguments for complete metric data, the $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$ packet names the finite extraction surface used before a diagonal-limit consumer reaches a $\mathsf{Real}^{\uparrow}$ seal. It sits after the dyadic tolerance carrier of chapter 291, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the real-name seal of chapter 38, and the selection-free diagonal route of chapter 4080. The packet records diagonal extraction through displayed finite rows; it is not a selected representative, not countable choice, not open-cover compactness, not a quotient stream, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7902.1 (Finite net diagonal extraction carrier)**.** *A* $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (G, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite net-row ledger. Each row records the inspected net stage, its finite entries, and the diagonal index selected from displayed finite data.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger whose finite windows read the entries of G needed by the diagonal row.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row governing the error allowed for each displayed net row and diagonal comparison.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the finite windows and dyadic tolerance budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after G, W, D, R have been displayed.*
6. *H records componentwise* hsame *transport for the net-row ledger, window ledger, tolerance budget, readback, seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a diagonal request through G, W, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows. It has no coordinate for selected representatives, countable choice, open-cover compactness, quotient streams, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7902.2 (Finite net diagonal extraction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$ *carrier*

$$F = (G, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite net rows, StreamName windows, DyadicRatCore tolerance budget, RegSeqRat readback, Real seal, transport, continuation, provenance, and local naming; classifier stability under the componentwise* hsame *rows; route exactness from* G, W, D, R *to* E*; and refusal rows excluding selected representatives, countable choice, open-cover compactness, quotient streams, host real equality, and ambient completeness.*

Proof. Project the carrier of Definition 7902.1. The projection exposes only the finite net-row ledger, finite windows, dyadic tolerance budget, regular readback, Real seal, transport, continuation, provenance, and local naming rows.

Classifier stability is componentwise. The rows in H transport G, W, D, R, E and the administrative rows C, P, N to a common finite comparison surface.

Route exactness is read from the continuation row C. A diagonal request first displays the net rows G, then the finite StreamName windows W, then the DyadicRatCore tolerance row D, then the RegSeqRat readback R, and only then the Real seal E.

The refusal rows are exhausted by the carrier inventory. Since no listed row contains selected representatives, countable choice, open-cover compactness, quotient streams, host equality, or ambient completeness, no local NameCert obligation can export those objects. □

Theorem 7902.3 (Finite net diagonal extraction window route)**.** *Every diagonal-limit consumer of an accepted* $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$ *carrier must read the route*

$$G, W, D, R, E, H, C, P, N$$

before consuming the $\mathsf{Real}^{\uparrow}$ *seal. Thus the diagonal extraction passes through displayed finite net rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budgets,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}}$ *row.*

No selected representative, countable-choice schedule, open-cover compactness row, quotient stream, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle may replace this finite route.*

Proof. Start with the carrier projection. The terminal $\mathsf{Real}^{\uparrow}$ seal is the row E, and it appears only after G, W, D, R in the displayed packet.

Replay the continuation row. Its route takes a diagonal request through the finite net-row ledger, then through the StreamName windows, the dyadic tolerance budget, and the RegSeqRat readback before the seal row is visible.

Transport and provenance do not add another seal. The row H moves only the displayed coordinates, while P and N record provenance and local naming for the same finite packet.

Consequently every diagonal-limit consumer reaches $\mathsf{Real}^{\uparrow}$ through the displayed finite route. Since the carrier has no coordinate for selected representatives, countable choice, open-cover compactness, quotient streams, host equality, or ambient completeness, none can replace the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteNetDiagonalExtraction}^{\uparrow}$ packet is generated from finite net rows, StreamName windows, a DyadicRatCore tolerance budget, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\mathsf{FiniteNetDiagonalExtraction}\uparrow}$, seed)

Scope closed: Definition 7902.1, Definition 7902.2, and Definition 7902.3 seed the finite diagonal-extraction route over net rows, finite windows, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteNetDiagonalExtraction}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected representatives, countable choice, open-cover compactness, quotient streams, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite net-row exposure, StreamName window stability, DyadicRatCore tolerance accounting, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteNetDiagonalExtractionUp.

Chapter 7903

A Concrete Naming Certificate for $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completion, the $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$ packet realizes the finite budget route used by the diagonal-limit construction of section 9238.1. It binds precision requests to finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budgets, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal from chapter 126, chapter 291, chapter 301, and chapter 38. The packet is a finite precision-to-window-to-readback-to-seal carrier; it is not a quotient stream, not a selected limit, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7903.1 (Real completion diagonal budget carrier)**.** *A* $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the precision-request row naming the diagonal index and requested regular-Cauchy tolerance.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the requested diagonal index.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row that accounts for the endpoint, middle-modulus, and readback error allowances.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the window and tolerance budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row consumed only after Q, W, D, R are displayed.*
6. *H records componentwise* hsame *transport for the precision, window, tolerance, readback, seal, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a diagonal-limit request through Q, W, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalBudget}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting the displayed precision, window, tolerance, readback, Real seal, continuation, provenance, and local naming rows to a common finite surface.

Theorem 7903.2 (Real completion diagonal budget NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$ *carrier*

$$B = (Q, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalBudget}^{\uparrow}}$ *surface consists exactly of carrier admission for the precision request, StreamName window, DyadicRatCore budget, RegSeqRat readback, Real seal, transport, continuation, provenance, and local naming; classifier stability under the displayed* hsame *rows; route exactness from* Q, W, D, R *to* E*; and refusal rows excluding quotient streams, selected limits, countable choice, host real equality, open-cover compactness, and ambient completeness.*

Proof. Project the carrier of Definition 7903.1. The listed coordinates are exactly the precision request, finite window, dyadic budget, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Classifier stability is componentwise. Transport through H moves those rows to a common finite surface without adding another representative or quotient coordinate.

Route exactness follows from C. A diagonal-limit request first exposes the precision row Q, then the finite window W, then the dyadic tolerance budget D, then the regular readback R, and only then the Real seal E.

The refusal rows are not extra data. They state that no coordinate of the packet contains quotient streams, selected limits, countable choice, host equality, open-cover compactness, or ambient completeness, so no NameCert obligation can export them. □

Theorem 7903.3 (Real completion diagonal budget vision route)**.** *The diagonal-limit representative of Definition 9238.3 is consumed through an accepted* $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$ *carrier only by the route*

$$Q, W, D, R, E, H, C, P, N.$$

Thus the real-completion vision route factors each precision request through a finite $\mathsf{StreamName}^{\uparrow}$ *window, a* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalBudget}^{\uparrow}}$ *naming.*

No quotient stream, selected limit, countable-choice schedule, host real equality, open-cover compactness row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle may replace this finite budget route.*

Proof. Start from the source vision section section 9238.1. Its diagonal representative uses a requested precision to choose a displayed diagonal readback; the carrier records that request as Q.

Replay the finite route. The request opens the StreamName window W, spends the DyadicRatCore budget D, reads the RegSeqRat row R, and only then reaches the Real seal E.

Transport, replay, provenance, and naming stay local to the same packet. The rows H, C, P, N preserve and name the displayed route rather than adding a second completion principle.

Therefore the vision route lands as finite NameCert data. Since the carrier has no quotient stream, selected limit, countable-choice schedule, host equality, open-cover compactness row, or ambient completeness coordinate, none can replace the finite diagonal budget. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionDiagonalBudget}^{\uparrow}$ packet is generated from a precision request, StreamName window, DyadicRatCore tolerance budget, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletionDiagonalBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7903.1, Definition 7903.2, and Definition 7903.3 seed the finite real-completion diagonal-budget route.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealCompletionDiagonalBudget}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, host real equality, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked precision requests, StreamName window stability, DyadicRatCore budget accounting, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionDiagonalBudgetUp.

Chapter 7904

Metric Completion Unit NameCert Construction

Following Bishop and Bridges constructive completion theory, the $\mathsf{MetricCompletionUnit}^{\uparrow}$ packet records the unit map that sends a displayed metric point into its completion by the constant regular name. It sits between the metric completion carrier of chapter 1506, the Cauchy-completion adjunction of chapter 1456, the stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the completion unit as finite NameCert data, not as an ambient embedding into a preexisting completed object.

Definition 7904.1 (Metric completion unit carrier)**.** *A* $\mathsf{MetricCompletionUnit}^{\uparrow}$ *carrier is a finite packet*

$$U = (X, x, S, R, T, E, H, C, P, N)$$

with the following rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *carrier and x is the displayed source-point history.*
2. *S is the constant* $\mathsf{StreamName}^{\uparrow}$ *row repeatedly exposing x at each precision request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff certifying the constant stream as a regular rational Cauchy name.*
4. *T is the target* $\mathsf{MetricCompletion}^{\uparrow}$ *row receiving that regular name.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *and metric seal row comparing source distances with the completed endpoint.*
6. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionUnit}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient Cauchy classes, selected limits, ambient completion equality, or a host embedding function.

Theorem 7904.2 (Metric completion unit NameCert obligations)**.** *Every accepted* $\mathsf{MetricCompletionUnit}^{\uparrow}$ *carrier $U = (X, x, S, R, T, E, H, C, P, N)$ exposes the source metric point, constant stream row, regular-sequence handoff, completion target row, metric-real seal, transport, replay, provenance, and local naming rows before any completion-unit consumer reads the completed endpoint. The consumer cannot replace these rows by an ambient dense embedding, a quotient class of Cauchy names, a selected limit, or host equality in the completion.*

Proof. Project the carrier rows of Definition 7904.1. The only source data are the metric carrier X and point history x, and the only completion-facing source is the constant $\mathsf{StreamName}^{\uparrow}$ row S.

Read the regular handoff and target rows. The row R certifies the constant stream as a regular rational name, while T records that same name as a $\mathsf{MetricCompletion}^{\uparrow}$ target; the seal row E is therefore downstream of the displayed stream and regular-sequence data.

Finally apply the structural rows H, C, P, N. They replay exactly the same route under hsame and Cont, record provenance, and name the local certificate, so no quotient class, selected limit, ambient embedding, or host equality coordinate is available. □

Theorem 7904.3 (Metric completion unit real handoff)**.** *For every accepted* $\mathsf{MetricCompletionUnit}^{\uparrow}$ *carrier* $U = (X, x, S, R, T, E, H, C, P, N)$*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E *may be read only after the constant* $\mathsf{StreamName}^{\uparrow}$ *row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, and the* $\mathsf{MetricCompletion}^{\uparrow}$ *target row have been exposed. The handoff is the finite constant-name route from the source metric point to the completed endpoint; it is not an appeal to ambient real completeness or an external limit operation.*

Proof. Start with the constant stream row S. It repeats the displayed source point history, so every later precision request remains tied to the same metric source row.

Next read the regular rational handoff R and the completion target row T. These rows certify the constant stream as a regular name and then as the completion endpoint named by the packet.

The seal row E is projected only after those rows. Since H, C, P, N merely transport and replay the displayed route, the $\mathsf{Real}^{\uparrow}$ handoff cannot be replaced by an external completion map, a selected Cauchy-class representative, or ambient real completeness. □

Independence witness: metriccompletion, cauchy-completion-adjunction, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{MetricCompletionUnit}^{\uparrow}$ because this packet jointly carries a source metric point, constant stream name, regular handoff, completion target, real seal, transport, replay, provenance, and local naming as one finite unit-map surface.

Chapter 7905

Compact Uniform Radius Selector NameCert Construction

Following Heine–Cantor compact-uniform-continuity practice in Bishop–Bridges constructive analysis, the $\mathsf{CompactUniformRadiusSelector}^{\uparrow}$ packet names the finite lower-bound selector that turns compact local-radius data into a tolerance-only uniform-radius row. It realizes the radius-selection branch of chapter 9237 beside the compact metric source of chapter 129, the continuous-map rows of chapter 130, the uniform-modulus consumer of chapter 369, the rational lower-bound ledger of chapter 37, and the metric-space distance surface of chapter 4230. The packet records finite ProbeBundle data only; it is not an open-cover compactness theorem, an external choice of radii, or a host modulus function.

Definition 7905.1 (Compact uniform radius selector carrier)**.** *A* $\mathsf{CompactUniformRadiusSelector}^{\uparrow}$ *carrier is a finite packet*

$$R = (K, F, B, L, U, T, H, C, P, N)$$

whose rows have the following roles:

1. K *is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source over the same metric carrier used by the consumer.*
2. F *is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-radius source exposing local radii for the requested tolerance.*
3. B *is the finite* ProbeBundle *row of compact centers and source coverage witnesses.*
4. L *is the* $\mathsf{Rat}^{\uparrow}$ *positive lower-bound fold over the bundled local radii.*
5. U *is the* $\mathsf{UniformModulus}^{\uparrow}$ *target row receiving the selected radius.*
6. T *is the* $\mathsf{Met}^{\uparrow}$ *triangle and distance-transport row used to move from center radii to arbitrary source points.*
7. H, C, P, N *are componentwise* hsame *transport, displayed* Cont *replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{CompactUniformRadiusSelector}^{\uparrow}}$ *row.*

The carrier has no coordinate for selected subcovers, countable choice, host infima over radii, quotient maps, or an external modulus selector.

Theorem 7905.2 (Compact uniform radius selector NameCert obligations)**.** *Every accepted* CompactUniformRadiu *carrier* $R = (K, F, B, L, U, T, H, C, P, N)$ *exposes the compact metric finite-net row, continuous pointwise-radius row, finite ProbeBundle coverage row, rational lower-bound fold, uniform-modulus target, metric triangle transport,* hsame *transport,* Cont *replay, provenance, and local naming rows*

before a compact-uniform-continuity consumer reads a selected radius. The selection cannot be replaced by an ambient infimum, an unrestricted open-cover argument, countable choice, selected representatives, or a host modulus function.

Proof. Project the carrier of Definition 7905.1. The compact source K, pointwise-radius source F, and finite bundle B are the only rows from which a radius-selection consumer may start.

Read the lower-bound and target rows next. The rational fold L is built over the finite bundle and supplies the radius consumed by the $\mathsf{UniformModulus}^{\uparrow}$ row U, while the metric row T provides the triangle transport needed for arbitrary source points.

Finally apply the structural rows H, C, P, N. They replay the same finite route under transport and provenance, so no ambient infimum, open-cover compactness principle, countable choice, selected representative, or host modulus coordinate is exposed. □

Theorem 7905.3 (Compact uniform radius selector vision handoff)**.** *The finite lower-bound fold used in chapter 9237 is realized by the* $\mathsf{CompactUniformRadiusSelector}^{\uparrow}$ *route*

$$K, F, B, L \longmapsto U, T, H, C, P, N.$$

Thus the compact-uniform-continuity consumer reads a radius through compact finite-net data, continuous pointwise-radius data, a finite ProbeBundle *fold, rational positivity, metric triangle transport, and local NameCert rows, rather than through a host proof that a positive minimum of radii exists.*

Proof. Begin with the compact finite-net and pointwise-radius rows. They supply the bundled centers and local radii that the compact-uniform-continuity construction needs before any global radius is visible.

Use the finite lower-bound fold row L. Because the fold is carried by the displayed ProbeBundle and $\mathsf{Rat}^{\uparrow}$ positivity data, the selected radius is a named history, not an external minimum or choice.

Transport the selected row through U, T, H, C, P, N. The uniform-modulus target receives the radius only after metric triangle transport and structural replay, so the vision's lower-bound step is a concrete NameCert route. □

Independence witness: compactmetric, continuousmap, uniformmodulus, rat, metric-space: no listed sibling is bijective to $\mathsf{CompactUniformRadiusSelector}^{\uparrow}$ because this packet jointly carries compact finite-net data, pointwise-radius rows, finite ProbeBundle lower-bound folding, UniformModulus handoff, metric triangle transport, replay, provenance, and local naming.

Chapter 7906

Located Dyadic Apartness Window NameCert Construction

Following Bishop and Bridges-style constructive real analysis, the $\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}$ packet records the finite dyadic window in which two regular real names are witnessed apart before a Real-facing comparison may be consumed. It sits over the dyadic endpoint arithmetic of chapter 291, the finite observation rows of chapter 126, the regular rational readback of chapter 301, the terminal seal of chapter 38, and the located apartness surface of chapter 6450. The packet supplies a constructive comparison window for Real and Completion routes without importing trichotomy, quotient Real equality, or ambient completeness.

Definition 7906.1 (Located dyadic apartness window carrier)**.** *A* $\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (L, U, S_0, S_1, R_0, R_1, G, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the finite lower-endpoint history in* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording the dyadic lower cells inspected for the two regular names.*
2. *U is the finite upper-endpoint history in* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording the matching upper cells and the endpoint-order ledger used by the window.*
3. *S_0 and S_1 are the two* $\mathsf{StreamName}^{\uparrow}$ *observation windows opened at the displayed dyadic precision.*
4. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for those windows.*
5. *G is a positive dyadic gap row proving that the displayed lower and upper endpoint histories are separated before the terminal Real seal is read.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It is consumed only after $L, U, S_0, S_1, R_0, R_1, G$ have already been displayed.*
7. *H stores componentwise* hsame *transport for endpoints, stream windows, readback rows, gap ledger, seal, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay through the same finite endpoint and readback route.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LocatedRealApartness}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}}$ *row.*
The carrier has no coordinate for trichotomy, quotient Real equality, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Theorem 7906.2 (Located dyadic apartness window stability)**.** *For every accepted* LocatedDyadicApartnessWindow *carrier*

$$W = (L, U, S_0, S_1, R_0, R_1, G, E, H, C, P, N),$$

componentwise hsame *transport of the dyadic endpoint histories, stream observations, regular rational readbacks, positive dyadic gap ledger, and terminal Real seal preserves the same located apartness window. Consequently every Real or Completion consumer receives the transported finite window through* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows, not through trichotomy, quotient Real equality, selected representatives, countable choice, or ambient completeness.*

Proof. Project the carrier of Definition 7906.1. The only analytic rows are the dyadic endpoint histories L, U, the finite stream windows S_0, S_1, the regular rational readbacks R_0, R_1, the positive gap ledger G, and the terminal Real seal E.

Transport first applies to the endpoint histories. Componentwise hsame sends the displayed lower and upper dyadic cells to transported endpoint histories while preserving the endpoint-order ledger carried by L, U.

Transport then applies to the observation and readback rows. The windows S_0, S_1 and readbacks R_0, R_1 remain attached to the same dyadic precision because the replay row C follows the displayed $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ route.

Finally transport preserves the positive dyadic gap row G and the terminal seal E. The gap is still read before the Real seal, and the provenance and local naming rows P, N name exactly that transported packet. Since no row contains trichotomy, quotient Real equality, selected representatives, countable choice, or ambient completeness, the transported window exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}$ packet is generated from finite dyadic lower and upper endpoint histories, paired StreamName windows, RegSeqRat readbacks, a positive dyadic gap ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}}$, seed)

Scope closed: Definition 7906.1 and Definition 7906.2 seed the finite located dyadic apartness window route from endpoint histories through stream and regular-rational readback to the Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedDyadicApartnessWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient Real equality, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order exactness, paired-window readback, positive dyadic gap preservation, Real seal nonescape, transport and replay stability, and exclusion coverage for BEDC.Derived.LocatedDyadicApartnessWindowUp.

Chapter 7907

A Concrete Naming Certificate for $\mathsf{LipschitzBanach}^{\uparrow}$

Following Weaver and Heinonen on Lipschitz functions, the $\mathsf{LipschitzBanach}^{\uparrow}$ packet records the completion-facing surface for a bounded family of real-valued Lipschitz maps whose shared Lipschitz control and uniform Cauchy ledger are displayed before any complete function-space read is public. It sits after the Lipschitz function-space row of chapter 7502, the uniform limit boundary of chapter 463, and the terminal real-name route of chapter 38; it also consumes the finite-window and regular-rational completion spine supplied by $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$. The packet names a complete Lipschitz function-space handoff as finite BEDC data, not as a quotient function space or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7907.1 (LipschitzBanach carrier)**.** *A* $\mathsf{LipschitzBanach}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, F, K, U, V, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LipschitzSpace}^{\uparrow}$ *row, exposing the metric-domain, real-valued graph, and Lipschitz-inequality surface before any function-space consumer reads the packet.*
2. *F is the bounded Real-valued map family row, listing the inspected maps and their finite value bounds as* $\mathsf{Real}^{\uparrow}$*-facing data.*
3. *K is the shared* $\mathsf{LipschitzConstant}^{\uparrow}$ *row used by every listed map in F.*
4. *U is the uniformly Cauchy ledger for the family, recording finite tolerance windows and pairwise comparison budgets without selecting a limit function.*
5. *V is the* $\mathsf{UniformLimit}^{\uparrow}$ *row, available only after F, K, U have been displayed.*
6. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row for the displayed function-space metric boundary, read as a completion-facing obligation surface rather than as host Banach-space completeness.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected indices, source probes, value probes, and tolerance requests.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and comparison budgets.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for displayed values and norms, reached only after S, R, U, V have been consumed.*

10. *H records componentwise* hsame *transport for the Lipschitz-space, bounded-family, shared-constant, uniform-Cauchy, uniform-limit, complete-metric, stream-window, regular-readback, real-seal, replay, provenance, and local-name rows.*
11. *C records displayed* Cont *replay from a finite function-space request through $L, F, K, U, V, M, S, R, E$.*
12. *P is the* Pkg *provenance over* $\mathsf{LipschitzBanach}^{\uparrow}$, $\mathsf{LipschitzSpace}^{\uparrow}$, $\mathsf{LipschitzConstant}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzBanach}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, F, K, U, V, M, S, R, E, H, C, P, N$. It has no coordinate for host Banach-space completeness, quotient equality of functions, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a hidden complete function-space object.*

Theorem 7907.2 (LipschitzBanach NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzBanach}^{\uparrow}$ *carrier $B = (L, F, K, U, V, M, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LipschitzBanach}^{\uparrow}}$ *surface consists exactly of carrier admission for the LipschitzSpace row, bounded Real-valued map family row, shared Lipschitz constant row, uniformly Cauchy ledger, UniformLimit row, CompleteMetric row, StreamName windows, RegSeqRat readback, Real seal, componentwise transport, displayed continuation replay, package provenance, and local naming. The obligations require the same shared constant K to control every listed map, the uniform Cauchy ledger U to be displayed before the uniform-limit row V, the StreamName and RegSeqRat rows S, R to account for the finite value and norm windows, and the Real seal E to remain downstream of those rows.*

Proof. Project the accepted carrier. Its analytic rows are $L, F, K, U, V, M, S, R, E$, and its structural rows are H, C, P, N.

The Lipschitz route starts with L, F, K. The LipschitzSpace row supplies the displayed graph and inequality surface, the bounded family row lists the inspected maps and value bounds, and the shared Lipschitz row is read once for every listed member.

The completion-facing route then uses U, V, M. The uniformly Cauchy ledger records finite pairwise comparison budgets, the UniformLimit row is exposed only after those budgets are visible, and the CompleteMetric row names the displayed metric boundary without importing a host Banach-space theorem.

Finally S, R, E, H, C, P, N keep the read inside finite BEDC data. Since no carrier coordinate stores quotient equality of functions, a selected limit, countable choice, ambient Real completeness, or a hidden complete function space, the listed rows exhaust the local NameCert surface. □

Theorem 7907.3 (LipschitzBanach complete uniform-limit route)**.** *Every completion-facing consumer of an accepted* $\mathsf{LipschitzBanach}^{\uparrow}$ *packet must factor through*

$$\mathsf{LipschitzSpace}^{\uparrow},\quad \mathsf{LipschitzConstant}^{\uparrow},\quad \mathsf{UniformLimit}^{\uparrow},\quad \mathsf{CompleteMetric}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

The route supplies a bounded Real-valued map family, one shared Lipschitz constant, a uniformly Cauchy ledger, finite value and norm windows, regular rational readback, and terminal Real seals before any complete uniform-limit handoff is public. It exports no host Banach-space completeness, quotient equality of functions, selected limit, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or unledgered function-space metric.*

Proof. Begin with the obligation theorem Definition 7907.2. It makes the LipschitzSpace row, bounded-family row, shared constant, uniformly Cauchy ledger, UniformLimit row, and CompleteMetric row visible carrier data.

Read the sibling routes in order. The LipschitzSpace surface of chapter 7502 supplies the function-space graph and inequality rows, while chapter 463 is reached only after the uniform Cauchy ledger has been displayed.

The Real and Completion handoff is finite. The StreamName windows and RegSeqRat readback feed the terminal Real seal of chapter 38, and the CompleteMetric row records only the displayed completion-facing metric boundary.

Transport, replay, provenance, and local naming preserve that same route. Therefore every complete uniform-limit consumer receives the listed finite packet and no quotient function-space equality, selected limit, countable-choice object, host Banach-space completeness theorem, or ambient Real completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzBanach}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzBanach}^{\uparrow}$ packet is generated from a LipschitzSpace row, bounded Real-valued map family row, shared Lipschitz constant row, uniformly Cauchy ledger, UniformLimit row, CompleteMetric row, StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzBanach}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7907.1, Definition 7907.2, and Definition 7907.3 seed the finite complete Lipschitz function-space packet over shared Lipschitz control, uniform Cauchy data, uniform-limit handoff, completion boundary, finite windows, regular readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzBanach}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host Banach-space completeness, quotient equality of functions, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared Lipschitz exactness, uniformly Cauchy ledger exactness, uniform-limit ordering, complete-metric boundary, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzBanachUp.

Chapter 7908

A Concrete Naming Certificate for $\mathsf{LocatedCompletionMonad}^{\uparrow}$

Following Bishop and Bridges and Mac Lane, the $\mathsf{LocatedCompletionMonad}^{\uparrow}$ packet records the finite naming certificate by which located completion routes compose through unit and join rows. It sits after the located completion surface of chapter 4150, the Cauchy completion monad of chapter 378, the monad-law ledger of chapter 3834, the StreamName windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the Real seal boundary of chapter 38. The packet is a displayed NameCert for composing located completion data; it is not a quotient completion, a selected limit, a countable-choice schedule, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7908.1 (Located completion monad carrier)**.** *A* $\mathsf{LocatedCompletionMonad}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, M, U, J, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCompletion}^{\uparrow}$ *source row, including the displayed located-completion route consumed before any monad operation is public.*
2. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row naming the finite completion transformer and its schedule discipline.*
3. *U is the unit row, sending source located data to the completion-facing packet through displayed windows and regular rational readback.*
4. *J is the join row, flattening a completion-of-completion read by replaying the same located completion and Cauchy-completion schedules.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used by both unit and join reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling requested precision, located comparison, and replay.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, M, U, J, S, R, D have been displayed.*
9. *H records componentwise* hsame *transport for the located completion, monad, unit, join, stream, readback, dyadic, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *routes from a completion request through the same ordered rows.*
11. *P is the* Pkg *provenance over* LocatedCompletionMonad$^{\uparrow}$, LocatedCompletion$^{\uparrow}$, CauchyCompletionMonad$^{\uparrow}$, CauchyCompletionMonadLaw$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{LocatedCompletionMonad}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, M, U, J, S, R, D, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, host equality of completed points, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.LocatedCompletionMonadUp.LocatedCompletionMonadTasteGate single carrier alignment`

Theorem 7908.2 (Located completion monad NameCert obligations)**.** *For every accepted* LocatedCompletionMona *carrier $Q = (L, M, U, J, S, R, D, E, H, C, P, N)$, the local* NameCert$_{\text{LocatedCompletionMonad}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows, located-source visibility through L, completion-monad visibility through M, unit visibility through U, join visibility through J,* StreamName$^{\uparrow}$ *window preservation through S,* RegSeqRat$^{\uparrow}$ *readback preservation through R,* DyadicRatCore$^{\uparrow}$ *tolerance preservation through D,* Real$^{\uparrow}$ *seal preservation through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. The carrier exports no quotient completion, selected limit, countable-choice schedule, host equality of completed points, or ambient* Real$^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7908.1. The analytic rows are the located completion source L, the Cauchy completion monad row M, the unit and join rows U, J, the finite stream windows S, the regular rational readback R, the dyadic tolerance ledger D, and the Real seal E.

Read the unit route first. A source located-completion request must display L and M, then pass through the same S, R, D readback discipline before the terminal seal E is visible.

Read the join route next. A completion-of-completion request is flattened only by replaying the displayed unit and monad schedules through J, with the StreamName windows, regular readback, dyadic tolerances, and Real seal preserved as the same finite rows.

Finally attach H, C, P, N. These rows transport, replay, source, and name the displayed packet, and none supplies quotient completion equality, selected limits, countable choice, host equality, or ambient Real completeness. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 7908.3 (Located completion monad unit exactness)**.** *For every accepted* LocatedCompletionMonad$^{\uparrow}$ *carrier $Q = (L, M, U, J, S, R, D, E, H, C, P, N)$, every unit read through U exposes the located completion source row L, the Cauchy completion monad row M, the shared finite-window row S, the regular rational readback row R, the DyadicRatCore tolerance row D, and the Real seal row E before the local* NameCert$_{\text{LocatedCompletionMonad}^{\uparrow}}$ *row is read. In particular, the unit route is the displayed finite route*

$$L, M \longmapsto U \longmapsto S, R, D \longmapsto E, H, C, P, N,$$

not a selected limit, quotient completion equality, countable-choice schedule, or ambient completeness premise.

Proof. Project the carrier of Definition 7908.1. The unit row U is not independent data; it is listed between the source rows L, M and the finite readback rows S, R, D, E.

A unit request therefore first displays the located completion source and the completion-monad row. It can then read U only as the route that sends those source rows into the shared StreamName, RegSeqRat, and DyadicRatCore corridor.

The Real seal and local certificate are terminal for the unit route. The rows E, H, C, P, N preserve, replay, source, and name the same displayed packet, and none supplies a quotient, selected limit, choice schedule, host equality, or ambient completeness coordinate. □

Theorem 7908.4 (Located completion monad join exactness)**.** *For every accepted* $\mathsf{LocatedCompletionMonad}^{\uparrow}$ *carrier* $Q = (L, M, U, J, S, R, D, E, H, C, P, N)$*, every join read through* J *flattens completion-of-completion data by replaying the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$ *seal rows that the unit route uses. The join route is the displayed finite route*

$$L, M, U \longmapsto J \longmapsto S, R, D \longmapsto E, H, C, P, N.$$

It exports no detached completed point, selected representative, quotient completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start from a completion-of-completion read of the accepted carrier. The join row J is downstream of the located source row L, the monad row M, and the unit row U, so flattening cannot begin from a detached completed point.

The replayed readback rows are exactly S, R, D, E. The same StreamName windows, regular rational readbacks, dyadic tolerance ledger, and Real seal used by the unit route are inspected again when J flattens the nested completion data.

Finally the structural rows close the route without adding new analytic data. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same finite packet, so no quotient, selector, choice schedule, host equality, or ambient completeness premise is available to the join read. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionMonad}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCompletionMonad}^{\uparrow}}$, obligation)

Scope closed: Definition 7908.1, Definition 7908.2, Definition 7908.3, and Definition 7908.4 display the finite located completion monad obligation surface over $\mathsf{LocatedCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionMonadLaw}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCompletionMonad}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host equality of completed points, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located-source visibility, unit and join exactness, StreamName window preservation, RegSeqRat readback preservation, DyadicRatCore tolerance preservation, Real seal preservation, transport, replay, provenance, and non-escape over the same displayed packet.

Constructive story: A $\mathsf{LocatedCompletionMonad}^{\uparrow}$ packet is generated from located completion source data, a Cauchy completion monad row, unit and join rows, finite stream windows, regular rational readback, dyadic tolerances, a Real seal, and structural NameCert rows.

Chapter 7909

A Concrete Naming Certificate for $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$

Following Bishop and Bridges and the Bourbaki-style reflector discipline for completions, the $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$ packet records the finite triangle by which a Cauchy-completion reflector, its unit route, and the Real-facing regular Cauchy handoff are read as one NameCert object. It consumes the completion source discipline of chapter 3717, the monad and unit rows of chapter 378 and chapter 2256, the metric reflector route of chapter 2149, and the finite rational readback stack of chapter 291, chapter 126, chapter 301, and chapter 38. The chapter names the displayed completion-reflector triangle; it does not assert quotient completion equality, selected limits, host equality of completed objects, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7909.1 (CauchyCompletionReflectorTriangle carrier)**.** *A* $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, R, U, M, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BishopCompletion}^{\uparrow}$ *source row naming the constructive completion source before any reflector consumer reads it;*
2. *R is the* $\mathsf{MetricCompletionReflector}^{\uparrow}$ *comparison row, recording the displayed reflector comparison against the source metric presentation;*
3. *U is the* $\mathsf{CompletionUnitTriangle}^{\uparrow}$ *unit-triangle row, tying the source point, its unit image, and the reflector comparison to one finite route;*
4. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row recording the completion-facing unit and bind surface consumed by the triangle;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for finite dyadic comparison;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected rational name;*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance cells;*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after B, R, U, M, D, S, Q have been displayed;*
9. *H records componentwise* hsame *transport for the source, reflector, unit-triangle, completion, tolerance, window, readback, Real-seal, provenance, and local naming rows;*

10. *C records the displayed* Cont *replay route from the completion source through the reflector comparison, unit triangle, finite rational readback, and Real seal;*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$, $\mathsf{BishopCompletion}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$ $\mathsf{CompletionUnitTriangle}^{\uparrow}$, $\mathsf{MetricCompletionReflector}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, U, M, D, S, Q, E, H, C, P, N$ and their displayed hsame *and* Cont *transports. It has no coordinate for quotient completion equality, selected representatives, host equality of completed objects, countable-choice schedules, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CauchyCompletionReflectorTriangleUp.CauchyCompletionReflectorTriangleUp single carrier alignment`

Theorem 7909.2 (CauchyCompletionReflectorTriangle NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$ *carrier $T = (B, R, U, M, D, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}}$ *surface consists exactly of carrier admission, completion-source exposure, reflector comparison, unit-triangle exposure, completion monad scheduling, DyadicRatCore tolerance accounting, StreamName finite-window readback, RegSeqRat regular readback, Real-seal ordering, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. No local obligation is stored outside those rows.*

Proof. Project the carrier of Definition 7909.1. The displayed tuple is exactly $B, R, U, M, D, S, Q, E, H, C, P, N$, so every accepted packet exposes the completion source, reflector comparison, unit triangle, monad schedule, finite rational readback stack, Real seal, and structural rows before any consumer can read the triangle.

Read the analytic rows in order. The source row B enters the reflector comparison R, the unit-triangle row U binds the source and reflected point, and the monad row M records the completion-facing unit and bind surface. The dyadic tolerance, finite-window, and regular-readback rows D, S, Q then supply the finite rational data needed before E is exposed.

The structural rows close the certificate. Componentwise hsame transport and displayed Cont replay preserve the same finite triangle through H and C, while P and N record provenance and local naming. Since the carrier has no further coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 7909.3 (CauchyCompletionReflectorTriangle handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing or metric-reflector consumer of an accepted* $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$ *packet must read the route*

$$\mathsf{BishopCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionReflector}^{\uparrow} \longmapsto \mathsf{CompletionUnitTriangle}^{\uparrow} \longmapsto \mathsf{CauchyCompletionMonad}^{\uparrow} \longmapsto$$

through the same displayed carrier $T = (B, R, U, M, D, S, Q, E, H, C, P, N)$. The handoff exports no quotient completion, selected limit, host equality of completed objects, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the NameCert obligations of Definition 7909.2. They force every accepted handoff to expose the completion source, reflector comparison, unit triangle, completion monad row, dyadic tolerance row, finite windows, regular rational readback, Real seal, transport, replay, provenance, and local naming.

The reflector-facing part is read from B, R, U, M. These rows record the displayed completion source, comparison map, unit-triangle route, and completion-facing schedule before any metric reflector consumer can treat the packet as a triangle.

The Real-facing part is read from D, S, Q, E. The dyadic tolerance and finite window rows determine the regular rational readback, and the Real seal is downstream of those finite rows rather than a selected quotient representative.

Finally use H, C, P, N to transport, replay, source, and name the same finite handoff. Because none of the rows stores quotient equality, selected limits, host equality, choice, or ambient completeness, no such object can be exported by the triangle packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}$ packet is generated from a BishopCompletion source row, MetricCompletionReflector comparison, CompletionUnitTriangle route, CauchyCompletionMonad schedule, DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7909.1, Definition 7909.2, and Definition 7909.3 seed the finite completion-reflector triangle route through source, reflector, unit, rational readback, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionReflectorTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, host equality of completed objects, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reflector comparison, unit-triangle routing, rational readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionReflectorTriangleUp.

Chapter 7910

A Concrete Naming Certificate for $\mathsf{DeckTransformation}^{\uparrow}$

Following Hatcher and Spanier on covering-space automorphisms, the $\mathsf{DeckTransformation}^{\uparrow}$ packet records the finite BEDC surface by which a covering projection admits a fiber-preserving automorphism route with displayed inverse and composition rows. It sits beside the path-lifting certificate of chapter 2275, the homotopy rows of chapter 156, the continuous-map carrier of chapter 130, and the topology surface of chapter 88. The packet names deck transformation data as finite carrier and NameCert rows; it does not import a universal cover, monodromy action, quotient path space, selected global sheet, or host equality of maps.

Definition 7910.1 (DeckTransformation carrier)**.** *A* $\mathsf{DeckTransformation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (\pi, a, u, i, c, s, h, r, p, n)$$

with the following displayed rows:

1. *π is the covering projection row, read as a* $\mathsf{ContinuousMap}^{\uparrow}$ *packet from the displayed total-space topology to the base* $\mathsf{Topology}^{\uparrow}$ *row.*
2. *a is the automorphism route. It records a displayed total-space self-map whose projection readback follows π on every accepted finite test row.*
3. *u is the base-preservation ledger. It exposes the row-by-row comparison witnessing that π after a reads as the same covering projection route.*
4. *i is the inverse row. It records the displayed inverse route and the two finite identity readbacks for a followed by i and i followed by a.*
5. *c is the composition row. It records closure of accepted automorphism routes under displayed composition over the same projection ledger.*
6. *s is the sheet-action classifier. It compares finite sheet reads by the covering projection, path-lifting route, and endpoint seal, not by a host-level global sheet selector.*
7. *h records componentwise* hsame *transport for the projection, automorphism route, preservation ledger, inverse row, composition row, sheet classifier, replay, provenance, and local naming rows.*
8. *r records displayed* Cont *replay from a deck-transformation request through $\pi, a, u, i, c, s, h, p, n$.*
9. *p is the* Pkg *provenance over* $\mathsf{DeckTransformation}^{\uparrow}$, $\mathsf{CoveringSpacePathLifting}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. n is the local $\mathsf{NameCert}_{\mathsf{DeckTransformation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a universal covering space, monodromy action, quotient path object, hidden group representation, selected global sheet, or host equality of continuous maps.

Theorem 7910.2 (DeckTransformation NameCert obligations)**.** *For every accepted* $\mathsf{DeckTransformation}^{\uparrow}$ *carrier*

$$D = (\pi, a, u, i, c, s, h, r, p, n),$$

the local $\mathsf{NameCert}_{\mathsf{DeckTransformation}^{\uparrow}}$ *surface consists exactly of carrier admission, projection preservation through π, a, u, inverse exactness through i, composition closure through c, sheet-classifier stability through s, componentwise* hsame *transport through h, displayed* Cont *replay through r,* Pkg *provenance through p, and local naming through n. Every deck-transformation consumer can inspect these rows, but cannot escape to universal-cover data, quotient-path data, monodromy actions, fundamental-group representations, selected global sheets, or host equality of maps.*

Proof. Carrier admission is projection from Definition 7910.1. The accepted tuple displays the covering projection, automorphism route, base-preservation ledger, inverse row, composition row, sheet classifier, transport, replay, provenance, and local naming rows.

Projection preservation is the content of u. It forces every accepted read of a to return through the same covering projection route π, so the automorphism is fiber-preserving at the level visible to the packet.

Inverse exactness is read from i. The two identity readbacks are finite rows in the carrier, and no host-level equality of continuous maps is added beyond those displayed rows.

Composition closure is read from c. Whenever two accepted automorphism routes share the displayed covering projection ledger, their composite is admitted by the same finite surface and remains attached to π.

The sheet-action classifier s is stable because it is computed from the projection ledger, the path-lifting route of chapter 2275, and the endpoint seal already named there. Transport, replay, provenance, and naming through h, r, p, n preserve the same rows, so the certificate has no remaining place to store universal-cover data, quotient-path data, monodromy actions, or fundamental-group representations. □

Closure status for $\mathsf{NameCert}_{\mathsf{DeckTransformation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DeckTransformation}^{\uparrow}$ packet is generated from a covering projection, a fiber-preserving automorphism route, base-preservation ledger, inverse row, composition row, sheet-action classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DeckTransformation}^{\uparrow}}$, seed)

Scope closed: Definition 7910.1 and Definition 7910.2 seed the finite projection-preservation, inverse, composition, sheet-classifier, transport, replay, provenance, and local naming surface for covering-space automorphisms.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DeckTransformation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close universal covers, monodromy actions, fundamental-group representations, quotient path spaces, selected global sheets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked projection preservation, inverse exactness, composition closure, sheet-classifier stability, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DeckTransformationUp.

Chapter 7911

A Concrete Naming Certificate for DiniDerivativeLowerEnvelope$^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the DiniDerivativeLowerEnvelope$^{\uparrow}$ packet records the finite lower-envelope surface by which a displayed real-valued function exposes lower Dini rows before any derivative-envelope or semicontinuity consumer can inspect them. It sits beside the one-sided Dini carrier of chapter 2041, the upper envelope sibling of chapter 7459, the lower-semicontinuity packet of chapter 1536, the derivative quotient boundary of chapter 122, and the terminal real-name seal of chapter 38. The chapter names only finite lower-envelope windows and readback rows; it does not claim classical completeness, selected limiting slopes, quotient real equality, or a host lower semicontinuous hull.

Definition 7911.1 (DiniDerivativeLowerEnvelope carrier)**.** *A* DiniDerivativeLowerEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F, W, L, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed real-valued function row, read through the same finite observation surface used by the sibling* DiniDerivative$^{\uparrow}$ *and* Derivative$^{\uparrow}$ *packets.*
2. *W is the lower-envelope window row, listing the finite one-sided neighborhoods and lower secant comparisons available to the packet.*
3. *L is the* LowerSemicontinuous$^{\uparrow}$ *row that records the lower-envelope visibility surface for downstream epigraph or threshold consumers.*
4. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance row for radii, slope lower bounds, and comparison slack.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for endpoint values, secant numerators, step sizes, and dyadic lower-bound approximants.*
6. *E is the terminal* Real$^{\uparrow}$ *seal reached only after F, W, L, Q, R have been displayed.*
7. *H records componentwise* hsame *transport for the function, lower-envelope window, lower-semicontinuity, dyadic, readback, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for refinements of the same finite lower-envelope window.*
9. *P is the* Pkg *provenance over* DiniDerivativeLowerEnvelope$^{\uparrow}$, DiniDerivative$^{\uparrow}$, UpperDiniDerivative$^{\uparrow}$, LowerSemicontinuous$^{\uparrow}$, Derivative$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $F, W, L, Q, R, E, H, C, P, N$. It has no coordinate for a classical liminf, selected derivative value, quotient equality of real names, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an external lower-semicontinuous hull.*

Theorem 7911.2 (DiniDerivativeLowerEnvelope NameCert obligations)**.** *For every accepted* DiniDerivativeLowerE *carrier*

$$G = (F, W, L, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed function row, lower-envelope windows, lower-semicontinuity row, DyadicRatCore tolerance row, RegSeqRat readback, RealUp seal, componentwise transport, continuation replay, package provenance, and local naming; lower-envelope exactness requiring every lower-bound read to pass through W, Q, R; lower-semicontinuity compatibility requiring the row L to remain visible before threshold consumers read the envelope; and nonescape from classical liminf data, selected derivative values, quotient real equality, countable choice, ambient Real completeness, and host lower-semicontinuous hulls.*

Proof. Project the carrier of Definition 7911.1. The accepted packet exposes only the displayed function row F, lower-envelope windows W, lower-semicontinuity row L, dyadic tolerance row Q, regular readback row R, Real seal E, and structural rows H, C, P, N.

Lower-envelope exactness is finite. A lower-bound request must first read the inspected window in W, then the dyadic tolerance and slack data in Q, and then the regular rational readback in R before the Real seal can be consumed.

The lower-semicontinuity row remains attached to the same route. Thus an epigraph or threshold consumer can inspect the lower envelope only through the displayed row L, with transport and replay preserving the same finite packet.

Since no carrier coordinate stores a classical liminf, selected derivative value, quotient equality, choice schedule, ambient completeness theorem, or external hull, the listed rows exhaust the local NameCert obligations. □

Theorem 7911.3 (DiniDerivativeLowerEnvelope lower-envelope handoff)**.** *Every* $\mathsf{LowerSemicontinuous}^{\uparrow}$*-*, $\mathsf{DiniDerivative}^{\uparrow}$*-, or derivative-facing consumer of an accepted* $\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}$ *packet must read the finite route*

$$F, W, L, Q, R, E, H, C, P, N$$

before using the lower-envelope comparison. The handoff supplies displayed function data, lower-envelope windows, lower-semicontinuity visibility, DyadicRatCore tolerances, RegSeqRat readback, the terminal RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming, but it supplies no upper-envelope row, two-sided derivative, selected limiting slope, quotient real equality, countable-choice selector, or ambient Real completeness.

Proof. Begin with the obligation theorem Definition 7911.2. It identifies the lower envelope as a finite route through $F, W, L, Q, R, E, H, C, P, N$, not as an external limiting operator.

Read the sibling Dini and derivative surfaces next. The rows F, W, Q, R provide the finite secant-window and tolerance data needed by a Dini or derivative-facing consumer, while the Real seal E remains downstream of those rows.

Finally pass to lower-semicontinuity consumers through L. The row L keeps threshold and epigraph reads on the same displayed packet, and the structural rows preserve that packet under

transport, replay, provenance, and local naming. Therefore the handoff cannot export upper-envelope data, a two-sided derivative, selected limiting slopes, quotient equality, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}$ consumer reaching a lower-envelope read without the displayed function row, lower-envelope windows, LowerSemicontinuous row, DyadicRatCore tolerance row, RegSeqRat readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming refutes the carrier.

Independence witness: dini-derivative, upper-dini-derivative, lowersemicontinuous, derivative, real: no listed sibling supplies the whole lower-envelope packet $G = (F, W, L, Q, R, E, H, C, P, N)$, because each sibling contributes only one-sided Dini windows, upper rows, threshold visibility, quotient inspection, or a terminal real seal while this chapter binds the lower-envelope route in one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}$ packet is generated from displayed function data, lower-envelope windows, a LowerSemicontinuous visibility row, DyadicRatCore tolerance rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7911.1, Definition 7911.2, and Definition 7911.3 seed the finite lower-envelope packet from Dini derivative windows to lower-semicontinuity and derivative-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim classical liminf existence, selected derivative values, two-sided derivative existence, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-envelope exactness, lower-semicontinuity compatibility, DyadicRatCore tolerance exposure, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DiniDerivativeLowerEnvelopeUp.

Chapter 7912

A Concrete Naming Certificate for $\mathsf{MoorePlane}^{\uparrow}$

Following Moore and Kelley on the tangent-disc topology of the upper half-plane, the $\mathsf{MoorePlane}^{\uparrow}$ packet records the finite BEDC surface for the classical Moore plane boundary object. It sits beside the open-set and neighbourhood discipline of chapter 88 and the terminal real-coordinate carrier of chapter 38. The packet names upper-half-plane points, boundary-line points, tangent-disc neighbourhoods, real-coordinate seals, transport, replay, provenance, and local naming rows without importing a host topology, separation theorem, metrizability theorem, quotient equality of points, or selected neighbourhood basis.

Definition 7912.1 (MoorePlane carrier)**.** *A* $\mathsf{MoorePlane}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (U, B, T, R, H, C, P, N)$$

with the following displayed rows:

1. *U is the upper-half-plane point row, listing the inspected points with positive second coordinate.*
2. *B is the boundary-line point row, listing the inspected real-axis points.*
3. *T is the tangent-disc neighbourhood row, recording finite tangent-disc requests over U and B.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *coordinate seal for all displayed coordinates and radii.*
5. *H records componentwise* hsame *transport for the upper-half-plane, boundary-line, tangent-disc, real-seal, replay, provenance, and local-name rows.*
6. *C records displayed* Cont *replay from a topology-neighbourhood request through U, B, T, R.*
7. *P is the* Pkg *provenance over* $\mathsf{MoorePlane}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MoorePlane}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host topological space, a global basis theorem, selected infinitary neighbourhood basis, quotient equality of points, metrizability result, normality result, or ambient real-plane topology.

Theorem 7912.2 (MoorePlane NameCert obligations)**.** *For every accepted* $\mathsf{MoorePlane}^{\uparrow}$ *carrier $M = (U, B, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MoorePlane}^{\uparrow}}$ *surface consists exactly of carrier admission for upper-half-plane points, boundary-line points, tangent-disc neighbourhood requests, real-coordinate seals, componentwise transport, displayed continuation replay, package provenance, and*

local naming. Every neighbourhood consumer must read the topology surface through the displayed tangent-disc row T and the real-coordinate seal R before transport, replay, provenance, or local naming is consumed.

Proof. Project the carrier of Definition 7912.1. The point rows are U and B, the only neighbourhood row is T, and the only coordinate seal is R.

The topology-facing read is therefore finite. The tangent-disc row records the neighbourhood request, while the real-coordinate seal records the inspected center and radius data before the structural rows are available.

The rows H, C, P, N transport, replay, source, and name that same packet. Since no other row exists, the local NameCert obligations cannot require a host topology, selected basis, quotient equality of points, metrizability theorem, normality theorem, or ambient real-plane topology. □

Theorem 7912.3 (MoorePlane upper-half-plane route)**.** *Every* $\mathsf{MoorePlane}^{\uparrow}$ *consumer that reads an upper-half-plane neighbourhood must factor through the topology carrier of chapter 88, the real-coordinate seal of chapter 38, and the displayed rows U, T, R, H, C, P, N of Definition 7912.1. The route exposes finite upper-half-plane point data and tangent-disc neighbourhood data only; it exports no host open-set lattice, quotient point equality, selected neighbourhood basis, countable choice, metrizability claim, or ambient* $\mathsf{Real}^{\uparrow}$ *plane completeness.*

Proof. Start with Definition 7912.1. An upper-half-plane neighbourhood read begins at U and reaches the tangent-disc row T before any structural row can be consumed.

The coordinate data are sealed by R through the real-line carrier cited above. This keeps center and radius reads inside displayed $\mathsf{Real}^{\uparrow}$ data rather than a host plane.

Finally H, C, P, N preserve and name the same finite route. Because the carrier contains no separate open-set lattice, quotient equality, selected basis, countable-choice schedule, metrizability row, or ambient completeness row, the stated route exhausts the upper-half-plane consumer surface. □

Theorem 7912.4 (MoorePlane nonescape)**.** *Every* $\mathsf{MoorePlane}^{\uparrow}$ *consumer generated from U, B, T, R, H, C, P, N remains inside the displayed boundary-object route. Boundary-line neighbourhoods may use the tangent-disc row T and the real-coordinate seal R, but they cannot become host separation theorems, metrizability counterexamples, selected neighbourhood bases, quotient point equalities, countable-choice objects, or ambient real-plane topology.*

Proof. Induct over the displayed BHist packet. The base read exposes no topology beyond the listed point rows and real-coordinate seal.

In the finite step case, a new neighbourhood read is admitted only through T over the already displayed point and coordinate rows. The structural rows then transport, replay, source, and name that same read.

Thus every accepted consumer remains inside U, B, T, R, H, C, P, N. The excluded host-topology, basis-selection, quotient, choice, metrizability, and ambient-plane principles have no row in the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MoorePlane}^{\uparrow}}$.

Constructive story: A $\mathsf{MoorePlane}^{\uparrow}$ packet is generated from upper-half-plane points, boundary-line points, tangent-disc neighbourhood rows, Real coordinate seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MoorePlane}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7912.1, Definition 7912.2, Definition 7912.3, and Definition 7912.4 seed the finite Moore plane topology-neighbourhood packet over displayed real-coordinate data.

Formal verification: FormalStatus(NameCert$_{\mathsf{MoorePlane}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host topology, separation theorems, metrizability or nonmetrizability theorems, selected neighbourhood bases, quotient equality of points, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tangent-disc neighbourhood exactness, upper-half-plane routing, boundary-line nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MoorePlaneUp.

Chapter 7913

A Concrete Naming Certificate for $\mathsf{EventualEquality}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the cofinite-filter discipline familiar from Kelley-style topology, the $\mathsf{EventualEquality}^{\uparrow}$ packet records equality of two displayed streams after a finite tail cut. It reads finite observation windows through chapter 126, regular rational readback through chapter 301, the tail-comparison sibling chapter 1738, and the terminal real-name boundary of chapter 38. The packet names the cofinite-tail equality interface used by Real and Completion consumers; it does not form a quotient of streams, choose representatives, assert ambient completeness, or expose a hidden host equality.

The cofinite-tail equality packet therefore consumes the sibling route through chapter 126, chapter 301, chapter 1738, and chapter 38; those chapters supply the finite stream windows, regular rational readback, tail-comparison boundary, and terminal real-name seal that this packet replays.

Definition 7913.1 (Eventual equality carrier)**.** *An* $\mathsf{EventualEquality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, R, T, A, Q, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two finite* $\mathsf{StreamName}^{\uparrow}$ *window surfaces being compared.*
2. *T is the finite tail-cut ledger naming the cofinite region after which comparison is admitted.*
3. *A is the displayed agreement row on the post-cut windows.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the compared windows and their tail-cut ledger.*
5. *H records componentwise* hsame *transport for the two windows, the tail cut, agreement, readback, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from the two windows and the tail cut to the agreement and readback rows.*
7. *P is the* Pkg *provenance over* $\mathsf{EventualEquality}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyTailEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{EventualEquality}^{\uparrow}}$ *row naming exactly this cofinite-tail equality packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected representatives, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.EventualEqualityUp.TasteGate.EventualEqualityTasteGate single carrier alignment`

Theorem 7913.2 (Eventual equality NameCert obligations)**.** *For every accepted* $\mathsf{EventualEquality}^{\uparrow}$ *carrier*

$$E = (L, R, T, A, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EventualEquality}^{\uparrow}}$ *surface consists exactly of two stream-window admissions, one finite tail-cut ledger, one post-cut agreement row, regular rational readback, componentwise transport, displayed replay, provenance, and local naming. Every equality-facing read must pass through*

$$L, R, T, A, Q, H, C, P, N$$

and through no quotient stream equality, selected representative, hidden host equality, countable-choice selector, or ambient completeness row.

Proof. Project the carrier of Definition 7913.1. The rows L, R, T, A, Q expose the two finite windows, the cofinite tail cut, the agreement row, and regular rational readback before any equality-facing consumer can read the packet.

The structural rows H, C, P, N preserve and replay the same route. Componentwise transport cannot add a quotient coordinate, replay only follows the displayed windows and cut, provenance names the same dependencies, and the local naming row registers the same finite packet.

Thus the listed rows exhaust the NameCert surface. Since the carrier contains no quotient, selector, choice, host-equality, or ambient-completeness field, no downstream read can obtain such data from the $\mathsf{EventualEquality}^{\uparrow}$ packet. □

Theorem 7913.3 (Eventual equality RegSeqRat handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{EventualEquality}^{\uparrow}$ *packet receives the equality-facing route*

$$\mathsf{StreamName}^{\uparrow} \times \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{EventualEquality}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $L, R, T, A, Q, H, C, P, N$*. The handoff factors through the tail-comparison discipline of chapter 1738; it is not a quotient of stream names, a choice of representatives, an ambient completeness principle, or a host-level equality theorem.*

Proof. Begin with the two stream-window rows L and R. The tail-cut row T selects the finite boundary after which the displayed agreement row A is meaningful.

Next read the regular rational handoff Q. The handoff is downstream of the same finite windows and tail ledger, so it can be consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and then by a $\mathsf{Real}^{\uparrow}$-facing seal only through the displayed route.

Finally apply the structural rows H, C, P, N. They transport, replay, source, and locally name the same cofinite-tail equality packet. The sibling route through chapter 1738 supplies the tail-comparison boundary, while the carrier itself supplies no quotient, representative selector, completeness, or host-equality coordinate. □

Lean4 (statement) `BEDC.Derived.EventualEqualityUp`

Closure status for $\mathsf{NameCert}_{\mathsf{EventualEquality}^{\uparrow}}$**.**

Constructive story: An EventualEquality$^{\uparrow}$ packet is generated from two finite StreamName windows, one tail-cut ledger, one post-cut agreement row, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{EventualEquality}^{\uparrow}}$, seed)

Scope closed: Definition 7913.1, Definition 7913.2, and Definition 7913.3 seed the cofinite-tail equality route over stream windows, tail cuts, agreement rows, regular rational readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{EventualEquality}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.EventualEqualityUp`

Bridge status: none

Not claimed: The chapter does not claim quotient stream equality, selected representatives, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-cut visibility, post-cut agreement, regular rational handoff, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.EventualEqualityUp.

Chapter 7914

A Concrete Naming Certificate for $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$ packet records the finite locator surface by which a regular Cauchy readback becomes positive apartness evidence for Real and Completion consumers. It sits after the positive apartness interface of chapter 7270, the Cauchy located-apartness boundary of chapter 3895, the regular rational readback route of chapter 301, the dyadic tolerance core of chapter 291, the finite stream-name window surface of chapter 126, and the terminal real-name seal of chapter 38. The packet names a local apartness locator for regular Cauchy data; it does not assert trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7914.1 (Regular Cauchy apartness locator carrier)**.** *A* $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, A, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to schedule the regular Cauchy observations.*
2. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row computed from the displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row fixing the positive gap scale used by the locator.*
4. *A is the* $\mathsf{RealApartnessLocator}^{\uparrow}$ *positive-apartness locator row exposed at that tolerance and window.*
5. *L is the* $\mathsf{CauchyLocatedApartness}^{\uparrow}$ *handoff row that records the Cauchy locator request and its located-apartness answer.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D, A, L have been displayed.*
7. *H stores componentwise* hsame *transport for stream windows, regular readbacks, dyadic tolerance, apartness locator rows, Cauchy located-apartness handoff rows, Real seals, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from a regular Cauchy apartness request through $S, R, D, A, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$*,* $\mathsf{RealApartnessLocator}^{\uparrow}$*,* $\mathsf{CauchyLocatedApartness}^{\uparrow}$ $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessLocator}^{\uparrow}}$ *row.*
The carrier has no coordinate for trichotomy, quotient real equality, selected limits, countable choice, an independently chosen representative sequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7914.2 (Regular Cauchy apartness locator NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$ *carrier*

$$K = (S, R, D, A, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessLocator}^{\uparrow}}$ *surface consists exactly of paired stream-window exposure, paired regular-rational readback, dyadic-tolerance exactness, positive apartness-locator exposure, Cauchy located-apartness handoff, Real-seal routing, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7914.1. The analytic rows are S, R, D, A, L, E, and the structural rows are H, C, P, N.

The stream row S fixes the finite observations, the readback row R records the regular rational data read from those observations, and the dyadic row D fixes the positive tolerance at which apartness is inspected.

The apartness locator row A and the Cauchy located-apartness handoff row L are downstream of the same S, R, D route. The Real seal E is reached only after those rows are displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since none of the excluded principles is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7914.3 (Regular Cauchy apartness locator Real handoff)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$ *packet reads the terminal seal only through the displayed route*

$$S, R, D, A, L, E, H, C, P, N.$$

The handoff therefore exposes positive apartness for regular Cauchy readbacks without exporting trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 7914.2. They require stream windows, regular readbacks, dyadic tolerance, apartness locator evidence, and the Cauchy located-apartness handoff to be displayed before the Real seal is visible.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. They do not add a total order branch, a quotient equality test, a selected limit, a choice schedule, or an ambient completeness theorem.

Thus every Real-facing or Completion-facing read factors through the finite carrier rows and no excluded principle can be read from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyApartnessLocator}^{\uparrow}$ packet is generated from paired StreamName finite windows, paired RegSeqRat readbacks, a DyadicRatCore tolerance row, a RealApartnessLocator row, a CauchyLocatedApartness handoff row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessLocator}^{\uparrow}}$, seed)

Scope closed: Definition 7914.1, Definition 7914.2, and Definition 7914.3 seed the finite regular Cauchy apartness locator route over stream windows, regular-rational readbacks, dyadic tolerance, positive apartness locators, Cauchy located-apartness handoff, Real seals, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyApartnessLocator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular-rational read-back, dyadic-tolerance exactness, positive apartness-locator exposure, Cauchy located-apartness handoff, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyApartnessLocatorUp.

Chapter 7915

A Concrete Naming Certificate for $\mathsf{RegularCauchyMajorant}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMajorant}^{\uparrow}$ packet names the finite majorant certificate used when a regular Cauchy rational route needs a displayed bound before entering the L10 completion readback. It sits between the dyadic tolerance arithmetic of chapter 291, the finite observation schedules of chapter 126, the regular rational source of chapter 301, the explicit majorant siblings chapter 4215 and chapter 5900, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet records a finite majorant row for regular Cauchy completion consumers; it does not import quotient completion, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7915.1 (Regular Cauchy majorant carrier)**.** *A* $\mathsf{RegularCauchyMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, Q, J, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming the inspected regular Cauchy requests;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger against which the requested error bounds are checked;*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose rational tail is read only through S and D;*
4. *J is the majorant row assigning a finite bound to each displayed tolerance window;*
5. *T is the tail-majorant comparison row, relating J to the sibling tail-majorant service of chapter 5900;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *completion-seal row available only after the regular tail and its majorant row have been displayed;*
7. *H records componentwise* hsame *transport for the schedule, tolerance, regular source, majorant, tail comparison, seal, provenance, and local naming rows;*
8. *C records displayed* Cont *replay from finite windows through dyadic tolerances, regular readback, majorant comparison, and the Real-seal handoff;*
9. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMajorant}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, D, Q, J, T, E, H, C, P, N$ and their displayed transport and replay rows. It has no coordinate for a quotient-completion object, a selected limit, a hidden tail selector, countable choice, or ambient real completeness.

Theorem 7915.2 (Regular Cauchy majorant NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMajorant}^{\uparrow}$ *carrier*

$$M = (S, D, Q, J, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMajorant}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-window exposure through S, dyadic tolerance exposure through D, regular rational source exposure through Q, majorant readability through J, tail-majorant comparison through T, Real-seal ordering through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7915.1. The displayed tuple is exactly $S, D, Q, J, T, E, H, C, P, N$, so every accepted packet exposes the finite windows, dyadic tolerances, regular rational source, majorant row, tail comparison, Real seal, and structural rows before a completion consumer can read it.

Read the analytic rows in order. The schedule row S names the inspected windows, the dyadic row D supplies the tolerance data, and the regular rational source row Q is read only through those finite rows.

The majorant rows then close the estimate route. The row J gives the finite bound, while T compares it to the sibling tail-majorant service; the seal row E is downstream of that displayed comparison and not an independent limit.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient completion, selected limits, hidden tail choice, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 7915.3 (Regular Cauchy majorant completion handoff)**.** *Every L10 completion consumer of an accepted* $\mathsf{RegularCauchyMajorant}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyMajorant}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports a displayed majorant certificate for regular Cauchy readback; it exports no quotient completion, selected limit, hidden tail selector, countable-choice scheduler, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Apply Definition 7915.2. The rows S, D, Q, J, T, E place the finite observation schedule, dyadic tolerance ledger, regular rational source, majorant row, tail comparison, and Real seal in one accepted packet.

The completion consumer may therefore read the route only after the majorant row has been displayed against the same finite windows and tolerances. The sibling services named above supply comparison surfaces, not a separate completion object.

Use the structural rows H, C, P, N to transport, replay, source, and name the same handoff. Because the packet lacks quotient completion, selected limits, hidden tail choice, countable choice, and ambient completeness coordinates, none of those readings can be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMajorant}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyMajorant}^{\uparrow}$ packet is generated from a finite StreamName schedule, DyadicRatCore tolerance ledger, RegSeqRat source row, displayed majorant row, tail-majorant comparison, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyMajorant}\uparrow}$, seed)

Scope closed: Definition 7915.1, Definition 7915.2, and Definition 7915.3 seed the finite regular Cauchy majorant carrier and its L10 completion handoff.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyMajorant}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected limits, hidden tail selection, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, tolerance exactness, regular readback, majorant comparison, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMajorantUp.

Chapter 7916

A Concrete Naming Certificate for PoincareDiskAreaElement$^{\uparrow}$

The PoincareDiskAreaElement$^{\uparrow}$ packet realizes the local area-read branch of chapter 9463 as finite disk, metric, radius, Real-seal, and observer-expansion certificate data. It consumes the disk carrier of chapter 377, the Poincare disk metric surface of chapter 6209, the hyperbolic metric row of chapter 3474, the observer-expansion packet of chapter 4167, the dyadic shadow cone of chapter 7503, and the dyadic and Real substrate of chapter 291 and chapter 38. The packet names a local area-element readback, not a global hyperbolic surface, quotient disk equality, selected coordinate atlas, physical horizon law, or ambient measure-completeness theorem.

Definition 7916.1 (Poincare disk area-element carrier)**.** *A* PoincareDiskAreaElement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (U, M, G, D, B, O, R, F, T, C, P, N)$$

with the following displayed rows:

1. *U is the* UnitDisk$^{\uparrow}$ *disk-coordinate row for the displayed local point or finite disk window.*
2. *M is the* PoincareDiskMetric$^{\uparrow}$ *row that reads the Poincare disk metric over the same coordinate data.*
3. *G is the* HyperbolicMetric$^{\uparrow}$ *row comparing the disk metric read with the hyperbolic metric surface consumed downstream.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *dyadic-radius row, recording the finite radius scale at which local area is inspected.*
5. *B is the area-budget row, binding the displayed radius and metric rows to a finite area-element budget.*
6. *O is the* HyperbolicObserverExpansion$^{\uparrow}$ *provenance row that records which observer-expansion branch receives the local area readback.*
7. *R is the terminal* Real$^{\uparrow}$ *seal row for the displayed area budget, available only after U, M, G, D, B, O are visible.*
8. *F is the refusal row excluding completed disk quotients, selected coordinate atlases, global area measures, physical horizon semantics, and ambient completeness.*

9. *T records componentwise* hsame *transport for disk coordinates, metric rows, dyadic radii, area budgets, observer-expansion provenance, Real seals, refusal data, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a local disk-area request through $U, M, G, D, B, O, R, F, T, P, N$.*
11. *P is the* Pkg *provenance over* PoincareDiskAreaElement$^{\uparrow}$, UnitDisk$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicShadowCone$^{\uparrow}$, HyperbolicObserverExpansion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* NameCert$_{\text{PoincareDiskAreaElement}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed Poincare disk quotient, selected global chart, ambient measure object, physical observer law, or hyperbolic completeness theorem.

Theorem 7916.2 (Poincare disk area-element NameCert obligations)**.** *For every accepted* PoincareDiskAreaElement *carrier $A = (U, M, G, D, B, O, R, F, T, C, P, N)$, the local* NameCert$_{\text{PoincareDiskAreaElement}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *disk-and-metric admission through U, M, G;*
2. *dyadic-radius and area-budget exactness through D, B;*
3. *observer-expansion provenance and Real-seal routing through O, R;*
4. *refusal and transport preservation through F, T;*
5. *displayed replay, provenance, and local naming through C, P, N.*

Proof. Project the carrier of Definition 7916.1. The disk and metric rows are U, M, G, the finite radius and area-budget rows are D, B, and the observer-facing and Real-facing rows are O, R.

The budget row B is available only after the disk coordinate, metric comparison, and dyadic-radius rows have been displayed. Thus an area-element read is local and finite before any Real seal can be consumed.

The rows F, T, C, P, N then refuse nonlocal endpoints, transport the same displayed data, replay the route, record provenance, and name the local packet. No additional carrier coordinate can supply a global measure, quotient disk equality, selected chart, physical horizon law, or ambient completeness theorem. □

Falsifiable prediction: Every accepted PoincareDiskAreaElement$^{\uparrow}$ read factors through UnitDisk, PoincareDiskMetric, HyperbolicMetric, DyadicRatCore, Real, observer-expansion provenance, transport, replay, package, and local NameCert rows before an area budget is visible.

Independence witness: unitdisk, poincare-disk-metric, hyperbolic-metric, hyperbolic-observer-expansion, dyadic-shadow-cone: no listed sibling is bijective to PoincareDiskAreaElement$^{\uparrow}$ because this packet jointly carries disk coordinates, metric comparison, dyadic radius, area budget, observer-expansion provenance, Real sealing, refusal, transport, replay, provenance, and local naming as one finite route.

The Lean TasteGate route must provide `Nontrivial PoincareDiskAreaElementUp` and `FieldFaithful PoincareDiskAreaElementUp` instances in `lean4/BEDC/Derived/PoincareDiskAreaElementUp/TasteGate.lean`. Those instances must keep $U, M, G, D, B, O, R, F, T, C, P, N$ as distinct fields before any checked marker is used.

Closure status for NameCert$_{\text{PoincareDiskAreaElement}^{\uparrow}}$**.**

Constructive story: A PoincareDiskAreaElement$^{\uparrow}$ packet is generated from UnitDisk coordinate rows, PoincareDiskMetric rows, HyperbolicMetric rows, DyadicRatCore radius rows, area-budget rows, HyperbolicObserverExpansion

provenance, a RealUp seal, refusal data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{PoincareDiskAreaElement}\uparrow}$, seed)

Scope closed: Definition 7916.1 and Definition 7916.2 seed the finite local disk-area route over disk coordinates, metric rows, dyadic radii, area budgets, observer-expansion provenance, Real seals, refusal, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{PoincareDiskAreaElement}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim completed disk quotients, selected global charts, ambient measure objects, physical observer laws, hyperbolic completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-and-metric admission, dyadic-radius exactness, area-budget exactness, observer-expansion provenance, Real-seal routing, refusal, transport, replay, provenance, local naming, TasteGate nontriviality, and field faithfulness for BEDC.Derived.PoincareDiskAreaElementUp.

Chapter 7917

A Concrete Naming Certificate for $\mathsf{PoincareMap}^{\uparrow}$

Following Poincare and the standard return-map construction in dynamical systems, the $\mathsf{PoincareMap}^{\uparrow}$ packet records the finite section-to-section return surface used by a displayed flow before any downstream consumer treats the read as a map. It sits after the finite routed-flow carrier of chapter 195, the displayed ODE route of chapter 193, the map-continuity packet of chapter 130, the metric-distance surface of chapter 57, the terminal Real seal of chapter 38, the finite observation windows of chapter 126, and the regular rational readback of chapter 301. The packet names a finite return certificate, not global recurrence, selected orbit representatives, quotient flow equality, host smooth transversality, or ambient Real completeness.

Definition 7917.1 (Poincare map carrier)**.** *A* $\mathsf{PoincareMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (D, O, M, S, T, W, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *routed-flow row exposing the finite transition relation inspected by the packet.*
2. *O is the* $\mathsf{Ode}^{\uparrow}$ *local evolution row used only through its displayed solution-step ledger.*
3. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the section-to-section map surface.*
4. *S is the section row naming the displayed source and target section windows.*
5. *T is the first accepted return-time row inside the inspected window.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation-window row for source, flow, and return reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational return-time and section-coordinate data.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed return scale and coordinate reads.*
9. *H records componentwise* hsame *transport for the dynamic, ODE, map, section, return-time, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay through the route*

$$D, O, M, S, T, W, R \longmapsto E.$$

11. *Q is the* Pkg *provenance over* $\mathsf{PoincareMap}^{\uparrow}$, $\mathsf{DynSystem}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PoincareMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, O, M, S, T, W, R, E, H, C, Q, N$. It has no coordinate for a global recurrence theorem, selected complete orbit, quotient flow equality, host transversality theorem, ambient completeness principle, Lean verification, or bridge checking.

Theorem 7917.2 (Poincare map NameCert obligations)**.** *For every accepted* $\mathsf{PoincareMap}^{\uparrow}$ *carrier*

$$P = (D, O, M, S, T, W, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PoincareMap}^{\uparrow}}$ *surface consists exactly of routed dynamics through D, displayed ODE evolution through O, section-to-section map exposure through M, section-window admission through S, return-time admission through T, finite observation through W, regular rational readback through R, Real-seal handoff through E, and structural transport, replay, provenance, and local naming through H, C, Q, N.*

Proof. Project the carrier of Definition 7917.1. The rows D, O, M, S expose the only dynamic, evolution, map, and section data visible to the packet before a return is read.

The return data are then forced through T, W, R, E. The accepted return time is a displayed finite row, the observation window is a $\mathsf{StreamName}^{\uparrow}$ row, the coordinate readback is a $\mathsf{RegSeqRat}^{\uparrow}$ row, and the scalar boundary is sealed only through $\mathsf{Real}^{\uparrow}$.

Finally attach H, C, Q, N. Componentwise transport, continuation replay, package provenance, and local naming preserve the same finite packet and add no selected orbit, quotient flow equality, host transversality theorem, or ambient completeness principle. □

Theorem 7917.3 (Poincare map return nonescape)**.** *Every accepted* $\mathsf{PoincareMap}^{\uparrow}$ *return read remains inside the finite carrier of Definition 7917.1. In particular, a consumer can receive a section-to-section return map only after displaying the* $\mathsf{DynSystem}^{\uparrow}$ *route,* $\mathsf{Ode}^{\uparrow}$ *evolution ledger,* $\mathsf{ContinuousMap}^{\uparrow}$ *map row, section windows, finite return-time row,* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. No accepted read may replace this route by global recurrence, a selected orbit representative, quotient flow equality, a host smooth-transversality theorem, or ambient Real completeness.*

Proof. Let a consumer request a Poincare return map from an accepted carrier. Projection of Definition 7917.1 shows that the request first meets the displayed dynamic route D, ODE row O, map row M, and section row S.

The return-time row T is downstream from the displayed section data, and the observation row W fixes the finite source, flow, and target windows. The regular rational readback R and Real seal E then expose only the registered return scale and section-coordinate reads.

The structural rows H, C, Q, N do not add analytic primitives. They transport equal displayed histories, replay the finite route, record package provenance, and attach the local name. Therefore every accepted return read stays inside the finite Poincare map certificate surface and cannot escape to the excluded host principles. □

Falsifiable prediction: An accepted $\mathsf{PoincareMap}^{\uparrow}$ consumer that reads a section-to-section return without displaying the DynSystem route, ODE evolution row, ContinuousMap surface, section

window, finite return-time row, StreamName observations, RegSeqRat readback, and Real seal refutes the carrier surface.

Independence witness: dynsystem, ode, continuousmap, metric, real, streamname, regseqrat: no listed sibling supplies the whole packet $P = (D, O, M, S, T, W, R, E, H, C, Q, N)$, because each sibling contributes only a routed flow, evolution row, map surface, distance boundary, scalar seal, finite observation window, or rational readback while this chapter binds them into one return-map NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareMap}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareMap}^{\uparrow}$ packet is generated from a finite DynSystem route, ODE evolution row, ContinuousMap section-to-section surface, section windows, finite return-time row, StreamName observations, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7917.1, Definition 7917.2, and Definition 7917.3 seed the finite Poincare return-map route through dynamics, ODE evolution, continuous-map exposure, section windows, return-time admission, finite observations, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global recurrence, selected orbit representatives, quotient flow equality, host smooth transversality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dynamic routing, ODE evolution exposure, continuous-map exposure, section-window admission, return-time admission, observation-window exactness, regular rational readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.PoincareMapUp.

Chapter 7918

A Concrete Naming Certificate for $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$

Following Dini and Bishop–Bridges constructive analysis, the $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$ packet records the finite upper one-sided Dini derivative envelope through which displayed function windows expose upper secant comparison rows before any semicontinuity, regular-readback, or real-name consumer can inspect them. It sits beside the one-sided Dini carrier of chapter 2041, the lower envelope sibling of chapter 7911, the regular Cauchy majorant of chapter 7915, the finite stream-name schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only finite upper-envelope windows and readback rows; it does not claim classical limsup existence, selected derivative values, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7918.1 (UpperDiniDerivativeEnvelope carrier)**.** *An* $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (F, W, UQ, R, S, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed real-valued function row, read through the same finite observation surface used by the sibling* $\mathsf{DiniDerivative}^{\uparrow}$ *and* $\mathsf{UpperDiniDerivative}^{\uparrow}$ *packets.*
2. *W is the upper-envelope window row, listing the finite one-sided neighborhoods and upper secant comparisons available to the packet.*
3. *UQ is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for radii, slope upper bounds, and comparison slack.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint values, secant numerators, step sizes, and dyadic upper-bound approximants.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that records which finite function and base-point observations are available before a readback is public.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, W, UQ, R, S have been displayed.*
7. *H records componentwise* hsame *transport for the function, upper-envelope window, dyadic, readback, stream, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for refinements of the same finite upper-envelope window.*

9. *P is the* Pkg *provenance over* $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$, $\mathsf{DiniDerivative}^{\uparrow}$, $\mathsf{DiniDerivativeLowerEnvelope}^{\uparrow}$, $\mathsf{UpperDiniDerivative}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, W, UQ, R, S, E, H, C, P, N$. It has no coordinate for a lower-envelope row, two-sided derivative, selected limiting slope, classical limsup object, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7918.2 (UpperDiniDerivativeEnvelope NameCert obligations)**.** *For every accepted* UpperDiniDerivativeE *carrier*

$$U = (F, W, UQ, R, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed function row, upper-envelope windows, DyadicRatCore tolerance row, RegSeqRat readback, StreamName schedule, RealUp seal, componentwise transport, continuation replay, package provenance, and local naming; upper-envelope exactness requiring every upper-bound read to pass through W, UQ, R, S; sibling compatibility requiring the Dini and lower-envelope packets to remain cited only as comparison surfaces; and nonescape from lower-envelope export, two-sided derivative data, selected limiting slopes, classical limsup objects, quotient real equality, countable choice, and ambient Real completeness.*

Proof. Project the carrier of Definition 7918.1. The accepted packet exposes only the displayed function row F, upper-envelope windows W, dyadic tolerance row UQ, regular readback row R, stream schedule S, Real seal E, and structural rows H, C, P, N.

Upper-envelope exactness is finite. An upper-bound request must first read the inspected window in W, then the dyadic tolerance and slack data in UQ, then the regular rational readback in R, and then the scheduled observation row in S before the Real seal can be consumed.

The Dini and lower-envelope siblings are comparison anchors, not exported coordinates. They identify the surrounding one-sided derivative surface while the present packet keeps only the upper-envelope route visible.

Since no carrier coordinate stores a lower-envelope export, two-sided derivative, selected limiting slope, classical limsup object, quotient equality, choice schedule, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$ consumer reaching an upper-envelope read without the displayed function row, upper-envelope windows, DyadicRatCore tolerance row, RegSeqRat readback, StreamName schedule, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local naming refutes the carrier.

Independence witness: dini-derivative, dini-derivative-lower-envelope, upper-dini-derivative, regseqrat, streamname, real: no listed sibling supplies the whole upper-envelope packet $U = (F, W, UQ, R, S, E, H, C, P, N)$, because each sibling contributes only one-sided Dini windows, lower rows, upper derivative rows, rational readback, observation schedules, or a terminal real seal while this chapter binds the upper-envelope route in one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}}$ **·**

Constructive story: An $\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}$ packet is generated from displayed function data, upper-envelope windows, DyadicRatCore tolerance rows, RegSeqRat readback, StreamName schedules, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UpperDiniDerivativeEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 7918.1 and Definition 7918.2 seed the finite upper-envelope packet from Dini derivative windows to regular-readback and real-name consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{UpperDiniDerivativeEnvelope}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim classical limsup existence, lower-envelope export, two-sided derivative existence, selected derivative values, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-envelope exactness, sibling compatibility, DyadicRatCore tolerance exposure, RegSeqRat readback, StreamName scheduling, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UpperDiniDerivativeEnvelopeUp.

Chapter 7919

A Concrete Naming Certificate for $\mathsf{DyadicMeshLocator}^{\uparrow}$

Following Bishop and Bridges on constructive real approximation and finite dyadic partitions, the $\mathsf{DyadicMeshLocator}^{\uparrow}$ packet records the finite cell-location read used when a regular real window is compared with a displayed dyadic mesh. It sits over the mesh rows of chapter 7835, the rounded locator route of chapter 1972, the dyadic tolerance ledger of chapter 291, the finite stream window of chapter 126, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a finite locator primitive; it does not decide host trichotomy, select a nearest cell, quotient real names, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7919.1 (Dyadic mesh locator carrier)**.** *A* $\mathsf{DyadicMeshLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, Q, S, E, T, W, R, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{FiniteDyadicMesh}^{\uparrow}$ *row naming the finite mesh and its ordered cell rows.*
2. *Q is the locator request row containing the requested precision and the inspected real-window address.*
3. *S is the selected mesh-cell row returned by the finite locator.*
4. *E is the endpoint-tolerance row proving that the selected cell endpoints were read at the requested dyadic precision.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the endpoints and the window.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the locator.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to W.*
8. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, Q, S, E, T, W, R have been displayed.*
9. *H records componentwise* hsame *transport for the mesh, request, selected cell, endpoint tolerances, stream window, regular readback, real seal, and structural rows.*
10. *C records displayed* Cont *replay from a locator request through the mesh, selected cell, endpoint tolerances, stream window, regular readback, and real seal.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicMeshLocator}^{\uparrow}$*,* $\mathsf{FiniteDyadicMesh}^{\uparrow}$*,* $\mathsf{RoundedDyadicLocator}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{DyadicMeshLocator}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, Q, S, E, T, W, R, A, H, C, P, N$. It has no coordinate for host trichotomy, a nearest-cell selector, quotient real equality, countable choice, or ambient real completeness.

Theorem 7919.2 (Dyadic mesh locator NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshLocator}^{\uparrow}$ *carrier $L = (M, Q, S, E, T, W, R, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshLocator}^{\uparrow}}$ *surface consists exactly of finite mesh admission, locator-request admission, selected-cell row exposure, endpoint-tolerance accounting, dyadic tolerance comparison, StreamName window read, RegSeqRat readback, Real seal handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7919.1. The visible inventory is $M, Q, S, E, T, W, R, A, H, C, P, N$, and every locator obligation is assigned to one of those rows.

The finite mesh and request rows are read first. Row M supplies the inspected dyadic mesh, while Q records the precision and window address that the locator is allowed to use. The selected cell row S is therefore a finite row of the same mesh rather than a host-side nearest-cell choice.

The endpoint and tolerance data are then displayed. Row E records the endpoint tolerances, and row T supplies the dyadic rational comparison budget used by the locator. Rows W and R expose the stream window and regular rational readback that the real-facing request actually inspects.

Finally A, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier contains no trichotomy decision, nearest-cell selector, quotient real equality, countable-choice row, or ambient-completeness witness, those objects are not local obligations of the packet. □

Theorem 7919.3 (Dyadic mesh locator finite cell handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicMeshLocator}^{\uparrow}$ *carrier receives the finite route*

$$M \longrightarrow Q \longrightarrow S \longrightarrow E \longrightarrow T \longrightarrow W \longrightarrow R \longrightarrow A \longrightarrow H, C, P, N.$$

Thus the consumer reads a displayed finite dyadic mesh, locator request, selected cell, endpoint tolerance ledger, dyadic rational tolerance row, StreamName window, and RegSeqRat readback before it may consume the terminal real seal.

Proof. Start from the carrier definition. The terminal real seal is A, and it appears only after the finite mesh, request, selected cell, endpoint tolerance, dyadic tolerance, stream window, and regular readback rows have been displayed.

Apply Definition 7919.2. It makes the route through M, Q, S, E, T, W, R part of the local NameCert surface, so a consumer cannot replace the route by trichotomy, a nearest-cell selector, quotient equality of real names, or a choice-based search over mesh cells.

The transport and replay rows preserve the same finite order for downstream consumers, while P and N record provenance and local naming. The handoff is therefore the displayed mesh-cell route rather than an ambient completeness or choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshLocator}^{\uparrow}$ packet is generated from a finite dyadic mesh row, locator request row, selected cell row, endpoint tolerance rows, DyadicRatCore tolerance row, StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicMeshLocator}^{\uparrow}}$, seed)

Scope closed: Definition 7919.1, Definition 7919.2, and Definition 7919.3 seed the finite dyadic mesh cell-location packet for Real and Completion-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicMeshLocator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host trichotomy, selected nearest cells, quotient real equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh-row exactness, request exactness, selected-cell exposure, endpoint-tolerance accounting, StreamName and RegSeqRat handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMeshLocatorUp.

Chapter 7920

A Concrete Naming Certificate for $\mathsf{VerificationCoverageLedger}^{\uparrow}$

The $\mathsf{VerificationCoverageLedger}^{\uparrow}$ packet realizes certified-interpretability coverage as finite BEDC data: a component is counted as verified only through a displayed claim row, transcription row, backend proof row, coverage row, residue row, explanation scope, transport, replay, provenance, and local naming. It refines the formal-verification vision of Definition 9462.455 by giving the coverage accounting its own NameCert surface. The packet consumes classifier and explanation siblings such as chapter 6202, chapter 6138, chapter 7533, and chapter 6249; it does not certify the hidden model, replace the explanation ledger, prove classifier novelty, or turn proof coverage into semantic interpretability.

Definition 7920.1 (Verification coverage ledger carrier)**.** *A* $\mathsf{VerificationCoverageLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (K, T, B, C, R, E, F, H, D, P, N)$$

with the following displayed rows:

1. *K is the verified-component key naming the finite interpretability component under audit.*
2. *T is the transcription ledger row that states which BEDC claim was submitted to a proof backend.*
3. *B is the backend proof row naming the verifier transcript and proof object boundary.*
4. *C is the coverage row recording which component clauses are covered by T and B.*
5. *R is the residue row listing component clauses not covered by the verification transcript.*
6. *E is the scoped explanation row consumed from* $\mathsf{ScopedExplanationLedger}^{\uparrow}$*.*
7. *F is the classifier-facing row consumed from the positive-interpretability, novelty-witness, and black-box-fiber sibling packets.*
8. *H records componentwise* hsame *transport for the component key, transcription, backend proof, coverage, residue, explanation, classifier-facing, and structural rows.*
9. *D records displayed* Cont *replay from the component key through transcription, proof, coverage, residue, explanation, and classifier-facing rows.*
10. *P is the* Pkg *provenance over* $\mathsf{VerificationCoverageLedger}^{\uparrow}$*,* $\mathsf{PositiveInterpretabilityClassifier}^{\uparrow}$*,* $\mathsf{ClassifierNoveltyWitn}$ $\mathsf{BlackBoxFiberWitness}^{\uparrow}$*,* $\mathsf{ScopedExplanationLedger}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{VerificationCoverageLedger}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, T, B, C, R, E, F, H, D, P, N$. It has no coordinate for hidden backend trust, whole-model transparency, proof coverage outside the transcription ledger, unscoped explanation transfer, or discovery status without a classifier-novelty witness.

Theorem 7920.2 (Verification coverage ledger NameCert obligations)**.** *For every accepted* VerificationCoverageLedg *carrier $V = (K, T, B, C, R, E, F, H, D, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VerificationCoverageLedger}^{\uparrow}}$ *surface consists exactly of verified-component admission, transcription-ledger admission, backend proof-boundary exposure, coverage-row accounting, residue-row accounting, scoped-explanation handoff, classifier-facing handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7920.1. The visible verification inventory is $K, T, B, C, R, E, F, H, D, P, N$, so each accepted coverage claim must name the component, transcription, backend proof boundary, coverage row, and residue row.

The transcription row is the only path from a component claim to backend verification. Thus the backend proof row B cannot certify a claim not displayed by T, and the coverage row C cannot silently cover a clause listed in the residue row R.

The explanation and classifier-facing rows keep interpretability separate from proof accounting. Row E scopes the explanation ledger, while row F records the classifier and novelty surfaces that remain external obligations.

Finally H, D, P, N transport, replay, source, and name the same route. Since the carrier has no hidden backend-trust coordinate, whole-model transparency coordinate, unscoped explanation transfer, or discovery-status coordinate, those objects are not local obligations of the packet. □

Theorem 7920.3 (Verification coverage residue handoff)**.** *Every certified-interpretability consumer of an accepted* $\mathsf{VerificationCoverageLedger}^{\uparrow}$ *packet receives the route*

$$K \longrightarrow T \longrightarrow B \longrightarrow C, R \longrightarrow E, F \longrightarrow H, D, P, N.$$

Thus verification coverage is read together with its residue ledger before it can be consumed by scoped explanation or classifier-facing rows.

Proof. Start from Definition 7920.2. It requires the component key, transcription ledger, backend proof boundary, coverage row, and residue row before any consumer reads the packet.

The coverage and residue rows are paired. A covered clause must pass through C, while any uncovered clause remains visible in R and cannot be erased by the backend proof transcript.

The explanation and classifier-facing rows are downstream of the coverage ledger. They may consume the certified component only with its displayed residue, and they do not create novelty or whole-model transparency by themselves.

The transport, replay, provenance, and naming rows preserve the same route. The packet therefore exposes a falsifiable coverage surface rather than a hidden proof-quality score. □

Falsifiable prediction: Every accepted $\mathsf{VerificationCoverageLedger}^{\uparrow}$ read exposes a component key, transcription ledger, backend proof boundary, coverage row, residue row, scoped explanation row, classifier-facing row, transport, replay, provenance, and local naming before claiming certified interpretability coverage.

Independence witness: positive-interpretability-classifier, classifier-novelty-witness, black-box-fiber-witness, scoped-explanation-ledger, namecert: $\mathsf{VerificationCoverageLedger}^{\uparrow}$ is not bijective to

any listed sibling because it joins backend proof coverage with explicit residue accounting while leaving classifier novelty, black-box fiber exposure, scoped explanation, and generic NameCert obligations as separately named rows.

Future TasteGate work for $\mathsf{VerificationCoverageLedger}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ VerificationCoverageLedge}$ and $\mathsf{FieldFaithful\ VerificationCoverageLedger}^{\uparrow}$ instances. Nontriviality is witnessed by a packet with a nonempty residue row and the same component key, transcription, proof boundary, explanation, classifier-facing, transport, replay, provenance, and naming rows; field faithfulness requires every accepted read to preserve $K, T, B, C, R, E, F, H, D, P, N$ as displayed.

Closure status for $\mathsf{NameCert}_{\mathsf{VerificationCoverageLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{VerificationCoverageLedger}^{\uparrow}$ packet is generated from verified-component keys, transcription ledgers, backend proof-boundary rows, coverage rows, residue rows, scoped explanation rows, classifier-facing rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VerificationCoverageLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7920.1, Definition 7920.2, Definition 7920.3, the falsifiable prediction, the independence witness, and the future TasteGate obligations seed the certified-interpretability verification coverage packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VerificationCoverageLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, hidden backend trust, whole-model transparency, classifier novelty, black-box fiber exposure, unscoped explanation transfer, or discovery status.

Upgrade path: Obligation closure requires checked carrier admission, transcription exactness, backend proof-boundary exposure, coverage and residue accounting, scoped-explanation handoff, classifier-facing handoff, transport stability, replay, provenance, local naming, and TasteGate nontriviality with field faithfulness for BEDC.Derived.VerificationCoverageLedgerUp.

Chapter 7921

A Concrete Naming Certificate for $\mathsf{SchurProperty}^{\uparrow}$

Following Schur's classical sequence-space property for ℓ^1, the $\mathsf{SchurProperty}^{\uparrow}$ packet records the finite BEDC surface on which weakly convergent sequence data can be read as norm-convergent sequence data. It sits after the norm carrier of chapter 89, the vector-space rows of chapter 47, the linear-functional interface of chapter 48, and the metric readout of chapter 57. The packet names a displayed weak-to-norm sequence route; it is not a Banach-space classification theorem, a duality representation theorem, a selected subsequence principle, or an ambient completeness claim.

Definition 7921.1 (Schur property carrier)**.** *A* $\mathsf{SchurProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (V, N, L, W, M, H, C, P, A)$$

with the following displayed rows:

1. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row naming the finite vector expressions and scalar-action windows inspected by the packet.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row naming the norm observations on the same displayed sequence windows.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the finite family of linear-functional reads used to expose weak convergence.*
4. *W is the weak-sequence ledger, recording the displayed functional tests and their finite tail bounds.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *or norm-induced distance row that reads the displayed norm tails as a metric convergence claim.*
6. *H records componentwise* hsame *transport for V, N, L, W, M and for the replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from vector and functional windows through weak-tail checks into the norm-distance readout.*
8. *P is the* Pkg *provenance over* $\mathsf{SchurProperty}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *A is the local* $\mathsf{NameCert}_{\mathsf{SchurProperty}^{\uparrow}}$ *row naming exactly this finite weak-to-norm packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host Banach-space theorem, dual-space representation, selected subsequence, quotient equality of sequences, countable choice, or ambient completeness of the normed space.

Theorem 7921.2 (Schur property NameCert obligations)**.** *For every accepted* $\mathsf{SchurProperty}^{\uparrow}$ *carrier*

$$S = (V, N, L, W, M, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{SchurProperty}^{\uparrow}}$ *surface consists exactly of vector-space exposure through* V*, norm observation through* N*, finite linear-functional tests through* L*, weak-tail bookkeeping through* W*, norm-distance readout through* M*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* A*.*

Proof. Project the carrier of Definition 7921.1. The rows V, N, L, W, M are the only mathematical rows visible before a sequence consumer can read weak convergence or norm convergence.

The structural rows H, C, P, A preserve that same route. Transport is componentwise, replay follows the displayed functional tests and norm-distance readout, provenance names the same dependency packet, and local naming registers no extra analytic object.

Thus the listed rows exhaust the NameCert surface. Since the carrier contains no host Banach-space theorem, dual representation, selected subsequence, quotient sequence equality, choice schedule, or ambient completeness field, no downstream consumer can obtain such data from the $\mathsf{SchurProperty}^{\uparrow}$ packet. □

Theorem 7921.3 (Schur property sequence norm witness)**.** *Every accepted* $\mathsf{SchurProperty}^{\uparrow}$ *read that turns displayed weak sequence convergence into displayed norm convergence must expose the route*

$$\mathsf{VecSpace}^{\uparrow}, \mathsf{Norm}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{Met}^{\uparrow}, H, C, P, A$$

through the carrier rows $V, N, L, W, M, H, C, P, A$*. The norm-convergence witness is a finite tail-read over the displayed functional tests and norm-distance ledger, not a selected subsequence argument, a dual-space completeness theorem, a quotient equality of sequences, or an ambient Banach-space completeness claim.*

Proof. Start from the accepted carrier. The weak side of the read is visible only through the vector-space row V, the linear-functional row L, and the weak-tail ledger W.

The norm side is then read through N and M. These rows record the finite norm observations and the induced metric-distance tails that a consumer may inspect.

Finally attach H, C, P, A. They transport, replay, source, and locally name the same finite packet, so the witness remains a displayed sequence-norm route. Because no selected subsequence, quotient sequence equality, dual completeness, or ambient Banach completeness row appears in the carrier, the route exports none of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{SchurProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SchurProperty}^{\uparrow}$ packet is generated from VecSpaceUp sequence windows, NormUp observations, LinearMapUp functional tests, weak-tail bookkeeping, MetricUp distance readout, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SchurProperty}^{\uparrow}}$, seed)

Scope closed: Definition 7921.1, Definition 7921.2, and Definition 7921.3 seed the finite weak-to-norm sequence route over $\mathsf{Norm}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, and $\mathsf{Met}^{\uparrow}$ rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SchurProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a general Banach-space classification theorem, dual-space representation, selected subsequences, quotient sequence equality, countable choice, ambient completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-tail functional test exposure, norm-distance readout, sequence-witness routing, transport, replay, provenance, and local naming for BEDC.Derived.SchurPropertyUp.

Chapter 7922

A Concrete Naming Certificate for $\mathsf{EventFlowRecognizer}^{\uparrow}$

The $\mathsf{EventFlowRecognizer}^{\uparrow}$ packet realizes the inscription-event carrier of chapter 9397 as finite recognizer data. It sits after the inscription-event surface of chapter 519, the named route packet of chapter 582, the recognizer-flow dependency of chapter 1048, and the GAP-ledger boundary of chapter 520. The packet names event recognition as visible source, route, role, ledger, transport, replay, provenance, and local naming rows; it does not add private intention, hidden generator state, evaluator equality, or unbounded kernel authority.

Definition 7922.1 (Event-flow recognizer carrier)**.** *An* $\mathsf{EventFlowRecognizer}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, I, G, L, F, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{InscriptionEvent}^{\uparrow}$ *source row naming the accepted event transition and its public record boundary.*
2. *I is the* $\mathsf{InscribedRoute}^{\uparrow}$ *row naming the finite route from visible gap through accepted record and downstream consumer ledger.*
3. *G is the* $\mathsf{GroundCompilerRecognizerFlow}^{\uparrow}$ *row naming the recognizer flow that checks the accepted route against the compiler-facing record.*
4. *L is the* $\mathsf{InscriptionGapLedger}^{\uparrow}$ *row recording the gap residue, accountability, and non-escape boundary for the same event.*
5. *F is the recognizer-role row, naming which finite consumer role may read E, I, G, L as one event-flow packet.*
6. *H records componentwise* hsame *transport for source event, route, recognizer flow, gap ledger, role, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through the route*

$$E, I, G, L, F \longmapsto N.$$

8. *P is the* Pkg *provenance over* $\mathsf{EventFlowRecognizer}^{\uparrow}$, $\mathsf{InscriptionEvent}^{\uparrow}$, $\mathsf{InscribedRoute}^{\uparrow}$, $\mathsf{GroundCompilerRecognize}$ $\mathsf{InscriptionGapLedger}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{EventFlowRecognizer}^{\uparrow}}$ *row.*
The classifier compares accepted packets only by these rows. It has no coordinate for private agency, hidden generator choice, evaluator equality, quotient equality of routes, global kernel consistency, or an unbounded recognizer oracle.

Theorem 7922.2 (Event-flow recognizer NameCert obligations)**.** *For every accepted* $\mathsf{EventFlowRecognizer}^{\uparrow}$ *carrier*

$$R = (E, I, G, L, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EventFlowRecognizer}^{\uparrow}}$ *surface consists exactly of inscription-event exposure through E, inscribed-route exposure through I, ground-compiler recognizer flow through G, GAP-ledger accountability through L, recognizer role through F, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 7922.1. The rows E, I, G, L, F are the only event, route, recognizer-flow, gap-ledger, and consumer-role data visible before an event-flow consumer reads the packet.

The structural rows H, C, P, N preserve this route. Transport is componentwise, replay follows the displayed recognizer flow, provenance names the same source packets, and local naming registers the finite event-flow recognizer.

Thus the listed rows exhaust the NameCert surface. Since no private intention, hidden generator choice, evaluator equality, quotient route equality, global consistency theorem, or unbounded recognizer oracle appears in the carrier, no accepted consumer can read such data from the packet. □

Theorem 7922.3 (Event-flow recognizer ledger nonescape)**.** *Every* $\mathsf{EventFlowRecognizer}^{\uparrow}$ *consumer reading an inscription event as a recognizer flow must expose*

$$E, I, G, L, F, H, C, P, N$$

before it may use the recognized event. The GAP-ledger row L remains visible beside the route and recognizer-flow rows, so the read is a finite inscription-event recognition packet, not a hidden agency explanation, an evaluator-equality theorem, a quotient route equality, global kernel consistency, or a private generator-state claim.

Proof. Start with the event and route rows E and I. They display the accepted inscription transition and the finite route that carries it to a public record.

Next read the recognizer-flow and ledger rows G and L. These keep the ground-compiler-facing recognizer route and the gap-accountability ledger visible before the consumer role F can treat the transition as recognized.

Finally attach H, C, P, N. They transport, replay, source, and locally name the same finite packet. Because every consumed row is displayed, the route cannot escape to hidden agency, evaluator equality, quotient route equality, global kernel consistency, or private generator state. □

Falsifiable prediction: An accepted $\mathsf{EventFlowRecognizer}^{\uparrow}$ read is refuted if a consumer recognizes an inscription event without displaying the inscription-event source row, inscribed-route row, ground-compiler recognizer-flow row, GAP-ledger row, recognizer-role row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Independence witness: inscriptionevent, inscribedroute, groundcompilerrecognizerflow, inscriptiongap-ledger: $\mathsf{EventFlowRecognizer}^{\uparrow}$ is not bijective to any listed sibling because it binds event source,

accepted route, recognizer flow, gap accountability, consumer role, transport, replay, provenance, and local naming into one finite NameCert packet.

Later Lean TasteGate work supplies the nontriviality and field-faithfulness instances for the recognizer classifier. This chapter records only the concrete packet surface that those instances must inspect: the finite event, route, recognizer-flow, ledger, role, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EventFlowRecognizer}^{\uparrow}}$.

Constructive story: An $\mathsf{EventFlowRecognizer}^{\uparrow}$ packet is generated from an InscriptionEventUp source row, an InscribedRouteUp route row, a GroundCompilerRecognizerFlowUp recognizer row, an InscriptionGapLedgerUp accountability row, a recognizer-role row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EventFlowRecognizer}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7922.1, Definition 7922.2, and Definition 7922.3 seed the finite inscription-event recognizer route over source event, route, recognizer-flow, GAP-ledger, role, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EventFlowRecognizer}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim private intention, hidden generator choice, evaluator equality, quotient route equality, global kernel consistency, unbounded recognizer authority, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recognizer-role exactness, GAP-ledger nonescape, route compatibility, transport, replay, provenance, local naming, and TasteGate nontriviality and field-faithfulness instances for BEDC.Derived.EventFlowRecognizerUp.

Chapter 7923

A Concrete Naming Certificate for $\mathsf{FiniteWalshTransform}^{\uparrow}$

Following Walsh and Hadamard finite transform theory, the $\mathsf{FiniteWalshTransform}^{\uparrow}$ packet records a dyadic binary-character transform over finite data without importing host Fourier analysis, ambient Hilbert-space completion, or an external orthogonality theorem. It sits next to the finite observation surface of chapter 124, the butterfly schedule of chapter 226, the dyadic arithmetic ledger of chapter 291, and the finite stream-window discipline of chapter 126.

Definition 7923.1 (Finite Walsh transform carrier)**.** *A* $\mathsf{FiniteWalshTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, B, X, A, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-window row, listing the finite input coordinates and retained output coordinates.*
2. *B is the binary-character row, recording the displayed bitwise parity probes used to evaluate Walsh signs.*
3. *X is the signed accumulation row, containing the finite plus-minus summation ledger attached to the retained coordinates.*
4. *A is the Hadamard-stage row, naming the finite row/column stage data used by the transform read.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row for normalized sums, sign changes, and dyadic scaling.*
6. *R is the readback row consumed by finite harmonic-analysis neighbours after S, B, X, A, D have been displayed.*
7. *H records componentwise* hsame *transport for the displayed source windows, binary characters, accumulation rows, stage rows, arithmetic rows, readback rows, provenance, and local naming.*
8. *C records displayed* Cont *replay from a finite coordinate request through S, B, X, A, D, R.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteWalshTransform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{Fft}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWalshTransform}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, B, X, A, D, R, H, C, P, N$. It has no coordinate for host Fourier inversion, completed orthogonal bases, analytic convergence, quotient equality of functions, selected infinite spectra, or floating-point error analysis.

Theorem 7923.2 (Finite Walsh transform NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWalshTransform}^{\uparrow}$ *carrier $W = (S, B, X, A, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteWalshTransform}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source-window, binary-character, signed-accumulation, Hadamard-stage, dyadic-arithmetic, readback, transport, replay, provenance, and local naming rows; binary-character exactness through B; finite accumulation exactness through X; stage accountability through A; dyadic scaling through D; and public readback through R, H, C, P, N.*

Proof. Project the carrier of Definition 7923.1. Its visible inventory is exactly $S, B, X, A, D, R, H, C, P, N$, so every local naming duty begins with finite source and output windows rather than with a host transform.

The transform-specific rows are then read in order. The binary-character row B supplies the parity probes, the signed accumulation row X records the finite plus-minus ledger, and the Hadamard-stage row A names the row/column stage data used by the same finite request.

The arithmetic endpoint is also explicit. The dyadic row D accounts for scaling and sign changes before the readback row R can be consumed by Fourier or FFT-facing neighbours.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores inversion, completed orthogonality, convergence closure, quotient function equality, selected spectra, or floating-point analysis, the listed rows exhaust the local NameCert obligations. □

Theorem 7923.3 (Finite Walsh transform binary-character handoff)**.** *Every finite harmonic-analysis consumer of an accepted* $\mathsf{FiniteWalshTransform}^{\uparrow}$ *packet receives the Walsh read only through*

$$S, B \longmapsto X, A \longmapsto D, R \longmapsto H, C, P, N.$$

The handoff may be compared with the Fourier observation surface of chapter 124 and the butterfly schedule of chapter 226, but it exports only finite binary-character rows, finite signed sums, Hadamard-stage data, dyadic scaling, and displayed readback.

Proof. Start with the rows S and B. The source-window row fixes the finite coordinates under inspection, while the binary-character row fixes the parity probes that determine the Walsh signs.

Next read X and A. The signed accumulation row records the finite sum attached to the retained coordinates, and the Hadamard-stage row records the finite stage data used by the same transform request.

Only after those rows are displayed can the dyadic scaling and readback rows D, R be consumed. Thus a Fourier or FFT-facing consumer receives a finite binary-character handoff rather than an ambient Fourier transform, completed basis theorem, inversion theorem, or analytic convergence claim.

The structural rows H, C, P, N preserve this factorization under transport, replay, provenance, and local naming. The packet therefore supplies a finite Walsh neighbour for harmonic-analysis consumers without adding host analytic structure. □

Falsifiable prediction: Every accepted $\mathsf{FiniteWalshTransform}^{\uparrow}$ read factors through source windows, binary-character parity probes, signed accumulation rows, Hadamard-stage rows, dyadic scaling, readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any finite harmonic-analysis consumer may cite it.

Independence witness: streamname, dyadicratcore, fourier, fft: $\mathsf{FiniteWalshTransform}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite source windows, binary-character parity probes, signed plus-minus accumulation, Hadamard-stage data, dyadic scaling, readback, transport, replay, provenance, and local NameCert rows as one finite transform packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWalshTransform}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWalshTransform}^{\uparrow}$ packet is generated from finite source windows, binary-character parity probes, signed accumulation rows, Hadamard-stage data, dyadic scaling, readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWalshTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7923.1, Definition 7923.2, and Definition 7923.3 seed the finite binary-character transform route over StreamName, DyadicRatCore, Fourier, and FFT-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWalshTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Fourier inversion, completed orthogonality, analytic convergence, quotient equality of functions, selected infinite spectra, floating-point error analysis, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, binary-character exactness, finite accumulation exactness, Hadamard-stage accountability, dyadic scaling, readback, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWalshTransformUp.

Chapter 7924

A Concrete Naming Certificate for $\mathsf{OsgoodCurve}^{\uparrow}$

Following Osgood's positive-area curve construction, the $\mathsf{OsgoodCurve}^{\uparrow}$ packet records a finite Real/Completion-facing certificate for a continuous curve whose image carries a displayed positive-area witness. It consumes the terminal real-name boundary of chapter 38, the regular rational readback of chapter 301, the finite observation schedule of chapter 126, the continuous-map carrier of chapter 130, and the compact metric source of chapter 129. The chapter names the finite rows needed by a classical-analysis consumer without asserting ambient completeness, open-cover compactness, host measure theory, quotient function equality, or a selected parametrization outside the displayed data.

Definition 7924.1 (OsgoodCurve carrier)**.** *An* $\mathsf{OsgoodCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, I, S, R, M, A, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact metric source row, read through the* $\mathsf{CompactMetric}^{\uparrow}$ *interface;*
2. *I is the interval or curve-parameter window row, stored as finite* $\mathsf{StreamName}^{\uparrow}$ *observations;*
3. *S is the regular rational sampling schedule for the curve coordinates, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is exposed;*
4. *R is the displayed* $\mathsf{Real}^{\uparrow}$ *coordinate-readback row for the continuous image;*
5. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus and graph-window row tying the samples in S to the compact source K;*
6. *A is the finite positive-area witness row, consisting of dyadic rectangle windows, lower-area ledger entries, and the displayed cover-overlap exclusions used by the packet;*
7. *H stores componentwise* hsame *transports for compact-source, parameter-window, regular-sample, real-readback, continuity, positive-area, provenance, and local naming rows;*
8. *C stores the displayed* Cont *routes for reading the compact source, replaying the coordinate samples, checking the continuity window, and exposing the positive-area witness;*
9. *P is the* Pkg *provenance over* BHist, msame, hsame, Cont, *compact metric rows, stream rows, regular rational rows, real rows, continuous-map rows, positive-area ledgers, and the surrounding* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{OsgoodCurve}^{\uparrow}}$ *row.*

The carrier contains no host planar measure space, no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*, no open-cover compactness principle, no quotient equality of curves, and no selected parametrization beyond the displayed stream and regular-rational rows.*

Theorem 7924.2 (OsgoodCurve NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{OsgoodCurve}^{\uparrow}}$ *surface for the carrier of Definition 7924.1 consists of six finite obligations:*

1. *compact source: the accepted packet displays the compact metric source row K and the parameter-window row I through the cited compact and stream interfaces;*
2. *regular coordinate readback: every coordinate read passes through the regular rational schedule S before the terminal real row R is consumed;*
3. *continuity window: the row M supplies the finite modulus and graph-window evidence required by the* $\mathsf{ContinuousMap}^{\uparrow}$ *route;*
4. *positive-area witness: the row A lists the dyadic rectangles, lower-area ledger entries, and overlap exclusions that witness the displayed positive-area claim at the certificate level;*
5. *transport and replay: reads of K, I, S, R, M, A transport through H and replay only along the displayed continuation routes C;*
6. *provenance: the package row P and local naming row N bind the preceding rows as one* $\mathsf{OsgoodCurve}^{\uparrow}$ *NameCert packet.*

Thus the packet offers a finite Osgood-curve certificate for Real and Completion consumers, not a host theorem that every classical positive-area curve has been reconstructed inside BEDC.

Proof. Carrier admission is projection from Definition 7924.1. The compact source, parameter windows, regular coordinate samples, real readback rows, continuity evidence, positive-area ledger, transports, continuation routes, provenance, and local name are all displayed coordinates of the same finite packet.

The coordinate-readback obligation is finite because the stream and regular-rational rows I, S are the only schedules through which R may be read. The continuity obligation is finite because M stores the displayed modulus and graph-window rows rather than a host function-space equality.

The positive-area obligation reads only the dyadic rectangles and lower-area ledger entries stored in A. Overlap exclusions and lower bounds are replayed through C and transported through H, so the certificate never imports an ambient measure algebra or selected measurable representative.

Finally P and N bind the displayed rows as one local NameCert surface. The excluded host objects have no coordinate in O, so every Real or Completion consumer receives only the finite Osgood-curve data stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{OsgoodCurve}^{\uparrow}}$.

Constructive story: An $\mathsf{OsgoodCurve}^{\uparrow}$ packet is generated from a compact metric source, finite stream parameter windows, regular rational coordinate schedules, real readback rows, a continuous-map modulus and graph window, a dyadic positive-area ledger, componentwise hsame transports, displayed Cont routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{OsgoodCurve}^{\uparrow}}$, seed)

Scope closed: Definition 7924.1 and Definition 7924.2 bind the finite Osgood-curve carrier and its NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{OsgoodCurve}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close ambient real completeness, host planar measure theory, open-cover compactness, quotient equality of curves, a selected parametrization outside the displayed rows, or bridge checking.

Upgrade path: Obligation closure requires checked finite replay theorems for the coordinate-readback, continuity-window, and positive-area ledger obligations.

Chapter 7925

A Concrete Naming Certificate for $\mathsf{BarrBeckMonadicity}^{\uparrow}$

Following Barr and Beck on monadicity, the $\mathsf{BarrBeckMonadicity}^{\uparrow}$ packet records the finite categorical comparison surface where an adjunction, its induced monad, algebra rows, comparison functor, and exactness witnesses can be named without importing ambient category theory. The packet reads chapter 107, chapter 61, chapter 62, chapter 5827, and chapter 3836. It names the comparison route only; it does not assert existence of all coequalizers, preservation of arbitrary limits, host equality of Eilenberg–Moore categories, quotient completion equality, selected representatives, countable choice, Lean verification, or bridge checking.

Definition 7925.1 (Barr-Beck monadicity carrier)**.** *A* $\mathsf{BarrBeckMonadicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, C, D, F, U, T, E, K, X, Q, H, R, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Adjunction}^{\uparrow}$ *row, displaying the left and right comparison legs together with the unit and counit triangles.*
2. *C is the source* $\mathsf{Cat}^{\uparrow}$ *row from which the adjunction domain is read.*
3. *D is the target* $\mathsf{Cat}^{\uparrow}$ *row in which the monad and algebra rows are compared.*
4. *F is the* $\mathsf{Functor}^{\uparrow}$ *comparison row induced by the displayed adjunction data.*
5. *U is the induced monad row, recording unit and multiplication schedules visible to comparison consumers.*
6. *T is the algebra-action row over the same monad schedule.*
7. *E is the exactness row for the finite reflexive-pair or split-pair evidence exposed to the classifier.*
8. *K is the comparison-kernel row recording how the comparison functor reads algebra data back into the adjunction surface.*
9. *X is the* $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *specialization row available to completion-facing consumers.*
10. *Q is the* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *route that supplies the metric-completion adjunction anchor for categorical completion chapters.*

11. *H records componentwise* hsame *transport for the adjunction, category, functor, monad, algebra, exactness, comparison, completion-specialization, metric-completion route, replay, provenance, and local naming rows.*
12. *R records displayed* Cont *replay from any monadicity request through $A, C, D, F, U, T, E, K, X, Q, H, P, N$.*
13. *P is the* Pkg *provenance over* $\mathsf{BarrBeckMonadicity}^{\uparrow}$, $\mathsf{Adjunction}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$, $\mathsf{MetricCompletionAdjunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{BarrBeckMonadicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, C, D, F, U, T, E, K, X, Q, H, R, P, N$. The carrier has no coordinate for a host Eilenberg–Moore category, an external quotient object, a selected coequalizer, arbitrary-limit preservation, countable-choice schedules, Lean verification, or bridge checking.

Lean4 (statement) `BEDC.Derived.BarrBeckMonadicityUp`

Theorem 7925.2 (Barr-Beck monadicity NameCert obligations)**.** *For every accepted* $\mathsf{BarrBeckMonadicity}^{\uparrow}$ *carrier*

$$B = (A, C, D, F, U, T, E, K, X, Q, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BarrBeckMonadicity}^{\uparrow}}$ *surface consists exactly of carrier admission, adjunction visibility, source and target category exposure, comparison-functor exposure, induced monad schedule, algebra-action row, exactness witness row, comparison-kernel readback, Cauchy-completion monadicity specialization, metric-completion adjunction anchoring, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No local obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 7925.1. The displayed tuple lists every row available to the classifier, so local comparison can inspect only the adjunction, the two category rows, the comparison functor, the monad schedule, the algebra action, exactness, comparison-kernel readback, completion specialization, metric-completion anchor, transport, replay, provenance, and local naming.

The categorical rows are read first. The row A supplies the adjunction data, C and D supply the source and target categorical surfaces, and F records the comparison functor induced from the same visible data.

The monadicity rows then bind the comparison. The row U supplies unit and multiplication schedules, T records the algebra action over that schedule, E records the finite exactness witness exposed to the classifier, and K records the comparison-kernel readback.

Finally the completion-facing rows anchor downstream use. The row X points to the Cauchy-completion monadicity specialization and Q points to the metric-completion adjunction route, after which H, R, P, N transport, replay, source, and name exactly the displayed packet. Since no excluded coordinate occurs, no additional local obligation is available. □

Theorem 7925.3 (Barr-Beck comparison route)**.** *Every categorical-completion consumer of an accepted* $\mathsf{BarrBeckMonadicity}^{\uparrow}$ *carrier factors through the finite route*

$$A, C, D, F \longmapsto U, T, E, K \longmapsto X, Q \longmapsto H, R, P, N.$$

Thus the adjunction, category, functor, monad, algebra, exactness, and comparison-kernel rows are read before the $\mathsf{CauchyCompletionMonadicity}^{\uparrow}$ *specialization or the* $\mathsf{MetricCompletionAdjunction}^{\uparrow}$ *anchor is exported. The route exports no host Eilenberg–Moore category, quotient completion equality,*

selected coequalizer, selected limit representative, arbitrary-limit preservation theorem, countable-choice schedule, Lean verification, or bridge checking.

Proof. Start with the public categorical surface. The adjunction row A, source and target category rows C, D, and comparison-functor row F provide the only categorical coordinates available before monadicity is inspected.

Next consume the monadicity rows. The monad schedule U, algebra action T, finite exactness witness E, and comparison-kernel readback K form the visible comparison boundary; no host category equality or arbitrary coequalizer coordinate is present.

Now attach the completion-facing anchors. The Cauchy-specialization row X and metric-completion adjunction row Q identify the downstream completion route without adding quotient completion equality or selected representatives.

Finally route through transport, replay, provenance, and naming. The rows H, R, P, N exhaust the remaining classifier surface, so every exported categorical-completion consumer factors through the displayed finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BarrBeckMonadicity}^{\uparrow}}$.

Constructive story: A $\mathsf{BarrBeckMonadicity}^{\uparrow}$ packet is generated from an Adjunction row, two Category rows, a Functor comparison row, induced monad schedule, algebra-action row, finite exactness witness, comparison-kernel readback, CauchyCompletionMonadicity specialization, MetricCompletionAdjunction anchor, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BarrBeckMonadicity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7925.1, Definition 7925.2, and Definition 7925.3 seed the finite Barr-Beck comparison boundary for categorical completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BarrBeckMonadicity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Eilenberg–Moore category equality, selected coequalizers, arbitrary-limit preservation, quotient completion equality, selected representatives, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, adjunction visibility, source and target category exposure, comparison-functor exposure, induced monad schedule, algebra-action row, exactness witness row, comparison-kernel readback, completion specialization, metric-completion anchoring, transport, replay, provenance, and local naming for BEDC.Derived.BarrBeckMonadicityUp.

Chapter 7926

A Concrete Naming Certificate for $\mathsf{CartanDecomposition}^{\uparrow}$

Following Helgason and Knapp, the $\mathsf{CartanDecomposition}^{\uparrow}$ packet records the finite involution and eigenspace surface used to read a Lie algebra or Lie group through its compact and noncompact rows. It is grounded in the Lie-group route of chapter 140, the Lie-algebra carrier of chapter 141, the root-system and Weyl-group consumers of chapter 144 and chapter 145, and the bilinear-form row of chapter 146. The chapter names the displayed decomposition as finite NameCert data; it does not assert classification of real reductive groups, global symmetric-space theory, selected Cartan subalgebras, or analytic integration.

Definition 7926.1 (Cartan decomposition carrier)**.** *A* $\mathsf{CartanDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (G, L, \Theta, K, P, E, B, R, W, H, C, Q, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{LieGroup}^{\uparrow}$ *source row when a group-level source is present; otherwise it is the explicit absence row for group-level data.*
2. *L is the* $\mathsf{LieAlgebra}^{\uparrow}$ *row whose bracket and additive vector-space operations are the only algebraic operations read by the packet.*
3. *Θ is the involution row. It records an endomap of the displayed Lie-algebra carrier with Θ^2 classified with the identity by the local carrier relation.*
4. *K is the compact eigenspace row, recording the displayed fixed endpoints of Θ.*
5. *P is the noncompact eigenspace row, recording the displayed negated endpoints of Θ.*
6. *E is the eigenspace stability ledger. It records bracket routing for $[K, K]$ into K, $[K, P]$ into P, and $[P, P]$ into K whenever those brackets are displayed.*
7. *B is the* $\mathsf{BilinForm}^{\uparrow}$ *compatibility row used by consumers that inspect orthogonality, sign, or Killing-form-style pairings.*
8. *R is the* $\mathsf{RootSystem}^{\uparrow}$ *consumer row for restricted-root reads of the displayed P-side direction data.*
9. *W is the* $\mathsf{WeylGroup}^{\uparrow}$ *consumer row for reflection reads that are sourced through the same root-system row R.*

10. *H stores componentwise* hsame *transport for the group source, Lie algebra, involution, eigenspace, bracket-stability, bilinear-form, root, Weyl, replay, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from a decomposition request through the rows $G, L, \Theta, K, P, E, B, R, W, H$.*
12. *Q is the* Pkg *provenance over* $\mathsf{CartanDecomposition}^{\uparrow}$, $\mathsf{LieGroup}^{\uparrow}$, $\mathsf{LieAlgebra}^{\uparrow}$, $\mathsf{RootSystem}^{\uparrow}$, $\mathsf{WeylGroup}^{\uparrow}$, $\mathsf{BilinForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CartanDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host symmetric space, a selected maximal abelian subspace, analytic integration, or classification of real forms.

Theorem 7926.2 (Cartan decomposition involution eigenspace stability)**.** *For every accepted* $\mathsf{CartanDecomposition}^{\uparrow}$ *carrier*

$$D = (G, L, \Theta, K, P, E, B, R, W, H, C, Q, N),$$

any consumer that reads the public decomposition must first retain the involution row Θ, the compact row K, the noncompact row P, and the bracket-stability ledger E. The public read may then pass to the $\mathsf{BilinForm}^{\uparrow}$, $\mathsf{RootSystem}^{\uparrow}$, *and* $\mathsf{WeylGroup}^{\uparrow}$ *rows, but it cannot replace the finite rows by a host symmetric-space theorem, a selected Cartan subspace, analytic integration, or classification of real forms.*

Proof. Project the carrier of Definition 7926.1. The Lie-algebra source is the row L, and the decomposition data are exactly the involution Θ with the displayed fixed and negated rows K and P.

The stability claim is the row E. It keeps the three bracket routes $[K, K]$, $[K, P]$, and $[P, P]$ attached to the same involution and eigenspace rows before any downstream consumer can inspect the decomposition.

The bilinear-form and root-theoretic consumers are downstream from this retained surface. Rows B, R, W may read only the pairing, restricted-root, and reflection data named by the carrier, while H, C, Q, N transport, replay, source, and name the same finite packet. Since no excluded symmetric-space, selected-subspace, analytic, or classification row is present, the consumer is confined to the displayed NameCert route. □

Falsifiable prediction: Every $\mathsf{CartanDecomposition}^{\uparrow}$ consumer that reaches a restricted-root or Weyl read must first expose the Lie-algebra row, involution row, compact eigenspace row, noncompact eigenspace row, bracket-stability ledger, bilinear-form row, transport, replay, provenance, and local NameCert rows.

Independence witness: liegroup, liealgebra, rootsystem, weylgroup, bilinform: $\mathsf{CartanDecomposition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an involution, two eigenspace rows, a three-branch bracket-stability ledger, bilinear-form compatibility, root consumers, Weyl consumers, structural replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CartanDecomposition}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CartanDecomposition}^{\uparrow}$ packet is generated from optional LieGroup source data, a LieAlgebra carrier, an involutive endomap row, compact and noncompact eigenspace rows, a bracket-stability ledger, a BilinForm compatibility row, RootSystem and WeylGroup consumer rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CartanDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7926.1 and Definition 7926.2 seed the finite involution, eigenspace, bracket-stability, bilinear-form, root, and Weyl consumer surface.

Formal verification: FormalStatus(NameCert$_{\text{CartanDecomposition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close classification of real reductive groups, global symmetric-space theory, selected Cartan subspaces, analytic integration, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, involution exactness, eigenspace stability, bilinear-form compatibility, root and Weyl consumer routing, structural replay, provenance, and local naming for BEDC.Derived.CartanDecompo

Chapter 7927

A Concrete Naming Certificate for $\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}$

The $\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}$ packet realizes the Poincare-disk branch of chapter 9463 as finite boundary-anchored cocycle data. It sits after the disk metric packet of chapter 6209, the boundary-transport packet of chapter 6267, the additive Busemann-cocycle route of chapter 4134, the visual-metric packet of chapter 3866, and the horocycle carrier of chapter 3534. The packet names a finite disk-model cocycle read; it is not a quotient ideal boundary, a selected geodesic ray, a completed hyperbolic plane, a physical observer law, or an ambient curvature theorem.

Definition 7927.1 (Poincare disk Busemann cocycle carrier)**.** *A* $\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (D, B, M, U, V, Z, O, E, H, T, G, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-metric row over the displayed disk observations.*
2. *B is the boundary-anchor row, read through* $\mathsf{PoincareDiskBoundaryTransport}^{\uparrow}$*, that records the boundary endpoint held visible by the transport.*
3. *M is the* $\mathsf{HyperbolicBusemannCocycle}^{\uparrow}$ *additive cocycle row for the same boundary anchor and disk observations.*
4. *U is the boundary-transport update row. It records the finite handoff from one disk observation window to another while retaining the boundary anchor B.*
5. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *comparison row used when a visual-distance consumer reads the cocycle.*
6. *Z is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *horocycle row that supplies the boundary-tangent level surface consumed by Busemann-style reads.*
7. *O is the observer-expansion refusal row. It prevents the packet from being read as a physical observer trajectory, quotient boundary equality, selected ideal point, or completed disk model.*
8. *E is the exactness ledger. It ties D, B, M, U, V, Z, O to one cocycle read and records the displayed additivity and boundary-transport compatibility rows.*

9. *H stores componentwise* hsame *transport for disk metric, boundary anchor, cocycle, boundary transport, visual metric, horocycle, refusal, exactness, replay, provenance, and local naming rows.*

10. *T stores displayed* Cont *replay from a boundary-cocycle request through $D, B, M, U, V, Z, O, E, H$.*

11. *G is the* Pkg *provenance over* PoincareDiskBusemannCocycle$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, PoincareDiskBoundaryTranspo HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicHorocycle$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{PoincareDiskBusemannCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed ideal-boundary quotients, selected geodesic representatives, ambient hyperbolic planes, or physical observer dynamics.

Theorem 7927.2 (Poincare disk Busemann cocycle boundary transport)**.** *Every accepted* PoincareDiskBusemannCo *read that transports a Busemann comparison across disk windows must retain the route*

PoincareDiskMetric$^{\uparrow}$, PoincareDiskBoundaryTransport$^{\uparrow}$, HyperbolicBusemannCocycle$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, Hyp

The boundary transport may carry the cocycle to a visual-metric or horocycle consumer only while the boundary anchor B, additive cocycle row M, transport row U, exactness ledger E, and refusal row O remain displayed. It does not assert quotient boundary equality, selected geodesic rays, completed disk geometry, physical observer dynamics, or global curvature.

Proof. Project the carrier of Definition 7927.1. The disk observation row is D, the boundary anchor is B, and the additive Busemann comparison is M.

Read the boundary-transport and exactness rows next. The row U moves the displayed disk window only with the same boundary anchor, while E records that the additive cocycle and transport compatibility are inspected inside one finite packet.

The visual-metric and horocycle consumers are downstream. Rows V and Z may read only the comparison and horocycle data named by the same packet, and O prevents the read from escaping into quotient boundary equality, selected geodesic representatives, completed disk geometry, physical observer dynamics, or global curvature. Rows H, T, G, N then preserve, replay, source, and name the same finite route. □

Falsifiable prediction: Every accepted PoincareDiskBusemannCocycle$^{\uparrow}$ consumer must expose disk metric, boundary transport, Busemann cocycle, visual-metric, horocycle, exactness, refusal, transport, replay, provenance, and local NameCert rows before obtaining a boundary-cocycle handoff.

Independence witness: poincare-disk-metric, poincare-disk-boundary-transport, hyperbolic-busemann-cocycle, hyperbolic-visual-metric, hyperbolic-horocycle: none is bijective to PoincareDiskBusemannCocyc because this packet jointly carries disk metric data, a retained boundary anchor, additive cocycle, boundary-window transport, visual-metric comparison, horocycle level data, exactness, refusal, structural replay, provenance, and local naming.

The Lean TasteGate route must provide explicit Nontrivial PoincareDiskBusemannCocycle$^{\uparrow}$ and FieldFaithful PoincareDiskBusemannCocycle$^{\uparrow}$ instances. Nontriviality must distinguish an accepted packet with all rows $D, B, M, U, V, Z, O, E, H, T, G, N$ from a candidate missing the boundary anchor or exactness ledger. Field faithfulness must preserve those rows as distinct fields before a checked carrier-alignment theorem can serve as the TasteGate witness.

Closure status for $\mathsf{NameCert}_{\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}$ packet is generated from PoincareDiskMetric rows, PoincareDiskBoundaryTransport rows, HyperbolicBusemannCocycle rows, HyperbolicVisualMetric rows, HyperbolicHorocycle rows, an exactness ledger, a refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7927.1 and Definition 7927.2 seed the finite Poincare-disk Busemann cocycle route through disk metric, boundary transport, additive cocycle, visual metric, horocycle, exactness, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PoincareDiskBusemannCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient ideal-boundary equality, selected geodesic rays, completed hyperbolic-plane geometry, physical observer dynamics, global curvature, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked disk-metric admission, boundary-anchor transport, Busemann cocycle exactness, visual-metric and horocycle routing, TasteGate nontriviality, field faithfulness, structural replay, provenance, and local naming for BEDC.Derived.PoincareDiskBusemannCocycleUp.

Chapter 7928

A Concrete Naming Certificate for $\mathsf{CalderonZygmundOperator}^{\uparrow}$

Following Calderon–Zygmund and Stein on singular integral operators, the $\mathsf{CalderonZygmundOperator}^{\uparrow}$ packet records the finite kernel-window surface by which a truncated singular-integral request is named before any host principal value or measure completion is available. It sits beside the maximal domination route of chapter 3581, the finite cover ledger of chapter 2166, and the terminal real-name seal of chapter 38. The packet names only displayed source rows, kernel windows, size and cancellation ledgers, local test or average rows, scalar seals, transport, replay, provenance, and local naming; it does not assert selected principal values, completed measure spaces, quotient function equality, weak-type theorems, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7928.1 (Calderon-Zygmund operator carrier)**.** *A* $\mathsf{CalderonZygmundOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, W, S, A, L, M, D, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the metric or measure source row. It records the named points, measurable windows, local ball names, and source-side admission data actually inspected by the singular-integral request.*
2. *W is the truncated kernel-window row. Each entry records a finite exclusion radius, an outer cutoff, and the displayed source and target coordinates for the kernel read.*
3. *S is the kernel-size ledger. It stores the finite dyadic comparison budget for the displayed kernel windows, including the scale rows that compare kernel magnitude against the source distance.*
4. *A is the cancellation ledger. It records the displayed zero-average, antisymmetry, or subtraction row used on each accepted window before any operator value is read.*
5. *L is the local test-function or average row. It stores the finite test window, local average, or compactly supported probe against which the truncated kernel is evaluated.*
6. *M is the* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *domination handoff. It records the maximal-function comparison route used to control displayed local averages without selecting a host supremum.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scalar ledger for truncation radii, kernel-size comparisons, cancellation budgets, local averages, and domination tolerances.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is public only after W, S, A, L, M, D have all been displayed.*

9. *H stores componentwise* hsame *transport for X, W, S, A, L, M, D, E.*
10. *C stores displayed* Cont *replay of the finite route from a singular-integral request through truncation, kernel-size comparison, cancellation, local testing, maximal domination, dyadic accounting, and Real sealing.*
11. *P is the* Pkg *provenance over* CalderonZygmundOperator$^{\uparrow}$, HardyLittlewoodMaximal$^{\uparrow}$, FiniteVitaliCover$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{CalderonZygmundOperator}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, W, S, A, L, M, D, E, H, C, P, N$. It has no coordinate for a selected principal value, measure completion, quotient function representative, unbounded kernel family, hidden cancellation theorem, or ambient Real$^{\uparrow}$ *completeness principle.*

Lean4 ✓ `BEDC.Derived.CalderonZygmundOperatorUp.CalderonZygmundOperatorUp single carrier alignment`

Theorem 7928.2 (Calderon-Zygmund operator NameCert obligations)**.** *For every accepted* CalderonZygmundOper *carrier*

$$T = (X, W, S, A, L, M, D, E, H, C, P, N),$$

the local NameCert$_{\text{CalderonZygmundOperator}^{\uparrow}}$ *surface consists exactly of source admission, truncated kernel-window exposure, kernel-size ledger visibility, cancellation-ledger visibility, local test or average exposure,* HardyLittlewoodMaximal$^{\uparrow}$ *domination handoff,* DyadicRatCore$^{\uparrow}$ *scalar accounting, terminal* Real$^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. A singular-integral read is accepted only after W, S, A, L, M, D are all public in the same packet.*

Proof. Project the carrier of Definition 7928.1. The displayed tuple exposes exactly the source row, truncated windows, kernel-size ledger, cancellation ledger, local test or average rows, maximal handoff, dyadic ledger, Real seal, transport, replay, provenance, and local naming row.

The operator-facing rows are ordered by the carrier. A kernel read in W becomes admissible only together with the size ledger S and the cancellation ledger A, and a local output can be read only through the test or average row L.

The domination and scalar rows then close the finite numerical surface. The maximal-function handoff M supplies the displayed comparison route, while D records the dyadic tolerances and E seals the resulting real-name window.

Finally H, C, P, N preserve exactly the same packet. Since the carrier has no coordinate for selected principal values, completed measure spaces, quotient representatives, unbounded kernel families, hidden cancellation theorems, or ambient Real$^{\uparrow}$ completeness, those objects cannot appear as local NameCert obligations. □

Lean4 ✓ `BEDC.Derived.CalderonZygmundOperatorUp.CalderonZygmundOperatorNameCertObligations`

Theorem 7928.3 (Calderon-Zygmund kernel cancellation ledger)**.** *Every accepted* CalderonZygmundOperator$^{\uparrow}$ *read factors its kernel request through the finite route*

$$X, W \longmapsto S, A, L \longmapsto \text{HardyLittlewoodMaximal}^{\uparrow}, \text{DyadicRatCore}^{\uparrow} \longmapsto \text{Real}^{\uparrow}$$

before any operator-facing value is exported. Deleting the cancellation ledger A or the size ledger S leaves no public singular-integral read in the packet.

Proof. Start with the NameCert obligations of Definition 7928.2. They require each accepted read to expose the truncated kernel row W, the size ledger S, the cancellation ledger A, and the local test or average row L before domination or scalar sealing is available.

The handoff through M is therefore a domination route for a displayed finite window, not a host supremum or completed measure statement. The dyadic ledger D and Real seal E can only read the rows already exposed by W, S, A, L, M.

The structural rows H, C, P, N preserve this order. If S is absent, the packet has no public size comparison for the kernel window; if A is absent, the packet has no displayed cancellation or subtraction row. In either case there is no coordinate from which the singular-integral read can be exported. □

Falsifiable prediction: Every accepted $\mathsf{CalderonZygmundOperator}^{\uparrow}$ read is refuted if a Real seal is cited without the displayed truncated kernel windows, kernel-size ledger, cancellation ledger, local test or average row, HardyLittlewoodMaximal domination handoff, and DyadicRatCore scalar ledger.

Independence witness: hardy-littlewood-maximal, finite-vitali-cover, dyadicratcore, real: none is bijective to $\mathsf{CalderonZygmundOperator}^{\uparrow}$ because this packet jointly carries a source row, truncated kernel windows, kernel-size ledger, cancellation ledger, local test or average rows, maximal domination handoff, scalar ledger, Real seal, transport, replay, provenance, and local naming as one singular-integral operator certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CalderonZygmundOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{CalderonZygmundOperator}^{\uparrow}$ packet is generated from a metric or measure source row, truncated kernel windows, a kernel-size ledger, a cancellation ledger, local test or average rows, a HardyLittlewoodMaximalUp domination handoff, DyadicRatCoreUp scalar accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CalderonZygmundOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7928.1, Definition 7928.2, and Definition 7928.3 seed the finite singular-integral operator carrier, local NameCert surface, and kernel cancellation ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CalderonZygmundOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected principal values, measure completion, quotient function equality, weak-type or strong-type boundedness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, truncated kernel-window exposure, kernel-size ledger visibility, cancellation-ledger visibility, local test or average exposure, maximal domination handoff, scalar accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CalderonZygmundOperatorUp.

Chapter 7929

A Concrete Naming Certificate for LebesgueNumberCoverRefinement$^{\uparrow}$

Following Bishop–Bridges constructive compactness and Kelley's cover-refinement vocabulary, the LebesgueNumberCoverRefinement$^{\uparrow}$ packet records the finite route that turns a displayed compact cover, a positive Lebesgue-number radius, and a finite refinement request into a retained dyadic cover refinement. It sits over the radius lemma of chapter 2301, the finite comparison packet of chapter 3430, the star-refinement modulus route of chapter 6997, and the located finite-subcover route of chapter 3538. The packet names a finite cover-refinement certificate; it is not arbitrary open-cover compactness, not a selected subcover functional, and not ambient real completeness.

Definition 7929.1 (Lebesgue-number cover-refinement carrier)**.** *A* LebesgueNumberCoverRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, L, F, D, S, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, exposing the compact metric or located compact interval data only through the finite carrier already accepted by the surrounding chapter.*
2. *L is the* LebesgueNumberLemma$^{\uparrow}$ *positive-radius row attached to the displayed cover request.*
3. *F is the* FiniteCoverRefinement$^{\uparrow}$ *comparison row that records how the retained cover members refine the source cover.*
4. *D is the dyadic cover-refinement row, storing the mesh, ball, or cell comparisons used to compare the radius row with the retained finite cover.*
5. *S is the retained subcover row, listing only the finitely many cover witnesses reached through K, L, F, D.*
6. *E is the terminal* Real$^{\uparrow}$ *seal for radius, endpoint, and coverage observations used by the refinement read.*
7. *H stores componentwise* hsame *transport for the compact source, radius row, finite refinement row, dyadic refinement row, retained subcover row, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a compact cover request through $K, L, F, D, S, E, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}$, $\mathsf{LebesgueNumberLemma}^{\uparrow}$, FiniteCoverRefinemer $\mathsf{FiniteCoverStarRefinementModulus}^{\uparrow}$, $\mathsf{LocatedHeineBorelSubcover}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, L, F, D, S, E, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, choice-selected subcovers, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7929.2 (Lebesgue-number cover-refinement NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}$ *carrier*

$$R = (K, L, F, D, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed compact source, Lebesgue-number radius, finite cover refinement, dyadic cover refinement, retained subcover, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows; radius compatibility through L, D; finite refinement exactness through F, S; Real-seal non-escape through E; and structural preservation through H, C, P, N.*

Proof. Project the accepted carrier of Definition 7929.1. The analytic rows are K, L, F, D, S, E, and the structural rows are H, C, P, N.

The positive-radius data are read from L and compared with the dyadic refinement row D. The finite comparison row F then determines which retained witnesses may enter S.

The terminal seal E is downstream of those finite rows. Transport, replay, provenance, and local naming preserve the same displayed packet, so no obligation can be discharged by an arbitrary open-cover compactness principle, a selected subcover functional, quotient real equality, countable choice, or ambient completeness. □

Theorem 7929.3 (Lebesgue-number radius-to-refinement route)**.** *Every accepted* LebesgueNumberCoverRefinemen *cover read factors through the finite route*

$$\mathsf{LebesgueNumberLemma}^{\uparrow} \longmapsto \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto D, S \longmapsto \mathsf{Real}^{\uparrow}.$$

The exported object is the retained dyadic cover-refinement surface over $K, L, F, D, S, E, H, C, P, N$, not an arbitrary open-cover compactness theorem or a choice-selected subcover.

Proof. Start with an accepted carrier $R = (K, L, F, D, S, E, H, C, P, N)$. The compact source is K, the positive-radius row is L, and the finite comparison row is F.

The dyadic row D compares the radius with the displayed finite cells. The retained subcover row S is readable only after that comparison, so a consumer cannot bypass the radius ledger or the finite refinement packet.

Finally the Real seal E and the structural rows H, C, P, N replay the same finite route. Since the carrier has no coordinate for arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient completeness, the exported refinement is exactly the displayed BEDC packet. □

Falsifiable prediction: An accepted $\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}$ consumer that exports a retained cover refinement without displaying $K, L, F, D, S, E, H, C, P, N$ refutes the carrier surface.

Independence witness: Nearest siblings: lebesgue-number-lemma, finite-cover-refinement, finite-cover-star-refinement-modulus, and located-heine-borel-subcover. The packet binds the positive-radius row to a retained dyadic finite-refinement surface, while each sibling supplies only its own carrier route.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}$ packet is generated from a compact source row, a LebesgueNumberLemma positive-radius row, a FiniteCoverRefinement comparison row, dyadic cover-refinement rows, retained finite subcover witnesses, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7929.1, Definition 7929.2, and Definition 7929.3 seed the finite radius-to-refinement route over compact source rows, positive-radius ledgers, finite comparison rows, dyadic cover refinements, retained subcovers, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueNumberCoverRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius compatibility, finite refinement exactness, dyadic refinement admission, retained-subcover exactness, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueNumberCoverRefinementUp.

Chapter 7930

A Concrete Naming Certificate for $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$

Following Bishop and Bridges on constructive real numbers, a regular Cauchy comparison is allowed to produce apartness or located comparison data only after the finite equality-side readback has exposed the positive gap witness it uses. The $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ packet records that separator as NameCert data between the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, the located-cut comparison boundary of chapter 404, and the apartness-field route of chapter 5562. It is a finite boundary object for Real and Completion consumers; it does not claim trichotomy, quotient equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7930.1 (Regular sequence apartness separator carrier)**.** *A* $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, E, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the two regular sequence reads.*
2. *R is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row computed from those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that fixes the positive gap scale.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available after S, R, D have been displayed.*
5. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *comparison row read at the same dyadic scale.*
6. *A is the* $\mathsf{RealApartnessField}^{\uparrow}$ *apartness row exposed from the located comparison and the Real seal.*
7. *H stores componentwise* hsame *transport for the stream windows, regular readbacks, dyadic tolerance, Real seal, located comparison, apartness row, replay, provenance, and local naming.*
8. *C stores displayed* Cont *replay from a regular sequence comparison request through $S, R, D, E, L, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{RealApartnessField}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularSeqApartnessSeparator}^{\uparrow}}$ *row.*

The carrier has no coordinate for trichotomy, quotient stream equality, quotient real equality, selected representatives, countable choice, or ambient completeness.

Theorem 7930.2 (Regular sequence apartness separator obligation surface)**.** *For every accepted* $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ *carrier*

$$K = (S, R, D, E, L, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularSeqApartnessSeparator}^{\uparrow}}$ *surface consists exactly of paired finite-window exposure, paired regular-rational readback, dyadic positive-gap accounting, terminal Real-seal routing, located-cut comparison exposure, apartness-field exposure, componentwise transport, continuation replay, provenance, and local naming.*

Proof. Project the carrier of Definition 7930.1. The analytic rows are S, R, D, E, L, A, and the structural rows are H, C, P, N.

The stream and regular-rational rows S, R expose the two sequence reads before any comparison is consumed. The dyadic row D fixes the positive scale used by both the located comparison and the apartness read.

The terminal seal E is downstream of S, R, D. The located-cut row L and apartness-field row A are then read from that same displayed route, so no consumer can obtain apartness or located comparison data before the regular sequence and dyadic rows are visible.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since none of the excluded principles is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 7930.3 (Regular sequence apartness separator sibling dependency)**.** *Every Real-facing or Completion-facing consumer that reads apartness or located comparison data from a* RegularSeqApartnessSeparatc *packet must first pass through the sibling route*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{LocatedCut}^{\uparrow},\ \mathsf{RealApartnessField}^{\uparrow}.$$

The route exports only the displayed finite separator rows $S, R, D, E, L, A, H, C, P, N$ *and does not export trichotomy, quotient equality, selected representatives, countable choice, or ambient completeness.*

Proof. Apply the obligation surface of Definition 7930.2. It requires the stream windows, regular-rational readbacks, dyadic gap scale, Real seal, located-cut comparison, and apartness-field evidence to be displayed as one route before a local NameCert row is consumed.

The sibling chapters named in the route supply exactly those rows: $\mathsf{StreamName}^{\uparrow}$ supplies S, $\mathsf{RegSeqRat}^{\uparrow}$ supplies R, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies D, $\mathsf{Real}^{\uparrow}$ supplies E, $\mathsf{LocatedCut}^{\uparrow}$ supplies L, and $\mathsf{RealApartnessField}^{\uparrow}$ supplies A.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. They add no total order branch, quotient equality test, representative selector, choice schedule, or completeness theorem, so the separator remains a finite boundary between equality-side readback and apartness-side use. □

Lean4 (statement) `BEDC.Derived.RegularSeqApartnessSeparatorUp`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSeqApartnessSeparator}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSeqApartnessSeparator}^{\uparrow}$ packet is generated from paired StreamName finite windows, paired RegSeqRat readbacks, a DyadicRatCore positive-gap row, a RealUp seal, a LocatedCut comparison row, a RealApartnessField apartness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularSeqApartnessSeparator}\uparrow}$, seed)

Scope closed: Definition 7930.1, Definition 7930.2, and Definition 7930.3 seed the finite separator route between regular sequence equality-side readback, located comparison, and apartness-field exposure.

Formal verification: FormalStatus(NameCert$_{\text{RegularSeqApartnessSeparator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient stream equality, quotient real equality, selected representatives, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular-rational readback, dyadic positive-gap accounting, Real-seal routing, located-cut comparison exposure, apartness-field exposure, transport, replay, provenance, and local naming for BEDC.Derived.RegularSeqApartnessSeparatorUp.

Chapter 7931

A Concrete Naming Certificate for StoneRepresentationBooleanAlgebra$^{\uparrow}$

Following Stone and Birkhoff, the StoneRepresentationBooleanAlgebra$^{\uparrow}$ packet records the finite NameCert bridge that reads a displayed Boolean algebra through its Stone-space and clopen-row interface. It sits after the Boolean operation surface of chapter 3733, the Stone-duality classifier of chapter 261, the topology rows of chapter 88, and the regular-open comparison route of chapter 6835. The packet names the representation handoff as finite BEDC data; it does not import a host spectrum, choice-selected ultrafilter family, quotient Boolean algebra equality, or completed compact Hausdorff space.

Definition 7931.1 (Stone representation Boolean algebra carrier)**.** *A* StoneRepresentationBooleanAlgebra$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, U, T, L, M, H, C, P, N)$$

with the following displayed rows:

1. *B is the* BooleanAlgebra$^{\uparrow}$ *source row, exposing zero, one, join, meet, complement, order, and Boolean transport data.*
2. *U is the ultrafilter-observation row, recording only finite membership tests and finite compatibility checks against the Boolean source row.*
3. *T is the* StoneDuality$^{\uparrow}$ *Stone-space classifier row attached to the Boolean source.*
4. *L is the clopen-row ledger, reading each displayed Boolean element as a topology-facing clopen row through* Topology$^{\uparrow}$*.*
5. *M is the regular-open comparison row, allowing chapter 6835 to compare clopen rows with its closure-interior route without replacing the Boolean source.*
6. *H records componentwise* hsame *transport for Boolean rows, ultrafilter observations, Stone-space rows, clopen rows, regular-open comparisons, provenance, and local naming.*
7. *C records displayed* Cont *replay from a Boolean observation request through B, U, T, L, M and then through the structural rows.*
8. *P is the* Pkg *provenance over* StoneRepresentationBooleanAlgebra$^{\uparrow}$, BooleanAlgebra$^{\uparrow}$, StoneDuality$^{\uparrow}$, Topology$^{\uparrow}$, RegularOpenAlgebra$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, U, T, L, M, H, C, P, N$. It has no coordinate for a host powerset algebra, a choice-selected ultrafilter space, quotient Boolean equality, ambient compactness, or a replacement of the displayed Boolean-algebra carrier.

Lean4 ✓ `BEDC.Derived.StoneRepresentationBooleanAlgebraUp.StoneRepresentationBooleanAlgebraTasteGate single carrier alignment`

Theorem 7931.2 (Stone representation Boolean algebra NameCert obligations)**.** *For every accepted* $\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}$ *carrier $S = (B, U, T, L, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StoneRepresentat}}$ *surface consists exactly of carrier admission for the displayed Boolean source, ultrafilter-observation row, Stone-space classifier, clopen ledger, regular-open comparison, transport, replay, provenance, and local naming rows; Boolean operation exposure through B; finite ultrafilter compatibility through U; Stone-space classification through T; clopen readback through L; regular-open comparison through M; and non-escape through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.StoneRepresentationBooleanAlgebraUp.StoneRepresentationBooleanAlgebraCarrier namecert obligations`

Proof. Project the carrier of Definition 7931.1. Its Boolean source is B, its representation-facing rows are U, T, L, M, and its structural rows are H, C, P, N.

The Boolean obligations are inherited as displayed rows from chapter 3733. Zero, one, join, meet, complement, order, and transport data must be visible before any Stone-facing row is read.

The representation rows then remain finite. The ultrafilter row U records only displayed membership and compatibility tests, while T and L read the Stone-space classifier and clopen ledger supplied by chapter 261 and chapter 88.

Finally M, H, C, P, N compare, transport, replay, source, and name the same rows. Since no carrier coordinate stores a host spectrum, quotient Boolean equality, selected ultrafilter family, ambient compactness theorem, or replacement Boolean algebra, the listed obligations exhaust the local certificate surface. □

Theorem 7931.3 (Stone representation Boolean algebra duality handoff)**.** *Every Stone-duality or topology-facing consumer of an accepted* $\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}$ *carrier must read the handoff through*

$$\mathsf{BooleanAlgebra}^{\uparrow} \longrightarrow \mathsf{StoneDuality}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{RegularOpenAlgebra}^{\uparrow}$$

as displayed rows attached to B, T, L, M. The ultrafilter-observation row U, transport row H, replay row C, provenance row P, and local name N remain visible throughout the handoff.

The handoff exports a finite clopen representation route, not a host-level representation theorem, selected spectrum, quotient equality of Boolean algebras, or completed compact Hausdorff object.

Lean4 ✓ `BEDC.Derived.StoneRepresentationBooleanAlgebraUp.StoneRepresentationBooleanAlgebraCarrier duality handoff`

Proof. Start with the NameCert obligations of Definition 7931.2. They require every representation read to expose $B, U, T, L, M, H, C, P, N$ together.

For the source side, use the Boolean-algebra carrier of chapter 3733. The operations and order rows remain the source of the read; no topology row can replace them.

For the dual side, read the Stone-space classifier and clopen ledger through chapter 261 and chapter 88. The regular-open comparison of chapter 6835 is only a downstream comparison route through M.

The structural rows H, C, P, N preserve this factorization. Because the carrier contains no coordinate for the refused host objects, every downstream consumer receives exactly the displayed finite handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}$ packet is generated from BooleanAlgebra source rows, finite ultrafilter-observation rows, StoneDuality classifier rows, Topology clopen ledgers, RegularOpenAlgebra comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7931.1, Definition 7931.2, and Definition 7931.3 seed the finite Boolean-algebra Stone representation bridge and its duality handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StoneRepresentationBooleanAlgebra}^{\uparrow}}, \mathsf{encodedDef})$

Bridge status: none

Not claimed: This chapter does not close host Stone representation, selected spectra, quotient Boolean equality, compact Hausdorff completion, Lean theorem verification beyond the carrier definition, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Boolean operation exposure, finite ultrafilter compatibility, Stone-space classification, clopen readback, regular-open comparison, transport, replay, provenance, and local naming for BEDC.Derived.StoneRepresentationBooleanAlgebraUp.

Lean4 (definition) `BEDC.Derived.StoneRepresentationBooleanAlgebraUp`

Chapter 7932

A Concrete Naming Certificate for CauchyCondensationRemainderGauge$^{\uparrow}$

Following Cauchy and Hardy on condensation of monotone positive series, the CauchyCondensationRemainderGauge$^{\uparrow}$ packet records the finite remainder-budget surface used when a dyadic tail estimate is read through condensed blocks. It sits after the condensation witness of chapter 1464, the tail-diameter packet of chapter 1746, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies a named BEDC object for condensation-style remainder budgets; it is not a convergence theorem for arbitrary series, a quotient-real equality principle, a selected limit, or a completeness row.

Definition 7932.1 (Cauchy condensation remainder gauge carrier)**.** *A* CauchyCondensationRemainderGauge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, M, Q, B, R, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source positive monotone series or* RegSeqRat$^{\uparrow}$ *tail row whose remainder is being budgeted.*
2. *M is the monotonicity certificate row required before the condensation block route can be read.*
3. *Q is the* DyadicRatCore$^{\uparrow}$ *tolerance query requested by the downstream tail or real-completion consumer.*
4. *B is the finite block schedule row, naming the condensed dyadic blocks inspected by the gauge.*
5. *R is the block-remainder ledger, recording the displayed upper budget for all blocks beyond the named block schedule.*
6. *D is the* CauchyTailDiameter$^{\uparrow}$ *dependency row tying the block-remainder budget to tail-diameter control.*
7. *W is the window-stability row requiring the source, block schedule, dyadic tolerance, and remainder ledger to be read through the same finite* StreamName$^{\uparrow}$ *window family.*
8. *E is the* RegSeqRat$^{\uparrow}$ *or* Real$^{\uparrow}$ *handoff row reached only after S, M, Q, B, R, D, W are visible.*
9. *H records componentwise* hsame *transport for the source, monotonicity, tolerance, block schedule, remainder ledger, tail-diameter dependency, window stability, handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from the source row through the monotonicity, tolerance, block schedule, remainder, tail-diameter, window-stability, and handoff rows.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}$, $\mathsf{CauchyCondensation}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, Q, B, R, D, W, E, H, C, P, N$. It has no coordinate for a host summation theorem, arbitrary-series convergence, quotient real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Theorem 7932.2 (Cauchy condensation remainder gauge block stability)**.** *For every accepted* $\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}$ *carrier $G = (S, M, Q, B, R, D, W, E, H, C, P, N)$, a remainder read is stable under refinement of the displayed condensed block schedule precisely when the refined request preserves the same source row S, monotonicity row M, dyadic tolerance Q, block schedule face B, block-remainder ledger R, tail-diameter dependency D, window-stability row W, and handoff row E. The refined read therefore remains a finite block-budget comparison and exports no host summation theorem, arbitrary-series convergence, quotient real equality, selected limit, countable-choice row, ambient completeness claim, or standard bridge.*

Proof. Project the carrier. The only rows from which a condensed remainder can be read are S, M, Q, B, R, D, W, E together with the structural rows H, C, P, N.

For a refinement of the block schedule, require preservation of S, M, Q, B, R, D, W, E. The remainder ledger R is then still read against the same dyadic tolerance row Q, while D keeps the budget tied to the tail-diameter surface and W keeps all observations inside one finite window family.

Transport and replay do not add analytic coordinates. The row H moves exactly the displayed components, and C replays the same source-monotonicity-tolerance-block-remainder-tail route.

Thus the refined request is another presentation of the same finite budget. Since no carrier row names a host summation theorem, arbitrary-series convergence, quotient equality, selected limit, countable choice, ambient completeness, or bridge datum, none is exported by the refinement. □

Theorem 7932.3 (Cauchy condensation remainder gauge NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}$ *carrier $G = (S, M, Q, B, R, D, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}}$ *surface consists exactly of carrier admission, monotonicity exposure, dyadic tolerance routing, finite condensed-block scheduling, block-remainder ledger exactness, tail-diameter dependency, finite-window stability,* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise transport, displayed replay, package provenance, local naming, and refusal of host summation, arbitrary-series convergence, quotient real equality, selected limits, countable choice, ambient completeness, and standard-bridge data.*

Proof. Carrier admission exposes the tuple $S, M, Q, B, R, D, W, E, H, C, P, N$. The monotonicity row M and block schedule B are the only condensation-specific rows, while Q, R, D, W record the dyadic budget, remainder ledger, tail-diameter dependency, and finite-window discipline.

The handoff row E is downstream of those analytic rows. A $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer can therefore read a remainder budget only after the source, monotonicity, tolerance, block, remainder, tail-diameter, and window rows have been displayed.

The remaining rows are structural. Componentwise transport, displayed replay, provenance, and local naming preserve the same finite coordinates and do not introduce any ambient summation or completion object.

Therefore the NameCert obligations are exhausted by the listed rows. The refused host summation, arbitrary convergence, quotient equality, selected limit, countable-choice, completeness, and bridge objects are absent because no coordinate of the carrier stores them. □

Theorem 7932.4 (Cauchy condensation remainder gauge real handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *tail consumer that uses a* $\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}$ *packet must pass through the ordered finite route*

$$S, M, Q \longmapsto B, R \longmapsto D, W \longmapsto E \longmapsto H, C, P, N.$$

Consequently the consumer receives a displayed monotone-series source, dyadic tolerance, condensed block schedule, remainder ledger, tail-diameter dependency, finite-window stability, and regular-rational or real-name handoff. It receives no host summation theorem, arbitrary-series convergence, quotient real equality, selected limit, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or standard bridge.*

Proof. Begin with a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ tail consumer. The carrier gives the consumer a finite packet $G = (S, M, Q, B, R, D, W, E, H, C, P, N)$, so the read must start from the displayed source and monotonicity rows.

Next read the condensation budget. The dyadic tolerance Q fixes the requested size, the block schedule B names the condensed blocks, and the ledger R records the remainder budget for the tail beyond the displayed schedule.

The handoff is guarded by D and W. The tail-diameter dependency D ties the block budget to tail control, while the window-stability row W keeps the source observations, block rows, and remainder ledger in one finite $\mathsf{StreamName}^{\uparrow}$ family.

Finally, E, H, C, P, N hand the same data to the regular-rational or real-name consumer and preserve it under transport and replay. Since the route never opens any additional coordinate, it cannot export host summation, arbitrary convergence, quotient equality, selected limits, countable choice, ambient completeness, or a standard bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}$ packet is generated from a positive monotone source row, dyadic tolerance query, finite condensed-block schedule, block-remainder ledger, tail-diameter dependency, StreamName window-stability row, RegSeqRat or Real handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7932.1, Definition 7932.2, Definition 7932.3, and Definition 7932.4 seed the finite condensation remainder-budget packet over monotone source rows, dyadic tolerances, condensed block schedules, block-remainder ledgers, tail-diameter dependencies, finite-window stability, and RegSeqRat or Real handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationRemainderGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host summation, arbitrary-series convergence, quotient real equality, selected limits, countable choice, ambient RealUp completeness, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, block stability, NameCert obligations, and RegSeqRat or Real handoff for BEDC.Derived.CauchyCondensationRemainderGaugeUp.

Chapter 7933

A Concrete Naming Certificate for $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$

Bishop–Bridges grounding for constructive real analysis treats real approximation by finite rational brackets and explicit moduli before any completed real is consumed. The $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ packet records that finite means as BEDC NameCert data: it sits over the dyadic tolerance ledger of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric-facing distance route of chapter 1638. The packet supplies bracket evidence for Real-and-Completion consumers without asserting $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, trichotomy, or countable choice.

Definition 7933.1 (Finite dyadic bracketing-modulus carrier)**.** *A* $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, L, U, M, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger containing dyadic denominators, positive radii, midpoint arithmetic, endpoint comparisons, and slack inequalities for the bracket.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule naming exactly which observation windows are inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream windows and dyadic tolerances.*
4. *L and U are the lower and upper dyadic bracket rows, with $L \leq U$ witnessed inside D.*
5. *M is the finite modulus row assigning each admitted precision request to a displayed window in S and a displayed dyadic bracket in D, L, U.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after D, S, R, L, U, M have been displayed.*
7. *Q is the* $\mathsf{RealMetric}^{\uparrow}$ *distance-read row available to metric consumers only through the same dyadic bracket and readback route.*
8. *H stores componentwise* hsame *transport for the dyadic ledger, window schedule, regular readback, bracket endpoints, modulus row, Real seal, metric read, provenance, and local name.*
9. *C stores displayed* Cont *replay from a precision request through $M, S, D, L, U, R, E, Q, H$.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, trichotomy, countable choice, host real equality, or an unbounded completion selector.*

Theorem 7933.2 (Finite dyadic bracketing-modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ *carrier* $B = (D, S, R, L, U, M, E, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicBracket}}$ *surface consists exactly of carrier admission, dyadic ledger exposure, finite-window scheduling, regular rational readback, lower and upper bracket exposure, modulus exactness, Real seal handoff, metric-read handoff, componentwise transport, displayed replay, package provenance, and local naming.*

Modulus exactness means that every precision request accepted by M names a finite row of S and a finite dyadic bracket in D, L, U before R, E, or Q can be consumed.

Proof. Carrier admission is projection from Definition 7933.1. The accepted packet displays the dyadic ledger, stream windows, regular readback, bracket endpoints, modulus row, Real seal, metric-read row, transport, replay, provenance, and local name.

The modulus row is finite because every request in M points to a displayed window in S and a displayed dyadic comparison in D. The bracket rows L, U are not independent real-order decisions; they are named only after the dyadic ledger has supplied the endpoint arithmetic and slack comparisons.

The Real and metric-facing rows are downstream. A consumer reaches E or Q only after D, S, R, L, U, M have been read, and the structural rows H, C, P, N transport, replay, source, and name that same route. No omitted coordinate can supply quotient streams, selected limits, trichotomy, countable choice, or ambient completeness. □

Theorem 7933.3 (Finite dyadic bracketing-modulus Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RealMetric}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RealMetric}^{\uparrow}$$

as displayed by $D, S, R, E, Q, H, C, P, N$, with the bracket endpoints L, U and modulus row M read before the terminal seal or metric distance row is exposed. The handoff gives bracket evidence and a finite precision schedule, not $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, trichotomy, countable choice, or host real equality.*

Proof. Start from the NameCert obligations. They force every accepted request to expose D, S, R, L, U, M before a Real-facing row is read.

The dyadic stage reads D, L, U as one bracket ledger. The window and readback stage then reads S and R, so the bracket is attached to displayed finite observations rather than to an ambient completed real.

Only after those rows are present may the terminal seal E and metric read Q be consumed. The provenance row points to the sibling surfaces of chapter 291, chapter 126, chapter 301, chapter 38, and chapter 1638. Thus the handoff remains a finite route through displayed BEDC rows. □

Theorem 7933.4 (Finite dyadic bracketing-modulus non-escape)**.** *No accepted* $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ *packet exports* $\mathsf{Real}^{\uparrow}$ *completeness, quotient streams, selected limits, trichotomy, countable choice,*

host real equality, or an unbounded completion selector. Every consumer read factors through $D, S, R, L, U, M, E, Q, H, C, P, N$ and through the sibling rows named in Definition 7933.3.

Proof. Inspect the carrier of Definition 7933.1. Its analytic rows are the dyadic ledger, finite windows, regular readback, bracket endpoints, modulus row, Real seal, and metric-read row.

Apply the Real handoff theorem. The terminal rows E and Q are available only after the finite bracket and modulus route has been displayed.

The excluded principles require data absent from the tuple: an ambient completeness witness, quotient-stream equality, a selected limit object, a trichotomy branch, a countable-choice selector, host real equality, or unbounded completion selection. Since the packet contains none of those rows, every read remains inside the finite bracketing-modulus certificate. □

Falsifiable prediction: An accepted $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or $\mathsf{RealMetric}^{\uparrow}$ distance read without exposing $D, S, R, L, U, M, E, Q, H, C, P, N$ refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, realmetric: no listed sibling supplies the joint packet containing a DyadicRatCore ledger, finite StreamName windows, RegSeqRat readback, lower and upper dyadic brackets, a finite modulus row, a Real seal, a RealMetric read, transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}$ packet is generated from a DyadicRatCore ledger, finite StreamName windows, RegSeqRat readback, lower and upper dyadic bracket rows, a finite modulus row, a RealUp seal, a RealMetricUp read, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7933.1, Definition 7933.2, Definition 7933.3, and Definition 7933.4 seed the finite bracketing-modulus certificate for Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDyadicBracketingModulus}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, trichotomy, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic ledger exposure, finite-window scheduling, regular rational readback, bracket exactness, modulus exactness, Real seal handoff, metric-read handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDyadicBracketingModulusUp.

Chapter 7934

A Concrete Naming Certificate for $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ packet records common-modulus Cauchy name spaces as finite BEDC data before a completion or real-name consumer may read a terminal seal. It sits after the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the ordinary Cauchy sequence-space carrier of chapter 406. The packet names a family of Cauchy names controlled by one displayed modulus; it is not quotient sequence equality, a selected limit, host sequence extensionality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7934.1 (Uniform Cauchy sequence space carrier)**.** *A* $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, R, D, Q, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the inspected family of rational sequence names.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from the windows in S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare all inspected tails.*
4. *Q is the* $\mathsf{CauchySequenceSpace}^{\uparrow}$ *admission row for the underlying Cauchy sequence-space surface.*
5. *M is the common modulus row, displaying one tail budget shared by every admitted name in the packet.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, D, Q, M have been displayed.*
7. *H records componentwise* hsame *transport for the stream schedule, regular readback, dyadic ledger, sequence-space row, common modulus, seal row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a requested tolerance through $S, R, D, Q, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySequenceSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient sequence equality, selected limits, host sequence extensionality, countable-choice moduli, trichotomy, or ambient completeness.

Theorem 7934.2 (Uniform Cauchy sequence space obligations)**.** *For every accepted* $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ *carrier* $U = (S, R, D, Q, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformCauchySequenceSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed stream schedule, regular rational readback, dyadic tolerance ledger, Cauchy sequence-space row, common modulus row, terminal real-name seal, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing read must pass through*

$$S, R, D, Q, M, E, H, C, P, N$$

and through no quotient sequence equality, selected limit, host sequence extensionality, countable-choice modulus, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7934.1. The analytic rows are exactly S, R, D, Q, M, E, and the structural rows are exactly H, C, P, N.

The finite schedule S exposes the inspected windows, while R records the regular rational readback extracted from those windows. The dyadic ledger D supplies the tolerance cells used by every comparison.

The sequence-space row Q admits the ordinary Cauchy surface. The common modulus row M is the extra uniform coordinate: it binds all admitted names to one displayed tail budget before the terminal seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name only this packet. Since no carrier coordinate stores quotient equality, selected limits, host extensionality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the NameCert surface. □

Theorem 7934.3 (Uniform Cauchy sequence space nonescape)**.** *No accepted* $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ *packet exports data outside* $S, R, D, Q, M, E, H, C, P, N$*. In particular, a* $\mathsf{Real}^{\uparrow}$ *or completion consumer cannot read a selected limit, quotient sequence equality, host sequence extensionality, countable-choice modulus, trichotomy, or ambient completeness principle from the common-modulus surface.*

Proof. Inspect the carrier. Its only analytic coordinates are the finite stream schedule, regular rational readback, dyadic tolerance ledger, sequence-space row, common modulus, and terminal seal.

Apply Definition 7934.2. Every local obligation is a projection of those rows or a structural transport, replay, provenance, or naming row for the same packet.

Thus any downstream $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reaches the seal only through the displayed common-modulus route. The packet contains no coordinate from which a selected limit, quotient equality, host extensionality, countable-choice modulus, trichotomy, or ambient completeness object could be exported. □

Falsifiable prediction: An accepted $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ read is refuted if a completion or Real consumer obtains a common Cauchy tail budget without displaying the StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, CauchySequenceSpace row, common modulus, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, dyadic-rat-core, cauchy-sequence-space: none alone is bijective with $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ because the packet binds finite schedules,

regular rational readbacks, dyadic tolerance accounting, an underlying Cauchy sequence-space row, one common modulus, terminal sealing, transport, replay, provenance, and local NameCert data in a single common-modulus surface.

Lean4 (statement) `BEDC.Derived.UniformCauchySequenceSpaceUp`

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchySequenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, CauchySequenceSpace rows, one common modulus row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchySequenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7934.1, Definition 7934.2, and Definition 7934.3 seed the common-modulus Cauchy name-space surface over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, CauchySequenceSpaceUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchySequenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected limits, host sequence extensionality, countable-choice moduli, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite schedule exposure, regular rational readback, dyadic tolerance accounting, Cauchy sequence-space admission, common modulus exactness, seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.UniformCauchySequenceSpaceUp.

Chapter 7935

A Concrete Naming Certificate for $\mathsf{LocatedLimsup}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedLimsup}^{\uparrow}$ packet records constructive upper-limit data for a displayed bounded real sequence by exposing finite tail windows, regular-rational readback, located upper-envelope tests, and the terminal real seal before any completion-facing consumer reads a limit-superior claim. It sits over the terminal real-name surface of chapter 38, the regular sequence readback of chapter 301, the located supremum handoff of chapter 1427, and the bounded-sequence upper-envelope packet of chapter 7101. The packet names located limsup data for Real and Completion consumers; it does not assert classical subsequence compactness, select a maximizing subsequence, quotient real streams, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7935.1 (Located limsup carrier)**.** *A* $\mathsf{LocatedLimsup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, T, W, Q, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded real-sequence source row whose upper-tail behaviour is inspected.*
2. *T is the finite tail-index ledger, recording the displayed tail starts and successor rows available to the packet.*
3. *W is the finite window row, listing the inspected sequence entries and rational comparison requests inside the displayed tails.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the windowed tail data.*
5. *U is the located upper-envelope row, answering each displayed rational cut request by an upper-tail bound or a lower displayed occurrence before a limsup read is exported.*
6. *R is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row for the exposed tail-envelope surface.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row naming the upper-limit read after S, T, W, Q, U, R have been displayed.*
8. *H records componentwise* hsame *transport for source, tail, window, readback, located-envelope, handoff, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a rational upper-limit request through the same rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocatedLimsup}^{\uparrow}$, $\mathsf{BoundedRealLimsup}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedLimsup}^{\uparrow}}$ *row.*

The carrier has no coordinate for classical subsequence compactness, a selected subsequence, quotient stream equality, a host limsup operator, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7935.2 (Located limsup NameCert obligations)**.** *For every accepted* $\mathsf{LocatedLimsup}^{\uparrow}$ *carrier* $L = (S, T, W, Q, U, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedLimsup}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded source, finite tail ledger, finite windows, regular-rational readback, located upper-envelope row, located-supremum handoff, terminal real seal, componentwise transport, displayed replay, provenance, and local naming row. Every Real or Completion consumer must read* S, T, W, Q, U, R *before the seal* E*, and every located upper-limit request remains inside the displayed finite rows named by* H, C, P, N.

Lean4 (statement) `BEDC.Derived.LocatedLimsupUp`

Proof. Project the carrier of Definition 7935.1. The source, tail, window, readback, located-envelope, handoff, seal, transport, replay, provenance, and local naming rows are the only available coordinates.

The tail discipline starts with S and T. A consumer may inspect only the tail starts and successor rows displayed by T, and the inspected entries are exactly the entries listed in W.

The analytic readback then passes through Q, U, R, E. The regular-rational row Q reads the finite windows, the located-envelope row U answers each displayed rational cut request, the $\mathsf{LocatedSupremum}^{\uparrow}$ handoff row R packages the upper-envelope surface, and the $\mathsf{Real}^{\uparrow}$ seal E is exposed only after those rows are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since no coordinate stores a selected subsequence, quotient stream, host limsup, countable-choice selector, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{LocatedLimsup}^{\uparrow}$ Real-facing read factors through a bounded real-sequence source, finite tail ledger, finite windows, RegSeqRat readback, a located upper-envelope row, a LocatedSupremum handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: real, regseqrat, locatedsupremum, bounded-real-limsup: no listed sibling supplies the whole packet $L = (S, T, W, Q, U, R, E, H, C, P, N)$, because each sibling contributes only the terminal real seal, regular readback, located supremum handoff, or bounded upper-envelope route while this chapter binds them into one located upper-limit carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLimsup}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedLimsup}^{\uparrow}$ packet is generated from a bounded real-sequence source, a finite tail-index ledger, finite windows, RegSeqRat readback, a located upper-envelope row, a LocatedSupremum handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedLimsup}^{\uparrow}}$, seed)

Scope closed: Definition 7935.1 and Definition 7935.2 seed the constructive located upper-limit route for bounded real-sequence data and completion-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedLimsup}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close classical subsequence compactness, selected subsequences, quotient stream equality, a host limsup operator, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite tail-window coverage, RegSeqRat readback, located upper-envelope exactness, LocatedSupremum handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedLimsupUp.

Chapter 7936

A Concrete Naming Certificate for $\mathsf{BishopRealLocatedExtrema}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealLocatedExtrema}^{\uparrow}$ packet records the finite BEDC surface by which a located bounded family of constructive real names exposes both one-sided extrema reads. It sits beside the upper route of chapter 6496, the lower route of chapter 1452, and the regular rational readback of chapter 301. The packet joins those sibling rows through one shared window and one terminal $\mathsf{Real}^{\uparrow}$ seal discipline; it does not turn the family into an arbitrary subset completeness principle.

Definition 7936.1 (BishopRealLocatedExtrema carrier)**.** *A* $\mathsf{BishopRealLocatedExtrema}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, W, S, I, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *F is the located bounded-family row, listing the inspected real-name sources, their boundedness witnesses, and the family membership observations available to the extrema request.*
2. *W is the synchronized* $\mathsf{StreamName}^{\uparrow}$ *window row shared by the family entries, the supremum candidate, the infimum candidate, and the regular rational readback.*
3. *S is the supremum row, exposing the upper-bound and lower-hit handoff consumed from the* $\mathsf{RealLocatedSupremum}^{\uparrow}$ *sibling surface.*
4. *I is the infimum row, exposing the lower-bound and upper-hit handoff consumed from the* $\mathsf{LocatedInfimum}^{\uparrow}$ *sibling surface.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that reads the same window W before either extremum row reaches the terminal real seal.*
6. *Q is the paired* $\mathsf{Real}^{\uparrow}$ *seal row, with separate supremum and infimum endpoints but a shared nonescape ledger for the displayed family.*
7. *H records componentwise* hsame *transport for $F, W, S, I, R, Q, C, P, N$.*
8. *C records displayed* Cont *replay from an extrema-facing request through the family row, shared window, one-sided handoffs, regular rational readback, real seal, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealLocatedExtrema}^{\uparrow}$, $\mathsf{RealLocatedSupremum}^{\uparrow}$, $\mathsf{LocatedInfimum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealLocatedExtrema}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $F, W, S, I, R, Q, H, C, P, N$. It has no coordinate for arbitrary subset completeness, trichotomy, selected host extrema, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7936.2 (BishopRealLocatedExtrema NameCert obligations)**.** *For every accepted* BishopRealLocatedExtr *carrier*

$$E = (F, W, S, I, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRealLocatedExtrema}^{\uparrow}}$ *surface consists exactly of carrier admission through $F, W, S, I, R, Q, H, C,$ shared-window exposure through W, supremum handoff through S, infimum handoff through I,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealLocatedExtrema}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealLocatedExtrema}^{\uparrow}$ packet is generated from a located bounded-family row, one synchronized StreamName window, one supremum handoff, one infimum handoff, RegSeqRat readback, a paired RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealLocatedExtrema}^{\uparrow}}$, seed)

Scope closed: Definition 7936.1 and Definition 7936.2 seed the finite extrema packet that joins one supremum row and one infimum row over a shared located bounded-family window.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealLocatedExtrema}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary subset completeness, trichotomy, selected host extrema, quotient equality of real names, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exposure, supremum and infimum handoffs, seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealLocatedExtremaUp.

Chapter 7937

A Concrete Naming Certificate for $\mathsf{CompactDerivativeBound}^{\uparrow}$

Following Bishop and Bridges on differentiable functions over compact intervals, the $\mathsf{CompactDerivativeBound}^{\uparrow}$ packet records the finite derivative-control surface that a compact-uniform-continuity consumer may inspect before a Lipschitz or mean-value packet reads any bound. It sits over the compact metric source of chapter 129, the continuous-map rows of chapter 130, the derivative carrier of chapter 122, the uniform-modulus route of chapter 369, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a compact interval derivative-bound interface as displayed rows, not as a general mean-value theorem or a host compactness principle.

Definition 7937.1 (CompactDerivativeBound carrier)**.** *A* $\mathsf{CompactDerivativeBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (K, F, G, U, N_r, R, E, H, C, P, Q)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact interval source row, or an equivalent compact interval source row already admitted through the compact metric NameCert surface.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the displayed function whose derivative is being bounded.*
3. *G is the finite* $\mathsf{Derivative}^{\uparrow}$ *observation row, listing the derivative endpoints and local difference-quotient windows visible to the packet.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row that synchronizes the compact interval source with the continuous-map and derivative observation windows.*
5. *N_r is the finite compact-net radius row, storing the selected net radii, local derivative-control windows, and rational comparison budgets.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for those rational budgets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed derivative bound.*
8. *H records componentwise* hsame *transport for $K, F, G, U, N_r, R, E, C, P, Q$.*
9. *C records displayed* Cont *replay from a derivative-bound request through the compact source, continuous-map row, derivative row, uniform-modulus row, compact-net radius row, regular rational readback, real seal, transport, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactDerivativeBound}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{CompactDerivativeBound}^{\uparrow}}$ *row.*

The carrier has no coordinate for a general mean-value theorem, open-cover compactness, choice-selected extrema, quotient equality of functions, a host derivative norm, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7937.2 (CompactDerivativeBound NameCert obligations)**.** *For every accepted* CompactDerivativeBound *carrier*

$$D = (K, F, G, U, N_r, R, E, H, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{CompactDerivativeBound}^{\uparrow}}$ *surface consists exactly of compact interval source admission through K, continuous-map exposure through F, derivative-observation exposure through G, uniform-modulus synchronization through U, finite compact-net radius accounting through N_r,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through Q.*

Closure status for $\mathsf{NameCert}_{\mathsf{CompactDerivativeBound}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactDerivativeBound}^{\uparrow}$ packet is generated from compact interval or CompactMetric source rows, ContinuousMap rows, Derivative observation rows, UniformModulus synchronization, finite compact-net radius rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactDerivativeBound}^{\uparrow}}$, seed)

Scope closed: Definition 7937.1 and Definition 7937.2 seed the finite derivative-bound packet consumed by compact-uniform-continuity, Lipschitz, and mean-value-facing routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactDerivativeBound}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a general mean-value theorem, classical compactness, open-cover compactness, choice-selected extrema, quotient equality of functions, a host derivative norm, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact source admission, continuous-map exposure, derivative-observation exposure, uniform-modulus synchronization, finite compact-net radius accounting, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactDerivativeBoundUp.

Chapter 7938

A Concrete Naming Certificate for $\mathsf{LocatedSequenceSubspace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedSequenceSubspace}^{\uparrow}$ packet records the constructive carrier for located subspaces of real sequences as finite NameCert data. It sits after the located real sequence surface of chapter 1984, the regular rational readback of chapter 301, the stream naming discipline of chapter 126, and the terminal Real seal of chapter 38. The packet names a sequence-subspace membership classifier with finite-window stability and transport rows, without importing a host powerset of sequences, a quotient completion, a selected dense enumeration, or a Heine–Borel compactness principle.

Definition 7938.1 (LocatedSequenceSubspace carrier)**.** *A* $\mathsf{LocatedSequenceSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, M, W, T, L, H, C, P, N)$$

whose rows have the following roles:

1. *A is the admitted located real sequence ambient row, routed through the sibling located-sequence carrier.*
2. *M is the located membership classifier for the displayed subspace.*
3. *W is the finite-window stability row for truncations and regular rational readback.*
4. *T is the subspace transport row preserving membership under componentwise sequence equality.*
5. *L is the ledger boundary recording the non-escape of membership reads from the displayed rows.*
6. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceSubspace}^{\uparrow}}$ *naming.*

The carrier has no coordinate for ambient powersets of sequence spaces, quotient equality of Cauchy representatives, selected representatives of Real values, countable choice, or compactness data.

Theorem 7938.2 (LocatedSequenceSubspace NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSequenceSubspac}$ *carrier $S = (A, M, W, T, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedSequenceSubspace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the ambient located real sequence row A together with provenance P and local naming N;*

2. *located membership classifier exposure through M, read only after the stream and Real-seal rows cited above are visible;*
3. *finite-window stability through W, using* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rather than host convergence;*
4. *subspace transport through T, H, C, preserving the displayed classifier under componentwise sequence equality and replay;*
5. *ledger non-escape through L, excluding host powersets, quotient completion, selected representatives, countable choice, and Heine–Borel compactness.*

Proof. Project the carrier of Definition 7938.1. The row A supplies the admitted ambient sequence surface, while M is the only membership classifier made public.

The finite-window row W routes every stability read through stream windows and regular rational readback before the Real seal is consumed. Thus no host convergence or quotient-completion row can replace the displayed finite data.

Transport is then componentwise through T, H, C. These rows preserve the same membership classifier under accepted sequence equality and replay, while P, N source and name the finite packet.

Finally the ledger row L records the boundary of the export. Since the carrier contains no coordinate for powersets, selected representatives, countable choice, or compactness, the listed five rows exhaust the local NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSequenceSubspace}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSequenceSubspace}^{\uparrow}$ packet is generated from an ambient located real sequence row, a located membership classifier, finite-window stability, subspace transport, ledger non-escape, componentwise transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSequenceSubspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7938.1 and Definition 7938.2 name the carrier and its five-row obligation surface for located subspaces of real sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSequenceSubspace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close separability, compactness, choice principles, quotient completion, Lean-side verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located membership, finite-window stability, subspace transport, and ledger non-escape routes for BEDC.Derived.LocatedSequenceSubspaceUp.

Chapter 7939

A Concrete Naming Certificate for CauchyCondensationFiniteWindow$^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the CauchyCondensationFiniteWindow$^{\uparrow}$ packet isolates the finite inspection window that sits between the broad condensation packet of chapter 7794 and the tail-lock consumer of chapter 6052. It records a source series window, dyadic block schedule, comparison ledger, readback route, and local naming surface before any completion-facing consumer may read a tail-lock seal.

Definition 7939.1 (Cauchy condensation finite-window carrier)**.** *A* CauchyCondensationFiniteWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, D, L, M, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-series window, recording the inspected monotone nonnegative* RealSeries$^{\uparrow}$ *terms inherited from the condensation packet.*
2. *D is the dyadic block schedule, recording finite powers-of-two cut points, block endpoints, and block lengths as* DyadicRatCore$^{\uparrow}$ *data.*
3. *L is the finite block ledger, storing the displayed source block sums and condensed representative terms on the same schedule.*
4. *M is the monotone comparison row, recording the endpoint comparisons that bind each source block to its condensed representative.*
5. *T is the tail-lock handoff row, recording exactly the finite tail data handed to* CauchyCondensationTailLock$^{\uparrow}$*.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row produced from S, D, L, M, T.*
7. *E is the* Real$^{\uparrow}$ *seal row available only after the regular readback has been displayed.*
8. *H stores componentwise* hsame *transport for the source window, dyadic schedule, block ledger, comparison row, tail-lock handoff, regular readback, real seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a finite precision request through $S, D, L, M, T, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* CauchyCondensationFiniteWindow$^{\uparrow}$*,* CauchyCondensationPacket$^{\uparrow}$*,* CauchyCondensationTailLock$^{\uparrow}$*,* RealSeries$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}}$ *row.*
The carrier has no coordinate for a quotient of term streams, a selected infinite sum, countable choice, order trichotomy outside the displayed window, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7939.2 (Cauchy condensation finite-window NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}$ *carrier* $W = (S, D, L, M, T, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}}$ *surface consists exactly of source-window exposure by* S*, dyadic schedule exposure by* D*, finite block-ledger exposure by* L*, monotone comparison exposure by* M*, tail-lock handoff by* T*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback by* R*,* $\mathsf{Real}^{\uparrow}$ *sealing by* E*, componentwise transport by* H*, displayed replay by* C*, provenance by* P*, and local naming by* N*.*

Proof. Project the accepted packet. The analytic rows S, D, L, M, T are the entire finite condensation window: they name the inspected source terms, the dyadic block cuts, the block ledger, the monotone endpoint comparisons, and the tail data exported to the tail-lock consumer.

The readback rows are downstream of that window. The row R repacks only the displayed finite data as $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the seal row E is reachable only through R.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Since the carrier has no additional analytic coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7939.3 (Cauchy condensation finite-window tail-lock handoff)**.** *Every accepted* CauchyCondensationFinite *carrier hands condensation data to* $\mathsf{CauchyCondensationTailLock}^{\uparrow}$ *only through the displayed route*

$$S, D, L, M \longmapsto T \longmapsto R \longmapsto E.$$

Thus a tail-lock consumer may read the source series window, dyadic block schedule, finite block ledger, monotone comparison row, $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local NameCert rows, but it receives no quotient stream equality, selected sum, choice functional, trichotomy oracle, or ambient completeness field.*

Proof. Begin with a tail-lock read. By Definition 7939.1, the only rows available before the handoff are the source window S, dyadic schedule D, finite block ledger L, and monotone comparison row M.

Read T next. It is the unique row whose purpose is to present the finite condensation window to $\mathsf{CauchyCondensationTailLock}^{\uparrow}$.

The regular readback and seal are downstream. The row R consumes the displayed handoff, and E is read only after R. Transport, replay, provenance, and local naming preserve this order, so no unlisted infinite or classical principle can supply an alternate tail-lock route. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}$ consumer that reaches a tail-lock or $\mathsf{Real}^{\uparrow}$ seal without first reading S, D, L, M, T, R refutes the finite-window carrier.

Independence witness: cauchy-condensation-packet, cauchy-condensation-tail-lock, realseries, dyadicratcore, regseqrat, real: no listed sibling is bijective to $\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}$ because this packet binds the source series window, dyadic block schedule, finite block ledger, monotone comparison row, tail-lock handoff, regular readback, real seal, transport, replay, provenance, and local NameCert in one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationFiniteWindow}^{\uparrow}}$ **.**

Constructive story: A CauchyCondensationFiniteWindow$^{\uparrow}$ packet is generated from a source series window, dyadic block schedule, finite block ledger, monotone comparison row, tail-lock handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCondensationFiniteWindow}^{\uparrow}}$, seed)

Scope closed: Definition 7939.1, Definition 7939.2, and Definition 7939.3 seed the finite condensation window between the packet and tail-lock surfaces.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCondensationFiniteWindow}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host infinite sums, quotient stream equality, selected sums, order trichotomy, countable choice, bridge checking, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked source-window exposure, dyadic scheduling, finite block-ledger exactness, monotone comparison stability, tail-lock handoff, regular readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationFiniteWindowUp.

Chapter 7940

A Concrete Naming Certificate for $\mathsf{LocatedCutGap}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCutGap}^{\uparrow}$ packet names the finite gap surface between located lower and upper cut evidence before any consumer reads a completed real. It sits beside the located bracket completion of chapter 5554, the Dedekind-cut completion interface of chapter 2138, the dyadic endpoint ledger of chapter 291, the finite stream interface of chapter 126, the regular rational readback row of chapter 301, and the terminal real seal of chapter 38. The chapter records a gap carrier for finite readback only; it does not assert Dedekind completeness, quotient cuts, selected suprema, or a construction of $\mathsf{Real}^{\uparrow}$ from primitive cut data.

Definition 7940.1 (LocatedCutGap carrier)**.** *A* $\mathsf{LocatedCutGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (L, U, A, B, Q, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower located-cut observation row. It records only finitely displayed lower cells, lower endpoint witnesses, and lower refinement requests.*
2. *U is the upper located-cut observation row. It records only finitely displayed upper cells, upper endpoint witnesses, and upper refinement requests.*
3. *A is the lower–upper admission row. It records that each displayed lower request and upper request belongs to the same located-cut comparison packet.*
4. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger. It stores the common dyadic scale on which the displayed lower and upper endpoint rows can be compared.*
5. *Q is the finite gap row. It records, for each displayed comparison request, whether the packet supplies a separated dyadic gap, an overlap witness, or a refinement demand back into B.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes only the requested finite observations of L, U, B, Q.*
7. *S is the* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *route row. It packages the displayed lower row, upper row, dyadic bracket ledger, and gap row as a located-completion-facing read.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It records the regular rational Cauchy approximants read from the displayed window and gap data.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, U, A, B, Q, W, S, R have been displayed.*

10. *H records componentwise* hsame *transport for the lower row, upper row, admission row, dyadic bracket ledger, gap row, stream window, located-completion route, regular readback, real seal, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$L, U, A, B, Q \longmapsto W, S, R \longmapsto E, H, P, N.$$

12. *P is the* Pkg *provenance over* $\mathsf{LocatedCutGap}^{\uparrow}$, $\mathsf{LocatedCutCompletion}^{\uparrow}$, $\mathsf{DedekindCutCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

13. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCutGap}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying both located cut sides, their shared admission row, a common dyadic bracket ledger, the finite gap row, the stream window, the located-completion route, the regular rational readback row, the terminal real seal, and the structural rows. It has no coordinate for quotient cut equality, arbitrary suprema, trichotomy, selected limits, or an ambient completeness theorem.

Theorem 7940.2 (LocatedCutGap NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCutGap}^{\uparrow}$ *carrier* $G = (L, U, A, B, Q, W, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCutGap}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lower located-cut row, upper located-cut row, common admission row, dyadic bracket ledger, gap row, stream window, located-completion route, regular rational readback, real seal, transport, replay, provenance, and local naming row;*

2. *two-sided gap discipline, requiring every comparison-facing read to pass through L, U, A, B, Q before it can be exposed to a stream or completion consumer;*

3. *dyadic common-scale stability, requiring lower and upper refinements to remain inside the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *bracket ledger B;*

4. *finite-window readback, requiring W to determine which displayed rows are opened before the* $\mathsf{LocatedCutCompletion}^{\uparrow}$ *route S or the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R is visible;*

5. *classifier transport, requiring componentwise* hsame *transport in H and displayed* Cont *replay in C to preserve the same row route;*

6. *ledger exhaustion, requiring P and N to name exactly the displayed packet and no Dedekind completeness principle, quotient cut, selected supremum, trichotomy, or hidden real representative.*

No $\mathsf{LocatedCutGap}^{\uparrow}$ *NameCert obligation is stored outside these rows.*

Proof. Carrier admission is projection from Definition 7940.1. The accepted packet exposes the lower row, upper row, common admission row, dyadic bracket ledger, gap row, stream window, located-completion route, regular rational readback, real seal, and structural rows.

Two-sided gap discipline follows because Q is the only row relating displayed lower and upper requests after they have entered the same admission row A and common dyadic scale B. Without Q, a consumer has two finite located-cut sides but no displayed gap surface.

The common-scale condition is forced by B. Lower and upper refinements remain in the same dyadic ledger, so a read cannot replace the packet by independent cut refinements.

The window and readback rows then expose only finitely requested observations. The rows S and R read the same displayed gap data through located completion and regular rational Cauchy routes before the terminal real seal E is available.

Finally, H, C, P, N transport, replay, source, and name the displayed route. Since the excluded principles have no carrier coordinate, the local certificate cannot export them as hidden obligations. □

Theorem 7940.3 (LocatedCutGap Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedCutGap}^{\uparrow}$ *carrier factors through*

$\mathsf{LocatedCutCompletion}^{\uparrow}$, $\mathsf{DedekindCutCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cor

The terminal seal E is reached only after the lower located-cut row, upper located-cut row, common admission row, dyadic bracket ledger, finite gap row, stream window, located-completion route, and regular rational readback row have been displayed. The handoff therefore records a finite readback route between located cuts and the real-name seal, not Dedekind completeness or quotient equality of cuts.

Proof. Start from the two located cut sides L, U and the common admission row A. The dyadic bracket ledger B fixes the shared endpoint scale on which the finite gap row Q can be read.

The stream row W exposes only bounded observations of those rows. The located-completion route S then reads the lower side, upper side, bracket ledger, and gap row as the finite surface already used by chapter 5554; the Dedekind-cut completion sibling of chapter 2138 is reached only as a comparison interface for displayed cut-shaped evidence.

The regular rational row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ readback from the same windowed data, while chapter 291, chapter 126, and chapter 301 provide the dyadic, stream, and regular Cauchy carrier surfaces used by the route.

Only after these finite rows are visible does the terminal $\mathsf{Real}^{\uparrow}$ seal E become readable, as in chapter 38. The structural rows H, C, P, N preserve and name that handoff, so the packet has no projection to Dedekind completeness, quotient cut equality, selected suprema, trichotomy, or hidden representatives. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCutGap}^{\uparrow}$ Real or Completion read factors through displayed lower located-cut, upper located-cut, common admission, dyadic bracket, finite gap, stream window, located-completion, regular rational readback, Real seal, transport, replay, provenance, and local naming rows.

Independence witness: located-cut-completion, dedekind-cut-completion, dyadicratcore, streamname, regseqrat, real: $\mathsf{LocatedCutGap}^{\uparrow}$ is not bijective to any listed sibling because it carries the finite lower–upper gap row and common admission row before the located-completion, regular-Cauchy, and Real-seal handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutGap}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCutGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7940.1, Definition 7940.2, and Definition 7940.3 seed the finite located lower–upper gap surface between located cuts and regular Cauchy real-name readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCutGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient cuts, selected suprema, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-sided gap discipline, dyadic common-scale stability, finite-window readback, classifier transport, ledger exhaustion, and Real seal handoff for BEDC.Derived.LocatedCutGapUp.

Constructive story: A LocatedCutGap$^{\uparrow}$ packet is generated from lower and upper located-cut rows, a common admission row, a DyadicRatCore bracket ledger, a finite gap row, StreamName windows, LocatedCutCompletion routing, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7941

A Concrete Naming Certificate for $\mathsf{SubsequenceModulusSelection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ packet records the constructive act of extracting a displayed subsequence schedule together with the modulus rows used by later Cauchy and compactness arguments. It sits after the common-modulus sequence-space surface of chapter 7934, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names finite subsequence windows and modulus handoffs; it is not a selected limit, countable-choice schedule, trichotomy principle, quotient sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 7941.1 (Subsequence modulus selection carrier)**.** *A* $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, R, D, U, K, M, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the source sequence names under inspection.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the same windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare source windows, selected windows, and tail budgets.*
4. *U is the* $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$ *common-modulus row that supplies the ambient family discipline.*
5. *K is the finite subsequence-index schedule, listing only inspected source positions and their order relation inside the displayed windows.*
6. *M is the modulus-selection row assigning each accepted tolerance request to a displayed tail budget in D, S, R, U, K.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the source schedule, readback, dyadic ledger, uniform Cauchy row, subsequence schedule, and selected modulus row have been displayed.*
8. *H records componentwise* hsame *transport for the stream schedule, readback, dyadic ledger, uniform Cauchy row, subsequence schedule, modulus row, terminal seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a tolerance request through* $S, R, D, U, K, M, E, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{SubsequenceModulusSelection}^{\uparrow}$, $\mathsf{UniformCauchySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SubsequenceModulusSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected limit, an infinite choice function, trichotomy, quotient sequence equality, host sequence equality, or ambient Real completeness.

Theorem 7941.2 (Subsequence modulus selection obligations)**.** *For every accepted* $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ *carrier* $X = (S, R, D, U, K, M, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SubsequenceModulusSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, finite source-window exposure, regular rational readback, dyadic tolerance accounting, common-modulus sequence-space admission, finite subsequence-index scheduling, selected-modulus exactness, terminal Real seal handoff, componentwise transport, displayed replay, package provenance, and local naming. Every compactness-facing or completion-facing read must pass through*

$$S, R, D, U, K, M, E, H, C, P, N$$

and through no selected limit, countable-choice schedule, trichotomy, quotient sequence equality, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 7941.1. The analytic rows are exactly S, R, D, U, K, M, E, and the structural rows are exactly H, C, P, N.

The source schedule S exposes only finite inspected windows, while R records regular rational readback and D records the tolerance cells used by the comparison. The uniform sequence-space row U imports the common-modulus discipline of chapter 7934.

The subsequence-index row K and modulus row M are the additional selection data. They name displayed positions and displayed tail budgets before the terminal seal E can be consumed; neither row stores an infinite selector or a completed limit.

Finally H, C, P, N transport, replay, source, and name only this finite packet. Since no carrier coordinate stores countable choice, trichotomy, quotient equality, host sequence equality, a selected limit, or ambient completeness, the displayed rows exhaust the NameCert surface. □

Theorem 7941.3 (Subsequence modulus selection nonescape)**.** *No accepted* $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ *packet exports data outside* $S, R, D, U, K, M, E, H, C, P, N$*. In particular, a compactness-facing, Cauchy-extraction-facing, or* $\mathsf{Real}^{\uparrow}$ *consumer cannot read a selected limit, countable-choice schedule, trichotomy principle, quotient sequence equality, host sequence equality, or ambient completeness theorem from the subsequence/modulus surface.*

Proof. Inspect the carrier. Its only analytic coordinates are the finite source schedule, regular rational readback, dyadic tolerance ledger, uniform Cauchy sequence-space row, subsequence-index schedule, modulus-selection row, and terminal Real seal.

Apply Definition 7941.2. Every local obligation is a projection of those rows or a structural transport, replay, provenance, or naming row for the same packet.

Thus any downstream compactness, Cauchy extraction, completion, or $\mathsf{Real}^{\uparrow}$ consumer reaches the seal only through the displayed subsequence/modulus route. The packet contains no coordinate from which a selected limit, infinite selector, trichotomy branch, quotient equality, host sequence equality, or ambient completeness object could be exported. □

Falsifiable prediction: An accepted $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ read is refuted if a compactness or Real consumer obtains a subsequence modulus without displaying the StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, UniformCauchySequenceSpace row, finite subsequence-index schedule, selected modulus row, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: uniform-cauchy-sequence-space, streamname, regseqrat, dyadic-rat-core, real: none alone is bijective with $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ because the packet binds finite source windows, regular rational readbacks, dyadic tolerance accounting, a common-modulus sequence-space row, a finite subsequence-index schedule, a selected modulus row, terminal sealing, transport, replay, provenance, and local NameCert data in one surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SubsequenceModulusSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{SubsequenceModulusSelection}^{\uparrow}$ packet is generated from StreamName schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, UniformCauchySequenceSpace rows, finite subsequence-index schedules, selected modulus rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SubsequenceModulusSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7941.1, Definition 7941.2, and Definition 7941.3 seed the constructive subsequence/modulus selection surface over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, UniformCauchySequenceSpaceUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SubsequenceModulusSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, countable-choice schedules, trichotomy, quotient sequence equality, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite source-window exposure, regular rational readback, dyadic tolerance accounting, uniform Cauchy sequence-space admission, subsequence-index scheduling, modulus exactness, Real seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.SubsequenceModulusSelectionUp.

Chapter 7942

A Concrete Naming Certificate for $\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}$

Following Bishop and Bridges and the classical Arzela–Ascoli theorem, the $\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}$ packet records the finite dyadic-net modulus surface by which an equicontinuous family of maps on a compact source is read before a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ value seal is consumed. It sits after the Arzela–Ascoli carrier of chapter 412, the compact source of chapter 60, the continuous-map graph rows of chapter 130, the dyadic tolerance ledger of chapter 291, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a displayed finite-net modulus certificate; it does not assert open-cover compactness, select a subsequence, quotient function-space equality, use countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7942.1 (Dyadic Arzela–Ascoli modulus carrier)**.** *A* $\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, F, D, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row, exposing only the compact object through the finite-net boundary already named by the Arzela–Ascoli packet.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family row, listing the maps whose values may be inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic radii, mesh scales, comparison cells, and half-radius splits.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the sampled source points and map-value observations.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, binding the displayed stream windows and dyadic tolerance cells to regular rational value observations.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for value-facing consumers, exposed only after K, F, D, S, R have been displayed.*
7. *M is the finite dyadic-net modulus row, assigning each displayed tolerance request to a displayed mesh scale and finite inspection window.*
8. *H records componentwise* hsame *transport for the compact source, map family, dyadic ledger, stream windows, readback, real seal, modulus row, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$K, F, D, S, R \longmapsto E, M.$$

10. *P is the* Pkg *provenance over* DyadicArzelaAscoliModulus$^{\uparrow}$, ArzelaAscoli$^{\uparrow}$, Compact$^{\uparrow}$, ContinuousMap$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* NameCert$_{\text{DyadicArzelaAscoliModulus}^{\uparrow}}$ *row naming exactly this finite modulus packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for an open cover, selected subsequence, quotient function space, countable-choice selector, detached real representative, or ambient compactness theorem.

Lean4 ✓ `BEDC.Derived.DyadicArzelaAscoliModulusUp.DyadicArzelaAscoliModulusTasteGate single carrier alignment`

Theorem 7942.2 (Dyadic Arzela–Ascoli modulus NameCert obligations)**.** *For every accepted* DyadicArzelaAscoliModulus$^{\uparrow}$ *carrier*

$$A = (K, F, D, S, R, E, M, H, C, P, N),$$

the local NameCert$_{\text{DyadicArzelaAscoliModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-source visibility, continuous-map family admission, dyadic tolerance visibility, finite stream-window admission, regular rational readback, terminal real-name sealing, finite dyadic-net modulus assignment, componentwise transport, displayed replay, provenance, and local naming. Every Arzela–Ascoli or compact-uniform consumer must pass through*

$$K, F, D, S, R, E, M, H, C, P, N$$

and through no selected subsequence, quotient function-space equality, open-cover compactness proof, countable-choice selector, host real equality, or ambient Real$^{\uparrow}$ *completeness row.*

Proof. Project the carrier rows of Definition 7942.1. The rows K, F, D, S, R, E, M expose the compact source, map family, dyadic tolerance ledger, finite observation windows, regular rational readback, real seal, and modulus assignment before any Arzela–Ascoli consumer is available.

Read the analytic route in order. The compact row K supplies only the displayed finite-net boundary, the map row F supplies only displayed continuous-map observations, and the dyadic row D fixes the tolerance scale inspected by S.

The readback row R binds those windows to regular rational observations, and the seal row E is downstream of the same route. The modulus row M therefore records a finite mesh-scale assignment justified by K, F, D, S, R rather than by an external compactness or selection principle.

The structural rows H, C, P, N preserve, replay, source, and locally name this route. Since the carrier has no coordinate for the excluded subsequence, quotient, cover, choice, host-equality, or completeness data, the listed rows exhaust the local NameCert surface. □

Theorem 7942.3 (Dyadic finite-net induction route)**.** *Let*

$$A = (K, F, D, S, R, E, M, H, C, P, N)$$

be an accepted DyadicArzelaAscoliModulus$^{\uparrow}$ *carrier. Every modulus read from A is obtained by finite induction over the displayed dyadic net rows in S: the base read consumes the first displayed net*

point through D, R, E, and each induction step appends one displayed point using the same D-scale and the same $\mathsf{ContinuousMap}^{\uparrow}$ *family row F. The resulting route factors through*

$$\mathsf{Compact}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and then through the modulus, transport, replay, provenance, and local naming rows M, H, C, P, N.

Proof. Start from the displayed finite net inside S. The empty or first-point case has only the compact source row K, the map family row F, and the dyadic tolerance row D available before any value is read.

For the induction step, append one displayed net point. Its map-value observation is read through the same $\mathsf{ContinuousMap}^{\uparrow}$ row F, the same dyadic scale in D, and the same $\mathsf{StreamName}^{\uparrow}$ window discipline before R translates the observation into regular rational readback.

After each step, the terminal value seal E remains downstream of D, S, R. The modulus row M can therefore record only the mesh scale and finite window already displayed by the induction.

Finally, H, C, P, N transport, replay, source, and name the finite induction route. No open-cover proof, selected subsequence, quotient function-space equality, countable-choice selector, host real equality, or ambient Real-completeness row is present in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}$ packet is generated from a compact source row, continuous-map family row, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, RealUp seal, finite dyadic-net modulus assignment, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7942.1, Definition 7942.2, and Definition 7942.3 seed the finite dyadic-net modulus route over compact sources, continuous-map families, dyadic tolerances, stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicArzelaAscoliModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subsequences, quotient function-space equality, open-cover compactness, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source visibility, continuous-map family admission, dyadic tolerance visibility, finite window admission, regular rational readback, Real seal handoff, modulus assignment, transport, replay, provenance, and local naming for BEDC.Derived.DyadicArzelaAscoliModulusUp.

Chapter 7943

A Concrete Naming Certificate for $\mathsf{RieszProduct}^{\uparrow}$

Following F. Riesz and classical harmonic analysis, the $\mathsf{RieszProduct}^{\uparrow}$ packet records a finite trigonometric-product window before any Fourier-facing or Real-facing consumer may read a coefficient or scalar seal. It sits over the terminal real-name boundary of chapter 38, the regular rational readback route of chapter 301, the finite observation schedule of chapter 126, the dyadic tolerance ledger of chapter 291, and the positive summability-kernel neighbour of chapter 1939. The packet names only finite factor data, finite coefficient windows, dyadic budgets, regular readback, Real sealing, transport, replay, provenance, and local naming rows; it does not claim measure-theoretic convergence, an infinite product object, Haar measure, selected representatives, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7943.1 (Riesz product carrier)**.** *A* $\mathsf{RieszProduct}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (F, A, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite factor ledger, listing the retained frequencies, coefficients, signs, and normalising constants of the trigonometric factors under inspection.*
2. *A is the admissibility row, recording the displayed positivity and boundedness checks for the retained factors.*
3. *W is the coefficient-window row, naming the finite Fourier modes and product-expansion terms actually read by the consumer.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger for factor coefficients, finite products, coefficient sums, and positivity budgets.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after F, A, W, D have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for scalar coefficient or normalisation reads.*
7. *H records componentwise* hsame *transport for the factor ledger, admissibility row, coefficient windows, dyadic arithmetic, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a harmonic-analysis request through F, A, W, D, Q, E.*

9. *P is the* Pkg *provenance over* $\mathsf{RieszProduct}^{\uparrow}$, $\mathsf{FejerKernel}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszProduct}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, A, W, D, Q, E, H, C, P, N$. It has no coordinate for an infinite product, a measure-theoretic weak limit, Haar integration, quotient equality of functions, selected representatives, or ambient Real completeness.

Theorem 7943.2 (Riesz product NameCert obligations)**.** *For every accepted* $\mathsf{RieszProduct}^{\uparrow}$ *carrier $R = (F, A, W, D, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RieszProduct}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed factor ledger, admissibility row, coefficient-window row, dyadic arithmetic ledger, regular readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows. A harmonic-analysis consumer may read a Riesz-product coefficient only after the finite factor data, the admissibility checks, and the dyadic budget are all public in the same packet.*

Proof. Project the carrier of Definition 7943.1. Its visible inventory is exactly $F, A, W, D, Q, E, H, C, P, N$, so every local naming duty begins with finite factor rows and finite coefficient windows rather than with an infinite product.

The product-facing rows are read in order. The factor ledger F supplies retained frequencies and coefficients, the admissibility row A supplies the displayed positivity and boundedness checks, and the window row W fixes the finite Fourier modes and product-expansion terms under inspection.

The scalar endpoint is also explicit. The dyadic ledger D accounts for the arithmetic budget before the regular readback Q and the Real seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for an infinite product object, weak-limit measure, Haar integration, quotient function equality, selected representative, or Real completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 7943.3 (Riesz product finite-factor route)**.** *Every Fourier-facing, Fejer-kernel-facing, or Real-facing consumer of an accepted* $\mathsf{RieszProduct}^{\uparrow}$ *packet receives the product read only through the finite route*

$$F, A, W \longmapsto D \longmapsto Q, E \longmapsto H, C, P, N.$$

The route may be compared with the finite harmonic-analysis surface of chapter 1939, but it exports only retained factor rows, displayed coefficient windows, dyadic arithmetic, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Proof. Start with F, A, W. The factor ledger fixes the finite list of retained trigonometric factors, the admissibility row fixes the displayed positivity and boundedness checks, and the coefficient-window row fixes the finite modes available to the consumer.

Next read D. All coefficient arithmetic, finite products, normalising constants, and tolerance comparisons pass through the dyadic ledger, so no read reaches a scalar endpoint from a hidden analytic product.

Only after that finite arithmetic route is displayed can Q and E be consumed. The regular readback and Real seal therefore receive the finite factor route rather than an infinite-product limit, Haar-measure construction, quotient function, selected representative, or ambient completeness theorem.

The structural rows H, C, P, N preserve this factorization under transport, replay, provenance, and local naming. Thus every public product read remains a finite NameCert route over the displayed rows. □

Falsifiable prediction: An accepted $\mathsf{RieszProduct}^{\uparrow}$ consumer that reaches a coefficient, regular readback, or $\mathsf{Real}^{\uparrow}$ seal without displaying the retained factor ledger, admissibility row, coefficient windows, $\mathsf{DyadicRatCore}^{\uparrow}$ budget, $\mathsf{RegSeqRat}^{\uparrow}$ handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier surface.

Independence witness: real, regseqrat, streamname, dyadicratcore, fejer-kernel: no listed sibling supplies the whole packet $R = (F, A, W, D, Q, E, H, C, P, N)$, because each sibling contributes only a terminal seal, regular readback, observation schedule, dyadic arithmetic ledger, or summability-kernel neighbour while this chapter binds finite Riesz-product factor data into one harmonic-analysis carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RieszProduct}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszProduct}^{\uparrow}$ packet is generated from finite trigonometric factor rows, displayed admissibility checks, finite coefficient windows, DyadicRatCoreUp arithmetic budgets, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszProduct}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7943.1, Definition 7943.2, and Definition 7943.3 seed the finite harmonic-analysis route from retained Riesz-product factors to coefficient and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszProduct}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic convergence, infinite product existence, Haar measure, quotient function equality, selected representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, factor admissibility, coefficient-window exposure, dyadic arithmetic, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RieszProductUp.

Chapter 7944

A Concrete Naming Certificate for $\mathsf{RiemannSumMesh}^{\uparrow}$

Following Riemann and Bishop–Bridges, the $\mathsf{RiemannSumMesh}^{\uparrow}$ packet records the finite mesh data needed by constructive Riemann-sum consumers before any integral object is claimed. It sits between the dyadic arithmetic of chapter 291, finite stream windows of chapter 126, rational regular-sequence readback of chapter 301, the real-name seal of chapter 38, and the calculus-facing packet of chapter 3632.

Falsifiable prediction: Deleting the tag-containment row lets a consumer move a sample point outside its cell while keeping the same mesh width; the local classifier must reject that packet because the displayed Riemann sum no longer names a finite tagged partition.

Independence witness: dyadicratcore, streamname, regseqrat, real, calculus: none is bijective because each sibling omits at least one of finite cell ordering, tag containment, dyadic mesh width, sample-value readback, or Real-seal nonescape required by $\mathsf{RiemannSumMesh}^{\uparrow}$.

Definition 7944.1 (RiemannSumMesh carrier)**.** *A* $\mathsf{RiemannSumMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, C, W, T, S, V, R, H, K, P, N)$$

with the following displayed rows:

1. *I is the closed interval row, with dyadic endpoint names read through* $\mathsf{DyadicRatCore}^{\uparrow}$*;*
2. *C is the finite ordered cell row, listing adjacent subintervals whose endpoints cover I without overlap;*
3. *W is the dyadic mesh-width row, recording each cell width and the displayed maximum mesh bound;*
4. *T is the tag-containment row, assigning one sample tag to each cell and witnessing that the tag lies inside that cell;*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the sampled input names used by the tagged partition;*
6. *V is the* $\mathsf{RegSeqRat}^{\uparrow}$ *sample-value row, giving rational approximants for the sampled function values at the displayed precision;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording that real-name reads are only the finite seals needed for the sample values;*

8. *H records componentwise* hsame *transport for $I, C, W, T, S, V, R, K, P, N$;*
9. *K records displayed* Cont *replay from dyadic interval data to cells, mesh widths, tags, stream windows, regular-sequence sample values, and the real seal;*
10. *P is the* Pkg *provenance over* $\mathsf{RiemannSumMesh}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSumMesh}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $I, C, W, T, S, V, R, H, K, P, N$. It has no coordinate for a host integral, selected limiting process, quotient function equality, countable-choice sampling schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7944.2 (RiemannSumMesh NameCert obligations)**.** *For the carrier of Definition 7944.1, the local* $\mathsf{NameCert}_{\mathsf{RiemannSumMesh}^{\uparrow}}$ *surface consists exactly of finite interval admission, ordered cell exposure, dyadic mesh-width exposure, tag-containment exactness,* $\mathsf{StreamName}^{\uparrow}$ *finite-window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *sample-value readback,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same packet*

$$M = (I, C, W, T, S, V, R, H, K, P, N).$$

Proof. Project the carrier of Definition 7944.1. The accepted packet displays the interval, cells, mesh widths, tags, sample windows, sample values, real seal, transport, replay, provenance, and naming rows as $I, C, W, T, S, V, R, H, K, P, N$.

The dyadic rows provide the finite arithmetic support. The interval row I, ordered cell row C, and mesh row W are read through $\mathsf{DyadicRatCore}^{\uparrow}$, so adjacency, coverage, widths, and the maximum mesh bound are finite rational data.

The tag and sample rows provide the calculus-facing support. The containment row T fixes one displayed tag per cell, S restricts the sampled input names to finite $\mathsf{StreamName}^{\uparrow}$ windows, and V reads only the displayed $\mathsf{RegSeqRat}^{\uparrow}$ approximants.

The real seal and structural rows close the packet. The row R bars ambient completeness reads, while H, K, P, N preserve the same finite route under transport, replay, package provenance, and local naming. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 7944.3 (RiemannSumMesh Real-RegSeqRat handoff)**.** *Every accepted* $\mathsf{RiemannSumMesh}^{\uparrow}$ *packet exports its sampled values to* $\mathsf{Real}^{\uparrow}$ *consumers only through the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow} \to \mathsf{Calculus}^{\uparrow} \to \mathsf{BHist} \to \mathsf{hsame} \to \mathsf{Cont} \to \mathsf{Pkg} \to \mathsf{NameC}$$

The route may read finite cell data, tag containment, dyadic mesh widths, stream windows, rational regular-sequence samples, and the real-name seal of the same carrier. It may not export a host integral, select a limiting refinement, quotient functions by extensional equality, introduce countable choice, or use ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the dyadic mesh rows. The interval, cell, and mesh-width coordinates I, C, W determine the finite tagged partition support before a sampled value is read.

Next read the tag and sample rows. The row T keeps each sample tag inside its displayed cell, while S and V restrict evaluation to finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{RegSeqRat}^{\uparrow}$ rational approximants.

Finally pass through the real seal and calculus-facing provenance. The row R supplies only the displayed $\mathsf{Real}^{\uparrow}$ seal, and the replay and package rows K, P, N route the packet toward $\mathsf{Calculus}^{\uparrow}$ without adding a limit selector, integral value, quotient function equality, choice schedule, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSumMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSumMesh}^{\uparrow}$ packet is generated from a dyadic interval row, finite ordered cell row, dyadic mesh-width row, tag-containment row, finite StreamName window row, RegSeqRat sample-value row, Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSumMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7944.1, Definition 7944.2, and Definition 7944.3 specify the finite tagged mesh packet used by constructive calculus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSumMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not construct host integrals, selected refinement limits, quotient function equality, countable-choice sampling schedules, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cell ordering, tag containment, dyadic mesh-width exactness, RegSeqRat sample readback, Real-seal nonescape, transport, replay, provenance, and local naming for the same finite mesh packet.

Chapter 7945

A Concrete Naming Certificate for $\mathsf{CauchyRealEquivalenceModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyRealEquivalenceModulus}^{\uparrow}$ packet records equality of constructive real names by a displayed tail-modulus comparison between two regular Cauchy rational representatives. It sits over the dyadic tolerance core of chapter 291, the stream window surface of chapter 126, the regular rational sequence surface of chapter 301, and the real-name seal of chapter 38. The certificate names a finite modulus route for a pair of representatives; it does not identify host sequences, quotient streams, selected limits, real trichotomy, or ambient real completeness.

Definition 7945.1 (Cauchy real equivalence modulus carrier)**.** *A* $\mathsf{CauchyRealEquivalenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, B, T, D_A, D_B, Q_A, Q_B, E, H, C, P, N)$$

with the following visible rows:

1. *A and B are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *representative rows whose stream names are compared by the packet.*
2. *T is the shared dyadic tail-modulus row. For each requested dyadic tolerance, T names a finite tail bound after which the two representatives are read in the same tolerance window.*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance readback rows used to decode the two representative values at the requested dyadic precision.*
4. *Q_A and Q_B are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows exposing only the retained prefixes and tail cells needed by T, D_A, D_B.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal that downstream consumers may read only after the two regular representatives, shared tail modulus, dyadic readbacks, and stream windows have been displayed.*
6. *H records componentwise* hsame *transport for $A, B, T, D_A, D_B, Q_A, Q_B, E$ and the local naming row.*
7. *C records displayed* Cont *replay from the pair of representatives through the shared tail-modulus row and dyadic readbacks to the real-name seal:*

$$A, B, T, D_A, D_B \longmapsto Q_A, Q_B, E.$$

8. *P is the* Pkg *provenance over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{CauchyRealEquivalenceModulus}^{\uparrow}}$ *row.*

The carrier exports a finite modulus witness for equality of the two real names. It has no coordinate for quotient equality of streams, a selected representative of an equivalence class, real trichotomy, a host Cauchy-completion object, or an ambient completeness principle.

Lean4 (statement) `BEDC.Derived.CauchyRealEquivalenceModulusUp`

Theorem 7945.2 (Cauchy real equivalence modulus NameCert obligations)**.** *For every accepted* CauchyRealEquivalenceModulus$^{\uparrow}$ *carrier*

$$M = (A, B, T, D_A, D_B, Q_A, Q_B, E, H, C, P, N),$$

the local NameCert$_{\text{CauchyRealEquivalenceModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* RegSeqRat$^{\uparrow}$ *representatives, the shared dyadic tail-modulus row, the two* DyadicRatCore$^{\uparrow}$ *tolerance readbacks, the two* StreamName$^{\uparrow}$ *finite-window rows, the* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every equality read between the two real names must pass through T, D_A, D_B, Q_A, Q_B before E is public, and no obligation may call on quotient stream equality, chosen representatives, real trichotomy, host completion, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 7945.1. The packet exposes exactly the two regular rational representatives, one shared dyadic tail-modulus row, two dyadic readbacks, two stream windows, the Real-facing seal, and the structural rows.

The equality read is then forced through the displayed modulus route. A requested tolerance is decoded by the dyadic rows D_A, D_B, the shared tail bound is read from T, and only the finite stream windows Q_A, Q_B can expose the representative data at that tolerance.

Transport and replay preserve the same route. The row H carries componentwise hsame evidence for the listed coordinates, while C replays the continuation from the two representative rows through the shared tail-modulus comparison to the seal row E.

Finally inspect P, N. Provenance and local naming record only the displayed carrier rows, so a downstream Real consumer has no projection from which to read quotient stream equality, selected representatives, real trichotomy, host completion, or ambient completeness. □

Closure status for NameCert$_{\text{CauchyRealEquivalenceModulus}^{\uparrow}}$**.**

Constructive story: A CauchyRealEquivalenceModulus$^{\uparrow}$ packet is generated from two RegSeqRat$^{\uparrow}$ representatives, a shared dyadic tail-modulus row, DyadicRatCore$^{\uparrow}$ tolerance readbacks, StreamName$^{\uparrow}$ finite-window rows, a Real$^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRealEquivalenceModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7945.1 and Definition 7945.2 specify the finite modulus carrier and its local naming obligations over regular Cauchy representatives, dyadic tolerance readbacks, stream windows, and the Real seal.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRealEquivalenceModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, chosen representatives, real trichotomy, host Cauchy completion, ambient Real completeness, or a standard bridge.

Upgrade path: Scoped closure requires formal carrier exactness, transport stability, and downstream nonescape for the displayed Cauchy real equivalence modulus route.

Chapter 7946

A Concrete Naming Certificate for $\mathsf{AtsujiSpace}^{\uparrow}$

Following Atsuji's uniformly continuous metric spaces and the Bourbaki–Kelley treatment of metric continuity, the $\mathsf{AtsujiSpace}^{\uparrow}$ packet records the finite BEDC surface on which pointwise continuous maps from a displayed metric source may be handed to uniform-modulus consumers. It sits over the metric carrier of chapter 57, the continuous-map graph rows of chapter 130, the uniform-modulus consumer of chapter 369, the compact-metric comparison source of chapter 129, and the terminal real-name seal of chapter 38. The packet names the Atsuji condition as displayed finite rows; it does not assert open-cover compactness, select a modulus, quotient maps, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7946.1 (AtsujiSpace carrier)**.** *An* $\mathsf{AtsujiSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, F, U, K, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose accepted distance and neighbourhood reads are those of chapter 57.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *testing row: every admitted map from the source is read through the displayed graph and pointwise continuity data of chapter 130.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exposed only after the same metric and continuous-map rows have been replayed.*
4. *K is the compact-metric comparison row, allowing compact-metric Atsuji examples to read the sibling route of chapter 129 without making compactness part of the carrier.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *tolerance and distance-seal row used by metric, continuity, and modulus reads.*
6. *H records componentwise* hsame *transport for the metric, continuous-map, uniform-modulus, compact-comparison, real-seal, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from an Atsuji request through M, F, U, K, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{AtsujiSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{AtsujiSpace}^\uparrow}$ *row.*

The classifier compares accepted packets only through $M, F, U, K, R, H, C, P, N$. There is no coordinate for open-cover compactness, a chosen modulus, quotient map equality, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Lean4 ✓ `BEDC.Derived.AtsujiSpaceUp.AtsujiSpaceTasteGate single carrier alignment`

Theorem 7946.2 (AtsujiSpace NameCert obligations)**.** *For every accepted* $\mathsf{AtsujiSpace}^\uparrow$ *carrier $A = (M, F, U, K, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AtsujiSpace}^\uparrow}$ *surface consists exactly of carrier admission, metric-source exposure through M, continuous-map testing through F, uniform-modulus handoff through U, compact-metric comparison through K, real tolerance sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

No obligation may be discharged by open-cover compactness, a selected modulus, quotient maps, countable choice, a hidden host continuity theorem, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Project the carrier of Definition 7946.1. The displayed rows are exactly $M, F, U, K, R, H, C, P, N$, so carrier admission exposes only metric source data, pointwise continuous-map tests, a uniform-modulus handoff, compact-metric comparison, real tolerance sealing, transport, replay, provenance, and naming.

The continuity side starts with M and F. A map is not accepted as a host function; it is read through the metric source and the displayed continuous-map row before any downstream uniform claim is visible.

Next read the handoff and comparison rows. The row U is available only inside the same replay route, while K records the compact-metric sibling comparison without adding open-cover compactness to the Atsuji carrier.

Finally the structural rows H, C, P, N preserve the same packet. Since selected moduli, quotient maps, countable choice, host continuity theorems, and ambient completeness are absent from the carrier, the listed rows exhaust the local surface. □

Theorem 7946.3 (AtsujiSpace uniform-continuity handoff)**.** *Let $A = (M, F, U, K, R, H, C, P, N)$ be an accepted* $\mathsf{AtsujiSpace}^\uparrow$ *carrier. Every consumer that reads an admitted pointwise continuous map from the metric source as uniformly controlled must factor through*

$$\mathsf{Met}^\uparrow \longmapsto \mathsf{ContinuousMap}^\uparrow \longmapsto \mathsf{UniformModulus}^\uparrow$$

with the tolerance seal supplied through $\mathsf{Real}^\uparrow$ *and the compact-metric comparison row available only as K.*

Thus $\mathsf{AtsujiSpace}^\uparrow$ *exposes the standard metric-continuity to uniform-modulus handoff as finite NameCert data, but it does not export open-cover compactness, a selected modulus, quotient map equality, countable choice, or ambient* $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Begin with a consumer that asks for uniform control of an admitted map. The carrier exposes the metric source row M and the continuous-map row F before the uniform-modulus handoff row U can be inspected.

Replay the displayed continuation row C. The request passes through M, F, U and then uses R as the real tolerance seal, while H, P, N keep the transported packet, provenance, and local name fixed.

The compact-metric comparison row K does not turn the argument into a compactness theorem. It only records that compact-metric examples may be compared through the sibling compact-metric surface while the Atsuji handoff remains the route M, F, U, R, H, C, P, N.

Because no selected modulus, quotient map, choice functional, open-cover cover witness, or ambient completeness row occurs in A, every accepted uniform-continuity handoff factors through the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{AtsujiSpace}^{\uparrow}$ read factors through $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before it is consumed as a metric-continuity to uniform-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{AtsujiSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{AtsujiSpace}^{\uparrow}$ packet is generated from a Metric source row, ContinuousMap testing row, UniformModulus handoff row, CompactMetric comparison row, Real tolerance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AtsujiSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7946.1, Definition 7946.2, and Definition 7946.3 seed the L10 Atsuji route over MetricUp, ContinuousMapUp, UniformModulusUp, CompactMetricUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AtsujiSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected moduli, quotient maps, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, continuous-map testing, uniform-modulus handoff nonescape, compact-metric comparison scope, real tolerance sealing, and TasteGate field faithfulness for BEDC.Derived.AtsujiSpaceUp.

Chapter 7947

A Concrete Naming Certificate for SequentialBolzanoChoiceFreeSubsequence$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the SequentialBolzanoChoiceFreeSubsequence$^{\uparrow}$ packet records the finite subsequence-extraction surface used by sequential Bolzano arguments before Real and Completion consumers read a regular Cauchy subsequence. It sits after the dyadic tolerance carrier of chapter 291, the finite stream-name schedule of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the diagonal selector route of chapter 695. The packet names a displayed subsequence route; it is not open-cover compactness, countable choice, a selected host limit, a quotient stream, or ambient Real$^{\uparrow}$ completeness.

Definition 7947.1 (Sequential Bolzano choice-free subsequence carrier)**.** *A* SequentialBolzanoChoiceFreeSubsequen *carrier is a finite* BHist *packet*

$$B = (S, Q, D, W, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row, exposed only through inspected finite* StreamName$^{\uparrow}$ *windows.*
2. *Q is the finite subsequence schedule row, listing the inspected source positions and their monotone order inside those windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to compare source windows, selected windows, and Cauchy-tail requests.*
4. *W is the* StreamName$^{\uparrow}$ *window family opened by the selected schedule.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row assembled from the selected windows and tolerance ledger.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row available only after Q, D, W, R have been displayed.*
7. *A is the* ChoiceFreeDiagonalSelector$^{\uparrow}$ *selector row that binds the precision request to the displayed subsequence window rather than to a host choice function.*
8. *H records componentwise* hsame *transport for the source, schedule, tolerance, window, readback, seal, selector, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a sequential Bolzano request through $S, Q, D, W, R, E, A, H, P, N$.*
10. *P is the* Pkg *provenance over* SequentialBolzanoChoiceFreeSubsequence$^{\uparrow}$, ChoiceFreeDiagonalSelector$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these displayed rows. It has no coordinate for open-cover compactness, countable choice, a selected host limit, quotient stream equality, host sequence equality, or ambient Real completeness.

Theorem 7947.2 (Sequential Bolzano choice-free subsequence NameCert obligations)**.** *For every accepted* $\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}$ *carrier*

$$B = (S, Q, D, W, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}}$ *surface consists exactly of carrier admission, finite source-window exposure, subsequence schedule visibility, dyadic tolerance accounting, StreamName window replay, RegSeqRat readback, Real seal handoff, ChoiceFreeDiagonalSelector routing, componentwise transport, displayed continuation replay, package provenance, and local naming. Every sequential Bolzano or Real-completion read must pass through the displayed rows before it consumes any subsequence output.*

Proof. Project the carrier. The analytic rows are S, Q, D, W, R, E, A, and the structural rows are H, C, P, N.

The source row S is exposed only by finite StreamName windows. The schedule row Q selects inspected positions inside those windows, while D records the dyadic tolerance budget and R records the regular rational readback.

The selector row A imports the choice-free diagonal selector boundary of chapter 695. It binds precision requests to displayed finite windows rather than to an external choice function.

Finally E is downstream of Q, D, W, R, A, and H, C, P, N only transport, replay, source, and name the same route. Since no carrier coordinate stores open-cover compactness, countable choice, selected host limits, quotient streams, host sequence equality, or ambient completeness, the displayed rows exhaust the NameCert surface. □

Theorem 7947.3 (Sequential Bolzano choice-free real route)**.** *Every Real and Completion consumer of an accepted* $\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}$ *packet factors through*

$$\mathsf{ChoiceFreeDiagonalSelector}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed carrier rows before any subsequence output is public. The route exposes the selector, finite windows, dyadic tolerance ledger, regular rational readback, Real seal, transport, replay, provenance, and local naming; it exports no open-cover compactness, countable-choice schedule, selected host limit, quotient stream, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 7947.2. They force the selected subsequence schedule and tolerance ledger to be displayed before the readback and seal rows can be consumed.

Use the sibling selector route of chapter 695. The selector row sends each precision request to a finite StreamName window, so the consumer reads A, W, D, R, E as one displayed route.

The RegSeqRat and Real rows are downstream of that route. The readback row R is assembled from the selected windows and dyadic tolerance ledger, and the seal row E is available only after R has been displayed.

Thus a Real or Completion consumer receives only the finite route through $\mathsf{ChoiceFreeDiagonalSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. The excluded compactness, choice, host-limit, quotient-stream, and ambient-completeness objects are absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}$ packet is generated from source sequence rows, finite subsequence schedules, DyadicRatCore tolerance ledgers, StreamName windows, RegSeqRat readbacks, RealUp seals, a ChoiceFreeDiagonalSelector row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7947.1, Definition 7947.2, and Definition 7947.3 seed the choice-free sequential Bolzano subsequence route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialBolzanoChoiceFreeSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, selected host limits, quotient streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite subsequence scheduling, dyadic tolerance accounting, StreamName window replay, RegSeqRat readback, Real seal routing, ChoiceFreeDiagonalSelector handoff, transport, replay, provenance, and local naming for BEDC.Derived.SequentialBolzanoChoiceFreeSubsequenceUp.

Chapter 7948

A Concrete Naming Certificate for DyadicContractionModulus$^{\uparrow}$

Following Bishop and Bridges on regular Cauchy estimates, the DyadicContractionModulus$^{\uparrow}$ packet records the finite dyadic contraction budget used by the diagonal regularity route of section 9238.1. It binds the endpoint-leg estimates, middle-modulus estimate, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, and terminal Real seal as one NameCert surface. The packet realizes a three-leg regularity estimate; it is not a quotient stream, selected limit, countable-choice schedule, open-cover compactness theorem, or ambient Real$^{\uparrow}$ completeness principle.

The three-leg estimate consumes the tolerance-scale normalization of chapter 1768 and the diagonal-selection route of chapter 4080 before its StreamName, RegSeqRat, and Real seal rows are read.

Definition 7948.1 (Dyadic contraction modulus carrier)**.** *A* DyadicContractionModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, L, M, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the precision-request row naming the diagonal regularity comparison.*
2. *L is the left endpoint-leg dyadic contraction row.*
3. *M is the middle modulus row comparing the two selected regular Cauchy stages.*
4. *U is the right endpoint-leg dyadic contraction row.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger that sums the three contraction rows.*
6. *W is the* StreamName$^{\uparrow}$ *finite-window row opened by the comparison request.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained after the three dyadic legs are displayed.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row available only after Q, L, M, U, D, W, R have been replayed.*
9. *H records componentwise* hsame *transport for the request, three contraction rows, tolerance ledger, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a diagonal regularity request through $Q, L, M, U, D, W, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* DyadicContractionModulus$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{DyadicContractionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these finite rows to a common tolerance surface.

Theorem 7948.2 (Dyadic contraction modulus NameCert obligations)**.** *For every accepted* DyadicContractionModu *carrier*

$$K = (Q, L, M, U, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicContractionModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, precision-request exposure, left endpoint-leg contraction, middle-modulus contraction, right endpoint-leg contraction, DyadicRatCore tolerance summation, StreamName window replay, RegSeqRat readback, Real seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier. The three analytic contraction rows are L, M, U, the shared tolerance ledger is D, and the Real-completion readback rows are W, R, E.

The precision request Q determines which diagonal regularity comparison is being read. The left endpoint leg, middle modulus leg, and right endpoint leg are visible before the DyadicRatCore ledger D sums their tolerances.

StreamName and RegSeqRat consumption is downstream of the dyadic ledger. The finite window W is opened for the same request, R records the regular rational readback, and E seals the resulting Real row only after those displays.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient stream, selected limit, countable-choice schedule, open-cover compactness row, or ambient completeness coordinate, no local obligation can export those objects. □

Theorem 7948.3 (Dyadic contraction modulus real-completeness route)**.** *The diagonal regularity estimate of Definition 9238.4 is consumed through a* $\mathsf{DyadicContractionModulus}^{\uparrow}$ *packet only by the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route displays the left endpoint leg, middle modulus leg, right endpoint leg, dyadic tolerance ledger, StreamName window, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming before any Real-completion consumer may read the estimate.

Proof. Start with the carrier obligations of Definition 7948.2. They expose the three contraction rows L, M, U and the DyadicRatCore ledger D before any readback or seal row is available.

Use the source vision theorem Definition 9238.4. Its proof route has exactly the left endpoint leg, middle modulus comparison, and right endpoint leg named by L, M, U.

The finite window and readback rows are then forced by W and R. The Real seal E is downstream of those rows, so a Real-completion consumer reads the estimate only after the dyadic and regular-name data have been displayed.

Therefore the public route is the finite DyadicRatCore-to-StreamName-to-RegSeqRat-to-RealUp handoff. Quotient streams, selected limits, countable choice, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier and cannot replace that handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicContractionModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicContractionModulus}^{\uparrow}$ packet is generated from a precision request, left endpoint-leg contraction, middle-modulus contraction, right endpoint-leg contraction, a DyadicRatCore tolerance ledger, StreamName

windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{DyadicContractionModulus}\uparrow}$, seed)

Scope closed: Definition 7948.1, Definition 7948.2, and Definition 7948.3 seed the three-leg dyadic contraction route for Real-completeness consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicContractionModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked precision requests, three-leg dyadic contraction rows, DyadicRatCore tolerance summation, StreamName window replay, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.DyadicContractionModulusUp.

Chapter 7949

A Concrete Naming Certificate for $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$

Following Bishop and Bridges constructive compactness, the $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ packet records the finite modulus surface by which a compact-metric sequence exposes a monotone subsequence schedule before any regular-Cauchy or real-name readback is consumed. It sits over the compact metric source of chapter 129, the finite-net bridge of chapter 3569, the stream interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the sibling regular subsequence modulus of chapter 6116. The packet names the compact-metric subsequence-selection modulus as finite NameCert data; it does not import countable choice, quotient stream equality, open-cover compactness, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7949.1 (Cauchy subsequence selection modulus carrier)**.** *A* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, A, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose finite metric inspections and compact-source identifiers bound the sequence consumer.*
2. *T is the finite* $\mathsf{TotallyBounded}^{\uparrow}$ *net ledger read from K, including visible positive radii, center histories, and coverage witnesses.*
3. *A is the source* $\mathsf{StreamName}^{\uparrow}$ *sequence row, recording the finite windows of the sequence inspected by the selection procedure.*
4. *M is the subsequence selection modulus row. For each displayed dyadic tolerance it records a monotone index schedule, a retained finite-net cell, and the finite cofinality checks used to compare later selected terms.*
5. *W is the selected-window row, listing the source windows retained by M together with their dyadic comparison budgets.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row opened only after K, T, A, M, W have been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *cluster-seal row reached from the regular readback.*
8. *H records componentwise* hsame *transport for the compact source, finite nets, source stream, selection modulus, selected windows, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from compact-metric sequence requests through $K, T, A, M, W, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySubsequenceModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}}$ *row.*

Definition 7949.2 (Cauchy subsequence selection modulus classifier)**.** *The classifier of an accepted* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *packet compares two carriers only through the displayed rows $K, T, A, M, W, R, E, H, C, P, N$. It requires the same compact-metric source row, the same visible finite-net ledger, the same finite source windows, the same monotone selection modulus, the same selected-window and dyadic-budget rows, and the same downstream regular readback and real seal up to componentwise* hsame *transport and displayed* Cont *replay. It has no coordinate for a host-selected infinite subsequence, quotient equality of streams, open-cover compactness, countable choice, a chosen cluster point, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7949.3 (Selection modulus carrier admission)**.** *For every accepted* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *carrier $S = (K, T, A, M, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}}$ *surface admits exactly the compact metric source, finite-net ledger, source stream windows, selection modulus, selected-window budget, regular readback, Real seal, transport, replay, provenance, and local naming rows displayed in Definition 7949.1.*

Proof. Project the accepted carrier. The mathematical rows are K, T, A, M, W, R, E, and the structural rows are H, C, P, N.

No further coordinate is present. Thus carrier admission is exhausted by the compact source, finite nets, source stream, selection modulus, selected windows, regular readback, real seal, and the four structural rows. □

Theorem 7949.4 (Selection modulus classifier stability)**.** *The classifier of an accepted* CauchySubsequenceSelection *carrier is stable under componentwise* hsame *transport of K, T, A, M, W, R, E. The transported packet has the same displayed* Cont *replay,* Pkg *provenance, and local* NameCert *surface, and it does not gain a second subsequence selector.*

Proof. Use the transport row H. It moves each displayed mathematical row componentwise and also transports the structural rows that replay, source, and name the packet.

The classifier of Definition 7949.2 reads only those transported coordinates. Since the carrier contains no external selector coordinate, transport cannot introduce countable choice, quotient stream equality, or a hidden selected subsequence. □

Theorem 7949.5 (Selection modulus finite-net extraction)**.** *Every subsequence-selection read from an accepted* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *carrier factors through the finite-net row T and the monotone schedule row M. For each displayed tolerance, M retains only a finite-net cell supplied by T, a finite list of inspected source windows from A, and the selected-window comparison budget recorded in W.*

Proof. Begin with one displayed tolerance request. The finite-net data available to the packet are exactly the centers, coverage witnesses, and radius ledger in T.

The schedule row M can therefore choose only among the finite cells exposed by T and the source windows exposed by A. The retained windows and comparison budgets are then written in W.

Induct over the displayed tolerance list. The empty list asks for no selection, while the next request appends one retained finite cell and one finite source-window comparison. The induction never appeals to a global choice function. □

Theorem 7949.6 (Selection modulus regular handoff)**.** *Any regular-Cauchy readback exported by an accepted* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *packet reaches* $\mathsf{RegSeqRat}^{\uparrow}$ *only through the route*

$$K, T, A, M, W, R.$$

The row R reads the selected windows and dyadic budgets already displayed by M, W and exports no quotient stream equality, host sequence equality, or unrecorded fast Cauchy modulus.

Proof. The regular readback coordinate is R. It is placed downstream of the compact source, finite-net ledger, source windows, selection modulus, and selected-window budget.

The previous extraction theorem identifies M, W as finite rows built from T and A. Hence R receives only the displayed selected-window route and cannot replace it with a quotient stream, host equality, or hidden modulus. □

Theorem 7949.7 (Selection modulus real nonescape)**.** *Every cluster-facing read that reaches the* $\mathsf{Real}^{\uparrow}$ *seal E of an accepted* $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ *carrier must first expose K, T, A, M, W, R. The seal is the terminal observation of that finite route and exports no selected limit, open-cover compactness theorem, countable choice, quotient stream equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. The terminal seal coordinate is E. A consumer reaches it only after the regular readback row R has consumed the selected-window route.

By the regular handoff theorem, R itself is downstream of K, T, A, M, W. Therefore the real seal cannot be read without displaying the compact source, finite nets, source windows, selection modulus, selected windows, and regular readback.

The excluded principles are not coordinates of the carrier or classifier. The seal consequently remains a terminal row of the finite NameCert route. □

Falsifiable prediction: Every accepted $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ route to a RegSeqRat or Real boundary must display a compact metric source, finite-net ledger, source StreamName windows, monotone selection modulus, selected-window budget, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, totallybounded, streamname, regseqrat, real, regularcauchysubsequencemodulus: none is bijective with $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ because this packet jointly carries the compact source, finite nets, source sequence windows, monotone subsequence-selection modulus, selected-window budgets, regular handoff, real seal, transport, replay, provenance, and local naming for the same compact-metric extraction route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}$ packet is generated from a CompactMetric row, TotallyBounded finite-net ledger, StreamName source windows, monotone selection modulus, selected-window budget, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchySubsequenceSelectionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7949.1, Definition 7949.2, Definition 7949.3, Definition 7949.4, Definition 7949.5, Definition 7949.6, and Definition 7949.7 seed the compact-metric subsequence-selection modulus route from finite nets to RegSeqRat and Real boundaries.

Formal verification: FormalStatus(NameCert$_{\text{CauchySubsequenceSelectionModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, host-selected subsequences, quotient stream equality, open-cover compactness, selected cluster points, ambient RealUp completeness, Lean checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, finite-net extraction, regular handoff, real nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchySubsequenceSelectionModulusUp.

Chapter 7950

A Concrete Naming Certificate for $\mathsf{UniformBornology}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and bornologies, the $\mathsf{UniformBornology}^{\uparrow}$ packet records the finite interface in which a displayed uniform-space entourage row controls bounded-family reads without reducing them to metric-ball boundedness. It sits after the bornology carrier of chapter 3370, the uniform-space entourage discipline of chapter 339, the bounded-set row of chapter 1757, the Cauchy bounded-family route of chapter 1896, and the proper-metric completion boundary of chapter 3686. The packet gives L10 completion, properness, and Cauchy-bornology consumers a non-quotient bounded-uniform interface with no selected entourage scale, host bounded subset, metric-ball collapse, quotient completion, or ambient compactness principle.

Definition 7950.1 (Uniform bornology carrier)**.** *A* $\mathsf{UniformBornology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q_{\mathrm{ub}} = (U, B, E, H_f, F, K, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *row naming the finite entourage requests, refinements, inverse requests, and composition windows that may be inspected by a bounded-family consumer.*
2. *B is the bounded-family source row, read through the* $\mathsf{Bornology}^{\uparrow}$ *and* $\mathsf{BoundedSet}^{\uparrow}$ *carriers, and containing only the displayed bounded families admitted by the packet.*
3. *E is the entourage-boundedness ledger. For each displayed family in B, it records the finite entourage windows of U that keep that family inside the same bounded source row after a uniform thickening request.*
4. *H_f is the hereditary ledger, requiring every displayed subfamily or smaller bounded-set window inherited from B to remain accepted after the same entourage-boundedness read in E.*
5. *F is the finite-union ledger, requiring finite unions of displayed bounded families to be accepted by the same source row and to replay through the same finite entourage windows.*
6. *K is the Cauchy and proper-metric handoff row. It exposes the route by which* $\mathsf{CauchyBornology}^{\uparrow}$ *consumers read bounded Cauchy data and by which* $\mathsf{ProperMetricSpace}^{\uparrow}$ *consumers read closed-ball boundedness, always after U, B, E, H_f, F have been replayed.*
7. *H records componentwise* hsame *transport for the uniform-space row, bounded-family row, entourage-boundedness ledger, hereditary ledger, finite-union ledger, handoff row, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a uniform-bornology request through* $U, B, E, H_f, F, K, H, P, N$.
9. *P is the* Pkg *provenance over* $\mathsf{UniformBornology}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Bornology}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, $\mathsf{ProperMetricSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformBornology}^{\uparrow}}$ *row.*

The carrier contains no coordinate for a selected entourage scale, quotient completion class, host bounded subset, metric-ball-only boundedness theorem, open-cover compactness proof, or ambient completeness principle.

Theorem 7950.2 (Uniform bornology NameCert obligations)**.** *For every accepted* $\mathsf{UniformBornology}^{\uparrow}$ *carrier*

$$Q_{\mathrm{ub}} = (U, B, E, H_f, F, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformBornology}^{\uparrow}}$ *surface consists exactly of carrier admission, uniform-space row exposure, bounded-family source exposure, entourage-boundedness exactness, hereditary stability, finite-union stability, Cauchy and proper-metric handoff ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing consumer that asks for bounded-uniform data must read these rows before it can consume a Cauchy-bornological or proper-metric boundary.*

Proof. Carrier admission is projection from Definition 7950.1. The accepted packet exposes exactly $U, B, E, H_f, F, K, H, C, P, N$, so the uniform, bornological, bounded-set, ledger, handoff, transport, replay, provenance, and naming rows are finite BEDC data.

Entourage-boundedness is read from U, B, E. The uniform row supplies the finite entourage windows, the bounded-family row supplies the displayed source families, and the ledger E records that each admitted thickening request stays within the same bounded-family source.

Hereditary and finite-union stability are separate ledger reads. The row H_f handles displayed subfamilies and smaller bounded-set windows, while F handles finite unions. Both ledgers replay through E, so neither can introduce a host bounded subset or a metric-ball-only boundedness theorem.

Finally inspect K, H, C, P, N. The handoff row is available only after the bounded-uniform ledger has been replayed, and the structural rows preserve the same finite packet. Since no coordinate stores a selected entourage scale, quotient completion, open-cover compactness proof, or ambient completeness theorem, the NameCert obligations are exhausted by the displayed rows. □

Theorem 7950.3 (Uniform bornology uniform-space handoff)**.** *Every* $\mathsf{CauchyBornology}^{\uparrow}$ *or* $\mathsf{ProperMetricSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformBornology}^{\uparrow}$ *packet reads bounded-family data through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow},\quad \mathsf{Bornology}^{\uparrow},\quad \mathsf{BoundedSet}^{\uparrow},\quad \mathsf{CauchyBornology}^{\uparrow},\quad \mathsf{ProperMetricSpace}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Con}$$

The handoff row K may expose Cauchy boundedness or proper closed-ball boundedness only after the uniform entourage row U, bounded-family row B, entourage-boundedness ledger E, hereditary ledger H_f, and finite-union ledger F have been replayed. Thus the exported object is a bounded-uniform NameCert route, not a metric-ball collapse, selected radius, quotient completion, host subset, or ambient compactness principle.

Proof. Start with the uniform-space row U and the bounded-family source row B. These rows fix the entourage requests and the bounded families before any downstream consumer can inspect the handoff.

Use the entourage-boundedness ledger E to replay uniform thickenings of displayed bounded families. Then use H_f and F to close the same source row under displayed subfamilies and finite unions.

Only after those ledger reads is the row K available. Its Cauchy side routes bounded Cauchy reads to $\mathsf{CauchyBornology}^{\uparrow}$, while its proper-metric side routes closed-ball boundedness reads to $\mathsf{ProperMetricSpace}^{\uparrow}$; both sides share the same U, B, E, H_f, F prefix.

The transport, replay, provenance, and local naming rows preserve that prefix. Because the carrier has no coordinate for the excluded host principles, a consumer receives exactly the bounded-uniform handoff and nothing stronger. □

Falsifiable prediction: Every accepted $\mathsf{UniformBornology}^{\uparrow}$ consumer displays a $\mathsf{UniformSpace}^{\uparrow}$ row, a bounded-family source row through $\mathsf{Bornology}^{\uparrow}$ and $\mathsf{BoundedSet}^{\uparrow}$, an entourage-boundedness ledger, hereditary and finite-union ledgers, a Cauchy/proper-metric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any completion-facing boundedness read is available.

Independence witness: bornology, uniformspace, boundedset, cauchy-bornology, proper-metric-space: $\mathsf{UniformBornology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries uniform entourage control, bounded-family source data, entourage-boundedness, hereditary and finite-union ledgers, and Cauchy/proper-metric handoff rows as one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformBornology}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformBornology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7950.1, Definition 7950.2, and Definition 7950.3 seed the bounded-uniform interface over $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Bornology}^{\uparrow}$, $\mathsf{BoundedSet}^{\uparrow}$, $\mathsf{CauchyBornology}^{\uparrow}$, $\mathsf{ProperMetricSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformBornology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected entourage scales, quotient completion, metric-ball-only boundedness, host bounded subsets, open-cover compactness, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, entourage-boundedness exactness, hereditary stability, finite-union stability, Cauchy/proper-metric handoff ordering, transport replay, provenance, and local NameCert exactness for BEDC.Derived.UniformBornologyUp.

Constructive story: A $\mathsf{UniformBornology}^{\uparrow}$ packet is generated from UniformSpace entourage rows, Bornology and BoundedSet bounded-family rows, an entourage-boundedness ledger, hereditary and finite-union ledgers, a Cauchy and proper-metric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 7951

A Concrete Naming Certificate for $\mathsf{BrowderFixedPoint}^{\uparrow}$

Following Browder's fixed point theorem in nonlinear functional analysis, the $\mathsf{BrowderFixedPoint}^{\uparrow}$ packet records the finite BEDC route by which a compact convex self-map obligation is exposed through approximating finite-dimensional faces and monotone residual windows. It is anchored by the Schauder compact-convex surface of chapter 1923, the set-valued comparison surface of chapter 3511, the Brouwer finite-cell route of chapter 2030, the compact metric support of chapter 129, the convex carrier of chapter 208, the self-map rows of chapter 130, and the ambient rows of chapter 94. The packet names a constructive fixed-point frontier; it does not import a host fixed-point selector, an unrestricted compactness theorem, or a choice principle for limiting points.

Definition 7951.1 (BrowderFixedPoint carrier)**.** *A* $\mathsf{BrowderFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (K, V, Q, F, A, M, R, W, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row for the compact domain and its finite covering windows.*
2. *V is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *ambient row exposing only the carried vector, affine, and metric compatibility data needed by the fixed-point route.*
3. *Q is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the admitted compact convex carrier.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row, including graph access, source membership, target membership, and displayed modulus data.*
5. *A is the finite affine-approximation ledger, recording finite-dimensional faces, retractions into those faces, and the local comparison maps.*
6. *M is the monotone residual-window row that compares the self-map route with the affine approximation route at each displayed tolerance.*
7. *R is the Brouwer-Schauder reduction row, carrying the* $\mathsf{BrouwerFixedPoint}^{\uparrow}$ *cell witness route and the* $\mathsf{SchauderFixedPoint}^{\uparrow}$ *compact-convex handoff only through A and M.*
8. *W is the fixed-window boundary row recording the accepted residual boundary visible to downstream consumers.*
9. *H stores componentwise* hsame *transport for K, V, Q, F, A, M, R, W and the local certificate row.*

10. *C stores displayed* Cont *replay from compact support, convex membership, continuous-map reads, affine approximations, residual windows, reduction rows, and fixed-window export.*

11. *P is the* Pkg *provenance over* $\mathsf{BrowderFixedPoint}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{KakutaniFixedPoint}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BrowderFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected fixed point, an arbitrary weak compactness principle, a host topological-vector-space theorem, quotient equality of approximating faces, or any choice of a convergent subnet.

Theorem 7951.2 (BrowderFixedPoint NameCert obligations)**.** *For an accepted* $\mathsf{BrowderFixedPoint}^{\uparrow}$ *carrier $B = (K, V, Q, F, A, M, R, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BrowderFixedPoint}^{\uparrow}}$ *surface consists of exactly five obligation rows:*

1. *compact-convex domain admission through K, V, Q;*
2. *continuous self-map admission through F;*
3. *finite affine-approximation and monotone residual admission through A, M;*
4. *Brouwer-Schauder reduction and fixed-window exposure through R, W;*
5. *structural transport, replay, provenance, and local naming through H, C, P, N.*

No obligation may call on a host fixed-point selector, unrestricted compactness, ambient weak convergence, quotient equality of approximation ledgers, or an uncarried nonlinear-analysis theorem.

Proof. Project the accepted carrier of Definition 7951.1. The compact-convex domain data are exactly K, V, Q, so compact support, ambient compatibility, and convex membership enter as displayed packet rows.

The self-map route is then read only through F. The approximation and residual obligations consume A and M, which expose finite affine faces, retractions, comparison maps, and monotone residual windows without exporting a selected limiting point.

The reduction row R may cite the Brouwer and Schauder sibling surfaces, but only as finite handoffs attached to the displayed approximation and residual rows. The fixed-window row W records the boundary that downstream consumers can inspect.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no other coordinate, the listed five rows exhaust the local NameCert surface and exclude the host principles named in the statement. □

Theorem 7951.3 (BrowderFixedPoint compact-convex handoff)**.** *Every downstream read of an accepted* $\mathsf{BrowderFixedPoint}^{\uparrow}$ *packet factors through*

$$K, V, Q, F, A, M, R, W, H, C, P, N.$$

In particular, a consumer can reach the fixed-window boundary only after the compact metric support, functional-analysis ambient compatibility, convex carrier, continuous self-map, affine approximation ledger, monotone residual row, and Brouwer-Schauder reduction row have all been replayed.

Proof. Begin with a downstream consumer. The continuation row C is the only consumer-facing replay surface, and its compact-convex reads are attached to K, V, Q.

The continuous self-map row F is read next. It supplies graph access and membership replay for the displayed compact convex carrier, but it does not select a fixed point.

The affine-approximation ledger A and monotone residual row M then feed the reduction row R. This is the only place where the Brouwer, Schauder, and Kakutani sibling surfaces can be inspected, and their use remains tied to finite approximation and residual windows.

The fixed-window boundary W is therefore an exported boundary of the displayed route, not a host choice. The rows H, C, P, N preserve the same ordering under transport, replay, provenance, and local naming, so every downstream read factors through the surface named in the theorem. □

Falsifiable prediction: Every accepted $\mathsf{BrowderFixedPoint}^{\uparrow}$ consumer must expose compact metric support, functional-analysis ambient compatibility, convex carrier, continuous self-map, affine approximation, monotone residual, Brouwer-Schauder reduction, fixed-window boundary, transport, continuation, provenance, and local NameCert rows before it can read a fixed-window obligation.

Independence witness: schauder-fixed-point, kakutani-fixed-point, brouwer-fixed-point, compactmetric, convexset, continuousmap, functionalanalysis: $\mathsf{BrowderFixedPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries affine approximation faces, monotone residual windows, a Browder-facing reduction row, fixed-window export, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BrowderFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{BrowderFixedPoint}^{\uparrow}$ packet is generated from CompactMetric support rows, FunctionalAnalysis ambient compatibility rows, ConvexSet carrier rows, ContinuousMap self-map rows, affine-approximation ledgers, monotone residual windows, Brouwer-Schauder reduction rows, fixed-window boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrowderFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7951.1, Definition 7951.2, and Definition 7951.3 seed the finite Browder fixed-point naming route over the displayed compact metric, functional-analysis, convex, continuous-map, approximation, residual, reduction, fixed-window, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrowderFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host fixed-point selector, unrestricted compactness, ambient weak convergence, quotient equality of approximation ledgers, a choice principle for limiting points, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, compact-convex domain admission, continuous-map replay, affine-approximation coverage, monotone residual coverage, Brouwer-Schauder reduction coverage, fixed-window exposure, transport stability, replay stability, provenance, and local naming for BEDC.Derived.BrowderFixedPointUp.

Chapter 7952

A Concrete Naming Certificate for $\mathsf{LocatedCutSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCutSequence}^{\uparrow}$ packet records located lower and upper dyadic cut observations as finite rows, not as a Dedekind construction of $\mathsf{Real}^{\uparrow}$. It sits beside the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback route of chapter 301, and the terminal seal of chapter 38. The packet gives Real and Completion consumers a sequence-indexed located-cut observation surface while keeping quotient cuts, selected limits, trichotomy, and ambient completeness outside the carrier.

Definition 7952.1 (Located cut sequence carrier)**.** *A* $\mathsf{LocatedCutSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, D, W, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the side-tag row. Each finite observation is tagged as a lower cut read, an upper cut read, or a paired located-window request, and the tag is part of the packet data.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *bound row. It records the dyadic endpoint, tolerance cell, and finite refinement scale inspected by the tagged observation.*
3. *W is the located witness-window row. It records the finite bracket, separation, or refinement witness attached to the tagged endpoint request.*
4. *O is the* $\mathsf{StreamName}^{\uparrow}$ *observation row. It lists the finite sequence positions and stream windows through which the cut observation is read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It compares the finite window observations with a regular rational route before any real-name seal is consumed.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff. It is reached only after the side tag, dyadic bound, located witness window, stream observation, and regular readback rows have been displayed.*
7. *H records componentwise* hsame *transport for the tag, dyadic, witness-window, stream, regular-readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite located-cut request through S, D, W, O, R before the seal row E is read.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedCutSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCutSequence}^{\uparrow}}$ *row naming exactly this finite sequence of located cut observations.*

The classifier accepts only packets that display those rows. It has no coordinate for a primitive Dedekind cut, quotient cut equality, trichotomy branch, selected limit, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 7952.2 (Located cut sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCutSequence}^{\uparrow}$ *carrier* $L = (S, D, W, O, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedCutSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the side tag, dyadic bound, located witness window, finite* $\mathsf{StreamName}^{\uparrow}$ *observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming rows. Any Real or Completion consumer reading the packet factors through these rows and cannot cite the packet as a Dedekind-cut construction of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 7952.1. The analytic rows are exactly the side tag S, dyadic bound row D, located witness-window row W, finite stream observation row O, regular rational readback row R, and terminal seal row E.

The route order is load-bearing. A consumer first reads the side tag, then the dyadic endpoint and located witness window, then the finite stream positions, and only then the regular rational readback that can hand off to the real seal.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no row for quotient cuts, trichotomy, selected limits, or host completeness, the local naming certificate cannot export a Dedekind construction of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCutSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCutSequence}^{\uparrow}$ packet is generated from side-tagged lower and upper dyadic cut observations, located witness windows, finite StreamName rows, RegSeqRat readback, a terminal Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCutSequence}^{\uparrow}}$, seed)

Scope closed: Definition 7952.1 and Definition 7952.2 seed the finite sequence-indexed located-cut observation surface for Real and Completion boundary comparisons.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCutSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind-cut construction of reals, quotient cuts, trichotomy, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, side-tag exactness, dyadic bound readback, located witness-window locality, finite StreamName observation coverage, RegSeqRat handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCutSequenceUp.

Chapter 7953

A Concrete Naming Certificate for $\mathsf{LongLine}^{\uparrow}$

Following Munkres and Kelley on the long line, the $\mathsf{LongLine}^{\uparrow}$ packet records the classical lexicographic order-topology boundary as finite BEDC NameCert data. It sits beside the topology carrier of chapter 88, the order interface of chapter 1378, and the total-order comparison surface of chapter 54. The packet names inspected well-order prefixes, interval cells, lexicographic comparisons, order-topology neighbourhoods, transport, replay, provenance, and local naming without importing a host ordinal, uncountable choice, quotient point equality, selected representatives, or a compactness theorem.

Definition 7953.1 (Long line carrier)**.** *A* $\mathsf{LongLine}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, I, O, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the well-order-prefix schedule. Each inspected prefix is recorded as a finite named stage together with its predecessor and successor requests; the schedule is a displayed row of prefix evidence, not a host ordinal.*
2. *I is the interval-cell row. It records the unit-cell coordinate inside the displayed prefix stage, the left and right boundary requests, and the local interval membership tests needed by neighbourhood consumers.*
3. *O is the lexicographic comparison row. It compares two displayed points first by the prefix schedule S and then by the interval-cell coordinate I, exposing the comparison only through the order rows of chapter 1378 and chapter 54.*
4. *T is the order-topology neighbourhood row. It records finite open rays and finite open intervals generated from O and exports them to the topology carrier of chapter 88.*
5. *H records componentwise* hsame *transport for the prefix schedule, interval cells, lexicographic comparisons, order-topology neighbourhoods, provenance, replay, and local naming.*
6. *C records displayed* Cont *replay from a neighbourhood or comparison request through S, I, O, T and then through the structural rows.*
7. *P is the* Pkg *provenance over* $\mathsf{LongLine}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

8. N is the local $\mathsf{NameCert}_{\mathsf{LongLine}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through S, I, O, T, H, C, P, N. It has no coordinate for a host ordinal, an uncountable choice principle, quotient point equality, selected representatives, a completed open-set lattice, or a compactness theorem.

Lean4 ✓ `BEDC.Derived.LongLineUp.LongLineTasteGate single carrier alignment`

Theorem 7953.2 (LongLine NameCert obligations)**.** *For every accepted* $\mathsf{LongLine}^{\uparrow}$ *carrier $L = (S, I, O, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LongLine}^{\uparrow}}$ *surface consists exactly of the well-order-prefix schedule S, interval-cell row I, lexicographic comparison row O, order-topology neighbourhood row T, componentwise* hsame *transport H, displayed* Cont *replay C, package provenance P, and local naming N. Every topology- or order-facing consumer must expose these rows before reading a long-line point comparison, interval membership test, open ray, or open interval.*

Proof. Project the carrier of Definition 7953.1. The only prefix evidence is S, and the only within-prefix coordinate evidence is I.

The order-facing read is then forced through O. It first reads the displayed prefix schedule and then the interval-cell coordinate, so comparison data cannot be replaced by a host ordinal comparison or by quotient point equality.

The topology-facing read is forced through T. Its open rays and intervals are generated from the displayed lexicographic comparison row and are exported only through the topology surface cited above.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores uncountable choice, selected representatives, a completed open-set lattice, or compactness, the listed rows exhaust the local NameCert obligations. □

Theorem 7953.3 (LongLine lexicographic order route)**.** *Every* $\mathsf{LongLine}^{\uparrow}$ *consumer that reads a point comparison or an order-topology neighbourhood factors through the finite route*

$$S, I \longrightarrow O \longrightarrow T \longrightarrow H, C, P, N.$$

The route exposes the order comparison inherited from chapter 1378 and chapter 54 before it exposes the topology read of chapter 88. It exports no host ordinal, no uncountable choice, no quotient point equality, no selected representatives, and no compactness theorem.

Proof. Start with the displayed point data. A point read has only the prefix schedule S and interval-cell row I, so there is no separate representative or host ordinal from which a consumer can read comparison data.

Next read the lexicographic row O. It is the sole comparison row and therefore the only route to order-facing conclusions.

Then read the order-topology row T. Open rays and open intervals are generated from O, so a topology consumer reaches the open-neighbourhood surface only after the displayed lexicographic order route is visible.

The structural rows H, C, P, N preserve and name that same route. They do not add uncountable choice, quotient point equality, selected representatives, a completed open-set lattice, or compactness evidence. □

Falsifiable prediction: An accepted $\mathsf{LongLine}^{\uparrow}$ consumer is refuted if it reads a point comparison, open ray, open interval, topology membership, transport, replay, provenance, or local naming without first displaying the corresponding S, I, O, T, H, C, P, N rows.

Independence witness: topology, order, totalorder: no listed sibling is bijective to $\mathsf{LongLine}^{\uparrow}$ because the packet jointly carries a displayed well-order-prefix schedule, interval-cell row, lexicographic comparison row, order-topology neighbourhood row, componentwise transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LongLine}^{\uparrow}}$.

Constructive story: A $\mathsf{LongLine}^{\uparrow}$ packet is generated from a well-order-prefix schedule, interval-cell row, lexicographic comparison row, order-topology neighbourhood row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LongLine}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7953.1, Definition 7953.2, and Definition 7953.3 seed the finite long-line order-topology route over displayed prefix, interval, comparison, neighbourhood, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LongLine}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LongLineUp.LongLineTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim host ordinals, uncountable choice, quotient point equality, selected representatives, completed open-set lattices, compactness theorems, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-schedule exactness, interval-cell exactness, lexicographic comparison routing, order-topology neighbourhood routing, transport, replay, provenance, and local naming for BEDC.Derived.LongLineUp.

Chapter 7954

A Concrete Naming Certificate for $\mathsf{CompactUniformFanModulus}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity and Brouwer fan-bar arguments, the $\mathsf{CompactUniformFanModulus}^{\uparrow}$ packet records the finite fan-to-uniform-modulus route used by L10 Real and Completion consumers. It sits over the compact metric source of chapter 129, the pointwise continuous-map rows of chapter 130, the finite fan-bar modulus surface of chapter 4297, the uniform-modulus handoff of chapter 369, and the terminal real-name seal of chapter 38. The packet turns displayed compact finite-net and fan-bar data into a BEDC-native modulus certificate; it does not assert arbitrary open-cover compactness, choose an infinite branch, select an external Lebesgue number, quotient real names, invoke countable choice, import a host modulus function, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7954.1 (Compact uniform fan modulus carrier)**.** *A* $\mathsf{CompactUniformFanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, B, L, T, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row read through* $\mathsf{CompactMetric}^{\uparrow}$*; it displays the finite center schedule, mesh radius, and cover-membership data consumed by the fan route.*
2. *F is the pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus row, attaching a source-radius witness to each displayed center and requested target tolerance.*
3. *B is the* $\mathsf{FiniteFanBarModulus}^{\uparrow}$ *bar row; equivalently it may be read through the fan-theorem surface of chapter 400 when the fan proof has already exposed a finite bar.*
4. *L is the rational lower-bound fold, taking the finitely many radii displayed by K, F, B to one positive dyadic tolerance.*
5. *T is the dyadic tolerance ledger that records the requested target precision, the finite fold value, and the comparison budget used by the output route.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced by L and T.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the uniform-modulus request.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational approximants observed inside the opened windows.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after K, F, B, L, T, U, W, R have been replayed.*
10. *H records componentwise* hsame *transport for compact-net, continuous-map, fan-bar, lower-bound, tolerance, handoff, window, readback, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a compact-uniform-modulus request through $K, F, B, L, T, U, W, R, E, H, P,$*
12. *P is the* Pkg *provenance over* $\mathsf{CompactUniformFanModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteFanBarModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformFanModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by transporting these finite rows to a common compact-fan tolerance surface.

Theorem 7954.2 (Compact uniform fan modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformFanModulus}^{\uparrow}$ *carrier*

$$M = (K, F, B, L, T, U, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformFanModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net exposure, pointwise continuous-map modulus exposure, finite fan-bar exposure, rational lower-bound fold, dyadic tolerance ledger,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff,* $\mathsf{StreamName}^{\uparrow}$ *window replay,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7954.1. The only analytic source rows are $K, F, B, L, T, U, W, R, E$, and the only structural rows are H, C, P, N.

The compact and continuity data are read before the fan route. The finite-net row K supplies the displayed centers and mesh data, while F supplies the pointwise modulus rows attached to those centers.

The fan contribution is finite because B is a displayed bar-modulus row. The lower-bound fold L and tolerance ledger T consume the finitely many rows from K, F, B before the uniform-modulus output U is visible.

Finally W, R, E route the output into StreamName, RegSeqRat, and Real-facing reads, and H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for arbitrary open-cover compactness, selected infinite branches, selected external Lebesgue numbers, quotient map equality, countable choice, host modulus functions, or ambient Real completeness, no local obligation can export those objects. □

Theorem 7954.3 (Compact uniform fan modulus Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing compact-uniform-modulus read exported by an accepted* $\mathsf{CompactUniformFanModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{FiniteFanBarModulus}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegS}$$

The route displays compact finite-net data, pointwise continuous-map moduli, finite fan-bar data, the rational lower-bound fold, the dyadic tolerance ledger, the uniform-modulus handoff, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming before a Real consumer may read the output.

Proof. Start with the obligations of Definition 7954.2. They expose $K, F, B, L, T, U, W, R, E, H, C, P, N$ as the whole local NameCert surface.

The compact-to-fan prefix is K, F, B. The compact metric finite-net data in K and the pointwise continuous-map rows in F are consumed by the finite bar-modulus row B, so the route never needs an infinite branch or arbitrary open-cover selection.

The modulus output is then forced through L, T, U. The fold L and ledger T produce a displayed dyadic tolerance before U is available as a $\mathsf{UniformModulus}^{\uparrow}$ handoff.

The Real-facing suffix is W, R, E. StreamName windows are opened first, RegSeqRat readback follows, and the terminal $\mathsf{Real}^{\uparrow}$ seal is visible only after those finite rows have been replayed. The structural rows preserve the same route, so the exported Real read is exactly the displayed finite corridor. □

Theorem 7954.4 (Compact uniform fan modulus vision route)**.** *The compact-uniform-continuity vision consumes an accepted* $\mathsf{CompactUniformFanModulus}^{\uparrow}$ *packet only through* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteFanBarModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows. The route excludes arbitrary open-cover compactness, branch choice, external Lebesgue-number selection, quotient map equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7954.1 and the Real route of Definition 7954.3. The only vision-facing analytic rows are compact finite-net data, continuous-map modulus data, finite fan-bar data, uniform-modulus handoff data, stream windows, regular-rational readback, and the terminal Real seal.

Transport and replay preserve those same rows through H, C, P, N. Since no carrier coordinate stores open-cover compactness, an infinite branch, an external Lebesgue-number selector, quotient map equality, countable choice, or ambient real completeness, the vision can consume only the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFanModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformFanModulus}^{\uparrow}$ packet is generated from compact finite-net rows, pointwise continuous-map modulus rows, finite fan-bar rows, a rational lower-bound fold, a dyadic tolerance ledger, a UniformModulus handoff, StreamName windows, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFanModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7954.1, Definition 7954.2, and Definition 7954.3 seed the compact finite-net, continuous-map, finite fan-bar, uniform-modulus, StreamName, RegSeqRat, and Real route for L10 consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFanModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, selected infinite branches, selected external Lebesgue numbers, quotient map equality, countable choice, host modulus functions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked compact finite-net rows, pointwise continuous-map modulus rows, finite fan-bar rows, rational lower-bound fold, dyadic tolerance ledger, UniformModulus handoff, StreamName windows, RegSeqRat readback, Real seal, transport replay, provenance, and local NameCert exactness for BEDC.Derived.CompactUniformFanModulusUp

Chapter 7955

A Concrete Naming Certificate for $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ packet records the finite surface by which a displayed regular Cauchy name refines its modulus along a cofinal tail schedule before any Real and Completion consumer reads the result. It sits over the regular-name source of chapter 371, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names a finite cofinal-refinement carrier; it does not construct quotient streams, selected limits, countable-choice schedules, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7955.1 (Regular Cauchy modulus cofinal-refinement carrier)**.** *A* RegularCauchyModulusCofinalRefineme *carrier is a finite* BHist *packet*

$$R = (S, M, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegularCauchyName}^{\uparrow}$ *row whose modulus is being refined.*
2. *M is the displayed cofinal modulus-refinement row, listing the retained tail thresholds and the monotone comparison between the source modulus and the refined modulus.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the retained thresholds in M.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows W.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic budgets served by the refined tail windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, M, W, Q, D have been displayed.*
7. *H records componentwise* hsame *transport for the source name, refinement row, windows, readback, tolerance ledger, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from source regular Cauchy reads through the cofinal refinement, finite windows, regular rational readback, dyadic budgets, and terminal real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, M, W, Q, D, E, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected representative, countable choice over tails, host real equality, an unbounded search for a modulus, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegularCauchyModulusCofinalRefinementUp`

Theorem 7955.2 (Regular Cauchy modulus cofinal-refinement NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ *carrier $R = (S, M, W, Q, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}}$ *surface consists exactly of source regular-name exposure, displayed cofinal modulus refinement,* $\mathsf{StreamName}^{\uparrow}$ *finite-window scheduling,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed continuation replay, package provenance, local naming, and ledger refusal for quotient streams, selected limits, countable choice, host real equality, unbounded modulus search, and ambient completeness.*

Proof. Project the carrier of Definition 7955.1. The accepted packet displays the source row S, the refinement row M, the window row W, the readback row Q, the tolerance row D, and the terminal seal E.

The structural rows H, C, P, N transport, replay, source, and name exactly those mathematical rows. Since no further coordinate is present, every local NameCert obligation must be read through $S, M, W, Q, D, E, H, C, P, N$.

The refusal clauses are carrier-coordinate exclusions. Quotient streams, selected limits, countable choice over tails, host real equality, unbounded modulus search, and ambient completeness are not rows of R, so they cannot be exported by the local certificate. □

Theorem 7955.3 (Regular Cauchy modulus cofinal-refinement stability)**.** *The classifier of an accepted* $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ *carrier is stable under componentwise* hsame *transport of S, M, W, Q, D, E. The transported packet preserves the same cofinal tail thresholds, the same finite windows, the same regular rational readback, the same dyadic tolerance ledger, the same terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the same* Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

Proof. Use the transport row H. It transports the source name, cofinal-refinement row, window row, readback row, tolerance ledger, and Real seal componentwise.

The classifier of Definition 7955.1 reads only those coordinates together with C, P, N. Therefore any transported packet compares the same retained thresholds, windows, readbacks, dyadic budgets, seal, replay, provenance, and local naming rows.

No hidden selector is introduced by transport. The packet still lacks quotient streams, countable choice, host equality, unbounded modulus search, and ambient completeness coordinates. □

Theorem 7955.4 (Regular Cauchy modulus cofinal-refinement Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ *carrier factors through the finite route*

$$S, M, W, Q, D, E, H, C, P, N.$$

The route reaches the terminal seal only through the displayed regular Cauchy source, cofinal refinement, StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance ledger.

Proof. The terminal seal coordinate is E. By the carrier definition, E is downstream of the source row S, the refinement row M, the finite windows W, the regular rational readback Q, and the dyadic tolerance ledger D.

The NameCert obligations theorem shows that these rows are the complete public surface. Transport, replay, provenance, and local naming are then exactly H, C, P, N.

Thus a Real-facing consumer cannot bypass the finite route by using a quotient stream, selected representative, countable-choice tail schedule, host equality of real names, unbounded modulus search, or ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ route to RegSeqRat or Real data must display a source RegularCauchyName row, a cofinal modulus-refinement row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: regularcauchyname, streamname, regseqrat, dyadicratcore, real: none is bijective with $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ because this packet jointly carries the source regular Cauchy name, cofinal modulus refinement, finite windows, rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming for the same tail-refinement route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}$ packet is generated from a RegularCauchyName source row, a cofinal modulus-refinement row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7955.1, Definition 7955.2, Definition 7955.3, and Definition 7955.4 seed the finite cofinal-refinement route from regular Cauchy modulus data to RegSeqRat and Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyModulusCofinalRefinement}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice over tails, host real equality, unbounded modulus search, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal refinement exposure, window stability, RegSeqRat readback, DyadicRatCore tolerance accounting, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyModulusCofinalRefinementUp.

Chapter 7956

A Concrete Naming Certificate for $\mathsf{LocatedRealLowerCut}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRealLowerCut}^{\uparrow}$ packet records a finite lower-cut locatedness surface for Real and Completion consumers. It sits beside the located-real comparison route of **??**, the finite stream observations of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. The packet names lower-cut evidence available to downstream comparison or completion routes without asserting Dedekind-cut reals, quotient equality, selected suprema, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7956.1 (Located-real lower-cut carrier)**.** *A* $\mathsf{LocatedRealLowerCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the lower-cut query row. It lists the finitely many rational thresholds whose membership in the lower approximation is inspected.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row attached to those thresholds, including the finite precision and separation budget used by the locator.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row through which the threshold data are read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row comparing the observed windows with a regular rational route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, D, W, R have been displayed.*
6. *H records componentwise* hsame *transport for the threshold, tolerance, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a lower-cut query through Q, D, W, R before the seal row E is consumed.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealLowerCut}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLowerCut}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying these rows. It has no coordinate for a completed Dedekind cut, quotient equality of cuts, a least upper bound selector, trichotomy, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Theorem 7956.2 (Located-real lower-cut NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealLowerCut}^{\uparrow}$ *carrier* $L = (Q, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealLowerCut}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower-cut query row, dyadic tolerance row, finite* $\mathsf{StreamName}^{\uparrow}$ *observation windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. Any Real or Completion consumer reading the packet factors through these rows and cannot cite the packet as a Dedekind-cut construction of* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 7956.1. The analytic rows are exactly Q, D, W, R, E: a lower-cut query, a dyadic tolerance ledger, finite stream observations, regular rational readback, and the terminal real seal.

The route order is part of the packet. A consumer reads the rational threshold row Q, then the dyadic budget D, then the finite observation window W, and only then the regular rational readback R that can reach the real seal E.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no row for completed cuts, quotient equality, selected suprema, trichotomy, countable choice, or host completeness, the local naming certificate cannot export those objects. □

Theorem 7956.3 (Located-real lower-cut RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, or completion-facing read of an accepted* $\mathsf{LocatedRealLowerCut}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes only the lower-cut thresholds, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal seal, componentwise transport, replay, provenance, and local naming rows already displayed in the carrier.

Proof. Start with the obligations of Definition 7956.2. They expose $Q, D, W, R, E, H, C, P, N$ as the whole local NameCert surface.

The lower-cut information reaches a regular rational consumer through D, W, R. The dyadic threshold and tolerance row supplies the finite budget, the stream row supplies the inspected windows, and the readback row is the first point at which a $\mathsf{RegSeqRat}^{\uparrow}$ consumer can receive data.

The terminal Real or Completion consumer then reads only through E. The structural rows preserve the same packet under transport and replay, so the handoff cannot add Dedekind-cut equality, selected suprema, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealLowerCut}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealLowerCut}^{\uparrow}$ packet is generated from finite lower-cut threshold queries, a DyadicRatCore tolerance ledger, StreamName observation windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealLowerCut}^{\uparrow}}$, seed)

Scope closed: Definition 7956.1, Definition 7956.2, and Definition 7956.3 seed the finite lower-cut locatedness route through dyadic thresholds, stream windows, regular rational readback, and the terminal Real seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealLowerCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Dedekind-cut reals, quotient equality, selected suprema, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-cut query exactness, dyadic tolerance coverage, StreamName window exposure, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealLowerCutUp.

Chapter 7957

A Concrete Naming Certificate for $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$

Following Bishop and Bridges and Kelley on compactness via finite subcovers, the $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$ packet records only selection from already displayed finite open-cover rows. It sits after the compact metric source of chapter 129, the finite cover cells of chapter 2377, the stream schedules of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name surface of chapter 38. The packet names a finite selected subrow already visible in the cover ledger; it does not choose an arbitrary open cover, import countable choice, identify quotient real names, appeal to host compactness, select subcovers outside displayed finite rows, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7957.1 (Finite open cover selection carrier)**.** *A* $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, O, S, R, D, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the compact metric carrier and the finite cover request already admitted by that source.*
2. *O is the* $\mathsf{FiniteRealCover}^{\uparrow}$ *row, or equivalently the displayed finite cover-cell ledger, whose cells are the only candidates from which selection may read.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row attached to the cover cells and to the finite observation windows used by the consumer.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational observations visible in those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and tolerance row attached to the cover cells, stream windows, and readback comparisons.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after K, O, S, R, D have been displayed.*
7. *U is the selected finite subrow of O, recorded as a displayed sublist or subbundle of cover cells rather than as an external selector.*
8. *H records componentwise* hsame *transport for compact-source, finite-cover, stream, readback, dyadic, Real-seal, selected-subrow, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite cover-selection request through $K, O, S, R, D, E, U, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteRealCover}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverSelection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed finite cover row and its selected finite subrow, transported together with the stream, readback, tolerance, Real-seal, replay, provenance, and naming rows.

Theorem 7957.2 (Finite open cover selection NameCert obligations)**.** *For every accepted* FiniteOpenCoverSelection *carrier $F = (K, O, S, R, D, E, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverSelection}^{\uparrow}}$ *surface consists exactly of carrier admission, compact metric source exposure, displayed finite cover-cell exposure,* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius and tolerance exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal exposure, selected finite subrow exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7957.1. The only cover source is O, and the only selected object is the finite subrow U already carried inside that displayed cover ledger.

Read the analytic rows in order. The compact metric source K admits the finite cover request, O displays the finite cover cells, S schedules the finite observations, R reads them back as regular rational data, D attaches dyadic radius and tolerance comparisons, and E supplies the terminal real-name seal.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for arbitrary open-cover compactness, countable choice, quotient real equality, host compactness, selected subcovers outside O, or ambient $\mathsf{Real}^{\uparrow}$ completeness, those objects are not local NameCert obligations. □

Theorem 7957.3 (Finite open cover selection compact-uniform route)**.** *Every compact-uniform or Real-completion consumer of an accepted* $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$ *packet reads the selected subrow only through the finite corridor*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteRealCover}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The corridor exposes the selected finite subrow U as part of the displayed cover row O before any downstream uniform-modulus, finite-cover, or real-name consumer may use it.

Proof. Start with the NameCert obligations of Definition 7957.2. They force the compact source, finite cover cells, schedule, readback, dyadic tolerance, Real seal, selected subrow, and structural rows to be visible before the packet is consumed.

The selected subrow is read from O through U. Thus a downstream compact-uniform route receives a finite cover-cell subrow already displayed in the packet, not an open-cover selector and not a host compactness principle.

Finally replay the stream, regular-rational, dyadic, and Real-seal rows. They provide the finite observation and tolerance corridor through which the selected cover cells can feed a uniform-modulus or Real-completion consumer. The route has no coordinate for countable choice, quotient real equality, subcovers outside the displayed finite rows, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenCoverSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteOpenCoverSelection}^{\uparrow}$ packet is generated from CompactMetric source data, displayed finite cover cells, StreamName schedules, RegSeqRat readback, DyadicRatCore radius and tolerance rows, a RealUp seal, a selected finite subrow, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteOpenCoverSelection}^{\uparrow}}$, seed)

Scope closed: Definition 7957.1, Definition 7957.2, and Definition 7957.3 seed the finite cover-selection packet for compact-uniform and Real-completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteOpenCoverSelection}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim arbitrary open-cover compactness, countable choice, quotient real equality, host compactness, selected subcovers outside displayed finite rows, ambient Real$^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover-cell exposure, selected subrow exactness, StreamName schedule exposure, RegSeqRat readback, DyadicRatCore tolerance routing, Real seal handoff, transport replay, provenance, and local NameCert exactness for BEDC.Derived.FiniteOpenCoverSelectionUp.

Chapter 7958

A Concrete Naming Certificate for $\mathsf{ProfiniteMetricCompletion}^{\uparrow}$

Following Serre and Bourbaki on profinite completion and the Kelley/Bishop-style treatment of metric completion, the $\mathsf{ProfiniteMetricCompletion}^{\uparrow}$ packet records the finite inverse-limit metric completion neighbour obtained by reading profinite finite-stage data through a metric-completion boundary. It sits beside the finite quotient-stage certificate of chapter 5934, the projection-window metric route of chapter 2168, the finite observation discipline of chapter 126, the completion handoff of chapter 1506, and the compact metric readback of chapter 129. The packet names finite stages, finite projection checks, windowed metric readback, completion handoff, compact boundary evidence, transport, replay, provenance, and local naming; it does not construct quotient completions, select infinite representatives, import Haar measure, or assert ambient compactness beyond the displayed row.

Definition 7958.1 (Profinite metric completion carrier)**.** *A* $\mathsf{ProfiniteMetricCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (F, I, W, M, K, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ProfiniteCompletion}^{\uparrow}$ *finite quotient-stage row, carrying only the displayed finite stages and bonding checks accepted by the profinite packet;*
2. *I is the* $\mathsf{InverseLimitMetric}^{\uparrow}$ *projection-metric row that reads those finite stages as a finite inverse-limit metric diagram;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that selects the visible quotient stages, projection comparisons, and metric observations;*
4. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row reached from the inverse-limit metric route without choosing a quotient representative;*
5. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *boundary row used to read the resulting compact metric surface through finite evidence;*
6. *H records componentwise* hsame *transports for F, I, W, M, K and the structural rows;*
7. *C records displayed* Cont *replay of the route*

$$F \longmapsto I \longmapsto W \longmapsto M \longmapsto K;$$

8. *P is the* Pkg *provenance over* ProfiniteMetricCompletion$^{\uparrow}$, ProfiniteCompletion$^{\uparrow}$, InverseLimitMetric$^{\uparrow}$, StreamName$^{\uparrow}$, MetricCompletion$^{\uparrow}$, CompactMetric$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{ProfiniteMetricCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, I, W, M, K, H, C, P, N$. It has no coordinate for quotient completion equality, selected infinite representatives, Haar measure, host group completion, or ambient compactness outside the displayed CompactMetric$^{\uparrow}$ *row.*

Theorem 7958.2 (Profinite metric completion NameCert obligations)**.** *For every accepted* ProfiniteMetricCompletio *carrier $Q = (F, I, W, M, K, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ProfiniteMetricCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed* ProfiniteCompletion$^{\uparrow}$ *finite-stage row, the* InverseLimitMetric$^{\uparrow}$ *projection-metric row, the* StreamName$^{\uparrow}$ *finite-window row, the* MetricCompletion$^{\uparrow}$ *handoff row, the* CompactMetric$^{\uparrow}$ *boundary row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read must pass through the route stored in C before any compact metric boundary is exposed.*

Proof. Project the carrier of Definition 7958.1. The mathematical rows are F, I, W, M, K: profinite finite-stage data, inverse-limit metric projection data, finite StreamName windows, the metric-completion handoff, and the compact metric boundary.

The replay row C fixes the order of consumption. A reader first inspects the profinite stage row F, then the inverse-limit metric row I, then the finite window row W, and only then reaches the completion handoff M and compact boundary K.

The transport, provenance, and naming rows H, P, N preserve and source that same finite route. Since no coordinate supplies quotient completion equality, a selected infinite representative, Haar measure, host group completion, or ambient compactness outside K, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProfiniteMetricCompletion}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProfiniteMetricCompletion}^{\uparrow}}$, seed)

Scope closed: Definition 7958.1 and Definition 7958.2 seed the finite profinite metric completion packet over profinite finite-stage data, inverse-limit metric rows, StreamName windows, MetricCompletion handoff, CompactMetric boundary, transport, replay, provenance, and naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProfiniteMetricCompletion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected infinite representatives, Haar measure, host group completion, ambient compactness beyond the displayed CompactMetric row, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-stage routing, projection-metric compatibility, StreamName window routing, MetricCompletion handoff exactness, CompactMetric boundary readback, transport stability, provenance, and local naming for BEDC.Derived.ProfiniteMetricCompletionUp.

Constructive story: A ProfiniteMetricCompletion$^{\uparrow}$ packet is generated from ProfiniteCompletion finite-stage rows, InverseLimitMetric projection rows, StreamName finite-window rows, MetricCompletion handoff rows, CompactMetric boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 7959

A Concrete Naming Certificate for $\mathsf{ConstructiveBaireCategory}^{\uparrow}$

Following Baire's theorem and Bishop-style constructive analysis, the $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ packet records the finite dense-open cylinder surface by which a completion-facing consumer may use a Baire-category argument without importing classical countable choice. It sits beside the Baire-space source of chapter 334, the Cantor-space sibling of chapter 1475, the finite observation windows of chapter 126, the metric carrier of chapter 57, and the terminal real-name seal of chapter 38. The packet names only displayed cylinder rows, dense-open admission rows, finite meet witnesses, metric-window replay, transport, provenance, and local naming.

Definition 7959.1 (Constructive Baire category carrier)**.** *A* $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, C, D, F, M, W, R, H, K, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{BaireSpace}^{\uparrow}$ *source row, exposing the finite prefix cylinder currently inspected by the packet.*
2. *C is the* $\mathsf{CantorSpace}^{\uparrow}$ *comparison row used when the same finite-prefix argument is read through binary cylinders.*
3. *D is the dense-open admission row, listing the displayed dense-open cylinder requests visible to the packet.*
4. *F is the finite meet-witness row, recording a common cylinder refinement for the displayed finite family from D.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *window row that bounds the cylinder read by a displayed metric observation.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row attached to the inspected prefixes and metric observations.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for scalar radius or tolerance reads obtained only after S, C, D, F, M, W have been exposed.*
8. *H records componentwise* hsame *transport for the displayed source, cylinder, dense-open, finite-meet, metric, stream-window, and real-seal rows.*

9. *K records displayed* Cont *replay from finite cylinder requests through dense-open admission, finite meet witnesses, metric windows, stream windows, real sealing, transport, provenance, and local naming.*
10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveBaireCategory}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveBaireCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a classical choice sequence, an arbitrary countable meet of open sets, open-cover compactness, quotient equality of streams, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7959.2 (Constructive Baire category NameCert obligations)**.** *For every accepted* ConstructiveBaireCatego *carrier $B = (S, C, D, F, M, W, R, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveBaireCategory}^{\uparrow}}$ *surface consists exactly of Baire-space source exposure, Cantor-space cylinder comparison when present, dense-open cylinder admission, finite meet-witness exposure, metric-window exposure,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure,* $\mathsf{Real}^{\uparrow}$ *seal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer receives no classical countable-choice principle, no arbitrary countable intersection of open sets, no open-cover compactness theorem, no quotient stream equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Project the carrier of Definition 7959.1. The source and cylinder rows are S, C, D, F, the analytic observation rows are M, W, R, and the structural rows are H, K, P, N.

The dense-open obligations come from D and F. The row D lists only the dense-open cylinder requests already displayed by the packet, while F records a finite common refinement for that listed family.

The analytic handoff comes from M, W, R. The metric row bounds the cylinder read, the stream row records the finite prefix window that is actually inspected, and the real row seals scalar radius or tolerance reads only after those rows are visible.

Transport, replay, provenance, and local naming preserve this finite route. Since the carrier contains no coordinate for classical countable choice, arbitrary countable meets, open-cover compactness, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects belongs to the local NameCert surface. □

Theorem 7959.3 (Constructive Baire category countable-meet route)**.** *Every completion-facing or dense-open consumer of an accepted* $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ *packet that reads a countable-meet-shaped claim must factor the read through finite dense-open cylinder windows before reaching* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *The exported route is the finite chain*

$$\mathsf{BaireSpace}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

read through $S, C, D, F, M, W, R, H, K, P, N$, not a classical countable intersection theorem or a choice-selected branch.

Proof. Start with the dense-open rows of Definition 7959.2. A consumer may inspect only the finite family listed in D, and the common refinement it receives is the displayed witness F.

Next read the cylinder through the metric and stream windows. The row M bounds the observation and W fixes the finite prefix window, so the route remains a finite cylinder argument rather than a branch selected from an infinite family.

Finally pass through the $\mathsf{Real}^{\uparrow}$ seal and the structural rows. The seal R is downstream of the finite cylinder data, and H, K, P, N replay only the same finite route. Thus the countable-meet-shaped read is available only through finite dense-open cylinder obligations. □

Theorem 7959.4 (Constructive Baire category choice boundary)**.** *An accepted* $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ *packet separates finite dense-open cylinder witnesses from classical choice principles. It may export the displayed finite meet witness F and its* $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *route, but it cannot export a choice function over arbitrary dense-open sequences, a selected generic point, an arbitrary open-cover compactness principle, quotient equality of streams, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Read the carrier coordinates. The only witness coordinate is F, and F is indexed by the displayed dense-open rows in D together with the finite cylinder sources S, C.

The downstream analytic rows do not add a selector. They only bind the cylinder to metric observations, finite stream windows, and the terminal real-name seal.

The structural rows preserve the same packet. Since B has no coordinate for a choice function, selected generic point, arbitrary open-cover compactness, quotient stream equality, or ambient Real completeness, those objects cannot be recovered from the local NameCert route. □

Falsifiable prediction: Every accepted $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ read exposes BaireSpace cylinders, CantorSpace comparison cylinders, dense-open admission rows, finite meet witnesses, MetricSpace windows, StreamName finite windows, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing consumer uses the packet.

Independence witness: baire-space, cantor-space, streamname, metricspace, real: $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite dense-open cylinder obligations, finite meet witnesses, metric windows, stream windows, Real sealing, transport, replay, provenance, and local naming while refusing classical countable choice, arbitrary countable meets, open-cover compactness, quotient stream equality, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveBaireCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveBaireCategory}^{\uparrow}$ packet is generated from displayed BaireSpace cylinders, CantorSpace comparison cylinders, dense-open cylinder rows, finite meet witnesses, MetricSpace windows, StreamName finite windows, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveBaireCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7959.1, Definition 7959.2, Definition 7959.3, and Definition 7959.4 seed the finite constructive Baire-category NameCert surface over dense-open cylinder obligations.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveBaireCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim classical countable choice, arbitrary countable meets of open sets, arbitrary open-cover compactness, quotient equality of streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open cylinder admission, finite meet-witness exactness, MetricSpace window routing, StreamName finite-window exposure, Real seal preservation, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveBaireCategoryUp.

Chapter 7960

A Concrete Naming Certificate for $\mathsf{GoursatTheorem}^{\uparrow}$

Following Goursat and Ahlfors–Conway style complex analysis, the $\mathsf{GoursatTheorem}^{\uparrow}$ packet names the finite theorem-shaped route by which a holomorphic triangle contour is read as a zero-output contour-integral certificate. It consumes the contour-integral socket of chapter 583, the holomorphic input surface of chapter 68, and the complex coordinate carrier of chapter 39. The packet records only the displayed triangle contour, subdivision ledger, Riemann-sum modulus, zero-output seal, transport, replay, provenance, and local naming rows; it is not a host path integral theorem, not an open-cover compactness argument, not a primitive selector, and not a quotient equality principle.

Definition 7960.1 (Goursat theorem carrier)**.** *A* $\mathsf{GoursatTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, F, S, M, Z, H, C, P, N)$$

with the following displayed rows:

1. *T is the triangle-contour row. It records three* $\mathsf{Complex}^{\uparrow}$ *vertex histories, three oriented piecewise-linear edge rows, and the socket-facing boundary contour assembled from those edges.*
2. *F is the holomorphic input row, consumed from* $\mathsf{Holomorphic}^{\uparrow}$ *on a displayed neighbourhood of the triangle contour and its subdivision windows.*
3. *S is the finite subdivision ledger. Each entry stores a parent triangle, four child triangles, inherited orientation rows, and the internal-edge pairing visible to the contour socket.*
4. *M is the Riemann-sum modulus row. It records the unary mesh budget, local oscillation bounds for F, and the tolerance comparison attached to the leaves of S.*
5. *Z is the* $\mathsf{Complex}^{\uparrow}$ *zero-output row, displaying the target value* $0_{\mathsf{Complex}^{\uparrow}}$ *for the contour-integral socket read.*
6. *H records componentwise* hsame *transport for T, F, S, M, Z.*
7. *C records displayed* Cont *replay from the triangle contour request through the holomorphic input, subdivision ledger, Riemann-sum modulus, zero-output row, provenance, and local naming row.*
8. *P is the* Pkg *provenance over* $\mathsf{GoursatTheorem}^{\uparrow}$, $\mathsf{ContourIntegralSocket}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{GoursatTheorem}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $T, F, S, M, Z, H, C, P, N$. It has no coordinate for an ambient contour integral, selected antiderivative, host compactness proof, quotient path equality, or classical-choice schedule.

Theorem 7960.2 (Goursat theorem NameCert obligations)**.** *For every accepted* $\mathsf{GoursatTheorem}^{\uparrow}$ *carrier $G = (T, F, S, M, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GoursatTheorem}^{\uparrow}}$ *surface consists exactly of triangle-contour exposure, holomorphic-input exposure, subdivision-ledger exposure, Riemann-sum modulus exposure,* $\mathsf{Complex}^{\uparrow}$ *zero-output sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer receives no ambient contour-integral object, no selected primitive, no host compactness argument, no quotient equality of paths, and no classical-choice schedule.*

Proof. Project the carrier of Definition 7960.1. The analytic rows are exactly T, F, S, M, Z, and the structural rows are H, C, P, N.

The contour request enters through T and the contour-integral socket named in P. The holomorphic input row F supplies only the displayed local data on the triangle neighbourhood and subdivision windows.

The theorem-shaped content is carried by S, M, Z. The subdivision ledger exposes the child triangles and internal-edge pairings, the Riemann-sum modulus exposes the finite tolerance comparison on the leaves, and the zero-output row seals the socket read at $\mathsf{0}_{\mathsf{Complex}^{\uparrow}}$.

Transport, replay, provenance, and local naming preserve that finite route. Since the carrier contains no slot for the excluded ambient objects, the local NameCert surface is exhausted by the rows listed in the statement. □

Theorem 7960.3 (Goursat theorem triangle-subdivision route)**.** *Every contour-integral consumer that reads an accepted* $\mathsf{GoursatTheorem}^{\uparrow}$ *packet must factor the read through the finite route*

$$T, F \longmapsto S \longmapsto M \longmapsto Z \longmapsto H, C, P, N.$$

The internal-edge cancellations are visible only as entries of the subdivision ledger S, and the vanishing conclusion is visible only as the $\mathsf{Complex}^{\uparrow}$ *zero-output row Z. No consumer may replace this route by a host path integral theorem, a selected primitive, an open-cover compactness proof, quotient path equality, or a classical-choice schedule.*

Proof. Start with a public contour-integral read. By Definition 7960.2, the read first exposes the triangle contour row T and holomorphic input row F.

The read then enters S. Every child triangle and every internal opposite-edge pairing is a displayed ledger entry, so cancellation is inspected as finite subdivision data rather than as an ambient homology or path-quotient theorem.

The mesh and oscillation comparison is read from M. Its leafwise Riemann-sum bound is the only analytic estimate available before the conclusion is sealed.

Finally Z supplies the zero-output row, and H, C, P, N transport, replay, source, and name the same route. Because no excluded ambient object is a carrier coordinate, the displayed triangle-subdivision route is exhaustive. □

Falsifiable prediction: Every accepted $\mathsf{GoursatTheorem}^{\uparrow}$ read exposes triangle contour, holomorphic input, subdivision ledger, Riemann-sum modulus, Complex zero-output, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any contour-integral consumer may use the theorem-shaped vanishing route.

Independence witness: contourintegralsocket, holomorphic, complex, goursat: $\mathsf{GoursatTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a triangle contour, holomorphic input, subdivision ledger, Riemann-sum modulus, Complex zero-output seal, transport, replay, provenance, and local naming into one finite theorem-shaped packet.

Closure status for $\mathsf{NameCert}_{\mathsf{GoursatTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{GoursatTheorem}^{\uparrow}$ packet is generated from triangle-contour rows, Holomorphic input rows, finite subdivision ledgers, Riemann-sum modulus rows, a Complex zero-output seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GoursatTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7960.1, Definition 7960.2, and Definition 7960.3 seed the finite triangle-subdivision route for the Goursat theorem contour-integral socket read.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GoursatTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, the full Cauchy integral theorem, Morera theorem, analytic continuation, selected primitives, host contour integrals, open-cover compactness, quotient path equality, or classical choice.

Upgrade path: Obligation closure requires checked carrier admission, triangle-contour exactness, holomorphic-input locality, subdivision-ledger cancellation, Riemann-sum modulus control, Complex zero-output sealing, transport, replay, provenance, and local naming for BEDC.Derived.GoursatTheoremUp.

Chapter 7961

A Concrete Naming Certificate for $\mathsf{OscillationRank}^{\uparrow}$

Following classical oscillation-rank analyses of real-valued functions, the $\mathsf{OscillationRank}^{\uparrow}$ packet records the finite window by which a real-valued map on a displayed metric source exposes a bounded oscillation-stage comparison before any descriptive-analysis consumer reads rank data. It sits over the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, the $\mathsf{Met}^{\uparrow}$ route of chapter 57, the $\mathsf{CompactMetric}^{\uparrow}$ compact-window surface of chapter 129, the $\mathsf{ContinuousMap}^{\uparrow}$ source-map carrier of chapter 130, the Dini-window sibling of chapter 6110, and the finite rank-comparison sibling of chapter 6262. The packet names the finite inspection surface for a bounded oscillation-rank request; it is not a completed transfinite hierarchy, a quotient of functions, a selected ordinal rank for every map, or a host descriptive-set-theoretic completeness theorem.

Definition 7961.1 (OscillationRank carrier)**.** *An* $\mathsf{OscillationRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (X, K, F, M, R, D, W, S, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row naming the inspected metric carrier and its visible distance witnesses.*
2. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-window row naming the compact subwindow on which the oscillation request is inspected.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row naming the real-valued source map visible on K.*
4. *M is the finite mesh row listing the sampled source points and tolerance scale used by the request.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal through which all value and bound reads pass after X, K, F, M have been displayed.*
6. *D is the* $\mathsf{DiniDerivativeWindow}^{\uparrow}$ *or oscillation-derivative sibling row supplying the finite upper/lower comparison window used by the rank request.*
7. *W is the oscillation-threshold row recording the displayed rational bound and the two value observations compared at that bound.*
8. *S is the finite stage row naming the inspected derivative stage and its immediate predecessor window.*
9. *T is the rank-survival row saying whether the displayed oscillation set survives the named finite stage inside the visible window.*

10. *H records componentwise* hsame *transport for the metric source, compact window, continuous map, mesh, real seal, derivative window, threshold, stage, survival, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a bounded oscillation-rank request through $X, K, F, M, R, D, W, S, T$ and then through the structural rows.*
12. *P is the* Pkg *provenance over* $\mathsf{OscillationRank}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DiniDerivativeWindow}^{\uparrow}$, $\mathsf{OscillationRankFunction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationRank}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed descriptive-set-theoretic rank hierarchy, countable or dependent choice, a host supremum over all stages, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7961.2 (OscillationRank NameCert obligations)**.** *For every accepted* $\mathsf{OscillationRank}^{\uparrow}$ *carrier $O = (X, K, F, M, R, D, W, S, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{OscillationRank}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; metric-source compatibility for X; compact-window compatibility for K; continuous-map exposure through F; mesh and tolerance admission through M; terminal real sealing through R; Dini or oscillation-derivative window exposure through D; threshold exactness through W; finite-stage admission through S; rank-survival exactness through T; componentwise transport stability through H; continuation replay through C; provenance and local naming through P, N; and ledger refusal for completed rank hierarchies, choice principles, host suprema over all stages, quotient function equality, and ambient completeness.*

Proof. Project the carrier of Definition 7961.1. The accepted packet exposes exactly the rows $X, K, F, M, R, D, W, S, T, H, C, P, N$, so each local NameCert obligation must be read from one of those rows.

The source obligations are the route through X, K, F, M, R. The metric row fixes the visible source carrier, the compact row fixes the finite inspected window, the continuous-map row fixes the real-valued observations, the mesh row fixes the sampled tolerance schedule, and the real row seals every value read after those data have been displayed.

The rank-facing obligations are the route through D, W, S, T. The Dini or oscillation-derivative row supplies only the finite comparison window, the threshold row records the displayed oscillation bound, the stage row names the inspected derivative step, and the survival row records the finite yes/no comparison at that step.

Transport and replay preserve the same route. The rows H and C cannot add a completed hierarchy, a choice schedule, a host supremum, quotient function equality, or an ambient completeness principle, while P and N source and name only the listed coordinates. Hence the displayed obligations exhaust the local certificate surface. □

Theorem 7961.3 (OscillationRank finite-window handoff)**.** *Every descriptive-analysis consumer of an accepted* $\mathsf{OscillationRank}^{\uparrow}$ *carrier factors through the finite route*

$$X, K, F, M, R, D, W, S, T \longmapsto H, C, P, N.$$

Thus the consumer may inspect the metric source, compact window, continuous real-valued map, finite mesh, terminal real seal, Dini or oscillation-derivative window, oscillation threshold, displayed finite stage, and survival row, but it receives no full descriptive-set-theoretic rank completeness, no choice principle, no host supremum over all stages, no quotient function equality, and no ambient real-completion theorem.

Proof. Start with a consumer of the survival row T. Carrier admission makes T available only after the metric source X, compact window K, continuous map F, mesh M, real seal R, derivative window D, threshold row W, and finite stage row S have been displayed.

Replay the continuation row C. The request opens the source and compact-window data, reads the continuous-map observations through the real seal, consults the finite Dini or oscillation-derivative comparison window, and only then exposes the stage-survival row.

The handoff is therefore the stated finite route. Componentwise transport through H preserves the displayed rows, and P, N source and name only that packet. None of the excluded host objects can be recovered from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationRank}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7961.1, Definition 7961.2, and Definition 7961.3 seed the finite-window oscillation-rank certificate over displayed metric, compact, continuous-map, real, and Dini-window rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full descriptive-set-theoretic rank completeness, choice, host supremum over all stages, quotient function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, metric-source compatibility, compact-window compatibility, continuous-map exposure, mesh admission, real sealing, Dini-window exposure, threshold exactness, finite-stage admission, survival exactness, transport, replay, provenance, and local naming for BEDC.Derived.OscillationRankUp.

Constructive story: An $\mathsf{OscillationRank}^{\uparrow}$ packet is generated from MetricSpace, CompactMetric, ContinuousMap, RealUp, DiniDerivativeWindow, OscillationRankFunction, transport, continuation, provenance, and local NameCert rows.

Chapter 7962

A Concrete Naming Certificate for $\mathsf{MetacicResidualFuelRank}^{\uparrow}$

The $\mathsf{MetacicResidualFuelRank}^{\uparrow}$ packet realizes the residual-fuel branch of chapter 9370 as finite MetaCIC NameCert data. It sits beside the candidate-mediated boundary of chapter 5925, the normalization audit packet of chapter 750, the bounded fuel endpoint packet of chapter 5962, the residual-diamond readback packet of chapter 7893, and the residual substitution boundary of chapter 2181. The packet names the finite rank by which residual replay spends fuel before a normalization-facing or confluence-facing consumer may read an endpoint; it does not claim evidence-free strong normalization, global confluence, subject reduction, quotient syntax equality, a hidden normalizer, or MetaCIC kernel consistency.

Definition 7962.1 (MetaCIC residual fuel-rank carrier)**.** *A* $\mathsf{MetacicResidualFuelRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, K, F, Q, D, E, A, O, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the closed MetaCIC typed-term row whose residual replay is being inspected.*
2. *K is the candidate evidence row, displaying Candidate, ClosedCandidate, or CandidateSet membership before any strong-normalization read.*
3. *F is the residual fuel ledger, recording the visible fuel before and after each accepted residual step.*
4. *Q is the fuel-rank row, a finite lexicographic rank over residual depth, candidate scope, and bounded endpoint budget.*
5. *D is the residual descent row, pairing each replayed residual with a strict decrease in Q or a displayed timeout boundary.*
6. *E is the bounded endpoint row, read through* $\mathsf{BoundedNormalizationFuel}^{\uparrow}$ *and the normalization audit surface.*
7. *A is the audit-handoff row, tying T, K, F, Q, D, E to* $\mathsf{MetaCICCandidateStrongNormalization}^{\uparrow}$, $\mathsf{MetaCICNormalizationAudit}^{\uparrow}$, $\mathsf{MetacicResidualDiamondReadback}^{\uparrow}$, *and* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$.
8. *O is the obstruction row for evidence-free strong normalization, global confluence, subject reduction, quotient syntax equality, hidden normalizers, and MetaCIC kernel consistency.*

9. *G is the TasteGate-facing row requiring later Lean* Nontrivial MetacicResidualFuelRank$^{\uparrow}$ *and* FieldFaithful MetacicResidualFuelRank$^{\uparrow}$ *instances for the same carrier fields.*

10. *H records componentwise* hsame *transport for term, candidate, fuel, rank, descent, endpoint, audit-handoff, obstruction, TasteGate-facing, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay through the route*

$$T, K, F, Q, D \longmapsto E, A \longmapsto O, G.$$

12. *P is the* Pkg *provenance over* MetacicResidualFuelRank$^{\uparrow}$, MetaCICCandidateStrongNormalization$^{\uparrow}$, MetaCICNormalizationAudit$^{\uparrow}$, BoundedNormalizationFuel$^{\uparrow}$, MetacicResidualDiamondReadback$^{\uparrow}$, MetaCICResidualS BHist, hsame, Cont, Pkg, *and* NameCert.

13. *N is the local* NameCert$_{\text{MetacicResidualFuelRank}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, F, Q, D, E, A, O, G, H, C, P, N$. It has no coordinate for a global strong-normalization theorem, full Church–Rosser proof, closed subject-reduction theorem, quotient syntax equality, hidden evaluator, or MetaCIC consistency claim.

Theorem 7962.2 (MetaCIC residual fuel-rank obligations)**.** *For every accepted* MetacicResidualFuelRank$^{\uparrow}$ *carrier $R = (T, K, F, Q, D, E, A, O, G, H, C, P, N)$, the local* NameCert$_{\text{MetacicResidualFuelRank}^{\uparrow}}$ *surface consists exactly of closed typed-term admission, candidate evidence, residual fuel-ledger exposure, finite rank exposure, descent-or-timeout exposure, bounded endpoint readback, audit handoff, obstruction retention, TasteGate-facing nontriviality and field-faithfulness requirements, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7962.1. The term, candidate, fuel, rank, descent, endpoint, audit, obstruction, and TasteGate-facing rows are all visible coordinates.

The candidate row K prevents the read from becoming evidence-free strong normalization. The residual fuel ledger F and rank row Q make every replayed residual step fuel-sensitive before the endpoint row E can be read.

The descent row D either spends the displayed rank or records a timeout boundary. The audit-handoff row A then routes the endpoint read through the candidate strong-normalization, normalization audit, bounded fuel, residual readback, and residual-substitution sibling surfaces.

Rows O, G, H, C, P, N retain the refused endpoints, field-separation requirements, transport, replay, provenance, and local name. Since no carrier coordinate stores global normalization, confluence, subject reduction, quotient syntax equality, hidden evaluation, or kernel consistency, the listed rows exhaust the NameCert surface. □

Theorem 7962.3 (MetaCIC residual fuel-rank endpoint route)**.** *Every normalization-facing or confluence-facing consumer of an accepted* MetacicResidualFuelRank$^{\uparrow}$ *carrier must expose*

$$T, K, F, Q, D \longmapsto E, A \longmapsto H, C, P, N$$

before it can read an endpoint. The rank row Q is retained with the fuel ledger F, and each residual replay either decreases that rank through D or stops at the obstruction row O. The route exports a finite residual fuel-rank packet, not evidence-free strong normalization, global confluence, subject reduction, quotient syntax equality, a hidden normalizer, or MetaCIC kernel consistency.

Proof. Begin with the obligation surface of Definition 7962.2. It places the closed term T, candidate evidence K, fuel ledger F, rank row Q, and descent row D before endpoint readback.

The endpoint row E is bounded. It is consumed through the bounded-fuel sibling and the normalization audit surface named by A, so the consumer receives an audited residual route rather than an unrestricted normalizer.

If the residual replay continues, D records the strict rank decrease. If the replay cannot spend the displayed rank, the same row reaches the obstruction boundary O. In neither case can the route delete F or Q.

The structural rows H, C, P, N preserve only this displayed route. The TasteGate-facing row G records that later Lean instances must keep the fields noncollapsed before a checked carrier-alignment theorem can serve as a public realization. □

Falsifiable prediction: A purported $\mathsf{MetacicResidualFuelRank}^{\uparrow}$ consumer is refuted if it reaches a normalization endpoint while omitting the candidate row, residual fuel ledger, fuel-rank row, descent-or-timeout row, audit handoff, obstruction row, transport, replay, provenance, or local NameCert row.

Independence witness: metacic-candidate-strong-normalization, metacicnormalizationaudit, bounded-normalization-fuel, metacic-residual-diamond-readback, metacic-residual-substitution-boundary: none is bijective to $\mathsf{MetacicResidualFuelRank}^{\uparrow}$ because this packet jointly carries closed typed terms, candidate evidence, residual fuel, finite rank, descent-or-timeout data, bounded endpoint readback, audit handoff, obstruction retention, TasteGate-facing field separation, transport, replay, provenance, and local naming.

The Lean TasteGate file `lean4/BEDC/Derived/MetacicResidualFuelRankUp/TasteGate.lean` must provide explicit `Nontrivial` and `FieldFaithful` instances for $\mathsf{MetacicResidualFuelRank}^{\uparrow}$. Those instances must preserve $T, K, F, Q, D, E, A, O, G, H, C, P, N$ as distinct fields before any carrier-alignment theorem can serve as a public TasteGate realization.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicResidualFuelRank}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicResidualFuelRank}^{\uparrow}$ packet is generated from a closed MetaCIC typed-term row, candidate evidence row, residual fuel ledger, finite fuel-rank row, descent-or-timeout row, bounded endpoint row, audit handoff, obstruction row, TasteGate-facing field-separation requirements, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicResidualFuelRank}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7962.1, Definition 7962.2, and Definition 7962.3 seed the finite residual fuel-rank packet over MetaCIC candidates, fuel ledgers, descent rows, bounded endpoints, audit handoffs, obstruction, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicResidualFuelRank}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close evidence-free strong normalization, global confluence, subject reduction, quotient syntax equality, hidden normalization, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence, residual fuel-ledger exactness, rank decrease or timeout exactness, bounded endpoint readback, audit handoff, obstruction retention, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.MetacicResidualFuelRankUp.

Chapter 7963

A Concrete Naming Certificate for $\mathsf{DyadicContinuityModulus}^{\uparrow}$

Following Bishop and Bridges on moduli of continuity for constructive real functions, the $\mathsf{DyadicContinuityModulus}^{\uparrow}$ packet records a finite dyadic tolerance-to-window service for L10 continuity consumers. It sits after the dyadic tolerance ledger of chapter 291, the finite observation schedules of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the map-facing service of chapter 130. The packet names a local modulus table over displayed rows; it is not a host continuity function, a quotient-real equality principle, a selected external modulus, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 7963.1 (Dyadic continuity modulus carrier)**.** *A* $\mathsf{DyadicContinuityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, S, R, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the finite dyadic precisions requested by a continuity consumer.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row naming the finite input observations sufficient for those dyadic tolerances.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same source windows.*
4. *W is the response-window row naming the finite output observations certified for the requested tolerances.*
5. *H records componentwise* hsame *transport for E, S, R, W and the structural rows.*
6. *C records displayed* Cont *replay of the route*

$$E \longmapsto S \longmapsto R \longmapsto W.$$

7. *P is the* Pkg *provenance over* $\mathsf{DyadicContinuityModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicContinuityModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tolerance, source-window, readback, response-window, transport, replay, provenance, and naming rows. It has no coordinate for

quotient real equality, selected external moduli, host functions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7963.2 (DyadicContinuityModulus NameCert obligations)**.** *For an accepted* $\mathsf{DyadicContinuityModulus}^{\uparrow}$ *carrier* $M = (E, S, R, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicContinuityModulus}^{\uparrow}}$ *surface consists of exactly five obligations: carrier admission for the eight displayed rows; tolerance-window stability binding each* E *row to its source window* S*; regular readback compatibility binding* S *to* R*; response-window exactness binding* R *to* W *for the requested dyadic precision; and local provenance plus naming over* H, C, P, N*. These obligations export no quotient real equality, selected external modulus, host continuity function, countable-choice schedule, or ambient Real completeness.*

Proof. Carrier admission is projection from Definition 7963.1. The packet exposes exactly the tolerance, source-window, readback, response-window, transport, replay, provenance, and local naming rows.

Tolerance-window stability reads E, S, H, C. A transported dyadic tolerance request remains attached to the same finite source-window row, and the replay route prevents the request from being served by a hidden host modulus.

Regular readback compatibility reads S, R. The source window is inspected only through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ readback, so the input side of the modulus remains a finite BEDC readback route.

Response-window exactness reads R, W after the tolerance row. The output response window is certified only for the dyadic precision named in E and the readback named in R.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate supplies quotient real equality, selected external moduli, host functions, countable choice, or ambient completeness, the five obligations exhaust the local NameCert surface. □

Theorem 7963.3 (DyadicContinuityModulus unary-window induction)**.** *Let* $M = (E, S, R, W, H, C, P, N)$ *be an accepted* $\mathsf{DyadicContinuityModulus}^{\uparrow}$ *carrier. A finite chain of dyadic tolerance refinements read from* E *proceeds by unary-window induction: the base window is the displayed source window* S *with readback* R*, and each successor refinement tightens the same dyadic tolerance ledger before exposing the next response window* W*. The induction stays inside* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{ContinuousMap}^{\uparrow}$*, and the structural rows; it exports no quotient real equality, selected external modulus, host function, countable choice, or ambient Real completeness.*

Proof. For the base window, project the carrier. The source window S and readback R are already paired with the initial dyadic tolerance row E, so the first response window W is read without any external continuity function.

For the successor step, apply the tolerance-window stability and regular readback clauses of Definition 7963.2. A refined dyadic request remains attached to the transported source window and regular rational readback.

Now apply response-window exactness. The next response window is certified only after the refined tolerance and the corresponding readback have been displayed, so the refinement step is unary over the visible window row rather than a choice over an infinite family of representatives.

Induction over the finite displayed chain gives the claimed route. The structural rows H, C, P, N preserve the same finite packet at every step, and the absent coordinates exclude quotient equality, selected moduli, host functions, countable choice, and ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicContinuityModulus}^{\uparrow}}$.

Constructive story: A DyadicContinuityModulus$^{\uparrow}$ packet is generated from a dyadic tolerance row, source-window row, regular rational readback row, response-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\text{DyadicContinuityModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7963.1, Definition 7963.2, and Definition 7963.3 seed the finite dyadic tolerance-to-window route over DyadicRatCore, StreamName, RegSeqRat, Real, ContinuousMap, hsame, Cont, provenance, and local NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicContinuityModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected external moduli, host continuity functions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-window stability, regular readback compatibility, response-window exactness, provenance, and local naming for the dyadic continuity modulus packet.

Chapter 7964

A Concrete Naming Certificate for $\mathsf{RealFunctionSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the computable-analysis reading of represented real functions, the $\mathsf{RealFunctionSpace}^{\uparrow}$ packet records a finite function-space window rather than a host set of all functions. It sits over the terminal real-name seal of chapter 38, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the continuous-map carrier of chapter 130, and the pointwise comparison route of chapter 4139. The packet gives L10 Real-and-Completion consumers a named finite graph-window surface for real-valued functions before any host function extensionality, quotient function space, selected completion representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is available.

Definition 7964.1 (Real function-space carrier)**.** *A* $\mathsf{RealFunctionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, W, A, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the source-domain row naming the displayed input window on which the function-space read is inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *graph-window schedule listing the finite input and output-name windows opened by the request.*
3. *A is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row assigning the inspected graph-window data to a continuous real-valued map read through the same source window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *output readback attached to the displayed output names.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for each inspected output value.*
6. *M is the* $\mathsf{PointwiseStreamMetric}^{\uparrow}$ *comparison row, comparing two displayed function-space reads only through finite pointwise windows.*
7. *H records componentwise* hsame *transport for the source window, graph-window schedule, continuous-map row, regular readback, Real seal, pointwise metric, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite graph-window request through X, W, A, R, E, M, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RealFunctionSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{PointwiseStreamMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealFunctionSpace}^{\uparrow}}$ *row.*

Definition 7964.2 (Real function-space classifier)**.** *The classifier of an accepted* $\mathsf{RealFunctionSpace}^{\uparrow}$ *packet compares two carriers only through the displayed rows $X, W, A, R, E, M, H, C, P, N$. It requires the same source-window row, the same graph-window schedule, the same continuous-map read, the same regular-rational output readback, the same terminal real seals, and the same pointwise stream-metric comparison up to componentwise* hsame *transport and displayed* Cont *replay. It has no coordinate for host function extensionality, quotient equality of functions, a completed function space, a selected pointwise limit, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7964.3 (Real function-space NameCert obligations)**.** *For every accepted* $\mathsf{RealFunctionSpace}^{\uparrow}$ *carrier $F = (X, W, A, R, E, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealFunctionSpace}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed source window, graph-window schedule, continuous-map row, regular readback, Real seal, pointwise metric, transport, replay, provenance, and local naming rows;*
2. *graph-window exactness, requiring every inspected input/output pair to pass through X, W, A before any output value is read;*
3. *output seal nonescape, requiring R and E to remain downstream of the same displayed graph-window schedule;*
4. *pointwise comparison stability, requiring M to compare function-space reads only through finite pointwise windows and componentwise* hsame *transport;*
5. *ledger rows for displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}$ *name.*

No accepted obligation row is stored outside $X, W, A, R, E, M, H, C, P, N$.

Proof. Project the accepted carrier of Definition 7964.1. The mathematical rows are X, W, A, R, E, M, and the structural rows are H, C, P, N.

The graph-window and output-seal obligations are read in order. A consumer first sees the source window X, graph-window schedule W, and continuous-map row A; only then can it open the regular readback R and terminal real seal E.

The comparison obligation is read through M. Since M stores only finite pointwise windows, it cannot provide host function extensionality, quotient equality, a completed function space, a selected pointwise limit, countable choice, or ambient completeness.

Finally H, C, P, N transport, replay, source, and name the same displayed route. Thus the five listed obligation rows exhaust the local certificate surface. □

Theorem 7964.4 (Real function-space finite graph-window handoff)**.** *Every L10 Real-and-Completion consumer of an accepted* $\mathsf{RealFunctionSpace}^{\uparrow}$ *carrier factors through the finite route*

$$X, W, A \longmapsto R, E \longmapsto M, H, C, P, N.$$

The route exposes source-domain windows, graph-window schedules, continuous-map rows, regular rational output readback, terminal real seals, pointwise stream-metric comparisons, componentwise transport, displayed replay, provenance, and local naming before any later calculus, uniform-continuity, or completion consumer reads the function-space packet. It exports no host function extensionality, quotient function space, selected pointwise limit, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with an accepted carrier. Carrier admission and the NameCert obligations force every graph-window request through X, W, A before output values become visible.

The output values are then read through R, E. The regular-rational row supplies finite approximants attached to the same graph windows, and the terminal Real row seals only those displayed output reads.

Pointwise comparison and structural replay are downstream of the same route. The row M compares only finite pointwise windows, while H, C, P, N preserve, replay, source, and name the packet.

No carrier coordinate remains for host function equality, quotient completion, selected pointwise limits, countable choice, or ambient real completeness. Hence every L10 consumer factors through the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{RealFunctionSpace}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ output seal or $\mathsf{PointwiseStreamMetric}^{\uparrow}$ comparison without displaying $X, W, A, R, E, M, H, C, P, N$ refutes the carrier surface.

Independence witness: real, streamname, regseqrat, continuousmap, pointwise-stream-metric: no listed sibling supplies the whole packet $F = (X, W, A, R, E, M, H, C, P, N)$, because each sibling contributes only the real seal, stream window, regular readback, continuous-map, or pointwise comparison face while this chapter binds them into one finite function-space route.

Closure status for $\mathsf{NameCert}_{\mathsf{RealFunctionSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{RealFunctionSpace}^{\uparrow}$ packet is generated from a source-domain window, StreamName graph windows, a ContinuousMap row, RegSeqRat output readback, RealUp seals, PointwiseStreamMetric comparisons, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealFunctionSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7964.1, Definition 7964.2, Definition 7964.3, and Definition 7964.4 seed the finite graph-window function-space route over RealUp, StreamNameUp, RegSeqRatUp, ContinuousMapUp, and PointwiseStreamMetricUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealFunctionSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient function spaces, selected pointwise limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, graph-window exactness, output seal nonescape, pointwise comparison stability, transport, replay, provenance, and local naming for BEDC.Derived.RealFunctionSpaceUp.

Chapter 7965

A Concrete Naming Certificate for DyadicModulusChoiceFreeRefinement$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicModulusChoiceFreeRefinement$^{\uparrow}$ packet records the finite refinement route by which dyadic tolerance requests are sharpened before a regular rational sequence or Real-facing seal is read. It sits over the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the choice-free selector boundary of chapter 695. The packet gives L10 Real and Completion consumers a visible dyadic-modulus refinement surface without quotient reals, selected host limits, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 7965.1 (Dyadic modulus choice-free refinement carrier)**.** *A* DyadicModulusChoiceFreeRefinement$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, Q, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger naming the requested dyadic scale and the refined scale consumed downstream;*
2. *Q is the finite refinement certificate proving that the downstream tolerance is no coarser than the requested dyadic bound;*
3. *W is the finite window schedule that determines which observations are inspected at the refined scale;*
4. *S is the* StreamName$^{\uparrow}$ *observation family opened by W;*
5. *R is the* RegSeqRat$^{\uparrow}$ *witness row assembled from the finite observations and the refined dyadic tolerance;*
6. *E is the* Real$^{\uparrow}$ *seal boundary available only after the regular rational witness row has been displayed;*
7. *H records componentwise* hsame *transport for dyadic, window, stream, regular, Real-seal, replay, provenance, and local naming rows;*
8. *C records displayed* Cont *replay for the same route;*
9. *P is the* Pkg *provenance over* DyadicModulusChoiceFreeRefinement$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, ChoiceFreeDiagonalSelector$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $D, Q, W, S, R, E, H, C, P, N$. It has no coordinate for a hidden selector, quotient real, selected limit, countable-choice schedule, or ambient real-completeness principle.

Lean4 (definition) `BEDC.Derived.DyadicModulusChoiceFreeRefinementUp.DyadicModulusChoiceFreeRefinementUp`

Theorem 7965.2 (Dyadic modulus choice-free refinement obligations)**.** *For the carrier of Definition 7965.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row D, refinement certificate Q, finite window schedule W, StreamName observations S, RegSeqRat witness R, RealUp seal E, componentwise transport H, displayed replay C, provenance P, and local naming row N.*

Proof. Project the displayed carrier. The analytic content rows are D, Q, W, S, R, E, and they occur in the order needed by a Real-facing modulus consumer.

The dyadic row D and refinement row Q determine the tolerated scale before any observation is opened. The finite window W then bounds the StreamName reads S, and the RegSeqRat witness R is assembled only from those displayed rows before the RealUp seal E is available.

The structural rows H, C, P, N preserve and name the same route. Since the carrier contains no coordinate for hidden choice, quotient equality, selected limits, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 7965.3 (Dyadic modulus choice-free refinement stage induction)**.** *Let $M = (D, Q, W, S, R, E, H, C, P, N$ be an accepted* $\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}$ *carrier whose window schedule is displayed as finite stages W_j. Induction over the stages preserves the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and keeps every successor refinement inside the displayed dyadic tolerance, observation, regular-witness, and Real-seal rows. No stage may introduce a quotient real, selected host limit, hidden cofinal selector, countable-choice schedule, unbounded observation scan, or ambient completeness claim for $\mathsf{Real}^{\uparrow}$*.*

Proof. For the base stage, inspect the first displayed window row. Its dyadic scale is admitted by D, Q, its finite observations are exactly the corresponding part of S, and the partial regular witness is read through the same RegSeqRat route.

For the successor stage, assume the displayed route has been preserved through W_j. The next finite window refines the dyadic tolerance by the same certificate row Q, opens only the next displayed StreamName observations, and repacks the enlarged finite readback into the RegSeqRat witness row before any RealUp seal is read.

The transport, replay, provenance, and local naming rows are restrictions of H, C, P, N to the same finite route. Thus the induction invariant is the displayed path from dyadic tolerance to StreamName observations, then to RegSeqRat witness and RealUp seal, with no carrier coordinate for the refused endpoints. □

Falsifiable prediction: Every accepted $\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}$ read is refuted if it reaches a RegSeqRat or RealUp consumer without first displaying the dyadic tolerance row, refinement certificate, finite window schedule, StreamName observations, transport, replay, provenance, and local NameCert rows.

Independence witness: dyadicratcore, streamname, regseqrat, real, choicefreediagonalselector: no listed sibling is bijective to $\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}$ because this packet jointly carries dyadic refinement, finite observation scheduling, regular rational handoff, Real seal, choice-free selector provenance, transport, replay, and local naming as one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}$ packet is generated from a dyadic tolerance ledger, refinement certificate, finite window schedule, StreamName observations, RegSeqRat witness, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7965.1, Definition 7965.2, and Definition 7965.3 seed the choice-free dyadic modulus refinement route over DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicModulusChoiceFreeRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient real equality, selected host limits, countable choice, unbounded observation scans, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a public standard bridge.

Upgrade path: Formal closure requires checked carrier admission, dyadic refinement exactness, finite-window pullback, StreamName readback, RegSeqRat witness assembly, RealUp seal delivery, replay stability, and nonescape for the same finite packet.

Chapter 7966

A Concrete Naming Certificate for MetaCICResidualConfluenceFuel$^{\uparrow}$

The MetaCICResidualConfluenceFuel$^{\uparrow}$ packet realizes the residual-fuel inspection boundary named by the MetaCIC confluence audit map in chapter 9378. It sits beside the parallel-diamond frontier of chapter 4238, the critical-path packet of chapter 765, the normalization frontier of chapter 892, the residual-substitution boundary of chapter 2181, and the confluence audit packet of chapter 735. The carrier records bounded critical-pair and residual-substitution inspection data without claiming arbitrary closed Church–Rosser, subject reduction, quotient equality of terms, evaluator equality, or kernel consistency.

Definition 7966.1 (MetaCIC residual confluence fuel carrier)**.** *A* MetaCICResidualConfluenceFuel$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, K, R, J, B, S, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row naming the closed source and the bounded syntax fragment under inspection;*
2. *K is the critical-pair row naming the local peak or overlap to be checked;*
3. *R is the residual-substitution boundary row retained from the conditional confluence interface;*
4. *J is the candidate local-join row, available only under the displayed residual boundary;*
5. *B is the finite fuel budget for residual, substitution, and critical-pair inspection;*
6. *S is the closed checker or normal-fragment sibling row consumed by the bounded inspection;*
7. *O is the obstruction row retaining refused endpoints when the residual boundary is not discharged;*
8. *H records componentwise* hsame *transport for typed-window, critical-pair, residual, join, budget, checker, obstruction, replay, provenance, and local naming rows;*
9. *C records displayed* Cont *replay through the same rows;*
10. *P is the* Pkg *provenance over* MetaCICResidualConfluenceFuel$^{\uparrow}$*, the five cited MetaCIC sibling packets,* BHist*,* hsame*,* Cont*, and* NameCert*;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $T, K, R, J, B, S, O, H, C, P, N$. It does not identify a bounded inspection with a full parallel diamond, closed Church–Rosser theorem, subject-reduction theorem, evaluator equality, quotient equality, or kernel-consistency claim.

Theorem 7966.2 (MetaCIC residual fuel critical-pair boundary)**.** *Every accepted* $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ *carrier exposes the critical-pair row K, residual-substitution boundary R, candidate local-join row J, and finite fuel row B before any confluence-facing consumer may read the checker row S or obstruction row O. The inspection is therefore bounded by*

$$T, K, R, J, B, S, O, H, C, P, N$$

rather than by an ambient closed Church–Rosser endpoint.

Proof. Project the carrier of Definition 7966.1. The typed source, local peak, residual boundary, candidate join, and fuel budget are the only rows that can authorize a bounded residual inspection.

The checker row S is downstream of those rows. It can certify a bounded inspection result for the displayed source and fuel, but it cannot erase the residual-substitution boundary R or the obstruction row O.

Transport through H, replay through C, provenance through P, and local naming through N preserve that finite boundary. Hence a confluence-facing consumer receives a fuel-bounded inspection surface, not a premise-free Church–Rosser theorem. □

Theorem 7966.3 (MetaCIC residual fuel non-escape)**.** *An accepted* $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ *packet cannot export arbitrary closed Church–Rosser, full parallel diamond, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency. Any such read must first supply a separate discharge for the residual-substitution boundary and the typed critical-pair frontier named by R and K.*

Proof. Use the critical-pair boundary theorem. It forces every confluence-facing read through the typed window, critical-pair row, residual-substitution row, candidate join, finite fuel, checker row, and obstruction row before structural replay is available.

The refused endpoints require data that are not stored in the carrier. A full parallel diamond needs a discharged residual-substitution compatibility input; subject reduction needs its own typing-preservation surface; evaluator equality, quotient equality, and kernel consistency require separate public commitments.

Since H, C, P, N only transport, replay, source, and name the same finite inspection packet, none of those stronger endpoints can be recovered from $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ alone. □

The Lean TasteGate follow-up path for $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ must include explicit $\mathsf{Nontrivial}\ \mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ instances. These instances must distinguish the typed window, critical-pair, residual-substitution boundary, candidate join, fuel budget, checker, obstruction, transport, replay, provenance, and local NameCert rows.

Falsifiable prediction: If the residual-substitution boundary or critical-pair row is absent, a bounded MetaCIC residual-fuel inspection cannot be cited as a confluence endpoint.

Independence witness: metacic-parallel-diamond-frontier, metaciccriticalpath, metacicnormalizationfrontier, metacic-residual-substitution-boundary, metacicconfluenceauditpacket: none is bijective because $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ jointly carries typed-window, critical-pair, residual-boundary, local-join, finite-fuel, checker, obstruction, transport, replay, provenance, and local NameCert rows as one bounded inspection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}$ packet is generated from a typed-window row, critical-pair row, residual-substitution boundary, candidate local-join row, finite fuel budget, closed checker row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7966.1, Definition 7966.2, and Definition 7966.3 seed the bounded critical-pair and residual-substitution inspection surface for the MetaCIC confluence boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceFuel}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary closed Church–Rosser, full parallel diamond, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, Lean verification, or a public standard bridge.

Upgrade path: Formal closure requires checked carrier admission, critical-pair exactness, residual-boundary retention, local-join fuel accounting, checker replay, obstruction preservation, TasteGate nontriviality, and field faithfulness.

Chapter 7967

A Concrete Naming Certificate for $\mathsf{RegSeqRatFunctorialMap}^{\uparrow}$

Following Bishop and Bridges' constructive treatment of regular Cauchy sequences and uniformly continuous maps, the $\mathsf{RegSeqRatFunctorialMap}^{\uparrow}$ packet records the finite route by which a modulus-controlled map acts on regular Cauchy rational names before any Real-facing consumer reads the transported name. It sits over the dyadic tolerance ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the continuous-map carrier of chapter 130. The packet names a finite functorial action surface; it does not quotient regular names, select limits, assert ambient completeness, or export a host function-space equality theorem.

Definition 7967.1 (RegSeqRat functorial-map carrier)**.** *A* $\mathsf{RegSeqRatFunctorialMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, S, Q, D, R, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *modulus-controlled map row, including the displayed input tolerance and output tolerance schedule.*
2. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *finite-window row whose observations feed the map.*
3. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational name row read through S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger recording the dyadic input and output budgets used by M.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after M, S, Q, D have been displayed.*
6. *W is the transported finite-window row listing the output observations certified by the modulus schedule.*
7. *H records componentwise* hsame *transport for the map, source windows, source regular name, dyadic ledger, terminal seal, transported windows, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a regular Cauchy rational-name read through the modulus-controlled map and the transported output windows.*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRatFunctorialMap}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatFunctorialMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, S, Q, D, R, W, H, C, P, N$. It has no coordinate for quotient-stream equality, a selected representative, countable choice over moduli, host real equality, function extensionality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7967.2 (RegSeqRat functorial-map NameCert obligations)**.** *For every accepted* $\mathsf{RegSeqRatFunctorialMap}$ *carrier $F = (M, S, Q, D, R, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegSeqRatFunctorialMap}^{\uparrow}}$ *surface consists exactly of modulus-controlled map exposure, source* $\mathsf{StreamName}^{\uparrow}$ *finite-window scheduling, source* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, transported output-window admission, componentwise transport, displayed continuation replay, package provenance, local naming, and ledger refusal for quotient streams, selected limits, countable choice over moduli, host real equality, function extensionality, and ambient completeness.*

Proof. Project the carrier of Definition 7967.1. The accepted packet displays exactly the map row M, the source window row S, the source regular-rational row Q, the dyadic ledger D, the terminal seal R, and the transported output windows W.

The structural rows H, C, P, N transport, replay, source, and name only those displayed rows. Thus every local certificate obligation is read through $M, S, Q, D, R, W, H, C, P, N$.

The refusal clauses are coordinate exclusions. Quotient streams, selected representatives, countable choice over moduli, host real equality, function extensionality, and ambient completeness are not rows of F, so the local NameCert cannot export them. □

Theorem 7967.3 (RegSeqRat functorial-map regularity preservation)**.** *Every Real-facing consumer of an accepted* $\mathsf{RegSeqRatFunctorialMap}^{\uparrow}$ *carrier receives the transported regular Cauchy rational name only through the finite route*

$$M, S, Q, D, W \longmapsto R, H, C, P, N.$$

In particular, the output windows preserve the displayed regularity budget supplied by the $\mathsf{ContinuousMap}^{\uparrow}$ *modulus and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger before the terminal* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Proof. Start with the output-window row W. By the carrier definition, W is admitted only after the modulus-controlled map M, the source windows S, the source regular-rational row Q, and the dyadic tolerance ledger D have been displayed.

Read the continuation row C. It replays a regular Cauchy rational-name request through the same modulus schedule and dyadic budgets before the terminal seal R is exposed.

Componentwise transport through H preserves the displayed rows, and P, N source and name only that packet. Hence the consumer obtains regularity preservation along the stated finite route, without quotienting names, selecting a limit, invoking choice over moduli, or importing ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegSeqRatFunctorialMap}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegSeqRatFunctorialMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7967.1, Definition 7967.2, and Definition 7967.3 seed the finite functorial-map route from modulus-controlled maps on regular Cauchy rational names to Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegSeqRatFunctorialMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice over moduli, host real equality, function extensionality, ambient RealUp completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus-controlled map exposure, source window scheduling, RegSeqRat readback, DyadicRatCore tolerance accounting, transported output-window admission, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegSeqRatFunctorialMapUp.

Constructive story: A RegSeqRatFunctorialMap$^{\uparrow}$ packet is generated from a ContinuousMap modulus row, StreamName source windows, RegSeqRat regular rational readback, DyadicRatCore tolerance accounting, transported output windows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7968

A Concrete Naming Certificate for $\mathsf{SchottkyGroup}^{\uparrow}$

Following Klein's and Poincare's Schottky-group construction in the disk model, the $\mathsf{SchottkyGroup}^{\uparrow}$ packet records the finite ping-pong data by which paired boundary domains generate a free hyperbolic action. It realizes the hyperbolic observer-expansion route of chapter 9463 through the disk automorphism surface of chapter 6776, the metric readback of chapter 3474, the limit-set boundary row of chapter 7764, and the Fuchsian-action packet of chapter 7282. The packet names finite generator, inverse-pair, boundary-domain, and shadow rows; it does not import a host Kleinian group, quotient surface, selected fundamental domain, classical compactness theorem, or ambient boundary completion.

Definition 7968.1 (Schottky group carrier)**.** *A* $\mathsf{SchottkyGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, A, D, M, L, F, B, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite generator row, listing paired generator names and their inverse partners.*
2. *A is the* $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$ *row for the displayed disk automorphisms and inverse replays.*
3. *D is the boundary-domain row, listing the disjoint source and target arcs used by the ping-pong read.*
4. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row comparing the displayed disk and boundary windows used by the generator action.*
5. *L is the* $\mathsf{HyperbolicLimitSet}^{\uparrow}$ *row naming the finite boundary-shadow observations that later limit-set consumers may inspect.*
6. *F is the* $\mathsf{FuchsianGroupAction}^{\uparrow}$ *row, recording the word-action replay over the same automorphism and boundary-domain data.*
7. *B is the boundary-shadow ledger that records which paired domain is sent outside its complement by each displayed generator.*
8. *H records componentwise* hsame *transport for the generators, automorphisms, domains, metric row, limit-set row, action row, boundary-shadow ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite word or boundary-domain request through G, A, D, M, L, F, B, H.*
10. *P is the* Pkg *provenance over* $\mathsf{SchottkyGroup}^{\uparrow}$, $\mathsf{PoincareDiskAutomorphism}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicLimitSet}^{\uparrow}$, $\mathsf{FuchsianGroupAction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchottkyGroup}^{\uparrow}}$ *row.*

Definition 7968.2 (Schottky ping-pong classifier)**.** *The classifier of an accepted* $\mathsf{SchottkyGroup}^{\uparrow}$ *packet compares two carriers only through $G, A, D, M, L, F, B, H, C, P, N$. It requires the same displayed generator pairing, the same disk-automorphism row, the same paired boundary domains, the same hyperbolic-metric comparison surface, the same limit-set observation row, the same Fuchsian word-action replay, and the same boundary-shadow ledger up to componentwise* hsame *transport and displayed* Cont *replay. It has no coordinate for a host Kleinian group, quotient surface, selected fundamental domain, hidden boundary compactification, countable choice, or ambient hyperbolic completion.*

Theorem 7968.3 (Schottky group NameCert obligations)**.** *For every accepted* $\mathsf{SchottkyGroup}^{\uparrow}$ *carrier $S = (G, A, D, M, L, F, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SchottkyGroup}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; generator-pair admission for G; disk-automorphism and inverse replay through A; boundary-domain disjointness and ping-pong target exposure through D, B; hyperbolic metric compatibility through M; limit-set observation through L; Fuchsian word-action replay through F; componentwise transport through H; displayed replay through C; and provenance and local naming through P, N.*

Proof. Project the accepted carrier. The generator and automorphism rows are G, A, the boundary and metric rows are D, M, B, the downstream hyperbolic rows are L, F, and the structural rows are H, C, P, N.

The ping-pong obligation is read through D, B. The row D displays the paired source and target boundary domains, while B records the finite shadow relation saying how each generator moves the complement of one domain into its paired target domain.

The metric, limit-set, and action obligations are then read through M, L, F. These rows keep hyperbolic distance comparisons, boundary accumulation observations, and word-action replay attached to the same finite automorphism data.

Finally H, C, P, N transport, replay, source, and name the packet. Since the carrier has no coordinate for a host Kleinian group, quotient surface, selected fundamental domain, hidden compactification, choice principle, or ambient completion, the listed rows exhaust the local certificate surface. □

Theorem 7968.4 (Schottky ping-pong boundary-domain route)**.** *Every hyperbolic boundary or Fuchsian-action consumer of an accepted* $\mathsf{SchottkyGroup}^{\uparrow}$ *carrier factors through the finite route*

$$G, A, D, B \longmapsto M \longmapsto L, F \longmapsto H, C, P, N.$$

Thus the consumer reads paired generators, Poincare disk automorphisms, boundary domains, ping-pong shadow rows, hyperbolic metric comparisons, limit-set observations, Fuchsian word-action replay, transport, displayed replay, provenance, and local naming before it treats the packet as a Schottky group. The route exports no host Kleinian group, quotient Riemann surface, selected fundamental domain, open-cover compactness, countable choice, or ambient boundary completion.

Proof. Start with the NameCert obligations. They place G, A, D, B before any metric, limit-set, or action consumer can read the group packet.

The metric row M is downstream of those ping-pong rows. It compares only the displayed disk and boundary windows attached to the automorphism data, so a consumer cannot replace the route by a host-level hyperbolic action.

The limit-set and Fuchsian-action rows L, F are then read from the same finite route. The limit-set observations are boundary-shadow rows, and the action replay is a displayed word-action ledger over the accepted automorphism pairs.

Structural transport and replay through H, C, P, N preserve the same packet. Because no excluded host object occurs among the carrier coordinates, every consumer factors through the displayed boundary-domain route. □

Falsifiable prediction: An accepted $\mathsf{SchottkyGroup}^{\uparrow}$ consumer that reaches a $\mathsf{HyperbolicLimitSet}^{\uparrow}$ or $\mathsf{FuchsianGroupAction}^{\uparrow}$ read without displaying $G, A, D, M, L, F, B, H, C, P, N$ refutes the carrier surface.

Independence witness: poincare-disk-automorphism, hyperbolic-metric, hyperbolic-limit-set, fuchsian-group-action: no listed sibling supplies the whole Schottky packet because each contributes only disk automorphisms, metric comparisons, boundary accumulation, or action replay while this chapter binds the finite ping-pong boundary-domain route in one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SchottkyGroup}^{\uparrow}}$.

Constructive story: A $\mathsf{SchottkyGroup}^{\uparrow}$ packet is generated from paired generator rows, PoincareDiskAutomorphism rows, paired boundary domains, HyperbolicMetric comparisons, HyperbolicLimitSet boundary observations, FuchsianGroupAction word replay, boundary-shadow ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchottkyGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7968.1, Definition 7968.2, Definition 7968.3, and Definition 7968.4 seed the finite Schottky ping-pong route over PoincareDiskAutomorphismUp, HyperbolicMetricUp, HyperbolicLimitSetUp, and FuchsianGroupActionUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchottkyGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Kleinian groups, quotient Riemann surfaces, selected fundamental domains, open-cover compactness, countable choice, ambient boundary completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, generator-pair admission, disk-automorphism replay, boundary-domain ping-pong exactness, metric compatibility, limit-set observation, Fuchsian action replay, transport, replay, provenance, and local naming for BEDC.Derived.SchottkyGroupUp.

Chapter 7969

A Concrete Naming Certificate for $\mathsf{BromwichInversionWindow}^{\uparrow}$

Following Bromwich and Doetsch on inverse Laplace transforms, the $\mathsf{BromwichInversionWindow}^{\uparrow}$ packet records only the finite vertical-line window data that BEDC consumers may inspect before any inversion theorem is available. It sits after the transform packet of chapter 3649, the contour socket of chapter 583, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names a finite abscissa, height window, rational quadrature readback, contour-socket handoff, Real output seal, transport, replay, provenance, and local NameCert row; it does not assert a host Bromwich inversion theorem, analytic continuation of a transform, selected improper integrals, quotient path equality, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 7969.1 (Bromwich inversion window carrier)**.** *A* $\mathsf{BromwichInversionWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (L, A, W, Q, S, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LaplaceTransform}^{\uparrow}$ *input row whose transform data are being read.*
2. *A is the abscissa row naming the finite vertical line* $\mathrm{Re}(s) = a$ *inspected by the window.*
3. *W is the height-window row naming the finite interval* $[-T, T]$ *on that vertical line.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite quadrature samples attached to W.*
5. *S is the* $\mathsf{ContourIntegralSocket}^{\uparrow}$ *row that supplies the contour-window socket used by the read.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the windowed inversion value returned to Real-facing consumers.*
7. *H records componentwise* hsame *transport for L, A, W, Q, S, R and the structural rows.*
8. *C records displayed* Cont *replay of the route*

$$L \longmapsto A \longmapsto W \longmapsto Q \longmapsto S \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{BromwichInversionWindow}^{\uparrow}$, $\mathsf{LaplaceTransform}^{\uparrow}$, $\mathsf{ContourIntegralSocket}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BromwichInversionWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed transform, vertical-line, height-window, rational readback, contour socket, Real seal, transport, replay, provenance, and naming rows. It has no coordinate for a host inversion theorem, ambient complex analytic continuation, quotient contour equality, selected improper integral, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7969.2 (BromwichInversionWindow NameCert obligations)**.** *For an accepted* $\mathsf{BromwichInversionWindow}$ *carrier* $B = (L, A, W, Q, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BromwichInversionWindow}^{\uparrow}}$ *surface consists exactly of six finite obligations: carrier admission for the ten displayed rows; transform-source compatibility binding* L *to the same window; vertical-line stability binding* A *and* W *under componentwise transport; regular readback exactness for the quadrature row* Q*; contour-socket handoff through* S*; and local provenance plus naming over* H, C, P, N*. These obligations export no host Bromwich inversion theorem, analytic-continuation theorem, selected improper integral, quotient contour equality, countable-choice schedule, or ambient Real completeness.*

Proof. Carrier admission is projection from Definition 7969.1. The packet exposes exactly the transform row, abscissa row, height window, regular rational readback, contour socket, Real seal, transport, replay, provenance, and local naming rows.

Transform-source compatibility reads L, A, W. The window may inspect only the finite transform data attached to the displayed abscissa and height rows, so it cannot call an external inverse-transform operator.

Vertical-line stability reads A, W, H, C. A transported abscissa row and height row remain the same finite vertical-line window through the displayed replay route.

Regular readback exactness reads Q after W. The finite samples attached to the height window are returned only through the displayed $\mathsf{RegSeqRat}^{\uparrow}$ row, not through a selected improper integral.

The contour-socket handoff reads S and then the Real seal R. The socket row supplies the contour-window boundary, and the terminal seal is the only Real-facing output coordinate.

Finally, H, C, P, N transport, replay, source, and name the same finite packet. Since no carrier coordinate supplies a host inversion theorem, analytic continuation, quotient contour equality, selected improper integral, countable choice, or ambient completeness, the six obligations exhaust the local NameCert surface. □

Theorem 7969.3 (BromwichInversionWindow Real seal non-escape)**.** *Every Real-facing consumer of an accepted* $\mathsf{BromwichInversionWindow}^{\uparrow}$ *packet must read the displayed route*

$$\mathsf{LaplaceTransform}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{ContourIntegralSocket}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

through the finite rows L, Q, S, R *before any windowed inversion value is public. The packet returns only the terminal* $\mathsf{Real}^{\uparrow}$ *seal* R *for the displayed finite window; it does not certify a host Bromwich inversion theorem, analytic continuation of the transform, a selected improper integral, quotient contour equality, countable choice, or ambient completeness for* $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier. The only Real-facing coordinate is R, and it is listed after the transform row L, the height-window readback row Q, and the contour socket row S.

Apply the obligation surface from Definition 7969.2. Transform-source compatibility, regular readback exactness, and contour-socket handoff force a consumer to expose L, Q, S before R can be read.

The absence clauses in the carrier then give non-escape. There is no coordinate for an inverse-transform theorem, analytic-continuation theorem, selected improper integral, quotient contour equality, countable-choice schedule, or ambient Real completeness, so no such object can be returned as part of the window seal. □

Closure status for $\mathsf{NameCert}_{\mathsf{BromwichInversionWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{BromwichInversionWindow}^{\uparrow}$ packet is generated from a Laplace-transform row, a vertical-line abscissa row, a finite height window, a RegSeqRat quadrature readback row, a ContourIntegralSocket row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BromwichInversionWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7969.1, Definition 7969.2, and Definition 7969.3 seed the finite vertical-line inversion window over LaplaceTransform, ContourIntegralSocket, RegSeqRat, Real, hsame, Cont, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BromwichInversionWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Bromwich inversion theorem, analytic continuation of a transform, selected improper integrals, quotient contour equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transform-source compatibility, vertical-line stability, regular readback exactness, contour-socket handoff, Real seal non-escape, provenance, and local naming for the Bromwich inversion window packet.

Chapter 7970

A Concrete Naming Certificate for $\mathsf{AbelPlana}^{\uparrow}$

Following Abel and Plana's summation formula, the $\mathsf{AbelPlana}^{\uparrow}$ packet records a finite boundary between a discrete sum window, an integral-window readback, and the vertical correction terms needed by constructive analytic consumers. It is grounded beside the Euler–Maclaurin boundary of chapter 2059, the Fourier boundary of chapter 3951, the summation-by-parts surface of chapter 1763, the dyadic tolerance rows of chapter 291, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The certificate names only the finite BEDC route by which a boundary correction is inspected before a $\mathsf{Real}^{\uparrow}$ read; it does not assert a meromorphic continuation theorem, a contour integral value, a selected infinite sum, countable choice, trichotomy, host complex equality, or ambient completeness.

Definition 7970.1 (Abel-Plana carrier)**.** *An* $\mathsf{AbelPlana}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, I, V, B, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite discrete summand-window row, recording the inspected values, endpoint indices, and partial-sum cells.*
2. *I is the finite integral-window row, recording the interval cells and rational enclosure data used by the continuous side of the comparison.*
3. *V is the vertical-boundary row, storing the two inspected correction corridors and their displayed orientation data.*
4. *B is the boundary-kernel row, recording the denominator and sign windows used to read the Abel-Plana correction without selecting an ambient contour value.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that budgets the summand, integral, and boundary-kernel inspections.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed tolerance and boundary data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the discrete, integral, vertical-boundary, dyadic, and regular-rational rows have been read.*
8. *H records componentwise* hsame *transport for all displayed data and the structural rows.*

9. *C records displayed* Cont *replay from a consumer request through S, I, V, B, D, R, E and then to the provenance and naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{AbelPlana}^{\uparrow}$, $\mathsf{EulerMaclaurin}^{\uparrow}$, $\mathsf{PoissonSummation}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelPlana}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for a host contour integral, a meromorphic continuation principle, an infinite choice of residues, a selected completed sum, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7970.2 (Abel-Plana NameCert obligations)**.** *For every accepted* $\mathsf{AbelPlana}^{\uparrow}$ *carrier $A = (S, I, V, B, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelPlana}^{\uparrow}}$ *surface consists exactly of carrier admission, discrete summand-window exposure, integral-window exposure, vertical-boundary exposure, boundary-kernel compatibility, dyadic tolerance budgeting, regular rational readback, Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The rows S, I, V, B expose the finite discrete, integral, vertical-boundary, and boundary-kernel data that make the Abel-Plana comparison readable.

Read the tolerance and readback layer next. The dyadic row D budgets the three analytic faces, and the regular rational row R supplies the only completion-facing readback available before the seal.

Finally use the structural rows. The seal row E is downstream of S, I, V, B, D, R, while H, C, P, N only transport, replay, source, and name the same displayed route. Since no row carries a host contour value, continuation theorem, selected residue family, completed sum, quotient equality, or ambient completeness principle, the listed obligations exhaust the local certificate. □

Theorem 7970.3 (Abel-Plana Real-seal nonescape)**.** *For every accepted* $\mathsf{AbelPlana}^{\uparrow}$ *carrier $A = (S, I, V, B, D, R, E, H, C, P, N)$, any* $\mathsf{Real}^{\uparrow}$ *seal-facing read of E factors through the finite route*

$$S, I, V, B, D \longmapsto R \longmapsto E, H, C, P, N.$$

Thus the packet exports the displayed summation-boundary correction only after the discrete window, integral window, vertical-boundary corridor, boundary kernel, dyadic tolerance row, and regular rational readback have been inspected.

Proof. Start from the NameCert obligations of Definition 7970.2. They force every accepted read to expose the discrete summand row, integral row, vertical-boundary row, boundary-kernel row, dyadic tolerance row, and regular rational readback before the seal row can be consumed.

The rows H, C, P, N preserve that route componentwise. They do not add an alternate analytic coordinate, so a seal-facing consumer receives the same displayed packet and no detached contour object.

The carrier omits meromorphic continuation, selected residues, countable choice, trichotomy, host equality, completed infinite sums, and ambient $\mathsf{Real}^{\uparrow}$ completeness. Therefore the displayed route is the whole Real-seal boundary. □

Falsifiable prediction: An accepted $\mathsf{AbelPlana}^{\uparrow}$ packet that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the discrete summand window, integral window, vertical-boundary corridor, boundary kernel, dyadic tolerance row, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: EulerMaclaurin, PoissonSummation, AbelSummation, DyadicRatCore, RegSeqRat, Real: no listed sibling supplies the full eleven-row packet $A = (S, I, V, B, D, R, E, H, C, P, N)$, because each sibling contributes only a summation boundary, Fourier boundary, summation-by-parts route, dyadic tolerance layer, regular readback, or seal face while this chapter binds all six faces into one Abel-Plana boundary certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelPlana}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelPlana}^{\uparrow}$ packet is generated from finite discrete summand windows, integral-window data, vertical-boundary corridors, boundary-kernel rows, DyadicRatCoreUp tolerance budgets, RegSeqRatUp readbacks, a RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelPlana}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7970.1, Definition 7970.2, and Definition 7970.3 seed the finite Abel-Plana summation-boundary route over $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelPlana}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim meromorphic continuation, contour integral values, selected residues, selected sums, countable choice, trichotomy, host equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the eleven-row carrier and prove the finite NameCert obligation surface and Real-seal nonescape theorem.

Chapter 7971

A Concrete Naming Certificate for $\mathsf{GreenTheorem}^{\uparrow}$

Following Green's theorem as the plane Stokes specialization, and the Cartan–de Rham reading of boundary integration, the $\mathsf{GreenTheorem}^{\uparrow}$ packet records the finite BEDC route by which an oriented planar region, its boundary curve, a differential-form row, a scalar curl or divergence row, and a Riemann integral handoff are read as one plane-boundary certificate. It consumes the Stokes theorem packet of chapter 5720, the differential-form surface of chapter 136, and the tagged integration boundary of chapter 1526. The packet names only this finite plane route; it does not provide a host vector-calculus theorem, selected parametrizations, a measure-completion carrier, quotient equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7971.1 (Green theorem carrier)**.** *A* $\mathsf{GreenTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (R, B, F, S, T, I, H, C, P, N)$$

whose rows have the following BEDC-facing meaning.

- *R is the plane-region row, including the displayed chart window, orientation, and finite boundary incidence data.*
- *B is the oriented boundary row for the same region, read as the plane curve boundary consumed by the Stokes packet.*
- *F is the vector-field or differential-form row, routed through* $\mathsf{DiffForm}^{\uparrow}$ *and carrying the two scalar component reads needed for the planar expression.*
- *S is the scalar curl or divergence row obtained from the same displayed form data, with no separate host vector-field equality.*
- *T is the* $\mathsf{StokesTheorem}^{\uparrow}$ *specialization row that reads the planar boundary as the two-dimensional Stokes boundary route.*
- *I is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *handoff for the displayed line and region integral reads over the same rows R, B, F, S, T.*
- *H records componentwise* hsame *transport for the region, boundary, form, scalar, Stokes, and integration rows.*
- *C records displayed* Cont *replay from the plane-region source through the boundary and differential-form rows to the integration handoff.*

- *P is the* Pkg *provenance over* $\mathsf{GreenTheorem}^{\uparrow}$, $\mathsf{StokesTheorem}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows.*
- *N is the local* $\mathsf{NameCert}_{\mathsf{GreenTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host smooth-domain theorem, a chosen boundary parametrization, measure completion, quotient equality of vector fields, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7971.2 (Green theorem NameCert obligations)**.** *For every accepted* $\mathsf{GreenTheorem}^{\uparrow}$ *carrier $G = (R, B, F, S, T, I, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GreenTheorem}^{\uparrow}}$ *surface is exhausted by carrier admission for the plane region, oriented boundary, differential-form or vector-field row, scalar curl or divergence row, Stokes specialization, Riemann integral handoff, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. The obligations are discharged only over the finite route*

$$R, B, F, S, T, I, H, C, P, N.$$

The certificate exports no selected parametrization, host Green theorem, measure-space integral, quotient function equality, or ambient real-completeness principle.

Proof. Project the carrier of Definition 7971.1. The analytic rows are exactly the plane-region row R, boundary row B, differential-form or vector-field row F, scalar curl or divergence row S, Stokes specialization row T, and Riemann handoff row I.

The boundary compatibility is local. The row B is read over the same oriented plane region R, while T routes that boundary through the Stokes packet of chapter 5720. The scalar row S is read from the displayed form data F, so the packet does not compare hidden host vector fields.

Finally attach H, C, P, N. These structural rows transport, replay, source, and name the same finite route. Since none of the carrier coordinates contains a selected parametrization, host theorem, measure-completion carrier, quotient equality, or ambient completeness assertion, the listed rows exhaust the NameCert obligations. □

Theorem 7971.3 (Green theorem Stokes plane boundary route)**.** *Every* $\mathsf{GreenTheorem}^{\uparrow}$ *consumer of a plane boundary integration statement must first read the finite route*

$$\mathsf{DiffForm}^{\uparrow},\ \mathsf{StokesTheorem}^{\uparrow},\ \mathsf{RiemannIntegral}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

through the rows F, T, I, H, C, P, N of Definition 7971.1, after the plane-region row R and oriented-boundary row B have been displayed. The Green packet is therefore the planar specialization of the Stokes boundary route, with the scalar curl or divergence row S tied to the same differential-form data before the Riemann handoff is read. It is not an independent host vector-calculus theorem, a measure-completion route, a quotient equality of vector fields, or a selected boundary parametrization.

Proof. Begin with the carrier inventory. The rows R and B expose the region and its oriented boundary before any analytic read is public.

The differential-form and scalar rows are then read through F and S. The form row is the $\mathsf{DiffForm}^{\uparrow}$ input of chapter 136, while the scalar curl or divergence row is a displayed read from that same plane data rather than a second host object.

Next consume the Stokes specialization row T and the Riemann handoff row I. The Stokes packet of chapter 5720 supplies the boundary comparison, and the Riemann packet of chapter 1526 supplies the finite tagged-integration read. The structural rows H, C, P, N preserve this route without adding any of the excluded host principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{GreenTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{GreenTheorem}^{\uparrow}$ packet is generated from a plane-region row, oriented-boundary row, differential-form or vector-field row, scalar curl or divergence row, Stokes-specialization row, Riemann-integral handoff, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GreenTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7971.1, Definition 7971.2, and Definition 7971.3 bind the finite plane-boundary route through $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{StokesTheorem}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GreenTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not close a host vector-calculus theorem, selected boundary parametrizations, quotient equality of vector fields, measure completion, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, scalar-row exactness, Stokes specialization, Riemann handoff, transport, replay, provenance, and ledger non-escape for BEDC.Derived.GreenTheoremUp.

Chapter 7972

A Concrete Naming Certificate for $\mathsf{CauchyLimitSeparation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyLimitSeparation}^{\uparrow}$ packet records the finite separation data needed when two regular Cauchy presentations are compared at the real-name boundary. It sits after the dyadic arithmetic ledger of chapter 291, the finite stream windows of chapter 126, the regular rational carrier of chapter 301, the real-name seal of chapter 38, and the uniqueness route of chapter 3942. The packet names limit separation as finite BEDC data; it does not assert quotient real equality, trichotomy, located apartness, selected limits, or ambient completeness.

Definition 7972.1 (CauchyLimitSeparation carrier)**.** *A* $\mathsf{CauchyLimitSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the two inspected Cauchy windows.*
2. W *is the paired* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the two presentations.*
3. R *is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
4. E *is the* $\mathsf{Real}^{\uparrow}$ *boundary row reached only after the dyadic and regular-rational rows are displayed.*
5. U *is the* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *handoff row that records uniqueness-facing compatibility without quotienting the two presentations.*
6. H *stores componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, real boundary, uniqueness handoff, replay, provenance, and local naming rows.*
7. C *stores displayed* Cont *replay of the separation query through* D, W, R, E, U, H.
8. P *is the* Pkg *provenance over* $\mathsf{CauchyLimitSeparation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeparation}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. No coordinate stores quotient real equality, trichotomy, a selected limiting point, ambient completeness of $\mathsf{Real}^{\uparrow}$, *located apartness of arbitrary reals, or host sequence extensionality.*

Definition 7972.2 (CauchyLimitSeparation classifier)**.** *The* $\mathsf{CauchyLimitSeparation}^{\uparrow}$ *classifier accepts a packet* $S = (D, W, R, E, U, H, C, P, N)$ *exactly when the dyadic tolerance ledger* D*, paired stream windows* W*, regular rational readback* R*, real boundary* E*, and uniqueness handoff* U *are all displayed before transport, replay, provenance, and local naming are read. The classifier is therefore finite-row separation data over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$*; it is not a quotient of real names or an ambient separation theorem.*

Theorem 7972.3 (CauchyLimitSeparation NameCert)**.** *For every accepted* $\mathsf{CauchyLimitSeparation}^{\uparrow}$ *carrier* $S = (D, W, R, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyLimitSeparation}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier stability for the displayed dyadic and stream windows, regular rational readback, real-boundary routing, uniqueness handoff compatibility, componentwise transport, displayed replay, provenance, and local naming. The surface refuses quotient real equality, trichotomy, located apartness for arbitrary real names, selected limits, host sequence extensionality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 7972.1. The mathematical rows are D, W, R, E, U, and the structural rows are H, C, P, N.

Use the classifier of Definition 7972.2. It requires the dyadic tolerance ledger and paired stream windows before the regular rational readback, then routes that readback to the real boundary and uniqueness handoff.

Transport, replay, provenance, and naming preserve that same finite route. Since no carrier coordinate stores quotient equality, trichotomy, arbitrary located apartness, selected limits, host sequence extensionality, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7972.4 (CauchyLimitSeparation Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *uniqueness or separation consumer of an accepted* $\mathsf{CauchyLimitSeparation}^{\uparrow}$ *packet must read the dyadic tolerance ledger* D*, paired* $\mathsf{StreamName}^{\uparrow}$ *windows* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, real boundary row* E*, and* $\mathsf{RegularCauchyLimitUniqueness}^{\uparrow}$ *handoff row* U *before any conclusion about limit compatibility is consumed. The handoff supplies a finite Real-facing separation seal; it does not supply quotient real equality, selected limits, trichotomy, located apartness for arbitrary real names, or ambient completeness.*

Proof. Start with Definition 7972.3. The local NameCert surface forces every accepted read to expose $D, W, R, E, U, H, C, P, N$.

The real-facing consumer then reads E only after the dyadic tolerance ledger, stream windows, and regular rational readback have been displayed. The uniqueness-facing consumer reads U as compatibility with chapter 3942, not as quotient equality of real names.

Finally inspect the structural rows. The rows H, C, P, N transport, replay, source, and name the same finite separation packet. Since the excluded global claims have no coordinate in S, the Real handoff remains a finite seal over the displayed rows. □

Falsifiable prediction: An accepted $\mathsf{CauchyLimitSeparation}^{\uparrow}$ read is refuted if the real boundary row E or uniqueness handoff U is consumed while the dyadic tolerance ledger D, paired stream windows W, or regular rational readback R is absent.

Independence witness: dyadicratcore, streamname, regseqrat, real, regular-cauchy-limit-uniqueness: no listed sibling supplies the joint dyadic ledger, paired stream windows, regular rational readback, real boundary, uniqueness handoff, transport, replay, provenance, and local NameCert rows while refusing quotient real equality and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyLimitSeparation}\uparrow}$.

Constructive story: A $\mathsf{CauchyLimitSeparation}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, paired StreamName windows, RegSeqRat readback, a RealUp boundary row, a RegularCauchyLimitUniqueness handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyLimitSeparation}\uparrow}, \mathsf{seed})$

Scope closed: Definition 7972.1, Definition 7972.2, Definition 7972.3, and Definition 7972.4 seed the finite limit-separation packet consumed by Real-facing uniqueness arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyLimitSeparation}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, located apartness for arbitrary real names, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, dyadic tolerance routing, stream-window readback, regular rational handoff, Real boundary routing, uniqueness compatibility, transport, replay, provenance, and local naming for BEDC.Derived.CauchyLimitSeparationUp.

Chapter 7973

A Concrete Naming Certificate for $\mathsf{KyFanMinimax}^{\uparrow}$

Following Ky Fan and the KKM minimax tradition, the $\mathsf{KyFanMinimax}^{\uparrow}$ packet records a finite convex-compact minimax route as NameCert data rather than as a host separation or selection principle. It consumes the finite KKM cover surface of chapter 6671, the convex carrier of chapter 208, the compact metric support of chapter 129, and the terminal scalar readback of chapter 38. The chapter separates this convex KKM route from the finite payoff-table certificate of chapter 7060 and the spectral min-max route of chapter 7431.

Definition 7973.1 (KyFanMinimax carrier)**.** *A* $\mathsf{KyFanMinimax}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, K, A, L, U, V, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *support row for the compact convex source surface and its finite observation windows.*
2. *Y is the* $\mathsf{ConvexSet}^{\uparrow}$ *row recording the convex carrier and the finite affine-spine data used by the minimax read.*
3. *K is the* $\mathsf{KKMFiniteCover}^{\uparrow}$ *row carrying the finite face-cover witness used to route the minimax inequality.*
4. *A is the admissible-bifunction row, recording the displayed two-variable real-valued comparison surface and its finite domain membership checks.*
5. *L is the lower-level-set convexity row, exposing the finite convex slices read by the KKM cover route.*
6. *U is the upper semicontinuity and compact-window row, tying each displayed scalar threshold to compact finite observations.*
7. *V is the minimax-value row, read as a* $\mathsf{Real}^{\uparrow}$ *seal only after the KKM, convexity, and compact-window rows have been displayed.*
8. *W is the witness-budget row, recording the finite threshold, cover, and comparison windows retained by downstream consumers.*
9. *H stores componentwise* hsame *transport for X, Y, K, A, L, U, V, W and the local certificate row.*

10. *C stores displayed* Cont *replay for compact support, convex membership, KKM cover reads, bifunction comparisons, scalar threshold reads, and value-seal export.*
11. *P is the* Pkg *provenance over* $\mathsf{KyFanMinimax}^{\uparrow}$, $\mathsf{KKMFiniteCover}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KyFanMinimax}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host minimax selector, Hahn–Banach separation, arbitrary open-cover compactness, quotient equality of level sets, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7973.2 (KyFanMinimax NameCert obligations)**.** *For every accepted* $\mathsf{KyFanMinimax}^{\uparrow}$ *carrier $F = (X, Y, K, A, L, U, V, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KyFanMinimax}^{\uparrow}}$ *surface consists exactly of compact source admission, convex carrier admission, finite KKM cover admission, bifunction comparison admission, lower-level convexity, compact-window upper-semicontinuity, value-seal readback, witness-budget exposure, componentwise transport, displayed replay, provenance, and local naming. A minimax read is admitted only after the compact, convex, KKM, bifunction, level-set, threshold-window, value, and witness rows are visible in the same finite packet.*

Proof. Project the carrier of Definition 7973.1. The compact and convex support rows are X and Y, while K supplies the finite KKM cover surface.

Read the bifunction and level-set rows next. The row A exposes only displayed comparison data, L keeps the lower-level slices inside the convex carrier, and U ties scalar thresholds to compact finite windows.

The value and witness rows are downstream. The $\mathsf{Real}^{\uparrow}$ seal V is read only after K, L, U have supplied the finite KKM route, and W records the finite cover and threshold windows consumed by later readers.

Finally H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Since the carrier has no row for host selection, separation, arbitrary compactness, quotient level-set equality, countable choice, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7973.3 (KyFanMinimax finite KKM route)**.** *Every accepted* $\mathsf{KyFanMinimax}^{\uparrow}$ *minimax-value read factors through the finite route*

$$\mathsf{KKMFiniteCover}^{\uparrow}, \quad \mathsf{ConvexSet}^{\uparrow}, \quad \mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

More explicitly, the consumer must expose $X, Y, K, A, L, U, V, W, H, C, P, N$ before the value seal is public. The route exports no finite-game payoff-table saddle theorem, no spectral min-max theorem, no host minimax selector, no unrestricted compactness theorem, and no quotient equality of convex level sets.

Proof. Start with the accepted carrier. The only cover-facing row is K, and it is the finite KKM cover row tied to the same compact and convex support rows X, Y.

The level-set and compact-window rows L, U are the bridge from the bifunction comparison row A to the KKM cover. Thus a minimax consumer reads convex slices and compact finite windows before any scalar value seal is available.

The terminal scalar read is V, and W records the finite threshold and cover budget that reaches it. Transport, replay, provenance, and naming through H, C, P, N preserve this route without adding a payoff-table, spectral, or host selection coordinate.

Therefore every public value read is a finite KKM route through the named sibling surfaces, not a finite-game minimax theorem, Courant–Fischer theorem, host minimax selector, unrestricted compactness theorem, or quotient level-set equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{KyFanMinimax}^{\uparrow}}$.

Constructive story: A $\mathsf{KyFanMinimax}^{\uparrow}$ packet is generated from CompactMetric support rows, ConvexSet carrier rows, a KKMFiniteCover row, bifunction comparison rows, lower-level convexity rows, compact-window threshold rows, a RealUp value seal, witness-budget rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KyFanMinimax}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7973.1, Definition 7973.2, and Definition 7973.3 seed the finite Ky Fan minimax route over displayed compact, convex, KKM, bifunction, level-set, threshold, value, witness, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KyFanMinimax}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host minimax selection, Hahn–Banach separation, arbitrary open-cover compactness, finite-game minimax, spectral min-max, quotient equality of level sets, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, KKM cover admission, convex level-set stability, compact-window stability, value-seal readback, witness-budget exposure, transport stability, replay stability, provenance, and local naming for BEDC.Derived.KyFanMinimaxUp.

Chapter 7974

A Concrete Naming Certificate for $\mathsf{LawlikeStreamBoundary}^{\uparrow}$

Following Kleene, Troelstra–van Dalen, and Bishop–Bridges on lawlike sequences and constructive real names, the $\mathsf{LawlikeStreamBoundary}^{\uparrow}$ packet records the finite boundary at which a certified lawlike source may be read as a countable stream name without selecting a host sequence. It sits over the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the constructive warning surface of chapter 1406, and the refusal boundary of chapter 773. The packet names a lawlike stream boundary for Real and Completion consumers; it is not countable choice, not quotient stream equality, not trichotomy, not a selected host sequence, and not ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7974.1 (Lawlike stream boundary carrier)**.** *A* $\mathsf{LawlikeStreamBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, R, E, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the lawlike source row. It records the displayed rule, finite source ledger, and admissible request boundary for the stream name being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row. It lists exactly the windows through which the lawlike source may be queried before any rational or real-facing read is public.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and the rational tolerance discipline already exposed by the stream route.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row. It is reached only after the lawlike source row, StreamName window row, and RegSeqRat readback row have been displayed.*
5. *O is the obstruction and refusal row. It records that the packet refuses selected host sequences, countable-choice selectors, quotient stream equality, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness, matching the constructive warning surfaces of* $\mathsf{SpeckerSequence}^{\uparrow}$ *and* $\mathsf{BrouwerianCounterexample}^{\uparrow}$.
6. *H records componentwise* hsame *transport for the lawlike source, StreamName windows, RegSeqRat readback, Real seal, obstruction row, continuation replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from lawlike source inspection through finite windows, regular rational readback, Real sealing, and refusal checking.*

8. *P is the* Pkg *provenance over* LawlikeStreamBoundary$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, SpeckerSequence$^\uparrow$, BrouwerianCounterexample$^\uparrow$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{LawlikeStreamBoundary}^\uparrow}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $S, W, R, E, O, H, C, P, N$ and has no coordinate for a selected host sequence, a global choice function, quotient stream equality, trichotomy, or a completeness theorem for Real$^\uparrow$.

Theorem 7974.2 (Lawlike stream boundary NameCert obligations)**.** *For an accepted* LawlikeStreamBoundary$^\uparrow$ *carrier $L = (S, W, R, E, O, H, C, P, N)$, the local* NameCert$_{\text{LawlikeStreamBoundary}^\uparrow}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the lawlike source row,* StreamName$^\uparrow$ *finite-window row,* RegSeqRat$^\uparrow$ *readback row, terminal* Real$^\uparrow$ *seal, obstruction and refusal row, transport, replay, provenance, and local naming row;*

2. *source-window compatibility, requiring every public request to start at the displayed lawlike source row S and then pass through the finite window row W;*

3. *regular readback discipline, requiring rational observations to pass through the* RegSeqRat$^\uparrow$ *row R before the* Real$^\uparrow$ *seal E is exposed;*

4. *refusal stability, requiring the obstruction row O to remain visible whenever a consumer asks for host sequence selection, countable choice, quotient stream equality, trichotomy, or Real completeness;*

5. *transport and replay, requiring H and C to preserve the same ordered route under* hsame *transport and displayed* Cont *replay;*

6. *provenance and naming, requiring P and N to name only the finite lawlike-window surface and not an ambient stream object.*

No NameCert obligation is stored outside these rows.

Proof. Project the accepted carrier. Its public data are exactly the rows $S, W, R, E, O, H, C, P, N$.

The source-window obligation follows from the first two rows. A consumer begins at the lawlike source row S and then reads only the finite windows displayed in W before asking for rational or Real-facing data.

The regular readback obligation is the row R. It binds the finite StreamName observations to the regular rational readback surface before the terminal seal E can be consumed.

The obstruction row O is part of the same packet, so a request for selected host sequences, countable choice, quotient stream equality, trichotomy, or Real completeness is refused at the boundary rather than supplied by another coordinate.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no additional coordinate appears in the carrier, the local NameCert surface is exactly the displayed lawlike-window boundary. □

Theorem 7974.3 (Lawlike stream boundary Real nonescape)**.** *For an accepted* LawlikeStreamBoundary$^\uparrow$ *carrier*

$$L = (S, W, R, E, O, H, C, P, N),$$

every Real-facing read factors through the finite route consisting of the lawlike source row S, StreamName$^\uparrow$ *window row W,* RegSeqRat$^\uparrow$ *readback row R, terminal* Real$^\uparrow$ *seal E, obstruction row O,* hsame *transport row H,* Cont *replay row C,* Pkg *provenance row P, and local* NameCert$_{\text{LawlikeStreamBoundary}^\uparrow}$

row N. The route exports no selected host sequence, no countable-choice selector, no quotient stream equality, no trichotomy, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier and project its displayed rows. The Real-facing endpoint is E, and the carrier places E after the lawlike source, finite StreamName windows, and regular rational readback.

The row S supplies only the lawlike source ledger. The row W then restricts inspection to finite windows, and R supplies the regular rational readback attached to those windows.

The Real seal E is terminal for this route. If a consumer asks for a selected host sequence, countable choice, quotient stream equality, trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$, the request has to pass through the obstruction row O, which records precisely the refusal.

Componentwise transport through H and replay through C preserve the same route, while P and N supply provenance and local naming. Hence every Real-facing read remains inside the finite lawlike-window boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{LawlikeStreamBoundary}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawlikeStreamBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7974.1, Definition 7974.2, and Definition 7974.3 seed the finite lawlike-source, StreamName window, RegSeqRat readback, Real seal, obstruction, transport, replay, provenance, and local NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawlikeStreamBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a selected host sequence, countable choice, quotient stream equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window compatibility, regular readback discipline, refusal stability, transport replay, provenance, and non-escape for BEDC.Derived.LawlikeStreamBoundaryUp.

Constructive story: A $\mathsf{LawlikeStreamBoundary}^{\uparrow}$ packet is generated from a lawlike source ledger, finite StreamName windows, RegSeqRat readback, a Real seal, an obstruction row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7975

A Concrete Naming Certificate for $\mathsf{BishopRealNumber}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopRealNumber}^{\uparrow}$ packet records the ordinary real-number interface as a finite BEDC NameCert surface rather than as a host quotient or completed object. It is a sibling of the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the located Cauchy modulus route of chapter 1035. The chapter names a traditional constructive real-number carrier for Real and Completion consumers without asserting trichotomy, quotient stream equality, Dedekind-cut completeness, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7975.1 (BishopRealNumber carrier)**.** *A* $\mathsf{BishopRealNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, E, M, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule that opens the inspected approximation windows;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback assembled from those windows;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger governing the displayed rational errors;*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational readback and dyadic ledger have been exposed;*
5. *M is the* $\mathsf{LocatedCauchyModulus}^{\uparrow}$ *row recording located tail control for the same readback route;*
6. *H records componentwise* hsame *transport for the schedule, readback, tolerance ledger, seal, modulus, and structural rows;*
7. *C records the displayed* Cont *replay for window inspection, rational readback, tolerance comparison, Real seal delivery, located modulus use, and non-escape inspection;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedCauchyModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealNumber}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the rows $S, R, D, E, M, H, C, P, N$.

Lean4 ✓ `BEDC.Derived.BishopRealNumberUp.BishopRealNumberTasteGate single carrier alignment`

Theorem 7975.2 (BishopRealNumber NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealNumber}^{\uparrow}$ *carrier* $B = (S, R, D, E, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealNumber}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, located Cauchy modulus row, componentwise transport, displayed replay, provenance, and local naming row. Any Real or Completion consumer of the packet must read those rows before treating the carrier as a constructive real-number name.*

Proof. Project the carrier of Definition 7975.1. The analytic rows are the displayed schedule S, regular readback R, dyadic ledger D, terminal seal E, and located modulus M.

The structural rows H, C, P, N transport, replay, package, and name those same analytic rows. Since no coordinate stores quotient stream equality, a selected host limit, trichotomy, Dedekind-cut completeness, countable choice, open-cover compactness, or ambient RealUp completeness, the NameCert obligation surface is exactly the displayed finite packet. □

Theorem 7975.3 (BishopRealNumber RegSeqRat seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal read from an accepted* $\mathsf{BishopRealNumber}^{\uparrow}$ *carrier factors first through the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*. The located Cauchy modulus row* M *records tail control for that same route, while* H, C, P, N *preserve it by transport, replay, provenance, and naming.*

Proof. Read the accepted carrier $B = (S, R, D, E, M, H, C, P, N)$. The only rows before the Real-facing endpoint are the finite schedule, regular rational readback, dyadic tolerance ledger, and located modulus.

The seal row E is displayed after those rows in the carrier. Therefore a consumer reaches $\mathsf{Real}^{\uparrow}$ only through the route supplied by S, R, D, M, with R providing the regular rational handoff and D providing the dyadic error ledger.

The structural rows do not add another Real seal route. Componentwise transport through H, replay through C, provenance through P, and local naming through N preserve the same finite readback route, so the packet supplies a RegSeqRat-facing constructive real-number seal and nothing stronger. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealNumber}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopRealNumber}^{\uparrow}$ packet is generated from a StreamName schedule, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, located Cauchy modulus row, componentwise transport, displayed replay, provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopRealNumber}^{\uparrow}}$, seed)

Scope closed: Definition 7975.1, Definition 7975.2, and Definition 7975.3 bind the finite constructive real-number carrier and its RegSeqRat-to-Real seal route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopRealNumber}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close trichotomy, quotient stream equality, Dedekind-cut completeness, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or a public standard bridge.

Upgrade path: Formal closure requires checked carrier admission, StreamName scheduling, RegSeqRat readback, dyadic tolerance compatibility, RealUp seal delivery, located modulus stability, transport stability, route replay, provenance, and non-escape for the same finite packet.

Chapter 7976

A Concrete Naming Certificate for $\mathsf{RieszProjection}^{\uparrow}$

Following Dunford–Schwartz and standard Banach-algebra spectral theory, the $\mathsf{RieszProjection}^{\uparrow}$ packet records the finite contour-resolvent surface by which an isolated spectral window is read as a projection before any ambient functional calculus, host spectral measure, or quotient operator equality is available. It sits after the resolvent identity route of chapter 3715, the spectral-radius separator of chapter 2352, and the bounded-operator carrier of chapter 1644.

Definition 7976.1 (RieszProjection carrier)**.** *A* $\mathsf{RieszProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, T, G, C, R, S, E, H, K, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{BanachAlgebra}^{\uparrow}$ *source row carrying the complete normed algebra surface in which the operator and resolvent products are read.*
2. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row for the displayed operator whose isolated spectral window is inspected.*
3. *G is the contour-window row. It stores the finite contour samples, orientation ledger, and inside/outside window labels used by the projection read.*
4. *C is the shifted-resolvent graph. For each contour sample it records the displayed shifted operator and the inverse-check row supplied to the resolvent route.*
5. *R is the* $\mathsf{ResolventIdentity}^{\uparrow}$ *row, exposing the finite identity checks that keep neighbouring shifted-resolvent reads on one contour route.*
6. *S is the* $\mathsf{SpectralRadius}^{\uparrow}$ *separator row. It records the radius and gap evidence that keeps the contour window separated from the refused spectral side.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *tolerance seal for contour mesh, separator gap, and norm-bound readback.*
8. *H records componentwise* hsame *transport for A, T, G, C, R, S, E and the structural rows.*
9. *K records displayed* Cont *replay of the route*

$$\mathsf{BanachAlgebra}^{\uparrow}, \mathsf{BoundedLinearOperator}^{\uparrow}, \mathsf{ResolventIdentity}^{\uparrow}, \mathsf{SpectralRadius}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RieszProjection}^{\uparrow}.$$

10. *P is the* Pkg *provenance over* $\mathsf{RieszProjection}^{\uparrow}$, $\mathsf{BanachAlgebra}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{ResolventIdentity}^{\uparrow}$, $\mathsf{SpectralRadius}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszProjection}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $A, T, G, C, R, S, E, H, K, P, N$ and has no coordinate for a host spectral projection, a selected contour integral value, spectral-measure additivity, quotient operator equality, maximal ideal space, countable choice, or an ambient holomorphic functional calculus.

Theorem 7976.2 (RieszProjection NameCert obligations)**.** *For every accepted* $\mathsf{RieszProjection}^{\uparrow}$ *carrier*

$$Q = (A, T, G, C, R, S, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszProjection}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the Banach-algebra source, bounded-operator row, contour window, shifted-resolvent graph, resolvent-identity row, spectral-radius separator, Real tolerance seal, transport, replay, provenance, and local naming row;*

2. *contour-window stability, requiring every projection read to use only the finite samples and orientation ledger stored in G;*

3. *shifted-resolvent locality, requiring each sample read to pass through C and then the displayed* $\mathsf{ResolventIdentity}^{\uparrow}$ *row R before it is used by the projection route;*

4. *separator discipline, requiring the gap and refusal side to be read through the* $\mathsf{SpectralRadius}^{\uparrow}$ *row S and the* $\mathsf{Real}^{\uparrow}$ *tolerance seal E;*

5. *classifier transport, requiring H and K to preserve the contour, resolvent, separator, tolerance, provenance, and local name componentwise;*

6. *consumer non-escape, excluding host spectral projections, selected contour integrals, spectral-measure algebra, quotient operator equality, maximal ideal spaces, choice schedules, and ambient functional calculus from the packet.*

No NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 7976.1. The accepted packet exposes exactly the Banach-algebra source, bounded-operator row, contour window, shifted-resolvent graph, resolvent-identity row, spectral-radius separator, Real tolerance seal, transport, replay, provenance, and local naming row.

Contour stability is finite. The row G names the contour samples and orientation ledger, so a projection read cannot enlarge the contour or replace it by an unbounded functional-calculus object.

The shifted-resolvent graph C and the resolvent identity row R then bind the local inverse checks. Every sample read reaches the projection route only through the same displayed resolvent-contour data.

The separator row S and the Real seal E record the finite gap and tolerance evidence. Since H, K, P, N only transport, replay, source, and name those rows, none of the excluded host-side spectral objects can appear as a local NameCert obligation. □

Theorem 7976.3 (RieszProjection resolvent-contour route)**.** *For every accepted* $\mathsf{RieszProjection}^{\uparrow}$ *carrier* $Q = (A, T, G, C, R, S, E, H, K, P, N)$*, each projection-facing read factors through the displayed route*

$$\mathsf{BoundedLinearOperator}^{\uparrow},\ \mathsf{ResolventIdentity}^{\uparrow},\ \mathsf{SpectralRadius}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The read first fixes the operator row T*, then the finite contour window* G*, then the shifted-resolvent graph* C*, then the identity row* R*, then the separator row* S *and tolerance seal* E*, before* H, K, P, N *export the local name. It does not pass through a host spectral projection, selected contour integral, quotient operator equality, or ambient holomorphic functional calculus.*

Proof. Project the accepted packet. The only operator-facing coordinate is T, and the only contour-facing coordinate is G. Thus a projection read begins with the bounded-operator row and the finite contour ledger.

The next coordinates are C and R. These rows expose shifted-resolvent checks and the sibling resolvent identity route; no projection value is public before those rows are replayed.

The separator and tolerance rows S, E then guard the spectral side of the contour. Finally H, K, P, N transport, replay, source, and name the same finite route, so every projection-facing read factors through the displayed resolvent-contour surface. □

Falsifiable prediction: Every accepted $\mathsf{RieszProjection}^{\uparrow}$ consumer exposes the Banach-algebra source, bounded-operator row, finite contour window, shifted-resolvent graph, resolvent identity row, spectral-radius separator, Real tolerance seal, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before reading a projection-facing boundary.

Independence witness: resolvent-identity, spectral-radius, boundedlinearoperator, banachalgebra, real: ResolventIdentityUp supplies shifted inverse identity rows without an isolated contour window; SpectralRadiusUp supplies radius and gap evidence without a projection carrier; BoundedLinearOperatorUp supplies operator action and norm-bound rows without contour-resolvent data; BanachAlgebraUp supplies the product surface without the isolated-window separator; RealUp seals tolerances without naming the projection route.

Closure status for $\mathsf{NameCert}_{\mathsf{RieszProjection}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RieszProjection}^{\uparrow}$ packet is generated from a BanachAlgebraUp source, a BoundedLinearOperatorUp row, a finite contour window, shifted-resolvent graph data, a ResolventIdentityUp row, a SpectralRadiusUp separator, a RealUp tolerance seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7976.1, Definition 7976.2, and Definition 7976.3 seed the finite resolvent-contour projection route over BanachAlgebraUp, BoundedLinearOperatorUp, ResolventIdentityUp, SpectralRadiusUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host spectral projections, selected contour integrals, spectral-measure algebra, quotient operator equality, maximal ideal spaces, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contour-window stability, shifted-resolvent locality, separator discipline, classifier transport, and consumer non-escape for BEDC.Derived.RieszProjectionUp.

Chapter 7977

A Concrete Naming Certificate for MetaCICResidualCommutationWitness$^{\uparrow}$

The MetaCICResidualCommutationWitness$^{\uparrow}$ packet realizes the residual-substitution boundary isolated by chapter 9378 as finite NameCert data. It records the local residual window, substitution-site ledger, candidate join row, and conditional confluence handoff that a later MetaCIC proof must consume before a residual beta branch can be read as commuting with substitution.

Theorem 7977.1 (MetaCIC residual-commutation witness sibling route)**.** *Every* MetaCICResidualCommutationWit *consumer that reads a candidate join as confluence-facing evidence must first pass through the residual-substitution boundary of chapter 2181 and the residual-substitution compatibility surface of chapter 4370. The witness records local residual windows and substitution-site ledgers, while those siblings provide the premise and compatibility surfaces that the witness cannot discharge by itself.*

Proof. Project the witness carrier. Its rows record a MetaCIC source window, a residual window, a substitution-site ledger, a candidate join row, and a conditional handoff, but no row supplies the residual-substitution premise.

Read the residual-substitution boundary sibling first. It names the boundary that must be present before a local residual window can be treated as a substitution-sensitive branch rather than an isolated candidate.

Then read the compatibility sibling. That surface supplies the comparison discipline needed before the candidate join can face the confluence audit map. The present witness therefore remains a local ledger until those sibling rows are displayed, and it cannot export premise-free confluence evidence. □

Definition 7977.2 (MetaCIC residual-commutation witness carrier)**.** *A* MetaCICResidualCommutationWitness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, R, S, J, D, T, C, P, N)$$

with the following displayed rows:

1. *M is the MetaCIC source row, naming the term constructor window, closure side condition, beta branch, and parallel-step boundary under inspection.*
2. *R is the residual window. It records the finite residual redex positions that remain visible after the displayed beta branch is taken.*

3. *S is the substitution-site ledger, listing the binder depth, substituted argument window, freshness side rows, and transported site indices used by the residual branch.*
4. *J is the candidate join row. It records the two displayed reducts and the bounded local join data that would close the residual beta peak.*
5. *D is the conditional confluence handoff row, pointing to the named substitution-compatibility premise consumed by the MetaCIC confluence bridge.*
6. *T records componentwise* hsame *transport for M, R, S, J, D and the structural rows.*
7. *C records displayed* Cont *replay of the route*

$$\mathsf{MetaCICResidualCommutationWitness}^{\uparrow} \longmapsto D \longmapsto \textit{conditional MetaCIC confluence bridge.}$$

8. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualCommutationWitness}^{\uparrow}$*, the MetaCIC confluence audit map, residual windows, substitution-site ledgers, candidate joins, conditional handoffs,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualCommutationWitness}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $M, R, S, J, D, T, C, P, N$ and has no coordinate for an unconditional closed Church–Rosser theorem, a hidden substitution axiom, quotient term equality, host freshness choice, global normalization, or an ambient confluence oracle.

Lean4 (statement) `BEDC.Derived.MetaCICResidualCommutationWitnessUp`

Theorem 7977.3 (MetaCIC residual-commutation witness obligations)**.** *For every accepted* MetaCICResidualComm *carrier*

$$W = (M, R, S, J, D, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualCommutationWitness}^{\uparrow}}$ *surface consists exactly of carrier admission, residual-window exposure, substitution-site ledger exposure, candidate-join recording, conditional confluence handoff, componentwise transport, replay, provenance, and local naming. A confluence consumer may read the witness only after it has displayed the same residual window R, the same substitution ledger S, the same candidate join row J, and the same conditional handoff D.*

The certificate exports no unconditional MetaCIC confluence theorem, no hidden substitution principle, no quotient term equality, no selected freshness schedule, no global normalization theorem, and no ambient confluence oracle.

Proof. Carrier admission is projection from Definition 7977.2. The accepted packet exposes exactly the MetaCIC source row, residual window, substitution-site ledger, candidate join row, conditional handoff, transport, replay, provenance, and local naming.

The residual and substitution rows R, S are finite. They name the positions and binder-site data used by the local branch, so the packet cannot silently quantify over all residual beta branches.

The candidate join row J is then read only as displayed local join data. The handoff row D keeps the confluence result conditional on the named substitution-compatibility boundary rather than presenting the witness as a closed Church–Rosser theorem.

Finally T, C, P, N transport, replay, source, and name only those rows. Since the excluded confluence and equality principles have no coordinate in the carrier, they cannot appear as local NameCert obligations. □

Theorem 7977.4 (MetaCIC residual-commutation witness confluence-map route)**.** *Every confluence-map read of an accepted* MetaCICResidualCommutationWitness$^{\uparrow}$ *packet factors through the displayed route*

residual window, *substitution-site ledger*, *candidate join*, *conditional handoff*, hsame, Cont, Pkg, NameCert.

The read first fixes the MetaCIC source row M, then the residual window R, then the substitution-site ledger S, then the candidate join row J, and only then the conditional handoff D consumed by the confluence audit map. It does not claim the missing substitution-compatibility input, arbitrary closed-term Church–Rosser, quotient term equality, or global normalization.

Proof. Project the accepted packet. A confluence-map consumer receives no row except $M, R, S, J, D, T, C, P, N$, so its first data are the displayed source and residual window.

The substitution-site ledger S and candidate join row J then bind the local peak. They provide bounded branch data, not a global substitution theorem.

The handoff D keeps the route aligned with chapter 9378. Transport, replay, provenance, and local naming preserve that same conditional boundary, so every confluence-map read factors through the stated finite route. □

Falsifiable prediction: Every accepted MetaCICResidualCommutationWitness$^{\uparrow}$ consumer exposes a MetaCIC source row, residual window, substitution-site ledger, candidate join row, conditional confluence handoff, componentwise hsame transport, Cont replay, Pkg provenance, and local naming before reading the confluence-map boundary.

Independence witness: metacic-confluence-audit, metacic-residual-substitution-boundary, metacic-local-join-ledger, metacic-confluence-residual-checker, parallel-diamond-residual: the confluence audit map names the conditional boundary without a local witness carrier; the residual-substitution boundary stores premise shape without the candidate join row; the local-join ledger records joins without substitution-site commutation data; the residual checker exposes bounded checks without the confluence handoff; the parallel-diamond residual packet names a diamond-facing route without this residual-substitution witness.

Closure status for NameCert$_{\text{MetaCICResidualCommutationWitness}^{\uparrow}}$.

Constructive story: A MetaCICResidualCommutationWitness$^{\uparrow}$ packet is generated from a MetaCIC source row, a residual window, a substitution-site ledger, a candidate join row, a conditional confluence handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICResidualCommutationWitness}^{\uparrow}}$, seed)

Scope closed: Definition 7977.2, Definition 7977.3, and Definition 7977.4 seed the finite residual-commutation witness route over MetaCIC residual windows, substitution-site ledgers, candidate joins, conditional handoffs, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICResidualCommutationWitness}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim substitution compatibility, arbitrary closed-term Church–Rosser, quotient term equality, selected freshness schedules, global normalization, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-window exposure, substitution-site ledger exposure, candidate-join recording, conditional handoff exactness, classifier transport, and consumer non-escape for BEDC.Derived.MetaCICResidualCommutationWitnessUp.

Chapter 7978

A Concrete Naming Certificate for $\mathsf{FiniteDimensionalBanach}^{\uparrow}$

Following Banach-space and finite-dimensional normed-space treatments, the $\mathsf{FiniteDimensionalBanach}^{\uparrow}$ packet records the coordinate route by which a displayed finite-dimensional normed vector space is consumed as complete. It sits after the Banach certificate of chapter 90, the vector-space carrier of chapter 47, the norm interface of chapter 89, the real-name seal of chapter 38, the regular rational sequence surface of chapter 301, the finite norm-comparison route of chapter 5566, and the finite-net compactness packet of chapter 6043. The packet names finite coordinate completeness as displayed NameCert data; it is not general Hahn–Banach separation, arbitrary open-cover compactness, quotient vector equality, or a selected completion carrier.

Definition 7978.1 (FiniteDimensionalBanach carrier)**.** *A* $\mathsf{FiniteDimensionalBanach}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, N, R, S, E, K, L, W, H, C, P, Q)$$

with the following displayed rows:

1. *V is the finite* $\mathsf{VecSpace}^{\uparrow}$ *row, including the displayed coordinate-window dimension, basis-window ledger, zero, addition, negation, scalar source, and scalar action.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row attached to V, naming the norm read used by every Cauchy and limit comparison.*
3. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row through which norm values, comparison constants, and error budgets are read.*
4. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row recording the regular rational error schedule for the inspected Cauchy sequence.*
5. *E is the* $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$ *row tying the norm comparison to the same finite coordinate window.*
6. *K is the coordinate-Cauchy ledger, listing the finitely many coordinate sequences extracted from the norm-Cauchy read.*
7. *L is the coordinate-limit ledger, recording the regular rational names that serve as limits for the displayed coordinate sequences.*
8. *W is the reconstructed limit-window row, repacking the coordinate limits as a vector row over V before any Banach-facing read is exported.*

9. *H stores componentwise* hsame *transport for V, N, R, S, E, K, L, W and the local naming row.*
10. *C stores displayed* Cont *replay from a finite-dimensional completeness request through the coordinate extraction, coordinate limits, and reconstructed limit window.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteDimensionalBanach}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{FiniteDimensionalNormEquivalence}^{\uparrow}$, $\mathsf{FiniteDimensionalCompactness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *Q is the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBanach}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host completion functor, quotient vector equality, unrestricted Hahn–Banach separation, arbitrary open-cover compactness, selected bases outside the packet, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7978.2 (FiniteDimensionalBanach NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDimensionalBanach}^{\uparrow}$ *carrier $F = (V, N, R, S, E, K, L, W, H, C, P, Q)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBanach}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed vector-space, norm, real-seal, regular-rational error, finite norm-equivalence, coordinate-Cauchy, coordinate-limit, reconstructed limit-window, transport, replay, provenance, and local naming rows. A completeness-facing read is admitted only after the coordinate Cauchy ledger K, coordinate-limit ledger L, and reconstructed limit window W are visible in the same finite packet.*

Proof. Project the carrier of Definition 7978.1. The vector, norm, scalar, and regular-rational source rows are exactly V, N, R, S.

Read the finite-dimensional comparison row next. The row E keeps norm comparisons on the displayed coordinate window, so Cauchy control can be transferred only through named finite coordinates.

The completeness data is then K, L, W. The coordinate-Cauchy ledger K exposes finitely many coordinate sequences, L records their regular rational limits, and W repacks those limits as the vector read consumed by Banach-facing users.

Finally H, C, P, Q preserve the same packet under componentwise transport, displayed replay, provenance, and local naming. Since the carrier has no row for a host completion functor, quotient vector equality, unrestricted separation, arbitrary compactness, selected external bases, countable choice, or ambient real completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 7978.3 (FiniteDimensionalBanach coordinate completeness handoff)**.** *Every Banach-facing read of an accepted* $\mathsf{FiniteDimensionalBanach}^{\uparrow}$ *carrier factors through the finite coordinate route*

$$\mathsf{VecSpace}^{\uparrow},\quad \mathsf{Norm}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{FiniteDimensionalNormEquivalence}^{\uparrow},\quad \mathsf{FiniteDimensionalCompactnes}$$

The route first displays the finite vector and norm rows, then reads the regular rational Cauchy budget, transfers it to finitely many coordinate sequences, records their coordinate limits, and repacks the resulting vector through the reconstructed limit window. It exports finite-coordinate completeness only for the named packet and does not export general Hahn–Banach, choice-based compactness, quotient completion, or ambient real completeness.

Proof. Start from the obligation surface of Definition 7978.2. A Banach-facing consumer must open V, N, R, S before any Cauchy or limit read is available.

Next use the finite norm-comparison row E. It is the only route from the norm-Cauchy budget to coordinate Cauchy data, so the handoff remains tied to the displayed finite coordinate window.

The coordinate ledgers K and L supply the finite limit data, and W repacks those limits as the vector-window read. The compactness-facing sibling of chapter 6043 may supply bounded-window consumers, but no compactness or choice principle is added to this packet.

The structural rows H, C, P, Q replay and name the same route for downstream Banach consumers. Therefore the exported completeness claim is finite-coordinate completeness over the listed rows, not a host completion theorem, a quotient construction, general Hahn–Banach separation, arbitrary open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBanach}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalBanach}^{\uparrow}$ packet is generated from a displayed VecSpaceUp row, NormUp row, RealUp scalar seal, RegSeqRat error schedule, finite-dimensional norm-equivalence row, coordinate-Cauchy ledger, coordinate-limit ledger, reconstructed limit-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalBanach}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7978.1, Definition 7978.2, and Definition 7978.3 seed the finite-coordinate completeness route over displayed vector, norm, real, regular-rational, coordinate-limit, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalBanach}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general Hahn–Banach, arbitrary open-cover compactness, quotient vector equality, selected external bases, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite vector and norm exposure, coordinate Cauchy extraction, coordinate-limit readback, reconstructed limit-window exactness, transport stability, replay stability, provenance, and local naming for BEDC.Derived.FiniteDimensionalBanachUp.

Chapter 7979

A Concrete Naming Certificate for $\mathsf{BanachMazurDistance}^{\uparrow}$

Following Banach and Mazur's finite-dimensional distance formalism, the $\mathsf{BanachMazurDistance}^{\uparrow}$ packet records a finite distortion comparison between two displayed normed or Banach rows as NameCert data. It sits over the metric carrier of chapter 57, the norm carrier of chapter 89, the Banach-facing carrier of chapter 90, the located-limit route of chapter 1420, and the real-name seal of chapter 38. The packet names a displayed pair of inverse-candidate rows and a finite $\mathsf{Real}^{\uparrow}$ distortion ledger; it does not assert a host infimum, a quotient isometry class, a Hahn–Banach separation theorem, or a choice-selected optimal isomorphism.

Definition 7979.1 (Banach–Mazur distance carrier)**.** *A* $\mathsf{BanachMazurDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (X, Y, F, G, L, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source space row, read through* $\mathsf{NormedSpace}^{\uparrow}$ *or* $\mathsf{Banach}^{\uparrow}$ *and carrying its displayed norm, metric, finite-dimensional coordinate window, and completion-facing* $\mathsf{LocatedLimit}^{\uparrow}$ *references when present.*

2. *Y is the target space row, read through the same normed or Banach-facing surface and carrying its displayed norm, metric, finite-dimensional coordinate window, and located-limit references when present.*

3. *F is the forward inverse-candidate row from X to Y, recording the displayed finite matrix or finite linear-action table, its domain window, and its* $\mathsf{Real}^{\uparrow}$ *operator-bound ledger.*

4. *G is the reverse inverse-candidate row from Y to X, recording the displayed finite matrix or finite linear-action table, its domain window, and its* $\mathsf{Real}^{\uparrow}$ *operator-bound ledger.*

5. *L is the distortion ledger, storing the two forward and reverse norm-bound seals and the displayed product bound as* $\mathsf{Real}^{\uparrow}$ *data.*

6. *R is the inverse-replay row, recording that $G \circ F$ and $F \circ G$ return to the displayed source and target windows by finite coordinate checks, not by a host quotient or an ambient isometry class.*

7. *H stores componentwise* hsame *transport for the source row, target row, forward candidate, reverse candidate, distortion ledger, inverse replay, provenance, and local naming.*

8. *C stores displayed* Cont *replay from a distance-facing request through X, Y, F, G, L, R, H.*

9. *P is the* Pkg *provenance over* $\mathsf{BanachMazurDistance}^{\uparrow}$, $\mathsf{NormedSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachMazurDistance}^{\uparrow}}$ *row.*

The carrier has no coordinate for an external infimum over all isomorphisms, a quotient isometry class, an unrestricted Hahn–Banach separation argument, a selected optimal map, or an appeal to countable choice.

Definition 7979.2 (Banach–Mazur distance classifier)**.** *Two accepted* $\mathsf{BanachMazurDistance}^{\uparrow}$ *packets*

$$D = (X, Y, F, G, L, R, H, C, P, N) \quad \text{and} \quad D' = (X', Y', F', G', L', R', H', C', P', N')$$

are classified together exactly when the transported distortion ledgers L and L' expose the same displayed $\mathsf{Real}^{\uparrow}$ *product-bound comparison after the same source and target rows have been read. The classifier does not compare host spaces, quotient isometry classes, optimal maps, or external infima; it compares only the finite ledger reached through H, C from X, Y, F, G, R.*

Theorem 7979.3 (Banach–Mazur distance NameCert obligations)**.** *For every accepted* $\mathsf{BanachMazurDistance}^{\uparrow}$ *carrier $D = (X, Y, F, G, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BanachMazurDistance}^{\uparrow}}$ *surface consists exactly of five finite obligation rows:*

1. *source and target admission: X and Y are displayed normed or Banach-facing rows with metric and located-limit dependencies available only through their named packets;*
2. *inverse-candidate admission: F and G are the only forward and reverse rows available to the certificate;*
3. *distortion-ledger exactness: L stores the displayed* $\mathsf{Real}^{\uparrow}$ *norm-bound product read from F and G;*
4. *inverse replay: R records the finite coordinate-window checks for $G \circ F$ and $F \circ G$;*
5. *structural preservation: H, C, P, N transport, replay, source, and name the same rows without adding an optimal isomorphism, host infimum, quotient isometry class, Hahn–Banach theorem, or choice principle.*

Proof. Project the carrier of Definition 7979.1. The source and target rows are X, Y, and all norm, metric, Banach, and located-limit dependencies are read through those displayed rows.

Read the inverse-candidate rows next. The packet contains exactly F and G as finite forward and reverse action data, so every distance-facing request must use those two rows before consulting any distortion value.

The distortion row is L. It records the two operator-bound reads and their displayed $\mathsf{Real}^{\uparrow}$ product, while the inverse-replay row R records the finite coordinate-window return checks.

Finally H, C, P, N preserve the same finite packet under transport, replay, provenance, and local naming. Since the carrier has no row for a host infimum, quotient isometry class, selected optimal map, Hahn–Banach separation, or countable choice, the listed rows exhaust the NameCert surface. □

Theorem 7979.4 (Banach–Mazur distance distortion ledger route)**.** *Every distortion-facing consumer of an accepted* $\mathsf{BanachMazurDistance}^{\uparrow}$ *packet factors through*

$$X, Y, F, G, L, R, H, C, P, N.$$

The terminal comparison is the displayed $\mathsf{Real}^{\uparrow}$ *ledger L, transported and replayed through H, C after the source, target, forward, reverse, and inverse-replay rows have been exposed.*

Proof. Start with the source and target rows X, Y. They bind the normed or Banach-facing carrier, the $\mathsf{Met}^{\uparrow}$ readback, and any $\mathsf{LocatedLimit}^{\uparrow}$ completion-facing references before a distortion request is allowed.

Next read F and G. These rows are finite inverse candidates with displayed operator-bound data, and they are the only rows from which the distortion ledger may be computed.

The ledger route then passes through R and L. The row R records the finite inverse replay, and L seals the two norm-bound reads as a $\mathsf{Real}^{\uparrow}$ product comparison.

The structural rows H, C, P, N preserve this same route. No later consumer may replace the displayed ledger by an external infimum, quotient-isometry class, selected optimal isomorphism, Hahn–Banach argument, or choice-derived map. □

Theorem 7979.5 (Banach–Mazur distance composition boundary)**.** *If two accepted* $\mathsf{BanachMazurDistance}^{\uparrow}$ *packets share a displayed middle space row, then a composition-facing consumer may concatenate their finite inverse-candidate rows only by constructing a new displayed ledger from the two source ledgers and the two inverse-replay rows. The boundary exports a composed finite distortion row; it does not export the host multiplicative infimum law for Banach–Mazur distance, a quotient isometry-class statement, or a choice-selected optimal factorization.*

Proof. Take the two accepted packets and inspect their source, middle, and target rows. The shared middle space must be the displayed row transported by the two packets, not a host-identified quotient or an unnamed isometry class.

Concatenate the finite candidate rows. The forward action is read by composing the two displayed forward candidates, and the reverse action is read by composing the two displayed reverse candidates; both reads remain inside the finite coordinate windows named by the packets.

Build the new ledger from the old ledgers. The composed $\mathsf{Real}^{\uparrow}$ bound is obtained by multiplying the displayed product-bound rows already stored in the two distortion ledgers, while the inverse-replay evidence is rebuilt from the two replay rows.

The result is therefore a finite composition boundary for ledgers, not the external Banach–Mazur distance inequality over all isomorphisms. Since no packet contains a host infimum, quotient isometry class, selected optimum, Hahn–Banach separation row, or choice principle, none of those objects can be exported by composition. □

Falsifiable prediction: An accepted $\mathsf{BanachMazurDistance}^{\uparrow}$ read is refuted if the $\mathsf{Real}^{\uparrow}$ distortion ledger L is consumed before the source row X, target row Y, forward candidate F, reverse candidate G, and inverse-replay row R are displayed.

Independence witness: metric, norm, banach, locatedlimit, real: no listed sibling supplies the joint source-space rows, two inverse-candidate rows, finite RealUp distortion ledger, inverse replay, transport, continuation, provenance, and local NameCert row while refusing host infima, quotient isometry classes, selected optimal maps, Hahn–Banach separation, and choice.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachMazurDistance}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BanachMazurDistance}^{\uparrow}$ packet is generated from two displayed normed or Banach-facing source rows, two finite inverse-candidate rows, a RealUp distortion ledger, inverse replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachMazurDistance}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7979.1, Definition 7979.2, Definition 7979.3, Definition 7979.4, and Definition 7979.5 seed the finite distortion-ledger packet consumed by normed-space and Banach-facing comparison arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachMazurDistance}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infimum existence, quotient isometry classes, Hahn–Banach separation, selected optimal isomorphisms, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, inverse-candidate admission, distortion-ledger exactness, inverse replay, composition-boundary routing, transport, replay, provenance, and local naming for BEDC.Derived.BanachMazurDistanceUp.

Chapter 7980

A Concrete Naming Certificate for $\mathsf{SequentialContinuityReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{SequentialContinuityReal}^{\uparrow}$ packet specializes the existing $\mathsf{SequentialContinuity}^{\uparrow}$ route to Real-and-Completion consumers over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. It sits after the certified sequence-consumer packet of chapter 1466, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives completion-facing consumers a finite handoff surface without restating the general sequential-continuity carrier or importing host completeness.

Definition 7980.1 (Sequential continuity Real carrier)**.** *A* $\mathsf{SequentialContinuityReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, S, L, W_X, W_Y, A_X, A_Y, E_X, E_Y, H, C, P, N)$$

with the following displayed rows:

1. *Q is the already accepted* $\mathsf{SequentialContinuity}^{\uparrow}$ *packet whose pointwise-continuity, metric-row, and inspected-threshold data are being consumed.*
2. *S is the source sequence surface, exposed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
3. *L is the finite ledger of inspected convergence thresholds read from the sequential-continuity packet.*
4. *W_X and W_Y are the displayed source and image windows used by the Real-facing consumer.*
5. *A_X and A_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to the source and image windows.*
6. *E_X and E_Y are the corresponding* $\mathsf{Real}^{\uparrow}$ *seal rows available only after the regular-rational readbacks.*
7. *H records componentwise* hsame *transport for the sequential-continuity packet, stream rows, regular readbacks, Real seals, continuation, provenance, and local naming.*
8. *C records displayed* Cont *replay from Q, S, L to $W_X, W_Y, A_X, A_Y, E_X, E_Y$.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialContinuityReal}^{\uparrow}$*,* $\mathsf{SequentialContinuity}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuityReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host sequential-continuity theorem, quotient stream equality, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 7980.2 (Sequential continuity Real NameCert obligations)**.** *For every accepted* $\mathsf{SequentialContinuityReal}^{\uparrow}$ *carrier* $R = (Q, S, L, W_X, W_Y, A_X, A_Y, E_X, E_Y, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SequentialContinuityReal}^{\uparrow}}$ *surface consists exactly of carrier admission, consumption of the displayed* $\mathsf{SequentialContinuity}^{\uparrow}$ *row* Q*, finite stream-window exposure through* S, L, W_X, W_Y*, source and image* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* A_X, A_Y*, source and image* $\mathsf{Real}^{\uparrow}$ *seal handoff through* E_X, E_Y*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7980.1. The only analytic input from sequential continuity is the displayed row Q, and the only sequence observations are the finite windows W_X and W_Y read from the stream surface S at the thresholds listed in L.

The Real-facing rows are downstream from regular readback. The source side passes through A_X before E_X can be consumed, and the image side passes through A_Y before E_Y can be consumed.

The remaining rows do not add a second analytic surface. They transport, replay, source, and name the same finite route through H, C, P, N, so the listed obligations exhaust the local certificate surface. □

Theorem 7980.3 (Sequential continuity Real stream readback)**.** *Every accepted* $\mathsf{SequentialContinuityReal}^{\uparrow}$ *packet reads any source or image stream observation through a finite* $\mathsf{StreamName}^{\uparrow}$ *window before presenting it to a* $\mathsf{RegSeqRat}^{\uparrow}$ *row. In particular, every Real-facing route factors through*

$$Q, S, L \longmapsto W_X, W_Y \longmapsto A_X, A_Y \longmapsto E_X, E_Y$$

together with H, C, P, N*.*

Proof. Begin with the stream coordinates. The carrier exposes S only through the finite threshold ledger L, and the displayed windows W_X, W_Y are the only observations obtained from that schedule.

Next read the regular-rational rows. The rows A_X and A_Y are attached to those same windows, so a consumer cannot reach the source or image Real seal directly from S or from an unrecorded stream equality.

Finally the seal rows E_X, E_Y are downstream from the regular readbacks, while H, C, P, N preserve and name the same dependency route. This proves the stated factorization. □

Theorem 7980.4 (Sequential continuity Real composition handoff)**.** *Let* $R = (Q, S, L, W_X, W_Y, A_X, A_Y, E_X, E_Y,$ *be an accepted* $\mathsf{SequentialContinuityReal}^{\uparrow}$ *carrier. Any completion-facing consumer that composes the displayed sequential-continuity packet with Real readback must use* Q *only before the finite window and regular-rational stages, and must use* E_X, E_Y *only after* A_X, A_Y*. Thus the handoff is a finite BEDC route over* $\mathsf{SequentialContinuity}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, not a separate host theorem about completed real functions.*

Proof. Read the composition order from the carrier. The row Q supplies the certified sequential-continuity route, but the Real consumer does not inspect it as a completed function; it is consumed only through the stream windows named by S, L, W_X, W_Y.

The regular readback stage then mediates the passage to Real seals. The rows A_X, A_Y are the only regular-rational handoffs in the packet, and the rows E_X, E_Y are downstream from them.

The transport, replay, provenance, and naming rows keep this order stable under componentwise comparison of accepted packets. Therefore the completion-facing composition is exactly the finite handoff named in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialContinuityReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialContinuityReal}^{\uparrow}$ packet is generated from an accepted SequentialContinuity row, finite StreamName windows, RegSeqRat readback rows, RealUp seal rows, componentwise transport, displayed replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialContinuityReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7980.1, Definition 7980.2, Definition 7980.3, and Definition 7980.4 seed the Real-and-Completion handoff surface for sequential-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialContinuityReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sequential-continuity theorems, quotient stream equality, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window readback, RegSeqRat handoff, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.SequentialContinuityRealUp.

Chapter 7981

A Concrete Naming Certificate for $\mathsf{RasiowaSikorski}^{\uparrow}$

Following Rasiowa and Sikorski on dense-set forcing and its constructive readings, the $\mathsf{RasiowaSikorski}^{\uparrow}$ packet records the finite dense-open refinement route that a completion-facing consumer may inspect before any generic-filter claim is public. It sits beside the finite Baire-category surface of chapter 7959, the Baire-space source of chapter 334, the metric carrier of chapter 57, the finite observation schedule of chapter 126, and the terminal real-name seal of chapter 38. The packet names only displayed condition rows, dense-open request rows, finite refinements, finite-meet witnesses, generic-prefix rows, transport, replay, provenance, and local naming.

Definition 7981.1 (Rasiowa-Sikorski carrier)**.** *A* $\mathsf{RasiowaSikorski}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (P, D, Rf, F, G, H, C, Q, N)$$

with the following displayed rows:

1. *P is the condition row, listing the finite condition prefix currently visible to the packet.*
2. *D is the dense-open request row, recording only the displayed dense-open obligations being met.*
3. *Rf is the refinement row, naming the finite strengthening relation from the visible condition prefix into the requested dense-open row.*
4. *F is the finite-meet row, recording compatibility for the finite family of refinements already displayed.*
5. *G is the generic-prefix row, exposing a finite prefix that meets the displayed dense-open requests without selecting a host generic filter.*
6. *H records componentwise* hsame *transport for the condition, dense-open request, refinement, finite-meet, generic-prefix, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from condition inspection through dense-open admission, refinement, finite meets, generic-prefix exposure, transport, provenance, and local naming.*
8. *Q is the* Pkg *provenance over* $\mathsf{RasiowaSikorski}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RasiowaSikorski}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host generic filter, countable choice, arbitrary countable meets, quotient streams, selected generic points, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7981.2 (Rasiowa-Sikorski NameCert obligations)**.** *For every accepted* $\mathsf{RasiowaSikorski}^{\uparrow}$ *carrier* $R = (P, D, Rf, F, G, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RasiowaSikorski}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the condition row, dense-open request row, refinement row, finite-meet row, generic-prefix row, componentwise transport, replay, provenance, and local naming rows;*
2. *dense-open admission, requiring every public request in* D *to be displayed before any refinement row can be consumed;*
3. *refinement monotonicity, requiring* Rf *to strengthen the visible condition prefix rather than replace it by an external selector;*
4. *finite meet compatibility, requiring the finite family of displayed refinements to be checked by* F *before the generic-prefix row is public;*
5. *generic-prefix nonescape, requiring* G *to expose only finite prefix data and no host generic filter or selected point;*
6. *provenance, requiring* Q *and* N *to keep the route inside the displayed BaireSpace, MetricSpace, StreamName, Real,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

Proof. Project the carrier of Definition 7981.1. The rows P, D, Rf, F, G provide the condition, dense-open request, refinement, finite-meet, and generic-prefix data, while H, C, Q, N provide transport, replay, provenance, and local naming.

Dense-open admission is the row D. Since Rf is downstream of D, a consumer cannot read a refinement before the corresponding displayed request is visible.

Refinement monotonicity and finite meet compatibility are the rows Rf and F. The refinement strengthens the visible condition prefix, and the finite meet row checks the displayed finite family before the prefix row G can be exposed.

The structural rows preserve the same route. Transport through H, replay through C, provenance through Q, and naming through N do not add coordinates outside the finite packet, so the NameCert surface is exactly the listed obligation set. □

Theorem 7981.3 (Rasiowa-Sikorski finite dense-open route)**.** *Every completion-facing consumer of an accepted* $\mathsf{RasiowaSikorski}^{\uparrow}$ *carrier receives only finite dense-open refinement rows. More precisely, the consumer can read the condition row* P*, the dense-open request row* D*, the refinement row* Rf*, the finite-meet row* F*, the generic-prefix row* G*, and the structural rows* H, C, Q, N*, and it cannot read a host generic filter, countable choice, arbitrary countable meets, quotient stream equality, selected generic points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the obligation surface of Definition 7981.2. It places every public completion-facing request behind the displayed condition and dense-open rows.

The refinement row Rf and finite-meet row F are finite data. They record only the strengthenings and compatibility checks already present in the accepted packet.

The generic-prefix row G is downstream of those finite rows. It exposes a prefix meeting the displayed requests, not a completed generic filter or selected point.

Finally H, C, Q, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for countable choice, arbitrary countable meets, quotient streams, selected generic points, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those objects can be exported to a completion-facing consumer. □

Falsifiable prediction: Every accepted $\mathsf{RasiowaSikorski}^{\uparrow}$ read exposes condition rows, dense-open request rows, refinement rows, finite-meet rows, generic-prefix rows, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any completion-facing consumer receives the packet.

Independence witness: baire-space, constructive-baire-category, metricspace, streamname, real: $\mathsf{RasiowaSikorski}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite dense-open requests, monotone refinements, finite-meet compatibility, generic-prefix nonescape, transport, replay, provenance, and local naming while refusing host generic filters, countable choice, arbitrary countable meets, quotient streams, selected generic points, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{RasiowaSikorski}^{\uparrow}}$.

Constructive story: A $\mathsf{RasiowaSikorski}^{\uparrow}$ packet is generated from displayed condition rows, dense-open request rows, refinement rows, finite-meet rows, generic-prefix rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RasiowaSikorski}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7981.1, Definition 7981.2, and Definition 7981.3 seed the finite dense-open refinement surface for completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RasiowaSikorski}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, arbitrary countable meets, selected generic points, quotient streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-open admission, refinement monotonicity, finite meet compatibility, generic-prefix nonescape, transport replay, provenance, and local naming for BEDC.Derived.RasiowaSikorskiUp.

Chapter 7982

A Concrete Naming Certificate for $\mathsf{CompactIntervalChain}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{CompactIntervalChain}^{\uparrow}$ packet records a nested finite chain of located compact interval rows as BEDC NameCert data. It sits over the compact interval carrier of chapter 5553, the located endpoint surface of chapter 394, the dyadic tolerance core of chapter 291, the StreamName finite-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite chain data needed by nested-interval and compact-real consumers; it is not an arbitrary open-cover compactness theorem, a selected-subcover principle, a quotient real equality test, a countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7982.1 (Compact interval chain carrier)**.** *A* $\mathsf{CompactIntervalChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (L, E, D, W, R, A, H, C, P, N)$$

with the following rows:

1. *L is the finite chain ledger of nested located compact interval rows, each row carrying displayed left and right endpoint names and an inclusion witness into the previous row.*
2. *E records endpoint rows for the chain, including the visible* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{CompactRealInterval}^{\uparrow}$ *boundary data consumed by interval-local readers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh and tolerance ledger, recording common scales, endpoint slack, diameter bounds, and dyadic containment checks for every row in the finite chain.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to inspect endpoint and mesh data without opening an infinite stream or selecting a real representative.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the endpoint, nesting, diameter, mesh, and tolerance checks as finite regular rational windows.*
6. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed endpoint reads and compact interval seals.*
7. *H records componentwise* hsame *transport for chain rows, endpoint rows, dyadic mesh rows, StreamName windows, regular rational readbacks, Real seals, replay rows, provenance rows, and local naming rows.*
8. *C records displayed* Cont *replay from a chain request through $L, E, D, W, R, A, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalChain}^{\uparrow}$, $\mathsf{CompactRealInterval}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $L, E, D, W, R, A, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, quotient real equality, countable choice, or ambient real completeness.

Theorem 7982.2 (Compact interval chain NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalChain}^{\uparrow}$ *carrier*

$$Q = (L, E, D, W, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}$ *surface consists exactly of the displayed finite obligations: chain-row admission for L, endpoint and compact-interval admission for E, dyadic mesh and diameter admission for D, finite StreamName window admission for W, regular rational readback for R, terminal Real sealing for A, componentwise* hsame *transport for H, displayed replay for C, provenance for P, and local naming for N.*

Proof. Project the carrier of Definition 7982.1. The chain ledger L gives only finitely many nested interval rows, and E exposes the endpoint and compact-interval boundary attached to each row.

Read the analytic rows next. The dyadic ledger D supplies the common-scale, mesh, containment, endpoint-slack, and diameter data; W restricts endpoint and mesh inspection to finite StreamName windows.

The regular and Real-facing rows are downstream. The row R repacks the inspected chain data as regular rational windows, and A seals exactly those endpoint and compact-interval reads as $\mathsf{Real}^{\uparrow}$ data.

Finally, H, C, P, N transport, replay, source, and locally name the same finite packet. Since no carrier coordinate stores arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, or ambient completeness, the displayed rows exhaust the NameCert obligations. □

Theorem 7982.3 (Compact interval chain finite-cover induction)**.** *Every accepted finite* $\mathsf{CompactIntervalChain}^{\uparrow}$ *consumer that propagates a compact-interval estimate along the chain may use only induction over the displayed finite ledger L. At the base row it reads the endpoint, dyadic, StreamName, RegSeqRat, Real seal, transport, replay, provenance, and naming rows of the first interval; at each successor row it consumes the next inclusion and diameter data from $L, E, D, W, R, A, H, C, P, N$. The induction does not select subcovers, quotient real representatives, countable-choice schedules, or an ambient completeness witness.*

Proof. The base step is the first displayed interval row of L. By Definition 7982.2, the consumer receives its endpoint rows, dyadic mesh and diameter data, StreamName windows, regular rational readback, Real seal, transport, replay, provenance, and local name as finite data.

For the successor step, read the next chain row in L together with the endpoint and compact-interval boundary in E. The dyadic ledger D records the containment, diameter, and endpoint slack needed to pass the estimate from the previous row to the next row.

The handoff remains finite because W, R, A expose only the inspected windows, regular readbacks, and Real seals for the current row. The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming.

Induction over the finite ledger therefore proves the advertised propagation route. No step asks for an open-cover selector, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, because none of those objects appears in the carrier. □

Falsifiable prediction: Every $\mathsf{CompactIntervalChain}^{\uparrow}$ read factors through finite nested interval rows, compact endpoint rows, dyadic mesh and diameter ledgers, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seals, componentwise hsame, displayed Cont, Pkg, and a local $\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}$ row.

Independence witness: compactrealinterval, locatedinterval, dyadicratcore, streamname, regseqrat, real: $\mathsf{CompactIntervalChain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite nested-chain ledger, compact endpoint rows, dyadic containment and diameter rows, finite stream windows, regular readbacks, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalChain}^{\uparrow}$ packet is generated from finite nested located compact interval rows, endpoint rows, dyadic mesh and diameter ledgers, StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7982.1, Definition 7982.2, and Definition 7982.3 seed the finite nested compact interval chain carrier over compact endpoint rows, dyadic meshes, finite windows, regular readback, Real seals, and finite chain induction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, quotient real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{CompactIntervalChain}^{\uparrow}$.

Upgrade path: Obligation closure requires checked chain-row admission, endpoint sealing, dyadic containment and diameter stability, StreamName window pullback, RegSeqRat readback, replay stability, and nonescape for BEDC.Derived.CompactIntervalChainU

Chapter 7983

A Concrete Naming Certificate for $\mathsf{LocatedRealSpread}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{LocatedRealSpread}^{\uparrow}$ packet realizes the Real-completeness direction of chapter 9238 as a finite located-window NameCert object. It binds the terminal real-name seal of chapter 38, the finite-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the tail-budget siblings used by the completion route. The packet records finite located reads for a spread of Real-facing windows; it does not assert full $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, countable choice, or an ambient Cauchy completion theorem.

Definition 7983.1 (Located real spread carrier)**.** *A* $\mathsf{LocatedRealSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, L, D, R, E, H, C, P, N)$$

with the following rows:

1. *W is the finite spread-window ledger, listing the StreamName requests and local indices at which Real-facing reads are inspected.*
2. *L is the located read row, carrying lower and upper dyadic bracketing data for every displayed window together with apartness refusals outside the inspected spread.*
3. *D is the dyadic tail-budget row over* $\mathsf{DyadicRatCore}^{\uparrow}$*, recording precision thresholds, common-scale tolerances, and finite tail comparisons.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the located windows and dyadic tail budgets as regular rational finite data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed located reads and their regular rational witnesses.*
6. *H records componentwise* hsame *transport for spread windows, located Real reads, dyadic tail budgets, regular rational readbacks, Real seals, replay rows, provenance rows, and local naming rows.*
7. *C records displayed* Cont *replay from a located-spread request through W, L, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealSpread}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, the Cauchy-tail budget siblings,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $W, L, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, full Real completeness, or ambient completion.

Theorem 7983.2 (Located real spread NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealSpread}^{\uparrow}$ *carrier*

$$S = (W, L, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$ *surface consists exactly of finite spread-window admission for W, located read admission for L, dyadic tail-budget admission for D, regular rational readback for R, terminal Real sealing for E, componentwise* hsame *transport for H, displayed replay for C, provenance for P, and local naming for N.*

Proof. Project the carrier of Definition 7983.1. The row W lists the finite windows being inspected, and L supplies the located bracketing reads attached to those windows.

Read the tail-budget row D. It records precision thresholds, common dyadic scales, and finite tail comparisons before any regular rational or Real-facing row is consumed.

The readback row R repacks the located windows and dyadic budgets as $\mathsf{RegSeqRat}^{\uparrow}$ data, and E seals exactly those finite reads as $\mathsf{Real}^{\uparrow}$ data.

The structural rows H, C, P, N then transport, replay, source, and locally name the same packet. Since the carrier contains no quotient stream equality, selected-limit operator, countable-choice schedule, full completeness theorem, or ambient completion coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7983.3 (Located real spread regular readback)**.** *Every completion-facing consumer of an accepted* $\mathsf{LocatedRealSpread}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{StreamName}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through $W, L, D, R, E, H, C, P, N$ before using the located spread as Real-completeness data. The route exports finite located-window reads, dyadic tail budgets, regular rational readbacks, terminal Real seals, transport, replay, provenance, and local naming, but not quotient stream equality, selected limits, countable choice, full $\mathsf{Real}^{\uparrow}$ *completeness, or an ambient completion operator.*

Proof. Start with the finite window ledger W and located read row L. These rows expose only the inspected spread windows and their dyadic bracketing data.

Use the dyadic tail-budget row D next. It attaches each located read to a displayed precision threshold and common-scale comparison before the readback row is available.

The regular readback row R is the only handoff to $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal row E is the only handoff to $\mathsf{Real}^{\uparrow}$. Thus a completion-facing reader receives regular rational evidence before it reads a Real seal.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. None of these rows adds quotient stream equality, a selected limit, countable choice, full Real completeness, or an ambient completion operator, so every accepted read remains inside the displayed finite route. □

Theorem 7983.4 (Located real spread obligation closure)**.** *The carrier of Definition 7983.1, the NameCert surface of Definition 7983.2, and the regular readback route of Definition 7983.3 form the obligation surface for* $\mathsf{LocatedRealSpread}^{\uparrow}$*. Every local obligation is one of the displayed rows $W, L, D, R, E, H, C, P, N$, and every completion-facing read factors through those rows before it can be used as located Real-spread data.*

Proof. Use the carrier projection. The rows W, L, D, R, E provide the finite spread windows, located bracketing reads, dyadic tail budgets, regular rational readbacks, and Real seals.

Apply the NameCert obligations to identify the structural rows H, C, P, N as transport, replay, provenance, and local naming for the same packet.

Finally use the regular readback theorem. It forces every completion-facing consumer through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the located spread is exported, so no additional local obligation remains outside $W, L, D, R, E, H, C, P, N$. □

Theorem 7983.5 (Located real spread L10 scope)**.** *The* $\mathsf{LocatedRealSpread}^{\uparrow}$ *packet is scoped to the L10 Real and Completion substrate consisting of* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, displayed* Cont *replay, componentwise* hsame *transport, and finite located-window rows. It exports no obligation that reads a quotient stream, selected limit, countable-choice schedule, full* $\mathsf{Real}^{\uparrow}$ *completeness theorem, or ambient completion operator.*

Proof. Read the finite located-window rows first. The window ledger W and located row L determine the inspected spread requests and their dyadic bracketing data.

The dyadic row D, regular readback row R, and Real seal row E place those requests inside $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

The structural rows H and C provide exactly componentwise hsame transport and displayed Cont replay, while P, N record provenance and local naming. Since the carrier has no coordinate for quotient streams, selected limits, countable choice, full Real completeness, or ambient completion, the L10 scope is precisely the listed substrate. □

Falsifiable prediction: Every $\mathsf{LocatedRealSpread}^{\uparrow}$ read factors through finite spread windows, located Real reads, dyadic tail budgets, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seals, componentwise hsame, displayed Cont, Pkg, and a local $\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$ row.

Independence witness: streamname, regseqrat, dyadicratcore, real, tailbudget: $\mathsf{LocatedRealSpread}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite spread windows, located bracketing reads, dyadic tail-budget rows, regular rational readbacks, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealSpread}^{\uparrow}$ packet is generated from finite spread windows, located Real reads, dyadic tail budgets, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$, obligation)

Scope closed: Definition 7983.1, Definition 7983.2, Definition 7983.3, Definition 7983.4, and Definition 7983.5 bind the finite located-window, dyadic-tail, RegSeqRat readback, StreamName, Real seal, transport, replay, provenance, and local naming obligation packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealSpread}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, full $\mathsf{Real}^{\uparrow}$ completeness, ambient completion, Lean verification, or bridge checking for $\mathsf{LocatedRealSpread}^{\uparrow}$.

Upgrade path: Obligation closure requires checked spread-window admission, located read stability, dyadic tail-budget exactness, RegSeqRat readback, Real sealing, replay stability, and nonescape for BEDC.Derived.LocatedRealSpreadUp.

Chapter 7984

A Concrete Naming Certificate for $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$

Bishop and Bridges, in the constructive treatment of real-number comparison, keep located interval evidence, regular Cauchy names, and terminal real seals as displayed data before any quotient equality or trichotomy principle is used. The $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$ packet records that comparison route as a finite BEDC NameCert surface over the located-interval witness, the regular rational stream, the dyadic tolerance ledger, the finite StreamName schedule, and the Real-facing seal. It sits beside the real-name chapter chapter 38, the regular rational route of chapter 301, the stream schedule of chapter 126, and the dyadic arithmetic ledger of chapter 291; it does not identify representatives, select limits, decide trichotomy, or import ambient completeness.

Definition 7984.1 (Bishop located Cauchy real comparison carrier)**.** *A* $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, R, D, S, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval witness row, giving the positive separation or enclosure evidence used for the requested comparison.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *stream row whose rational approximants are being compared.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic scale, endpoint, and comparison-budget rows used by the located witness.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that opens the finite windows required by I, R, D.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the located witness, regular stream, dyadic ledger, and stream schedule have been displayed.*
6. *H records componentwise* hsame *transport for located witnesses, regular rational stream rows, dyadic tolerance rows, stream schedules, Real seals, continuation replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from the comparison request through the stream window, from the window through the dyadic tolerance ledger, from the ledger through the regular rational row, and from that row to the Real-facing seal.*

8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$*, located interval data,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, R, D, S, E, H, C, P, N$. It has no coordinate for quotient real equality, a selected completed limit, trichotomy, countable choice, host real comparison, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7984.2 (Bishop located Cauchy real comparison NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$ *carrier*

$$L = (I, R, D, S, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}}$ *obligations are exactly carrier admission, located interval witness exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *stream readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance compatibility,* $\mathsf{StreamName}^{\uparrow}$ *schedule ordering,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every comparison read factors through*

$$I, S, D, R, E, H, C, P, N.$$

No quotient equality of Cauchy names, selected limit, trichotomy, host real order, countable-choice schedule, or ambient completeness row is exported.

Proof. Project the carrier of Definition 7984.1. Its rows expose the located witness, regular rational stream, dyadic tolerance ledger, stream schedule, Real seal, transport, replay, provenance, and local naming as the only classifier-visible data.

The comparison route first reads the finite witness rows. The schedule S opens the windows required by the located evidence I, the ledger D supplies the dyadic tolerance and endpoint rows for those windows, and the regular stream row R records the rational Cauchy data being compared.

The Real-facing part is downstream. The seal E is read only after I, S, D, R are displayed, while H, C, P, N transport, replay, source, and name the same finite route.

Since none of the excluded principles is a carrier coordinate, no accepted consumer can extract quotient real equality, selected limits, trichotomy, host order, countable choice, or ambient completeness from the local certificate. □

Theorem 7984.3 (Bishop located Cauchy real comparison sibling route)**.** *Every accepted* BishopLocatedCauchyRea *comparison consumes the L10 real-name corridor in the order*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

as displayed by chapter 126, chapter 291, chapter 301, and chapter 38. The located interval witness is a comparison row over that corridor, not a replacement for the regular Cauchy name or the terminal Real seal.

Proof. Read the carrier rows S, D, R, E from Definition 7984.1. They are the stream window, dyadic tolerance ledger, regular rational readback, and terminal Real seal used by the comparison packet.

Apply the NameCert obligations of Definition 7984.2. The comparison read must factor through $I, S, D, R, E, H, C, P, N$, so the located witness I is attached to the same L10 corridor rather than to a hidden host real.

The non-escape clause then rules out quotient equality, selected limits, trichotomy, host order, countable choice, and ambient completeness. Thus the sibling route is the displayed finite real-name corridor with one located comparison witness over it. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}$ packet is generated from a located interval witness, a RegSeqRat stream row, a DyadicRatCore tolerance ledger, a StreamName schedule, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7984.1, Definition 7984.2, and Definition 7984.3 seed the located Cauchy real comparison packet over the L10 real-name corridor.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCauchyRealComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, selected limits, trichotomy, host real order, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, located witness exposure, regular rational readback, dyadic tolerance compatibility, schedule ordering, Real seal non-escape, transport, replay, provenance, and local naming.

Chapter 7985

A Concrete Naming Certificate for $\mathsf{Demicontinuity}^{\uparrow}$

Following Browder and Minty on weak-to-strong continuity for nonlinear operators, the $\mathsf{Demicontinuity}^{\uparrow}$ packet records the finite certificate surface for a map whose admissible input is read through weak tests while its output is controlled in a strong metric row. It sits over the Banach carrier of **??**, the Hilbert weak-test surface of chapter 6896, the monotone-operator route of chapter 6215, the scalar seal of chapter 38, and the metric readback surface of chapter 4230. The packet names only the displayed weak-input and strong-output handoff; it does not assert compactness, selected weak subsequences, maximal monotonicity, norm convergence of the input, or an ambient theorem turning weak convergence into strong convergence.

Definition 7985.1 (Demicontinuity carrier)**.** *A* $\mathsf{Demicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, W, M, R, A, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *source row, including the normed carrier, linear structure, and completeness-facing provenance inspected by the nonlinear map.*
2. *W is the weak-input row, read through* $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ *when the source is Hilbert-facing and through the displayed Banach weak-test rows otherwise.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *strong-output row, carrying the target distance, strong tolerance boundary, and metric readback used by consumers.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal for weak-test values and strong-output radii.*
5. *A is the action row for the displayed nonlinear operator. It records the finite graph window, accepted input names, output names, and the local handoff ledger from weak input tests to strong output estimates.*
6. *S is the demicontinuity stability row. Each entry records a weak-input budget, the finite scalar tests that certify it, the strong-output radius requested by M, and the displayed comparison sending the operator image into that radius.*
7. *H records componentwise* hsame *transport for Banach source, weak-input, metric target, real scalar seal, action, stability, replay, provenance, and naming rows.*

8. *C records displayed* Cont *replay from a weak-input request through*

$$B, W, M, R, A, S \longmapsto H, C, P, N.$$

9. *P is the* Pkg *provenance over* Demicontinuity$^{\uparrow}$, BanachSpace$^{\uparrow}$, WeakConvergenceHilbert$^{\uparrow}$, MintyBrowderMonotone Real$^{\uparrow}$, Met$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{Demicontinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, W, M, R, A, S, H, C, P, N$. It has no coordinate for compactness, selected weakly convergent subsequences, maximal-monotone closure, quotient graph equality, input norm convergence, or a host theorem that replaces the finite handoff ledger.

Lean4 (statement) `BEDC.Derived.DemicontinuityUp`

Theorem 7985.2 (Demicontinuity NameCert obligations)**.** *For every accepted* Demicontinuity$^{\uparrow}$ *carrier $D = (B, W, M, R, A, S, H, C, P, N)$, the local* NameCert$_{\text{Demicontinuity}^{\uparrow}}$ *surface consists exactly of carrier admission for the Banach source row, weak-input row, strong-output metric row, real scalar seal, displayed nonlinear action row, demicontinuity stability row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row.*

Proof. Project the carrier of Definition 7985.1. The analytic rows are exactly B, W, M, R, A, S: source admission, weak-input observation, strong-output metric readback, real scalar sealing, the nonlinear action window, and the handoff stability ledger.

The handoff is finite. A consumer first reads the weak-input budget and scalar tests from W, R, then reads the requested strong-output radius from M, and finally checks the displayed comparison stored in S for the action row A.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since compactness, selected subsequences, maximality, quotient graph equality, input norm convergence, and ambient weak-to-strong theorems are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 7985.3 (Demicontinuity weak-to-strong handoff)**.** *Every* BanachSpace$^{\uparrow}$, WeakConvergenceHilbert$^{\uparrow}$, MintyBrowderMonotoneOperator$^{\uparrow}$, Real$^{\uparrow}$, *or* Met$^{\uparrow}$ *consumer of an accepted* Demicontinuity$^{\uparrow}$ *packet reads the demicontinuity witness only through the finite route*

$$\mathsf{BanachSpace}^{\uparrow}, \mathsf{WeakConvergenceHilbert}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto A, S \longmapsto \mathsf{Met}^{\uparrow}$$

together with H, C, P, N. The route exports weak-input tests and strong-output metric control for the displayed action, not compactness, a selected weak limit, maximal-monotone closure, input norm convergence, or an ambient strong-convergence theorem.

Proof. Start with the source and weak-input rows. The Banach row B provides the accepted domain carrier, while W and R provide only the displayed scalar tests and real tolerance values used to recognize a weak-input request.

Read the action and stability rows next. The action row A supplies the finite operator window, and S records the comparison from the accepted weak-input budget to the requested strong-output metric radius.

Finally pass through M, H, C, P, N. The metric row is the only strong-output interface, while transport, replay, provenance, and local naming preserve the same finite handoff without adding compactness, selected limits, maximality, quotient graph equality, input norm convergence, or a host convergence theorem. □

Falsifiable prediction: An accepted $\mathsf{Demicontinuity}^{\uparrow}$ read is refuted if a nonlinear-analysis consumer exports a strong-output conclusion without displaying the $\mathsf{BanachSpace}^{\uparrow}$ source row, weak-input tests through $\mathsf{WeakConvergenceHilbert}^{\uparrow}$ or sibling Banach weak rows, the $\mathsf{Real}^{\uparrow}$ scalar seal, the $\mathsf{Met}^{\uparrow}$ strong-output radius, the action row, the stability ledger, transport, replay, provenance, and local naming.

Independence witness: banach-space, weak-convergence-hilbert, minty-browder-monotone-operator, real, metric-space: none alone is bijective with $\mathsf{Demicontinuity}^{\uparrow}$ because the packet jointly carries a Banach source, weak-input observations, real scalar budgets, an action row, strong metric output control, a finite stability ledger, transport, replay, provenance, and local NameCert while refusing compactness, selected weak limits, maximality, and input norm convergence.

Closure status for $\mathsf{NameCert}_{\mathsf{Demicontinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{Demicontinuity}^{\uparrow}$ packet is generated from a Banach source row, weak-input observation rows, Real scalar seals, a strong-output MetricSpace row, a nonlinear action row, a demicontinuity stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Demicontinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7985.1, Definition 7985.2, and Definition 7985.3 seed the finite weak-input and strong-output handoff certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Demicontinuity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, compactness, selected weak subsequences, maximal monotonicity, quotient graph equality, input norm convergence, or ambient weak-to-strong convergence.

Upgrade path: Obligation closure requires checked carrier admission, weak-input stability, strong-output metric exactness, action ledger transport, replay, provenance, and local naming for BEDC.Derived.DemicontinuityUp.

Chapter 7986

A Concrete Naming Certificate for $\mathsf{CauchyConvergenceSpace}^{\uparrow}$

Following Beattie and Butzmann's convergence-space treatment, the $\mathsf{CauchyConvergenceSpace}^{\uparrow}$ packet records the finite naming surface by which Cauchy filter data, regular rational tails, and real-name readback travel toward completion-facing consumers. It sits over the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the completion-existence route of chapter 5721. The packet names convergence as displayed BEDC data; it does not identify quotient limits, choose subsequences, or import open-cover compactness.

Definition 7986.1 (Cauchy convergence space carrier)**.** *A* $\mathsf{CauchyConvergenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, B, T, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the certified-points row, recording the finite point names and their local classifier data.*
2. *B is the Cauchy-filter basis row, recording the finite basis requests available to convergence consumers.*
3. *T is the regular tail and modulus row, recording* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback bounds for the displayed basis requests.*
4. *L is the candidate limit real-name row, recording the* $\mathsf{Real}^{\uparrow}$ *seal reached only after B and T have been displayed.*
5. *H records componentwise* hsame *transport for certified points, basis requests, regular tail data, candidate limit names, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from point rows and Cauchy-filter basis rows through regular tail readback to the candidate* $\mathsf{Real}^{\uparrow}$ *seal.*
7. *P is the* Pkg *provenance over* $\mathsf{CauchyConvergenceSpace}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletionExistence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient limit classes, choice-selected subsequences, host equality of limits, open-cover compactness, or ambient completeness.

Theorem 7986.2 (Cauchy convergence space NameCert obligations)**.** *For every accepted* CauchyConvergenceSpace *carrier* $G = (X, B, T, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyConvergenceSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier stability for certified points and basis requests, Cauchy-basis transport, regular-tail compatibility, completion readback through the candidate* $\mathsf{Real}^{\uparrow}$ *seal, ledger exactness through* hsame *and* Cont*, package provenance, and local naming. The certificate refuses quotient limit classes, choice-selected subsequences, host equality of limits, open-cover compactness, and ambient completeness.*

Proof. Project the carrier of Definition 7986.1. The rows display certified points, a Cauchy-filter basis, regular tail and modulus data, a candidate real-name limit, transport, replay, provenance, and local naming.

Read the convergence rows in order. The basis row B is attached to the certified point row X, the regular tail row T supplies the finite $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, and the candidate row L is available only after those rows have been inspected.

The structural rows preserve the same route. Componentwise hsame transport and displayed Cont replay keep the basis, tail, and candidate-limit rows on the same packet, while P and N source and name the packet.

Since the carrier contains no quotient-limit coordinate, selected-subsequence coordinate, host-equality oracle, open-cover compactness row, or ambient-completeness theorem, the displayed rows exhaust the local NameCert surface. □

Theorem 7986.3 (Cauchy convergence space real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or* MetricCompletionExistence *facing consumer of an accepted* $\mathsf{CauchyConvergenceSpace}^{\uparrow}$ *carrier receives only finite regular-Cauchy convergence data: certified points, Cauchy-filter basis rows, regular tail and modulus readbacks, the candidate real-name seal, componentwise transport, displayed replay, package provenance, and local naming. The handoff exports no quotient limit, choice-selected subsequence, host equality of limits, open-cover compactness claim, or ambient completeness claim.*

Proof. Start with $G = (X, B, T, L, H, C, P, N)$. The only route from the Cauchy-basis data to the candidate real name passes through the finite basis row B and the regular tail row T before L can be read.

Apply Definition 7986.2. It identifies the carrier admission, classifier stability, Cauchy-basis transport, regular-tail compatibility, completion readback, and ledger exactness rows that a consumer must preserve.

The downstream handoff is therefore finite. A $\mathsf{Real}^{\uparrow}$ consumer reads the candidate seal only after regular Cauchy data have been displayed, and a $\mathsf{MetricCompletionExistence}^{\uparrow}$ consumer receives the same displayed route as completion-facing evidence.

The excluded objects have no carrier coordinate. Thus the handoff cannot supply quotient limits, selected subsequences, host equality of limits, open-cover compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyConvergenceSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyConvergenceSpace}^{\uparrow}$ packet is generated from certified point rows, a Cauchy-filter basis, regular tail and modulus readback, a candidate Real name, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyConvergenceSpace}^{\uparrow}}$, seed)

Scope closed: Definition 7986.1, Definition 7986.2, and Definition 7986.3 seed the finite Cauchy-convergence handoff from filter bases and regular Cauchy readback to Real and metric-completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyConvergenceSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient limits, choice-selected subsequences, host equality of limits, open-cover compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, Cauchy-basis transport, regular-tail compatibility, completion readback, ledger exactness, provenance, and local naming for BEDC.Derived.CauchyConvergenceSpaceUp

Chapter 7987

A Concrete Naming Certificate for $\mathsf{BoundedMonotoneSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ packet names the finite data by which a monotone real sequence and its displayed bounds are read by Real-and-Completion consumers. It sits after the finite stream interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the apartness-facing real comparison route of chapter 304. The packet records bounded monotonicity as a NameCert surface, not as a completeness theorem or a selected limit.

Definition 7987.1 (Bounded monotone sequence carrier)**.** *A* $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, R, M, U, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row naming the finite observation schedule for the sequence.*
2. *W is the family of finite stream windows inspected by Real and Completion consumers.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison-tail ledger attached to those windows.*
4. *M is the monotone-step row, recording the displayed adjacent or tail comparison used by the sequence direction.*
5. *U is the upper-bound row, read through the same regular-rational tail ledger.*
6. *L is the lower-bound row, retained for apartness and interval-facing consumers even when the monotone direction only needs one bound.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the sequence values and bound endpoints.*
8. *H records componentwise* hsame *transport for the stream windows, regular tails, monotone rows, bound rows, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from stream-window reads through regular-rational comparison tails and then to the Real seal rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BoundedMonotoneSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected supremum, a convergent subsequence, Bolzano–Weierstrass, quotient real equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 7987.2 (Bounded monotone sequence NameCert obligations)**.** *For every accepted* BoundedMonotoneSequ *carrier* $B = (S, W, R, M, U, L, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSequence}^{\uparrow}}$ *surface consists exactly of carrier admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *comparison-tail readback, monotone-step exposure, upper-bound and lower-bound row exposure, terminal* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7987.1. The sequence is visible only through the stream row S and the finite windows W, so no consumer can inspect an unbounded host sequence directly.

The comparison data are the regular-rational tail row R together with the monotone-step row M and the bound rows U, L. These rows expose bounded monotonicity before any Real endpoint is read.

The Real seal row E is downstream from the displayed stream and regular-tail data. The structural rows H, C, P, N transport, replay, source, and name the same route, so the listed rows exhaust the local certificate obligations. □

Theorem 7987.3 (Bounded monotone sequence comparison-tail route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ *packet reads the route*

$$S, W \longmapsto R \longmapsto M, U, L \longmapsto E$$

together with H, C, P, N*. The route may expose bounded monotone comparison data to completion-facing consumers, but it does not export a limit, a least upper bound, a convergent subsequence, or a Bolzano–Weierstrass conclusion.*

Proof. Begin with the finite-window stage. The only sequence observations are the windows W named by the $\mathsf{StreamName}^{\uparrow}$ row S.

Next read the $\mathsf{RegSeqRat}^{\uparrow}$ comparison tails. The monotone row M and the bound rows U, L are meaningful only after those regular-rational tails have been displayed.

Finally the $\mathsf{Real}^{\uparrow}$ seal row E records the sequence values and bound endpoints reached by the same tail route. Since no carrier coordinate names a limit, supremum, subsequence selection, or compactness principle, the consumer obtains only the bounded-monotone packet surface. □

Falsifiable prediction: An accepted $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ read is refuted if the monotone row M is preserved while the StreamName windows W or RegSeqRat comparison tails R are removed.

Independence witness: streamname, regseqrat, real, apartnessreal: the stream packet supplies finite windows without monotone and bound rows; the regular rational route supplies tail readback without the Real seal; the Real packet supplies endpoint seals without sequence monotonicity; and apartness-facing comparison packets do not jointly carry bounded monotone sequence windows.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedMonotoneSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat comparison tails, monotone-step rows, upper and lower bound rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedMonotoneSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7987.1, Definition 7987.2, and Definition 7987.3 seed the bounded monotone sequence surface over StreamName, RegSeqRat, RealUp, apartness-facing comparison, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedMonotoneSequence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, selected limits, least upper bounds, convergent subsequences, Bolzano–Weierstrass, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, comparison-tail read-back, monotone-step exposure, bound-row exposure, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BoundedMonotoneSequenceUp.

Chapter 7988

A Concrete Naming Certificate for $\mathsf{CollectionwiseNormal}^{\uparrow}$

Following Engelking and Kelley on collectionwise normal spaces, the $\mathsf{CollectionwiseNormal}^{\uparrow}$ packet records the finite BEDC surface in which a displayed discrete family of closed rows receives pairwise disjoint open neighborhoods and a locally finite refinement ledger. It sits above the closed-pair separation route of chapter 1866, beside the locally finite cover discipline of chapter 1963, and before separation-function consumers such as **??**. The packet strengthens the normal-space and paracompact lattice by naming the finite familywise separation route; it does not import arbitrary choice of neighborhoods, host powersets, open-cover compactness, partition-of-unity weights, or an ambient point-set theorem.

Definition 7988.1 (Collectionwise normal carrier)**.** *A* $\mathsf{CollectionwiseNormal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, N, D, O, L, P, U, H, C, Z)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row on which the closed-family, open-neighborhood, and cover-refinement observations are read.*
2. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *separation row, exposing the closed-pair route used for each displayed member of the family.*
3. *D is the discrete closed-family ledger, recording the finite family window and the local discreteness observations visible to the packet.*
4. *O is the disjoint open-neighborhood ledger, assigning to every displayed closed row in D an open row over T and recording pairwise disjointness inside the finite window.*
5. *L is the locally finite refinement ledger, read through the paracompact cover surface of chapter 1963.*
6. *P is the paracompact handoff row that keeps locally finite refinement data visible without selecting a subcover from an arbitrary host family.*
7. *U is the* $\mathsf{UrysohnLemma}^{\uparrow}$ *handoff row, available only after the displayed normal-space and disjoint-neighborhood rows have been read.*
8. *H records componentwise* hsame *transport for the topology, normal-space, discrete-family, disjoint-neighborhood, locally finite refinement, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from the discrete closed-family request through the normal-space route, disjoint open-neighborhood ledger, locally finite refinement ledger, paracompact handoff, and Urysohn handoff.*

10. *Z is the local* $\mathsf{NameCert}_{\mathsf{CollectionwiseNormal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, N, D, O, L, P, U, H, C, Z$. It has no coordinate for host-indexed families, selected complements, arbitrary choice of separating neighborhoods, open-cover compactness, quotient topology equality, or partition-of-unity data.

Lean4 (statement) `BEDC.Derived.CollectionwiseNormalUp`

Theorem 7988.2 (Collectionwise normal NameCert obligations)**.** *For every accepted* $\mathsf{CollectionwiseNormal}^{\uparrow}$ *carrier $Q = (T, N, D, O, L, P, U, H, C, Z)$, the local* $\mathsf{NameCert}_{\mathsf{CollectionwiseNormal}^{\uparrow}}$ *surface consists exactly of topology-source admission, normal-space separation exposure, discrete closed-family exposure, disjoint open-neighborhood exactness, locally finite refinement exposure, paracompact handoff, Urysohn handoff, componentwise* hsame *transport, displayed* Cont *replay, and local naming. No obligation is discharged by a selected family of host neighborhoods, arbitrary open-cover compactness, a host powerset, quotient topology equality, or partition-of-unity weights.*

Proof. Project the carrier of Definition 7988.1. The rows $T, N, D, O, L, P, U, H, C, Z$ are the whole local surface.

The familywise separation rows are N, D, O. The normal-space route supplies closed-pair separation data, the discrete-family row fixes the finite family window, and the open-neighborhood ledger records the disjoint neighborhoods visible to the packet.

The refinement and handoff rows are L, P, U. They route locally finite cover data through the paracompact sibling and expose the Urysohn-facing handoff only after the separation rows are visible.

Transport, replay, and local naming are exhausted by H, C, Z. Since none of the excluded host objects is a carrier coordinate, the listed rows are exactly the NameCert obligations. □

Theorem 7988.3 (Collectionwise normal paracompact handoff)**.** *Every locally finite refinement read exported by an accepted* $\mathsf{CollectionwiseNormal}^{\uparrow}$ *packet must pass through the displayed route*

$$\mathsf{NormalSpace}^{\uparrow},\ D,\ O \longmapsto \mathsf{Paracompact}^{\uparrow} \longmapsto \mathsf{UrysohnLemma}^{\uparrow}.$$

The route exposes the closed-family separation data, disjoint open-neighborhood rows, paracompact locally finite refinement ledger, and Urysohn-facing handoff as finite BEDC rows; it does not select arbitrary subcovers, choose host neighborhoods, or import open-cover compactness as a primitive.

Proof. Start with the normal-space and discrete-family rows. They determine which displayed closed rows are being separated and keep the family window visible before any refinement read occurs.

Read the disjoint open-neighborhood ledger next. It supplies only the finite neighborhood rows stored in the carrier and does not choose a host family of separators.

The locally finite refinement row then passes through the paracompact handoff. A separation-function consumer may continue to the Urysohn sibling only after the normal-space, disjoint-neighborhood, and refinement rows have been displayed.

The structural rows preserve this same order under transport and replay. Because no coordinate stores arbitrary subcovers, selected neighborhoods, or open-cover compactness, the handoff remains a finite BEDC dependency route. □

Falsifiable prediction: An accepted $\mathsf{CollectionwiseNormal}^{\uparrow}$ read is refuted if it exports collectionwise separation without displaying the TopologyUp source row, NormalSpaceUp separation row, discrete closed-family ledger, disjoint open-neighborhood ledger, locally finite refinement row, ParacompactUp handoff, UrysohnLemmaUp handoff, hsame transport, Cont replay, and local NameCert row.

Independence witness: normalspace, paracompact, urysohn-lemma: $\mathsf{CollectionwiseNormal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a discrete closed-family ledger, disjoint open-neighborhood ledger, locally finite refinement handoff, paracompact route, Urysohn route, transport, replay, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CollectionwiseNormal}^{\uparrow}}$.

Constructive story: A $\mathsf{CollectionwiseNormal}^{\uparrow}$ packet is generated from a TopologyUp source row, NormalSpaceUp separation row, discrete closed-family ledger, disjoint open-neighborhood ledger, locally finite refinement row, ParacompactUp handoff, UrysohnLemmaUp handoff, componentwise hsame transport, displayed Cont replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CollectionwiseNormal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7988.1, Definition 7988.2, and Definition 7988.3 seed the finite collectionwise normal separation surface over normal-space, paracompact, and Urysohn rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CollectionwiseNormal}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CollectionwiseNormalUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary host-indexed collectionwise normality, selected complements, open-cover compactness, partition-of-unity data, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, discrete-family exposure, disjoint-neighborhood exactness, locally finite refinement handoff, paracompact route stability, Urysohn handoff discipline, transport, replay, provenance, and local naming for BEDC.Derived.CollectionwiseNormalUp.

Chapter 7989

A Concrete Naming Certificate for MetaCICParallelDiamondSelector$^{\uparrow}$

The MetaCICParallelDiamondSelector$^{\uparrow}$ packet realizes the closed parallel-diamond selector frontier named in chapter 9386 and section 9386.3 as finite MetaCIC NameCert data. It sits beside the confluence audit packet of chapter 735, the decidability boundary of chapter 749, the normalization frontier of chapter 892, the residual-diamond witness of chapter 7219, and the source confluence frontier of chapter 9386. The packet names a selector ledger for one closed parallel-diamond candidate and its residual-substitution compatibility boundary; it does not assert arbitrary closed confluence, unrestricted residual substitution, subject reduction, quotient syntax equality, or a hidden evaluator oracle.

Definition 7989.1 (MetaCIC parallel diamond selector carrier)**.** *A* MetaCICParallelDiamondSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, R, D, K, L, O, G, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-window row, recording the bounded closed MetaCIC source and type window under inspection.*
2. *R is the residual-pair frontier row, naming the two parallel residual branches whose diamond candidate is being selected.*
3. *D is the closed parallel-diamond candidate row, recording the displayed join candidate and its finite endpoint window.*
4. *K is the residual-substitution compatibility boundary row consumed before the candidate can be read as diamond-facing data.*
5. *L is the selector ledger, recording the finite rule that chooses between accepted candidate rows and retained obstruction rows inside the displayed window.*
6. *O is the obstruction-retention row for the surrounding confluence frontier.*
7. *G is the TasteGate route row, recording that the proposed Lean path requires both* Nontrivial *and* FieldFaithful *instances before the selector can be checked as a genuine carrier rather than a smoke packet.*

8. *H stores componentwise* hsame *transport for the typed window, residual frontier, candidate row, compatibility boundary, selector ledger, obstruction row, TasteGate route, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the route*

$$T, R, K \longmapsto D, L \longmapsto O, G.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}$*, MetaCIC confluence audit data, decidability-boundary data, normalization-frontier data, residual-diamond witness data,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, D, K, L, O, G, H, C, P, N$. It has no coordinate for full confluence, unrestricted residual substitution compatibility, global subject reduction, quotient syntax equality, hidden evaluator state, or host-level Church–Rosser.

Lean4 (statement) `BEDC.Derived.MetaCICParallelDiamondSelectorUp`

Theorem 7989.2 (MetaCIC parallel diamond selector obligations)**.** *For every accepted* MetaCICParallelDiamondSel *carrier $S = (T, R, D, K, L, O, G, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}}$ *surface consists exactly of typed-window exposure, residual-pair frontier exposure, closed parallel-diamond candidate exposure, residual-substitution compatibility boundary exposure, selector-ledger exactness, obstruction retention, TasteGate route retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The analytic rows are T, R, D, K, L, O, G, and the rows H, C, P, N transport, replay, source, and name those rows.

The selector is boundary-sensitive. The typed window and residual frontier determine the candidate range, while the compatibility row K must be displayed before the diamond candidate D can be consumed.

The ledger row L records the finite selector decision, and the obstruction row O keeps the surrounding frontier visible. The TasteGate row G prevents the paper carrier from being read as a checked Lean gate until the required Nontrivial and FieldFaithful instances exist.

No further row is present. Thus full confluence, unrestricted substitution compatibility, subject reduction, quotient syntax equality, hidden evaluator state, and host Church–Rosser remain outside the local certificate. □

Theorem 7989.3 (MetaCIC parallel diamond selector frontier route)**.** *Every accepted* MetaCICParallelDiamondSele *selector read routes its closed parallel-diamond candidate through*

$$T, R, K \longmapsto D, L \longmapsto O, G.$$

The selector can be consumed by the MetaCIC confluence frontier only as a finite candidate-and-obstruction packet requiring later Nontrivial *and* FieldFaithful *TasteGate instances; it is not a proof of arbitrary closed parallel diamond, unrestricted residual substitution compatibility, or closed Church–Rosser.*

Proof. Read the typed closed window T and residual-pair frontier R first. These rows determine the bounded source and the two residual branches under inspection.

Next read the compatibility boundary K. The diamond candidate row D is downstream from this boundary, so a consumer cannot treat the selector as evidence-free residual substitution.

The selector ledger L then chooses inside the displayed finite candidate range, while O retains the open confluence frontier and G records the Lean TasteGate obligations. Transport through H, replay through C, provenance through P, and naming through N preserve the same route. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}$ read exposes metacic-confluenceauditpacket, metacicdecidableboundary, metacicnormalizationfrontier, metacicparallel_diamond_fronti metacic-residual-diamond-witness, typed-window, residual-frontier, residual-substitution boundary, selector ledger, obstruction retention, TasteGate route, transport, replay, provenance, and local NameCert rows before any selector handoff is consumed.

Independence witness: metacicconfluenceauditpacket, metacicdecidableboundary, metacicnormalizationfrontier, metacicparallel_diamond_frontier, metacic-residual-diamond-witness: MetaCICParallelDiamond is not bijective to any listed sibling because it jointly carries a typed closed-window row, residual-pair frontier, closed parallel-diamond candidate, residual-substitution compatibility boundary, selector ledger, obstruction retention, TasteGate route, transport, replay, provenance, and local naming.

The proposed Lean path for $\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}$ requires Nontrivial and FieldFaithful TasteGate instances for the typed window, residual frontier, diamond candidate, residual-substitution boundary, selector ledger, and obstruction-retention rows before the selector can be checked as more than carrier syntax.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}$ packet is generated from a typed closed-window row, residual-pair frontier row, closed parallel-diamond candidate row, residual-substitution compatibility boundary row, selector ledger, obstruction-retention row, TasteGate route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7989.1, Definition 7989.2, and Definition 7989.3 seed one finite selector packet for the MetaCIC closed parallel-diamond frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICParallelDiamondSelector}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MetaCICParallelDiamondSelectorUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary closed parallel diamond, unrestricted residual substitution compatibility, closed Church–Rosser, subject reduction, quotient syntax equality, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked typed-window exposure, residual-pair frontier exposure, diamond-candidate exposure, residual-substitution boundary exposure, selector-ledger exactness, obstruction retention, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICParallelDiamondSelectorUp.

Chapter 7990

A Concrete Naming Certificate for $\mathsf{BarRecursiveModulus}^{\uparrow}$

Following Bishop and Bridges on bars, spreads, and moduli in constructive analysis, the $\mathsf{BarRecursiveModulus}^{\uparrow}$ packet records the finite modulus row by which a bar-recursive inspection can be handed to the L10 Real and Completion route. It sits after the finite stream surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the bar-recursive source of chapter 5532, and the fan-theorem bar-modulus sibling of chapter 6151. The packet names a displayed modulus extracted from finite bar-recursive rows; it is not a quotient-stream construction, selected limit operator, countable-choice principle, ambient $\mathsf{Real}^{\uparrow}$ completeness theorem, Lean verification, or bridge certificate.

Definition 7990.1 (Bar-recursive modulus carrier)**.** *A* $\mathsf{BarRecursiveModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, Q, R, E, H, C, P, N)$$

with the following rows:

1. *B is the bar-recursive source row, carrying the displayed barred-spread tree, accepted branch prefix, and recursion ledger read from chapter 5532.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that records which stream prefixes are inspected before the modulus is read.*
3. *Q is the modulus row, storing a unary bound, the finite bar level that justifies it, and the local stopping evidence attached to the accepted branch prefix.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, repacking the bounded stream windows as regular rational finite data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the same bounded windows and regular rational witnesses.*
6. *H records componentwise* hsame *transport for the bar-recursive source, stream windows, modulus row, regular rational readback, real seal, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay through the rows B, S, Q, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BarRecursiveModulus}^{\uparrow}$, $\mathsf{BarRecursion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FanTheoremBarModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, S, Q, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, ambient real completeness, or bridge checking.

Theorem 7990.2 (Bar-recursive modulus NameCert obligations)**.** *For every accepted* $\mathsf{BarRecursiveModulus}^{\uparrow}$ *carrier*

$$M = (B, S, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}$ *surface consists exactly of bar-recursive source admission for B, finite stream-window admission for S, modulus-bound admission for Q, regular rational readback for R, terminal Real sealing for E, componentwise* hsame *transport for H, displayed replay for C, provenance for P, and local naming for N.*

Proof. Project the carrier of Definition 7990.1. The rows B, S, Q expose the bar-recursive source, the finite stream windows, and the bound justified by the displayed bar level.

The readback rows R and E consume only that bounded window data. The regular rational row repacks the inspected prefixes, and the Real row seals the same finite evidence.

The structural rows H, C, P, N transport, replay, source, and name the packet without adding a quotient stream, selected limit, countable-choice schedule, ambient completeness theorem, Lean verification, or bridge certificate. Hence the listed rows exhaust the local NameCert surface. □

Theorem 7990.3 (Bar-recursive modulus RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *consumer of an accepted* $\mathsf{BarRecursiveModulus}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{BarRecursion}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{BarRecursiveModulus}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}$$

through B, S, Q, R, H, C, P, N before exporting a regular rational window. The handoff supplies a bounded prefix schedule and regular rational readback only; it does not identify quotient streams, choose a completed branch, or import countable choice.

Proof. Start with the bar-recursive source row B. It displays the barred-spread tree, accepted branch prefix, and recursion ledger before any modulus row is available.

Read the finite stream row S and modulus row Q. Together they bind a concrete prefix schedule to a unary bound justified by the displayed bar level.

Only after those rows are present may the handoff row R be read as $\mathsf{RegSeqRat}^{\uparrow}$ data. The remaining rows H, C, P, N preserve the same finite route, so the consumer receives a regular rational window rather than a selected limit or quotient stream. □

Theorem 7990.4 (Bar-recursive modulus Real-seal boundary)**.** *Every Real-facing consumer of an accepted* $\mathsf{BarRecursiveModulus}^{\uparrow}$ *packet reaches the terminal seal through*

$$\mathsf{BarRecursion}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

with the modulus row Q binding the finite prefix bound before the $\mathsf{Real}^{\uparrow}$ *row E is read. The boundary exports only the displayed real-name seal for those finite windows, not ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected limits, quotient stream equality, countable choice, Lean verification, or bridge checking.*

Proof. The carrier exposes the source, window, and modulus rows first. The bar-recursive source B and stream schedule S determine the inspected prefixes, while Q records the bound justified by the bar level.

The readback row R is then the sole regular rational route attached to those prefixes. The terminal row E seals exactly that readback as $\mathsf{Real}^{\uparrow}$ data.

Since no carrier coordinate stores quotient equality, a selected limit, countable choice, ambient completeness, Lean verification, or bridge data, any Real-facing consumer remains inside the displayed finite boundary. □

Falsifiable prediction: Every $\mathsf{BarRecursiveModulus}^{\uparrow}$ read factors through a bar-recursive source row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a displayed modulus row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ sealing, componentwise hsame, displayed Cont, Pkg, and a local $\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}$ row.

Independence witness: bar-recursion, streamname, regseqrat, real, fan-theorem-bar-modulus: $\mathsf{BarRecursiveModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds bar-recursive source data, finite stream windows, a modulus bound, regular rational readback, a real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BarRecursiveModulus}^{\uparrow}$ packet is generated from a bar-recursive source row, finite stream windows, a displayed modulus bound, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7990.1, Definition 7990.2, Definition 7990.3, and Definition 7990.4 seed the finite bar-recursive modulus route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BarRecursiveModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BarRecursiveModulus}^{\uparrow}$.

Upgrade path: Obligation closure requires checked bar-recursive source admission, finite stream-window admission, modulus-bound exactness, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BarRecursiveModulusUp.

Chapter 7991

A Concrete Naming Certificate for $\mathsf{PrincipalIdealDomain}^{\uparrow}$

Following Atiyah–Macdonald and Lang, the $\mathsf{PrincipalIdealDomain}^{\uparrow}$ packet records the traditional principal-ideal-domain interface as finite BEDC NameCert data over a displayed commutative ring carrier. It sits after the algebraic operation rows of chapter 43 and chapter 44, reads ideal membership through chapter 81, accepts Euclidean-domain evidence from chapter 7053 as one sufficient producer, and supplies the principal-ideal matrix surface consumed by chapter 2262. The packet names finite ideal-generator ledgers; it does not claim quotient ideals, selected generators by choice, unique-factorization classification, or a Euclidean algorithm.

Definition 7991.1 (Principal ideal domain carrier)**.** *A* $\mathsf{PrincipalIdealDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (R, C, I, G, E, H, K, Q, N)$$

with the following displayed rows:

1. *R is the underlying* $\mathsf{Ring}^{\uparrow}$ *row for addition, multiplication, zero, one, negation, and distributivity;*
2. *C is the* $\mathsf{CommRing}^{\uparrow}$ *row making multiplication commute on the same displayed carrier;*
3. *I is the finite* $\mathsf{Ideal}^{\uparrow}$ *membership and absorption surface for the ideal under inspection;*
4. *G is the principal-generator ledger, displaying a generator row and the two containment reads between the ideal row and the generated principal row;*
5. *E is the optional* $\mathsf{EuclideanDomain}^{\uparrow}$ *producer row when the packet is supplied through division-with-remainder evidence;*
6. *H records componentwise* hsame *transport for the ring, commutative-ring, ideal, generator, producer, provenance, and local naming rows;*
7. *K records displayed* Cont *routes for ideal membership, generator readback, containment in both directions, and downstream matrix consumers;*
8. *Q is the* Pkg *provenance over* $\mathsf{PrincipalIdealDomain}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{CommRing}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{EuclideanDomain}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PrincipalIdealDomain}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through the displayed rows $R, C, I, G, E, H, K, Q, N$.

Theorem 7991.2 (Principal ideal domain NameCert obligations)**.** *Every accepted* $\mathsf{PrincipalIdealDomain}^{\uparrow}$ *packet exposes exactly the rows*

$$R, C, I, G, E, H, K, Q, N$$

of Definition 7991.1. The local $\mathsf{NameCert}_{\mathsf{PrincipalIdealDomain}^{\uparrow}}$ *surface consists of ring-source admission, commutative multiplication, ideal membership and absorption, a displayed principal-generator ledger, optional Euclidean-domain producer evidence, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. It has no coordinate for quotient ideals, selected generators by choice, unique-factorization classification, or a Euclidean algorithm.*

Proof. Project the carrier of Definition 7991.1. The algebraic source is read through R and C, while ideal membership and absorption are read through I.

The generator ledger G supplies the only principal-ideal assertion available to the packet: the named generator row and the two displayed containment reads between the ideal and the principal row it generates.

The optional producer row E records that a $\mathsf{EuclideanDomain}^{\uparrow}$ packet can supply this surface, but it is not itself the Euclidean algorithm and does not add quotient ideal data. Transport through H, replay through K, provenance through Q, and local naming through N preserve the same finite row family, so the listed rows exhaust the NameCert obligations. □

Theorem 7991.3 (Principal ideal domain ideal-generator ledger)**.** *For every accepted* $\mathsf{PrincipalIdealDomain}^{\uparrow}$ *packet, an ideal-facing consumer may read a generator only by passing through*

$$\mathsf{Ring}^{\uparrow},\ \mathsf{CommRing}^{\uparrow},\ \mathsf{Ideal}^{\uparrow},\ G,\ H,\ K,\ Q,\ N.$$

The $\mathsf{SmithNormalForm}^{\uparrow}$ *consumer receives this ledger as a principal-ideal matrix input, not as a quotient module, selected basis, chosen generator function, unique-factorization classification, or Euclidean algorithm. If the generator row is supplied by a* $\mathsf{EuclideanDomain}^{\uparrow}$ *producer, that producer is recorded in* E *and remains a dependency row rather than an ambient division service.*

Proof. Start with the ideal row I and the generator ledger G in the carrier. The containment reads in G are the only route from ideal membership to a principal row.

Next use the structural rows. Componentwise hsame transport through H keeps the ring, commutative-ring, ideal, and generator endpoints aligned; Cont replay through K records the finite readback route; and Q, N provide provenance and local naming.

Finally read the Smith-normal-form edge through chapter 2262. A matrix consumer may use the principal-ideal ledger only after the displayed algebra and ideal rows have been exposed, so the route exports generator bookkeeping without adding quotient ideals, a selected generator function, unique-factorization classification, or Euclidean algorithm access. □

Closure status for $\mathsf{NameCert}_{\mathsf{PrincipalIdealDomain}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PrincipalIdealDomain}^{\uparrow}$ packet is generated from a ring row, commutative-ring row, ideal membership and absorption row, displayed generator ledger, optional Euclidean-domain producer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PrincipalIdealDomain}^{\uparrow}}$, seed)

Scope closed: Definition 7991.1, Definition 7991.2, and Definition 7991.3 name the finite carrier and ideal-generator surface for principal ideal domain consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PrincipalIdealDomain}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient ideals, selected generators by choice, unique-factorization classification, Euclidean algorithm access, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, generator-ledger exactness, transport stability, route stability, and SmithNormalForm-facing nonescape for the same finite packet.

Chapter 7992

A Concrete Naming Certificate for $\mathsf{CauchyModulusSum}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyModulusSum}^{\uparrow}$ packet records the finite data needed to add two regular Cauchy modulus presentations before any quotient sequence equality, selected representative, or ambient completeness principle is available. It sits over the two $\mathsf{CauchyModulus}^{\uparrow}$ source rows, the finite observation schedules of chapter 126, the dyadic tolerance ledgers of chapter 291, the regular rational readback route of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names finite addition of modulus-controlled regular data; it is not a construction of quotient reals, countable-choice representatives, or a host-level addition theorem.

Definition 7992.1 (Cauchy modulus sum carrier)**.** *A* $\mathsf{CauchyModulusSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M_0, M_1, W_0, W_1, D_0, D_1, D_+, R_0, R_1, R_+, E, H, C, P, N)$$

with the following displayed rows:

1. *M_0 and M_1 are the two* $\mathsf{CauchyModulus}^{\uparrow}$ *source rows whose regular Cauchy data are being added.*
2. *W_0 and W_1 are* $\mathsf{StreamName}^{\uparrow}$ *schedule rows selecting the finite source windows consumed at the requested dyadic tolerance.*
3. *D_0 and D_1 are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers for the two summands, while D_+ is the dyadic ledger for the output tolerance and the finite addition budget.*
4. *R_0 and R_1 are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for the two summands, and R_+ is the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the summed rational values.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the source modulus rows, finite schedules, dyadic ledgers, and regular rational readbacks have been displayed.*
6. *H records componentwise* hsame *transport for the two modulus rows, schedule rows, dyadic ledgers, readback rows, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from M_0, M_1 through $W_0, W_1, D_0, D_1, D_+, R_0, R_1, R_+$ to the Real-facing seal E.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusSum}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M_0, M_1, W_0, W_1, D_0, D_1, D_+, R_0, R_1, R_+, E, H, C, P, N$. *It has no coordinate for quotient sequence equality, selected representatives, countable choice over moduli, host real equality, unbounded limit selection, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7992.2 (Cauchy modulus sum NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusSum}^{\uparrow}$ *carrier*

$$S = (M_0, M_1, W_0, W_1, D_0, D_1, D_+, R_0, R_1, R_+, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyModulusSum}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{CauchyModulus}^{\uparrow}$ *source rows, finite* $\mathsf{StreamName}^{\uparrow}$ *schedule exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting for the summands and sum,* $\mathsf{RegSeqRat}^{\uparrow}$ *source readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *summed readback, downstream* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and refusal of quotient sequence equality, selected representatives, countable-choice modulus selection, host real equality, unbounded limit selection, and ambient completeness.*

Proof. Project the carrier of Definition 7992.1. The accepted packet displays exactly the two source modulus rows, the two finite schedule rows, the three dyadic ledgers, the two source readbacks, the summed readback, and the terminal Real seal.

The addition read is then forced through the displayed finite route. The requested tolerance is decoded by D_+, the summand budgets are read through D_0, D_1, and the inspected source values are exposed only through W_0, W_1, R_0, R_1 before the summed readback row R_+ is available.

Transport and replay preserve the same rows. The componentwise hsame row H moves the listed coordinates together, while C replays the continuation from the two modulus rows through the schedules, dyadic ledgers, and rational readbacks to the seal E.

Finally inspect P, N. Provenance and local naming record only the displayed carrier rows, so no public obligation can call on quotient sequence equality, selected representatives, countable choice, host real equality, unbounded limit selection, or ambient completeness. □

Falsifiable prediction: Deleting either source $\mathsf{CauchyModulus}^{\uparrow}$ row or the output dyadic ledger D_+ makes the summed $\mathsf{RegSeqRat}^{\uparrow}$ readback indistinguishable from an unbudgeted rational addition request; the accepted carrier must reject that packet because the finite tolerance route can no longer be reconstructed.

Independence witness: cauchymodulus, streamname, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{CauchyModulusSum}^{\uparrow}$ because this packet jointly carries two modulus source rows, two finite schedules, summand and sum dyadic ledgers, source readbacks, summed readback, terminal Real seal, transport, replay, provenance, and local naming for the same finite addition route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusSum}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyModulusSum}^{\uparrow}$ packet is generated from two CauchyModulus source rows, StreamName schedule rows, DyadicRatCore tolerance ledgers for the summands and sum, RegSeqRat source and sum readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyModulusSum}^{\uparrow}}$, seed)

Scope closed: Definition 7992.1 and Definition 7992.2 seed the finite addition route for regular Cauchy modulus data through schedule, tolerance, readback, and Real-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyModulusSum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient sequence equality, selected representatives, countable-choice modulus selection, host real equality, unbounded limit selection, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source modulus exposure, schedule stability, dyadic tolerance accounting, summed RegSeqRat readback, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyModulusSumUp.

Chapter 7993

A Concrete Naming Certificate for $\mathsf{CauchyExponential}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CauchyExponential}^{\uparrow}$ packet records the classical exponential Cauchy series as a finite real-name constructor for the L10 Real and Completion route. It sits over the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the product-completion route of chapter 3797. The packet names a displayed exponential-series constructor; it does not import a host exponential function, quotient real equality, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 7993.1 (CauchyExponential carrier)**.** *A* $\mathsf{CauchyExponential}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, W, A, F, D, Q, S, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Real}^{\uparrow}$ *row whose exponential is being named through inspected finite windows.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *schedule selecting finitely many source and partial-sum windows.*
3. *A is the coefficient ledger for the factorial denominators of the exponential series, stored as rational and dyadic rows rather than as a host analytic function.*
4. *F is the finite partial-sum family for the Cauchy series $\sum_n X^n/n!$ over the displayed windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger bounding the tail and product-budget requests visible in the packet.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the partial sums.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal produced from the regular readback.*
8. *M is the* $\mathsf{CauchyProductCompletion}^{\uparrow}$ *handoff row used whenever a consumer asks for product compatibility of the series constructor.*
9. *H records componentwise* hsame *transport for source, windows, coefficients, partial sums, dyadic tolerance rows, regular readback, Real seal, product-completion handoff, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay along the same finite route.*

11. *P is the* Pkg *provenance over* $\mathsf{CauchyExponential}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyProductCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyExponential}^{\uparrow}}$ *row.*

The carrier stores no host exponential operator, no quotient equality of real names, no chosen limit of an infinite series, no unrestricted product algebra, no countable-choice schedule, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 7993.2 (CauchyExponential NameCert obligations)**.** *For every accepted* $\mathsf{CauchyExponential}^{\uparrow}$ *carrier* $E = (X, W, A, F, D, Q, S, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyExponential}^{\uparrow}}$ *surface consists exactly of carrier admission, source-window exposure, factorial coefficient accounting, finite partial-sum display, dyadic tail control, regular rational readback, terminal Real sealing, product-completion handoff, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 7993.1. The visible analytic data are the source row X, the window schedule W, the coefficient ledger A, the finite partial sums F, the dyadic tolerance row D, the regular readback Q, and the terminal seal S.

The coefficient and partial-sum rows are downstream of the finite windows. Thus a consumer first reads $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances before it can inspect any factorial denominator, power product, or partial-sum value.

The readback and seal rows keep the same route visible. The row Q is the $\mathsf{RegSeqRat}^{\uparrow}$ readback attached to the displayed partial sums, and S is the resulting $\mathsf{Real}^{\uparrow}$ seal; neither row selects a host limit or identifies quotient real names.

Finally read M, H, C, P, N. The product-completion handoff, transport, replay, provenance, and local name record only the displayed packet. Since no other coordinate exists, the NameCert surface cannot export a host exponential, chosen series limit, unrestricted product algebra, countable choice, or ambient Real completeness. □

Theorem 7993.3 (CauchyExponential Cauchy-product handoff)**.** *Every product-facing or completion-facing consumer of an accepted* $\mathsf{CauchyExponential}^{\uparrow}$ *packet must first read the source* $\mathsf{Real}^{\uparrow}$ *row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, factorial coefficient ledger, finite partial-sum family,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail budget,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before the* $\mathsf{CauchyProductCompletion}^{\uparrow}$ *handoff row is available. The handoff exports no host exponential, quotient real equality, selected series limit, unrestricted product algebra, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a product-facing read of the carrier in Definition 7993.1. The row M is present only as a handoff from the displayed series constructor, so it cannot be consumed before the source, window, coefficient, partial-sum, tolerance, readback, and seal rows have been opened.

The finite series route is ordered by the windows and tolerance ledger. The rows W, A, F, D expose exactly the finite Cauchy-series data needed by the consumer, while Q and S route that data through regular rational readback and the terminal Real seal.

Now use the sibling product-completion boundary of chapter 3797. That boundary accepts a product read only after displayed stream windows, dyadic observations, regular readback, and Real sealing remain visible.

Composing the two routes gives the stated handoff. Since both routes refuse host analytic functions, quotient real equality, selected limits, unrestricted product algebra, countable choice, and ambient Real completeness, the $\mathsf{CauchyExponential}^{\uparrow}$ product-facing read exports none of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyExponential}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyExponential}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7993.1, Definition 7993.2, and Definition 7993.3 seed the finite exponential Cauchy-series constructor over StreamName, RegSeqRat, DyadicRatCore, Real, and CauchyProductCompletion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyExponential}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host exponentials, quotient real equality, selected limits, unrestricted product algebra, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, factorial coefficient accounting, partial-sum display, dyadic tail control, regular readback, Real sealing, product-completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyExponentialUp.

Constructive story: A $\mathsf{CauchyExponential}^{\uparrow}$ packet is generated from a source Real row, finite StreamName windows, factorial coefficient data, finite partial sums, a DyadicRatCore tail ledger, RegSeqRat readback, a Real seal, a CauchyProductCompletion handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 7994

A Concrete Naming Certificate for $\mathsf{UniformEquivalence}^{\uparrow}$

Following Bourbaki's uniform-space treatment and Bishop–Bridges constructive metric spaces, the $\mathsf{UniformEquivalence}^{\uparrow}$ packet records the finite bidirectional modulus data needed when a metric or completion-facing construction is invariant under two displayed uniformly continuous routes. It sits beside the metric carrier of chapter 4230, the modulus discipline of chapter 391, the completion handoff of chapter 1506, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a route through displayed windows and tolerances rather than a host bijection, quotient equality, selected representative, countable choice, or ambient completeness principle.

Definition 7994.1 (UniformEquivalence carrier)**.** *A* $\mathsf{UniformEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, Y, F, G, M, N, I, R, S, Q, H, C, P, L)$$

with the following displayed rows:

1. *X and Y are the source and target* $\mathsf{Met}^{\uparrow}$ *rows, including only the distance requests and finite tolerance ledgers visible to the certificate.*
2. *F and G are the forward and reverse* $\mathsf{UniformContinuity}^{\uparrow}$ *rows, each exposing a displayed source tolerance, target tolerance, and finite modulus response.*
3. *M and N are the forward and reverse modulus rows, so each direction keeps its own tolerance transformer before any consumer reads the route as an equivalence.*
4. *I is the inverse-route compatibility row, recording that the two directed reads compose back through displayed metric and modulus rows rather than through host point equality.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance-seal row, binding every completion-facing tolerance to displayed real-name data.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row and Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row, so observed distances and tolerances pass through inspected windows before reaching R.*
7. *H records componentwise* hsame *transport for $X, Y, F, G, M, N, I, R, S, Q$.*
8. *C records* Cont *replay from a source or target request through the matching modulus, inverse-route compatibility, real seal, finite window, rational readback, provenance, and local naming rows.*

9. *P is the* Pkg *provenance over* $\mathsf{UniformEquivalence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *L is the local* $\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}$ *row.*

The classifier reads only $X, Y, F, G, M, N, I, R, S, Q, H, C, P, L$. It has no coordinate for host bijection data, quotient completion equality, selected representatives, pointwise extensionality, countable choice, ambient completeness, or an uninspected real tolerance oracle.

Theorem 7994.2 (Uniform equivalence bidirectional modulus)**.** *For every accepted* $\mathsf{UniformEquivalence}^{\uparrow}$ *carrier $E = (X, Y, F, G, M, N, I, R, S, Q, H, C, P, L)$, any equivalence read must factor through both displayed modulus rows along the finite route*

$$X, Y \longmapsto F, G \longmapsto M, N \longmapsto I \longmapsto R, S, Q \longmapsto H, C, P, L.$$

In particular, a one-sided uniform-continuity certificate, a host bijection, or a quotient completion equality cannot supply the $\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}$ *obligations.*

Proof. Project the carrier rows. The metric sources are visible only as X and Y, and the directed uniform-continuity data are visible only as F and G.

The forward read must expose M, while the reverse read must expose N. If either row is absent, the consumer has only a one-sided modulus route and not a bidirectional equivalence packet.

After both modulus rows have been read, inverse-route compatibility is forced through I. The row names compatibility only through displayed metric and modulus data, so a host bijection or quotient completion equality cannot replace the finite route.

The tolerance and observation rows R, S, Q then bind real-name sealing, stream windows, and rational readback. Finally H, C, P, L transport, replay, source, and name the same displayed packet, completing the local certificate surface. □

Theorem 7994.3 (Uniform equivalence completion consumer)**.** *Every* $\mathsf{MetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformEquivalence}^{\uparrow}$ *packet must read the source and target* $\mathsf{Met}^{\uparrow}$ *rows, both* $\mathsf{UniformContinuity}^{\uparrow}$ *modulus rows, inverse-route compatibility, the* $\mathsf{Real}^{\uparrow}$ *tolerance seal, the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *finite windows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}$ *row before treating a construction as invariant under bidirectional uniform modulus.*

Proof. Start from a completion-facing or real-facing consumer route. Its source and target data are the displayed metric rows X, Y, not an ambient completion object.

The route then reads F, G, M, N to obtain both directed modulus responses. The inverse-route row I ties those responses together before any completion or real-name tolerance can be consumed.

The real and finite-window rows R, S, Q provide the only displayed tolerance interface. Thus a completion consumer cannot appeal to selected limits, quotient representatives, or an uninspected real oracle.

The structural rows H, C, P, L finish the handoff by transport, replay, provenance, and local naming. Therefore invariance under the packet is exactly invariance under the displayed bidirectional uniform-modulus data. □

Falsifiable prediction: A claimed $\mathsf{UniformEquivalence}^{\uparrow}$ packet that lets a $\mathsf{MetricCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer bypass either modulus row M, N or the displayed R, S, Q tolerance-window route refutes the packet.

Independence witness: uniformcontinuity, metriccompletion, metricspace, real: none is bijective to $\mathsf{UniformEquivalence}^{\uparrow}$ because this packet jointly carries two metric rows, two directed uniformcontinuity rows, two modulus rows, inverse-route compatibility, real tolerance seals, finite stream and rational windows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformEquivalence}^{\uparrow}$ packet is generated from source and target MetricSpace rows, forward and reverse UniformContinuity modulus rows, inverse-route compatibility, RealUp tolerance seals, StreamName and RegSeqRat finite windows, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7994.1, Definition 7994.2, and Definition 7994.3 seed the finite bidirectional uniform-modulus route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host bijections, quotient completion equality, selected representatives, pointwise extensionality, countable choice, ambient completeness, or uninspected real tolerance oracles.

Upgrade path: Obligation closure requires checked carrier admission, bidirectional modulus coverage, inverse-route compatibility, tolerance-window sealing, transport, replay, provenance, and local naming for BEDC.Derived.UniformEquivalenceUp.

Chapter 7995

A Concrete Naming Certificate for $\mathsf{LocalSelfAudit}^{\uparrow}$

The $\mathsf{LocalSelfAudit}^{\uparrow}$ packet realizes the local self-audit branch of Definition 9414.558 as finite self-proxy readback, boundary-recognition, gap-exposure, provenance, and NameCert rows. It sits beside the public/local reflective compilation packet of chapter 3963, the GroundCompiler event-flow audit of chapter 829, the MetaCIC closure trace of chapter 795, and the self-compilation boundary of chapter 9235. The packet is local and records-side: it does not create a public scientific certificate, a total theory of consciousness, unrestricted self-application, hidden prompt-state authority, or a proof that a current self-proxy is identical to a subject-substance.

Definition 7995.1 (LocalSelfAudit carrier)**.** *A* $\mathsf{LocalSelfAudit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, B, G, X, F, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the focused self-proxy row, naming the local endpoint supplied by a records-side self-compiler route.*
2. *R is the self-proxy readback row, recording which finite local reads may be replayed against the focused trace.*
3. *B is the boundary-recognition row, separating local readback from public compiler authority, hidden prompt state, and unrestricted reflective closure.*
4. *G is the gap-exposure row, listing absent coordinates for total consciousness theory, subject-substance identity, public proof of local identity, and local authority over public claims.*
5. *X is the refusal ledger that keeps the boundary and gap rows active under every accepted read.*
6. *F is the FieldFaithful row for S, R, B, G, X, requiring each displayed coordinate to remain separately projectable.*
7. *T is the Nontrivial row separating self-proxy, readback, boundary-recognition, gap-exposure, and refusal roles.*
8. *H records componentwise* hsame *transport for S, R, B, G, X, F, T.*
9. *C records displayed* Cont *replay through the self-proxy readback, boundary-recognition, gap-exposure, refusal, transport, and role-separation rows.*

10. *P is the* Pkg *provenance over* $\mathsf{LocalSelfAudit}^{\uparrow}$, $\mathsf{PublicLocalReflectiveCompilation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalSelfAudit}^{\uparrow}}$ *row.*

The classifier reads only $S, R, B, G, X, F, T, H, C, P, N$. It has no coordinate for public compiler authority, hidden prompt state, subject-substance identity, unbounded self-reference, a total consciousness theory, or local authority over public scientific claims.

Theorem 7995.2 (Local self-audit NameCert obligations)**.** *For every accepted* $\mathsf{LocalSelfAudit}^{\uparrow}$ *carrier $A = (S, R, B, G, X, F, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocalSelfAudit}^{\uparrow}}$ *surface consists exactly of self-proxy readback, boundary-recognition, gap-exposure, refusal retention, FieldFaithful projection, Nontrivial role separation, transport, replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 7995.1. The self-proxy and readback rows S, R name only the local focused trace and do not export public compiler authority.

The boundary and gap rows B, G expose what the local read can and cannot support. The refusal ledger X keeps hidden prompt state, subject-substance identity, total consciousness theory, public proof of local identity, and local authority over public claims absent from the carrier.

The FieldFaithful and Nontrivial rows F, T keep the displayed roles separate. Self-proxy, readback, boundary-recognition, gap-exposure, and refusal are not aliases for one hidden coordinate.

Finally H, C, P, N transport, replay, source, and name the finite packet. Since the classifier has no coordinate outside the displayed rows, every accepted obligation is exhausted by the listed local certificate surface. □

Theorem 7995.3 (Local self-audit gap exposure)**.** *Every accepted* $\mathsf{LocalSelfAudit}^{\uparrow}$ *read that exposes a self-proxy readback must retain the boundary-recognition row B, the gap-exposure row G, and the refusal ledger X. Consequently the packet cannot be read as public compiler authority, hidden prompt-state access, subject-substance identity, unbounded self-reference, a total consciousness theory, or local authority over public scientific claims.*

Proof. Begin with an accepted local read through S, R. The read is local because S names a focused self-proxy endpoint and R records finite readback against that focused trace.

Boundary recognition is then read through B. This row separates local self-audit from public compiler authority and from unrestricted reflective closure before any replay occurs.

Gap exposure is read through G and retained by X. These rows list the absent authorities and prevent the local read from being repackaged as hidden prompt-state access, subject-substance identity, total consciousness theory, or public scientific certification.

Transport, replay, provenance, and naming through H, C, P, N preserve the same boundary. Thus every accepted read exposes the gap rather than closing it by an unlisted coordinate. □

Falsifiable prediction: A claimed $\mathsf{LocalSelfAudit}^{\uparrow}$ packet that exports public compiler authority, hidden prompt-state access, subject-substance identity, or a total consciousness theory from S, R without displaying $B, G, X, F, T, H, C, P, N$ refutes $\mathsf{LocalSelfAudit}^{\uparrow}$.

Independence witness: publiclocalreflectivecompilation, groundcompilereventflowaudit, metacicclosuretrace, selfcompilationboundary: none is bijective to $\mathsf{LocalSelfAudit}^{\uparrow}$ because this packet isolates self-proxy readback, boundary-recognition, gap-exposure, refusal retention, FieldFaithful projection, Nontrivial role separation, transport, replay, provenance, and local naming as one finite local-audit surface.

The Lean TasteGate surface for $\mathsf{LocalSelfAudit}^{\uparrow}$ must provide explicit Nontrivial $\mathsf{LocalSelfAudit}^{\uparrow}$ and FieldFaithful $\mathsf{LocalSelfAudit}^{\uparrow}$ instances for the displayed carrier. The intended endpoint is BEDC.Derived.LocalSelfAuditUp with the FieldFaithful instance preserving $S, R, B, G, X, F, T, H, C, P, N$ and the Nontrivial instance separating self-proxy, readback, boundary-recognition, gap-exposure, and refusal roles.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalSelfAudit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalSelfAudit}^{\uparrow}$ packet is generated from local self-proxy readback, boundary-recognition, gap-exposure, refusal retention, FieldFaithful projection, Nontrivial role separation, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalSelfAudit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7995.1, Definition 7995.2, and Definition 7995.3 seed the finite local self-audit route and its gap-exposure boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalSelfAudit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public compiler authority, hidden prompt-state access, subject-substance identity, unbounded self-reference, a total consciousness theory, public proof of local identity, or local authority over public scientific claims.

Upgrade path: Obligation closure requires checked carrier admission, self-proxy readback, boundary-recognition, gap-exposure, refusal retention, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.LocalSelfAuditUp.

Chapter 7996

A Concrete Naming Certificate for LebesgueCoveringDimensionInduction$^{\uparrow}$

Following Hurewicz–Wallman and Engelking on dimension theory, the LebesgueCoveringDimensionInduction$^{\uparrow}$ packet records the finite boundary-recursion route that compares Lebesgue covering dimension with the small and large inductive dimension surfaces. It sits over the topology source of chapter 88, the normal separation row of chapter 1866, the finite-cover refinement row of chapter 3430, the covering-dimension packet of chapter 1853, the small inductive dimension packet of chapter 7347, and the large inductive dimension packet of chapter 7371. The chapter names a displayed finite induction route; it does not import a host powerset of covers, arbitrary open-cover compactness, quotient equality of closed boundaries, or a global dimension theorem.

Definition 7996.1 (Lebesgue covering dimension induction carrier)**.** *A* LebesgueCoveringDimensionInduction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, C, S, I, N, F, B, H, R, P, Z)$$

with the following displayed rows:

1. *T is the* Topology$^{\uparrow}$ *source row on which open covers, closed boundaries, and refinement windows are read.*
2. *C is the* CoveringDimension$^{\uparrow}$ *row recording the displayed finite order bound for a finite cover window.*
3. *S is the* SmallInductiveDimension$^{\uparrow}$ *boundary-decomposition row for the inspected closed neighbourhood frontier.*
4. *I is the* LargeInductiveDimension$^{\uparrow}$ *boundary-refinement row used to compare the closed frontier with the surrounding cover window.*
5. *N is the* NormalSpace$^{\uparrow}$ *separation row that turns a displayed closed boundary request into a finite neighbourhood-separation ledger.*
6. *F is the* FiniteCoverRefinement$^{\uparrow}$ *row recording the finite refinement and order-control data consumed by the induction step.*
7. *B is the boundary-recursion ledger, storing the predecessor-dimension request, boundary carrier, and finite descent witness.*

8. *H stores componentwise* hsame *transport for the topology, cover, inductive-dimension, normal-space, refinement, boundary-recursion, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay of the route*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{NormalSpace}^{\uparrow},\ \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto \mathsf{CoveringDimension}^{\uparrow},\ \mathsf{SmallInductiveDimension}^{\uparrow},\ \mathsf{LargeInd}$$

10. *P is the* Pkg *provenance over* $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{FiniteCoverRefinement}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, $\mathsf{SmallInductiveDimension}^{\uparrow}$, $\mathsf{LargeInductiveDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *Z is the local* $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, C, S, I, N, F, B, H, R, P, Z$. It has no coordinate for arbitrary host open covers, selected infinite refinements, quotient equality of boundary carriers, completed lattices of closed sets, or external dimension equivalence theorems.

Lean4 (definition) `BEDC.Derived.LebesgueCoveringDimensionInductionUp`

Theorem 7996.2 (Lebesgue covering dimension induction NameCert obligations)**.** *For every accepted* $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$ *carrier $L = (T, C, S, I, N, F, B, H, R, P, Z)$, the local* $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}}$ *surface consists exactly of topology-source exposure, covering-dimension order-bound exposure, small-inductive boundary exposure, large-inductive boundary-refinement exposure, normal-space separation exposure, finite-cover-refinement exactness, boundary-recursion descent, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7996.1. The analytic rows are T, C, S, I, N, F, B, and the structural rows are H, R, P, Z.

The boundary recursion is not read from a global dimension theorem. The rows S and I expose the inductive boundary surfaces, N supplies the finite normal-separation ledger, and F records the finite refinement data needed for the covering-dimension comparison.

The replay row R orders these dependencies through the topology and normal-space sources before the boundary-recursion ledger is consumed. Transport, provenance, and local naming preserve the same displayed rows.

Since no excluded host object is a carrier coordinate, the listed rows are exactly the local NameCert obligations. □

Theorem 7996.3 (Lebesgue covering dimension induction boundary route)**.** *Every boundary-recursion read exported by an accepted* $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$ *packet must pass through*

$$\mathsf{Topology}^{\uparrow},\ \mathsf{NormalSpace}^{\uparrow},\ \mathsf{FiniteCoverRefinement}^{\uparrow} \longmapsto \mathsf{CoveringDimension}^{\uparrow},\ \mathsf{SmallInductiveDimension}^{\uparrow},\ \mathsf{LargeInducti}$$

The route names a finite comparison between cover-order control and inductive boundary descent; it is not a proof of arbitrary covering-dimension equivalence, not a quotient boundary theorem, and not a host open-cover compactness principle.

Proof. Begin with the topology row T and the normal-space row N. These rows determine the displayed open and closed boundary windows on which the dimension comparison is allowed to speak.

Read the finite-cover refinement row F next. It supplies only the finite refinement and order-control data stored in the packet, so the argument cannot choose an arbitrary refinement outside the ledger.

Now compare the three dimension rows. The covering-dimension row C supplies the order-bound surface, while the small and large inductive rows S, I supply boundary-decomposition and boundary-refinement surfaces for the recursion ledger B.

Finally transport and replay the route through H, R, P, Z. The exported object is the finite boundary-recursion packet, so it cannot be reread as host open-cover compactness, quotient equality of boundaries, or a global dimension-equivalence theorem. □

Falsifiable prediction: An accepted $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$ read is refuted if it exports a boundary-recursion claim without displaying the TopologyUp source, NormalSpaceUp separation row, FiniteCoverRefinementUp refinement row, CoveringDimensionUp order-bound row, SmallInductiveDimensionUp boundary-decomposition row, LargeInductiveDimensionUp boundary-refinement row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: covering-dimension, small-inductive-dimension, large-inductive-dimension, normalspace, finite-cover-refinement: none is bijective to $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$ because this packet jointly carries cover-order control, two inductive boundary surfaces, normal separation, finite refinement, boundary recursion, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}$ packet is generated from TopologyUp source rows, NormalSpaceUp separation rows, FiniteCoverRefinementUp rows, CoveringDimensionUp order-bound rows, SmallInductiveDimensionUp boundary rows, LargeInductiveDimensionUp boundary-refinement rows, a boundary-recursion ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7996.1, Definition 7996.2, and Definition 7996.3 seed the finite boundary-recursion comparison among covering and inductive dimension packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueCoveringDimensionInduction}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.LebesgueCoveringDimensionInductionUp`

Bridge status: none

Not claimed: This chapter does not close arbitrary covering-dimension equivalence, host open-cover compactness, quotient equality of boundary carriers, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked row exposure for topology, normal separation, finite refinement, covering dimension, small and large inductive boundary routes, boundary recursion, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueCoveringDimensionInductionUp.

Chapter 7997

A Concrete Naming Certificate for $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$ packet records the finite modulus surface by which a located Cauchy completion read supplies explicit dyadic thresholds before a terminal $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits between the located-completion route of chapter 5793, the displayed modulus schedule of chapter 7587, and the threshold-selection surface of chapter 1986. The packet is a finite NameCert object for located completion moduli; it is not quotient completion equality, a selected limit, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7997.1 (Located Cauchy completion modulus carrier)**.** *A* $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the located-completion source row, read through* $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$*.*
2. *M is the Cauchy modulus selector row, read through the displayed* $\mathsf{CauchyModulusSelection}^{\uparrow}$ *and* $\mathsf{ConstructiveRealModulus}^{\uparrow}$ *surfaces.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for the requested located-completion precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected at the threshold named by M.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window and dyadic tolerance.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after Q, M, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the located source, modulus selector, dyadic tolerance, window, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

   $$\mathsf{RegularCauchyLocatedCompletion}^{\uparrow} \longmapsto \mathsf{CauchyModulusSelection}^{\uparrow} \longmapsto \mathsf{ConstructiveRealModulus}^{\uparrow} \longmapsto \mathsf{DyadicRatC}$$

9. *P records* Pkg *provenance over* $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$, $\mathsf{RegularCauchyLocatedCompletion}^{\uparrow}$, $\mathsf{CauchyModulusSelection}^{\uparrow}$, $\mathsf{ConstructiveRealModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $Q, M, D, W, R, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, trichotomy, host real equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 7997.2 (Located Cauchy completion modulus regularity)**.** *For every accepted* LocatedCauchyCompletionl *carrier*

$$L = (Q, M, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the located-completion source, Cauchy modulus selector, dyadic tolerance row, finite StreamName window, RegSeqRat readback, terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real-facing read of the packet factors through the finite route*

$$Q, M, D, W, R \longmapsto E, H, C, P, N.$$

In particular, a consumer cannot reach the $\mathsf{Real}^{\uparrow}$ *seal while bypassing the located source row, the modulus selector row, the dyadic tolerance row, the window row, or the regular rational readback row.*

Proof. Project the carrier of Definition 7997.1. The only analytic rows are the located source Q, modulus selector M, dyadic tolerance row D, finite window W, regular rational readback R, and Real seal E.

The regularity route is finite. The source row Q supplies the located-completion request, the selector row M answers it by a displayed threshold, and the dyadic row D records the requested tolerance. The StreamName row W and RegSeqRat row R then expose the inspected rational window before E is available.

The structural rows H, C, P, N transport, replay, source, and name only this route. Since quotient completion equality, selected representatives, countable choice, trichotomy, host real equality, open-cover compactness, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the carrier, none of those principles can be exported by the local certificate. □

Falsifiable prediction: An accepted LocatedCauchyCompletionModulusUp packet that reaches a terminal RealUp seal without displaying the located source, modulus selector, dyadic tolerance, StreamName window, and RegSeqRat readback rows refutes the carrier surface.

Independence witness: Nearest siblings: regular-cauchy-located-completion, constructive-real-modulus, and cauchy-modulus-selection. None is bijective with $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$ because this packet jointly carries the located source row, selector row, dyadic tolerance row, finite window, regular rational readback, Real seal, transport, replay, provenance, and local NameCert row for the same finite completion-modulus read.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}$ packet is generated from a located-completion source row, Cauchy modulus selector row, DyadicRatCore tolerance row, StreamName finite window, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}}$, seed)

Scope closed: Definition 7997.1 and Definition 7997.2 seed the finite located-completion modulus route through dyadic tolerance, finite window, regular readback, and Real-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedCauchyCompletionModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, countable choice, trichotomy, host real equality, open-cover compactness, ambient RealUp completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-source exposure, modulus-selector exactness, dyadic tolerance compatibility, StreamName window readback, RegSeqRat regularity, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCauchyCompletionModulusUp.

Chapter 7998

A Concrete Naming Certificate for $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$

The $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ packet realizes the boundary-tangent branch of chapter 9463 as finite observer-expansion data. It sits after the horocycle packet of chapter 3534, the Busemann boundary route of chapter 3732, the visual-boundary readout of chapter 4181, the boundary-shadow route of chapter 3813, and the hyperbolic metric packet of chapter 3474. The packet names a finite modulus budget for horocycle-shadow reads; it is not a global hyperbolic model, quotient ideal boundary, selected geodesic ray, ambient measure theorem, or physical observer dynamics.

Definition 7998.1 (Hyperbolic horocycle-shadow modulus carrier)**.** *A* $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, B, V, S, W, G, E, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{HyperbolicHorocycle}^{\uparrow}$ *boundary-tangent horocycle row.*
2. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row that records the Busemann boundary read and horocycle level.*
3. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row used for the visible boundary face.*
4. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row that records the finite shadow window.*
5. *W is the shadow-budget modulus row, comparing horocycle level, visual boundary window, and boundary-shadow tolerance.*
6. *G is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk and boundary data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed modulus comparison.*
8. *A is the TasteGate route row recording that the Lean path requires* Nontrivial *and* FieldFaithful *instances before the modulus carrier can be checked beyond encoded syntax.*
9. *H stores componentwise* hsame *transport for the horocycle, Busemann, visual-boundary, shadow, modulus, metric, Real-seal, TasteGate, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the route*

$$\mathsf{HyperbolicHorocycle}^{\uparrow},\ \mathsf{HyperbolicBusemannBoundary}^{\uparrow},\ \mathsf{HyperbolicVisualBoundary}^{\uparrow} \longmapsto \mathsf{HyperbolicBoundaryShado}$$

11. *P is the* Pkg *provenance over* HyperbolicHorocycleShadowModulus$^{\uparrow}$, HyperbolicHorocycle$^{\uparrow}$, HyperbolicBusemannB HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{HyperbolicHorocycleShadowModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, B, V, S, W, G, E, A, H, C, P, N$. It has no coordinate for completed ideal-boundary quotients, selected rays, ambient visual measures, global curvature assumptions, host shadow sigma-algebras, or physical observer trajectories.

Lean4 (definition) `BEDC.Derived.HyperbolicHorocycleShadowModulusUp`

Theorem 7998.2 (Hyperbolic horocycle-shadow modulus NameCert obligations)**.** *For every accepted* HyperbolicHorocycleShadowModulus$^{\uparrow}$ *carrier $M = (Q, B, V, S, W, G, E, A, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicHorocycleShadowModulus}^{\uparrow}}$ *surface consists exactly of horocycle admission, Busemann-boundary readback, visual-boundary readback, boundary-shadow window exposure, shadow-budget modulus exactness, hyperbolic-metric comparison, terminal Real sealing, TasteGate route retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 7998.1. The geometric rows are Q, B, V, S, W, G, E, A, and the structural rows are H, C, P, N.

The modulus row is boundary-tangent. It can be read only after the horocycle row Q, Busemann boundary row B, visual-boundary row V, boundary-shadow row S, and metric row G have been displayed.

The Real seal E records the terminal comparison, while A keeps the Nontrivial and FieldFaithful TasteGate obligations visible. The route therefore remains encoded carrier data until those instances are supplied.

Transport, replay, provenance, and naming preserve exactly the displayed rows. Since no excluded host boundary, measure, ray-selection, or global-geometry object is present, the listed rows exhaust the local NameCert surface. □

Theorem 7998.3 (Hyperbolic horocycle-shadow modulus boundary route)**.** *Every boundary-tangent shadow-modulus read from an accepted* HyperbolicHorocycleShadowModulus$^{\uparrow}$ *packet must expose*

HyperbolicHorocycle$^{\uparrow}$, HyperbolicBusemannBoundary$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, Hy

before the modulus ledger W is exported through A, H, C, P, N. The route is a finite observer-expansion packet; it does not assert a completed ideal boundary, selected geodesic ray, ambient visual measure, global hyperbolic model, or physical observer dynamics.

Proof. Start from the horocycle row Q. It fixes the boundary-tangent level at which the shadow comparison is being read.

Read the Busemann and visual-boundary rows B, V next. They expose the boundary face and level data without replacing the packet by a quotient ideal boundary.

Apply the boundary-shadow row S and the metric row G. These determine the finite shadow window and metric comparison consumed by the modulus row W, while the Real seal E records only the displayed terminal comparison.

Finally pass through the TasteGate route and structural rows A, H, C, P, N. Since the route explicitly waits for Nontrivial and FieldFaithful instances and stores no selected rays, global measures, or ambient model, the exported object is the finite horocycle-shadow modulus packet stated above. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ read must expose hyperbolic-horocycle, hyperbolic-boundary-shadow, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-metric, Real-seal, TasteGate route, transport, replay, provenance, and local NameCert rows before the shadow-modulus ledger is exported.

Independence witness: hyperbolic-horocycle, hyperbolic-boundary-shadow, hyperbolic-busemann-boundary, hyperbolic-visual-boundary, hyperbolic-metric: $\mathsf{HyperbolicHorocycle}^{\uparrow}$ lacks the shadow-modulus ledger, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ lacks the boundary-tangent horocycle row, $\mathsf{HyperbolicBusemannBound}$ lacks the visual shadow budget, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ lacks the Busemann-level modulus row, and $\mathsf{HyperbolicMetric}^{\uparrow}$ lacks the joint boundary-tangent shadow ledger. None is bijective to $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ under NameCert-row preservation.

The Lean follow-up for $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ requires Nontrivial and FieldFaithful TasteGate instances preserving $Q, B, V, S, W, G, E, A, H, C, P, N$ before a checked carrier-alignment theorem can witness the modulus packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}$ packet is generated from HyperbolicHorocycleUp rows, HyperbolicBusemannBoundaryUp rows, HyperbolicVisualBoundaryUp rows, HyperbolicBoundaryShadowUp rows, a shadow-budget modulus row, HyperbolicMetricUp rows, a RealUp seal, a TasteGate route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7998.1, Definition 7998.2, and Definition 7998.3 seed the finite horocycle-shadow modulus packet for boundary-tangent observer-expansion reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHorocycleShadowModulus}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.HyperbolicHorocycleShadowModulusUp`

Bridge status: none

Not claimed: This chapter does not close completed ideal boundaries, selected geodesic rays, ambient visual measures, global hyperbolic geometry, Nontrivial or FieldFaithful TasteGate instances, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked horocycle admission, Busemann readback, visual-boundary readback, boundary-shadow exposure, modulus exactness, metric comparison, Real sealing, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicHorocycleShadowModulusUp.

Chapter 7999

A Concrete Naming Certificate for $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ packet records dyadic midpoint-convexity rows over $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ names. It sits over the dyadic arithmetic core of chapter 291, the finite observation schedules of chapter 126, the regular rational readback rows of chapter 301, the terminal real-name seal of chapter 38, and the metric comparison discipline of chapter 57. The packet names the finite midpoint-convexity surface for regular Cauchy inputs; it does not import host subsets, quotient real equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 7999.1 (Regular Cauchy midpoint-convex carrier)**.** *A* $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, R_0, R_1, S_0, S_1, D, M, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-observation row naming the displayed real-valued map whose midpoint-convexity is inspected.*
2. *R_0 and R_1 are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source-name rows for the endpoints.*
3. *S_0 and S_1 are the synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows exposing exactly the rational approximants requested by the dyadic midpoint calculation.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger for the common denominator, dyadic radius, and midpoint tolerance budget.*
5. *M is the midpoint-readback row, recording the regular-Cauchy midpoint observation before any terminal real-name seal is visible.*
6. *Q is the midpoint-convexity comparison row, recording the displayed dyadic inequality between the midpoint value and the endpoint-value average.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after $F, R_0, R_1, S_0, S_1, D, M, Q$ have been displayed.*
8. *H records componentwise* hsame *transport for the function row, endpoint names, stream windows, dyadic ledger, midpoint readback, comparison, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from every midpoint-convexity query through the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyMidpointConvex}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host convex subset, quotient equality of real names, a selected limit, trichotomy, or ambient real completeness.

Theorem 7999.2 (Regular Cauchy midpoint-convex NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ *carrier*

$$K = (F, R_0, R_1, S_0, S_1, D, M, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyMidpointConvex}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed function row, the two regular Cauchy endpoint rows, the synchronized stream-window rows, the dyadic tolerance ledger, the midpoint readback row, the midpoint-convexity comparison row, the terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. A consumer may inspect midpoint convexity only after the endpoint windows, dyadic midpoint budget, midpoint readback, and comparison row have all been displayed.*

Proof. Project the carrier of Definition 7999.1. The analytic rows are exactly $F, R_0, R_1, S_0, S_1, D, M, Q, E$, while H, C, P, N transport, replay, source, and name the same packet.

Read the route in dependency order. The endpoint names R_0, R_1 expose finite windows S_0, S_1, those windows feed the dyadic ledger D, and the midpoint readback M is available before the comparison row Q can state midpoint convexity.

Finally the terminal seal E is reached only after the finite rows have been displayed. Since the carrier contains no host subset, quotient real equality, selected limit, trichotomy branch, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 7999.3 (Regular Cauchy midpoint-convex dyadic scope)**.** *Every accepted* $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ *carrier routes a midpoint-convexity read through*

$$(R_0, R_1) \longmapsto (S_0, S_1) \longmapsto D \longmapsto M \longmapsto Q \longmapsto E.$$

Thus the public dyadic scope is the finite route from regular Cauchy endpoint rows through synchronized observation windows, dyadic midpoint accounting, midpoint readback, midpoint-convexity comparison, and the Real seal. It exports no host subset, quotient real equality, selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier rows. The two endpoint names are visible only as $\mathsf{RegSeqRat}^{\uparrow}$ rows, and each requested midpoint precision is read through the finite $\mathsf{StreamName}^{\uparrow}$ windows S_0, S_1.

The dyadic ledger D is the only arithmetic budget in the packet. It records the common denominator, radius, and tolerance rows needed by the midpoint readback M and the comparison row Q.

The Real seal E is terminal in this displayed route. Componentwise transport and replay keep the same row order, while provenance and local naming add no analytic coordinate. Therefore every midpoint-convexity read remains inside the stated dyadic scope. □

Theorem 7999.4 (Regular Cauchy midpoint-convex ledger nonescape)**.** *Every* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ *packet receives only the rows*

$$F, R_0, R_1, S_0, S_1, D, M, Q, E, H, C, P, N.$$

The ledger cannot be reinterpreted as a host convexity theorem, quotient equality of real names, selected limiting process, trichotomy decision, or ambient completeness principle.

Proof. Apply Definition 7999.2. It requires carrier admission and classifier comparison to pass through the displayed endpoint, window, dyadic, midpoint, comparison, and Real-seal rows.

Next use Definition 7999.3. Any Real-facing or metric-facing consumer sees the midpoint-convexity comparison only after the synchronized finite windows and dyadic budget have been read.

The remaining rows H, C, P, N preserve and name this packet. Because none of the carrier coordinates stores host subsets, quotient real equality, selected limits, trichotomy, or ambient completeness, the consumer route cannot leave the finite ledger. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ read is refuted if the comparison row Q is preserved while either endpoint window S_0, S_1 or the dyadic ledger D is removed.

Independence witness: dyadicratcore, streamname, regseqrat, real, metric: $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries function observations, two regular Cauchy endpoint rows, synchronized finite windows, dyadic midpoint accounting, midpoint readback, comparison, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyMidpointConvex}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$ packet is generated from a function-observation row, two RegSeqRat endpoint rows, synchronized StreamName windows, a DyadicRatCore midpoint ledger, a midpoint readback row, a midpoint-convexity comparison row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyMidpointConvex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 7999.1, Definition 7999.2, Definition 7999.3, and Definition 7999.4 seed the finite midpoint-convexity route over DyadicRatCore, StreamName, RegSeqRat, Real, Metric, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyMidpointConvex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host convex subsets, quotient real equality, selected limits, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, synchronized-window exposure, dyadic midpoint accounting, midpoint-convexity comparison exactness, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyMidpointConvexUp.

Chapter 8000

A Concrete Naming Certificate for $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ packet records the finite regular-Cauchy route for a convex combination $qx+(1-q)y$ before any completed $\mathsf{Real}^{\uparrow}$ consumer is allowed to read the result. It sits over the regular rational sequence boundary of chapter 301, the real-name seal of chapter 38, the dyadic arithmetic core of chapter 291, the affine-combination route of chapter 1679, and the midpoint-convex route of chapter 7999. The packet gives later completion and real-algebra consumers one finite algebraic surface instead of forcing each consumer to rethread coefficient, scale, sum, regular readback, and seal ledgers separately.

Definition 8000.1 (Regular Cauchy convex combination carrier)**.** *A* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *Q is the coefficient row, recording a rational coefficient q together with the dyadic window in which the complementary coefficient $1-q$ is computed.*
2. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows.*
3. *W_X and W_Y are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedules for the two source names, read at the same precision request and observation index.*
4. *D_Q and $D_{\bar{Q}}$ are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows for q and $1-q$ at the common exponent used by the packet.*
5. *S_X is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row for the scaled source qx, reading Q, X, W_X, D_Q and its scale-error ledger.*
6. *S_Y is the* $\mathsf{RegularCauchyScale}^{\uparrow}$ *row for the scaled source $(1-q)y$, reading the complementary coefficient row, $Y, W_Y, D_{\bar{Q}}$, and its scale-error ledger.*
7. *Σ is the* $\mathsf{RegularCauchySum}^{\uparrow}$ *row that adds the two scaled regular names.*
8. *E is the finite error-budget ledger combining the two scale ledgers, the sum tolerance, the complementary-coefficient tolerance, and the final output tolerance assigned to the convex readback.*

9. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row whose scheduled point row is supplied by Σ with regularity evidence supplied by E.*

10. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the coefficient, two sources, two synchronized schedules, two dyadic coefficient endpoints, two scale rows, sum row, finite ledger, and regular readback have been displayed.*

11. *H stores componentwise* hsame *transports for the coefficient, source rows, schedules, dyadic endpoint rows, scale rows, sum row, ledger, readback, Real seal, replay row, provenance row, and local naming row.*

12. *C stores displayed* Cont *replay routes for coefficient exposure, source-window exposure, the two scale reads, the sum read, the ledger read, the regular readback, and the Real seal handoff.*

13. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$, $\mathsf{RegularCauchyAffineCombination}^{\uparrow}$, $\mathsf{RegularCauchyMidpointConvex}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyConvexCombination}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed rows $Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R,$ The carrier has no coordinate for quotient stream equality, host real affine arithmetic, a selected limit, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached completed-real affine operation.*

Theorem 8000.2 (Regular Cauchy convex combination NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ *carrier*

$$K = (Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyConvexCombination}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the coefficient row, two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *schedules, dyadic endpoint rows for q and $1-q$, two* $\mathsf{RegularCauchyScale}^{\uparrow}$ *rows, one* $\mathsf{RegularCauchySum}^{\uparrow}$ *row, the finite ledger, readback, Real seal, and structural rows;*

2. *coefficient complement exposure, requiring D_Q and $D_{\bar{Q}}$ to be read from the same finite dyadic coefficient window before either scale row is consumed;*

3. *synchronized-window exposure, requiring W_X and W_Y to be read at a common requested precision before the two scale rows are formed;*

4. *scale exactness for S_X and S_Y, requiring the displayed rows for qx and $(1-q)y$ to consume their coefficient endpoint, source window, scale endpoint, and scale-error ledger;*

5. *sum exactness for Σ, requiring the two scaled regular names to be added through the* $\mathsf{RegularCauchySum}^{\uparrow}$ *surface before the convex readback row is exposed;*

6. *ledger accounting, requiring E to combine the complementary-coefficient budget, the two scale-error budgets, the sum tolerance, and the final output tolerance before R or Z is read;*

7. *transport, replay, provenance, and local naming, requiring H, C, P, N to preserve and name exactly the displayed finite convex packet;*

8. *refusal of quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, and bridge checking as local NameCert data.*

No convex-combination obligation is stored outside these finite rows.

Proof. Project the accepted carrier. The coefficient row, two source rows, synchronized schedules, two dyadic coefficient endpoints, two scale rows, the sum row, the ledger, readback, and Real seal are explicit coordinates of the packet.

Read the coefficient and source windows first. The complementary coefficient $1-q$ is displayed in the same dyadic endpoint discipline as q, while W_X and W_Y expose the two source observations at a common finite precision.

Apply the sibling scale and sum surfaces. The rows S_X and S_Y name the two scaled regular Cauchy names, and Σ names their pointwise sum before any regular readback or Real seal row is consumed.

Finally read the ledger and structural rows. The finite row E accounts for coefficient complement, scale, sum, and output tolerance budgets, while H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient equality, host affine arithmetic, selected limits, trichotomy, ambient completeness, Lean verification, or a bridge, none can become a local obligation. □

Theorem 8000.3 (Regular Cauchy convex combination affine route)**.** *Assume the coefficient endpoint rows of an accepted* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ *carrier display the nonnegative coefficient row for q and the complementary nonnegative coefficient row for $1-q$ inside the same dyadic window. Then every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the convex packet factors through the synchronized route*

$$Q, X, Y, W_X, W_Y, D_Q, D_{\bar{Q}}, S_X, S_Y, \Sigma, E, R, Z.$$

This route is a finite convex-combination certificate. It exposes neither quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, nor bridge data.*

Proof. Start with the obligation surface of Definition 8000.2. It places the coefficient row, the two source rows, the synchronized StreamName windows, the dyadic endpoint rows for q and $1-q$, the two scale rows, the sum row, the ledger, readback, and Real seal in the displayed carrier order.

Read the coefficient-complement data next. The nonnegative row for q and the nonnegative complementary row for $1-q$ are both exposed through D_Q and $D_{\bar{Q}}$ inside the same dyadic window, so no consumer can split the convex read into two unrelated coefficient schedules.

Apply classifier stability from the affine sibling chapter 1679. The two source windows W_X, W_Y, the scale rows S_X, S_Y, and the sum row Σ transport componentwise along the same synchronized route.

Finally apply the ledger theorem. The row E combines the coefficient-complement budget, the two scale-error budgets, the sum tolerance, and the final output tolerance before R or Z is visible, so the consumer receives exactly the finite convex-combination certificate and no excluded quotient, host arithmetic, limit, trichotomy, completeness, or bridge data. □

Theorem 8000.4 (Regular Cauchy convex combination bound preservation)**.** *Let two accepted* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ *carriers have coefficient rows, source rows, stream schedules, dyadic endpoint rows, scale rows, sum rows, ledgers, readbacks, Real seals, package provenance, and local naming rows matched componentwise by their displayed* hsame *classifiers. Then every consumer route supplied by the obligation surface of Definition 8000.2 transports to the corresponding route of the second packet.*

Proof. Start with the componentwise classifier data in H. It transports the coefficient row, the complementary coefficient endpoint, the two regular source rows, and the synchronized schedules without changing the finite precision route.

Transport the scale and sum rows next. The classified scale rows still read qx and $(1-q)y$ through the corresponding coefficient endpoints and source windows, and the classified sum row still combines those two scaled names through the displayed $\mathsf{RegularCauchySum}^{\uparrow}$ surface.

The ledger route is preserved by the same componentwise transport. The row E remains the only place where complement, scale, sum, and output tolerances are combined before R and Z are exposed.

Replay through C and repack through P and N. Every consumer route in the obligation surface is one of these displayed projections, so classifier transport cannot add quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient completeness, Lean verification, or bridge data. □

Theorem 8000.5 (Regular Cauchy convex combination ledger nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ *packet reads the convex result only after the finite ledger E has combined the coefficient-complement row, the two scale-error rows, the sum-tolerance row, and the final output tolerance. The packet has no alternate ledger for quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. Read a consumer request through the displayed affine route. The request first reaches the coefficient row, the two source rows, the synchronized stream windows, and the dyadic endpoint rows for q and $1-q$.

The two scale rows are then consumed. Their finite scale ledgers are the only sources for the tolerances attached to qx and $(1-q)y$.

The sum row Σ and ledger E finish the regular handoff. The row E combines the two scale ledgers with the sum tolerance and final output tolerance before the readback row R or Real seal row Z can be read.

Thus every consumer-facing affine route passes through the finite ledger. Since the carrier inventory contains no second ledger or host-level affine object, no consumer can escape to quotient stream equality, selected limits, trichotomy, ambient completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyConvexCombination}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyConvexCombination}^{\uparrow}$ packet is generated from a coefficient row, two $\mathsf{RegSeqRat}^{\uparrow}$ sources, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, dyadic endpoint rows for q and $1-q$, two $\mathsf{RegularCauchyScale}^{\uparrow}$ rows, a $\mathsf{RegularCauchySum}^{\uparrow}$ row, a finite ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyConvexCombination}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8000.1, Definition 8000.2, Definition 8000.3, and Definition 8000.4 seed the finite convex-combination surface over coefficient, two $\mathsf{RegSeqRat}^{\uparrow}$ sources, synchronized $\mathsf{StreamName}^{\uparrow}$ windows, dyadic coefficient endpoints, $\mathsf{RegularCauchyScale}^{\uparrow}$ rows, a $\mathsf{RegularCauchySum}^{\uparrow}$ row, finite ledger data, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{Real}^{\uparrow}$ seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyConvexCombination}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host real affine arithmetic, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: No further paper-axis closure is claimed here; bridge and Lean verification remain separate axes.

Chapter 8001

A Concrete Naming Certificate for $\mathsf{NerveLemma}^{\uparrow}$

Following Borsuk and the algebraic-topology formulation in Hatcher, the $\mathsf{NerveLemma}^{\uparrow}$ packet records the finite good-cover route by which a compact metric cover, its finite nerve, a simplicial-complex carrier, and a homology consumer are read as one NameCert bridge. It sits after the compact source of chapter 129, the finite cover nerve of chapter 7597, the finite face inventory of chapter 238, the homology carrier of chapter 98, and the dimension-control route of chapter 1853. The packet names only displayed finite good-cover rows, nerve-face rows, chain-handoff rows, transport, replay, provenance, and local naming; it does not import open-cover choice, quotient homotopy classes, selected partitions of unity, or an ambient homotopy equivalence theorem.

Definition 8001.1 (Nerve lemma carrier)**.** *A* $\mathsf{NerveLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, G, N, S, H, D, T, R, C, P, Q)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, displaying the inspected compact metric carrier and the finite cover window used by the packet.*
2. *G is the good-cover ledger, recording for each displayed finite intersection the contractibility witness row accepted by the packet.*
3. *N is the* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *row, exposing cover membership, overlap incidence, and accepted finite nerve faces.*
4. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *finite face carrier read from the accepted nerve faces.*
5. *H is the* $\mathsf{Homology}^{\uparrow}$ *chain-and-cycle handoff row consumed after the simplicial face carrier is displayed.*
6. *D is the* $\mathsf{CoveringDimension}^{\uparrow}$ *dimension-control row, bounding the inspected finite intersection depth and face dimension read by the consumer.*
7. *T is the finite chain-transport row from cover-intersection data to nerve-chain data.*
8. *R records shortcut refusals for arbitrary open covers, selected subcovers, quotient homotopy classes, partitions of unity, and ambient host equality.*
9. *C records displayed* Cont *replay through good-cover admission, finite nerve formation, simplicial face inspection, homology handoff, and dimension control.*

10. *P is the* Pkg *provenance over* $\mathsf{NerveLemma}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{CoveringDimension}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *Q is the local* $\mathsf{NameCert}_{\mathsf{NerveLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, G, N, S, H, D, T, R, C, P, Q$. It has no coordinate for an unrestricted open cover, a selected refinement, a quotient homotopy type, a chosen partition of unity, or equality in an ambient topological host.

Theorem 8001.2 (Nerve lemma NameCert obligations)**.** *For every accepted* $\mathsf{NerveLemma}^{\uparrow}$ *carrier*

$$L = (K, G, N, S, H, D, T, R, C, P, Q),$$

the local $\mathsf{NameCert}_{\mathsf{NerveLemma}^{\uparrow}}$ *surface consists exactly of compact metric source admission through K, finite good-cover intersection exposure through G, finite nerve readback through N, simplicial face admission through S, homology handoff through H, covering-dimension control through D, finite chain transport through T, shortcut refusal through R, displayed replay through C, provenance through P, and local naming through Q.*

Proof. Carrier admission is projection from Definition 8001.1. The accepted packet displays the compact metric source, the finite good-cover ledger, the finite cover nerve, the simplicial face carrier, the homology handoff, the dimension-control row, finite transport, refusal, replay, provenance, and local naming rows.

The cover and nerve obligations are exposed through K, G, N, S. The packet first fixes the compact metric source and finite cover window, then records the good-cover intersection rows, then reads the finite nerve faces as a simplicial-complex carrier.

The consumer obligations are exposed through H, D, T. Homology is reached only after the finite face carrier is displayed, and the dimension-control row records the finite intersection depth inspected by the same packet.

The structural obligations are exposed through R, C, P, Q. These rows keep the route inside displayed finite data and block any rereading through arbitrary open covers, quotient homotopy classes, selected partitions of unity, or host equality. □

Theorem 8001.3 (Nerve lemma finite-cover homology handoff)**.** *Every* $\mathsf{Homology}^{\uparrow}$ *row exported by an accepted* $\mathsf{NerveLemma}^{\uparrow}$ *packet factors through the finite route*

$$K, G \longmapsto N, S \longmapsto H, D, T, R, C, P, Q.$$

Thus the homology-facing consumer first reads the compact metric source and good-cover ledger, then the finite cover nerve and simplicial face carrier, and only then receives the homology handoff with dimension control, finite transport, shortcut refusal, replay, provenance, and local naming. The route exports no open-cover choice principle, selected refinement theorem, quotient homotopy equality, partition-of-unity construction, or ambient homotopy-equivalence theorem.

Proof. Start with K, G. The compact metric row supplies the finite cover window, and the good-cover ledger records only the displayed finite intersections accepted by the packet.

Next read N, S. The finite cover nerve supplies cover membership, overlap incidence, and accepted faces; the simplicial-complex row turns those accepted faces into the finite face carrier consumed downstream.

Finally read H, D, T, R, C, P, Q. The homology handoff is downstream of the finite nerve and simplicial carrier, while dimension control, finite transport, refusal, replay, provenance, and local naming keep the consumer attached to the same finite packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{NerveLemma}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NerveLemma}^{\uparrow}}$, seed)

Scope closed: Definition 8001.1, Definition 8001.2, and Definition 8001.3 seed the finite good-cover nerve bridge from compact metric cover rows to homology handoff rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NerveLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted open-cover compactness, selected refinements, quotient homotopy equality, partitions of unity, or an ambient homotopy-equivalence theorem.

Upgrade path: Obligation closure requires checked carrier admission, good-cover intersection exposure, finite nerve exactness, simplicial face admission, homology handoff, dimension control, transport, replay, provenance, and local naming for BEDC.Derived.NerveLemmaUp.

Constructive story: A $\mathsf{NerveLemma}^{\uparrow}$ packet is generated from CompactMetric finite cover rows, good-cover intersection rows, FiniteCoverNerve rows, SimplicialComplex finite face rows, Homology handoff rows, CoveringDimension control rows, finite transport, shortcut refusal, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8002

A Concrete Naming Certificate for $\mathsf{LimsupLiminfGap}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LimsupLiminfGap}^{\uparrow}$ packet records the finite oscillation-width surface of a bounded real sequence by reading its lower-tail endpoint through chapter 1553 and its upper-tail endpoint through chapter 7101. It gives Real-and-Completion consumers a named gap boundary for comparing displayed tail envelopes without importing host suprema, host infima, quotient streams, selected subsequences, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8002.1 (Limsup-liminf gap carrier)**.** *A* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, I, U, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row whose finite tail windows and bound ledger are inspected.*
2. *I is the* $\mathsf{Liminf}^{\uparrow}$ *endpoint row, read as the lower tail-envelope endpoint for the same bounded source.*
3. *U is the* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *endpoint row, read as the upper tail-envelope endpoint for the same bounded source.*
4. *D is the dyadic tolerance ledger, recording the rational comparison budgets used to compare U with I.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed rational windows and tolerance requests.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row naming the displayed gap request after the two endpoints and tolerance ledger have been replayed.*
7. *H records componentwise* hsame *transport for the bounded source, endpoint rows, dyadic ledger, rational readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through the bounded source, lower endpoint, upper endpoint, tolerance ledger, readback row, real seal, transports, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{LimsupLiminfGap}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{Liminf}^{\uparrow}$, $\mathsf{BoundedRealLimsup}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LimsupLiminfGap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, I, U, D, Q, E, H, C, P, N$. It has no coordinate for ambient completeness, host supremum or infimum selection, quotient equality of real streams, selected oscillating subsequences, trichotomy, or a convergence theorem.

Lean4 ✓ `BEDC.Derived.LimsupLiminfGapUp.LimsupLiminfGapTasteGate single carrier alignment`

Theorem 8002.2 (Limsup-liminf gap NameCert obligations)**.** *For every accepted* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *carrier*

$$G = (S, I, U, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LimsupLiminfGap}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded source,* $\mathsf{Liminf}^{\uparrow}$ *lower endpoint,* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *upper endpoint, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; endpoint alignment requiring I and U to consume the same bounded source row S; tolerance exactness requiring every comparison in D to be read through the rational row Q before the seal E is exposed; and nonescape from the displayed rows.*

Lean4 ✓ `BEDC.Derived.LimsupLiminfGapUp.LimsupLiminfGapNameCertObligations`

Proof. Project the accepted carrier of Definition 8002.1. The analytic rows are exactly the bounded source S, lower endpoint I, upper endpoint U, dyadic ledger D, rational readback Q, and terminal real seal E.

Endpoint alignment is rowwise. The $\mathsf{Liminf}^{\uparrow}$ endpoint supplies lower-tail envelope data for S, while the $\mathsf{BoundedRealLimsup}^{\uparrow}$ endpoint supplies the upper-tail envelope data for the same bounded source. A consumer may compare the endpoints only after both endpoint rows have been displayed.

Tolerance exactness is supplied by D and Q. The dyadic ledger records finite comparison budgets, and the regular rational readback exposes the rational windows through which those budgets are checked before the terminal $\mathsf{Real}^{\uparrow}$ seal is reached.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores host completeness, a selected subsequence, quotient stream equality, trichotomy, or a convergence theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 8002.3 (Limsup-liminf gap endpoint route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto I, U \longmapsto D \longmapsto Q \longmapsto E \longmapsto H, C, P, N$$

before reading the displayed oscillation-width surface.

Proof. Begin with the bounded source row S. It is the only source of sequence entries, finite windows, and bound data available to the packet.

The endpoint rows I and U are then read as lower and upper tail-envelope data for that same source. The packet therefore compares two displayed endpoint certificates, not two host-selected limits.

The dyadic ledger D and rational readback Q carry the finite comparison budget. Only after those rows are replayed can a consumer reach the terminal $\mathsf{Real}^{\uparrow}$ seal E and the structural rows H, C, P, N. □

Lean4 ✓ `BEDC.Derived.LimsupLiminfGapUp.LimsupLiminfGapEndpointRoute`

Falsifiable prediction: Every accepted $\mathsf{LimsupLiminfGap}^{\uparrow}$ Real-facing read factors through a bounded real sequence source, Liminf endpoint, bounded Real limsup endpoint, dyadic tolerance ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: liminf, bounded-real-limsup, boundedrealsequence, regseqrat, real: no listed sibling supplies the whole packet $G = (S, I, U, D, Q, E, H, C, P, N)$, because each sibling contributes only the lower endpoint, upper endpoint, bounded source, rational readback, or terminal real seal while this chapter binds them into one oscillation-width carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LimsupLiminfGap}^{\uparrow}}$.

Constructive story: A $\mathsf{LimsupLiminfGap}^{\uparrow}$ packet is generated from a bounded real sequence source, a Liminf endpoint row, a bounded Real limsup endpoint row, a dyadic tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transports, Cont replay routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LimsupLiminfGap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8002.1, Definition 8002.2, and Definition 8002.3 seed the finite oscillation-width surface for bounded real sequences.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LimsupLiminfGap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, host supremum or infimum selection, quotient stream equality, selected subsequences, zero-gap convergence, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, shared-source endpoint alignment, dyadic tolerance exactness, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.LimsupLiminfGapUp.

Chapter 8003

A Concrete Naming Certificate for $\mathsf{QuasiPolishSpace}^{\uparrow}$

Following de Brecht and the Brattka–Gherardi treatment of represented countably based spaces, the $\mathsf{QuasiPolishSpace}^{\uparrow}$ packet records the finite BEDC surface in which countable open information and sober point reconstruction are displayed without requiring a compatible complete metric. It sits between the complete-separable metric boundary of chapter 1490, the point-reconstruction route of chapter 6495, the point-free open route of chapter 5153, the indexed-open source of chapter 88, and the finite observation schedules of chapter 126. The packet supplies a non-metric countably based sober-space bridge; it does not import host powersets, choice-indexed generic points, quotient spatial reflection, or a selected Polish presentation.

Definition 8003.1 (Quasi-Polish space carrier)**.** *A* $\mathsf{QuasiPolishSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, B, S, L, P, W, H, C, G, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing indexed open observations and their finite refinement tests.*
2. *B is the countable-base ledger, recording finite windows of basic opens and their cover-refinement reads.*
3. *S is the* $\mathsf{SoberSpace}^{\uparrow}$ *handoff row, available only after the topology and base rows have been displayed.*
4. *L is the* $\mathsf{LocaleSpace}^{\uparrow}$ *comparison row, reading the same open data point-free before any point-facing reconstruction is consumed.*
5. *P is the optional* $\mathsf{PolishSpace}^{\uparrow}$ *comparison row, present only when a complete-separable metric presentation has already been displayed by a sibling packet.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule for finite windows of basic-open and neighborhood reads.*
7. *H records componentwise* hsame *transport for the topology, base, sober, locale, Polish-comparison, stream, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from base-window requests through topology rows, locale comparison, sober reconstruction, and optional Polish comparison.*

9. *G is the* Pkg *provenance over* $\mathsf{QuasiPolishSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{SoberSpace}^{\uparrow}$, $\mathsf{PolishSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{QuasiPolishSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, B, S, L, P, W, H, C, G, N$. It has no coordinate for host powersets, arbitrary open-set quantification, selected completely prime filters, quotient spatial reflection, choice-indexed generic points, or a forced compatible complete metric.

Lean4 ✓ `BEDC.Derived.QuasiPolishSpaceUp.TasteGate.QuasiPolishSpaceTasteGate single carrier alignment`

Theorem 8003.2 (Quasi-Polish space NameCert obligations)**.** *For every accepted* $\mathsf{QuasiPolishSpace}^{\uparrow}$ *carrier $Q = (T, B, S, L, P, W, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{QuasiPolishSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission, countable-base window exposure, locale comparison, sober reconstruction handoff, optional Polish comparison, finite stream scheduling, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every consumer must read these rows before treating the packet as a quasi-Polish space boundary.*

Proof. Project the carrier of Definition 8003.1. The rows $T, B, S, L, P, W, H, C, G, N$ are the only classifier-visible coordinates.

The open-information side is finite. The topology row T and base ledger B expose indexed opens through finite windows, while the stream row W records the schedule by which those windows are read.

The reconstruction side is routed. The locale row L compares the same open data point-free, the sober row S supplies the point-reconstruction handoff, and the Polish row P is only a comparison surface when a sibling complete-separable metric presentation is already displayed.

Transport, replay, provenance, and local naming are exhausted by H, C, G, N. Since no row stores host powersets, selected generic points, quotient spatial reflection, or a forced metric presentation, the listed rows are exactly the NameCert obligations. □

Theorem 8003.3 (Quasi-Polish sober-Polish handoff)**.** *Every accepted* $\mathsf{QuasiPolishSpace}^{\uparrow}$ *consumer that compares sober reconstruction with Polish-style readback factors through*

$$\mathsf{Topology}^{\uparrow},\ B,\ \mathsf{LocaleSpace}^{\uparrow},\ \mathsf{SoberSpace}^{\uparrow},\ \mathsf{StreamName}^{\uparrow}$$

before it may inspect the optional $\mathsf{PolishSpace}^{\uparrow}$ *comparison row. The handoff lets a complete-separable metric sibling feed a quasi-Polish consumer, and lets a sober countably based route feed a non-metric consumer, but it does not identify the packet with a host powerset topology, a quotient spatial reflection, a selected generic point, or a chosen compatible complete metric.*

Proof. Start with the topology and base rows. They expose the countably based open information as finite indexed windows rather than as a host powerset.

Next read the locale and sober rows. The locale comparison keeps the frame-of-opens route visible, and the sober handoff reads point reconstruction only after those open rows are displayed.

The stream schedule preserves finiteness of the comparison. Any Polish row is downstream from these windows and appears only as a sibling comparison surface, so it cannot force a metric presentation for the whole packet.

Thus the quasi-Polish handoff separates the sober countably based route from the Polish complete-separable comparison while preserving both as displayed BEDC rows. □

Falsifiable prediction: An accepted $\mathsf{QuasiPolishSpace}^{\uparrow}$ read is refuted if it exports sober point reconstruction or Polish comparison without displaying the TopologyUp source row, countable-base ledger, LocaleSpaceUp comparison row, SoberSpaceUp handoff row, StreamNameUp schedule, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert row.

Independence witness: polishspace, sober-space, locale-space, topology, streamname: $\mathsf{QuasiPolishSpace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries countable-base windows, topology rows, locale comparison, sober reconstruction, optional Polish comparison, stream scheduling, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{QuasiPolishSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{QuasiPolishSpace}^{\uparrow}$ packet is generated from a TopologyUp source row, countable-base ledger, SoberSpaceUp handoff, LocaleSpaceUp comparison, optional PolishSpaceUp comparison, StreamNameUp schedule, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{QuasiPolishSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8003.1, Definition 8003.2, and Definition 8003.3 seed the finite non-metric countably based sober-space bridge over topology, locale, sober, Polish-comparison, and stream rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{QuasiPolishSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host powersets, choice-indexed generic points, quotient spatial reflection, arbitrary locale spatiality, selected compatible complete metrics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked topology admission, countable-base exposure, locale comparison, sober reconstruction handoff, optional Polish comparison discipline, stream scheduling, transport, replay, provenance, and local naming for BEDC.Derived.QuasiPolishSpaceUp.

Chapter 8004

A Concrete Naming Certificate for $\mathsf{EngelExpansionReal}^{\uparrow}$

Following Engel and the constructive real-number treatment in Bishop and Bridges, the $\mathsf{EngelExpansionReal}^{\uparrow}$ packet names the finite route by which an Engel denominator schedule becomes a displayed real-name surface. It sits after the Engel expansion carrier of chapter 2007, the rational row of chapter 37, the dyadic tail ledger of chapter 291, the finite stream window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet records an Engel-generated real presentation as finite BEDC NameCert data; it does not identify quotient representatives, choose an infinite sum, invoke trichotomy, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8004.1 (EngelExpansionReal carrier)**.** *An* $\mathsf{EngelExpansionReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (E, Q, D, W, R, L, H, C, P, N)$$

with the following displayed rows:

1. *E is the source* $\mathsf{EngelExpansion}^{\uparrow}$ *packet, including its denominator schedule, rational partial sums, dyadic remainder bounds, stream windows, regular readback, and terminal Real seal rows.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *partial-sum row read from the Engel denominator schedule.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-control row used to bound every unread Engel remainder visible to the packet.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row selecting the denominator prefixes, partial sums, and tail bounds under inspection.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational sequence row produced from Q, D, W.*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row attached only after the regular rational route has been displayed.*
7. *H records componentwise* hsame *transport for the Engel source, rational partial sums, dyadic tail bounds, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-name request through*

$$E, Q, W \longmapsto D \longmapsto R \longmapsto L.$$

9. *P is the* Pkg *provenance over* EngelExpansion$^{\uparrow}$, Rat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{EngelExpansionReal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for quotient representatives of reals, a selected value of an infinite Engel sum, trichotomy, countable choice, ambient Real$^{\uparrow}$ *completeness, or bridge checking.*

Theorem 8004.2 (EngelExpansionReal NameCert obligations)**.** *For every accepted* EngelExpansionReal$^{\uparrow}$ *carrier $X = (E, Q, D, W, R, L, H, C, P, N)$, the local* NameCert$_{\text{EngelExpansionReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the Engel source row, rational partial-sum exposure, dyadic remainder control, finite stream-window selection, regular rational readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier $X = (E, Q, D, W, R, L, H, C, P, N)$. The projection exposes the Engel source packet, the rational partial-sum row, the dyadic tail-control row, the stream-window row, the regular readback row, and the real-name seal.

Use Definition 2007.2. The source row E already displays the Engel denominator schedule and its finite NameCert obligations, so the real-facing packet does not introduce a separate infinite series object.

Read Q, D, W before any completion-facing data. The rational partial sums are visible only through the finite windows, and every unread tail claim passes through the dyadic remainder-control row before R or L can be consumed.

Finally form the regular readback and the Real seal. The rows H, C, P, N transport, replay, source, and name exactly this route, so quotient representatives, trichotomy, selected sums, ambient completeness, and bridge checking remain outside the local obligation surface. □

Theorem 8004.3 (EngelExpansionReal regular-Cauchy route)**.** *Every accepted* EngelExpansionReal$^{\uparrow}$ *carrier exposes its real-name readback only through the finite route*

$$E, Q, W \longmapsto D \longmapsto R \longmapsto L$$

with structural support H, C, P, N. Thus every real-facing consumer first reads an EngelExpansion$^{\uparrow}$ *source,* Rat$^{\uparrow}$ *partial sums,* DyadicRatCore$^{\uparrow}$ *tail bounds,* StreamName$^{\uparrow}$ *windows, a* RegSeqRat$^{\uparrow}$ *regular readback, and a terminal* Real$^{\uparrow}$ *seal before any* Real$^{\uparrow}$ *observation is available.*

Proof. Start from a consumer of the Real seal L. By the carrier definition, L is not an independent completed object; it is downstream of the regular rational row R and the finite Engel data displayed by E, Q, D, W.

Apply the real readback boundary of Definition 2007.3. That theorem forces the Engel source to pass through rational partial sums, dyadic tail bounds, stream windows, regular readback, and the terminal Real seal before any real-facing interpretation is available.

Use the sibling L10 route through chapter 291, chapter 126, chapter 301, and chapter 38. These chapters supply the dyadic bound, finite-window, regular-sequence, and real-seal rows consumed by the route.

The structural rows H, C, P, N then transport, replay, source, and name the same finite passage. Since no carrier coordinate stores quotient representatives, selected real limits, trichotomy, ambient completeness, Lean verification, or a checked bridge, none of those claims is exported by the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{EngelExpansionReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EngelExpansionReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8004.1, Definition 8004.2, and Definition 8004.3 seed the Engel-generated real presentation through finite rational partial sums, dyadic tail bounds, stream windows, regular rational readback, and terminal Real seal data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EngelExpansionReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient representatives, trichotomy, selected real limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, regular-Cauchy routing, and non-escape proofs for the finite Engel source, rational partial-sum, dyadic tail-bound, stream-window, regular-readback, Real-seal, transport, replay, provenance, and local naming rows.

Constructive story: An $\mathsf{EngelExpansionReal}^{\uparrow}$ packet is generated from an EngelExpansion source, RatUp partial sums, DyadicRatCore tail bounds, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Chapter 8005

A Concrete Naming Certificate for $\mathsf{ThreeDistanceTheorem}^{\uparrow}$

Following Steinhaus and the classical three-distance theorem, the $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ packet records the finite orbit-window certificate for rotations on the circle. It sits beside the circle-name surface $\mathsf{S}^{1\uparrow}$, the approximation route of chapter 1974, the distribution route of chapter 7520, the dyadic comparison core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite circle-rotation windows, adjacent gap ledgers, dyadic tolerance rows, StreamName and RegSeqRat readback, Real and $\mathsf{S}^{1\uparrow}$ sealing, transport, replay, provenance, and local naming.

Definition 8005.1 (Three-distance theorem carrier)**.** *A* $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (A, W, O, G, D, S, Q, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the rotation-angle source row, carried only through displayed rational and real-name observations.*
2. *W is the finite orbit-window row for the points $\{0, A, 2A, \ldots, nA\}$ read on the circle.*
3. *O is the cyclic ordering row for the inspected orbit window.*
4. *G is the adjacent gap ledger obtained from consecutive rows of O.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the displayed gaps with the accepted tolerance rows.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule used to expose the finite real-name windows.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the gap lengths and tolerance budgets.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the inspected gap lengths.*
9. *U is the* $\mathsf{S}^{1\uparrow}$ *seal stating that the cyclic order is read on the circle surface.*
10. *E is the local three-distance classifier row: the adjacent gap ledger has at most three displayed gap classes through D, Q, R, U.*
11. *H records componentwise* hsame *transport for the angle, window, cyclic order, gap ledger, dyadic tolerance, stream schedule, readback, seals, classifier, replay, provenance, and naming rows.*

12. *C records displayed* Cont *replay from any theorem-facing query back through the same finite rows.*

13. *P is the* Pkg *provenance over* $\mathsf{ThreeDistanceTheorem}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{KroneckerApproximation}^{\uparrow}$, $\mathsf{WeylEquidistribution}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{ThreeDistanceTheorem}^{\uparrow}}$ *row.*

The carrier contains no measure argument, quotient-circle equality oracle, selected limiting subsequence, ambient real completeness principle, or countable-choice route.

Theorem 8005.2 (Three-distance theorem NameCert obligations)**.** *For every accepted* $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ *carrier*

$$T = (A, W, O, G, D, S, Q, R, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ThreeDistanceTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the rotation-angle row, finite orbit-window row, cyclic ordering row, adjacent gap ledger, dyadic tolerance ledger, StreamName schedule, RegSeqRat readback, Real and* $\mathsf{S}^{1\uparrow}$ *seals, three-gap classifier, componentwise transport, displayed replay, provenance, and local naming. A consumer may cite the theorem only after the finite window has been inspected and the adjacent gap ledger has been classified into at most three displayed gap classes.*

Proof. Project the carrier of Definition 8005.1. The only circle data available to a theorem-facing consumer are the angle source A, the finite orbit window W, and the cyclic order O.

Inspect the finite window. Consecutive entries of O determine the adjacent gap ledger G, and the dyadic row D compares the displayed gap lengths against the finite tolerance rows read through S, Q, R.

Classify the ledger. The row E records that the displayed adjacent gaps fall into at most three gap classes after the $\mathsf{S}^{1\uparrow}$ seal U and the $\mathsf{Real}^{\uparrow}$ seal R are visible.

Finally transport and replay through H, C, P, N. These rows preserve and name the inspected finite packet, so the certificate cannot import measure, quotient-circle equality, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8005.3 (Three-distance finite window inspection)**.** *Every accepted* $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ *read factors through the finite route*

$$A \longmapsto W \longmapsto O \longmapsto G \longmapsto D \longmapsto (S, Q, R, U) \longmapsto E.$$

The route supplies the three-gap statement by inspection of the displayed orbit window and adjacent gap ledger; it does not use measure, a quotient equality test for circle points, an infinite equidistribution theorem, a selected subsequence, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Proof. Read the rotation source and finite window first. The cyclic order row O is part of the packet, so the adjacent gap ledger G is generated from displayed neighboring rows rather than from a host quotient of the circle.

Next read the numeric side. The dyadic ledger D, stream schedule S, regular rational readback Q, Real seal R, and circle seal U are the only routes by which gap lengths become visible.

The classifier row E consumes exactly those rows and records the at-most-three gap classes. Componentwise transport, replay, provenance, and local naming expose no additional analytic principle, so the theorem remains a finite window certificate. □

Falsifiable prediction: An accepted $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ read is refuted if the adjacent gap ledger G or dyadic tolerance ledger D is removed while the three-gap classifier row E is still claimed.

Independence witness: sone, kroneckerapproximation, weylequidistribution, dyadicratcore, regseqrat, real: $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite rotation windows, cyclic ordering, adjacent gap classification, dyadic tolerance rows, StreamName scheduling, RegSeqRat readback, Real and circle seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ThreeDistanceTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{ThreeDistanceTheorem}^{\uparrow}$ packet is generated from a rotation-angle row, finite orbit-window row, cyclic ordering row, adjacent gap ledger, dyadic tolerance ledger, StreamName schedule, RegSeqRat readback, Real and circle seals, three-gap classifier, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ThreeDistanceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8005.1, Definition 8005.2, and Definition 8005.3 seed the finite three-distance route over circle windows, adjacent gap ledgers, dyadic tolerance, regular rational readback, Real and circle seals, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ThreeDistanceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-theoretic equidistribution, quotient-circle equality, selected subsequences, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, orbit-window inspection, cyclic-order exposure, adjacent gap ledger exactness, dyadic tolerance readback, Real and circle sealing, transport, replay, provenance, and local naming for BEDC.Derived.ThreeDistanceTheoremUp.

Chapter 8006

A Concrete Naming Certificate for ClosedSubstitutionSelfCompile$^{\uparrow}$

The ClosedSubstitutionSelfCompile$^{\uparrow}$ packet realizes the closed-term substitution self-compile boundary as finite MetaCIC NameCert data. It sits after the closed boundary of chapter 527, the substitution spine realizer of chapter 6990, the kernel acceptance witness of chapter 549, and the MetaCIC critical-path packet of chapter 765. The packet records closed-term, substitution, binder-seal, replay, refusal, transport, provenance, and local naming rows before any compiler-facing consumer may read the self-compile handoff.

Definition 8006.1 (Closed substitution self-compile carrier)**.** *A* ClosedSubstitutionSelfCompile$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, D, V, Q, B, L, R, F, K, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the MetaCIC closed-term source row.*
2. *D is the de Bruijn depth row at which the closed boundary is read.*
3. *V is the substitution payload row.*
4. *Q is the* `ClosedAt` *classifier row for T at depth D.*
5. *B is the binder-seal row ensuring that the boundary is read before any recursive binder descent.*
6. *L is the displayed closed-substitution row for substituting V into T at depth D.*
7. *R is the replay row exposing the same closed substitution route to the compiler-facing consumer.*
8. *F is the refusal row for open-term substitution, unrestricted binder descent, and host evaluator equality.*
9. *K is the kernel-acceptance witness row tying the displayed MetaCIC packet to an accepted kernel-facing certificate.*
10. *A is the self-compile audit row recording that the compiler reads only $T, D, V, Q, B, L, R, F, K$.*
11. *H records componentwise* hsame *transport for the term, depth, payload, classifier, binder seal, substitution, replay, refusal, kernel, and audit rows.*

12. *C records displayed* Cont *replay from each compiler-facing query back through the same finite rows.*

13. *P is the* Pkg *provenance over* $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$, $\mathsf{ClosedSubstitutionBoundary}^{\uparrow}$, MetaCICSubstitution
KernelAcceptanceWitness$^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted substitution, host evaluator equality, open-term semantic preservation, quotient syntax equality, or global compiler correctness.

Theorem 8006.2 (Closed substitution self-compile NameCert obligations)**.** *For every accepted* $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$ *carrier*

$$S = (T, D, V, Q, B, L, R, F, K, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}}$ *surface consists exactly of carrier admission for the closed MetaCIC term row, depth row, substitution payload row, closedness classifier, binder seal, closed-substitution row, replay row, refusal row, kernel-acceptance witness, self-compile audit row, componentwise transport, displayed replay, provenance, and local naming. A compiler-facing consumer may read the self-compile handoff only through those displayed rows.*

Proof. Project the carrier of Definition 8006.1. The closed term, depth, payload, closedness classifier, binder seal, substitution row, replay row, refusal row, kernel row, and audit row are explicit coordinates.

Read the boundary rows in order. The classifier Q and binder seal B are exposed before the substitution row L, so the packet is confined to the closed boundary rather than to unrestricted substitution under binders.

Read the replay and refusal rows. The replay row R is the only compiler-facing route for the closed substitution, while F keeps open-term substitution, host evaluator equality, and quotient syntax equality outside the packet.

Finally consume K, A, H, C, P, N. Kernel acceptance, self-compile audit, transport, replay, provenance, and local naming preserve the same finite surface and do not add global compiler correctness. □

Theorem 8006.3 (Closed substitution self-compile refusal boundary)**.** *Every accepted* ClosedSubstitutionSelfCompi
read keeps the refusal row F visible whenever the compiler-facing handoff A is consumed. Thus the packet can replay closed-term substitution through R, A, H, C, P, N, but it cannot claim unrestricted substitution, open-term semantic preservation, host evaluator equality, quotient syntax equality, or full compiler correctness.

Proof. Start with the handoff row A. By the carrier definition, A reads only the displayed rows $T, D, V, Q, B, L, R, F, K$ before transport, continuation, provenance, and local naming are consumed.

The refusal row F is part of that handoff inventory. Removing F changes the carrier read, so an accepted handoff cannot silently turn the closed-boundary packet into an unrestricted substitution theorem.

The structural rows H, C, P, N replay and name the same finite packet. They preserve the visible refusal boundary and therefore block host evaluator equality, quotient syntax equality, open-term preservation, and full compiler correctness claims. □

Theorem 8006.4 (Closed substitution self-compile TasteGate readiness)**.** *The Lean follow-up for* $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$ *must provide explicit* $\mathsf{Nontrivial\ ClosedSubstitutionSelfCompile}^{\uparrow}$ *and* $\mathsf{FieldFaithful\ ClosedSubstitutionSelfCompile}^{\uparrow}$ *instances for the same finite carrier. These instances must keep* $T, D, V, Q, B, L, R, F, K, A, H, C, P, N$ *as separate displayed rows before any checked TasteGate theorem can serve as a public self-compile gate.*

Proof. Use the carrier of Definition 8006.1. Nontriviality is forced by the distinction between an accepted closed-boundary packet and a refused open-term substitution packet.

Field faithfulness is forced by the row inventory. A read that collapses the binder seal, refusal row, kernel row, or audit row does not preserve the displayed carrier and therefore cannot serve as the public gate for this packet. □

Falsifiable prediction: Every accepted $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$ compiler-facing read exposes the closed term, substitution row, binder seal, replay row, refusal row, kernel acceptance row, self-compile audit row, transport, provenance, and local NameCert rows before the handoff is visible.

Independence witness: closedtermsubstitutionboundary, metacic-substitution-spine-realizer, kernelacceptancewitness, metaciccriticalpath: $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the closed substitution boundary, binder seal, replay row, refusal row, kernel witness, self-compile audit, transport, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}$ packet is generated from a closed MetaCIC term row, de Bruijn depth row, substitution payload row, ClosedAt classifier, binder seal, closed-substitution row, replay row, refusal row, kernel acceptance witness, self-compile audit row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8006.1, Definition 8006.2, Definition 8006.3, and Definition 8006.4 seed the finite closed-substitution self-compile carrier, refusal boundary, handoff discipline, and TasteGate readiness surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedSubstitutionSelfCompile}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted substitution, open-term semantic preservation, host evaluator equality, quotient syntax equality, full compiler correctness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, binder-seal routing, closed-substitution replay, refusal preservation, kernel acceptance handoff, self-compile audit visibility, transport, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.ClosedSubstitutionSelfCompileUp.

Chapter 8007

A Concrete Naming Certificate for $\mathsf{MobiusInversion}^{\uparrow}$

Following Rota on finite incidence algebras, the $\mathsf{MobiusInversion}^{\uparrow}$ packet records Mobius inversion over a finite poset as ledger data rather than as an ambient algebra theorem. It sits after the relation skeletons of chapter 52 and chapter 53, the meet-and-join comparison surface of chapter 55, the finite enumeration discipline of chapter 112, and the membership-facing carrier route of chapter 3668. The packet names zeta and Mobius rows only on displayed finite intervals; it does not add an infinite incidence algebra, a host ring completion, an unbounded summation principle, selected inverse matrices, or ambient choice.

Definition 8007.1 (Mobius inversion carrier)**.** *A* $\mathsf{MobiusInversion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (P, I, Z, K, W, Q, H, C, G, N)$$

with the following displayed rows:

1. *P is the finite poset source row, recording the* $\mathsf{Poset}^{\uparrow}$ *comparison data and the underlying* $\mathsf{Preorder}^{\uparrow}$ *reflexive-transitive ledger.*
2. *I is the interval ledger. For every displayed comparable pair $x \leq y$, it lists the finite interval members as a* $\mathsf{FinSet}^{\uparrow}$ *row with membership readback through* $\mathsf{SetLike}^{\uparrow}$*.*
3. *Z is the zeta row, assigning the displayed unit value to every accepted interval entry in I and refusing non-comparable pairs.*
4. *K is the Mobius row, recording the recursively checked alternating interval coefficients attached to the same finite interval ledger.*
5. *W is the finite convolution window, listing exactly the intermediate z with $x \leq z \leq y$ that may be used in a zeta-Mobius product.*
6. *Q is the inverse-check ledger, recording both finite convolution checks: the zeta-then-Mobius and Mobius-then-zeta rows collapse to the displayed diagonal row on each accepted interval.*
7. *H records componentwise* hsame *transport for the poset source, interval ledger, zeta row, Mobius row, convolution window, inverse-check ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an inversion request through $P, I, Z, K, W, Q, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{MobiusInversion}^{\uparrow}$*,* $\mathsf{Preorder}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*,* $\mathsf{Lattice}^{\uparrow}$*,* $\mathsf{FinSet}^{\uparrow}$*,* $\mathsf{SetLike}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MobiusInversion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $P, I, Z, K, W, Q, H, C, G, N$. The carrier has no coordinate for an infinite incidence algebra, host matrix inversion, selected global inverse, unbounded summation, quotient equality of functions, or ambient algebraic completion.

Theorem 8007.2 (Mobius inversion NameCert obligations)**.** *For every accepted* $\mathsf{MobiusInversion}^{\uparrow}$ *carrier $M = (P, I, Z, K, W, Q, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MobiusInversion}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite poset source, interval ledger, zeta row, Mobius row, finite convolution window, inverse-check ledger, componentwise transport, displayed replay, package provenance, and local naming rows. A consumer may read inversion data only after it displays the route*

$$P, I \longmapsto Z, K \longmapsto W, Q \longmapsto H, C, G, N.$$

Proof. Project the carrier of Definition 8007.1. The poset source P supplies the comparison row, while I supplies the finite interval members through the Finset and SetLike routes.

The algebra-facing rows are then read from the same interval ledger. The zeta row Z and the Mobius row K attach coefficients only to displayed comparable pairs, and W lists the finite intermediates allowed in a convolution.

Finally inspect Q, H, C, G, N. The inverse-check ledger Q records the two finite convolution identities, and the structural rows transport, replay, source, and name the same packet. Since no accepted row stores infinite incidence algebra data, host matrix inversion, selected inverse matrices, unbounded sums, quotient equality of functions, or ambient completion, the listed rows exhaust the NameCert obligations. □

Theorem 8007.3 (Mobius inversion incidence ledger)**.** *Every accepted* $\mathsf{MobiusInversion}^{\uparrow}$ *incidence consumer receives the inverse relation only through the displayed finite ledger*

$$P, I, Z, K, W, Q, H, C, G, N.$$

In particular, the consumer must preserve the same $\mathsf{Preorder}^{\uparrow}$ *and* $\mathsf{Poset}^{\uparrow}$ *comparison rows, the same* $\mathsf{FinSet}^{\uparrow}$ *interval enumeration, the same* $\mathsf{SetLike}^{\uparrow}$ *membership readback, the same zeta and Mobius rows, and the same finite convolution window before it may cite an inversion check.*

Proof. Start with a request for inversion on an interval. The comparison is first routed through P, so the request is bounded by the finite poset source rather than by a host incidence algebra.

Use the interval ledger I and the convolution window W. They list the only intermediate elements available to the consumer, with membership read through the Finset and SetLike rows. The zeta and Mobius rows are therefore attached to the same finite interval.

The inverse-check ledger Q may then be read, but only for those displayed finite windows. The structural rows H, C, G, N preserve the same route under transport, replay, provenance, and local naming, so the consumer never receives an unbounded summation principle or an ambient inverse object. □

Falsifiable prediction: Every accepted $\mathsf{MobiusInversion}^{\uparrow}$ read factors through finite Poset and Preorder source rows, interval ledgers, zeta rows, Mobius rows, finite convolution windows, inverse-check ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any incidence consumer may cite inversion.

Independence witness: preorder, poset, lattice, finset, setlike: $\mathsf{MobiusInversion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite interval ledgers, zeta rows, Mobius rows,

convolution windows, inverse-check ledgers, transport, replay, provenance, and local NameCert data as one incidence packet.

Future Lean TasteGate obligations for $\mathsf{MobiusInversion}^{\uparrow}$ must certify the finite incidence route at `lean4/BEDC/Derived/MobiusInversionUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{MobiusInversion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MobiusInversion}^{\uparrow}$ packet is generated from a finite Poset source row, a Preorder comparison ledger, Finset interval enumeration, SetLike membership readback, zeta and Mobius rows, finite convolution windows, inverse-check ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MobiusInversion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8007.1, Definition 8007.2, and Definition 8007.3 seed the finite incidence-ledger route over Preorder, Poset, Lattice, Finset, and SetLike rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MobiusInversion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim infinite incidence algebras, host matrix inversion, selected inverse matrices, quotient equality of functions, unbounded summation, ambient algebraic completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-ledger exactness, zeta-row exactness, Mobius-row exactness, finite convolution checks, inverse-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.MobiusInversionUp.

Chapter 8008

A Concrete Naming Certificate for $\mathsf{AnalyticSet}^{\uparrow}$

Following Suslin and Luzin in descriptive set theory, the $\mathsf{AnalyticSet}^{\uparrow}$ packet records analytic subsets as finite BEDC data for a projection-coded tree over Baire-space names. It sits after the sequence carrier of chapter 334, the Borel-code hierarchy of chapter 4020, the membership surface of chapter 3668, the topological source rows of chapter 88, and the terminal real-name boundary of chapter 38. The chapter names the projection-code surface used by later descriptive-set and measurable-function consumers; it is not a universal classical separation theorem, a quotient point-set equality, a selected witness branch, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8008.1 (AnalyticSet carrier)**.** *An* $\mathsf{AnalyticSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, B, T, S, P, R, H, C, G, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{BaireSpace}^{\uparrow}$ *row whose finite sequence windows name candidate witnesses.*
2. *B is the* $\mathsf{BorelHierarchy}^{\uparrow}$ *code row for the subset of the product space whose projection is under inspection.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *row supplying the product, cylinder, and projection-domain reads used by the Borel code.*
4. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership row recording finite positive and negative membership probes against the projected set.*
5. *P is the projection-code row, recording that a displayed Baire witness window and Borel-code read are consumed before the projected membership row is visible.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *boundary row used when the source topology or later measurable-function consumers read real-valued probes.*
7. *H records componentwise* hsame *transport for the Baire-space, Borel-code, topology, membership, projection-code, real-boundary, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a membership request through*

$$X, B, T \longmapsto P \longmapsto S, R.$$

9. *G is the* Pkg *provenance over* $\mathsf{AnalyticSet}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BorelHierarchy}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AnalyticSet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a selected infinite witness branch, quotient equality of subsets, classical separation, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8008.2 (AnalyticSet NameCert obligations)**.** *For every accepted* $\mathsf{AnalyticSet}^{\uparrow}$ *carrier* $A = (X, B, T, S, P, R, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AnalyticSet}^{\uparrow}}$ *surface consists exactly of carrier admission, Baire-space witness-window exposure, Borel-code exposure, topology compatibility, set-membership readback, projection-code binding, real-boundary nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the carrier $A = (X, B, T, S, P, R, H, C, G, N)$. The only analytic-set data available to a consumer are the Baire-space windows, Borel-code row, topology row, membership row, projection-code row, and real-boundary row.

Read X, B, T before projection membership. The Baire-space row supplies finite witness windows, the Borel hierarchy row supplies the code being projected, and the topology row supplies the product and cylinder reads needed to interpret the code.

The projection row P then binds those reads to S. A membership consumer may inspect the projected set only through the displayed witness-window and Borel-code route, while R records real-valued topological probes without adding a completion principle.

Finally H, C, G, N transport, replay, source, and name the same packet. Since no carrier coordinate stores a selected infinite branch, quotient subset equality, classical separation, countable choice, or ambient real completeness, none of those principles is part of the local NameCert surface. □

Theorem 8008.3 (AnalyticSet Suslin projection handoff)**.** *Every descriptive-set or measurable-function consumer of an accepted* $\mathsf{AnalyticSet}^{\uparrow}$ *packet receives the analytic set only through the finite projection-code route*

$$\mathsf{BaireSpace}^{\uparrow},\ \mathsf{BorelHierarchy}^{\uparrow},\ \mathsf{Topology}^{\uparrow} \longmapsto P \longmapsto \mathsf{SetLike}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

with structural support H, C, G, N. The handoff records the Suslin projection surface as named BEDC data; it does not export a selected witness branch, a universal separation theorem, quotient equality of subsets, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier definition. The projection-code row P is downstream of the Baire-space witness windows, Borel-code row, and topology rows, so a consumer cannot read projected membership before those rows have been displayed.

Apply the NameCert obligation theorem, Definition 8008.2. It identifies carrier admission, Baire-space exposure, Borel-code exposure, topology compatibility, membership readback, projection binding, and real-boundary nonescape as the complete local obligation surface.

The structural rows H, C, G, N then preserve the same route under transport, continuation replay, provenance, and local naming. They do not add a branch selector, a quotient of subsets, a separation theorem, countable choice, or Real completeness.

Thus the public handoff is exactly a finite Suslin projection-code packet over the named sibling chapters. Downstream consumers may reuse that packet as a descriptive-set boundary, but any stronger classical object would require a coordinate absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{AnalyticSet}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AnalyticSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8008.1, Definition 8008.2, and Definition 8008.3 seed the finite projection-code surface for analytic sets over Baire-space, Borel-code, topology, set-membership, and Real-boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AnalyticSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical separation, selected witness branches, quotient subset equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection-code binding, Baire-space and Borel-code exposure, topology compatibility, SetLike membership readback, Real-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AnalyticSetUp.

Constructive story: An $\mathsf{AnalyticSet}^{\uparrow}$ packet is generated from BaireSpace witness windows, BorelHierarchy code rows, Topology product and cylinder reads, SetLike membership rows, a projection-code row, a RealUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8009

A Concrete Naming Certificate for $\mathsf{InjectiveModule}^{\uparrow}$

Following Baer and Cartan–Eilenberg, the $\mathsf{InjectiveModule}^{\uparrow}$ packet records the finite homological-algebra interface in which maps out of a displayed submodule inclusion extend into a chosen module row. It sits over the ring and module surfaces of chapter 43 and chapter 46, reads linear maps through chapter 48, and keeps its exactness boundary compatible with the exact-sequence obligation surface of chapter 176 and the displayed $\mathsf{ExactSequence}^{\uparrow}$ handoff in chapter 7321. The packet is an extension-lifting certificate; it is not a host injective object, a derived-functor computation, a quotient representative, or an ambient choice principle.

Definition 8009.1 (Injective module carrier)**.** *An* $\mathsf{InjectiveModule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, M, S, F, E, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the scalar* $\mathsf{Ring}^{\uparrow}$ *row and M is the target* $\mathsf{Module}^{\uparrow}$ *row over that scalar source.*
2. *S is the submodule inclusion row, recording a displayed inclusion $A \hookrightarrow B$ inside the same module classifier window.*
3. *F is the source hom row, read as a* $\mathsf{LinMap}^{\uparrow}$ *map from the submodule row A into M.*
4. *E is the extended hom row, read as a* $\mathsf{LinMap}^{\uparrow}$ *map from the ambient row B into M.*
5. *B is the exact-sequence boundary row, recording that the restriction of E along S is the displayed source hom row F.*
6. *H records componentwise* hsame *transport for $R, M, S, F, E, B, C, P, N$.*
7. *C records displayed* Cont *replay from an extension request through the module, inclusion, source hom, extended hom, and boundary rows.*
8. *P is the* Pkg *provenance over* $\mathsf{InjectiveModule}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{ExactSequence}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{InjectiveModule}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, S, F, E, B, H, C, P, N$. It has no coordinate for a host category of modules, a selected quotient representative, a global Ext calculation, an arbitrary splitting, or an unstated choice of extension.

Theorem 8009.2 (Injective module NameCert obligations)**.** *For every accepted* $\mathsf{InjectiveModule}^{\uparrow}$ *carrier*

$$I = (R, M, S, F, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{InjectiveModule}^{\uparrow}}$ *surface consists exactly of scalar-ring admission, target-module admission, submodule-inclusion exposure, source-hom exposure, extended-hom exposure, exact-sequence boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every extension-facing consumer must expose* R, M, S, F, E, B *before it may consume transport, replay, provenance, or naming rows.*

Proof. Project the carrier of Definition 8009.1. The scalar row R and target row M are the only module data available to the classifier, and the inclusion row S is the only displayed submodule input.

The source hom row F and extended hom row E are both read through the $\mathsf{LinMap}^{\uparrow}$ surface over the same scalar source. The boundary row B records their restriction contact, so an extension request cannot bypass S, F, E, or the exact-sequence boundary by appealing to a host quotient or an external lifting theorem.

Transport and replay preserve the same finite route componentwise, while provenance and the local naming row bind it to $\mathsf{InjectiveModule}^{\uparrow}$. Since no other coordinates occur in the carrier, these rows exhaust the NameCert obligations. □

Theorem 8009.3 (Injective module extension lifting)**.** *Every extension-lifting read of an accepted* $\mathsf{InjectiveModule}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{Ring}^{\uparrow}, \mathsf{Module}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{ExactSequence}^{\uparrow} \longmapsto \mathsf{InjectiveModule}^{\uparrow}.$$

Concretely, a consumer must read the scalar ring row R*, target module row* M*, submodule inclusion row* S*, source hom row* F*, extended hom row* E*, and exact-sequence boundary row* B *before it may claim that the source map has been extended. The exported lift is the displayed row* E *together with its boundary contact* B*; it is not a host injective-object theorem, Baer criterion over all ideals, Ext-vanishing statement, selected splitting, quotient representative, or ambient choice principle.*

Proof. Begin with the obligation surface of Definition 8009.2. It forces every extension-facing consumer to expose the ring, module, inclusion, source hom, extended hom, and boundary rows before any structural support row is read.

The lift is therefore not a separate existence principle. It is the row E already present in the finite carrier, checked against F through the boundary row B and replayed through the same Cont route.

The sibling chapters supply the route components: $\mathsf{Ring}^{\uparrow}$ and $\mathsf{Module}^{\uparrow}$ provide the scalar and target module rows, $\mathsf{LinMap}^{\uparrow}$ provides the hom rows, and the exact-sequence surfaces keep the restriction boundary visible. The missing host coordinates exclude global injectivity, Ext computations, arbitrary splittings, quotient representatives, and choice-based extension selection. □

Closure status for $\mathsf{NameCert}_{\mathsf{InjectiveModule}^{\uparrow}}$.

Constructive story: An $\mathsf{InjectiveModule}^{\uparrow}$ packet is generated from a scalar RingUp row, target ModuleUp row, submodule inclusion row, source LinearMapUp hom row, extended LinearMapUp hom row, ExactSequenceUp boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{InjectiveModule}^{\uparrow}}$, seed)

Scope closed: Definition 8009.1, Definition 8009.2, and Definition 8009.3 seed the finite extension-lifting surface over ring, module, submodule inclusion, linear-map, exact-sequence boundary, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{InjectiveModule}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, Baer criterion, Ext-vanishing, host injective objects, arbitrary splittings, quotient representatives, or choice-based extension selection.

Upgrade path: Obligation closure requires checked carrier admission, module-row exposure, submodule-inclusion exposure, source-hom and extended-hom exposure, exact-boundary contact, transport, replay, provenance, and local naming for BEDC.Derived.InjectiveModuleUp.

Chapter 8010

A Concrete Naming Certificate for $\mathsf{LocatedRealReciprocal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRealReciprocal}^{\uparrow}$ packet records the finite reciprocal boundary for a located positive real name. It sits after the apartness evidence of chapter 304, the positive source discipline of chapter 1587, the dyadic lower-bound ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the guarded reciprocal route of chapter 6251. The packet names a reciprocal request only after located apartness from zero has been displayed; it is not host division, division by zero, quotient real equality, trichotomy, a selected inverse, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8010.1 (Located real reciprocal carrier)**.** *A* $\mathsf{LocatedRealReciprocal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, A, P, D, Q, I, E, H, C, G, N)$$

with the following displayed rows:

1. *R is the source* $\mathsf{Real}^{\uparrow}$ *row whose reciprocal is requested.*
2. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *row witnessing that R is apart from the zero boundary.*
3. *P is the* $\mathsf{PositiveReal}^{\uparrow}$ *orientation row that presents the apartness witness as a positive located radius.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *lower-bound ledger for the displayed radius and tolerance budget.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the dyadic budget into regular rational reciprocal windows.*
6. *I is the guarded* $\mathsf{RealReciprocal}^{\uparrow}$ *row served by the same apartness, positivity, dyadic, and regular-readback data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the reciprocal candidate.*
8. *H records componentwise* hsame *transport for $R, A, P, D, Q, I, E, C, G, N$.*
9. *C records displayed* Cont *replay from the located source through apartness, positive-radius, dyadic-budget, regular-readback, guarded-reciprocal, and terminal-seal rows.*
10. *G is the* Pkg *provenance over* $\mathsf{LocatedRealReciprocal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealReciprocal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealReciprocal}^{\uparrow}}$ *row.*

The carrier stores a finite located-domain reciprocal surface. It has no coordinate for host division, division by zero, quotient real equality, trichotomy, selected inverse choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Definition 8010.2 (Located real reciprocal classifier)**.** *Two* $\mathsf{LocatedRealReciprocal}^{\uparrow}$ *carriers*

$$L = (R, A, P, D, Q, I, E, H, C, G, N) \qquad \textit{and} \qquad L' = (R', A', P', D', Q', I', E', H', C', G', N')$$

are classified as the same displayed located reciprocal packet exactly when the real source rows match through the displayed real-name classifier, the apartness and positive-radius rows expose the same finite separation from zero, the dyadic ledgers carry the same lower-bound and tolerance budgets, the regular rational readbacks serve the same reciprocal windows, the guarded $\mathsf{RealReciprocal}^{\uparrow}$ *rows are transported with the same terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the replay, provenance, and local naming rows preserve the same route. The classifier is rowwise over $R, A, P, D, Q, I, E, H, C, G, N$ and does not identify carriers by host real equality, quotient streams, trichotomy, division by zero, or a selected inverse.*

Theorem 8010.3 (Located real reciprocal NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealReciprocal}^{\uparrow}$ *carrier*

$$L = (R, A, P, D, Q, I, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealReciprocal}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier formation for the real source, apartness row, positive-radius orientation, dyadic lower-bound ledger, regular rational readback, guarded reciprocal row, terminal real seal, transports, continuations, provenance, and local name;*
2. *classifier stability for the rowwise comparison of Definition 8010.2;*
3. *located-domain admission, requiring the apartness row A and positive-radius row P to be exposed before any reciprocal readback is consumed;*
4. *dyadic-budget exactness, requiring every reciprocal tolerance read in Q to be served by the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D;*
5. *guarded reciprocal handoff, requiring I to be consumed through* $\mathsf{RealReciprocal}^{\uparrow}$ *before the terminal seal E is read;*
6. *ledger non-escape, excluding host division, division by zero, quotient real equality, trichotomy, selected inverse choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier formation is projection from Definition 8010.1. The displayed packet lists exactly the source, apartness, positive-radius, dyadic-budget, regular-readback, reciprocal, terminal-seal, transport, replay, provenance, and naming rows.

Classifier stability is the componentwise comparison of Definition 8010.2. The transport row H can replace visible representatives only with representatives carrying the same located-domain evidence, budget ledger, reciprocal handoff, and terminal seal.

Located-domain admission reads A and P before D, Q, I, E. Thus a reciprocal request with no displayed apartness from zero, or no positive located radius attached to that apartness row, never enters the accepted packet surface.

Dyadic-budget exactness and guarded reciprocal handoff are the roles of D, Q, I, E. The regular readback Q is downstream of the dyadic ledger D, while the terminal seal E is downstream of the guarded $\mathsf{RealReciprocal}^{\uparrow}$ row I.

The non-escape row follows from the carrier inventory. No field stores host division, division by zero, quotient real equality, trichotomy, selected inverse choice, or ambient real completeness, and the structural rows only transport and replay the displayed finite route. □

Theorem 8010.4 (Located real reciprocal non-escape)**.** *Every accepted* $\mathsf{LocatedRealReciprocal}^{\uparrow}$ *read reaches its reciprocal candidate only through the route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{ApartnessReal}^{\uparrow},\ \mathsf{PositiveReal}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{RealReciprocal}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

Consequently the packet exports no host division, no division by zero, no quotient real equality, no trichotomy principle, no selected inverse, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness witness.*

Proof. Use the obligation surface of Definition 8010.3. Located-domain admission places the real source, apartness witness, and positive-radius row before any reciprocal read.

The dyadic ledger and regular rational readback then provide the finite tolerance route. The guarded reciprocal row is consumed only after those budgets are exposed, and the terminal real seal is read only after the guarded reciprocal handoff.

The route displayed in the statement is therefore the entire value-facing path through the carrier. Since the omitted principles have no coordinates in $L = (R, A, P, D, Q, I, E, H, C, G, N)$, neither componentwise transport nor continuation replay can export them. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealReciprocal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealReciprocal}^{\uparrow}$ packet is generated from a displayed Real source, apartness from zero, a positive located radius, a dyadic lower-bound ledger, RegSeqRat reciprocal windows, a guarded RealReciprocal row, a terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealReciprocal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8010.1, Definition 8010.2, Definition 8010.3, and Definition 8010.4 seed the finite located reciprocal surface over apartness, positive-radius, dyadic-budget, regular-readback, guarded reciprocal, and terminal Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealReciprocal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host division, division by zero, quotient real equality, trichotomy, selected inverse choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, located-domain admission, dyadic-budget exactness, guarded reciprocal handoff, terminal seal routing, and non-escape for the displayed packet.

Chapter 8011

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$ packet records the finite coherence surface tying compact nets, pointwise moduli, rational lower-bound folds, metric-triangle estimates, and uniform-modulus handoff rows into one reusable certificate. It sits over the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the rational fold route of chapter 619, the final triangle estimate of chapter 1159, and the consumer boundary of chapter 369. The packet realizes the compact-uniform-continuity route as a shared finite coherence object; it is not an open-cover compactness theorem, a selected Lebesgue number, a host modulus function, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8011.1 (CompactUniformModulusCoherence carrier)**.** *A* $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, L, T, U, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including the inspected centers, coverage windows, and compact-source metric data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the same source and target metric carriers.*
3. *L is the rational lower-bound fold row, read through the finite ProbeBundle route and the* $\mathsf{Rat}^{\uparrow}$ *comparison surface of chapter 619.*
4. *T is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *row that reuses the selected compact-net center for the source and target triangle estimates.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff row produced only after K, F, L, T have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *or regular rational readback boundary used when the uniform threshold is inspected by Real and Completion consumers.*
7. *H records componentwise* hsame *transport for the compact-net, pointwise-modulus, lower-bound fold, triangle-estimate, uniform-modulus, readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through*

$$K, F \longmapsto L \longmapsto T \longmapsto U, R.$$

9. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCoherence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows. It has no coordinate for open-cover compactness, selected subsequences, selected Lebesgue numbers outside the fold, host modulus functions, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8011.2 (CompactUniformModulusCoherence NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$ *carrier* $M = (K, F, L, T, U, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCoherence}^{\uparrow}}$ *surface consists exactly of carrier admission, compact finite-net exposure, continuous-map pointwise-modulus exposure, rational lower-bound fold exactness, metric-triangle uniform-estimate coherence, uniform-modulus handoff, Real-facing readback nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the finite carrier $M = (K, F, L, T, U, R, H, C, P, N)$. The only rows available to a uniform-modulus consumer are the compact finite-net row, continuous-map pointwise rows, rational lower-bound fold, triangle-estimate row, uniform-modulus handoff, and readback boundary.

Read K and F first. The compact metric row supplies the finite net and coverage windows, while the continuous-map row supplies the pointwise modulus data at the displayed centers.

Next read the fold and triangle rows. The lower-bound fold L turns the finite radius family into a single tolerance threshold, and T keeps the source and target metric-triangle estimates locked to the same selected center and tolerance request.

Finally U, R, H, C, P, N export, read back, transport, replay, source, and name the same finite route. Since no carrier coordinate stores open-cover compactness, a selected subsequence, an external Lebesgue number, a host modulus function, countable choice, quotient real equality, or ambient real completeness, none of those objects is part of the local NameCert surface. □

Theorem 8011.3 (CompactUniformModulusCoherence vision handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or Real-facing consumer of an accepted* $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$ *packet must read the shared route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto L \longmapsto \mathsf{MetricTriangleUniformEstimate}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

with structural support H, C, P, N. The handoff realizes the compact-uniform-continuity finite-net, pointwise-modulus, rational-fold, triangle-estimate, and uniform-modulus route as one coherence packet, not as a host compactness theorem or an external modulus selector.

Proof. Begin with the carrier definition. The handoff row U is downstream of the compact finite-net row K, continuous-map pointwise rows F, rational fold L, and triangle-estimate row T.

Apply the NameCert obligation theorem, Definition 8011.2. It identifies finite-net exposure, pointwise-modulus exposure, fold exactness, triangle-estimate coherence, uniform-modulus handoff, and Real-facing readback as the complete local obligation surface.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. They do not add open-cover compactness, a selected subsequence, a host modulus, countable choice, quotient real equality, or Real completeness.

Thus the compact-uniform-continuity vision is consumed here as a single finite coherence packet. Downstream modulus, Real, and Completion consumers may reuse the displayed route, but any stronger compactness or selection principle would require a coordinate absent from the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusCoherence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusCoherence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8011.1, Definition 8011.2, and Definition 8011.3 seed the shared compact-net, pointwise-modulus, rational-fold, triangle-estimate, and UniformModulus handoff packet.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusCoherence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequences, selected Lebesgue numbers, host modulus functions, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous-map pointwise-modulus exposure, rational lower-bound fold exactness, metric-triangle coherence, uniform-modulus handoff, Real-boundary nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusCoherenceUp.

Constructive story: A $\mathsf{CompactUniformModulusCoherence}^{\uparrow}$ packet is generated from compact finite-net rows, ContinuousMap pointwise-modulus rows, a rational lower-bound fold, MetricTriangleUniformEstimate rows, a UniformModulus handoff, RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8012

A Concrete Naming Certificate for StepFunctionUniformApproximation$^{\uparrow}$

Following Bishop and Bridges on regulated functions and uniform approximation, the StepFunctionUniformApproxim packet records the finite certificate by which a regulated target is read through displayed step approximants and uniform tolerance rows. It sits between the dyadic step approximation source of chapter 3774, the regulated step-function surface of chapter 7169, the uniform limit route of chapter 463, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the real boundary of chapter 38. The packet names uniform approximation as finite BEDC data before any host function equality, quotient stream equality, selected limiting function, countable-choice schedule, or ambient real-completeness theorem is available.

Definition 8012.1 (Step-function uniform approximation carrier)**.** *A* StepFunctionUniformApproximation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, R, U, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicStepApproximation$^{\uparrow}$ *source row, recording the displayed dyadic mesh, finite cell ledger, step values, and oscillation bounds used by the approximation.*
2. *R is the regulated-function target row, read through the* RegulatedStepFunction$^{\uparrow}$ *surface and recording the regulated target boundary to which the step data is compared.*
3. *U is the shared uniform tolerance ledger. It records one finite tolerance budget whose dyadic reads are shared by the step source, regulated target, finite windows, and terminal real seal.*
4. *W is the* StreamName$^{\uparrow}$ *finite-window row through which the target and approximants are inspected.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the displayed window comparisons and tolerance witnesses.*
6. *E is the* Real$^{\uparrow}$ *seal row, reached only after D, R, U, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the step source, regulated target, tolerance ledger, finite windows, readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the dyadic step source and regulated target through the shared uniform tolerance ledger, finite windows, readback, real seal, transports, provenance, and local name.*

9. *P is the* Pkg *provenance over* StepFunctionUniformApproximation$^{\uparrow}$, DyadicStepApproximation$^{\uparrow}$, RegulatedStepFunction$^{\uparrow}$, UniformLimit$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{StepFunctionUniformApproximation}^{\uparrow}}$ *row.*

The carrier predicate asserts that these rows form one finite uniform-approximation surface. It contains no host function equality, quotient stream equality, selected limit, countable-choice schedule, or ambient Real$^{\uparrow}$ *completeness coordinate.*

Theorem 8012.2 (Step-function uniform approximation NameCert obligations)**.** *For every accepted* StepFunctionUniformApproximation$^{\uparrow}$ *carrier $S = (D, R, U, W, Q, E, H, C, P, N)$, the local* NameCert$_{\text{StepFunctionUniformApproximation}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic step-source admission through D, regulated-target admission through R, shared uniform-tolerance exactness through U, finite-window readback through W and Q,* Real$^{\uparrow}$ *seal nonescape through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8012.1. The analytic rows are the dyadic step source D, the regulated target row R, the shared tolerance ledger U, the finite window row W, the regular rational readback row Q, and the terminal real seal E.

Read the source side first. The dyadic step approximation chapter supplies finite cells, displayed values, and oscillation data, while the regulated step-function chapter supplies the target-facing regulated row. These two rows are the only places where step data and regulated-target data enter the packet.

The uniform comparison is then finite. The tolerance ledger U supplies one shared budget, W selects the finite windows on which that budget is inspected, and Q records the regular rational readback of the displayed comparisons before E is available.

Finally, H, C, P, N preserve and name the same route. Since the carrier has no host-function coordinate, quotient-stream coordinate, selected-limit coordinate, choice schedule, or ambient completeness row, the listed rows exhaust the local NameCert surface. □

Theorem 8012.3 (Step-function uniform approximation regulated route)**.** *Every* Real$^{\uparrow}$*-facing regulated approximation read of an accepted* StepFunctionUniformApproximation$^{\uparrow}$ *carrier factors through*

$$D, R, U, W, Q, E, H, C, P, N.$$

The route exports only the displayed dyadic step source, regulated target, shared uniform tolerance ledger, finite windows, regular rational readback, real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows. It exports no host function equality, quotient stream equality, selected limit, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start from the obligation surface of Definition 8012.2. It confines every accepted packet to the rows $D, R, U, W, Q, E, H, C, P, N$.

Apply the step-source and regulated-target sibling chapters. The source row D supplies finite dyadic step data, and the target row R keeps the regulated function boundary displayed before the uniform comparison is read.

The Real-facing handoff is available only after U, W, Q. The shared tolerance ledger fixes the finite budget, the stream windows expose the finite observations, and the regular rational readback records the comparison before the Real$^{\uparrow}$ seal is public.

The remaining rows are structural. Transport, replay, provenance, and local naming repack the same finite route, while the refused host equality, quotient equality, selected limit, countable choice, and ambient completeness objects have no coordinate through which to enter. □

Closure status for $\mathsf{NameCert}_{\mathsf{StepFunctionUniformApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{StepFunctionUniformApproximation}^{\uparrow}$ packet is generated from a dyadic step approximation source, a regulated target row, a shared uniform tolerance ledger, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StepFunctionUniformApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8012.1, Definition 8012.2, and Definition 8012.3 seed the finite uniform-approximation packet connecting dyadic step data and regulated-function consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StepFunctionUniformApproximation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient stream equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, step-source admission, regulated-target admission, uniform-tolerance exactness, finite-window readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.StepFunctionUniformApproximationUp.

Chapter 8013

A Concrete Naming Certificate for $\mathsf{GaloisConnectionClosureOperator}^{\uparrow}$

Birkhoff and Ore-style Galois-connection closure operators enter BEDC as finite closure-operator NameCert carriers rather than as ambient powerset laws. The $\mathsf{GaloisConnectionClosureOperator}^{\uparrow}$ packet refines the adjunction packet of chapter 6259: it names the source-side composite $G \circ F$ as its own closure surface, while leaving the bare two-map adjunction available to lattice, topological, and metric consumers. It also gives the closure-facing packets of chapter 3559 and chapter 3342 a reusable order-theoretic source for inflation, monotonicity, idempotence replay, and finite provenance.

Definition 8013.1 (Galois-connection closure-operator carrier)**.** *A* $\mathsf{GaloisConnectionClosureOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (P, Q, F, G, M, A, O, I, D, H, R, L, N)$$

with the following rows:

1. *P is the source ordered carrier inherited from the* $\mathsf{GaloisConnection}^{\uparrow}$ *source row.*
2. *Q is the target ordered carrier inherited from the* $\mathsf{GaloisConnection}^{\uparrow}$ *target row.*
3. *F is the displayed monotone map from P to Q.*
4. *G is the displayed monotone map from Q to P.*
5. *M records the two monotonicity ledgers for F and G.*
6. *A records the adjunction inequality equivalence $F(x) \leq_Q y$ iff $x \leq_P G(y)$.*
7. *O is the displayed closure-operator row naming the composite $G \circ F$ on P.*
8. *I records the inflation ledger $x \leq_P O(x)$ obtained through the adjunction row.*
9. *D records the idempotence replay ledger $O(O(x)) \leq_P O(x)$ together with the reverse inequality supplied by inflation and monotonicity.*
10. *H records componentwise* hsame *transport for the two ordered carriers, the two maps, the adjunction row, the closure row, the inflation row, the idempotence row, provenance, and local naming.*
11. *R records displayed* Cont *replay for order reads, adjunction reads, closure reads, lattice handoff, topological-closure handoff, and metric-closure handoff.*

12. *L is the* Pkg *provenance over* GaloisConnectionClosureOperator$^{\uparrow}$, GaloisConnection$^{\uparrow}$, Lattice$^{\uparrow}$, TopologicalClosure$^{\uparrow}$, MetricClosure$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
13. *N is the local* NameCert$_{\text{GaloisConnectionClosureOperator}^{\uparrow}}$ *row.*

The classifier compares packets only by the displayed ordered carriers, the two map rows, monotonicity, adjunction, the named composite closure row, inflation, idempotence replay, structural transport, continuation, provenance, and local naming. It has no coordinate for arbitrary joins, Moore families, quotient fixed-point lattices, choice-selected closures, or host powerset operations.

Lean4 (definition) `BEDC.Derived.GaloisConnectionClosureOperatorUp`

Theorem 8013.2 (Galois-connection closure-operator NameCert obligations)**.** *For every accepted* GaloisConnectionClosureOperator$^{\uparrow}$ *carrier* $C = (P, Q, F, G, M, A, O, I, D, H, R, L, N)$*, the local* NameCert$_{\text{GaloisConnecti}}$ *surface consists exactly of carrier admission for the ordered source and target rows, monotone-map exposure for F and G, monotonicity exposure through M, adjunction exposure through A, closure-row exposure through O, inflation exposure through I, idempotence replay through D, componentwise transport through H, displayed replay through R, provenance through L, and local naming through N.*

Proof. Project the finite packet $C = (P, Q, F, G, M, A, O, I, D, H, R, L, N)$. The rows P, Q, F, G, M, A reproduce the adjunction surface of chapter 6259, so no closure row is read before the ordered carriers, maps, monotonicity, and inequality equivalence are visible.

The row O names only the composite $G \circ F$ on the source carrier. The inflation ledger I is read from the adjunction row by specializing $F(x) \leq_Q F(x)$, and the monotonicity part of M transports source inequalities through O.

The row D records the replay that makes applying O twice return to the same displayed closure row. The reverse comparison is supplied by inflation applied to $O(x)$, while the forward comparison is the adjunction-and-monotonicity replay carried by D.

Finally, H, R, L, N transport, replay, source, and name the same finite packet. Since the carrier has no arbitrary joins, Moore-family row, quotient fixed-point lattice, choice-selected closure, or host powerset coordinate, the NameCert surface is exactly the listed finite surface. □

Theorem 8013.3 (Galois-connection closure-operator lattice handoff)**.** *Every* Lattice$^{\uparrow}$, TopologicalClosure$^{\uparrow}$, *or* MetricClosure$^{\uparrow}$ *consumer of an accepted* GaloisConnectionClosureOperator$^{\uparrow}$ *packet reads the closure operator through the finite route*

$$P \longrightarrow F \longrightarrow Q \longrightarrow G \longrightarrow P$$

together with the monotonicity ledger M, adjunction ledger A, closure row O, inflation ledger I, idempotence replay ledger D, componentwise transport H, displayed continuation R, provenance L, and local naming N. The handoff exports a reusable closure-operator NameCert packet, not an ambient complete lattice, a topological closure primitive, a metric completion theorem, or a host powerset operation.

Proof. Start with the route displayed in Definition 6259.3. The new packet does not replace that route; it records the composite as the explicit row O and keeps the original ordered carriers, maps, monotonicity ledger, and adjunction ledger visible.

A lattice consumer may use O only after reading I and D, because those rows witness the closure-operator boundary needed for lattice-facing fixed rows. A topological or metric closure consumer may use the same row only through R, which replays the finite closure surface without adding an ambient topology, metric completion, or powerset theorem.

The transport row H and provenance row L keep the handoff tied to the same adjunction packet. The local name N therefore certifies a reusable closure-operator NameCert packet, while any stronger complete-lattice, topological, or metric conclusion must be supplied by the receiving chapter. □

Falsifiable prediction: Deleting the adjunction row A leaves a named composite $G \circ F$ but no finite route that certifies the inflation row I of the closure operator.

Independence witness: galois-connection, lattice, topological-closure, metric-closure: $\mathsf{GaloisConnection}^{\uparrow}$ supplies the adjunction without a separate closure-operator NameCert row; $\mathsf{Lattice}^{\uparrow}$ supplies order consumers without the adjunction-derived composite; $\mathsf{TopologicalClosure}^{\uparrow}$ and $\mathsf{MetricClosure}^{\uparrow}$ supply closure evidence for their own substrates without naming the source-side $G \circ F$ packet. None is bijective to $\mathsf{GaloisConnectionClosureOperator}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{GaloisConnectionClosureOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{GaloisConnectionClosureOperator}^{\uparrow}$ packet is generated from two displayed ordered carrier rows, two monotone map rows, an adjunction-equivalence ledger, the named composite $G \circ F$, inflation, idempotence replay, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaloisConnectionClosureOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8013.1, Definition 8013.2, and Definition 8013.3 seed the finite closure-operator surface over displayed Galois-connection rows, adjunction-derived inflation, idempotence replay, lattice handoff, topological-closure handoff, metric-closure handoff, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaloisConnectionClosureOperator}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.GaloisConnectionClosureOperatorUp`

Bridge status: none

Not claimed: This chapter does not claim arbitrary joins, Moore-family representation, quotient fixed-point lattices, choice-selected closures, host powerset operations, metric completion, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, monotonicity ledgers, adjunction transport, inflation, idempotence replay, lattice handoff, closure-consumer handoff, provenance, and local naming for BEDC.Derived.GaloisConnectionClosu

Chapter 8014

A Concrete Naming Certificate for $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$

Following Brouwer, Bishop, and Bridges, the $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ packet records the finite fan compactness boundary at which bar-depth data may feed compact-uniform-continuity consumers without becoming open-cover compactness. It sits after the fan theorem route of chapter 400, the finite fan theorem route of chapter 5863, the compact metric source rows of chapter 129, the continuous-map graph rows of chapter 130, the uniform-modulus handoff of chapter 369, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet also borders the compact fan handoff of chapter 6522; its role is to expose the exact finite boundary consumed by L10 compact and continuous-map readers, not to supply selected infinite branches or ambient completeness.

Definition 8014.1 (Bishop fan compactness boundary carrier)**.** *A* $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (F, D, V, K, Q, M, U, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *bar row naming the fan bar whose inspected prefixes are available to the packet.*
2. *D is the fan-bar depth ledger, recording the finite depth bound at which the visible bar inspection stops.*
3. *V is the finite prefix coverage row supplied by* $\mathsf{FiniteFanTheorem}^{\uparrow}$*; it lists exactly the prefixes covered below depth D.*
4. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source-probe row, exposing the compact finite-net observations that the fan prefixes are allowed to inspect.*
5. *Q is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus window row, tying each displayed compact-source probe to a finite continuity read.*
6. *M is the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback window package used to inspect the prefix, compact-source, and pointwise-modulus rows without quotienting streams.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported to compact-uniform consumers after F, D, V, K, Q, M have been displayed.*

8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal boundary for the value and tolerance reads that enter Q and U.*
9. *H records componentwise* hsame *transport for the fan-bar, depth, prefix-coverage, compact-source, pointwise-modulus, window, uniform-handoff, Real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a compact-uniform request through*

    $\mathsf{FanTheorem}^{\uparrow}, \mathsf{FiniteFanTheorem}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{UniformM}$

11. *P is the* Pkg *provenance over* $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{FiniteFanTheorem}^{\uparrow}$, $\mathsf{BishopFanCompactUniform}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopFanCompactnessBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, D, V, K, Q, M, U, R, H, C, P, N$. It has no coordinate for arbitrary open covers, selected infinite branches, countable choice, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8014.2 (Bishop fan compactness boundary NameCert obligations)**.** *For every accepted* $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ *carrier*

$$B = (F, D, V, K, Q, M, U, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopFanCompactnessBoundary}^{\uparrow}}$ *surface consists exactly of fan-bar admission for F, fan-bar depth admission for D, finite prefix coverage for V, compact-source probe admission for K, pointwise-modulus window exposure for Q, StreamName and RegSeqRat readback for M, uniform-modulus handoff for U, Real-seal boundary exposure for R, componentwise* hsame *transport for H, displayed* Cont *replay for C,* Pkg *provenance for P, and local naming for N.*

Proof. Project the carrier of Definition 8014.1. The fan rows are F, D, V: the bar is named, the inspected depth is finite, and the covered prefixes are exactly those displayed by the finite fan theorem route.

Read the compact and continuity rows next. The compact-source probes K are finite metric observations, while Q records only pointwise-modulus windows tied to those probes.

The window and value rows are downstream. The row M keeps the prefix, compact-source, and modulus reads inside finite StreamName and RegSeqRat windows, while R seals the displayed value and tolerance reads as $\mathsf{Real}^{\uparrow}$ data.

Finally, U, H, C, P, N package the uniform-modulus handoff, transport, replay, provenance, and local naming. Since the carrier has no coordinate for open-cover compactness, selected branches, countable choice, quotient streams, selected limits, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8014.3 (Bishop fan compactness boundary handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{FanTheorem}^{\uparrow}, \mathsf{FiniteFanTheorem}^{\uparrow}, \mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The exported uniformity data are exactly the handoff row U together with the transport, replay, provenance, and naming rows H, C, P, N. The route exports no open-cover compactness, selected infinite branch, countable-choice schedule, quotient stream equality, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the fan boundary rows. The bar row F, depth ledger D, and prefix coverage row V expose a finite inspection boundary before any compact-source read is allowed.

Apply the compact-source and pointwise-modulus rows. The compact probes K and continuity windows Q show which finite observations are being used by the downstream uniform-modulus consumer.

Pass through the stream, regular-rational, and Real rows M, R. These rows seal the inspected windows and value comparisons without selecting an infinite branch, quotienting a stream, or appealing to a selected limit.

The handoff row U can now be exported through H, C, P, N. Because no host compactness or choice coordinate appears in the packet, every accepted consumer remains inside the finite boundary route stated above. □

Falsifiable prediction: Every accepted $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ read must expose fan-bar depth, finite prefix coverage, compact-source probes, pointwise-modulus windows, StreamName and RegSeqRat readback, a UniformModulus handoff, a Real-seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before a compact-uniform consumer may read the packet.

Independence witness: fan-theorem, finite-fan-theorem, compactmetric, continuousmap, uniformmodulus, streamname, regseqrat, real: $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ binds fan-bar depth, finite prefix coverage, compact-source probes, pointwise-modulus windows, finite readback, uniform handoff, Real sealing, transport, replay, provenance, and local naming in one boundary packet; each listed sibling lacks at least one of these local coordinates.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopFanCompactnessBoundary}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$ packet is generated from FanTheorem bar rows, finite fan-depth and prefix-coverage rows, CompactMetric source probes, ContinuousMap pointwise-modulus windows, StreamName and RegSeqRat readback, a UniformModulus handoff, a RealUp seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopFanCompactnessBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8014.1, Definition 8014.2, and Definition 8014.3 seed the finite fan compactness boundary over bar depth, prefix coverage, compact probes, pointwise modulus windows, finite readback, Real sealing, and uniform-modulus handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopFanCompactnessBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected infinite branches, countable choice, quotient streams, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{BishopFanCompactnessBoundary}^{\uparrow}$.

Upgrade path: Obligation closure requires checked fan-bar admission, depth and prefix coverage, compact-source probe exposure, pointwise-modulus window exposure, finite readback, uniform-modulus handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopFanCompactnessBoundaryUp.

Chapter 8015

A Concrete Naming Certificate for $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$

Following Bishop and Bridges on metric sequential compactness, the $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ packet records the general metric route by which a displayed sequence, a cofinal subsequence schedule, and a candidate point form finite limit-point evidence before any Real-specific cluster packet reads the result. It sits between the metric carrier of chapter 57, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the Real-only cluster packet of chapter 1580. The packet gives compactness and completion consumers a metric sequential limit-point interface without folding the concept into the Real sequence cluster-point carrier.

Definition 8015.1 (Metric sequential limit-point carrier)**.** *A* $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, A, D, R, E, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the source* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance-observation rows, and finite metric-law ledger used by the sequence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *sequence row, exposing only the inspected windows of the displayed metric sequence.*
3. *A is the cofinal schedule row, recording the finite subsequence indices and monotonicity comparisons used by the limit-point request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the inspected radius windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *distance-readback row, reading the distances $d(x_{a_i}, p)$ through regular rational approximants.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for those distance-readback comparisons.*
7. *W is the limit-window witness row, recording that the displayed scheduled tail enters every inspected tolerance window around the candidate point.*
8. *H records componentwise* hsame *transport for the metric source, stream windows, cofinal schedule, dyadic tolerance ledger, regular rational readback, Real seal, limit-window witness, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$M, S, A, D, R, E, W \longmapsto \mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}.$$

10. *P is the* Pkg *provenance over* $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealSequenceClusterPoint}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}$ *row.*

The carrier contains no selected subsequence functional, no selected cluster point beyond the displayed candidate row, no quotient stream equality, no countable-choice principle, and no ambient compactness or completeness theorem.

Theorem 8015.2 (Metric sequential limit-point NameCert obligations)**.** *For every accepted* MetricSequentialLimitP *carrier $L = (M, S, A, D, R, E, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}$ *obligation surface consists exactly of carrier admission, metric-source visibility, finite stream-window visibility, cofinal schedule compatibility, dyadic tolerance discipline, regular rational distance readback, terminal Real sealing, limit-window exactness, componentwise transport, displayed replay, provenance non-escape, and local naming for the rows $M, S, A, D, R, E, W, H, C, P, N$.*

Proof. Project the carrier. The rows available to a consumer are precisely the metric source, finite stream windows, cofinal schedule, dyadic tolerances, regular rational readbacks, Real seal, limit-window witness, and the structural rows.

Metric-source and stream-window visibility follow from M and S. The schedule row A may index only windows already named by S, and the tolerance row D supplies the displayed radii used by the limit-window request.

The readback and seal rows are downstream. Row R reads distances through $\mathsf{RegSeqRat}^{\uparrow}$, and row E seals those comparisons through $\mathsf{Real}^{\uparrow}$ only after the dyadic tolerance ledger has been displayed.

Finally inspect W, H, C, P, N. The window row records the finite limit-point evidence, while transport, replay, provenance, and local naming preserve exactly the same packet. Since no excluded selector, quotient, choice, compactness, or completeness row is present, the listed obligations exhaust the NameCert surface. □

Theorem 8015.3 (Metric sequential limit-point stream handoff)**.** *Every downstream consumer that passes from* $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ *to a Real-specific cluster or compactness packet must first read the finite handoff*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

In particular, the Real sequence cluster-point route of chapter 1580 may consume the metric limit-window witness only after the stream windows, regular rational readbacks, dyadic tolerances, and terminal Real seal have been displayed.

Proof. Start with the obligation surface of Definition 8015.2. It places the metric source, finite stream windows, cofinal schedule, dyadic tolerance ledger, regular rational readback, and terminal Real seal before the limit-window witness can be exported.

The stream handoff is therefore finite. A Real-specific cluster consumer reads the $\mathsf{StreamName}^{\uparrow}$ windows first, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerances, the $\mathsf{RegSeqRat}^{\uparrow}$ distance readbacks, and the $\mathsf{Real}^{\uparrow}$ seal.

Transport, replay, provenance, and local naming keep the same rows visible at the hand-off boundary. Because the carrier has no selector, quotient, countable-choice, compactness, or ambient-completeness coordinate, no downstream consumer can bypass the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ limit-point export factors through one metric source row, one finite stream-window row, one cofinal schedule row, one dyadic tolerance ledger, one regular rational distance-readback row, one terminal Real seal, one limit-window witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: metric, streamname, regseqrat, dyadicratcore, real, real-sequence-cluster-point: $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the metric source, sequence windows, cofinal schedule, dyadic tolerance ledger, regular rational distance readback, terminal Real seal, limit-window witness, transport, replay, provenance, and local naming rows for a general metric sequence.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$ packet is generated from a metric source row, finite stream windows, a cofinal schedule, dyadic tolerance ledger, regular rational distance readbacks, a terminal Real seal, a finite limit-window witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8015.1, Definition 8015.2, and Definition 8015.3 seed the general metric sequential limit-point packet over Metric, StreamName, DyadicRatCore, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricSequentialLimitPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close sequential compactness, Bolzano-Weierstrass, selected subsequence extraction, selected cluster points, quotient stream equality, countable choice, ambient compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window visibility, cofinal schedule compatibility, dyadic tolerance discipline, regular rational distance readback, Real seal exactness, limit-window non-escape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.MetricSequentialLimitPointUp.

Chapter 8016

A Concrete Naming Certificate for $\mathsf{ConstructiveDarboux}^{\uparrow}$

Following Bishop and Bridges on constructive real analysis, the $\mathsf{ConstructiveDarboux}^{\uparrow}$ packet records the finite interval-refinement surface behind the intermediate-value route for a continuous real-valued map on a located interval. It consumes the located interval carrier of chapter 394, the continuous-map and modulus rows of chapter 130, the sign-bracket and bisection route of chapter 1402, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite Darboux-style interval refinement data used by L10 real-completion consumers; it does not import quotient real equality, trichotomy, host real primitives, a selected root, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8016.1 (Constructive Darboux carrier)**.** *A* $\mathsf{ConstructiveDarboux}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, M, B, R, E, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row, carrying the displayed endpoint windows and interval-cell ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row for the inspected map on the interval.*
3. *M is the continuity-modulus row attached to F and to the requested rational output tolerance.*
4. *B is the interval-refinement row, storing the finite nested bracket, midpoint, and sign-change data inherited from the* $\mathsf{IntermediateValue}^{\uparrow}$ *route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint values, midpoint values, and tolerance comparisons opened by B.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the interval, continuity, refinement, sign, and readback rows are visible.*
7. *S is the sign-change and readback row, recording the displayed negative-side and positive-side value witnesses used by the refinement.*
8. *H records componentwise* hsame *transport for the interval, map, modulus, refinement, readback, Real seal, sign, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from an intermediate-value request through I, F, M, B, R, E, S, H.*

10. *P is the* Pkg *provenance over* ConstructiveDarboux$^{\uparrow}$, LocatedInterval$^{\uparrow}$, ContinuousMap$^{\uparrow}$, IntermediateValue$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{ConstructiveDarboux}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, F, M, B, R, E, S, H, C, P, N$. It has no coordinate for quotient classes of real names, real trichotomy, host real equality, an unrestricted zero search, a selected root, or ambient completeness.

Theorem 8016.2 (Constructive Darboux obligation basis)**.** *For every accepted* ConstructiveDarboux$^{\uparrow}$ *carrier $D = (I, F, M, B, R, E, S, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveDarboux}^{\uparrow}}$ *surface consists exactly of carrier admission, located-interval admission, continuous-map admission, continuity-modulus exposure, finite interval-refinement exposure, sign-change and readback exposure, terminal* Real$^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8016.1. The accepted packet displays one located interval row, one continuous-map row, one modulus row, one finite refinement row, one regular-rational readback row, one Real seal row, one sign-change row, and the structural rows.

The interval and map rows are the entry data. The located interval row I fixes the endpoint windows and interval cells, while F and M expose only a displayed continuity-modulus route for the requested tolerance.

The refinement and sign rows are then finite. Row B records the retained bracket and midpoint route, row S records the sign-change/readback witnesses, and row R supplies regular rational comparisons before the terminal seal E is read.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no other coordinate is present, the listed rows exhaust the local NameCert surface and exclude quotient equality, trichotomy, host real primitives, selected roots, and ambient completeness. □

Theorem 8016.3 (Constructive Darboux scope)**.** *Every* Real$^{\uparrow}$ *or intermediate-value consumer of an accepted* ConstructiveDarboux$^{\uparrow}$ *packet must first read the finite route*

$$\text{LocatedInterval}^{\uparrow},\ \text{ContinuousMap}^{\uparrow},\ M,\ B,\ S,\ \text{RegSeqRat}^{\uparrow},\ \text{Real}^{\uparrow}.$$

The route supplies interval-refinement, continuity-modulus, sign-change/readback, terminal Real seal, hsame, Cont, Pkg, *and local* NameCert *rows. It does not assert quotient real equality, real trichotomy, host real equality, a selected root, a host intermediate-value theorem, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the obligation basis in Definition 8016.2. It orders any consumer read through the located interval, continuous-map, continuity-modulus, refinement, sign, readback, Real seal, and structural rows.

The intermediate-value sibling contributes only the displayed bisection and sign-bracket route. Thus a consumer can inspect B and S as finite interval-refinement evidence, but it cannot replace them with a host theorem, a trichotomy decision, or an unbounded zero search.

The regular-rational and Real rows are terminal for this packet. Row R supplies finite comparisons for endpoint and midpoint values, while E seals the resulting Real-facing read only after I, F, M, B, S have been displayed.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. Therefore every consumer remains inside the finite Darboux packet and receives none of the excluded host or quotient data. □

Falsifiable prediction: A $\mathsf{ConstructiveDarboux}^{\uparrow}$ consumer that reads a RealUp seal without displaying the located interval, continuous-map row, continuity modulus, finite refinement row, sign-change/readback row, RegSeqRat readback, transport, replay, provenance, and local naming rows refutes the carrier of Definition 8016.1.

Independence witness: locatedinterval, continuousmap, intermediatevalue, regseqrat, real: no listed sibling is bijective with $\mathsf{ConstructiveDarboux}^{\uparrow}$ because this carrier alone binds interval-refinement, continuity-modulus, sign-change/readback, terminal Real seal, transport, replay, provenance, and local NameCert rows as one finite Darboux route.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveDarboux}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveDarboux}^{\uparrow}$ packet is generated from a LocatedInterval row, a ContinuousMap row, a displayed continuity modulus, finite interval-refinement data, sign-change/readback rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveDarboux}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8016.1, Definition 8016.2, and Definition 8016.3 seed the finite Darboux interval-refinement packet for L10 real-completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveDarboux}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient real equality, real trichotomy, host real equality, a selected root, a host intermediate-value theorem, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, interval-refinement exactness, continuity-modulus exposure, sign-change/readback exposure, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local naming for BEDC.Derived.ConstructiveDarbouxUp.

Chapter 8017

A Concrete Naming Certificate for $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$

Following classical hyperbolic geometry, the $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$ packet records a three-side geodesic triangle as finite BEDC NameCert data inside the hyperbolic observer-expansion vision of chapter 9463. It sits between the boundary quadruple route of chapter 7659, the disk-geodesic triangle route of chapter 7891, the hyperbolic metric packet of chapter 3474, the geodesic boundary packet of chapter 3491, the cross-ratio packet of chapter 3948, and the disk carrier of chapter 377. The chapter names the triangle-level carrier needed between ideal quadrilateral data and later phase-geometry consumers; it does not complete a hyperbolic plane, quotient boundary endpoints, select global geodesic representatives, or identify the observer-expansion reading with physical spacetime.

Definition 8017.1 (Hyperbolic geodesic triangle carrier)**.** *A* $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (U, M, V, G, I, A, X, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UnitDisk}^{\uparrow}$ *coordinate row for the inspected disk window and its boundary reads.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row over the same displayed disk data.*
3. *V is the three-boundary-vertex row, naming the ordered boundary or disk-facing vertices visible to the packet.*
4. *G records the three displayed* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *side rows joining the vertex pairs.*
5. *I is the incidence and cyclic-order ledger, checking that the side rows meet the displayed vertices in the stated order and that no fourth side is introduced.*
6. *A is the angle or orientation budget row, recording the finite comparison data available for triangle reads without importing an ambient smooth angle measure.*
7. *X is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *readback row attached to the same ordered triple and to an auxiliary displayed comparison end when such a read is requested.*
8. *H records componentwise* hsame *transport for disk coordinates, metric reads, vertices, sides, incidence, angle or order data, cross-ratio readback, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a hyperbolic triangle request through $U, M, V, G, I, A, X, H, P, N$.*

10. *P is the* Pkg *provenance over* HyperbolicGeodesicTriangle$^{\uparrow}$, UnitDisk$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicGeodesicBour HyperbolicCrossRatio$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{HyperbolicGeodesicTriangle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, M, V, G, I, A, X, H, C, P, N$. It has no coordinate for completed hyperbolic planes, quotient ideal-boundary equality, selected global geodesics, ambient smooth angle structures, host cross-ratio fields, or physical observer dynamics.

Theorem 8017.2 (Hyperbolic geodesic triangle NameCert obligations)**.** *For every accepted* HyperbolicGeodesicTria *carrier*

$$T = (U, M, V, G, I, A, X, H, C, P, N),$$

the local NameCert$_{\text{HyperbolicGeodesicTriangle}^{\uparrow}}$ *surface consists exactly of disk-coordinate admission for U, hyperbolic-metric visibility for M, three-vertex admission for V, three geodesic-side admissions for G, incidence and cyclic-order ledger exposure for I, finite angle or orientation budget exposure for A, finite cross-ratio readback for X, componentwise* hsame *transport for H, displayed* Cont *replay for C,* Pkg *provenance for P, and local naming for N.*

Proof. Project the carrier of Definition 8017.1. The disk and metric rows U, M are the only geometric source rows, and the vertex row V fixes the three displayed ends or disk-facing vertices.

Read the side and incidence data next. The row G lists exactly three geodesic sides, while I records their endpoint incidence and cyclic order, so a fourth side or detached boundary representative cannot be inserted.

The comparison rows are downstream. The row A stores only the finite angle or orientation budget available to the packet, and X stores only the finite cross-ratio readback attached to the same displayed triple and auxiliary comparison end.

Rows H, C, P, N transport, replay, source, and locally name the same packet. Since no carrier coordinate stores completed planes, quotient boundary equality, selected geodesics, ambient smooth angle structures, host cross-ratio fields, or physical observer dynamics, the listed rows exhaust the local NameCert obligations. □

Theorem 8017.3 (Hyperbolic geodesic triangle finite readback)**.** *Every triangle-level consumer of an accepted* HyperbolicGeodesicTriangle$^{\uparrow}$ *packet must read*

$$\text{UnitDisk}^{\uparrow}, \text{HyperbolicMetric}^{\uparrow}, \text{HyperbolicGeodesicBoundary}^{\uparrow}, \text{HyperbolicCrossRatio}^{\uparrow}$$

through the displayed rows $U, M, V, G, I, A, X, H, C, P, N$ before exporting a metric, incidence, angle-budget, or cross-ratio comparison. The export is a finite NameCert route between ideal quadrilateral data and later hyperbolic phase-geometry consumers; it is not a completed hyperbolic model, quotient boundary construction, selected geodesic representative, smooth angle theory, host field theorem, or physical observer trajectory.

Proof. Begin with the source rows U, M, V. They name the disk window, metric read, and three visible vertices used by the packet.

Use G, I to form the triangle spine. These rows display the three geodesic sides and their endpoint incidence before any comparison row is read.

Apply the finite comparison rows A, X. The angle or order budget and cross-ratio readback are attached to the same displayed triangle data and cannot be replaced by a host smooth angle measure or global cross-ratio field.

Finally replay the structural rows H, C, P, N. They preserve the finite source, side, incidence, comparison, provenance, and local naming data, so the exported triangle read remains inside the NameCert route stated above. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$ read must expose UnitDisk coordinates, HyperbolicMetric reads, three boundary vertices, three HyperbolicGeodesicBoundary side rows, incidence or cyclic-order data, finite angle or orientation budget rows, HyperbolicCross-Ratio readback, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: unitdisk, hyperbolic-metric, hyperbolic-geodesic-boundary, hyperbolic-cross-ratio, hyperbolic-ideal-quadrilateral, poincare-disk-geodesic-triangle: $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds three displayed vertices, three side rows, incidence or order data, a finite angle or orientation budget, cross-ratio readback, transport, replay, provenance, and local naming in one triangle packet.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$ packet is generated from UnitDisk coordinate rows, HyperbolicMetric reads, three displayed boundary vertices, three HyperbolicGeodesicBoundary side rows, incidence or cyclic-order ledgers, finite angle or orientation budget rows, HyperbolicCrossRatio readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8017.1, Definition 8017.2, and Definition 8017.3 seed the finite triangle route over disk coordinates, hyperbolic metric rows, displayed geodesic sides, incidence ledgers, comparison budgets, cross-ratio readback, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic planes, quotient ideal-boundary equality, selected global geodesics, ambient smooth angle structures, host cross-ratio fields, physical observer dynamics, Lean verification, or bridge checking for $\mathsf{HyperbolicGeodesicTriangle}^{\uparrow}$.

Upgrade path: Obligation closure requires checked disk-coordinate admission, hyperbolic-metric visibility, three-vertex admission, geodesic-side exactness, incidence and cyclic-order stability, angle or orientation budget exposure, cross-ratio readback, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicGeodesicTriangleUp.

Chapter 8018

A Concrete Naming Certificate for $\mathsf{MarkovDecisionProcess}^{\uparrow}$

Following Bellman and Puterman on Markov decision processes, the $\mathsf{MarkovDecisionProcess}^{\uparrow}$ packet records a finite policy-transition-reward interface before any optimality theorem or measurable selector is visible. It sits after the transition-row surface of chapter 189, the normalized probability carrier of chapter 184, the Bellman recursion route of chapter 5875, and the action-ledger surface of chapter 290. The packet names displayed state rows, action rows, transition rows, reward rows, policy rows, Bellman-consumer routes, transports, replay, provenance, and local naming as BEDC data; it does not import optimal policy existence, measurable selection, infinite-horizon convergence, or host stochastic-process equality.

Definition 8018.1 (MarkovDecisionProcess carrier)**.** *A* $\mathsf{MarkovDecisionProcess}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, A, K, R, \Pi, V, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite state-observation row read through the same normalized probability source used by* $\mathsf{ProbSpace}^{\uparrow}$ *consumers.*
2. *A is the finite action row whose visible choices are read through the action-ledger discipline of* $\mathsf{Policy}^{\uparrow}$*.*
3. *K is the one-step transition row, exposed as a Markov-transition packet before any Bellman consumer can inspect the next-state law.*
4. *R is the reward row, a finite value-facing ledger whose scalar endpoints are read as displayed* $\mathsf{Real}^{\uparrow}$ *names rather than as a host utility function.*
5. *Π is the displayed policy row, recording which action ledger is paired with each visible state row.*
6. *V is the Bellman-consumer boundary row, storing the finite continuation by which dynamic-programming readers consume S, A, K, R, Π.*
7. *H records componentwise* hsame *transports for the state, action, transition, reward, policy, Bellman-boundary, provenance, and local name rows.*
8. *C records the displayed* Cont *replay by which consumers read the probability source, Markov transition, policy ledger, reward ledger, Bellman boundary, transports, provenance, and local naming row.*

9. *P is the* Pkg *provenance over* $\mathsf{MarkovDecisionProcess}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{MarkovChain}^{\uparrow}$, $\mathsf{DynamicProgramming}^{\uparrow}$, $\mathsf{Policy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovDecisionProcess}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their rowwise transports, continuation routes, package provenance, and local naming provenance.

Theorem 8018.2 (MarkovDecisionProcess NameCert obligations)**.** *For an accepted* $\mathsf{MarkovDecisionProcess}^{\uparrow}$ *carrier* $D = (S, A, K, R, \Pi, V, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MarkovDecisionProcess}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed state, action, transition, reward, policy, Bellman-boundary, transport, replay, provenance, and naming rows; source compatibility with* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{MarkovChain}^{\uparrow}$*; policy-ledger compatibility with* $\mathsf{Policy}^{\uparrow}$*; Bellman-consumer compatibility with* $\mathsf{DynamicProgramming}^{\uparrow}$*; componentwise* hsame *stability through* H*; displayed* Cont *replay through* C*; and non-escape from the finite packet.*

Proof. Project the displayed carrier. Its rows name the probability-sourced state surface, action ledger, one-step transition packet, reward ledger, policy row, Bellman-facing boundary, transport, replay, package, and local certificate.

Read the dependency rows in consumer order. The normalized probability source is visible before the Markov transition row, the policy ledger is visible before an action-dependent reward row is consumed, and the dynamic-programming boundary is exposed only after S, A, K, R, Π have been displayed.

The structural rows H, C, P, N then transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for a selected optimizer, measurable policy selector, infinite-horizon limit, or host stochastic-process equality, the local NameCert obligations remain exactly the listed finite rows. □

Theorem 8018.3 (MarkovDecisionProcess Bellman consumer boundary)**.** *Every Bellman or dynamic-programming consumer of an accepted* $\mathsf{MarkovDecisionProcess}^{\uparrow}$ *packet reads the value-facing boundary through the finite route*

$$S \longmapsto A \longmapsto K \longmapsto R \longmapsto \Pi \longmapsto V.$$

The route first displays the probability and transition data of chapter 184 and chapter 189, then the policy action ledger of chapter 290, and only then the Bellman-facing continuation consumed by chapter 5875.

Proof. Start with a Bellman-facing read of the boundary row V. The carrier makes V available only through the continuation replay that has already exposed the source state row, action row, transition row, reward row, and policy row.

The source and transition reads are finite: S is attached to the probability carrier and K to the Markov-transition surface. The action read is also finite: A and Π are policy-ledger rows, not an external decision rule or measurable selector.

Finally the reward row R and boundary row V are replayed as displayed certificate data. Thus a dynamic-programming consumer receives only the finite Bellman boundary over S, A, K, R, Π, V, with H, C, P, N supplying transport, replay, provenance, and naming. Nothing in the route exports optimal policy existence, measurable selection, infinite-horizon convergence, or host stochastic-process equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovDecisionProcess}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovDecisionProcess}^{\uparrow}$ packet is generated from finite rows for displayed states, actions, one-step Markov transitions, rewards, policy ledgers, Bellman-consumer boundaries, componentwise hsame transports, Cont replay, package provenance, and local naming. Bellman-facing consumers read the packet through the finite route S, A, K, R, Π, V before any dynamic-programming boundary is exposed.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovDecisionProcess}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the MarkovDecisionProcess carrier, NameCert obligation surface, and Bellman consumer boundary as finite BEDC rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovDecisionProcess}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: It does not claim optimal policy existence, measurable selection, infinite-horizon convergence, host stochastic-process equality, stochastic-process completion, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier formation, policy-transition-reward compatibility, Bellman consumer routing, componentwise transport, and non-escape for the displayed packet.

Chapter 8019

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$ packet records a finite located envelope for a constructive real approximation before any quotient equality, trichotomy, choice-selected limit, or ambient completeness claim is available. It sits over the dyadic tolerance core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval boundary of chapter 1709. The packet gives Real and Completion consumers a named finite envelope surface rather than a completed real construction.

Definition 8019.1 (Bishop located real envelope carrier)**.** *A* $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, Q, R, L, U, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying dyadic radii, endpoint comparisons, midpoint arithmetic, and slack witnesses for the inspected envelope.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule listing exactly which approximation windows are exposed.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows and dyadic tolerances.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, Q have been displayed.*
5. *L and U are lower and upper dyadic envelope rows, with their order and width checked inside D.*
6. *A is the* $\mathsf{LocatedRealInterval}^{\uparrow}$ *adjacency row certifying that the displayed lower and upper rows form a located interval envelope around the inspected real name.*
7. *H stores componentwise* hsame *transport for the dyadic ledger, stream windows, regular readback, Real seal, envelope endpoints, located interval row, replay, provenance, and local name.*
8. *C stores displayed* Cont *replay from a precision request through S, D, L, U, Q, A, R, H.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedRealInterval}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopLocatedRealEnvelope}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, Q, R, L, U, A, H, C, P, N$. It has no coordinate for quotient equality of real names, trichotomy, countable choice, selected limits, supremum, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8019.2 (Bishop located real envelope NameCert obligations)**.** *For every accepted* BishopLocatedRealEnve *carrier $E = (D, S, Q, R, L, U, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealEnvelope}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite-window scheduling, regular rational readback, lower and upper envelope exposure, located interval adjacency, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming. Every Real-facing or Completion-facing read must pass through these rows before consuming the seal R.*

Proof. Project the carrier of Definition 8019.1. The analytic rows are D, S, Q, R, L, U, A, and the structural rows are H, C, P, N.

The dyadic and stream stages are finite. The row D supplies endpoint arithmetic and tolerance comparisons, while S names the inspected windows. The readback row Q is therefore attached to displayed observations rather than to an ambient completed real.

The envelope rows are downstream of those observations. The lower and upper rows L, U are checked by D, and the located interval row A records their envelope adjacency before the terminal seal R is available.

Finally H, C, P, N only transport, replay, source, and name the same route. Since no omitted coordinate stores quotient equality, trichotomy, countable choice, selected limits, supremum, open-cover compactness, or host completeness, the local NameCert surface is exactly the displayed finite envelope surface. □

Theorem 8019.3 (Bishop located real envelope finite-window readback)**.** *Every accepted* BishopLocatedRealEnvelo *read of a real approximation factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{LocatedRealInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as displayed by $D, S, Q, A, R, H, C, P, N$, with the lower and upper envelope rows L, U read before the terminal seal. Thus the packet exposes located real approximation without quotient equality, trichotomy, countable choice over precision requests, selected limits, supremum, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer request for an accepted envelope. The finite schedule S identifies the inspected windows, and the dyadic ledger D identifies the tolerances and endpoint comparisons visible at those windows.

The regular readback Q is the only row that turns those displayed windows into rational approximation data. The lower and upper envelope rows L, U are then read against the same dyadic ledger, so the packet has no independent real-order oracle.

The located interval row A binds the two endpoint rows as a finite located envelope. Only after that adjacency is displayed may the terminal seal R be consumed.

Transport, replay, provenance, and local naming preserve the same dependency route. Hence every read stays inside the finite-window envelope and cannot export the excluded quotient, choice, order, compactness, or completeness principles. □

Falsifiable prediction: Every $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal has already exposed $D, S, Q, L, U, A, H, C, P, N$ and the finite dyadic, stream, regular-readback, and located-interval route named by this chapter.

Independence witness: dyadicratcore, streamname, regseqrat, real, locatedrealinterval: BishopLocatedRealEnvel is not bijective to any listed sibling because it jointly carries a dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, lower and upper envelope rows, a LocatedRealInterval adjacency row, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealEnvelope}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealEnvelope}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readback, lower and upper envelope rows, a LocatedRealInterval adjacency row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealEnvelope}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8019.1, Definition 8019.2, and Definition 8019.3 seed the finite located-envelope route from dyadic tolerance rows through finite windows, regular readback, located interval adjacency, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealEnvelope}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of real names, trichotomy, countable choice, selected limits, supremum, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window scheduling, regular rational readback, envelope exactness, located interval adjacency, terminal Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealEnvelopeUp.

Chapter 8020

A Concrete Naming Certificate for $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$

Following Littlewood and Paley on dyadic frequency decompositions, the $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ packet records the block-level inspection surface used before a square-function, Sobolev, or step-function approximation consumer reads a Littlewood–Paley estimate. It refines the aggregate Littlewood–Paley carrier of chapter 7025, keeps dyadic endpoints on the $\mathsf{DyadicRatCore}^{\uparrow}$ route of chapter 291, seals scalar comparisons only through chapter 38, and sits beside the finite step-function approximation packet of chapter 8012. The packet names one displayed dyadic block and its local recomposition ledger; it does not assert Fourier inversion, unconditional series convergence, quotient function equality, a selected representative, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8020.1 (Littlewood–Paley dyadic-block carrier)**.** *A* $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, P, R, N, H, C, G)$$

with the following displayed rows:

1. *S is the dyadic scale row, recording the selected block scale and its* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data.*
2. *W is the frequency-window row, recording the annulus, cap, or finite window occupied by the block.*
3. *P is the projection row, recording the finite projection probe attached to W.*
4. *R is the recomposition and norm ledger, recording how this block contributes to the local square-function, Sobolev, or step-function readback before any global estimate is cited.*
5. *N is the local* $\mathsf{NameCert}_{\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}}$ *row.*
6. *H records componentwise* hsame *transport for the scale, window, projection, ledger, naming, replay, and provenance rows.*
7. *C records displayed* Cont *replay from the selected scale through the window, projection, recomposition ledger, local name, and transport rows.*
8. *G is the* Pkg *provenance over* $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$, $\mathsf{LittlewoodPaley}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StepFunctionUniformApproximation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*

The classifier compares accepted packets only through S, W, P, R, N, H, C, G. It has no coordinate for an infinite frequency partition, an ambient Fourier transform, equality of completed function-space representatives, a global square-function theorem, or completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 (statement) BEDC.Derived.LittlewoodPaleyDyadicBlockUp

Theorem 8020.2 (Littlewood–Paley dyadic-block NameCert obligations)**.** *For every accepted* $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ *carrier* $B = (S, W, P, R, N, H, C, G)$*, the local* $\mathsf{NameCert}_{\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic scale row* S*, frequency-window row* W*, projection row* P*, recomposition and norm ledger* R*, local naming row* N*, componentwise transport row* H*, displayed replay row* C*, and provenance row* G*. A downstream* $\mathsf{LittlewoodPaley}^{\uparrow}$*, Sobolev, square-function, or step-function consumer may read the block only after those rows are visible.*

Proof. Project the carrier of Definition 8020.1. The rows S, W, P, R, N, H, C, G are the full accepted packet, so a block read starts from a displayed dyadic scale and a displayed frequency window.

The analytic rows are local. The projection row P belongs to the same window W, and the recomposition ledger R records only this block's contribution before any aggregate Littlewood–Paley read is formed.

The structural rows preserve the same packet. Since H, C, G, N transport, replay, source, and name only the displayed block, the local certificate cannot introduce an infinite partition, host Fourier inversion, quotient representative equality, or ambient real-completeness row. □

Theorem 8020.3 (Littlewood–Paley dyadic-block frequency-window route)**.** *Every frequency-window read of an accepted* $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ S,\ W,\ P,\ R,\ N,\ H,\ C,\ G$$

before it can be handed to the aggregate $\mathsf{LittlewoodPaley}^{\uparrow}$ *carrier or to a step-function or Sobolev-facing consumer. The route exports a finite dyadic block, not Fourier inversion, unconditional recomposition, quotient function equality, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the dyadic row S. It fixes the block scale through displayed $\mathsf{DyadicRatCore}^{\uparrow}$ data, so the window cannot be read as an unbounded frequency partition.

Next read W, P, R. The window row names the finite frequency support, the projection row names the local probe, and the recomposition ledger records the block's contribution before an aggregate consumer is allowed to continue.

Finally use N, H, C, G. These rows name, transport, replay, and source the same finite packet. Thus the handoff remains a local dyadic-block route and supplies no coordinate for the excluded analytic endpoints. □

Falsifiable prediction: An accepted $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ read is refuted by any square-function or Sobolev-facing consumer that consumes the projection row before displaying the dyadic scale, frequency window, recomposition ledger, transport, replay, provenance, and local naming rows.

Independence witness: littlewood-paley, dyadicratcore, real, step-function-uniform-approximation, sobolev: none is bijective to $\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}$ because this packet jointly carries one dyadic scale, one frequency window, one projection row, a local recomposition and norm ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LittlewoodPaleyDyadicBlock}^{\uparrow}}$.

Constructive story: A LittlewoodPaleyDyadicBlock$^{\uparrow}$ packet is generated from one dyadic scale row, one frequency-window row, one projection row, one recomposition and norm ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LittlewoodPaleyDyadicBlock}\uparrow}$, seed)

Scope closed: Definition 8020.1, Definition 8020.2, and Definition 8020.3 seed the finite block-level Littlewood–Paley route over dyadic scale, frequency window, projection, recomposition, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{LittlewoodPaleyDyadicBlock}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, Fourier inversion, unconditional dyadic recomposition, quotient function equality, selected representatives, global square-function estimates, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, frequency-window exactness, projection exposure, recomposition-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.LittlewoodPaleyDyadicBlockUp.

Chapter 8021

A Concrete Naming Certificate for $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$

The $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ packet realizes the conditional MetaCIC confluence boundary of chapter 9378 as a finite residual-join window. It sits beside the parallel-diamond frontier of chapter 4238, the residual-substitution compatibility boundary of chapter 4370, the residual-join determinacy packet of chapter 5970, the local-join ledger of chapter 4126, and the finite residual-confluence window of chapter 7752. The packet keeps the retained premise visible while a bounded checker inspects a local join; it does not prove full confluence, subject reduction, residual-substitution compatibility, evaluator equality, quotient term equality, or kernel consistency.

Definition 8021.1 (Finite residual-join window carrier)**.** *A* $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (P, L, O, B, H, C, G, N)$$

with the following displayed rows:

1. *P is the retained residual-substitution premise row consumed by the conditional confluence boundary.*
2. *L is the local residual-join row, recording the finite peak, candidate join, and residual window inspected by the packet.*
3. *O is the obstruction row, retaining the unavailable global endpoints and preventing a local join from being reread as premise-free confluence.*
4. *B is the bounded checker row, recording the finite branch check performed inside the window.*
5. *H records componentwise* hsame *transport for the premise, local join, obstruction, checker, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from the retained premise through the local join, obstruction, bounded checker, transport, provenance, and local name.*
7. *G is the* Pkg *provenance over* $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, MetaCICResidualSub $\mathsf{MetaCICResidualJoinDeterminacy}^{\uparrow}$, $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$, $\mathsf{FiniteResidualConfluenceWindow}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteResidualJoinWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through P, L, O, B, H, C, G, N. It has no coordinate for discharging P, erasing O, promoting L to global Church–Rosser, or importing subject reduction, evaluator equality, quotient equality, or kernel consistency.

Lean4 (statement) `BEDC.Derived.FiniteResidualJoinWindowUp`

Theorem 8021.2 (Finite residual-join window NameCert obligations)**.** *For every accepted* FiniteResidualJoinWindo *carrier $J = (P, L, O, B, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteResidualJoinWindow}^{\uparrow}}$ *surface consists exactly of retained-premise exposure through P, local residual-join exposure through L, obstruction retention through O, bounded-checker exposure through B, componentwise transport through H, displayed replay through C, provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8021.1. The retained premise, local join, obstruction, and bounded checker rows are displayed before the structural rows can be consumed.

The confluence-facing content is local. The row L records only the finite residual join inside the window, while P and O remain visible as premise and obstruction rows for the same packet.

The rows H, C, G, N transport, replay, source, and name that finite packet. Since no row discharges the premise or removes the obstruction, the NameCert surface cannot export full confluence, subject reduction, evaluator equality, quotient equality, or kernel consistency. □

Theorem 8021.3 (Finite residual-join window conditional route)**.** *Every confluence-audit consumer of an accepted* $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ *packet may read the local residual join only through*

$$P, L, O, B, H, C, G, N.$$

The retained premise P, obstruction row O, bounded checker B, transport H, replay C, provenance G, and local name N remain attached to the local join L before any conditional handoff is read.

Proof. Start with the retained premise row P. It records the substitution-sensitive input that the MetaCIC confluence audit map keeps visible at the conditional boundary.

Next inspect L, O, B. The local residual join is bounded by the displayed window, the obstruction row records the unavailable global endpoints, and the checker row limits the read to the finite branch inspection.

Finally read H, C, G, N. These rows preserve the same finite window under transport, replay, provenance, and local naming, so the handoff remains a retained-premise local join rather than a full confluence theorem. □

Falsifiable prediction: An accepted $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ packet is refuted by any confluence consumer that reads a local residual join while erasing the retained premise row, obstruction row, bounded checker, transport, replay, provenance, or local naming row.

Independence witness: metacic-parallel-diamond-frontier, metacic-residual-substitution-compatibility, metacic-residual-join-determinacy, metacic-local-join-ledger, finite-residual-confluence-window: no listed sibling is bijective to $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ because this packet jointly carries retained premise, local join, obstruction, bounded checker, transport, replay, provenance, and local NameCert rows. The Lean follow-up must provide Nontrivial $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ and FieldFaithful FiniteResidualJoi instances.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteResidualJoinWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$ packet is generated from a retained residual-substitution premise, local residual-join row, obstruction row, bounded checker row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteResidualJoinWindow}\uparrow}$, seed)

Scope closed: Definition 8021.1, Definition 8021.2, and Definition 8021.3 seed the finite residual-join window over retained premise, local join, obstruction, bounded checker, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteResidualJoinWindow}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, residual-substitution discharge, full confluence, subject reduction, evaluator equality, quotient term equality, kernel consistency, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, retained-premise exposure, local-join exactness, obstruction retention, bounded-checker exposure, transport, replay, provenance, and local naming for BEDC.Derived.FiniteResidualJoinWindow

Chapter 8022

A Concrete Naming Certificate for $\mathsf{OscillationSeparation}^{\uparrow}$

Following Hardy and Bishop–Bridges, the $\mathsf{OscillationSeparation}^{\uparrow}$ packet records the finite lower-envelope and upper-envelope separation data carried by a bounded real sequence before any compactness or completeness principle is invoked. It binds the lower-tail endpoint of chapter 1553, the upper-tail endpoint of chapter 7101, the oscillation-facing row discipline of chapter 1839, the endpoint-gap packet of chapter 8002, and the terminal real-name seal of chapter 38. The packet is an L10 lower/upper envelope separation carrier; it does not assert compactness, host supremum or infimum selection, quotient sequence equality, trichotomy, selected subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8022.1 (Oscillation separation carrier)**.** *An* $\mathsf{OscillationSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (L, U, G, D, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-envelope row, read through the* $\mathsf{Liminf}^{\uparrow}$ *tail lower-cut surface for the displayed bounded real sequence.*
2. *U is the upper-envelope row, read through the* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *finite upper-window surface for the same displayed bounded real sequence.*
3. *G is the gap row, read through* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *as the finite separation request between the two envelope rows.*
4. *D is the dyadic tolerance ledger naming the rational budgets used when the gap row is replayed at the* $\mathsf{Real}^{\uparrow}$ *boundary.*
5. *H records componentwise* hsame *transport for the lower envelope, upper envelope, gap, dyadic tolerance, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from an oscillation-separation query through L, U, G, D, H.*
7. *P is the* Pkg *provenance over* $\mathsf{OscillationSeparation}^{\uparrow}$*,* $\mathsf{Liminf}^{\uparrow}$*,* $\mathsf{BoundedRealLimsup}^{\uparrow}$*,* $\mathsf{RealOscillation}^{\uparrow}$*,* $\mathsf{LimsupLiminfGap}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{OscillationSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through L, U, G, D, H, C, P, N. No coordinate stores a compactness theorem, ambient completeness, host supremum or infimum, quotient equality of streams, selected subsequences, trichotomy, or a zero-gap convergence conclusion.

Theorem 8022.2 (Oscillation separation seed obligations)**.** *For every accepted* $\mathsf{OscillationSeparation}^{\uparrow}$ *carrier*

$$O = (L, U, G, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{OscillationSeparation}^{\uparrow}}$ *surface contains the following seed obligations:*

1. *lower-envelope admission, requiring L to be displayed as a* $\mathsf{Liminf}^{\uparrow}$ *row before the packet can answer a separation query;*
2. *upper-envelope admission, requiring U to be displayed as a* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *row over the same bounded sequence source before it can be compared with L;*
3. *gap exactness, requiring G to read only the paired lower and upper envelope rows through the* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *packet;*
4. *dyadic replay, requiring every comparison budget in D to be replayed before the terminal* $\mathsf{Real}^{\uparrow}$ *boundary is consumed;*
5. *ledger nonescape, requiring H, C, P, N to transport, replay, source, and name only the rows of O.*

Proof. Project the carrier of Definition 8022.1. The analytic rows are exactly the lower envelope L, upper envelope U, gap row G, and dyadic ledger D.

The lower and upper envelope obligations are row admissions. The packet has no independent sequence coordinate, so the two endpoints must be read through the sibling $\mathsf{Liminf}^{\uparrow}$ and $\mathsf{BoundedRealLimsup}^{\uparrow}$ surfaces that already name the bounded sequence source.

The gap and dyadic obligations are the next route in the carrier. The row G can compare only the displayed envelope rows, and D names the finite rational budgets used to replay that comparison at the real-name boundary.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier inventory has no compactness, completeness, quotient, subsequence, trichotomy, or convergence coordinate, the listed seed obligations exhaust the local surface. □

Theorem 8022.3 (Oscillation separation envelope route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{OscillationSeparation}^{\uparrow}$ *carrier factors through the finite route*

$$L \longmapsto U \longmapsto G \longmapsto D \longmapsto H, C, P, N$$

before reading the displayed lower/upper envelope separation. The route supplies the $\mathsf{Liminf}^{\uparrow}$ *lower envelope, the* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *upper envelope, the* $\mathsf{LimsupLiminfGap}^{\uparrow}$ *separation row, dyadic replay, componentwise transport, continuation replay, provenance, and local naming; it supplies no compactness theorem, host endpoint selection, quotient stream equality, selected subsequence, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier. The consumer first receives the lower envelope row L and upper envelope row U, and these rows are visible only as sibling endpoint certificates.

The separation read then passes through G. Because G is the only gap row in the carrier, it can bind only the displayed lower and upper envelopes, not a host supremum or infimum.

The dyadic ledger D supplies the finite comparison budgets. The structural rows H, C, P, N preserve the same route by transport, replay, provenance, and local naming, so no omitted global principle can enter the consumer surface. □

Theorem 8022.4 (Oscillation separation Real-boundary nonescape)**.** *An accepted* $\mathsf{OscillationSeparation}^{\uparrow}$ *packet reaches the* $\mathsf{Real}^{\uparrow}$ *boundary only after the lower envelope, upper envelope, gap, and dyadic tolerance rows have been displayed. In particular, the packet does not export compactness, host supremum or infimum selection, quotient sequence equality, trichotomy, selected subsequences, zero-gap convergence, Lean verification, or a standard bridge.*

Proof. The only Real-facing content in the carrier is reached through the rows L, U, G, D. The lower and upper envelope rows name the endpoint data, the gap row binds them into a separation request, and the dyadic ledger names the finite comparison budgets.

Replay through C and transport through H cannot add coordinates absent from O. Provenance and local naming through P, N source the packet but do not create compactness, completeness, quotient, subsequence, trichotomy, convergence, verification, or bridge data. □

Falsifiable prediction: An accepted $\mathsf{OscillationSeparation}^{\uparrow}$ read is refuted if the gap row G is consumed while either the lower-envelope row L, the upper-envelope row U, or the dyadic tolerance ledger D is absent.

Independence witness: liminf, bounded-real-limsup, real-oscillation, limsup-liminf-gap, real: no listed sibling supplies the whole packet $O = (L, U, G, D, H, C, P, N)$, because each sibling contributes an endpoint, oscillation route, gap read, or terminal Real boundary while this chapter binds them into one finite separation carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationSeparation}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OscillationSeparation}^{\uparrow}$ packet is generated from a Liminf lower-envelope row, a bounded Real limsup upper-envelope row, a limsup-liminf gap row, a dyadic tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8022.1, Definition 8022.2, Definition 8022.3, and Definition 8022.4 seed the finite lower/upper envelope separation carrier for bounded real-sequence oscillation reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, host supremum or infimum selection, quotient sequence equality, trichotomy, selected subsequences, zero-gap convergence, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked lower-envelope admission, upper-envelope admission, gap exactness, dyadic replay, transport, replay, provenance, and local naming for BEDC.Derived.OscillationSeparationUp.

Chapter 8023

A Concrete Naming Certificate for $\mathsf{DistributionSpace}^{\uparrow}$

Following Schwartz and Treves distribution theory, the $\mathsf{DistributionSpace}^{\uparrow}$ packet records the finite test-action data needed to name a distribution-space interface without importing a host locally convex space, quotient of test functions, or selected representative of a distribution. It sits between the test-function and Schwartz-space carriers of chapter 6945 and chapter 5877, the weak-derivative boundary of chapter 2210, and the scalar readback rows of chapter 301 and chapter 38.

Definition 8023.1 (Distribution-space carrier)**.** *A* $\mathsf{DistributionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (T, A, B, U, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{TestFunction}^{\uparrow}$ *window row, listing the finite test probes, support windows, smoothness tags, and request indices visible to the packet.*
2. *A is the scalar action ledger, recording the displayed action value for each test probe and the finite dependency route by which the action is read.*
3. *B is the* $\mathsf{WeakDerivative}^{\uparrow}$ *boundary row, recording which candidate derivative actions may consume the same test-action ledger.*
4. *U is the source row over* $\mathsf{SchwartzSpace}^{\uparrow}$ *and* $\mathsf{TestFunction}^{\uparrow}$*, exposing the finite test carrier rather than a host test-function equality relation.*
5. *R is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *scalar readback row for action values, comparison tolerances, and terminal scalar boundaries.*
6. *H records componentwise* hsame *transport for test windows, scalar actions, weak-derivative boundaries, source rows, scalar readback, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from test selection through scalar action, derivative-boundary inspection, source readback, and scalar comparison.*
8. *P is the* Pkg *provenance over* $\mathsf{DistributionSpace}^{\uparrow}$, $\mathsf{TestFunction}^{\uparrow}$, $\mathsf{SchwartzSpace}^{\uparrow}$, $\mathsf{WeakDerivative}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DistributionSpace}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for a host distribution space, quotient equality of test functions, selected distribution representative, countable-choice selector, global LF-space topology, or ambient Real completeness theorem.

Theorem 8023.2 (Distribution-space NameCert obligations)**.** *For every accepted* $\mathsf{DistributionSpace}^{\uparrow}$ *carrier* $S = (T, A, B, U, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DistributionSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, finite test-window admission through* T*, scalar-action readback through* A*, weak-derivative boundary exposure through* B*,* $\mathsf{SchwartzSpace}^{\uparrow}$ *and* $\mathsf{TestFunction}^{\uparrow}$ *source admission through* U*,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *scalar readback through* R*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier $S = (T, A, B, U, R, H, C, P, N)$. The displayed mathematical rows are the test-window row, scalar action ledger, weak-derivative boundary, source row, and scalar readback row.

The structural rows transport, replay, source, and name the same displayed data. Since the carrier has no coordinate for a host distribution space, quotient test-function equality, selected representative, choice selector, global LF-space topology, or ambient Real completeness, none of those objects can discharge a local NameCert obligation.

Thus the obligation surface is exactly the finite packet displayed above. □

Theorem 8023.3 (Distribution-space test-action handoff)**.** *Every* $\mathsf{WeakDerivative}^{\uparrow}$ *or Sobolev-facing consumer of an accepted* $\mathsf{DistributionSpace}^{\uparrow}$ *packet reads the finite route*

$$T \longmapsto A \longmapsto B \longmapsto U \longmapsto R \longmapsto H, C, P, N$$

before it consumes any distribution-space action. The handoff exposes test windows, scalar action values, derivative-boundary access, source rows, scalar readback, transport, replay, provenance, and local naming, and it exports no host distribution-space object.

Proof. Start with a consumer request for distribution-space action data. The request first opens the finite $\mathsf{TestFunction}^{\uparrow}$ row T, so the visible tests and support windows are fixed before any scalar action is read.

The scalar action ledger A is then read against the same tests. The weak-derivative boundary row B records which derivative-facing reads may consume that ledger, while U keeps the source tied to the displayed $\mathsf{SchwartzSpace}^{\uparrow}$ and $\mathsf{TestFunction}^{\uparrow}$ rows.

Finally the scalar readback row R and the structural rows H, C, P, N preserve and name the route. No host distribution space or quotient equality can be exported, because such data never appears in the carrier. □

Theorem 8023.4 (Distribution-space weak-derivative boundary)**.** *Any* $\mathsf{WeakDerivative}^{\uparrow}$ *read that consumes a* $\mathsf{DistributionSpace}^{\uparrow}$ *packet must expose the same test-action row, scalar action ledger, weak-derivative boundary row,* $\mathsf{SchwartzSpace}^{\uparrow}$ *or* $\mathsf{TestFunction}^{\uparrow}$ *source row,* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *scalar readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows before the read can be handed to* $\mathsf{Sobolev}^{\uparrow}$*.*

Proof. Use Definition 8023.3 to obtain the ordered route through $T, A, B, U, R, H, C, P, N$. The weak-derivative consumer cannot reach B without first reading the test windows and scalar action ledger.

The scalar readback row R supplies the regular-rational and Real-facing boundary for the action values. The transport and replay rows keep the same test-action ledger visible when the packet is passed toward a Sobolev-facing consumer.

Therefore any Sobolev handoff through $\mathsf{WeakDerivative}^{\uparrow}$ must still display the distribution-space rows named in the statement. The absent host distribution-space, quotient, representative, choice, topology, and ambient completeness objects remain outside the boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{DistributionSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{DistributionSpace}^{\uparrow}$ packet is generated from finite TestFunctionUp windows, a scalar action ledger, a WeakDerivativeUp boundary, SchwartzSpaceUp and TestFunctionUp source rows, RegSeqRatUp and RealUp scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DistributionSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8023.1, Definition 8023.2, Definition 8023.3, and Definition 8023.4 seed the finite distribution-space interface over test actions, scalar readback, weak-derivative boundaries, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DistributionSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host distribution spaces, quotient test-function equality, selected representatives, countable choice, global LF-space topology, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, test-action exactness, scalar readback stability, weak-derivative boundary nonescape, and TasteGate field faithfulness for BEDC.Derived.DistributionSpaceUp.

Chapter 8024

A Concrete Naming Certificate for $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$

Following Hardy–Wright on the Stern–Brocot tree and Bishop–Bridges on finite rational approximation, the $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$ packet records a finite dyadic approximation window cut out by a displayed Stern–Brocot bracket. It sits after the tree route of chapter 1704, the bracketing packet of chapter 1431, the dyadic ledger of chapter 291, the rational source of chapter 37, the finite readback route of chapter 126 and chapter 301, and the terminal real-name seal of chapter 38. The packet names only inspected finite windows; it does not import infinite continued fractions, quotient real equality, trichotomy, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8024.1 (Stern–Brocot dyadic approximation carrier)**.** *A* $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, B, D, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{SternBrocot}^{\uparrow}$ *branch-prefix row, recording the left/right address and inspected mediant route.*
2. *B is the* $\mathsf{SternBrocotApproximation}^{\uparrow}$ *bracket row, exposing the lower and upper rational endpoints delivered by the branch-prefix route.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, storing the requested dyadic scale, endpoint-width comparison, and admissible error window.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *dyadic candidate row extracted from the displayed bracket and dyadic ledger.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window through which the bracket and candidate rows are read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from B, D, Q, W after the Stern–Brocot branch row has been displayed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after the rational bracket, dyadic candidate, finite window, and regular rational rows have been read.*
8. *H records componentwise* hsame *transport for the branch prefix, bracket, dyadic ledger, candidate, window, readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S, B, D, Q, W \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{SternBrocotApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SternBrocotDyadicApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, D, Q, W, R, E, H, C, P, N$. It has no coordinate for infinite continued fractions, quotient real equality, host trichotomy, a selected real representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.SternBrocotDyadicApproximationUp`

Theorem 8024.2 (Stern–Brocot dyadic approximation NameCert obligations)**.** *For every accepted* $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$ *carrier*

$$A = (S, B, D, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SternBrocotDyadicApproximation}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the displayed Stern–Brocot branch prefix, rational bracket, dyadic tolerance ledger, rational candidate, finite window, regular rational handoff, Real seal, transport, replay, provenance, and local naming rows;*
2. *branch-bracket exactness, requiring B to expose only rational endpoints reached by the finite branch-prefix row S;*
3. *dyadic-window compatibility, requiring D to bind the requested dyadic scale to the displayed bracket before the candidate row Q is read;*
4. *finite readback discipline, requiring W and R to preserve the same branch, bracket, tolerance, and candidate rows before the terminal seal E is available;*
5. *transport, replay, provenance, and naming exhaustion through H, C, P, N;*
6. *nonescape from infinite continued fractions, quotient real equality, host trichotomy, selected representatives, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8024.1. The accepted packet displays exactly the Stern–Brocot branch prefix, rational bracket, dyadic tolerance ledger, rational candidate, finite window, regular readback, Real seal, and structural rows.

Branch-bracket exactness reads S and B together. The bracket is not a host real interval; it is the finite rational endpoint pair reached by the inspected Stern–Brocot path.

Dyadic-window compatibility then reads D and Q over the same bracket. The dyadic ledger supplies the scale and endpoint-width comparison used to admit the rational candidate, so the candidate cannot be detached from the displayed branch.

The readback discipline follows the route through W, R, E. A consumer first sees the finite observation window, then the regular rational handoff, and only then the terminal Real seal.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no coordinate for infinite continued fractions, quotient equality, trichotomy, selected representatives, countable choice, or ambient completeness, the listed obligations exhaust the local certificate. □

Theorem 8024.3 (Stern–Brocot dyadic approximation rational bracket handoff)**.** *Every* $\mathsf{Rat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$ *packet must read through the finite handoff*

$$\mathsf{SternBrocot}^{\uparrow},\ \mathsf{SternBrocotApproximation}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff supplies a displayed rational bracket, a dyadic tolerance ledger, a rational candidate row, finite observation windows, regular rational readback, and a terminal Real seal. It supplies no infinite continued-fraction selector, quotient-real representative, host trichotomy, selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from an accepted carrier $A = (S, B, D, Q, W, R, E, H, C, P, N)$. The branch row S and bracket row B are the only source of rational endpoint data.

The dyadic and rational rows D, Q are downstream of that bracket. Thus a rational consumer must read the displayed branch and bracket before it can consume the dyadic candidate.

The finite observation route is then W, R, E. The window row records what was inspected, the regular rational row records the readback, and the Real seal is terminal with respect to that readback.

Transport, replay, provenance, and local naming preserve the same route. Therefore every rational-bracket handoff remains inside the finite Stern–Brocot and dyadic window packet and cannot export any of the excluded real-completeness or choice data. □

Closure status for $\mathsf{NameCert}_{\mathsf{SternBrocotDyadicApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{SternBrocotDyadicApproximation}^{\uparrow}$ packet is generated from a finite SternBrocot branch prefix, a SternBrocotApproximation bracket, a DyadicRatCore tolerance ledger, a RatUp dyadic candidate, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SternBrocotDyadicApproximation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8024.1, Definition 8024.2, and Definition 8024.3 seed the finite Stern–Brocot dyadic approximation window over displayed SternBrocot, DyadicRatCore, Rat, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SternBrocotDyadicApproximation}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SternBrocotDyadicApproximationUp`

Bridge status: none

Not claimed: This chapter does not close infinite continued fractions, quotient real equality, trichotomy, selected real representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean proof obligations, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-bracket exactness, dyadic-window compatibility, finite readback discipline, transport, replay, provenance, local naming, and rational bracket handoff for BEDC.Derived.SternBrocotDyadicApproximationUp.

Chapter 8025

A Concrete Naming Certificate for $\mathsf{DenjoyCarleman}^{\uparrow}$

Following Denjoy and Carleman on quasianalytic classes, the $\mathsf{DenjoyCarleman}^{\uparrow}$ packet records the finite derivative-growth surface by which a smooth real function is read through displayed weight data before any quasianalytic boundary claim is exported. It sits beside the $\mathsf{Calculus}^{\uparrow}$ dossier of chapter 3632, the derivative rows of chapter 122, the compact interval fixed-point boundary of chapter 1437, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names a constructive analysis carrier for derivative-growth bookkeeping; it is not a selected smooth function space, a host equality of functions, a completed Frechet topology, or a proof of the classical quasianalyticity theorem.

Definition 8025.1 (Denjoy–Carleman carrier)**.** *A* $\mathsf{DenjoyCarleman}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, F, M, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{CompactInterval}^{\uparrow}$ *row on which all derivative-growth reads are localized.*
2. *F is the* $\mathsf{Calculus}^{\uparrow}$ *function-observation row over the same interval data.*
3. *M is the finite weight row recording the displayed Denjoy–Carleman control sequence entries inspected by the packet.*
4. *G is the derivative-growth ledger tying the first finitely many* $\mathsf{Derivative}^{\uparrow}$ *rows to the corresponding entries of M.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for finite rational bounds on the displayed derivative windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, F, M, G, R have been replayed.*
7. *H records componentwise* hsame *transport for interval, function, weight, derivative-growth, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a derivative-growth request through $I, F, M, G, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DenjoyCarleman}^{\uparrow}$, $\mathsf{Calculus}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{CompactInterval}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DenjoyCarleman}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows, their displayed transports, continuation replay, provenance, and local naming. It has no coordinate for quotient function equality, selected Taylor coefficients, ambient smooth-space completeness, classical divergence tests, countable choice, or bridge checking.

Theorem 8025.2 (Denjoy–Carleman NameCert obligations)**.** *For every accepted* $\mathsf{DenjoyCarleman}^{\uparrow}$ *carrier* $D = (I, F, M, G, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DenjoyCarleman}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed compact interval, function-observation, weight, derivative-growth, readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *interval exactness, requiring every derivative-growth read to consume the same* $\mathsf{CompactInterval}^{\uparrow}$ *row* I *before it inspects* $F, M, G,$ *or* R*;*
3. *derivative-growth exactness, requiring the* $\mathsf{Derivative}^{\uparrow}$ *rows in* G *to be read only with the displayed finite weight row* M *and rational readback row* R*;*
4. *Real handoff, requiring the terminal seal* E *to remain downstream of* I, F, M, G, R *and the structural rows* H, C, P, N*;*
5. *non-escape from quotient function equality, selected Taylor coefficients, completed smooth-space topology, classical quasianalyticity criteria, countable choice, Lean verification, and bridge checking.*

No Denjoy–Carleman obligation is stored outside those rows.

Proof. Project the carrier of Definition 8025.1. The projection exposes exactly the compact interval, function-observation, weight, derivative-growth, readback, Real seal, transport, replay, provenance, and local naming rows.

The interval and derivative-growth obligations are finite. A read enters through I, inspects the function-observation row F, then reads only the displayed weight entries in M and the matching derivative-growth ledger G before obtaining rational bounds through R.

Finally the Real handoff is supplied by E, H, C, P, N. Since the carrier has no coordinate for quotient functions, selected Taylor data, completed smooth topologies, classical quasianalytic criteria, choice schedules, Lean targets, or bridge rows, the listed rows exhaust the local NameCert surface. □

Theorem 8025.3 (Denjoy–Carleman derivative-growth route)**.** *Every* $\mathsf{Calculus}^{\uparrow}$*,* $\mathsf{Derivative}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DenjoyCarleman}^{\uparrow}$ *carrier factors through the finite route*

$$I, F, M, G, R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a compact interval row, a calculus function-observation row, displayed finite weight data, derivative-growth rows, rational readback, a terminal Real seal, componentwise transport, replay, provenance, and local naming. It receives no quotient function equality, selected Taylor expansion, completed smooth-space topology, countable-choice schedule, or ambient quasianalyticity theorem.

Proof. Begin with a consumer of the packet. Carrier admission gives access to the derivative-growth ledger only as a row tied to the same compact interval and calculus observation rows.

Replay the continuation row C. The request reads I and F, then consults the displayed weight row M and the derivative-growth ledger G before it obtains rational readback through R and the terminal seal E.

The structural rows H, P, N preserve the same finite route under transport and provenance. No remaining carrier row can provide quotient function equality, a selected Taylor expansion, a completed smooth-space topology, a choice schedule, or an ambient quasianalyticity theorem. □

Falsifiable prediction: An accepted $\mathsf{DenjoyCarleman}^{\uparrow}$ read is refuted if a derivative-growth consumer reaches the terminal Real seal without displaying the CompactInterval row, Calculus observation row, finite weight row, derivative-growth ledger, RegSeqRat readback, componentwise transport, replay, provenance, and local NameCert row.

Independence witness: calculus, derivative, compact-interval, regseqrat, real: none alone is bijective with $\mathsf{DenjoyCarleman}^{\uparrow}$ because the packet jointly records localized function observation, finite Denjoy–Carleman weight data, derivative-growth bounds, rational readback, terminal Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{DenjoyCarleman}^{\uparrow}}$.

Constructive story: A $\mathsf{DenjoyCarleman}^{\uparrow}$ packet is generated from a CompactInterval row, a Calculus function-observation row, a finite Denjoy–Carleman weight row, derivative-growth rows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DenjoyCarleman}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8025.1, Definition 8025.2, and Definition 8025.3 seed the finite Denjoy–Carleman derivative-growth route over compact intervals, calculus observations, derivative rows, rational readback, and terminal Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DenjoyCarleman}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the classical Denjoy–Carleman quasianalyticity theorem, quotient function equality, selected Taylor coefficients, completed smooth-space topology, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval exactness, derivative-growth exactness, weight-row accountability, rational readback exactness, Real seal handoff, transport stability, replay stability, provenance, and local naming for BEDC.Derived.DenjoyCarlemanUp.

Chapter 8026

A Concrete Naming Certificate for $\mathsf{UniformPartitionVariation}^{\uparrow}$

Following Jordan's bounded-variation ledgers and the Bishop–Bridges treatment of finite mesh integration, the $\mathsf{UniformPartitionVariation}^{\uparrow}$ packet records the variation read available on a displayed uniform partition. It sits after the equal-mesh carrier of chapter 2033, the finite variation partition surface of chapter 6386, the Darboux-sum route of chapter 1880, the Riemann-sum chapter of chapter 1615, and the $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ numeric rows of chapter 38, chapter 301, and chapter 291. The packet names a finite uniform-mesh variation ledger; it does not claim a supremum over all partitions, selected refinement families, measure completion, quotient equality of functions, or ambient real completeness.

Definition 8026.1 (Uniform partition variation carrier)**.** *A* $\mathsf{UniformPartitionVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, M, V, D, R, S, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval and endpoint source row.*
2. *M is the accepted* $\mathsf{UniformPartition}^{\uparrow}$ *equal-mesh row over that interval.*
3. *V is the* $\mathsf{FiniteVariationPartition}^{\uparrow}$ *ledger row obtained from the same ordered cells.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-width and adjacent-difference budget row.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite adjacent-difference and tolerance data.*
6. *S is the* $\mathsf{DarbouxSum}^{\uparrow}$ *or Riemann-sum consumer handoff row, present only after M, V, D, R have been displayed.*
7. *L is the finite variation ledger, listing the adjacent absolute-difference reads and their finite sum along the uniform mesh.*
8. *H records componentwise* hsame *transport for I, M, V, D, R, S, L and the structural rows.*
9. *C records displayed* Cont *replay from the interval and uniform mesh through the variation ledger, numeric readback, Darboux or Riemann handoff, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{UniformPartitionVariation}^{\uparrow}$, $\mathsf{UniformPartition}^{\uparrow}$, $\mathsf{FiniteVariationPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformPartitionVariation}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $I, M, V, D, R, S, L, H, C, P, N$. It has no coordinate for a host variation supremum, a chosen refinement sequence, quotient equality of functions, measure completion, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8026.2 (Uniform partition variation NameCert obligations)**.** *For every accepted* UniformPartitionVariatio *carrier $U = (I, M, V, D, R, S, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{UniformPartitionVariation}^{\uparrow}}$ *surface consists exactly of carrier admission, uniform-mesh exposure through M, finite variation-partition exposure through V, dyadic budget exposure through D, regular-rational readback through R, Darboux or Riemann consumer handoff through S, finite variation-ledger exactness through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The only visible rows are the interval source, uniform mesh, finite variation partition, dyadic budget, regular-rational readback, consumer handoff, finite ledger, transport, replay, provenance, and local name.

The mesh and variation rows are tied to the same finite cells. Row M supplies the equal-width partition, and row V reads that partition as a finite variation ledger rather than as an arbitrary partition family.

The numeric side is finite. The dyadic row D stores mesh widths and adjacent-difference budgets, while R turns those displayed budgets into regular-rational readback before a real-facing consumer may use the ledger.

The handoff and structural rows do not add hidden analytic data. Row S exposes only the Darboux or Riemann consumer boundary, row L stores the finite variation sum, and H, C, P, N transport, replay, source, and name exactly that packet. □

Theorem 8026.3 (Uniform partition variation Darboux route)**.** *Every Darboux-facing or Riemann-sum-facing read of an accepted* $\mathsf{UniformPartitionVariation}^{\uparrow}$ *packet factors through*

$$\mathsf{UniformPartition}^{\uparrow} \longmapsto \mathsf{FiniteVariationPartition}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DarbouxSum}^{\uparrow}$$

before the finite ledger L is public. The route gives consumers a uniform-mesh variation ledger over displayed real endpoints and numeric readback rows, not a host supremum over all partitions or a selected refinement process.

Proof. Start with the uniform partition row M. It fixes the equal-width cells over the interval row I, so the variation packet has a displayed mesh before any adjacent difference is read.

Next apply the finite variation partition row V. It reads the same ordered cells as a finite adjacent-difference ledger and keeps the construction inside the sibling surface of chapter 6386.

The numeric rows D and R then expose dyadic budgets and regular-rational readback for the same finite differences. The Darboux or Riemann handoff S is available only after those rows have been displayed.

Finally the ledger row L records the finite variation sum, and the rows H, C, P, N preserve the route under transport, replay, provenance, and local naming. Since the carrier contains no supremum, refinement selector, quotient function equality, measure completion, or ambient completeness coordinate, none can be exported by the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformPartitionVariation}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformPartitionVariation}^{\uparrow}$ packet is generated from a RealUp interval row, UniformPartitionUp equal-mesh row, FiniteVariationPartitionUp ledger row, DyadicRatCoreUp budget row, RegSeqRatUp readback

row, Darboux or Riemann consumer handoff, finite variation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{UniformPartitionVariation}\uparrow}$, seed)

Scope closed: Definition 8026.1, Definition 8026.2, and Definition 8026.3 seed the finite uniform-mesh variation ledger over the uniform partition, finite variation partition, Darboux, Real, RegSeqRat, and DyadicRatCore rows.

Formal verification: FormalStatus(NameCert$_{\text{UniformPartitionVariation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a host supremum over all partitions, selected refinement families, quotient equality of functions, measure completion, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, uniform-mesh exposure, finite variation-partition exposure, dyadic budget readback, regular-rational readback, Darboux or Riemann handoff, variation-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.UniformPartitionVariationUp.

Chapter 8027

A Concrete Naming Certificate for $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ packet records the finite epsilon-tail witness surface for regular Cauchy real names. It sits over the finite stream-name discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the limit-facing handoff of chapter 1678. The packet supplies the Real and Completion route with displayed epsilon-tail evidence only; it does not import quotient stream equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8027.1 (Regular Cauchy epsilon-tail carrier)**.** *A* $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, D, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule row. It records the inspected indices, window requests, and tail-access cells used by the epsilon-tail witness.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row. It exposes the regular rational name only through the finite reads scheduled by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the requested epsilon, dyadic slack, radius comparison, and finite arithmetic budget.*
4. *Q is the precision-query row. It binds the external epsilon request to the displayed dyadic budget in D before any tail assertion is available.*
5. *T is the epsilon-tail witness row. It displays the tail threshold and the finitely checked later-window comparisons read from S, R, D, Q.*
6. *H records componentwise* hsame *transport for the stream schedule, regular rational row, dyadic budget, precision query, tail witness, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, R, D, Q \longmapsto T.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEpsilonTail}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, T, H, C, P, N$. It has no coordinate for quotient equality of streams, a host limit, a selected real representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegularCauchyEpsilonTailUp`

Theorem 8027.2 (Regular Cauchy epsilon-tail NameCert obligations)**.** *For every accepted* RegularCauchyEpsilonTa *carrier*

$$E = (S, R, D, Q, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEpsilonTail}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the stream schedule, regular rational source, dyadic tolerance budget, precision query, epsilon-tail witness, transport, replay, provenance, and local naming rows;*
2. *query-budget exactness, requiring Q to bind the requested epsilon to the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget before the tail threshold is read;*
3. *stream-readback exactness, requiring every later-window comparison in T to be read from the same* $\mathsf{StreamName}^{\uparrow}$ *schedule and* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows;*
4. *transport and replay stability through H and C for the same displayed epsilon-tail route;*
5. *provenance and local naming exhaustion through P and N;*
6. *refusal of quotient stream equality, host limits, selected real representatives, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Project the accepted carrier $E = (S, R, D, Q, T, H, C, P, N)$. The visible analytic rows are the finite stream schedule S, the regular rational source R, the dyadic budget D, the precision query Q, and the tail witness T.

The query first passes through Q and D. This forces the epsilon request to be recorded as a finite dyadic budget before any tail threshold or later-window comparison can be consumed.

The witness row T is downstream of the same schedule and source. Its threshold and later-window comparisons are read only from the windows listed in S and the rational observations exposed by R.

The structural rows preserve this route. The row H transports the displayed coordinates componentwise, C replays the same dependency order, and P, N source and name only the resulting packet.

Since none of the excluded principles is a coordinate of the carrier or a product of the replay route, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8027.3 (Regular Cauchy epsilon-tail Real seal route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or limit-facing consumer of an accepted* $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ *carrier factors through the finite route*

$$S, R, D, Q \longmapsto T \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed StreamName schedule, regular rational readback, dyadic epsilon budget, precision query, epsilon-tail witness, transport, replay, provenance, and local naming. It receives no quotient stream equality, host limit, selected real representative, countable-choice schedule, trichotomy principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the accepted packet. The stream and regular-rational rows S and R are the only source of observation data, and the dyadic row D is the only source of epsilon-budget data.

The precision query Q binds the requested tolerance to that dyadic budget. Hence a real-name or limit-facing read cannot access a tail threshold before the finite epsilon request has been displayed.

Read the witness row T next. It records the finite tail threshold and the later-window comparisons obtained from S, R, D, Q.

Finally apply the structural rows H, C, P, N. They transport, replay, source, and name the same route without adding any coordinate outside it. Therefore every Real or limit-facing handoff remains inside the finite epsilon-tail witness surface and cannot export the excluded quotient, selection, choice, trichotomy, host-limit, or completeness data. □

Falsifiable prediction: A $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ read is refuted whenever a $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or limit-facing consumer reaches an epsilon-tail witness without displaying the finite StreamName schedule, RegSeqRat source, DyadicRatCore tolerance row, precision query, componentwise transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, limit: none alone is bijective with $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ because the packet jointly records a finite stream schedule, a regular rational source, a dyadic epsilon budget, a precision query, a displayed tail witness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEpsilonTail}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEpsilonTail}^{\uparrow}$ packet is generated from a finite StreamName schedule, a RegSeqRat source row, a DyadicRatCore epsilon budget, a precision query, an epsilon-tail witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEpsilonTail}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8027.1, Definition 8027.2, and Definition 8027.3 seed the finite epsilon-tail witness route over displayed StreamName, RegSeqRat, DyadicRatCore, Real, Limit, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEpsilonTail}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyEpsilonTailUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, host limits, selected real representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean proof obligations, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, query-budget exactness, stream-readback exactness, epsilon-tail witness coverage, transport, replay, provenance, local naming, and Real-seal route nonescape for BEDC.Derived.RegularCauchyEpsilonTailUp.

Chapter 8028

A Concrete Naming Certificate for $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$

Following Baire and Lebesgue on pointwise hierarchies of real functions, the $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ packet records a real-valued function as a displayed pointwise limit of $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ rows. It sits after the Baire class one carrier of chapter 7703, the pointwise-limit packet of chapter 2314, the stream-name schedule of chapter 126, the regular-rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet gives later descriptive-analysis consumers a second pointwise layer without quotient function equality, selected representatives, countable choice, ambient measurability, or completeness of a host function space.

Definition 8028.1 (Baire class two real-function carrier)**.** *A* $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, S, B, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source real-domain row whose point requests are read through* $\mathsf{Real}^{\uparrow}$ *names.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule listing the inspected stages of the outer pointwise sequence.*
3. *B assigns each inspected outer stage to a displayed* $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ *row.*
4. *L is the* $\mathsf{PointwiseLimit}^{\uparrow}$ *handoff that compares the stage outputs only through finite pointwise windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to each inspected output window.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed second-level pointwise value.*
7. *H records componentwise* hsame *transport for source, schedule, Baire-one stage, pointwise-limit, readback, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a point request through $X, S, B, L, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$, $\mathsf{BaireClassOneRealFunction}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireClassTwoRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host equality of functions, quotient function spaces, selected representatives, countable choice, arbitrary measurability, or an ambient theorem identifying all Baire class two maps.

Theorem 8028.2 (Baire class two real-function NameCert obligations)**.** *For every accepted* $\mathsf{BaireClassTwoRealFunc}$ *carrier* $F = (X, S, B, L, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireClassTwoRealFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the source real-domain row, the* $\mathsf{StreamName}^{\uparrow}$ *outer stage schedule, the* $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ *stage rows, the* $\mathsf{PointwiseLimit}^{\uparrow}$ *handoff, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, package provenance, and local naming. Every downstream descriptive-analysis consumer must consume those rows before treating the packet as a Baire class two real-valued function.*

Proof. Project the carrier of Definition 8028.1. The accepted packet exposes only the source row, outer stage schedule, Baire-one stage rows, pointwise-limit handoff, regular-rational readback, Real seal, transport, replay, provenance, and local naming.

The second pointwise layer starts with X and S. A consumer first names the point request and the inspected outer stages, then reads the displayed $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ row at each inspected stage.

The output route is then forced through L, R, E. The pointwise-limit row records the finite comparison windows, the regular-rational row records the numerical readback, and the Real seal records the terminal pointwise value.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores host function equality, a quotient function space, selected representatives, countable choice, arbitrary measurability, or an ambient classification theorem, the listed obligations exhaust the local certificate surface. □

Theorem 8028.3 (Baire class two pointwise handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*, pointwise-limit, or descriptive-analysis consumer of an accepted* $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BaireClassOneRealFunction}^{\uparrow} \longmapsto \mathsf{PointwiseLimit}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the Baire class two row is a displayed pointwise sequence of Baire class one real-valued maps with finite readback, not a host function equality class, a selected second-level limit map, or an imported measurable-function hierarchy.

Proof. Begin with a downstream consumer. Carrier admission forces the consumer to read the $\mathsf{StreamName}^{\uparrow}$ schedule before any stage of the outer approximating sequence can be inspected.

The inspected stage is then a $\mathsf{BaireClassOneRealFunction}^{\uparrow}$ row. Its output is not exposed as a host function value; it passes through the $\mathsf{PointwiseLimit}^{\uparrow}$ handoff, the $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Transport and replay are supplied by H and C, while P and N keep the provenance and local name attached to the same finite tuple. Consequently the consumer receives only the displayed pointwise route over named sibling packets.

The carrier inventory excludes host function equality, quotient function spaces, selected pointwise limits, countable choice, arbitrary measurability, and imported hierarchy theorems, so the handoff is exactly the finite BEDC route stated above. □

Falsifiable prediction: An accepted $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ consumer is refuted if it treats a second-level pointwise limit as public before displaying the StreamName outer schedule, BaireClassOne stage rows, PointwiseLimit handoff, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: baireclassone, pointwiselimit, streamname, regseqrat, real: none is bijective because $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ binds a real-domain source, explicit outer stage schedule,

Baire-one stage rows, pointwise-limit handoff, numerical readback, Real seal, transport, replay, provenance, and local NameCert rows in one packet. Each sibling supplies one constituent surface, while only this packet names the second pointwise layer.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireClassTwoRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ packet is generated from a RealUp source row, a StreamName outer stage schedule, BaireClassOneRealFunction stage rows, a PointwiseLimit handoff, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireClassTwoRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8028.1, Definition 8028.2, and Definition 8028.3 seed the explicit pointwise-sequence-of-Baire-one-functions route over BaireClassOneRealFunctionUp, PointwiseLimitUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireClassTwoRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function equality, quotient function spaces, selected pointwise limits, countable choice, arbitrary measurability, or a full Baire hierarchy.

Upgrade path: Obligation closure requires checked carrier admission, outer stage schedule exactness, Baire-one stage exposure, pointwise-limit handoff, pointwise readback, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BaireClassTwoRealFunctionUp.

Chapter 8029

A Concrete Naming Certificate for $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$

Following Baire and Bishop–Bridges constructive analysis, the $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ packet records a real-valued function as a displayed pointwise limit of $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ rows. It consumes the Baire class two sibling of chapter 8028, the pointwise-limit handoff of chapter 2314, the continuous-map observation discipline of chapter 130, the finite $\mathsf{StreamName}^{\uparrow}$ schedules of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet gives later oscillation and rank consumers a third finite pointwise layer without importing quotient function equality, selected representatives, countable choice, arbitrary measurability, or ambient completeness of a host function space.

Definition 8029.1 (Baire class three real-function carrier)**.** *A* $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, S, B, L, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the source real-domain row whose point requests are read through* $\mathsf{Real}^{\uparrow}$ *names.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule listing the inspected stages of the outer pointwise sequence.*
3. *B assigns each inspected outer stage to a displayed* $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ *source row.*
4. *L is the* $\mathsf{PointwiseLimit}^{\uparrow}$ *handoff comparing the stage outputs only through finite pointwise windows.*
5. *O is the observation row: it records the* $\mathsf{ContinuousMap}^{\uparrow}$*-compatible point request surface and the* $\mathsf{StreamName}^{\uparrow}$ *windows inspected before an output value can be read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the observed stage outputs and tolerance requests.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed third-level pointwise value.*
8. *H records componentwise* hsame *transport for the source, schedule, Baire-two stage, pointwise-limit, observation, readback, Real-seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a point request through $X, S, B, L, O, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$, $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$, $\mathsf{PointwiseLimit}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireClassThreeRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host equality of functions, quotient function spaces, selected representatives, countable choice, arbitrary measurability, or an ambient theorem identifying all Baire class three maps.

Theorem 8029.2 (Baire class three real-function NameCert obligations)**.** *For every accepted* $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ *carrier* $F = (X, S, B, L, O, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireClassThreeRealFunctio}}$ *surface consists exactly of carrier admission for the source real-domain row, the* $\mathsf{StreamName}^{\uparrow}$ *outer stage schedule, the* $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ *stage rows, the* $\mathsf{PointwiseLimit}^{\uparrow}$ *handoff, the* $\mathsf{ContinuousMap}^{\uparrow}$*-compatible observation row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every downstream oscillation, rank, Real, or descriptive-analysis consumer must consume those rows before treating the packet as a Baire class three real-valued function.*

Proof. Project the carrier of Definition 8029.1. The accepted packet exposes only the source row, outer stage schedule, Baire-two stage rows, pointwise-limit handoff, observation row, regular-rational readback, Real seal, transport, replay, provenance, and local naming.

The third pointwise layer starts with X and S. A consumer first names the point request and the inspected outer stages, then reads the displayed $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ row at each inspected stage.

The output route is then forced through L, O, R, E. The pointwise-limit row records the finite comparison windows, the observation row keeps the point request on the displayed $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ surfaces, the regular-rational row records the numerical readback, and the Real seal records the terminal pointwise value.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no coordinate stores host function equality, a quotient function space, selected representatives, countable choice, arbitrary measurability, or an ambient classification theorem, the listed obligations exhaust the local certificate surface. □

Theorem 8029.3 (Baire class three pointwise ladder)**.** *Every* $\mathsf{Real}^{\uparrow}$*, pointwise-limit, oscillation-rank, or descriptive-analysis consumer of an accepted* $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BaireClassTwoRealFunction}^{\uparrow} \longmapsto \mathsf{PointwiseLimit}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeq}$$

Thus the Baire class three row is a displayed pointwise sequence of Baire class two real-valued maps with finite observation and readback, not a host function equality class, a selected third-level limit map, or an imported measurable-function hierarchy.

Proof. Begin with a downstream consumer. Carrier admission forces the consumer to read the $\mathsf{StreamName}^{\uparrow}$ schedule before any stage of the outer approximating sequence can be inspected.

The inspected stage is then a $\mathsf{BaireClassTwoRealFunction}^{\uparrow}$ row. Its output is not exposed as a host function value; it passes through the $\mathsf{PointwiseLimit}^{\uparrow}$ handoff and the observation row that binds point requests to $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ surfaces.

The readback route then reaches R and E. The $\mathsf{RegSeqRat}^{\uparrow}$ row records the finite numerical windows, and the terminal $\mathsf{Real}^{\uparrow}$ seal is downstream of the same displayed pointwise ladder.

Transport and replay are supplied by H and C, while P and N keep the provenance and local name attached to the same finite tuple. Consequently the consumer receives only the displayed pointwise route over named sibling packets.

The carrier inventory excludes host function equality, quotient function spaces, selected pointwise limits, countable choice, arbitrary measurability, imported hierarchy theorems, and ambient $\mathsf{Real}^{\uparrow}$ completeness, so the ladder is exactly the finite BEDC route stated above. □

Falsifiable prediction: An accepted $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ consumer is refuted if it treats a third-level pointwise limit as public before displaying the StreamName outer schedule, BaireClassTwo stage rows, PointwiseLimit handoff, ContinuousMap-compatible observation row, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: baireclasstwo, pointwiselimit, continuousmap, streamname, regseqrat, real: none is bijective because $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ binds a real-domain source, explicit outer stage schedule, Baire-two stage rows, pointwise-limit handoff, observation row, numerical readback, Real seal, transport, replay, provenance, and local NameCert rows in one packet. Each sibling supplies one constituent surface, while only this packet names the third pointwise layer.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireClassThreeRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireClassThreeRealFunction}^{\uparrow}$ packet is generated from a RealUp source row, a StreamName outer stage schedule, BaireClassTwoRealFunction stage rows, a PointwiseLimit handoff, ContinuousMap-compatible observation rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireClassThreeRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8029.1, Definition 8029.2, and Definition 8029.3 seed the explicit pointwise-sequence-of-Baire-two-functions route over BaireClassTwoRealFunctionUp, PointwiseLimitUp, ContinuousMapUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireClassThreeRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function equality, quotient function spaces, selected pointwise limits, countable choice, arbitrary measurability, oscillation ranks, or a full Baire hierarchy.

Upgrade path: Obligation closure requires checked carrier admission, outer stage schedule exactness, Baire-two stage exposure, pointwise-limit handoff, observation-row compatibility, pointwise readback, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BaireClassThreeRealFunctionUp.

Chapter 8030

A Concrete Naming Certificate for $\mathsf{RegularCauchyAdmission}^{\uparrow}$

Bishop and Bridges constructive analysis treats a regular Cauchy name as usable real data only after the finite rational observations, tolerance ledger, and terminal seal have been kept separate. The $\mathsf{RegularCauchyAdmission}^{\uparrow}$ packet records that admission surface between the regular rational sequence of chapter 301 and the real-name boundary of chapter 38. It also keeps the source schedule of chapter 126 and the dyadic arithmetic ledger of chapter 291 visible to completion-facing readers.

The packet is an admission route, not a real-completion theorem. It names the finite data that a later $\mathsf{Real}^{\uparrow}$ or completion chapter may consume when it reads a regular rational name as Real-facing data, while refusing quotient stream equality, selected representatives, countable choice, trichotomy, and ambient completeness.

Definition 8030.1 (Regular Cauchy admission carrier)**.** *A* $\mathsf{RegularCauchyAdmission}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source schedule, recording the finite observation windows through which downstream readers ask for rational data.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying the regular rational sequence data visible on the windows named by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic precision cells, slack conversions, and comparison budgets used to audit the regularity of R.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream schedule, regular readback, and dyadic tolerance ledger have been displayed.*
5. *H records componentwise* hsame *transport for S, R, D, E and for the local classifier row.*
6. *C records displayed* Cont *replay routes from a Real-facing request back through E, D, R, and S.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyAdmission}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAdmission}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by replaying these rows. It has no coordinate for quotient stream equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8030.2 (Regular Cauchy admission NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyAdmission}^{\uparrow}$ *carrier* $A = (S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyAdmission}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The obligations require every Real-facing read to expose* S*,* R*, and* D *before the seal row* E *is public.*

Proof. Project the carrier of Definition 8030.1. The analytic rows are exactly S, R, D, E, while H, C, P, N transport, replay, package, and name the same route.

The regular rational readback row R is not a Real object by itself. A consumer must first read the stream windows in S and the dyadic tolerance ledger in D before the seal row E can be exposed.

Transport through H and replay through C preserve the same finite order. Since neither row adds quotient stream equality, selected representatives, countable choice, trichotomy, or completeness, the local NameCert obligations are exhausted by the displayed packet surface. □

Theorem 8030.3 (Regular Cauchy admission Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyAdmission}^{\uparrow}$ *carrier factors through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto E.$$

Thus a completion or Real-facing consumer sees the stream schedule, regular rational readback, dyadic tolerance ledger, and terminal seal in order. The route exports no quotient stream equality, selected representative, countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the seal row E. By the carrier definition, E is the terminal row reached from the displayed regular rational data and its dyadic tolerance ledger.

The stream schedule S supplies the finite request windows, and R supplies the regular rational observations visible on those windows. The ledger D then records the precision and comparison data needed before the seal is public.

The structural rows H, C, P, N preserve and name this route without adding host-level or quotient coordinates. Hence every Real-facing read factors through S, R, D, E and cannot export the excluded principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyAdmission}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyAdmission}^{\uparrow}$ packet is generated from a StreamName schedule, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyAdmission}^{\uparrow}}$, seed)

Scope closed: Definition 8030.1, Definition 8030.2, and Definition 8030.3 seed the finite admission route from regular rational reads to the downstream $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyAdmission}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular readback, dyadic tolerance exactness, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyAdmissionUp.

Chapter 8031

A Concrete Naming Certificate for $\mathsf{LipschitzFixedPoint}^{\uparrow}$

Following Banach and Bishop–Bridges constructive fixed-point theory, the $\mathsf{LipschitzFixedPoint}^{\uparrow}$ packet records the finite endpoint certificate read by a Lipschitz contraction consumer after the contraction, modulus, and Cauchy-orbit rows are displayed. It sits after the Banach contraction route of chapter 3529, the constructive contraction modulus of chapter 7631, and the orbit endpoint seal of chapter 7047. The packet names the endpoint-facing certificate for a fixed-point read; it does not select a host fixed point, quotient a completion, use countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8031.1 (Lipschitz fixed-point carrier)**.** *A* $\mathsf{LipschitzFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, M, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachContraction}^{\uparrow}$ *row that supplies the contractive self-map route and separated endpoint discipline.*
2. *M is the* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ *row that exposes the finite contraction modulus before the orbit tail is read.*
3. *O is the* $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ *row that carries the Picard orbit, Cauchy-modulus handoff, and endpoint seal boundary.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite regular tail windows inspected by the endpoint consumer.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal available only after B, M, O, R have been replayed.*
6. *H records componentwise* hsame *transport for contraction, modulus, orbit seal, readback, endpoint seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a fixed-point request through B, M, O, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{LipschitzFixedPoint}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{ConstructiveContractionModulus}^{\uparrow}$, $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LipschitzFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows, their displayed transports, continuation replay, provenance, and local naming.

Lean4 ✓ `BEDC.Derived.LipschitzFixedPointUp.TasteGate.LipschitzFixedPointTasteGate single carrier alignment`

Theorem 8031.2 (Lipschitz fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzFixedPoint}^{\uparrow}$ *carrier* $L = (B, M, O, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LipschitzFixedPoint}^{\uparrow}}$ *surface consists exactly of contraction admission through* B*, modulus admission through* M*, orbit-seal admission through* O*, regular rational readback through* R*, terminal endpoint sealing through* E*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8031.1. The projection exposes the contraction row, modulus row, orbit-seal row, readback row, endpoint seal, transport, replay, provenance, and local naming rows.

The analytic rows are read in fixed order. The Banach contraction row supplies the contractive route, the constructive modulus row supplies the finite shrinkage budget, the orbit seal supplies the Picard Cauchy endpoint boundary, and the regular rational readback supplies the displayed tail windows before E is available.

The structural rows H, C, P, N preserve and identify that same packet. Since the carrier has no coordinate for host fixed-point selection, quotient completion equality, countable choice, or ambient RealUp completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8031.3 (Lipschitz fixed-point Picard orbit Cauchy route)**.** *Every fixed-point endpoint consumer of an accepted* $\mathsf{LipschitzFixedPoint}^{\uparrow}$ *carrier factors through the finite Picard orbit route*

$$\mathsf{BanachContraction}^{\uparrow} \longmapsto \mathsf{ConstructiveContractionModulus}^{\uparrow} \longmapsto \mathsf{CauchyFixedPointOrbitSeal}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Rea}$$

The endpoint read therefore consumes the displayed contraction, modulus, orbit seal, regular readback, terminal seal, componentwise transport, replay, provenance, and local naming rows before any fixed-point row is public.

Proof. Begin with an endpoint request. Carrier admission gives access to the contraction row B before the modulus or orbit rows can be consumed.

Next read M, O, R. The modulus row exposes the finite shrinkage data, the orbit-seal row exposes the Picard Cauchy boundary, and the regular rational readback records the finite tail windows inspected by the endpoint consumer.

Finally read E, H, C, P, N. These rows seal, transport, replay, source, and name the same finite endpoint route, so the public fixed-point read remains inside the displayed Picard orbit certificate. □

Theorem 8031.4 (Lipschitz fixed-point non-escape)**.** *An accepted* $\mathsf{LipschitzFixedPoint}^{\uparrow}$ *carrier exports only the rows* $B, M, O, R, E, H, C, P, N$ *of Definition 8031.1. It exports no host-selected fixed point, quotient completion representative, host equality of endpoints, countable-choice selector, untracked contraction modulus, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Inspect the carrier. Its only endpoint-facing rows are the contraction row B, modulus row M, orbit seal O, regular readback R, and terminal Real seal E.

Apply the NameCert obligations of Definition 8031.2. Every accepted read remains inside those displayed rows and the structural rows H, C, P, N.

The excluded objects would require additional carrier coordinates or continuation routes. Since none are present, no downstream consumer can recover host selection, quotient completion data, host endpoint equality, choice, an untracked modulus, or ambient RealUp completeness from the packet. □

Falsifiable prediction: An accepted $\mathsf{LipschitzFixedPoint}^{\uparrow}$ read is refuted if a fixed-point endpoint consumer reaches the terminal Real seal without displaying the BanachContraction row, ConstructiveContractionModulus row, CauchyFixedPointOrbitSeal row, RegSeqRat readback, componentwise transport, replay, provenance, and local NameCert row.

Independence witness: banach-contraction, constructive-contraction-modulus, cauchy-fixed-point-orbit-seal, regseqrat, real: none alone is bijective with $\mathsf{LipschitzFixedPoint}^{\uparrow}$ because the packet jointly records contraction admission, finite modulus data, orbit sealing, regular readback, endpoint sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzFixedPoint}^{\uparrow}$ packet is generated from a BanachContraction row, a ConstructiveContractionModulus row, a CauchyFixedPointOrbitSeal row, RegSeqRat readback, a terminal RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8031.1, Definition 8031.2, Definition 8031.3, and Definition 8031.4 seed the finite endpoint certificate over contraction, modulus, orbit seal, regular readback, terminal Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host fixed-point selection, quotient completion equality, host endpoint equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction exposure, modulus accountability, orbit-seal exactness, RegSeqRat readback, endpoint sealing, transport stability, replay stability, provenance, and local naming for BEDC.Derived.LipschitzFixedPointUp.

Chapter 8032

A Concrete Naming Certificate for $\mathsf{RiemannSumModulus}^{\uparrow}$

Following Riemann and Darboux, the $\mathsf{RiemannSumModulus}^{\uparrow}$ packet records the finite refinement-modulus surface that sits between the displayed Riemann sum of chapter 1615, the tagged partition carrier of chapter 7449, and the mesh-bound packet of chapter 7944. Its tolerance rows are read through chapter 291, its regular rational and real-name handoff follows chapter 301 and chapter 38, and its only public promise is a finite modulus for comparing sufficiently refined displayed sums.

Definition 8032.1 (Riemann sum modulus carrier)**.** *A* $\mathsf{RiemannSumModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, R, T, Q, D, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the mesh-budget row, carrying a dyadic mesh bound read through* $\mathsf{RiemannSumMesh}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *R is the refinement-witness row, recording that a displayed tagged partition refines the budget named by M.*
3. *T is the* $\mathsf{TaggedPartition}^{\uparrow}$ *row whose cells, endpoints, and tag-containment data are the only partition data visible to the packet.*
4. *Q is the Riemann-sum comparison row, relating two displayed* $\mathsf{RiemannSum}^{\uparrow}$ *packets only through their common refinement budget and tagged-partition rows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for the displayed comparison bound.*
6. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row, sealing rational readback before any Real-facing consumer reads the comparison.*
7. *H records componentwise* hsame *transport for $M, R, T, Q, D, S, C, P, N$.*
8. *C records displayed* Cont *replay through mesh budgets, refinement witnesses, tagged partitions, Riemann-sum comparisons, dyadic tolerances, and the regular-real handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{RiemannSumModulus}^{\uparrow}$*,* $\mathsf{RiemannSum}^{\uparrow}$*,* $\mathsf{TaggedPartition}^{\uparrow}$*,* $\mathsf{RiemannSumMesh}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSumModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, R, T, Q, D, S, H, C, P, N$. It has no coordinate for host integrability, host limits, quotient equality of functions, selected tag families, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8032.2 (Riemann sum modulus NameCert obligations)**.** *For the carrier of Definition 8032.1, the local* $\mathsf{NameCert}_{\mathsf{RiemannSumModulus}^{\uparrow}}$ *surface consists exactly of mesh-budget exposure, refinement-witness exposure, tagged-partition readback, Riemann-sum comparison, dyadic tolerance readback, RegSeqRat/Real handoff, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming for the same packet*

$$U = (M, R, T, Q, D, S, H, C, P, N).$$

Proof. Project the accepted carrier. The rows $M, R, T, Q, D, S, H, C, P, N$ are exactly the mesh budget, refinement witness, tagged partition, comparison, tolerance, regular-real handoff, transport, replay, provenance, and local naming rows.

Read the supporting packets in order. The budget row points to the finite mesh data of $\mathsf{RiemannSumMesh}^{\uparrow}$, the partition row points to $\mathsf{TaggedPartition}^{\uparrow}$, and the comparison row reads only displayed $\mathsf{RiemannSum}^{\uparrow}$ packets that share the same refinement budget.

The tolerance and handoff rows keep the comparison constructive. The dyadic row D supplies the finite rational bound, while S routes any later Real-facing read through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seals. Since no further coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 8032.3 (Riemann sum modulus refinement stability)**.** *Let $U = (M, R, T, Q, D, S, H, C, P, N)$ be an accepted* $\mathsf{RiemannSumModulus}^{\uparrow}$ *carrier. Any two accepted refinement reads that agree on the mesh-budget row M, the refinement-witness row R, the tagged-partition row T, and the dyadic tolerance row D must export the same Riemann-sum comparison boundary through Q, S, H, C, P, N. The packet therefore stabilizes finite refinement comparison before any consumer asks for a limiting integral.*

Proof. Start with the four controlling rows M, R, T, D. They fix the displayed mesh budget, the finite refinement witness, the tagged partition whose cells and tags are read, and the dyadic tolerance used to compare sums.

The comparison row Q has no independent source of partition or tolerance data. It can compare Riemann sums only by replaying the same mesh, refinement, tagged-partition, and tolerance rows.

Finally transport and replay through H, C, P, N. Componentwise hsame preserves the controlling rows, Cont replays the same finite route, and provenance and local naming add no selected refinement family or limiting process. Hence both reads expose the same comparison boundary. □

Theorem 8032.4 (Riemann sum modulus consumer handoff)**.** *Every Darboux-facing or Riemann-integral-facing consumer of an accepted* $\mathsf{RiemannSumModulus}^{\uparrow}$ *carrier receives only the finite route*

$$\mathsf{RiemannSumMesh}^{\uparrow} \longmapsto \mathsf{TaggedPartition}^{\uparrow} \longmapsto \mathsf{RiemannSum}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as instantiated by $M, R, T, Q, D, S, H, C, P, N$. The handoff supplies a tolerance-indexed refinement comparison for displayed sums, not integrability, host limits, quotient function equality, selected tags, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the mesh and partition side first. The consumer receives the finite budget M, the refinement witness R, and the tagged partition T before any Riemann-sum comparison is visible.

Next read the comparison and tolerance rows. The row Q compares displayed $\mathsf{RiemannSum}^{\uparrow}$ packets only inside the budget fixed by M, R, T, and the row D supplies the dyadic tolerance against which that comparison is checked.

The regular-real handoff is terminal. The row S seals the rational readback before a Real-facing consumer can inspect it, while H, C, P, N preserve the same finite route. Thus the export is a refinement-modulus boundary for sums, not an ambient integral or a choice-selected refinement process. □

Falsifiable prediction: Removing R permits a consumer to compare Riemann sums across unrelated partitions while retaining the same mesh budget; the local classifier must reject such a packet because refinement has no displayed witness.

Independence witness: riemannsum, taggedpartition, riemann-sum-mesh, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{RiemannSumModulus}^{\uparrow}$ because this carrier alone joins mesh budget, refinement witness, tagged-partition readback, sum comparison, dyadic tolerance, regular-real handoff, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSumModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannSumModulus}^{\uparrow}$ packet is generated from a mesh-budget row, refinement-witness row, TaggedPartition row, Riemann-sum comparison row, DyadicRatCore tolerance row, RegSeqRat/Real handoff row, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSumModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8032.1, Definition 8032.2, Definition 8032.3, and Definition 8032.4 seed the finite refinement-modulus handoff for displayed Riemann sums.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSumModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim integrability, host limits, quotient function equality, selected tags, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement-witness stability, Riemann-sum comparison exactness, dyadic tolerance readback, RegSeqRat/Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RiemannSumModulusUp.

Chapter 8033

A Concrete Naming Certificate for $\mathsf{CompactMetricSequentialComplete}^{\uparrow}$

Following Bishop and Bridges on compact metric spaces and Kelley on sequential compactness in metric topology, the $\mathsf{CompactMetricSequentialComplete}^{\uparrow}$ packet records the finite sequential-completeness route that becomes visible when compact-metric finite-net data and Cauchy readback data are carried by the same NameCert surface. It sits beside the compact metric certificate of chapter 129, the complete metric service of chapter 128, the totally bounded finite-net surface of chapter 127, and the Real readback route through $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet is a compact-metric sequential-completeness carrier; it is not an open-cover compactness theorem, a selected infinite subsequence, quotient stream equality, countable choice, host equality of limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8033.1 (Compact-metric sequential-complete carrier)**.** *A* $\mathsf{CompactMetricSequentialComplete}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, T, L, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, carrying the metric compactness interface inspected by the packet.*
2. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row for the displayed tolerances, centers, coverage witnesses, and refinement comparisons.*
3. *L is the* $\mathsf{CompleteMetric}^{\uparrow}$ *Cauchy service row receiving the sequential Cauchy window after the finite-net schedule has stabilized.*
4. *W is the sequential-window ledger recording finite source windows, tail indices, and Cauchy-readiness evidence for the displayed sequence.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tail bounds and distance comparisons used by T, W, L.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the readback row and complete-metric service row have been displayed.*
7. *H records componentwise* hsame *transport for the compact metric source, finite-net row, complete-service row, sequential windows, readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a compact-metric sequential request through $K, T, W, R, L, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricSequentialComplete}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricSequentialComplete}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, T, L, W, R, E, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subsequences, quotient Cauchy-name equality, countable choice, host real equality, or detached ambient completeness.

Theorem 8033.2 (Compact-metric sequential-complete obligations)**.** *For every accepted* CompactMetricSequential *carrier*

$$S = (K, T, L, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactMetricSequentialComplete}^{\uparrow}}$ *surface consists exactly of compact metric source admission through K, finite-net accountability through T, sequential Cauchy-window admission through W, rational tail readback through R, complete-metric service through L, terminal Real sealing through E, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 8033.1. The accepted packet exposes exactly the compact metric, finite-net, complete-service, sequential-window, readback, seal, transport, replay, provenance, and local naming rows.

Read the compact metric side first. The source row K supplies only the compact-metric interface, while T supplies the finite-net schedule and coverage rows used to force Cauchy windows at displayed tolerances.

Next read the sequential side. The row W records the finite tail windows and Cauchy-readiness evidence consumed by R; it does not store a selected infinite subsequence or a quotient stream equality.

Finally use R, L, E, H, C, P, N. Rational readback is passed to the complete-metric service row before the terminal Real seal is available, and transport and replay preserve the same displayed route. Since no excluded coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8033.3 (Compact-metric sequential-complete readback route)**.** *Every sequential-completeness consumer of an accepted* $\mathsf{CompactMetricSequentialComplete}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg},$$

Thus Cauchy-readback and finite-net obligations are displayed before any terminal Real seal is consumed. The route exports no open-cover compactness theorem, selected subsequence, quotient Cauchy-name equality, countable-choice schedule, host limit equality, or detached ambient completeness principle.

Proof. Start from the NameCert obligations of Definition 8033.2. They place every accepted sequential-completeness request on the same compact metric source row, finite-net row, sequential-window row, readback row, complete-service row, and terminal seal.

The finite-net and Cauchy-readback rows are adjacent but not collapsed. The row T accounts for displayed centers and covers; the row R accounts for rational tail comparisons; the row L consumes those comparisons as complete-metric service.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Therefore the consumer reaches $\mathsf{Real}^{\uparrow}$ only through the displayed finite packet, and the excluded open-cover,

selected-subsequence, quotient, choice, host-equality, and ambient-completeness coordinates are unavailable. □

Theorem 8033.4 (Compact-metric sequential-complete net handoff)**.** *Every accepted* CompactMetricSequentialCor *consumer that reads a sequential-net route must first pass through the sibling* CompactMetricSequentialNet$^{\uparrow}$ *finite-net extraction surface of chapter 4019. Only then may it read the compact metric source row K, total-bounded finite-net row T, sequential-window row W,* RegSeqRat$^{\uparrow}$ *readback row R,* CompleteMetric$^{\uparrow}$ *service row L, terminal* Real$^{\uparrow}$ *seal E, and structural rows H, C, P, N. The handoff exports no open-cover compactness theorem, selected infinite subsequence, quotient stream equality, countable-choice schedule, host limit equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with Definition 8033.2. It exposes the compact metric source, finite-net, sequential-window, readback, complete-service, Real seal, and structural rows as the whole accepted packet.

Apply the readback route of Definition 8033.3. This places every sequential-completeness consumer on the route from CompactMetric$^{\uparrow}$ through TotallyBounded$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CompleteMetric$^{\uparrow}$, and Real$^{\uparrow}$ before the structural rows are public.

Now read the sibling route through chapter 4019. The subsequence handoff of Definition 4019.3 supplies the finite-net extraction surface, so the sequential-complete packet can consume the net route only after that sibling surface is displayed.

The structural rows H, C, P, N preserve the same finite handoff. Since neither packet contains a coordinate for open-cover compactness, selected infinite subsequences, quotient stream equality, countable choice, host limit equality, or ambient Real completeness, the consumer receives only the displayed sequential-net route. □

Falsifiable prediction: An accepted CompactMetricSequentialComplete$^{\uparrow}$ read is refuted if a sequential-completeness consumer reaches the terminal Real seal without displaying the CompactMetric source row, TotallyBounded finite-net row, RegSeqRat readback row, CompleteMetric service row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: compactmetric, completemetric, totallybounded, regseqrat, real: none alone is bijective with CompactMetricSequentialComplete$^{\uparrow}$ because this packet jointly carries compact-metric source data, finite-net accountability, sequential Cauchy windows, rational readback, complete-metric service, terminal Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for NameCert$_{\text{CompactMetricSequentialComplete}^{\uparrow}}$**.**

Constructive story: A CompactMetricSequentialComplete$^{\uparrow}$ packet is generated from a CompactMetricUp source row, a TotallyBoundedUp finite-net row, a CompleteMetricUp service row, sequential Cauchy windows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactMetricSequentialComplete}^{\uparrow}}$, seed)

Scope closed: Definition 8033.1, Definition 8033.2, and Definition 8033.3 seed the compact-metric sequential-completeness route over finite-net and Cauchy-readback obligations.

Formal verification: FormalStatus(NameCert$_{\text{CompactMetricSequentialComplete}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected infinite subsequences, quotient Cauchy-name equality, countable choice, host equality of limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net accountability, sequential-window admission, RegSeqRat readback, CompleteMetric service, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactMetricSequentialCompleteUp.

Chapter 8034

A Concrete Naming Certificate for $\mathsf{LocalObservationDigestGate}^{\uparrow}$

Following standard hash and provenance interface discipline, the $\mathsf{LocalObservationDigestGate}^{\uparrow}$ packet realizes the local boundary question family of Definition 9402.35 as finite NameCert data. It sits beside the digest provenance packet of chapter 1062, the hash-like boundary gate of chapter 1359, and the observation-fiber digest surface of chapter 1357. The packet is local: it records a visible token, source fiber, GAP provenance, exactness status, far-end status, and hidden-source refusal as rows of one carrier, while refusing any global hash, hidden source oracle, object-level T value, or digest equality as source equality.

Definition 8034.1 (Local observation digest gate carrier)**.** *A* $\mathsf{LocalObservationDigestGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, F, Q, E, A, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the visible local digest token row exposed to observation consumers.*
2. *F is the source-fiber row that names the local observation fiber to which V belongs.*
3. *Q is the GAP provenance row recording the visible source route and the refused hidden-source route.*
4. *E is the exactness-status row stating whether the visible token is allowed to support a local exactness claim.*
5. *A is the apophatic far-end status row recording the boundary side of the observation.*
6. *R is the hidden-source refusal row preventing digest equality from becoming source equality.*
7. *H records componentwise* hsame *transport for the visible token, fiber, GAP provenance, exactness status, far-end status, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a local observation request through $V, F, Q, E, A, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{LocalObservationDigestGate}^{\uparrow}$, $\mathsf{DigestProvenancePacket}^{\uparrow}$, $\mathsf{HashLikeBoundaryGate}^{\uparrow}$, $\mathsf{ObservationFiberDigest}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocalObservationDigestGate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, F, Q, E, A, R, H, C, P, N$. It has no coordinate for a global hash of the universe, hidden source recovery, object-level T*, quotient source equality, host collision semantics, theorem-input parameters, or detached certificate names.*

Theorem 8034.2 (Local observation digest gate obligations)**.** *For every accepted* $\mathsf{LocalObservationDigestGate}^{\uparrow}$ *carrier*

$$G = (V, F, Q, E, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocalObservationDigestGate}^{\uparrow}}$ *surface consists exactly of visible token admission through V, source-fiber admission through F, GAP provenance through Q, exactness status through E, apophatic far-end status through A, hidden-source refusal through R, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier of Definition 8034.1. The accepted packet exposes exactly the visible token, source fiber, GAP provenance, exactness status, far-end status, hidden-source refusal, transport, replay, provenance, and local naming rows.

Read the digest side through V, F, Q, E. A consumer may use the visible token only together with the displayed fiber, the GAP provenance route, and the exactness-status row.

Read the refusal side through A, R. The far-end status and hidden-source refusal rows block any conversion of digest equality into source equality or hidden source recovery.

Finally H, C, P, N preserve, replay, source, and name the same local packet. Since no global hash, object-level T value, quotient equality, host collision row, theorem-input parameter, or detached certificate name occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 8034.3 (Local observation digest gate boundary nonescape)**.** *Every accepted* $\mathsf{LocalObservationDigestGate}$ *consumer factors through the finite route*

$$\mathsf{DigestProvenancePacket}^{\uparrow} \longmapsto \mathsf{HashLikeBoundaryGate}^{\uparrow} \longmapsto V, F, Q, E, A, R \longmapsto \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The route supplies visible token, source fiber, GAP provenance, exactness status, far-end status, hidden-source refusal, transport, replay, provenance, and local naming. It supplies no global hash, hidden-source oracle, object-level T *value, quotient source equality, host collision semantics, or detached theorem input.*

Proof. Start from Definition 8034.2. They require every consumer-visible digest read to pass through the displayed token, fiber, GAP provenance, exactness, far-end, refusal, and structural rows.

The sibling $\mathsf{DigestProvenancePacket}^{\uparrow}$ route supplies the provenance discipline for visible digest tokens, while the sibling $\mathsf{HashLikeBoundaryGate}^{\uparrow}$ route supplies the boundary audit questions. This packet binds both to the same local observation rows V, F, Q, E, A, R.

The transport, replay, provenance, and naming rows H, C, P, N keep the route local. Therefore a consumer cannot leave the displayed packet to recover a hidden source, introduce a global hash, treat T as an object-level digest value, or use digest equality as source equality. □

Falsifiable prediction: An accepted $\mathsf{LocalObservationDigestGate}^{\uparrow}$ consumer is refuted if it uses a visible digest token without displaying the source fiber, GAP provenance, exactness status, apophatic far-end status, hidden-source refusal, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: digestprovenancepacket, hashlikeboundarygate, observationfiberdigest: none alone is bijective with $\mathsf{LocalObservationDigestGate}^{\uparrow}$ because this packet jointly binds the

visible token, source fiber, GAP provenance, exactness status, far-end status, hidden-source refusal, transport, replay, provenance, and local NameCert rows as one local gate.

Closure status for $\mathsf{NameCert}_{\mathsf{LocalObservationDigestGate}^{\uparrow}}$.

Constructive story: A $\mathsf{LocalObservationDigestGate}^{\uparrow}$ packet is generated from a visible token row, source-fiber row, GAP provenance row, exactness-status row, apophatic far-end status row, hidden-source refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocalObservationDigestGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8034.1, Definition 8034.2, and Definition 8034.3 seed the local observation digest boundary over visible token, source-fiber, GAP, exactness, far-end, and refusal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocalObservationDigestGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global hash semantics, hidden-source recovery, object-level T, quotient source equality, host collision semantics, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, visible-token admission, source-fiber admission, GAP provenance, exactness status, far-end status, hidden-source refusal, transport, replay, provenance, and local naming for BEDC.Derived.LocalObservationDigestGateUp.

Chapter 8035

A Concrete Naming Certificate for $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ packet records the finite cluster-window route by which regular Cauchy real names are grouped before a Real or Completion consumer reads a seal. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the Bishop regular Cauchy completion boundary of chapter 1639. The packet supplies a finite cluster ledger only; it does not import quotient representatives, selected limits, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8035.1 (Finite real Cauchy cluster carrier)**.** *A* $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row. It records the inspected stream names, finite index windows, and observation cells available to the cluster route.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It exposes only the rational observations scheduled by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the finite dyadic radius, comparison slack, and arithmetic budget used to compare the readbacks.*
4. *L is the cluster-window ledger. It records the accepted cluster cells, their finite membership evidence, the dyadic comparison used for each cell, and the finite overlap checks between cells.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row. It records the terminal real-facing seals that may be read after S, R, D, L have been displayed.*
6. *H records componentwise* hsame *transport for the stream windows, regular rational readbacks, dyadic tolerances, cluster ledger, Real seals, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$S, R, D \longmapsto L \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{FiniteRealCauchyCluster}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, L, E, H, C, P, N$. It has no coordinate for quotient representatives, selected limits, countable choice, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8035.2 (Finite real Cauchy cluster obligations)**.** *For every accepted* $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ *carrier*

$$K = (S, R, D, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRealCauchyCluster}^{\uparrow}}$ *surface consists exactly of the following five finite obligations:*

1. *carrier admission for the stream-window, regular-readback, dyadic-tolerance, cluster-ledger, Real-seal, transport, replay, provenance, and local naming rows;*
2. *finite window coverage, requiring every cluster cell in L to cite only windows displayed by S and readbacks displayed by R;*
3. *cluster ledger exactness, requiring each membership, overlap, and separation comparison in L to be checked against the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D;*
4. *Real-seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *seal in E to be reachable only after the finite route S, R, D, L has been displayed;*
5. *transport stability, requiring componentwise* hsame *transport through H and displayed* Cont *replay through C to preserve the same cluster-window route, with provenance and local naming exhausted by P, N.*

No obligation is stored outside these rows.

Proof. Project the accepted carrier $K = (S, R, D, L, E, H, C, P, N)$. The source rows are S for finite stream windows, R for regular rational readback, and D for dyadic tolerance data.

Finite window coverage follows because the cluster ledger L has no observation coordinate of its own. Each listed cluster cell must cite an inspected window from S and a readback from R before it can be accepted.

Ledger exactness follows from the placement of D. The membership, overlap, and separation entries in L are compared only against the displayed dyadic tolerance row, so a cluster claim cannot switch to a host metric or hidden real representative.

The Real-seal row E is downstream of L. Hence a Real or Completion consumer reaches E only after the finite stream, readback, tolerance, and cluster-ledger rows have already been displayed.

Finally, H and C transport and replay the same route, while P, N source and name the packet. Since the carrier contains no excluded coordinate, the five obligations exhaust the local NameCert surface. □

Falsifiable prediction: A $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ read is refuted whenever a Real or Completion consumer reaches a cluster seal without displaying the finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance row, cluster-window ledger, componentwise transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, bishop-regular-cauchy-completion: none alone is bijective with $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ because the packet jointly records finite stream windows, regular rational readbacks, dyadic tolerances, cluster cells, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealCauchyCluster}^{\uparrow}}$.

Constructive story: A FiniteRealCauchyCluster$^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerances, a cluster-window ledger, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteRealCauchyCluster}\uparrow}$, seed)

Scope closed: Definition 8035.1 and Definition 8035.2 seed the finite cluster-window route over displayed StreamName, RegSeqRat, DyadicRatCore, Real, Bishop regular Cauchy completion, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{FiniteRealCauchyCluster}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.FiniteRealCauchyClusterUp`

Bridge status: none

Not claimed: This chapter does not close quotient representatives, selected limits, countable choice, host completeness, ambient Real$^{\uparrow}$ completeness, Lean proof obligations, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite window coverage, cluster ledger exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRealCauchyClusterUp.

Chapter 8036

A Concrete Naming Certificate for $\mathsf{OdeComparison}^{\uparrow}$

Following Walter or Hartman on ODE comparison principles, the $\mathsf{OdeComparison}^{\uparrow}$ packet records the finite BEDC surface by which two displayed ODE rows, one shared interval window, and one monotonicity or majorant ledger can be read before a downstream comparison consumer reaches a scalar bound. It sits after the ODE source of chapter 193, the Gronwall handoff of chapter 2034, the zero-order comparison route of chapter 2338, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names comparison data as displayed rows only; it is not a host solution theorem, a selected flow, a quotient path equality, or an ambient completeness principle.

Definition 8036.1 (ODE comparison carrier)**.** *An* $\mathsf{OdeComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D_0, D_1, I, L, M, G, S, R, E, H, C, P, N)$$

whose rows have the following roles.

1. *D_0 and D_1 are displayed* $\mathsf{Ode}^{\uparrow}$ *source rows carrying the two differential data packets that will be compared.*
2. *I is the shared interval or window row over which both ODE source rows are read.*
3. *L is the located-order or monotonicity ledger for the comparison request, and M is the comparison majorant row.*
4. *G is the* $\mathsf{GronwallInequality}^{\uparrow}$ *handoff used when the comparison is controlled by an integral or differential majorant.*
5. *S is the* $\mathsf{SturmComparison}^{\uparrow}$ *handoff used when the request is a zero-order or oscillation-window comparison.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite comparison windows, and E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
7. *H, C, P, and N are the componentwise* hsame *transport row, displayed* Cont *replay row,* Pkg *provenance row, and local* $\mathsf{NameCert}_{\mathsf{OdeComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed tuple $D_0, D_1, I, L, M, G, S, R, E, H, C, P, N$. It has no coordinate for host solution equality, selected flows, quotient paths, trichotomy, global existence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.OdeComparisonUp.OdeComparisonTasteGate single carrier alignment`

Theorem 8036.2 (ODE comparison NameCert obligations)**.** *For every accepted* $\mathsf{OdeComparison}^{\uparrow}$ *carrier* $O = (D_0, D_1, I, L, M, G, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OdeComparison}^{\uparrow}}$ *surface consists exactly of carrier admission; two ODE source exposures through* D_0, D_1*; shared interval exposure through* I*; monotonicity or majorant exactness through* L, M*; Gronwall and Sturm handoff exactness through* G, S*; regular rational readback through* R*; real-name sealing through* E*; componentwise transport through* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Project the carrier tuple of Definition 8036.1. Each listed obligation is one coordinate of the finite packet or the local naming row attached to that coordinate.

The two ODE source obligations are exactly the projections D_0 and D_1, and the common-domain obligation is the projection I. The comparison ledger is exhausted by L and M, so no additional monotonicity or majorant witness remains outside the displayed rows.

The downstream handoff rows are G for Gronwall-style comparison and S for Sturm-style zero-order comparison. Readback and terminal sealing are then forced through R and E.

Finally H, C, P, N transport, replay, package, and name the same displayed tuple. Coordinate exhaustion leaves no host solution equality, selected flow, quotient path, trichotomy, global existence, or ambient real-completeness coordinate to export. □

Theorem 8036.3 (ODE comparison Gronwall and Sturm handoff)**.** *Every downstream local-flow or zero-window comparison consumer of an accepted* $\mathsf{OdeComparison}^{\uparrow}$ *packet must first read the displayed* $\mathsf{Ode}^{\uparrow}$ *source rows* D_0, D_1*, the shared interval row* I*, the* $\mathsf{GronwallInequality}^{\uparrow}$ *or* $\mathsf{SturmComparison}^{\uparrow}$ *handoff row, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger underlying the displayed comparison windows, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The consumer receives only the finite comparison route*

$$D_0, D_1, I, L, M, G, S, R, E, H, C, P, N$$

and no host solution equality, global existence theorem, selected flow, quotient path, trichotomy split, or ambient real-completeness principle.

Proof. Begin with the carrier projection of Definition 8036.1. The source rows D_0, D_1 and the shared window row I are the only places where the comparison request can read ODE and interval data.

For a local-flow comparison, the consumer reads the majorant ledger M through the Gronwall row G. For a zero-window comparison, it reads the order or oscillation ledger L through the Sturm row S. In both cases the finite windows then pass through the dyadic tolerance ledger, the regular rational readback row R, and the terminal Real seal E.

The rows H, C, P, N preserve the same packet by componentwise transport, displayed replay, provenance, and local naming. Since the packet has no coordinate for host solution equality, global existence, selected flows, quotient paths, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no downstream comparison consumer can read such data from this handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{OdeComparison}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OdeComparison}^{\uparrow}$ packet is generated from two displayed Ode source rows, one shared interval row, a located-order or majorant ledger, Gronwall or Sturm handoff rows, regular rational readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OdeComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8036.1, Definition 8036.2, and Definition 8036.3 bind the finite ODE comparison carrier, its local obligation surface, and the displayed Gronwall or Sturm handoff route.

Formal verification: FormalStatus(NameCert$_{\mathsf{OdeComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host solution equality, global existence, selected flows, quotient paths, trichotomy, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Formalization requires a Lean carrier and checked NameCert obligations for the displayed ODE source, comparison ledger, Gronwall or Sturm handoff, readback, sealing, transport, replay, provenance, and naming rows.

Chapter 8037

A Concrete Naming Certificate for $\mathsf{CauchyRateSpace}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyRateSpace}^{\uparrow}$ packet records the explicit rate ledger carried by a regular Cauchy presentation before any terminal real-name seal is read. It sits between the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance core of chapter 291, and the terminal real-name boundary of chapter 38. The packet is a finite rate substrate for L10 Real and Completion consumers, not a quotient stream, a selected limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8037.1 (Cauchy rate space carrier)**.** *A* $\mathsf{CauchyRateSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (L, W, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the rate ledger, storing the unary precision schedule and the finite tail thresholds licensed for each requested tolerance.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes only the inspected stream windows needed by the ledger.*
3. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that converts the displayed windows into regular rational observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-comparison row used to compare the requested precision with the displayed tail budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after L, W, S, D have been displayed.*
6. *H stores componentwise* hsame *transport for the rate ledger, stream windows, regular readback, dyadic comparisons, Real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from a Real-facing Cauchy-rate query through L, W, S, D, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyRateSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRateSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows and their structural provenance.

Theorem 8037.2 (CauchyRateSpace NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRateSpace}^{\uparrow}$ *carrier* $R = (L, W, S, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRateSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, classifier stability through* L, W, S, D, E*, rate-ledger exposure through* L*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*. A consumer may read a Real-facing Cauchy rate only after the rate ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparison, and terminal Real seal rows are displayed.*

Proof. Project the carrier of Definition 8037.1. Its analytic rows are exactly the rate ledger, stream windows, regular rational readback, dyadic tolerance comparison, and terminal Real seal.

The classifier-stability and ledger clauses read those rows in the displayed order. The structural rows then transport, replay, source, and name the same finite packet through H, C, P, N.

Since no coordinate stores a quotient stream, selected limit, countable-choice schedule, host real equality, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 8037.3 (CauchyRateSpace regularization handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyRateSpace}^{\uparrow}$ *carrier must first read the displayed route*

$$L \longmapsto W \longmapsto S \longmapsto D \longmapsto E.$$

Thus the rate ledger and $\mathsf{StreamName}^{\uparrow}$ *windows are visible before any regular-rational readback or terminal Real seal is consumed. The handoff exports no quotient stream equality, selected representative, countable-choice rate selector, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a consumer request for either the regular rational readback or the terminal Real seal. The carrier has a single readback row S and a single seal row E, and both are downstream of the rate ledger, stream windows, and dyadic comparison.

The continuation row C replays the route through L, W, S, D, E, while H preserves the same rows under componentwise transport. The provenance row P and local name N identify the route as the $\mathsf{CauchyRateSpace}^{\uparrow}$ packet.

The excluded objects would require extra carrier coordinates. Because the packet contains only finite BEDC rows and their structural provenance, no consumer can bypass the ledger and window rows to obtain a quotient stream, selected limit, choice-selected rate, host equality, or ambient completion principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRateSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyRateSpace}^{\uparrow}$ packet is generated from a finite rate ledger, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparisons, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyRateSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8037.1, Definition 8037.2, and Definition 8037.3 name the finite Cauchy-rate substrate used before regular-rational and Real-facing reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyRateSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable-choice rate selectors, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, rate-ledger exposure, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRateSpaceUp.

Chapter 8038

A Concrete Naming Certificate for $\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}$

Following Bishop–Bridges compact metric analysis, the $\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}$ packet records the finite center-indexed radius chain that lies between local pointwise moduli and the rational lower-bound fold in the compact-uniform-continuity route of chapter 9237. It consumes compact metric source rows from chapter 129, pointwise-modulus rows from chapter 130, finite lower-bound folding from chapter 619, and the metric-triangle handoff of chapter 1159. The packet names a finite radius-chain surface before a $\mathsf{UniformModulus}^{\uparrow}$ consumer reads the global handoff; it is not open-cover compactness, a selected Lebesgue number, countable choice, or ambient completeness.

Definition 8038.1 (CompactUniformPointwiseRadiusChain carrier)**.** *A* $\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (K, F, A, L, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row exposing the finite-net centers and their metric coverage data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row attached to the displayed centers.*
3. *A is the center-indexed radius-chain row that records, for each displayed center, the local radius budget and its successor comparison.*
4. *L is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold boundary consumed by the finite-net minimum fold.*
5. *T is the* $\mathsf{MetricTriangleUniformEstimate}^{\uparrow}$ *handoff row that turns centerwise estimates into the uniform comparison route.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *export row reached only after K, F, A, L, T have been displayed.*
7. *H stores componentwise* hsame *transport for the compact source, pointwise modulus, radius chain, lower-bound fold, triangle estimate, uniform export, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a compact-uniform query through K, F, A, L, T, U, H.*

9. *P is the* Pkg *provenance over* CompactUniformPointwiseRadiusChain$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, FiniteNetMinimumFold$^{\uparrow}$, MetricTriangleUniformEstimate$^{\uparrow}$, UniformModulus$^{\uparrow}$, Rat$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows, their transports, continuation replay, package provenance, and local naming.

Theorem 8038.2 (CompactUniformPointwiseRadiusChain obligations)**.** *For every accepted* CompactUniformPoint *carrier $R = (K, F, A, L, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-source exposure through K, pointwise-modulus exposure through F, center-indexed radius-chain exposure through A, rational lower-bound fold boundary through L, metric-triangle handoff through T, uniform-modulus export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8038.1. The compact source, pointwise-modulus rows, radius chain, lower-bound fold, triangle estimate, and uniform export are the only analytic rows visible to a consumer.

Read the compact-uniform route in the displayed order. The compact source row K supplies the finite centers, the pointwise-modulus row F supplies local bounds at those centers, the radius-chain row A records the centerwise budgets, the fold boundary L exposes their rational lower bound, and the triangle handoff T produces the uniform-modulus export U.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Because no coordinate stores open-cover compactness, a selected Lebesgue number, countable choice, quotient equality, or ambient completeness, the listed rows exhaust the NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}}$.

Constructive story: A CompactUniformPointwiseRadiusChain$^{\uparrow}$ packet is generated from compact metric source rows, continuous-map pointwise-modulus rows, center-indexed radius-chain rows, a RatUp lower-bound fold boundary, a MetricTriangleUniformEstimate handoff, a UniformModulus export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}}$, seed)

Scope closed: Definition 8038.1 and Definition 8038.2 name the finite radius-chain packet between local moduli and the global compact-uniform modulus handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactUniformPointwiseRadiusChain}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, countable choice, quotient equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, pointwise-modulus exposure, radius-chain exposure, rational fold boundary, triangle handoff, uniform export, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformPointwiseRadiusChainUp.

Chapter 8039

A Concrete Naming Certificate for $\mathsf{ChristoffelFunction}^{\uparrow}$

Following Szego and the finite orthogonal-polynomial formulation of Gaussian quadrature, the $\mathsf{ChristoffelFunction}^{\uparrow}$ packet records the reciprocal diagonal kernel row used to control polynomial evaluation from displayed orthogonal-polynomial data. It sits after the recurrence and moment ledgers of chapter 2264, the node-weight rule of chapter 7017, the coefficient source of chapter 50, the terminal scalar seal of chapter 38, and the dyadic comparison route of chapter 291. The packet names only finite kernel, denominator, tolerance, and replay rows; it does not claim measure-theoretic completeness, spectral completeness, selected roots, quotient polynomial equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8039.1 (Christoffel function carrier)**.** *A* $\mathsf{ChristoffelFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, Q, P, X, D, L, E, H, C, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{OrthogonalPolynomial}^{\uparrow}$ *source row, displaying the finite orthogonal-polynomial window, normalization ledger, recurrence coefficients, and moment reads used by the kernel.*
2. *Q is the* $\mathsf{GaussQuadrature}^{\uparrow}$ *source row, exposing the finite node-weight rule through which quadrature-facing consumers read Christoffel weights and diagonal kernel values.*
3. *P is the* $\mathsf{Poly}^{\uparrow}$ *coefficient row for the polynomial family and for the finite products inspected by the diagonal kernel.*
4. *X is the evaluation-window row. It lists the displayed real-name evaluation points and the finite polynomial rows inspected at those points.*
5. *D is the diagonal denominator ledger, displaying the finite sum of normalized square evaluations or the equivalent reciprocal-weight row attached to the same orthogonal-polynomial window.*
6. *L is the local Christoffel-value row. It records the displayed reciprocal read of D as a* $\mathsf{Real}^{\uparrow}$*-sealed scalar whenever the denominator row is admitted.*
7. *E is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison row for denominator positivity, reciprocal tolerance, and node-weight comparison.*
8. *H stores componentwise* hsame *transport for O, Q, P, X, D, L, E and the local naming data.*

9. *C stores displayed* Cont *replay from orthogonal-polynomial source rows through evaluation, denominator formation, reciprocal readback, quadrature handoff, dyadic comparison, provenance, and local naming.*

10. *N is the combined* Pkg *provenance and local* $\mathsf{NameCert}_{\mathsf{ChristoffelFunction}^\uparrow}$ *row over* $\mathsf{ChristoffelFunction}^\uparrow$, $\mathsf{OrthogonalPolynomial}^\uparrow$, $\mathsf{GaussQuadrature}^\uparrow$, $\mathsf{Poly}^\uparrow$, $\mathsf{Real}^\uparrow$, $\mathsf{DyadicRatCore}^\uparrow$, BHist, hsame, Cont, Pkg, *and* NameCert.

The classifier compares accepted packets only through $O, Q, P, X, D, L, E, H, C, N$. It has no coordinate for a host measure space, an infinite orthogonal expansion, a spectral-completeness theorem, quotient polynomial equality, selected quadrature nodes outside Q, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8039.2 (Christoffel function NameCert obligations)**.** *For every accepted* $\mathsf{ChristoffelFunction}^\uparrow$ *carrier*

$$K = (O, Q, P, X, D, L, E, H, C, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChristoffelFunction}^\uparrow}$ *surface consists exactly of the following five obligation rows:*

1. *source admission: the orthogonal-polynomial row O, quadrature row Q, and polynomial coefficient row P must be displayed before a Christoffel read is available;*

2. *evaluation admission: the point row X must name the finite evaluation windows and the polynomial rows inspected at those points;*

3. *denominator exactness: the row D must display the finite diagonal-kernel denominator or the equivalent reciprocal-weight row over the same source window;*

4. *reciprocal and comparison exposure: the row L must be read only after D, and the dyadic comparison row E must carry the displayed positivity, reciprocal tolerance, and node-weight comparisons;*

5. *preservation and naming: the transport, replay, provenance, and local naming rows H, C, N must preserve exactly O, Q, P, X, D, L, E and must not add a host measure space, spectral-completeness theorem, selected root solver, quotient polynomial equality, or ambient real-completeness principle.*

No Christoffel-function obligation is stored outside these rows.

Proof. Project the carrier of Definition 8039.1. The source rows are O, Q, P, so the packet starts from an already displayed orthogonal-polynomial window, quadrature rule, and polynomial coefficient ledger.

The evaluation and denominator rows are then finite. The row X lists the inspected evaluation points and polynomial rows, while D records the diagonal denominator or reciprocal-weight expression over the same displayed source window.

The reciprocal read is local to L and the comparison data are local to E. These rows expose only the admitted denominator, tolerance, and node-weight comparisons; they do not select roots or import an analytic measure object.

Finally, H, C, N transport, replay, source, and name the same finite rows. Since the carrier has no coordinate for measure-theoretic completeness, spectral completeness, quotient polynomial equality, selected roots outside the quadrature row, or ambient $\mathsf{Real}^\uparrow$ completeness, the five listed rows exhaust the NameCert surface. □

Theorem 8039.3 (Christoffel function quadrature handoff)**.** *Every quadrature-facing read of an accepted* $\mathsf{ChristoffelFunction}^\uparrow$ *packet factors through the finite route*

$$\mathsf{OrthogonalPolynomial}^\uparrow \longmapsto \mathsf{GaussQuadrature}^\uparrow \longmapsto X \longmapsto D \longmapsto L.$$

The consumer receives the displayed source rows, evaluation windows, diagonal denominator, reciprocal scalar, dyadic comparison row, transport, replay, provenance, and local name, but receives no measure-theoretic completeness, spectral completeness, quotient polynomial equality, selected root solver, undisplayed node family, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an integration- or quadrature-facing read. The packet first exposes the orthogonal-polynomial source O and the Gauss-quadrature source Q, so the consumer reads the Christoffel data only after the recurrence, moment, node, and weight ledgers are already visible.

Next inspect the evaluation and denominator rows. The row X fixes the displayed evaluation window, and D forms the finite diagonal-kernel denominator over that same window.

The local value row L records the reciprocal read, and E supplies the dyadic comparison data needed to inspect positivity and reciprocal tolerance. The rows H, C, N preserve and name this route without adding any further analytic principle. Hence every quadrature-facing read remains inside the displayed finite handoff. □

Falsifiable prediction: Every $\mathsf{ChristoffelFunction}^{\uparrow}$ read factors through an $\mathsf{OrthogonalPolynomial}^{\uparrow}$ source row, a $\mathsf{GaussQuadrature}^{\uparrow}$ node-weight row, a $\mathsf{Poly}^{\uparrow}$ coefficient row, a finite evaluation window, a diagonal denominator ledger, a reciprocal $\mathsf{Real}^{\uparrow}$ value row, dyadic comparison data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: orthogonal-polynomial, gauss-quadrature, polynomial, real, dyadicratcore: $\mathsf{ChristoffelFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the orthogonal-polynomial source, quadrature source, evaluation window, diagonal denominator, reciprocal value, dyadic comparison, transport, replay, provenance, and local naming rows as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ChristoffelFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{ChristoffelFunction}^{\uparrow}$ packet is generated from an OrthogonalPolynomialUp source row, a GaussQuadratureUp node-weight source row, a PolynomialUp coefficient row, a finite evaluation window, a diagonal denominator ledger, a reciprocal RealUp value row, DyadicRatCoreUp comparison data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ChristoffelFunction}^{\uparrow}}$, seed)

Scope closed: Definition 8039.1, Definition 8039.2, and Definition 8039.3 seed the finite Christoffel-function certificate over displayed orthogonal-polynomial, quadrature, polynomial, real-scalar, and dyadic comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ChristoffelFunction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure-theoretic completeness, spectral completeness, quotient polynomial equality, selected root solvers, infinite orthogonal expansions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source admission, evaluation-window admission, denominator exactness, reciprocal readback, quadrature handoff, dyadic comparison replay, transport, non-escape, and field faithfulness for BEDC.Derived.ChristoffelFunctionUp.

Chapter 8040

A Concrete Naming Certificate for $\mathsf{CauchyNetCriterion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria and Moore–Smith directed convergence, the $\mathsf{CauchyNetCriterion}^{\uparrow}$ packet records the finite route by which directed Cauchy-net data becomes usable by the L10 regular-sequence and filter-basis machinery. It sits between the Cauchy-filter surface of chapter 333, the real-uniformity rows of chapter 1624, the stream-window naming of chapter 126, the regular rational readback of chapter 301, the public real seal of chapter 38, and the completion handoff of chapter 1506. The chapter names only the displayed directed-tail criterion and its two finite handoffs; it does not provide quotient equality of nets, selected cofinal sequences, countable choice, or an ambient completion principle.

Definition 8040.1 (CauchyNetCriterion carrier)**.** *A* $\mathsf{CauchyNetCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, A, U, T, F, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the directed-index row naming the finite preorder comparisons, upper-window witnesses, and tail requests inspected by the criterion.*
2. *A is the net-value row, exposing the finite values whose common-tail comparisons are read by downstream consumers.*
3. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage row, displaying the uniform tolerance requests used to compare late net values.*
4. *T is the Cauchy-tail ledger, recording the displayed common-tail witnesses for each requested entourage in U.*
5. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *basis row obtained from the directed tails and their common-window evidence.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row extracted from finite directed tails without choosing a global cofinal sequence.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached from D, A, U, T, S.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after regular-rational readback has been displayed.*
9. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *handoff row that lets completion-facing consumers read the same Cauchy evidence as a completion criterion.*

10. *H records componentwise* hsame *transport for directed indices, net values, uniformity rows, Cauchy-tail ledgers, filter bases, stream windows, regular readback, real seals, completion handoffs, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay through the directed-tail, filter-basis, regular-sequence, real-seal, and completion routes.*
12. *P is the* Pkg *provenance over* $\mathsf{CauchyNetCriterion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, MetricCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyNetCriterion}^{\uparrow}}$ *row.*

The classifier accepts only packets whose criterion consumer first displays $D, A, U, T, F, S, R, E, M, H, C, P, N$. It has no coordinate for a selected cofinal sequence, quotient-net equality, countable choice, host completion, or ambient completeness.

Theorem 8040.2 (CauchyNetCriterion NameCert obligations)**.** *For every accepted* $\mathsf{CauchyNetCriterion}^{\uparrow}$ *carrier*

$$Q = (D, A, U, T, F, S, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyNetCriterion}^{\uparrow}}$ *surface consists exactly of directed-index admission, net-value exposure,* $\mathsf{RealUniformStructure}^{\uparrow}$ *entourage exposure, Cauchy-tail ledger exposure,* $\mathsf{CauchyFilter}^{\uparrow}$ *basis handoff,* $\mathsf{StreamName}^{\uparrow}$ *window readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal readback,* MetricCompletion$^{\uparrow}$ *completion handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of Q.*

Proof. Project the carrier of Definition 8040.1. The directed analytic data are exactly D, A, U, T: indices, values, entourages, and common-tail witnesses.

The filter-basis row F is read only after those directed rows have been displayed. It records the finite basis generated by tails and common-window evidence, not a quotient of nets or a completed limit object.

The sequence-facing rows S, R, E are then reached in order. Stream windows are extracted from displayed finite tails, the regular-rational handoff repacks those windows, and the real seal is read only after the regular row is present.

The completion-facing row M reads the same Cauchy evidence. The structural rows H, C, P, N transport, replay, source, and name the displayed route, so no hidden cofinal selector, quotient equality, choice principle, host completion, or ambient completeness witness can discharge a NameCert obligation. □

Theorem 8040.3 (CauchyNetCriterion regular-sequence handoff)**.** *Every regular-sequence consumer of an accepted* $\mathsf{CauchyNetCriterion}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealUniformStructure}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route uses the displayed directed-tail rows D, A, U, T and the structural rows H, C, P, N of the same packet; it does not export a selected cofinal sequence or a quotient equality of net limits.

Proof. Begin with a regular-sequence request. The carrier has no independent sequence coordinate, so the request must read the directed-tail rows D, A, U, T to obtain finite late-window evidence.

The stream row S supplies the only admissible sequence-facing window. It is extracted from displayed directed tails and is therefore still tied to the same common-tail ledger.

The handoff row R repacks the stream observations as regular rational readback, and E seals that readback as the Real-facing output. Transport, replay, provenance, and local naming through H, C, P, N preserve this route without adding a cofinal selector or quotient-limit equality. □

Theorem 8040.4 (CauchyNetCriterion filter-basis handoff)**.** *Every filter-basis or completion-facing consumer of an accepted* $\mathsf{CauchyNetCriterion}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealUniformStructure}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow},$$

using the displayed rows $D, A, U, T, F, M, H, C, P, N$*. The handoff exposes finite Cauchy-filter basis data and the completion criterion route, but it does not assert host completeness, arbitrary net convergence, selected subnet existence, or quotient equality of completion points.*

Proof. Read the uniformity and tail rows first. The entourage row U names the comparison requests, while T supplies the common-tail witnesses over the directed index row D and the net-value row A.

The Cauchy-filter row F is generated from those finite tails. A filter-basis consumer therefore sees only displayed basis elements and their Cauchy compatibility rows.

The completion handoff M reads the same basis evidence as a $\mathsf{MetricCompletion}^{\uparrow}$ criterion. Since H, C, P, N only transport, replay, source, and name the listed rows, the route cannot claim host completeness, arbitrary convergence, selected subnets, or quotient equality of completion points. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyNetCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyNetCriterion}^{\uparrow}$ packet is generated from directed indices, net values, RealUniformStructure entourages, Cauchy-tail ledgers, CauchyFilter basis rows, StreamName windows, RegSeqRat readback, Real seals, MetricCompletion handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchyNetCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 8040.1, Definition 8040.2, Definition 8040.3, and Definition 8040.4 seed the L10 route from directed Cauchy-net data to regular-sequence and filter-basis consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchyNetCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected cofinal sequences, selected subnets, quotient-net equality, quotient equality of completion points, countable choice, host completion, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, directed-tail exposure, uniformity tolerance exposure, Cauchy-filter basis handoff, StreamName extraction, RegSeqRat/Real readback, MetricCompletion handoff, transport preservation, replay, provenance, and local naming for BEDC.Derived.CauchyNetCriterionUp.

Chapter 8041

A Concrete Naming Certificate for $\mathsf{RegularCauchyCutoff}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyCutoff}^{\uparrow}$ packet records the finite tail-cutoff data by which a regular Cauchy rational name becomes readable by Real and Completion consumers. It sits after the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet is a finite NameCert carrier for a displayed cutoff route; it is not quotient stream equality, a selected limit representative, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8041.1 (Regular Cauchy cutoff carrier)**.** *A* $\mathsf{RegularCauchyCutoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (n, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *n is the finite cutoff index at which the tail route begins.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule inspected at and beyond n.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the displayed tail.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the requested cutoff precision.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after n, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the cutoff index, window schedule, regular rational readback, dyadic tolerance ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real or Completion request through the cutoff route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCutoff}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCutoff}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $n, W, R, D, E, H, C, P, N$. It has no coordinate for quotient-name equality, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8041.2 (Regular Cauchy cutoff tail window)**.** *Every accepted* $\mathsf{RegularCauchyCutoff}^{\uparrow}$ *carrier*

$$K = (n, W, R, D, E, H, C, P, N)$$

exposes a finite tail window before any Real-facing seal can be read. A consumer must inspect the cutoff index n*, the* $\mathsf{StreamName}^{\uparrow}$ *window schedule* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D *before it reaches* E, H, C, P, N*.*

Lean4 ✓ `BEDC.Derived.RegularCauchyCutoffUp.RegularCauchyCutoffCarrier tail window`

Proof. Project the accepted carrier of Definition 8041.1. The first four rows display the cutoff index, stream window, regular rational readback, and dyadic tolerance ledger as finite data.

The terminal seal row E is downstream of those displayed rows. Transport, replay, provenance, and local naming preserve the same order because H, C, P, N act on the carried rows rather than replacing them with a hidden tail selector.

Thus an accepted consumer can read the Real-facing seal only through the displayed finite tail window. Any route that omits n, W, R, D has no carrier coordinate to project and is outside the local certificate. □

Theorem 8041.3 (Regular Cauchy cutoff RegSeqRat handoff)**.** *The* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff exported by an accepted* $\mathsf{RegularCauchyCutoff}^{\uparrow}$ *packet is attached to the same finite* $\mathsf{StreamName}^{\uparrow}$ *window and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that determine the cutoff. The route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}$$

therefore remains a displayed finite NameCert route and does not introduce a quotient of streams, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the tail-window theorem. It forces each Real-facing read to pass through the same rows n, W, R, D before the seal row is available.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is not a standalone limit witness. It is read together with the finite window W and tolerance ledger D, and the replay row C preserves that attachment for downstream Real and Completion requests.

Since the carrier has no coordinate for quotient stream equality, selected representatives, countable choice, or ambient completeness, the handoff can export only the displayed finite route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and the local structural rows. □

Theorem 8041.4 (Regular Cauchy cutoff non-escape)**.** *No accepted* $\mathsf{RegularCauchyCutoff}^{\uparrow}$ *consumer reaches the* $\mathsf{Real}^{\uparrow}$ *seal without first reading the cutoff index, finite stream window, regular rational row, dyadic tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *rows. A claimed Real-facing route that bypasses any of those rows is outside the packet.*

Proof. Start with the carrier inventory. The Real seal is one displayed row of K, and the rows n, W, R, D, H, C, P, N specify the finite route by which it is exposed.

Apply the handoff theorem. It ties the regular rational readback to the same stream window and dyadic tolerance ledger that determine the cutoff, so the Real-facing consumer cannot detach E from the tail window.

The remaining rows transport, replay, source, and name that route. Omitting any of them changes the carrier rather than preserving an accepted $\mathsf{RegularCauchyCutoff}^{\uparrow}$ packet, so the attempted bypass is refuted by the local NameCert surface. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCutoff}^{\uparrow}$ consumer is refuted if it reaches the $\mathsf{Real}^{\uparrow}$ seal without first reading the finite cutoff index, $\mathsf{StreamName}^{\uparrow}$ window schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, real: none is bijective with $\mathsf{RegularCauchyCutoff}^{\uparrow}$ because the cutoff packet jointly binds one finite cutoff index, one finite stream window, one regular rational row, one dyadic tolerance ledger, one Real seal, transport, replay, provenance, and local naming as a single tail-cutoff route.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCutoff}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCutoff}^{\uparrow}$ packet is generated from a finite cutoff index, StreamName finite-window schedules, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCutoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8041.1, Definition 8041.2, Definition 8041.3, and Definition 8041.4 seed the finite tail-cutoff route over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCutoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove tail-window exposure, RegSeqRat handoff preservation, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCutoffUp.

Chapter 8042

A Concrete Naming Certificate for LawlikeLocatedRealSequence$^{\uparrow}$

Following Bishop and Brouwer on lawlike sequences in constructive analysis, the LawlikeLocatedRealSequence$^{\uparrow}$ packet records a finite interface for a displayed lawlike sequence of located real names. It sits over the stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the located-real comparison surface of chapter 1933. The packet names the sequence interface used by Real and Completion consumers; it does not choose a host sequence, quotient streams, select limits, use countable choice, or assert ambient completeness of Real$^{\uparrow}$.

Definition 8042.1 (Lawlike located real sequence carrier)**.** *A* LawlikeLocatedRealSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, D, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the lawlike source row, recording the finite rule ledger and admissible request boundary for the indexed sequence.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row, listing the inspected sequence indices and the finite observation windows available at those indices.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, carrying the dyadic precision budget for each inspected located real name.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from the displayed windows and dyadic tolerance data.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after W, D, R have been displayed.*
6. *Q is the* LocatedReal$^{\uparrow}$ *row, exposing the located comparison or bracketing surface attached to the same Real seal.*
7. *H records componentwise* hsame *transport for lawlike source data, stream windows, dyadic tolerances, regular readbacks, Real seals, located comparisons, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from lawlike sequence inspection through finite windows, dyadic tolerances, regular readback, Real sealing, and located comparison.*

9. *P is the* Pkg *provenance over* $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LawlikeLocatedRealSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, R, E, Q, H, C, P, N$. It has no coordinate for a selected host sequence, quotient stream equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8042.2 (Lawlike located real sequence RegSeqRat readback)**.** *For every accepted* LawlikeLocatedRealSequ *carrier $L = (S, W, D, R, E, Q, H, C, P, N)$, a Real-facing or LocatedReal-facing consumer may read the regular rational data only after the lawlike source row S, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row W, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D have been displayed. The readback row R is therefore the unique local route from lawlike finite observations to the terminal* $\mathsf{Real}^{\uparrow}$ *seal E and the located comparison row Q.*

Proof. Project the carrier of Definition 8042.1. The rows S, W, D expose the lawlike source, inspected stream windows, and dyadic tolerance budget before any rational or real-facing row is available.

The readback row R is the only row typed as $\mathsf{RegSeqRat}^{\uparrow}$ data in the packet. It repacks the displayed windows and tolerance ledger as regular rational finite data, so a consumer cannot obtain a regular readback by bypassing S, W, D.

The endpoint rows E and Q are downstream of the same readback. The Real seal E and located comparison row Q may be consumed only after R, while H, C, P, N transport, replay, source, and name the same finite route. □

Theorem 8042.3 (Lawlike located real sequence choice-free modulus)**.** *Every modulus or comparison read exported by an accepted* $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$ *carrier is bounded by the displayed finite route*

$$S, W, D, R, E, Q, H, C, P, N.$$

The route may expose dyadic tolerance budgets, regular rational readbacks, Real seals, and located comparison rows for inspected windows, but it exports no selected infinite subsequence, countable-choice selector, quotient stream equality, selected limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the accepted carrier. Its only analytic rows are the lawlike source S, finite stream windows W, dyadic tolerance budget D, regular readback R, Real seal E, and located comparison row Q.

A modulus request can inspect only the displayed tolerance row D and its attached finite windows. By Definition 8042.2, any rational readback then passes through R before the Real or located endpoint is consumed.

The structural rows H, C, P, N preserve this packet under componentwise transport, displayed replay, provenance, and local naming. Since the carrier has no coordinate for an infinite selector, quotient stream equality, selected limit, trichotomy, or ambient completeness, every exported modulus remains choice-free and finite-window based. □

Falsifiable prediction: Every accepted $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$ consumer that reaches $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{LocatedReal}^{\uparrow}$ data without displaying the lawlike source row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, structural replay, provenance, and local NameCert evidence refutes the carrier of Definition 8042.1.

Independence witness: streamname, regseqrat, dyadicratcore, real, located-real: $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a lawlike source row, finite sequence-window ledger, dyadic tolerance budget, regular readback, Real seal, located comparison row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LawlikeLocatedRealSequence}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$ packet is generated from a lawlike source row, finite StreamName windows, DyadicRatCore tolerance budgets, RegSeqRat readback, Real seals, LocatedReal comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawlikeLocatedRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8042.1, Definition 8042.2, and Definition 8042.3 seed the finite lawlike located-sequence interface over StreamName windows, dyadic tolerance budgets, RegSeqRat readback, Real seals, LocatedReal comparison rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawlikeLocatedRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected infinite subsequences, countable choice, selected limits, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window compatibility, dyadic tolerance exactness, RegSeqRat readback, LocatedReal comparison stability, transport replay, provenance, and nonescape for BEDC.Derived.LawlikeLocatedRealSequenceUp.

Chapter 8043

A Concrete Naming Certificate for $\mathsf{MonotoneBoundedConvergence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{MonotoneBoundedConvergence}^{\uparrow}$ packet records the finite route by which a bounded monotone real sequence is handed to a located supremum surface and then read back as a regular Cauchy real name. It sits beside the monotone bounded sequence carrier of chapter 3407, the located-supremum handoff of chapter 1427, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet records a convergence certificate for the displayed sequence route; it does not claim Dedekind completeness, trichotomy, quotient equality, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8043.1 (Monotone bounded convergence carrier)**.** *A* $\mathsf{MonotoneBoundedConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, L, B, U, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ *source row, exposing the inspected real-sequence windows and their monotonicity ledger.*
2. *L is the monotonicity ledger stability row, recording that the displayed order comparisons are preserved under the finite window extensions used downstream.*
3. *B is the boundedness exactness row, naming the upper-bound evidence available for the same displayed sequence route.*
4. *U is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row attached to the bounded monotone source, not to an ambient host set.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the located-supremum handoff and the displayed sequence windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, read only after S, L, B, U, R have been displayed.*
7. *H stores componentwise* hsame *transport for the sequence source, ledger, boundedness row, located-supremum handoff, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a convergence request through S, L, B, U, R, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{MonotoneBoundedConvergence}^{\uparrow}$, $\mathsf{MonotoneBoundedSequence}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MonotoneBoundedConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their structural provenance.

Lean4 (statement) `BEDC.Derived.MonotoneBoundedConvergenceUp`

Theorem 8043.2 (MonotoneBoundedConvergence obligation surface)**.** *For every accepted* MonotoneBoundedConve *carrier $M = (S, L, B, U, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MonotoneBoundedConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, monotonicity ledger stability through L, boundedness exactness through B, located-supremum handoff through U, regular-Cauchy real-seal readback through R, E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is the projection of Definition 8043.1. The analytic route is the displayed tuple S, L, B, U, R, E, and no convergence-facing consumer can enter the packet before those rows are named.

The monotonicity ledger remains stable because L is attached to the same $\mathsf{MonotoneBoundedSequence}^{\uparrow}$ source row S used by every later window read. Extending a displayed window therefore preserves the listed order comparisons rather than opening a second sequence classifier.

Boundedness is exact at row B. The upper-bound evidence is read from the same finite source route as the monotonicity ledger, so it cannot be replaced by a host least-upper-bound theorem, trichotomy, or an unrecorded completeness principle.

The located-supremum handoff is row U. It consumes the monotone bounded source through S, L, B and exports only the located supremum boundary needed for the downstream regular readback.

Finally the regular-Cauchy real-seal readback passes through R, E, H, C, P, N. Row R supplies the $\mathsf{RegSeqRat}^{\uparrow}$ presentation obtained from the handoff, row E supplies the terminal $\mathsf{Real}^{\uparrow}$ seal, and the structural rows transport, replay, source, and name the same route. Since no coordinate stores Dedekind completeness, quotient equality, countable choice, or ambient real completeness, the listed rows exhaust the local obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneBoundedConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneBoundedConvergence}^{\uparrow}$ packet is generated from a MonotoneBoundedSequence source row, a monotonicity ledger stability row, boundedness exactness, a LocatedSupremum handoff, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MonotoneBoundedConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 8043.1 and Definition 8043.2 name the finite convergence route from bounded monotone sequence data to located-supremum and regular-Cauchy real-seal readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MonotoneBoundedConvergence}^{\uparrow}}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not close Dedekind completeness, trichotomy, quotient equality, countable choice, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotonicity ledger stability, boundedness exactness, located-supremum handoff, regular readback, Real seal, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneBoundedConvergenceUp.

Chapter 8044

A Concrete Naming Certificate for $\mathsf{VisionLedgerRoute}^{\uparrow}$

The $\mathsf{VisionLedgerRoute}^{\uparrow}$ packet realizes the top-level visions hub of chapter 9236 as finite route data over the concrete-instance ledger. It records the source hub row from `parts/visions/_index_files.tex`, the concrete target label, the hub-input route, the displayed marker row, and the replay/provenance rows that let a coverage audit move from the visions index to the concrete-instance chapter without consulting cached counts. The packet sits beside the coverage index of chapter 7381 and the coverage ledger of chapter 7484; it is a route certificate for one hub-to-target edge, not a coverage theorem for all vision files.

Definition 8044.1 (Vision ledger route carrier)**.** *A* $\mathsf{VisionLedgerRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, I, T, M, L, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-hub row naming the top-level visions index under* `parts/visions/_index_files.tex`*.*
2. *I is the input-route row, listing the finite hub edge by which the source hub reaches a thematic visions subhub or leaf.*
3. *T is the concrete-target row naming the realized concrete-instance chapter label.*
4. *M is the marker row containing the displayed* `\concretizedIn` *route from the source hub to T.*
5. *L is the local route-ledger row, recording whether the edge is root-index, subhub, or leaf-facing coverage.*
6. *A is the audit-readback row that lets a consumer reread both the source hub and the target chapter before counting the route.*
7. *H records componentwise* hsame *transport for source hub, input route, target label, marker, route ledger, audit readback, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the source hub to the concrete target through I, M, L, A, H.*
9. *P is the* Pkg *provenance over* $\mathsf{VisionLedgerRoute}^{\uparrow}$*,* $\mathsf{VisionCoverageIndex}^{\uparrow}$*,* $\mathsf{VisionCoverageLedger}^{\uparrow}$*, the referenced visions hub, the referenced concrete-instance target,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{VisionLedgerRoute}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, I, T, M, L, A, H, C, P, N$. It has no coordinate for hidden coverage totals, semantic endorsement of source prose, automatic coverage of sibling vision files, or a concrete target without a displayed chapter label.

Theorem 8044.2 (Vision ledger route NameCert obligations)**.** *For every accepted* $\mathsf{VisionLedgerRoute}^{\uparrow}$ *carrier $R = (S, I, T, M, L, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{VisionLedgerRoute}^{\uparrow}}$ *surface consists exactly of source-hub admission, input-route exposure, concrete-target exposure, marker-row exposure, route-ledger classification, audit-readback exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of R.*

Proof. Project the carrier of Definition 8044.1. The source side is exactly S and I: a named visions hub and the finite input edge being audited.

The target side is exactly T and M. The concrete target label is displayed, and the marker row records the concretized-in route rather than inferring it from a title or nearby prose.

The route ledger L and audit row A make the route replayable. They classify the edge and let the consumer reread the hub and target before counting it.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no hidden total, semantic endorsement, sibling coverage, or target-without-label coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 8044.3 (Vision ledger route replay handoff)**.** *Every route consumer of an accepted* $\mathsf{VisionLedgerRoute}^{\uparrow}$ *packet factors through*

$$S \longmapsto I \longmapsto M \longmapsto T \longmapsto A \longmapsto H, C, P, N.$$

Thus the visions index contributes a concrete coverage route only through a displayed hub edge, a displayed marker row, and a replayable concrete target. The route exports no hidden coverage count, no source-prose semantics, and no coverage claim for unmarked siblings.

Proof. Start with the source-hub and input-route rows. A consumer first reads S and I, so the edge being counted is the displayed hub route rather than an implicit scan of the visions tree.

Next read the marker and target rows. The marker row M binds the source route to the concrete target T and prevents a cached target list from replacing the displayed route.

The audit row A is consumed before replay completes. It points the consumer back to the source hub and to the concrete-instance target, so the route remains inspectable.

The structural rows H, C, P, N preserve this order under transport, continuation replay, provenance, and local naming. Hence no hidden count, prose semantics, or unmarked sibling coverage can be exported. □

Theorem 8044.4 (Vision ledger route concrete-index boundary)**.** *For every accepted* $\mathsf{VisionLedgerRoute}^{\uparrow}$ *carrier $R = (S, I, T, M, L, A, H, C, P, N)$, the concrete target T must remain a concrete-instance NameCert chapter label and the source row S must remain the visions hub route named by the carrier. The packet may point from the visions index to the concrete-instances ledger, but it cannot move theorem content into the visions tree or treat a visions hub as a proof chapter.*

Proof. Project the target row T and the source row S. The carrier separates the visions hub from the concrete target, so a consumer can identify which side supplies route context and which side supplies the NameCert chapter.

Use the marker row M and route ledger L. They record the direction from source hub to concrete target and classify the route edge before the audit row is read.

The audit row A reopens both endpoints without merging their roles. Transport and replay through H and C preserve the same endpoints, while P and N source and name the route.

Therefore the packet is a concrete-index boundary. It records a route from the visions hub into concrete instances, but it does not relocate proof content into the visions tree or certify a visions hub as a proof chapter. □

Falsifiable prediction: Every accepted $\mathsf{VisionLedgerRoute}^{\uparrow}$ coverage read names a source hub row, input-route row, concrete target label, marker row, route ledger, audit-readback row, transport row, replay row, provenance row, and local NameCert row before it is counted.

Independence witness: vision-coverage-index, vision-coverage-ledger, affine-filter-hull, regular-cauchy-filter-seal: $\mathsf{VisionLedgerRoute}^{\uparrow}$ is not bijective to any listed sibling because it stores the top-level visions hub edge and concrete-index boundary as route data rather than storing a general coverage account, a mathematical hull, or an analytic Cauchy seal.

Lean Nontrivial and FieldFaithful TasteGate instances for $\mathsf{VisionLedgerRoute}^{\uparrow}$ should inspect the carrier rows directly: Nontriviality is witnessed by distinct source-hub and concrete-target rows, while field faithfulness requires projections of $S, I, T, M, L, A, H, C, P, N$ to preserve the displayed hub edge, marker route, and audit-readback boundary. Neither instance may read hidden coverage totals, cached source scans, source prose outside the marker row, or unmarked sibling files.

Closure status for $\mathsf{NameCert}_{\mathsf{VisionLedgerRoute}^{\uparrow}}$.

Constructive story: A $\mathsf{VisionLedgerRoute}^{\uparrow}$ packet is generated from a source-hub row, input-route row, concrete-target row, marker row, route ledger, audit-readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{VisionLedgerRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8044.1, Definition 8044.2, Definition 8044.3, and Definition 8044.4 seed the finite route packet that turns the visions hub edge into displayed concrete-instance coverage data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{VisionLedgerRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close total vision coverage, semantic approval of source prose, proof content inside the visions tree, Lean verification, bridge checking, hidden coverage totals, or coverage for unmarked sibling files.

Upgrade path: Obligation closure requires checked carrier admission, source-hub exactness, input-route exactness, target-label exactness, marker-route replay, route-ledger classification, audit-readback stability, transport, provenance, and local naming for BEDC.Derived.VisionLedgerRouteUp.

Chapter 8045

A Concrete Naming Certificate for HenstockKurzweilGaugeIntegral$^{\uparrow}$

Following Henstock and Kurzweil, the HenstockKurzweilGaugeIntegral$^{\uparrow}$ packet records the constructive gauge-integral route in which finite tagged partitions are admitted by a displayed gauge and finite Riemann sums are compared through regular rational readback before any Real-facing integral value is exported. It sits beside the gauge-integral packet of chapter 1999, the tagged-partition surface of chapter 4296, the Riemann-sum gauge row of chapter 4115, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the dyadic tolerance core of chapter 291. The chapter names one finite gauge-integral certificate; it does not import measure completion, countable choice, selected tags, quotient equality of functions, ambient completeness, or a standard bridge.

Definition 8045.1 (Henstock–Kurzweil gauge-integral carrier)**.** *A* HenstockKurzweilGaugeIntegral$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, G, T, S, C, H, R, P, N)$$

with the following displayed rows:

1. *I is the interval source row, carrying the located endpoint window on which the integrand is inspected.*
2. *G is the gauge ledger, recording positive local gauge data and the dyadic tolerance requests used by the packet.*
3. *T is the* TaggedRealPartition$^{\uparrow}$ *row, exposing only finite tagged subintervals that are G-fine.*
4. *S is the* RiemannSumGauge$^{\uparrow}$ *row, carrying the finite Riemann-sum observations attached to the tagged partition.*
5. *C is the Cauchy sum-window row, recording finite comparison windows for pairs of G-fine sums.*
6. *H records componentwise* hsame *transport for the interval, gauge, partition, sum, Cauchy-window, readback, replay, provenance, and local naming rows.*
7. *R is the* RegSeqRat$^{\uparrow}$ *handoff row, read only after the finite Cauchy sum windows and dyadic tolerance ledger have been displayed.*
8. *P is the* Pkg *provenance over* HenstockKurzweilGaugeIntegral$^{\uparrow}$, GaugeIntegral$^{\uparrow}$, TaggedRealPartition$^{\uparrow}$, RiemannSumGauge$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, G, T, S, C, H, R, P, N$. It has no coordinate for Lebesgue measure, countable choice, selected tags, quotient equality of functions, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a standard bridge.*

Theorem 8045.2 (Henstock–Kurzweil gauge-fine partition obligation)**.** *For every accepted* HenstockKurzweilGauge *carrier $K = (I, G, T, S, C, H, R, P, N)$, a partition-facing consumer must read the interval source I, the gauge ledger G, and the tagged finite partition row T before any Riemann-sum or Cauchy-window row is available. Thus gauge fineness is stored as displayed finite packet data, not as a choice-selected partition family or an ambient compactness principle.*

Proof. Project the carrier of Definition 8045.1. The only interval source is I, the only gauge data are in G, and the only partition data are the finite tagged windows in T.

The Riemann-sum row S is downstream from those three rows. A consumer therefore cannot inspect a sum before the interval window, gauge ledger, and tagged partition are visible.

Transport through H and provenance through P, N preserve the same row order. Since the carrier contains no selected tag family, open-cover compactness row, countable-choice schedule, or host partition quotient, the obligation is exactly the displayed finite gauge-fineness route. □

Theorem 8045.3 (Henstock–Kurzweil Cauchy criterion obligation)**.** *For every accepted* HenstockKurzweilGaugeInte *carrier $K = (I, G, T, S, C, H, R, P, N)$, a Real-facing integral read must pass through the finite Cauchy sum-window row C and the regular rational handoff R after the gauge-fine partition and Riemann-sum rows have been displayed. The packet exports only a Cauchy comparison route for displayed gauge-fine sums; it does not supply measure completion, quotient equality of functions, selected tags, countable choice, ambient completeness, or a standard bridge.*

Proof. Start with the gauge-fine route in Definition 8045.2. It exposes I, G, T before any sum row is read.

Next read the finite sum and Cauchy rows. The row S records the displayed Riemann sums, while C records the finite comparison windows used for the Cauchy criterion. Both rows remain tied to the same interval source, gauge ledger, and tagged partition.

Finally pass through R, H, P, N. The $\mathsf{RegSeqRat}^{\uparrow}$ handoff records regular rational readback before any $\mathsf{Real}^{\uparrow}$ consumer can interpret the integral value, and the structural rows transport, source, and name the same route. None of the excluded measure, quotient, selection, choice, completeness, or bridge coordinates occurs in the carrier. □

Falsifiable prediction: Every accepted $\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}$ Real-facing read factors through interval source, gauge ledger, tagged fine partition, Riemann-sum gauge row, finite Cauchy sum windows, componentwise hsame transport, RegSeqRat handoff, provenance, and local NameCert rows.

Independence witness: gauge-integral, tagged-real-partition, riemann-sum-gauge, regseqrat, real, dyadicratcore: no listed sibling is bijective with $\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}$ because this carrier jointly binds gauge fineness, tagged finite partitions, Riemann-sum observations, Cauchy sum-window comparisons, regular rational readback, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}$ packet is generated from an interval source, gauge ledger, tagged fine partition row, Riemann-sum gauge row, finite Cauchy sum-window row, componentwise hsame transport, RegSeqRat handoff, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenstockKurzweilGaugeIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8045.1, Definition 8045.2, and Definition 8045.3 seed the finite gauge-integral route over tagged partitions, Riemann-sum windows, Cauchy sum comparisons, and regular rational readback.

Formal verification: FormalStatus(NameCert$_{\text{HenstockKurzweilGaugeIntegral}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lebesgue measure, countable choice, selected tags, quotient equality of functions, ambient completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, gauge-fineness exposure, tagged-partition admission, Riemann-sum readback, Cauchy sum-window comparison, RegSeqRat handoff, transport, provenance, and local naming for BEDC.Derived.HenstockKurzweilGaugeIntegralUp.

Chapter 8046

A Concrete Naming Certificate for $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$

The $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ packet realizes the residual-substitution confluence frontier of chapter 9386 as a finite local-diamond witness for one admitted residual pair. It sits beside the conditional parallel-diamond frontier of chapter 4238, the existing residual-diamond witness of chapter 7219, the residual-substitution boundary of chapter 2181, and the residual-checker packet of chapter 3827. The packet records bounded local-join visibility and obstruction retention; it does not claim global confluence, subject reduction, kernel consistency, unrestricted residual-substitution compatibility, evaluator equality, or quotient term equality.

Definition 8046.1 (MetaCIC residual local-diamond witness carrier)**.** *A* $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (A, P, J, O, H, C, G, N)$$

with the following displayed rows:

1. *A is the residual-pair admission row, naming the typed window, source term, two residual branches, and finite observation budget for the local diamond.*
2. *P is the residual-substitution boundary row retained from the confluence frontier.*
3. *J is the bounded local-join checker row, recording the visible join candidate and finite checker status for the admitted pair.*
4. *O is the obstruction-retention row, recording that the packet does not discharge global confluence, subject reduction, kernel consistency, or unrestricted residual-substitution compatibility.*
5. *H records componentwise* hsame *transport for the admission, boundary, checker, obstruction, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay through the route*

$$A, P \longmapsto J \longmapsto O.$$

7. *G is the* Pkg *provenance over* $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICResidualDiamondWitness}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICConfluenceResidualChecker}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through A, P, J, O, H, C, G, N. It has no coordinate for premise-free parallel diamond, global Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Theorem 8046.2 (MetaCIC residual local-diamond witness obligations)**.** *For every accepted* $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ *carrier* $L = (A, P, J, O, H, C, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalDia}}$ *surface consists exactly of residual-pair admission through A, residual-substitution boundary visibility through P, bounded local-join checker visibility through J, obstruction retention through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8046.1. The confluence-facing rows are exactly the residual-pair admission, retained substitution boundary, bounded local-join checker, and obstruction-retention rows.

The witness direction is local. The row A fixes the admitted residual pair and finite observation budget, while P keeps the residual-substitution boundary visible before the checker row is consumed.

The checker row J records only the bounded local join for that admitted pair. The obstruction row O remains attached, and the structural rows H, C, G, N transport, replay, source, and name the same finite packet. Since no global confluence, subject-reduction, quotient, evaluator, or consistency coordinate occurs, the listed rows exhaust the local NameCert surface. □

Theorem 8046.3 (MetaCIC residual local-diamond nonescape)**.** *Every confluence-frontier consumer of an accepted* $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ *packet must read*

$$A, P, J, O, H, C, G, N$$

before using the local-diamond witness. The handoff may feed the conditional $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$ *route, but it cannot erase the residual-substitution boundary, promote the bounded checker to global confluence, discharge subject reduction, or certify kernel consistency.*

Proof. Start with the admission row A. It exposes only one finite residual pair, its typed window, and the observation budget inspected by the packet.

Next read P, J, O. The residual-substitution boundary remains visible, the bounded checker supplies only local-join status for the admitted pair, and the obstruction row records every surrounding endpoint that remains outside the packet.

Finally read the structural rows. Transport through H, replay through C, provenance through G, and local naming through N preserve the same finite route. Thus the consumer receives a local-diamond witness with retained obstruction rows, not a global confluence or consistency theorem. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ consumer that reads a local join without displaying residual-pair admission, residual-substitution boundary visibility, bounded checker status, obstruction retention, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: metacic-parallel-diamond-frontier, metacic-residual-diamond-witness, metacic-residual-substitution-boundary, metacic-confluence-residual-checker: no listed sibling is bijective with $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ because this packet jointly carries residual-pair admission, retained substitution boundary, bounded local-join checker visibility, obstruction retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}$ packet is generated from residual-pair admission, residual-substitution boundary visibility, bounded local-join checker visibility, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8046.1, Definition 8046.2, and Definition 8046.3 seed the finite residual-pair local-diamond witness route for the MetaCIC confluence frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualLocalDiamondWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, subject reduction, kernel consistency, unrestricted residual-substitution compatibility, evaluator equality, quotient term equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked residual-pair admission, residual-substitution boundary visibility, bounded local-join checker visibility, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualLocalDiamondWitnessUp.

Chapter 8047

A Concrete Naming Certificate for $\mathsf{HyperbolicBarycenter}^{\uparrow}$

Following Bridson–Haefliger and the standard finite comparison view of hyperbolic metric geometry, the $\mathsf{HyperbolicBarycenter}^{\uparrow}$ packet records a weighted barycenter readback as finite NameCert data. It sits after the metric rows of chapter 3474, the four-point coarse-negative-curvature surface of chapter 6862, the boundary-direction rows of chapter 3732, and the terminal scalar seal of chapter 38. The packet names a finite averaging-style route over displayed metric, boundary, weight, and seal rows; it is not a completed hyperbolic space, a quotient boundary measure, a selected minimizer in an ambient space, countable choice, or a global convexity theorem.

Definition 8047.1 (Hyperbolic barycenter carrier)**.** *A* $\mathsf{HyperbolicBarycenter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, G, W, U, R, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row for the finite family being averaged.*
2. *G is the* $\mathsf{GromovHyperbolicMetric}^{\uparrow}$ *comparison row, recording the four-point or coarse hyperbolicity budget used by the read.*
3. *W is the finite weight ledger, recording the nonnegative displayed weights and their finite normalization row.*
4. *U is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-direction row used when the barycenter is read through a boundary-facing shadow.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the scalar comparison budget attached to the weighted readback.*
6. *T is the transport row binding the same metric, hyperbolicity, weight, boundary, and scalar rows under componentwise comparison.*
7. *H records componentwise* hsame *transport for the metric, comparison, weight, boundary, scalar, transport, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a barycenter request through $M, G, W, U, R, T, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBarycenter}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{GromovHyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBarycenter}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, G, W, U, R, T, H, C, P, N$. It has no coordinate for a host minimizer, quotient boundary probability measure, selected global convexity center, countable-choice family, or ambient hyperbolic completion.

Theorem 8047.2 (Hyperbolic barycenter NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBarycenter}^{\uparrow}$ *carrier*

$$B = (M, G, W, U, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicBarycenter}^{\uparrow}}$ *surface consists exactly of metric-read admission, Gromov-hyperbolic comparison exposure, finite weight-ledger admission, Busemann-boundary handoff, Real-seal scalar budgeting, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8047.1. The rows $M, G, W, U, R, T, H, C, P, N$ are the complete accepted packet.

The metric and comparison rows supply the hyperbolic geometry that the barycenter read may inspect. The finite weight ledger records the displayed coefficients, while the Busemann-boundary and Real-seal rows expose boundary direction and scalar budget only as named rows.

Transport, replay, provenance, and local naming preserve this inventory. Since no carrier coordinate stores a host minimizer, quotient measure, selected center, countable-choice family, or completed hyperbolic space, those objects are outside the local NameCert surface. □

Theorem 8047.3 (Hyperbolic barycenter boundary handoff)**.** *Every boundary-facing read of an accepted* $\mathsf{HyperbolicBarycenter}^{\uparrow}$ *packet factors through*

$$\mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{GromovHyperbolicMetric}^{\uparrow},\ \mathsf{HyperbolicBusemannBoundary}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ H, C, P, N.$$

The exported barycenter row is therefore a finite weighted readback over displayed metric, coarse-hyperbolic, boundary, and scalar rows, not a quotient boundary measure or selected global center.

Proof. Start with the NameCert obligations. They require the metric row M, comparison row G, weight ledger W, boundary row U, and scalar seal R before any barycenter read is exported.

The boundary-facing consumer can read U only as part of that same packet. It cannot detach the Busemann row from the metric and hyperbolicity rows, because replay through C preserves the carried order.

Thus the handoff remains finite and row-scoped. The structural rows H, P, N transport, source, and name the same route, leaving no surface for a quotient measure, selected center, or ambient completion. □

Theorem 8047.4 (Hyperbolic barycenter non-escape)**.** *No accepted* $\mathsf{HyperbolicBarycenter}^{\uparrow}$ *consumer reaches a barycenter read without first displaying the hyperbolic metric row, Gromov comparison row, finite weight ledger, Busemann-boundary row, Real scalar seal, componentwise transport, replay, provenance, and local naming rows.*

Proof. Use the carrier inventory of Definition 8047.1. A barycenter read is exposed only through $M, G, W, U, R, T, H, C, P, N$.

Apply Definition 8047.3. It keeps boundary-facing and scalar-facing reads attached to the same finite weighted route. Omitting any listed row changes the carrier rather than preserving the accepted packet.

Therefore a claimed barycenter read that bypasses metric, comparison, weight, boundary, scalar, transport, replay, provenance, or local naming data has no local NameCert row and is rejected. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBarycenter}^{\uparrow}$ packet exposes HyperbolicMetric, GromovHyperbolicMetric, finite weight-ledger, HyperbolicBusemannBoundary, Real-seal, hsame, Cont, Pkg, and NameCert rows before any barycenter read is exported.

Independence witness: hyperbolic-metric, gromov-hyperbolic-metric, hyperbolic-busemann-boundary, real: none is bijective with $\mathsf{HyperbolicBarycenter}^{\uparrow}$ because the barycenter packet jointly binds metric reads, coarse-hyperbolic comparison, finite weights, boundary direction, scalar seal, transport, replay, provenance, and local naming as one finite weighted readback route.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBarycenter}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBarycenter}^{\uparrow}$ packet is generated from HyperbolicMetric rows, GromovHyperbolic-Metric comparison rows, finite weight ledgers, HyperbolicBusemannBoundary rows, a RealUp scalar seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBarycenter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8047.1, Definition 8047.2, Definition 8047.3, and Definition 8047.4 seed the finite weighted hyperbolic barycenter route over metric, coarse-hyperbolic, boundary, scalar, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBarycenter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a completed hyperbolic space, quotient boundary measure, selected global center, countable-choice family, ambient convexity theorem, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the displayed carrier and prove metric exposure, finite weight-ledger admission, Busemann-boundary handoff, scalar-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicBarycenterUp.

Chapter 8048

A Concrete Naming Certificate for $\mathsf{LocatedClosedSetDistance}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis, the $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ packet records the finite data by which a distance-to-a-closed-set read is consumed without a host subset equality, a selected nearest point, countable choice, or ambient completeness. It sits over the metric source of chapter 57, the stream-name and regular rational readback rows of chapter 126 and chapter 301, the scalar real seal of chapter 38, and the located-real comparison surface of **??**.

Definition 8048.1 (Located closed-set distance carrier)**.** *A* $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (M, S, Q, L, D, R, W, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row naming the ambient metric comparison used by the distance read.*
2. *S is the closed-set name row, exposed only through finite negative and positive location tests.*
3. *Q is the query-point row naming the inspected point of the metric source.*
4. *L is the located-window row recording finite lower and upper distance cuts for Q against S.*
5. *D is the dyadic tolerance row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$ *schedules.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{LocatedReal}^{\uparrow}$ *scalar seal for the resulting distance name.*
7. *W stores the finite witness ledger tying each accepted cut to a displayed metric comparison.*
8. *H records componentwise* hsame *transport for the metric, set-name, query, located-window, tolerance, scalar, witness, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a distance query through the visible rows.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedClosedSetDistance}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedClosedSetDistance}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a host closed subset, equality of subsets, a chosen nearest point, quotient equality of metric spaces, countable choice, or ambient completeness.

Theorem 8048.2 (Located closed-set distance NameCert obligations)**.** *For every accepted* LocatedClosedSetDistanc *carrier* $Z = (M, S, Q, L, D, R, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedClosedSetDistance}^{\uparrow}}$ *surface consists exactly of carrier admission, metric-source exposure through* M*, closed-set name exposure through* S*, query-point exposure through* Q*, located-window admission through* L*, dyadic tolerance scheduling through* D*, scalar sealing through* R*, witness-ledger exactness through* W*, componentwise transport through* H*, replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8048.1. Its analytic rows are exactly M, S, Q, L, D, R, W, followed by structural transport, replay, provenance, and naming rows.

The located-window row L may be read only with the query row Q, the closed-set name row S, and the metric source M still visible. The tolerance row D supplies finite $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{StreamName}^{\uparrow}$ schedules, while R seals the result at the $\mathsf{Real}^{\uparrow}$ and $\mathsf{LocatedReal}^{\uparrow}$ boundary.

Finally W, H, C, P, N record witness exactness, transport, replay, provenance, and local naming for the same displayed rows. Since no carrier coordinate stores a host subset, selected nearest point, quotient metric equality, choice principle, or completeness theorem, these rows exhaust the local NameCert obligations. □

Theorem 8048.3 (Located closed-set distance metric handoff)**.** *Every metric consumer of an accepted* $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ *packet must read the finite route*

$$M, S, Q, L, D, R, W \longmapsto H, C, P, N$$

before using the distance name. The handoff supplies a metric-source row, a closed-set name row, a query-point row, located lower and upper cuts, dyadic tolerance schedules, a real located scalar seal, finite witness exactness, transport, replay, provenance, and local naming; it does not supply a host subset equality, a selected nearest point, an ambient completion theorem, or countable choice.

Proof. Use Definition 8048.2. It forces any accepted distance read to expose M, S, Q, L, D, R, W before the structural rows may transport, replay, source, or name the result.

Now pass to a metric consumer. The consumer receives the distance as a located scalar row sealed by R, with its dyadic tolerance schedule D and finite metric witness ledger W still attached to the source metric M.

The remaining rows H, C, P, N preserve and name that route only. Because the carrier contains no coordinate for a host subset equality, selected minimizer, ambient completion, or choice principle, the metric handoff is exactly the displayed finite packet. □

Falsifiable prediction: An accepted $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ read is refuted if it preserves the scalar distance row R while removing the metric source M, closed-set name S, query row Q, located-window row L, or witness ledger W.

Independence witness: metric, streamname, regseqrat, real, locatedreal: none is bijective with $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ because this packet jointly binds a metric source, closed-set name, query row, located distance cuts, dyadic tolerance schedules, scalar sealing, finite witness exactness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedClosedSetDistance}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedClosedSetDistance}^{\uparrow}$ packet is generated from a metric source row, a closed-set name row, a query-point row, located lower and upper distance cuts, dyadic tolerance schedules, real and located-real scalar seals, finite metric witness rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LocatedClosedSetDistance}\uparrow}$, seed)

Scope closed: Definition 8048.1, Definition 8048.2, and Definition 8048.3 seed the finite constructive distance-to-closed-set certificate surface over metric, stream-name, regular-rational, real, and located-real rows.

Formal verification: FormalStatus(NameCert$_{\text{LocatedClosedSetDistance}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.LocatedClosedSetDistanceUp`

Bridge status: none

Not claimed: This chapter does not close host closed-set equality, selected nearest points, ambient completeness, countable choice, quotient metric equality, full Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-window exactness, tolerance scheduling, scalar sealing, witness-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.LocatedClosedSetDistanceUp.

Lean4 (statement) `BEDC.Derived.LocatedClosedSetDistanceUp`

Chapter 8049

A Concrete Naming Certificate for $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$

Following Bishop–Bridges constructive compactness and Kelley-style finite-net compactness, the $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$ packet records a finite chain of epsilon-net rows at displayed tolerances before a compactness or completion consumer reads a terminal real-name boundary. It sits after the compact-metric source of chapter 129, the total-bounded finite-net surface of chapter 127, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet packages the compactness and completion finite route as displayed NameCert rows, not as an open-cover compactness proof, a host finite subset, a selected Cauchy limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8049.1 (Finite epsilon-net chain carrier)**.** *A* $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, K, T, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact metric source row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *before any finite-net chain is inspected.*
2. *K is the total-bounded finite-net family. For each displayed tolerance cell it exposes the corresponding* $\mathsf{TotallyBounded}^{\uparrow}$ *center bundle and coverage ledger.*
3. *T is the finite tolerance chain, ordered by the* $\mathsf{DyadicRatCore}^{\uparrow}$ *comparison rows that relate successive epsilon levels.*
4. *D records the dyadic slack and mesh-budget rows used when the chain refines one finite net into the next.*
5. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row consumed by completion-facing readers before any regular rational readback is available.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows and dyadic tolerances.*
7. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after X, K, T, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for compact-metric, total-bounded, dyadic, stream, regular-rational, Real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite-chain request through* $X, K, T, D, S, R, L, H, P, N$.
10. *P is the* Pkg *provenance over* $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetChain}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $X, K, T, D, S, R, L, H, C, P, N$. It has no coordinate for an ambient open cover, a host enumeration of centers, a selected completion point, quotient equality of streams, countable choice, or ambient real completeness.

Theorem 8049.2 (Finite epsilon-net chain NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$ *carrier $E = (X, K, T, D, S, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetChain}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, the total-bounded finite-net family, the dyadic tolerance chain, mesh-budget rows, finite StreamName windows, RegSeqRat readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. Every compactness or completion-facing obligation must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{TotallyBounded}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{RegSeqRat}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},$$

No obligation is stored outside those rows.

Proof. Project the carrier of Definition 8049.1. Its compactness source is X, its finite-net data are K, and the only refinement data are the dyadic tolerance chain T and mesh-budget rows D.

Read the completion-facing boundary next. The finite StreamName windows S and RegSeqRat readback R are displayed before the terminal Real seal L can be consumed, so the Real handoff remains downstream of finite observations.

The structural rows H, C, P, N transport, replay, source, and name only the same packet. Since open covers, host center enumerations, selected completion points, quotient stream equality, countable choice, and ambient completeness are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8049.3 (Finite epsilon-net chain Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$ *carrier must consume the compact-metric row X, the total-bounded finite-net family K, the dyadic tolerance chain T, the mesh-budget row D, the finite StreamName windows S, and the RegSeqRat readback R before it may inspect the terminal seal L. The handoff is the finite route*

$$X, K, T, D \longmapsto S, R \longmapsto L \longmapsto H, C, P, N,$$

not an open-cover compactness argument, not a selected Cauchy limit, not quotient stream equality, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a Real or completion-facing consumer of E. By Definition 8049.1, the consumer enters through the compact metric source and the displayed finite-net chain, so the compactness data available to it are X, K, T, D.

The readback rows are then forced by the same carrier. The consumer must expose S and R before L is available, and those rows are tied to the displayed dyadic tolerances rather than to a detached stream representative.

Finally apply the NameCert obligations of Definition 8049.2. Transport, replay, provenance, and local naming preserve the same finite route, while the missing classical and ambient principles have no carrier coordinate from which they could be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetChain}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteEpsilonNetChain}^{\uparrow}$ packet is generated from a CompactMetric source row, a Totally-Bounded finite-net family, a DyadicRatCore tolerance chain, finite StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8049.1, Definition 8049.2, and Definition 8049.3 seed the finite compactness and completion route over compact-metric, total-bounded, dyadic, stream, regular-rational, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Cauchy limits, quotient stream equality, countable choice, ambient RealUp completeness, Lean verification, axiom-purity audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance-chain exactness, finite-net refinement, StreamName window consumption, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteEpsilonNetChainUp.

Chapter 8050

A Concrete Naming Certificate for $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$

Following Mac Lane on idempotent splittings and Eilenberg–Moore completion algebras, the $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ packet records the finite categorical surface where a completion idempotent is consumed by an explicit splitting row. It sits beside the category surface of chapter 61, the monad surface of chapter 108, the completion category of chapter 7554, the Eilenberg–Moore completion algebra of chapter 2139, and the regular rational and real completion route through chapter 301 and chapter 38. The packet names a splitting interface for L10 completion consumers; it is not a quotient completion, not a selected limit, and not host equality of completed objects.

Definition 8050.1 (Idempotent completion splitting carrier)**.** *An* $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, E, S, R, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the object row, naming the completion object read through* $\mathsf{CauchyCompletionCategory}^{\uparrow}$ *and the underlying* $\mathsf{Cat}^{\uparrow}$ *surface.*
2. *E is the idempotent row, naming the displayed endomorphism on O and its finite idempotence witness.*
3. *S is the splitting row, carrying the displayed retract object together with section and retraction arrows inside the completion category.*
4. *R is the retract law row, exposing the two composite equalities only as finite category-law and completion-algebra comparisons.*
5. *T is the terminal completion-readback row through* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *when the splitting is consumed by the L10 route.*
6. *H records componentwise* hsame *transport for object, idempotent, splitting, retract-law, readback, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route from object and idempotent rows to the splitting row and then to the completion readback row.*

8. *P is the* Pkg *provenance over* $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$, $\mathsf{CauchyCompletionCategory}^{\uparrow}$, EilenbergMooreComp
   $\mathsf{Cat}^{\uparrow}$, $\mathsf{Monad}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{IdempotentCompletionSplitting}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, E, S, R, T, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, ambient split-idempotent completion, countable choice, host equality, or Real completeness.

Theorem 8050.2 (Idempotent completion splitting NameCert obligations)**.** *For every accepted* $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ *carrier $K = (O, E, S, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{IdempotentCompletionSplitting}^{\uparrow}}$ *surface consists exactly of object exposure, idempotent exposure, splitting-row exposure, retract-law exposure, completion-readback exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from quotient completion equality, selected representatives, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier in Definition 8050.1. The only displayed rows are $O, E, S, R, T, H, C, P, N$, so each local obligation must be read from one of those rows.

The categorical obligations are exhausted by O, E, S, R. The object and idempotent rows name the endomorphism being split, the splitting row names the retract data, and the retract-law row names the two finite composites inside the completion category and Eilenberg–Moore algebra surface.

The analytic completion readback is downstream of the splitting data. Row T may expose the regular rational, dyadic, and Real-facing route, but only after the categorical splitting rows have already been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier contains no quotient, selection, countable-choice, host-equality, or completeness coordinate, the non-escape obligation follows by exhaustion. □

Theorem 8050.3 (Idempotent completion splitting nonescape)**.** *Every* $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ *consumer must expose $O, E, S, R, T, H, C, P, N$ before reading a completed object through a split idempotent. The packet cannot export a quotient completion, a selected splitting, ambient Karoubi completion, host equality of completed objects, countable choice, trichotomy, or* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer that reads a completed object through an idempotent. The carrier first exposes O and E, so the read is attached to the displayed object and displayed endomorphism.

The consumer then reaches the splitting only through S and the retract laws only through R. These rows live inside the finite completion-category and completion-algebra surfaces, so they do not import an ambient category of all split idempotents.

The terminal readback row T is reached after the splitting rows. It may pass through $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, but it does not add quotient completion equality or a selected representative.

The structural rows H, C, P, N preserve the same finite route. Therefore a consumer receives the displayed splitting packet and no stronger quotient, selection, choice, trichotomy, host-equality, or completeness principle. □

Falsifiable prediction: A purported $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ consumer is refuted if it reads a split completion object without displaying the object, idempotent, splitting, retract-law, completion-readback, transport, replay, provenance, and local NameCert rows.

Independence witness: cauchy-completion-category, eilenberg-moore-completion-algebra, category, monad, regseqrat, real: none is bijective to $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ because this

packet jointly carries object, idempotent, splitting, retract-law, completion-readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{IdempotentCompletionSplitting}^{\uparrow}}$.

Constructive story: An $\mathsf{IdempotentCompletionSplitting}^{\uparrow}$ packet is generated from completion-object rows, idempotent rows, splitting rows, retract-law rows, RegSeqRat/DyadicRatCore/Real readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IdempotentCompletionSplitting}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8050.1, Definition 8050.2, and Definition 8050.3 seed the finite idempotent-splitting packet for L10 completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IdempotentCompletionSplitting}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected representatives, ambient Karoubi completion, countable choice, trichotomy, host equality, RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, idempotent exposure, splitting-row exposure, retract-law exactness, completion-readback ordering, transport, replay, provenance exhaustion, and local NameCert non-escape.

Chapter 8051

A Concrete Naming Certificate for MetaCICResidualConfluenceBudget$^{\uparrow}$

The MetaCICResidualConfluenceBudget$^{\uparrow}$ packet realizes the MetaCIC residual-substitution confluence frontier as a finite budget surface. It sits beside the residual-fuel packet of chapter 7966, the local diamond witness of chapter 8046, the commutation witness of chapter 7977, the residual-substitution boundary of chapter 2181, and the parallel-diamond frontier of chapter 4238. The carrier records the rows a bounded confluence checker must display before it may retain or discharge a local residual peak; it is not a global closed Church–Rosser theorem.

Definition 8051.1 (MetaCIC residual confluence budget carrier)**.** *A* MetaCICResidualConfluenceBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, R, J, Q, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row naming the closed source term, typing context, and bounded syntax window under inspection.*
2. *R is the residual-pair row naming the two residual branches and the substitution boundary retained with them.*
3. *J is the local-join row, available only after the typed window and residual-pair rows have been displayed.*
4. *Q is the bounded-checker row, recording the finite checker budget for residual replay, substitution replay, and local-join inspection.*
5. *O is the obstruction-retention row, preserving the refused endpoint when the displayed rows do not close a local join.*
6. *H records componentwise* hsame *transport for typed-window, residual-pair, local-join, bounded-checker, obstruction, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through the same residual-confluence route.*
8. *P is the* Pkg *provenance over* MetaCICResidualConfluenceBudget$^{\uparrow}$*,* MetaCICResidualConfluenceFuel$^{\uparrow}$*,* MetaCICResidualLocalDiamondWitness$^{\uparrow}$*,* MetaCICResidualCommutationWitness$^{\uparrow}$*,* MetaCICResidualSubstitutionBo MetaCICParallelDiamondFrontier$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $T, R, J, Q, O, H, C, P, N$. It has no coordinate for arbitrary confluence, subject reduction, evaluator equality, quotient syntax equality, selected normal forms, kernel consistency, or host-level proof search.

Theorem 8051.2 (MetaCIC residual confluence budget obligations)**.** *For every accepted* MetaCICResidualConfluenc *carrier $B = (T, R, J, Q, O, H, C, P, N)$, a confluence-facing consumer must expose the typed window T, residual-pair row R, local-join row J, bounded-checker row Q, obstruction-retention row O, componentwise transport H, replay row C, provenance P, and local naming row N before reading any residual-confluence conclusion.*

Proof. Project the carrier in Definition 8051.1. The rows $T, R, J, Q, O, H, C, P, N$ are the only displayed fields of the budget packet.

The confluence-facing rows are ordered. A local join can be read only after the typed window and residual pair have been displayed, and the bounded checker can only inspect that same finite route.

The obstruction row remains visible when the checker does not close the join. The structural rows then transport, replay, source, and name the same packet, with no extra endpoint for arbitrary confluence or kernel consistency. □

Theorem 8051.3 (MetaCIC residual confluence budget nonescape)**.** *An accepted* MetaCICResidualConfluenceBudge *packet cannot export closed Church–Rosser, full parallel diamond, subject reduction, evaluator equality, quotient equality of terms, selected normal forms, or MetaCIC kernel consistency. Any such endpoint must come from a separate downstream discharge that consumes the displayed residual-pair and bounded-checker rows.*

Proof. Use the obligation theorem. Every confluence-facing read is confined to the typed window, residual-pair, local-join, bounded-checker, obstruction, transport, replay, provenance, and naming rows.

Those rows are budget rows rather than global theorem rows. They can retain a local obstruction or certify a displayed bounded check, but they do not contain a subject-reduction discharge, quotient syntax equality, evaluator equality, normal-form selector, or kernel-consistency witness.

Because H, C, P, N preserve the same finite rows componentwise, they cannot manufacture any of the refused endpoints. The packet therefore remains a residual-confluence budget and not a closed confluence theorem. □

The Lean TasteGate follow-up path for $\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$ instances. These instances must keep $T, R, J, Q, O, H, C, P, N$ as distinct fields before a checked carrier-alignment theorem can serve downstream confluence consumers.

Falsifiable prediction: If a residual-confluence checker reaches a local-join conclusion without exposing the typed window, residual pair, bounded checker, obstruction-retention, transport, replay, provenance, and local NameCert rows, then it is not consuming $\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$.

Independence witness: metacic-residual-confluence-fuel, metacic-residual-local-diamond-witness, metacic-residual-commutation-witness, metacic-residual-substitution-boundary, metacic-parallel-diamond-frontier: none is bijective to $\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$ because this packet jointly carries typed-window, residual-pair, local-join, bounded-checker, obstruction-retention, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}$ packet is generated from a typed-window row, residual-pair row, local-join row, bounded-checker row, obstruction-retention row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8051.1, Definition 8051.2, and Definition 8051.3 seed the finite residual-confluence budget surface for the MetaCIC confluence frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualConfluenceBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close arbitrary confluence, closed Church–Rosser, full parallel diamond, subject reduction, evaluator equality, quotient syntax equality, selected normal forms, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-pair exactness, local-join ordering, bounded-checker replay, obstruction retention, TasteGate nontriviality, and field faithfulness.

Chapter 8052

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailSeal}^{\uparrow}$

Following Bishop–Bridges regular-Cauchy completion, the $\mathsf{RegularCauchyTailSeal}^{\uparrow}$ packet names the finite tail-seal surface that a completion consumer must expose before a displayed $\mathsf{Real}^{\uparrow}$ endpoint can be read. It sits between the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet also factors through the sequential-completeness route of chapter 1794; it is a reusable finite tail object, not a quotient stream, selected host limit, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 8052.1 (RegularCauchy tail-seal carrier)**.** *A* $\mathsf{RegularCauchyTailSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (D, S, R, M, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, including the dyadic endpoints and comparison budget used by the tail request.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposed by the request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S and checked against the tolerances in D.*
4. *M is the tail threshold and modulus row assigning each displayed tolerance a finite tail bound for R.*
5. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *tail seal reached after D, S, R, M have been displayed.*
6. *H records componentwise* hsame *transport for the tolerance ledger, stream window, readback, modulus, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a tail-seal request through D, S, R, M, T.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailSeal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySequentialCompleteness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSeal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, M, T, H, C, P, N$. There is no coordinate for quotient stream equality, host real equality, a selected limit point, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyTailSealUp`

Theorem 8052.2 (RegularCauchy tail-seal NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailSeal}^{\uparrow}$ *carrier* $Q = (D, S, R, M, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSeal}^{\uparrow}}$ *surface consists exactly of these finite obligation rows:*

1. *carrier admission for the displayed dyadic tolerance ledger, stream window, regular rational readback, threshold/modulus row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming row;*
2. *route exposure, requiring a consumer of* T *to expose* D, S, R, M *before the terminal tail seal is read;*
3. *classifier stability, requiring componentwise* hsame *transport in* H *to preserve the rows* D, S, R, M, T *before accepted packets are identified;*
4. *replay stability, requiring the displayed* Cont *row* C *to replay the same tolerance-window-readback-threshold route;*
5. *provenance and local naming, requiring* P *and* N *to name only the displayed finite packet and its sibling dependencies;*
6. *ledger non-escape, requiring the packet to export no quotient stream equality, selected host limit, countable-choice schedule, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem, Lean verification, or bridge checking.*

No NameCert obligation is stored outside $D, S, R, M, T, H, C, P, N$*.*

Proof. Carrier admission is projection from Definition 8052.1. The accepted packet displays exactly the tolerance ledger D, window row S, readback row R, threshold/modulus row M, terminal seal T, and structural rows H, C, P, N.

Route exposure is forced by the order of the displayed rows. A consumer must first read the dyadic tolerance in D, then the finite window in S, then the regular rational readback in R, and then the threshold/modulus row M before T is available as the $\mathsf{Real}^{\uparrow}$ tail seal.

Classifier stability and replay stability are componentwise. The transport row H preserves the visible rows, while C replays the same route without adding a second tail source or a hidden limit coordinate.

Finally P and N record provenance and local naming for the finite packet. Since none of the excluded objects occurs among the carrier coordinates, the ledger cannot export quotient streams, selected limits, choice schedules, host equality, ambient completeness, Lean verification, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailSeal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyTailSeal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName window, RegSeqRat readback, threshold/modulus row, terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSeal}^{\uparrow}}$, seed)

Scope closed: Definition 8052.1 and Definition 8052.2 seed the finite tail-seal surface between regular-Cauchy readback data and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyTailSeal}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.RegularCauchyTailSealUp`

Bridge status: none

Not claimed: This chapter excludes quotient stream equality, selected host limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, route exposure, replay stability, and ledger non-escape for BEDC.Derived.RegularCauchyTailSealUp.

Chapter 8053

A Concrete Naming Certificate for $\mathsf{LawlikeCauchyModulus}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Brouwer–Troelstra on lawlike sequences, the $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ packet records the finite route by which a lawlike located real sequence exposes an explicit Cauchy modulus before any regular-rational or real-name consumer reads it. It sits after the lawlike located-sequence surface of chapter 8042, the Bishop choice-sequence boundary of $\mathsf{BishopCauchyChoiceSequence}^{\uparrow}$, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the located comparison surface of chapter 1933. The packet supplies the L10 Real and Completion route with displayed lawlike Cauchy-modulus data; it refuses quotient streams, selected limits, countable choice, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8053.1 (Lawlike Cauchy modulus carrier)**.** *A* $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, W, D, M, R, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the lawlike source row, recording the finite rule ledger and admissible request boundary for the indexed sequence.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, listing the inspected indices, source windows, and modulus-query windows available to the packet.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-budget row, carrying the requested precision, dyadic slack, and comparison budget used by the modulus ledger.*
4. *M is the explicit Cauchy modulus ledger, displaying the threshold assigned to each admitted dyadic tolerance request and the finite later-window checks attached to it.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after S, W, D, M have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the regular readback row R.*
7. *Q is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row attached to the same readback and terminal seal.*
8. *H records componentwise* hsame *transport for the lawlike source, stream windows, dyadic tolerances, modulus ledger, regular readback, Real seal, located comparison, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from lawlike source inspection through finite windows, tolerance budgets, modulus thresholds, regular readback, Real sealing, and located comparison.*

10. *P is the* Pkg *provenance over* $\mathsf{LawlikeCauchyModulus}^{\uparrow}$, $\mathsf{LawlikeLocatedRealSequence}^{\uparrow}$, BishopCauchyChoiceSequen StreamName$^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{LawlikeCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, M, R, E, Q, H, C, P, N$. It has no coordinate for quotient stream equality, a selected host limit, countable choice, trichotomy, selected representatives, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8053.2 (Lawlike Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ *carrier*

$$L = (S, W, D, M, R, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LawlikeCauchyModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the lawlike source, finite StreamName windows, dyadic tolerance budget, explicit Cauchy modulus ledger, RegSeqRat readback, Real seal, LocatedReal comparison, transport, replay, provenance, and local naming rows;*

2. *source-window exactness, requiring every modulus request in M to read the lawlike source row S and the finite window row W before a threshold is exported;*

3. *tolerance-budget exactness, requiring each threshold in M to be bound to the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *request and slack data in D;*

4. *readback handoff, requiring* $\mathsf{RegSeqRat}^{\uparrow}$ *row R,* $\mathsf{Real}^{\uparrow}$ *seal E, and* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row Q to consume the same S, W, D, M route;*

5. *transport and replay stability through H and C for the same displayed modulus route;*

6. *provenance and local naming exhaustion through P and N;*

7. *refusal of quotient streams, selected limits, countable choice, trichotomy, selected representatives, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local lawlike Cauchy-modulus obligation is stored outside these rows.

Proof. Project the accepted carrier. The rows S, W, D, M are the only analytic source for a modulus request: S records the lawlike rule ledger, W records inspected finite windows, D records the dyadic tolerance budget, and M records the displayed thresholds.

The threshold row is therefore local to the packet. A consumer cannot read a threshold from M before the source, window, and tolerance rows have been exposed, and it cannot replace that threshold by a host selector or a countable-choice schedule.

The readback rows are downstream of the same route. The regular row R repacks the displayed windows and modulus ledger as regular rational data, while E and Q seal only that readback as real and located-real information.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since none of the carrier coordinates stores quotient stream equality, a selected limit, trichotomy, selected representatives, host real equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8053.3 (Lawlike Cauchy modulus RegSeqRat handoff)**.** *For every accepted* $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ *carrier $L = (S, W, D, M, R, E, Q, H, C, P, N)$, a* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *or* $\mathsf{LocatedReal}^{\uparrow}$ *consumer may*

read the regular sequence data only after the lawlike source row S, the finite $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the explicit modulus ledger M have all been displayed. Thus the handoff to R, E, Q is a non-quotient finite-window route and not an appeal to selected limits, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the accepted carrier. The regular readback row R is not a free-standing real-name row; by Definition 8053.1 it is reached only from the displayed source, window, tolerance, and modulus rows.

Read S, W, D, M in order. The lawlike source determines which requests are admitted, the window row lists the finite observations, the dyadic row fixes the tolerance budget, and the modulus ledger displays the threshold used for later-window comparison.

Only after those rows are visible may R be consumed. The terminal seal E and located comparison Q are downstream of R, so they inherit the same finite-window route.

The structural rows H, C, P, N do not add a quotient stream, a selected host limit, a choice schedule, a trichotomy decision, or a completeness witness. They identify the same displayed handoff for transport, replay, provenance, and local naming. □

Falsifiable prediction: A $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ read is refuted whenever a $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{LocatedReal}^{\uparrow}$ consumer reaches regular data, a real seal, or located comparison without displaying the lawlike source row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance budget, explicit modulus ledger, structural replay, provenance, and local $\mathsf{NameCert}$ evidence.

Independence witness: lawlike-located-real-sequence, bishop-cauchy-choice-sequence, stream-name, regseqrat, dyadicratcore, real, located-real: $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a lawlike source, finite stream windows, dyadic tolerance budgets, explicit Cauchy-modulus thresholds, regular readback, Real seal, located comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LawlikeCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{LawlikeCauchyModulus}^{\uparrow}$ packet is generated from a lawlike source row, finite StreamName windows, DyadicRatCore tolerance budgets, an explicit Cauchy modulus ledger, RegSeqRat readback, Real seals, LocatedReal comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LawlikeCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8053.1, Definition 8053.2, and Definition 8053.3 seed the finite lawlike Cauchy-modulus route over StreamName windows, DyadicRatCore tolerance budgets, explicit modulus thresholds, RegSeqRat readback, Real seals, LocatedReal comparison rows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LawlikeCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected limits, countable choice, trichotomy, selected representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exactness, tolerance-budget exactness, explicit modulus ledger coverage, RegSeqRat handoff, LocatedReal comparison stability, transport replay, provenance, and nonescape for BEDC.Derived.LawlikeCauchyModulusUp.

Chapter 8054

A Concrete Naming Certificate for $\mathsf{InfimalConvolution}^{\uparrow}$

Following Rockafellar's convex analysis and the Boyd–Vandenberghe finite convex-optimization presentation, the $\mathsf{InfimalConvolution}^{\uparrow}$ packet records the binary lower-envelope operation by displayed epigraph, value-window, and Fenchel handoff rows. It separates the lower-envelope certificate consumed by the Moreau envelope chapter chapter 7622 from the proximal smoothing packet itself, while staying anchored in the convex source of chapter 208, the convex-conjugate boundary of chapter 3563, the Fenchel duality ledger of chapter 321, the Fenchel–Young inequality surface of chapter 7804, and the terminal real-name seal of chapter 38. The carrier names finite candidate decompositions and lower-bound comparisons; it is not a host infimum operator, selected minimizer, quotient function space, or ambient lower-semicontinuity theorem.

Definition 8054.1 (Infimal convolution carrier)**.** *An* $\mathsf{InfimalConvolution}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, G, X, V, L, D, Y, E, H, C, P, N)$$

with the following displayed rows:

1. *F and G are the two source function rows, each read through finite domain, value, and convexity observations.*
2. *X is the split-variable window, listing the displayed decompositions $x = u + v$ that are available to the lower-envelope read.*
3. *V is the value-sum ledger, recording the visible rows $F(u)$, $G(v)$, and $F(u) + G(v)$ for each displayed split.*
4. *L is the lower-bound ledger, recording finite comparison rows that any proposed lower envelope must satisfy against the displayed value sums.*
5. *D is the* $\mathsf{ConvexConjugate}^{\uparrow}$ *and* $\mathsf{FenchelDuality}^{\uparrow}$ *handoff row, exposing the conjugate and dual comparison data visible at the same split window.*
6. *Y is the* $\mathsf{FenchelYoungInequality}^{\uparrow}$ *row, recording the local inequality witnesses used when a downstream Fenchel consumer reads the lower-envelope packet.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for value readback, reachable only after F, G, X, V, L, D, Y have been displayed.*

8. *H records componentwise* hsame *transport for the source functions, split window, value ledger, lower-bound ledger, Fenchel handoff, inequality row, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from source-function admission through split inspection, value-sum comparison, lower-bound readback, Fenchel handoff, and real-seal export.*
10. *P is the* Pkg *provenance over* $\mathsf{InfimalConvolution}^{\uparrow}$, $\mathsf{MoreauEnvelope}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{FenchelYoungInequality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{InfimalConvolution}^{\uparrow}}$ *row.*

The accepted carrier compares lower-envelope reads only through these rows. It has no coordinate for an arbitrary host infimum, a selected minimizing split, quotient equality of functions, global lower-semicontinuous hulls, or ambient convex completeness.

Theorem 8054.2 (Infimal convolution NameCert obligations)**.** *For the carrier of Definition 8054.1, the local* $\mathsf{NameCert}_{\mathsf{InfimalConvolution}^{\uparrow}}$ *surface consists exactly of carrier admission for $I = (F, G, X, V, L, D, Y, E, H, C,$ source-function exposure, split-window exposure, value-sum ledger exactness, lower-bound comparison, Fenchel handoff visibility, Fenchel–Young inequality replay,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed continuation replay, package provenance, and local naming. Every accepted lower-envelope read factors through*

$$F, G \longmapsto X \longmapsto V \longmapsto L \longmapsto E$$

with D, Y, H, C, P, N attached as Fenchel, inequality, transport, replay, provenance, and naming rows.

Proof. Project the accepted carrier. The source-function rows are F and G, and the only displayed decompositions are those listed in the split window X.

The value-sum row V is therefore the first lower-envelope ledger a consumer can inspect. The lower-bound row L compares proposed envelope data only against the sums already displayed by V, and the real seal E is downstream of those same rows.

The Fenchel-facing rows do not add an alternate envelope. The handoff D and inequality row Y replay conjugate and Fenchel–Young evidence at the same split window, while H, C, P, N transport, replay, source, and name the same finite packet. Since no row stores a host infimum, selected minimizing split, quotient function equality, global lower-semicontinuous hull, or ambient convex-completeness object, the listed rows exhaust the local NameCert obligations. □

Theorem 8054.3 (Infimal convolution Fenchel handoff)**.** *Every* $\mathsf{ConvexConjugate}^{\uparrow}$, $\mathsf{FenchelDuality}^{\uparrow}$, $\mathsf{FenchelYoungInequality}^{\uparrow}$, *or* $\mathsf{MoreauEnvelope}^{\uparrow}$ *consumer of an accepted* $\mathsf{InfimalConvolution}^{\uparrow}$ *carrier must first read the source rows F, G, the split-variable window X, the value-sum ledger V, and the lower-bound ledger L before it consumes the Fenchel handoff row D, inequality row Y, or terminal* $\mathsf{Real}^{\uparrow}$ *seal E. The handoff is a finite lower-envelope route, not a host optimization theorem or selected minimizing decomposition.*

Proof. Start with the local obligations of Definition 8054.2. They force every lower-envelope read through the displayed source rows, split window, value-sum ledger, and lower-bound ledger.

Now read the Fenchel-facing side. The row D exposes only conjugate and dual comparison data attached to the same split window, and the row Y exposes only the corresponding Fenchel–Young witnesses. A $\mathsf{MoreauEnvelope}^{\uparrow}$ consumer can cite this packet only after that lower-envelope route has been displayed, so smoothing data cannot replace the binary lower-envelope certificate.

Finally pass to the real seal. The seal E is reached after F, G, X, V, L, D, Y, and the structural rows H, C, P, N preserve that route under transport and replay. Hence the downstream Fenchel and Moreau consumers receive exactly the finite handoff displayed by the carrier and no host optimization, selected minimizer, quotient function equality, or ambient convex-completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{InfimalConvolution}^{\uparrow}}$.

Constructive story: An $\mathsf{InfimalConvolution}^{\uparrow}$ packet is generated from two source function rows, a split-variable window, a value-sum ledger, a lower-bound ledger, ConvexConjugate and FenchelDuality handoff rows, a FenchelYoungInequality row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InfimalConvolution}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8054.1, Definition 8054.2, and Definition 8054.3 seed the finite binary lower-envelope certificate consumed by MoreauEnvelopeUp, ConvexConjugateUp, FenchelDualityUp, FenchelYoungInequalityUp, and RealUp routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InfimalConvolution}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, selected minimizers, quotient function equality, global lower-semicontinuous hulls, host infimum operators, or ambient convex completeness.

Upgrade path: Formal verification can encode carrier admission, split-window exposure, value-ledger exactness, lower-bound comparison, Fenchel handoff, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.InfimalConvolutionUp.

Chapter 8055

A Concrete Naming Certificate for $\mathsf{MetricEntropy}^{\uparrow}$

Following Kolmogorov–Tikhomirov metric entropy and Bishop-style finite nets, the $\mathsf{MetricEntropy}^{\uparrow}$ packet records the finite covering-number ledger attached to an inspected metric or compact metric carrier. It sits after the metric source of chapter 57, the compact metric source of chapter 129, the totally bounded finite-net route of chapter 127, the finite net surface of chapter 1767, the rational tolerance boundary of chapter 37, and the terminal real-name readback of chapter 38. The packet is a finite cover-count carrier for later compactness, dimension, and entropy estimates; it does not import open-cover compactness, selected subcovers, quotient real equality, or ambient completeness.

Definition 8055.1 (Metric entropy carrier)**.** *A* $\mathsf{MetricEntropy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, \varepsilon, N, C, M, H, K, P, L)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, or the* $\mathsf{CompactMetric}^{\uparrow}$ *source row when the entropy ledger is read over a compact carrier.*
2. *ε is a positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row, recording the scale at which finite covering data is inspected.*
3. *N is the finite* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, displaying the centers and coverage witnesses used at scale ε.*
4. *C is the cover-count ledger, recording the finite number of displayed centers and the associated covering-number bound.*
5. *M is the monotonicity transport row, recording how a cover at a smaller inspected tolerance supplies a cover-count upper bound at a larger inspected tolerance over the same metric source.*
6. *H records componentwise* hsame *transport for the metric source, tolerance, net, cover-count ledger, monotonicity transport, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from a metric-entropy request through $X, \varepsilon, N, C, M, H$.*
8. *P is the* Pkg *provenance over* $\mathsf{MetricEntropy}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{MetricEntropy}^{\uparrow}}$ *row naming exactly this finite cover-count ledger.*

The classifier compares accepted packets only through these rows. It has no coordinate for Hausdorff measure, box dimension, selected subcovers, open-cover compactness, quotient real equality, or ambient completeness.

Lean4 ✓ `BEDC.Derived.MetricEntropyUp.TasteGate.MetricEntropyTasteGate single carrier alignment`

Theorem 8055.2 (Metric entropy NameCert obligations)**.** *For every accepted* $\mathsf{MetricEntropy}^{\uparrow}$ *carrier*

$$E = (X, \varepsilon, N, C, M, H, K, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetricEntropy}^{\uparrow}}$ *surface consists exactly of carrier admission, metric or compact-metric source visibility, positive rational scale visibility, finite epsilon-net coverage, cover-count ledger visibility, monotonicity transport, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every metric-entropy consumer must pass through* $X, \varepsilon, N, C, M, H, K, P, L$ *before it reads a finite cover count.*

Proof. Carrier admission is projection from Definition 8055.1. The rows X, ε, N, C expose the metric source, inspected positive scale, displayed finite net, and finite cover-count ledger.

The row M records the only monotonicity route supplied by the carrier. It transports cover-count bounds between inspected rational scales over the same metric source, but it does not select additional centers or invoke open-cover compactness.

The rows H, K, P, L preserve, replay, source, and name the same finite route. Since the carrier has no coordinate for Hausdorff measure, box dimension, selected subcovers, quotient real equality, or ambient completeness, these rows exhaust the local NameCert obligation surface. □

Theorem 8055.3 (Metric entropy finite-cover monotonicity)**.** *Let*

$$E = (X, \varepsilon, N, C, M, H, K, P, L)$$

be an accepted $\mathsf{MetricEntropy}^{\uparrow}$ *carrier. Any consumer that compares cover counts at two displayed positive rational scales over the same* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *source must read the comparison through the monotonicity row* M *after exposing the source row* X*, the inspected scale row* ε*, the finite net row* N*, and the cover-count ledger* C*. The comparison cannot be derived from an unlisted compactness selector, a quotient real equality rule, or ambient completeness.*

Proof. Read X and ε first. These rows identify the metric source and the positive rational scale at which the finite cover is being counted.

Read N and C next. The finite net row displays the centers and coverage witnesses, while the ledger row records the finite number attached to that displayed cover.

The only carrier row that relates two displayed scales is M. Transport through H and replay through K preserve this same comparison, and P, L source and name it. Therefore every finite-cover monotonicity read factors through the listed rows and cannot use unlisted compactness or real-equality data. □

Falsifiable prediction: An accepted $\mathsf{MetricEntropy}^{\uparrow}$ consumer that reads a cover count without first displaying the metric source, positive rational scale, finite epsilon-net row, cover-count ledger, and monotonicity transport refutes the carrier surface.

Independence witness: metric, compactmetric, totallybounded, finite-epsilon-net, rat, real: no listed sibling is bijective with $\mathsf{MetricEntropy}^{\uparrow}$ because this packet jointly carries metric or compact-metric source data, a positive rational scale, a displayed finite net, a finite cover-count ledger, monotonicity transport, replay, provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricEntropy}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricEntropy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8055.1, Definition 8055.2, and Definition 8055.3 seed the finite cover-count route over metric and compact metric carriers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricEntropy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Hausdorff measure, box dimension, selected subcovers, open-cover compactness, quotient real equality, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, scale visibility, finite-net coverage, cover-count ledger visibility, monotonicity transport, replay, provenance, and local naming for BEDC.Derived.MetricEntropyUp.

Constructive story: A $\mathsf{MetricEntropy}^{\uparrow}$ packet is generated from MetricUp or CompactMetricUp source data, a positive RatUp scale, FiniteEpsilonNetUp coverage rows, a finite cover-count ledger, monotonicity transport, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8056

A Concrete Naming Certificate for $\mathsf{MinCostFlow}^{\uparrow}$

Following Ahuja, Magnanti, and Orlin, the $\mathsf{MinCostFlow}^{\uparrow}$ packet records the finite minimum-cost network-flow certificate surface. It sits after the feasible-flow rows of chapter 233, the residual shortest-path and potential discipline of chapter 236, and the primal-dual comparison ledger of chapter 235. The packet names displayed capacity, conservation, cost, residual-potential, dual-certificate, transport, replay, provenance, and local naming rows; it is not a host optimizer, selected optimal flow, unbounded graph search, or ambient linear-programming oracle.

Definition 8056.1 (Minimum-cost flow carrier)**.** *A* $\mathsf{MinCostFlow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, U, B, K, F, R, D, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{NetworkFlow}^{\uparrow}$ *source row, carrying the directed graph, source and sink endpoints, and finite edge inventory.*
2. *U is the capacity row, recording displayed lower and upper capacity bounds on each inspected edge.*
3. *B is the conservation row, recording the finite supply, demand, and balance equations for the displayed vertices.*
4. *K is the integer or rational cost ledger, attaching a cost row to each displayed edge and naming the total-cost accumulator.*
5. *F is the feasible-flow row, exposing edge-flow values that obey U and B through the* $\mathsf{NetworkFlow}^{\uparrow}$ *route.*
6. *R is the residual shortest-path and potential row, read through* $\mathsf{ShortestPath}^{\uparrow}$ *and recording reduced-cost comparisons on the displayed residual arcs.*
7. *D is the* $\mathsf{LPDuality}^{\uparrow}$ *certificate row, pairing the primal feasible flow with displayed dual potentials, slack rows, and complementary tightness checks.*
8. *H records componentwise* hsame *transport for network source, capacity, conservation, cost, feasible-flow, residual-potential, dual-certificate, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a minimum-cost-flow query through G, U, B, K, F, R, D, H.*

10. *P is the* Pkg *provenance over* $\mathsf{MinCostFlow}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{ShortestPath}^{\uparrow}$, $\mathsf{LPDuality}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MinCostFlow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected optimal flow, a host simplex method, an unrestricted residual search, quotient equality of flows, or an ambient existence theorem for arbitrary instances.

Theorem 8056.2 (Minimum-cost flow NameCert obligations)**.** *For every accepted* $\mathsf{MinCostFlow}^{\uparrow}$ *carrier* $M = (G, U, B, K, F, R, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MinCostFlow}^{\uparrow}}$ *surface consists exactly of network-flow source admission through* G*, capacity exposure through* U*, conservation exposure through* B*, integer or rational cost-ledger exposure through* K*, feasible-flow exposure through* F*, residual shortest-path and potential exposure through* R*,* $\mathsf{LPDuality}^{\uparrow}$ *certificate exposure through* D*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8056.1. The source, capacity, conservation, cost, feasible-flow, residual-potential, and dual-certificate data are exactly G, U, B, K, F, R, D.

The feasible-flow row is read only after the capacity and conservation rows. Thus the packet cannot detach a flow value from the displayed $\mathsf{NetworkFlow}^{\uparrow}$ source or from the finite balance ledger.

The residual shortest-path and potential row R then records the reduced-cost boundary used by improvement and non-improvement consumers, while D records the corresponding primal-dual certificate through $\mathsf{LPDuality}^{\uparrow}$. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since no carrier coordinate stores a selected optimizer, host residual oracle, quotient flow equality, or ambient existence theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 8056.3 (Minimum-cost flow LP-duality handoff)**.** *Every optimality-facing consumer of an accepted* $\mathsf{MinCostFlow}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{NetworkFlow}^{\uparrow},\ \mathsf{ShortestPath}^{\uparrow},\ \mathsf{LPDuality}^{\uparrow} \longmapsto G, U, B, K, F, R, D, H, C, P, N.$$

The handoff supplies a displayed feasible flow, cost ledger, residual shortest-path or potential row, and primal-dual certificate row. It does not assert existence of an optimal flow beyond the displayed certificate, does not choose an optimizer for every network, and does not export a host linear-programming theorem outside the finite rows.

Proof. Begin with Definition 8056.2. A consumer must expose G, U, B, K, F before any optimality row can be inspected, so feasibility remains attached to the displayed network-flow source.

Next read R through the residual shortest-path surface. This row records the inspected residual arcs and potentials, not an unrestricted shortest-path oracle over an ambient graph.

Finally read the dual-certificate row D. It packages the $\mathsf{LPDuality}^{\uparrow}$ comparison and complementary tightness checks for the same displayed rows G, U, B, K, F, R. Transport, replay, provenance, and local naming through H, C, P, N preserve that route, so the handoff is a finite certificate and not a global optimizer-existence claim. □

Falsifiable prediction: A purported $\mathsf{MinCostFlow}^{\uparrow}$ consumer is refuted if it reads a cost-optimality conclusion while omitting any of the displayed network source, capacity, conservation, cost, feasible-flow, residual-potential, LP-duality, transport, replay, provenance, or local NameCert rows.

Independence witness: networkflow, shortestpath, lpduality: none is bijective to $\mathsf{MinCostFlow}^{\uparrow}$ because this packet jointly carries feasible-flow, cost-ledger, residual-potential, LP-duality, transport, replay, provenance, and local NameCert rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{MinCostFlow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MinCostFlow}^{\uparrow}$ packet is generated from NetworkFlowUp source rows, capacity rows, conservation rows, integer or rational cost ledgers, feasible-flow rows, residual shortest-path and potential rows, LPDualityUp certificate rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MinCostFlow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8056.1, Definition 8056.2, and Definition 8056.3 seed the finite minimum-cost-flow certificate over feasible-flow, cost, residual-potential, dual-certificate, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MinCostFlow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close optimal-flow existence beyond the displayed finite certificate, selected optimizers for arbitrary networks, unrestricted residual search, quotient equality of flows, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, capacity exposure, conservation exposure, cost-ledger exactness, feasible-flow exposure, residual-potential ordering, LP-duality certificate exposure, transport, replay, provenance, and local naming for BEDC.Derived.MinCostFlowUp.

Chapter 8057

A Concrete Naming Certificate for MetaCICBoundedNormalEqualityBudget$^{\uparrow}$

The MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ packet realizes the bounded normal-equality checker frontier of chapter 9379 as finite MetaCIC NameCert data. It packages the `normalizeBounded` fuel ledger and the `decideClosedBetaConv` comparison row before a consumer may interpret bounded normal-form equality. The packet sits beside the bounded checker surface of chapter 752, the fuel trace of chapter 3889, the neutral-spine route of chapter 3909, the decidable boundary of chapter 749, and the bounded normal-equality frontier of chapter 6947. It is a finite budget object, not a global closed beta-conversion decider, fuel-erased normalizer, subject-reduction theorem, or kernel-consistency principle.

Definition 8057.1 (MetaCIC bounded normal-equality budget carrier)**.** *A* MetaCICBoundedNormalEqualityBudget *carrier is a finite* BHist *packet*

$$B = (T, F, N, E, Q, R, H, C, P, L)$$

with the following displayed rows:

1. *T is the closed typed-term window row naming the two inspected terms, their common type boundary, and the finite context read by the checker.*
2. *F is the fuel ledger for `normalizeBounded`, recording the displayed bound and every consumed reduction step.*
3. *N is the bounded normal-form output row, carrying the two computed normal-form candidates at the displayed fuel.*
4. *E is the endpoint row, recording finished-normal evidence when the bounded comparison is allowed to become a finished-normal statement.*
5. *Q is the `decideClosedBetaConv` answer row for the two bounded normal-form candidates.*
6. *R is the refusal row retained when the endpoint evidence is absent or the consumer asks for fuel-erased conversion decidability.*
7. *H records componentwise* hsame *transport for typed windows, fuel, bounded normal outputs, endpoints, comparison answers, refusal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded normal-equality query through T, F, N, E, Q, R, H.*

9. *P is the* Pkg *provenance over* MetaCICBoundedNormalEqualityBudget$^{\uparrow}$, BoundedNormalEqualityChecker$^{\uparrow}$, MetaCICFuelTrace$^{\uparrow}$, MetaCICDecidableNeutralSpine$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, BoundedNormalEqualityFront BHist, hsame, Cont, *and* NameCert.

10. *L is the local* NameCert$_{\text{MetaCICBoundedNormalEqualityBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, F, N, E, Q, R, H, C, P, L$. It has no coordinate for unbounded conversion decidability, fuel-erased normalization, subject reduction, confluence, quotient syntax equality, or MetaCIC kernel consistency.

Theorem 8057.2 (MetaCIC bounded normal-equality budget obligations)**.** *For every accepted* MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ *carrier $B = (T, F, N, E, Q, R, H, C, P, L)$, the local* NameCert$_{\text{MetaCICBounded}}$ *surface consists exactly of typed-window exposure through T, fuel-ledger exposure through F, bounded normal-form output exposure through N, endpoint exposure through E, bounded comparison exposure through Q, refusal retention through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8057.1. The computational rows are T, F, N, E, Q, R, and the structural rows are H, C, P, L.

The bounded normalizer is read through F before the normal-output row N is exposed. This keeps each output attached to the displayed fuel rather than to a fuel-erased normalizer.

The comparison answer Q can be consumed as finished normal equality only through the endpoint row E. If that endpoint is absent, the refusal row R remains part of the exported packet. Transport, replay, provenance, and local naming then preserve exactly the displayed rows. □

Theorem 8057.3 (MetaCIC bounded normal-equality nonescape)**.** *An accepted* MetaCICBoundedNormalEqualityBu *packet cannot export global closed beta-conversion decidability, unrestricted normalization, subject reduction, confluence, quotient syntax equality, or MetaCIC kernel consistency. Any consumer of the checker result must keep the typed window, fuel ledger, bounded normal-form outputs, endpoint row, comparison answer, refusal row, transport, replay, provenance, and local NameCert rows visible.*

Proof. Use Definition 8057.2. Every checker read is confined to $T, F, N, E, Q, R, H, C, P, L$.

The rows F, N, Q are bounded computation rows. The endpoint row E may license a finished-normal statement for the displayed terms, while R records the refused endpoints when that evidence is missing.

None of the rows stores a fuel-erased normalizer, subject-reduction discharge, confluence proof, quotient syntax equality, or kernel-consistency witness. The structural rows preserve the same packet, so the refused endpoints cannot be produced by replay or provenance. □

The Lean TasteGate route for MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ must provide explicit Nontrivial MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ and FieldFaithful MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ instances. These instances must keep $T, F, N, E, Q, R, H, C, P, L$ as separate fields before any checked carrier-alignment theorem can serve a decidability-facing consumer.

Falsifiable prediction: A purported MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ consumer is refuted if it exports closed beta-conversion while omitting the displayed typed window, normalizeBounded fuel ledger, bounded normal-form outputs, decideClosedBetaConv answer, endpoint row, refusal row, transport, replay, provenance, or local NameCert row.

Independence witness: bounded-normal-equality-checker, metacic-fuel-trace, metacic-decidable-neutral-spine, metacicdecidableboundary, bounded-normal-equality-frontier: none is bijective to

MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ because this packet jointly carries typed windows, normalizeBounded fuel, bounded normal outputs, endpoint evidence, decideClosedBetaConv answers, refusal, transport, replay, provenance, and local NameCert rows.

Closure status for NameCert$_{\text{MetaCICBoundedNormalEqualityBudget}^{\uparrow}}$ ·

Constructive story: A MetaCICBoundedNormalEqualityBudget$^{\uparrow}$ packet is generated from closed typed-term windows, normalizeBounded fuel ledgers, bounded normal-form output rows, endpoint rows, decideClosedBetaConv answer rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICBoundedNormalEqualityBudget}^{\uparrow}}$, seed)

Scope closed: Definition 8057.1, Definition 8057.2, and Definition 8057.3 seed the finite bounded normal-equality budget object over typed windows, fuel, endpoint, comparison, refusal, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICBoundedNormalEqualityBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global closed beta-conversion decidability, fuel-erased normalization, subject reduction, confluence, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, normalizeBounded fuel exactness, bounded normal-form output exposure, endpoint exposure, decideClosedBetaConv answer exactness, refusal retention, TasteGate nontriviality, and field faithfulness for BEDC.Derived.MetaCICBoundedNormalEqualityBudgetUp.

Chapter 8058

A Concrete Naming Certificate for $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$

Following Bourbaki and Kelley on metric and uniform-space terminology, the $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$ packet records the finite certificate by which a metric space with a displayed positive separation radius presents a uniform-space entourage base. It sits between the metric carrier of chapter 57, the uniform-space interface of chapter 339, the entourage-base route of chapter 1819, and the dyadic and real-name corridor of chapter 291, chapter 126, chapter 301, and chapter 38. The chapter names a finite metric-to-uniformity certificate; it does not assert quotient equality, countable choice, selected completions, or ambient Real completeness.

Definition 8058.1 (UniformlyDiscreteSpace carrier)**.** *A* $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row whose distance comparisons and point rows are exposed before any uniform-space read is public.*
2. *R is a positive dyadic separation radius read through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and sealed by the displayed* $\mathsf{Real}^{\uparrow}$ *tolerance route.*
3. *E is the* $\mathsf{EntourageBase}^{\uparrow}$ *and* $\mathsf{UniformSpace}^{\uparrow}$ *handoff row generated by the condition that distinct displayed points are separated by the radius R.*
4. *H records componentwise* hsame *transport for the metric source, radius, entourage-base handoff, and structural rows.*
5. *C records displayed* Cont *replay from metric comparisons through dyadic radius exposure and the uniformity handoff.*
6. *P is the* Pkg *provenance over* $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient metric equality, a hidden selector of apart points, countable choice, selected completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8058.2 (UniformlyDiscreteSpace NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$ *carrier* $U = (M, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteSpace}^{\uparrow}}$ *surface consists exactly of carrier admission, positive-radius exposure, metric separation, uniformity handoff, transport and replay stability, provenance, local naming, and nonescape from the displayed rows.*

Proof. Project the carrier of Definition 8058.1. Carrier admission exposes the metric source M, the positive dyadic radius R, the entourage-base handoff E, and the structural rows H, C, P, N.

Positive-radius exposure is read from R. Since R is a dyadic tolerance row sealed through the Real-name route, the packet exposes a finite separation budget rather than a host real parameter.

Metric separation and the uniformity handoff are read in order. The metric row M supplies the displayed distance comparisons, and E packages the radius-separated diagonal boundary as an $\mathsf{EntourageBase}^{\uparrow}$ row for $\mathsf{UniformSpace}^{\uparrow}$ consumers.

Transport through H and replay through C preserve the same route, while P and N record provenance and local naming. No further row stores quotient equality, countable choice, selected completions, or ambient Real completeness, so the listed obligations exhaust the local certificate. □

Theorem 8058.3 (UniformlyDiscreteSpace uniformity handoff)**.** *Every* $\mathsf{UniformSpace}^{\uparrow}$*-facing read of an accepted* $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{Met}^{\uparrow} \to \mathsf{DyadicRatCore}^{\uparrow} \to \mathsf{EntourageBase}^{\uparrow} \to \mathsf{StreamName}^{\uparrow} \to \mathsf{RegSeqRat}^{\uparrow} \to \mathsf{Real}^{\uparrow}$$

together with the displayed hsame*,* Cont*,* Pkg*, and* NameCert *rows. The handoff exports only the radius-separated metric entourage base and never supplies quotient equality, countable choice, selected completion, or ambient Real completeness.*

Proof. Start with the carrier rows M, R, E, H, C, P, N. A uniform-space consumer can read E only after the metric row M and the positive dyadic radius row R have been displayed.

The dyadic tolerance route named by R is the only numerical boundary available to the packet. Its StreamName, RegSeqRat, and Real seals provide the finite readback path for the radius, while E packages that readback as an entourage-base handoff.

The structural rows preserve the same path for downstream consumers. Thus every uniformity-facing read factors through the metric source, dyadic radius, entourage base, finite name route, Real seal, transport, replay, provenance, and local naming rows, with no hidden completion or quotient principle attached. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyDiscreteSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyDiscreteSpace}^{\uparrow}$ packet is generated from a MetricUp source row, a positive DyadicRatCore separation radius, an EntourageBase and UniformSpace handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformlyDiscreteSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8058.1, Definition 8058.2, and Definition 8058.3 seed the metric-to-uniformity certificate for a displayed positive separation radius.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformlyDiscreteSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient metric equality, countable choice, selected completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius exposure, metric separation, uniformity handoff, transport replay, provenance, local naming, and nonescape for BEDC.Derived.UniformlyDiscreteSpaceUp.

Chapter 8059

A Concrete Naming Certificate for $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed monotone cofinal subsequence carries the same regular Cauchy and Real-facing data as its source. It sits over the regular rational readback of chapter 301, the finite observation surface of chapter 126, the dyadic tolerance ledger of chapter 291, the tail-shift route of chapter 1578, and the terminal seal of chapter 38. The packet is a finite subsequence criterion for Real and Completion consumers; it does not choose a subsequence by countable choice, quotient streams, selected limits, host sequence equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8059.1 (RegularCauchySubsequenceCriterion carrier)**.** *A* $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, M, W, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row carrying the regular rational readback of the original name.*
2. *M is the monotone cofinal subsequence schedule, recording the finite source indices inspected for each subsequence window.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger comparing source windows with subsequence windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger transported from source windows to subsequence windows.*
5. *T is the* $\mathsf{RegularCauchyShift}^{\uparrow}$ *tail route that witnesses discarded prefixes before the subsequence readback is exposed.*
6. *R is the resulting* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the subsequence window.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, M, W, D, T, R are displayed.*
8. *H records componentwise* hsame *transport for all carrier rows.*
9. *C records displayed* Cont *replay of the same finite route.*
10. *P records* Pkg *provenance over* $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyShift}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}}$ *row.*

The classifier reads only $S, M, W, D, T, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a selected infinite subsequence, host sequence equality, a chosen limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8059.2 (RegularCauchySubsequenceCriterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$ *carrier $K = (S, M, W, D, T, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}}$ *surface consists exactly of the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row S, monotone cofinal schedule M, finite* $\mathsf{StreamName}^{\uparrow}$ *comparison windows W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{RegularCauchyShift}^{\uparrow}$ *tail route T, subsequence* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, terminal* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, continuation replay C, provenance P, and local naming row N.*

Proof. Project the accepted carrier of Definition 8059.1. Each row named in the statement is a displayed coordinate, and the definition lists no hidden coordinate for quotient streams, selected subsequences, or completion objects.

The analytic part of the criterion is the finite chain S, M, W, D, T, R, E. The source regular readback S is compared with subsequence windows by M and W, dyadic tolerances are transported by D, discarded prefixes are recorded by T, and the subsequence readback R is sealed by E.

The structural rows H, C, P, N transport, replay, source, and name the same finite chain. Since the carrier has no row for countable choice, host sequence equality, selected limits, quotient stream equality, or ambient Real completeness, none of those endpoints can enter the local NameCert surface. □

Theorem 8059.3 (RegularCauchySubsequenceCriterion Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$ *carrier must first read the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row, monotone cofinal schedule, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{RegularCauchyShift}^{\uparrow}$ *tail route, and subsequence* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the seal row E is exposed. Thus the criterion hands a cofinal subsequence to the Real route as finite displayed data, without quotient streams, selected subsequences, countable choice, selected limits, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a request for the Real seal. By the carrier definition, E is not available directly from the source row; it is reached only after S, M, W, D, T, R have been inspected.

The subsequence part is finite. The schedule M names the source indices for the displayed windows, W records the compared observations, and D carries the dyadic tolerances needed to preserve regularity along those windows.

The tail route T then records the finite shift discipline before R is read as a regular rational subsequence row. Only after this route is displayed can E be consumed as the terminal $\mathsf{Real}^{\uparrow}$ seal.

Transport, replay, provenance, and local naming preserve this same order. Because no carrier row stores quotient stream equality, a selected subsequence functional, a selected limit, host equality, countable choice, or Real completeness, the handoff cannot export those data. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}$ packet is generated from a source RegSeqRat row, monotone cofinal schedule, StreamName comparison windows, DyadicRatCore tolerance ledger, RegularCauchyShift tail route, subsequence RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchySubsequenceCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8059.1, Definition 8059.2, and Definition 8059.3 bind the finite subsequence criterion over RegSeqRat, StreamName, DyadicRatCore, RegularCauchyShift, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchySubsequenceCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected infinite subsequences, countable choice, selected limits, host sequence equality, host real equality, ambient Real completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, the NameCert obligation surface, the Real seal handoff, transport stability, and nonescape for BEDC.Derived.RegularCauchySubsequenceCriterionUp.

Chapter 8060

A Concrete Naming Certificate for $\mathsf{LpSpace}^{\uparrow}$

Following Bishop's constructive analysis and the Riesz tradition for normed function spaces, the $\mathsf{LpSpace}^{\uparrow}$ packet records the finite NameCert surface needed before later analysis chapters may use an L^p phrase. It depends on the measure carrier of chapter 92, the norm carrier of chapter 89, the vector-space carrier of chapter 47, the Banach-space boundary of **??**, and the real-number carrier of chapter 38.

Definition 8060.1 (Lp-space carrier)**.** *An* $\mathsf{LpSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, R, V, N, B, I, E, H, C, Q, A)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *row exposing the measurable substrate, finite measurable-window ledger, nonnegative measure readback, and local measure naming.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *row supplying nonnegative real bounds, rational comparison windows, and terminal real sealing for norm values.*
3. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row recording pointwise addition, scalar action, zero, and the finite compatibility witnesses used by simple-function representatives.*
4. *N is the* $\mathsf{Norm}^{\uparrow}$ *row exposing the candidate p-norm readback and its finite comparison witnesses.*
5. *B is the* $\mathsf{BanachSpace}^{\uparrow}$ *boundary row recording that any completeness read is routed through the displayed norm and Cauchy data rather than through an ambient completed quotient.*
6. *I is the finite integral-magnitude ledger over the measure row, recording simple-function windows and their nonnegative real bounds.*
7. *E is the exponent row recording the admitted p-slot, its comparison witnesses, and the refusal branch for exponent data outside the displayed range of the packet.*
8. *H records componentwise* hsame *transport for $M, R, V, N, B, I, E, C, Q, A$.*
9. *C records the displayed* Cont *routes by which measure, real bounds, vector operations, norm readback, completeness boundary, integral magnitude, exponent data, transport, provenance, and local naming are replayed.*

10. *Q is the* Pkg *provenance over* $\mathsf{LpSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{BanachSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

11. *A is the local* $\mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient completed L^p classes, almost-everywhere quotient equality, selected representatives, countable choice, ambient measure completion, or a host integration theorem outside the displayed finite ledger.

Lean4 ✓ `BEDC.Derived.LpSpaceUp.LpSpaceTasteGate single carrier alignment`

Theorem 8060.2 (Lp-space NameCert obligations)**.** *For the carrier of Definition 8060.1, the local* $\mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}$ *surface consists exactly of measure exposure through M, real-bound sealing through R, vector-operation exposure through V, norm readback through N, completeness-boundary routing through B, integral-magnitude exposure through I, exponent admission through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through Q, and local naming through A. Every downstream Sobolev, interpolation, Hausdorff–Young, martingale, or functional-analysis consumer must read those rows before treating an L^p phrase as a BEDC carrier.*

Lean4 ✓ `BEDC.Derived.LpSpaceUp.LpSpaceCarrier namecert obligations`

Proof. Project the accepted packet to its displayed rows. The rows M, R, V, N expose the measure, real-bound, vector-space, and norm coordinates, while B, I, E expose the completeness boundary, integral-magnitude ledger, and exponent admission row.

The remaining rows do not add hidden analytic power. Componentwise transport, continuation replay, provenance, and local naming only replay the displayed packet. Thus every accepted consumer receives exactly the listed NameCert obligations and no ambient quotient, selected representative, or external completion principle. □

Theorem 8060.3 (Lp-space norm readback handoff)**.** *Every accepted* $\mathsf{LpSpace}^{\uparrow}$ *norm read factors through the chain*

$$\mathsf{Measure}^{\uparrow},\quad \mathsf{Real}^{\uparrow},\quad \mathsf{VecSpace}^{\uparrow},\quad \mathsf{Norm}^{\uparrow},\quad \mathsf{BanachSpace}^{\uparrow},\quad \mathsf{Pkg},\quad \mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}.$$

The handoff records finite integral-magnitude windows and exponent comparison data before any norm value is read. It does not identify functions almost everywhere, choose quotient representatives, complete the measure space, invoke countable choice, or assert that the ambient L^p completion has been constructed.

Proof. Start with the carrier projection of Definition 8060.1. A norm read can reach N only after the measure row M, real-bound row R, vector row V, integral ledger I, and exponent row E have been displayed.

The Banach-space row B is a boundary marker for later completeness consumers, not a completed quotient object. It requires the same displayed norm and Cauchy-facing data before any completeness read can be routed.

Finally apply the structural rows H, C, Q, A. They transport and replay the finite packet, so the norm readback is a NameCert handoff from the listed carriers rather than an assertion of almost-everywhere quotient equality or ambient measure completion. □

Falsifiable prediction: An $\mathsf{LpSpace}^{\uparrow}$ consumer that reads an L^p norm while omitting the measure row, exponent row, integral-magnitude ledger, norm row, or local NameCert row refutes the packet.

Independence witness: measure, real, vecspace, norm, banachspace: non-bijection follows by row omission. $\mathsf{Measure}^{\uparrow}$ lacks vector operations and norm readback; $\mathsf{Real}^{\uparrow}$ lacks measure and exponent rows; $\mathsf{VecSpace}^{\uparrow}$ lacks integration and real-bound sealing; $\mathsf{Norm}^{\uparrow}$ lacks measure exposure and exponent admission; $\mathsf{BanachSpace}^{\uparrow}$ lacks the local finite integral-magnitude ledger and does not supply an almost-everywhere quotient carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}$.

Constructive story: An $\mathsf{LpSpace}^{\uparrow}$ packet is generated from measure, real-bound, vector-space, norm, Banach-boundary, integral-magnitude, exponent, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8060.1, Definition 8060.2, and Definition 8060.3 bind the finite Lp carrier, NameCert obligation surface, and norm-readback handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LpSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completed Lp classes, almost-everywhere quotient equality, selected representatives, countable choice, ambient measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligation coverage, norm-readback handoff, and field faithfulness for $M, R, V, N, B, I, E, H, C, Q, A$.

Chapter 8061

A Concrete Naming Certificate for $\mathsf{LovaszLocalLemma}^{\uparrow}$

Following Erdos–Lovasz on the Lovasz local lemma, the $\mathsf{LovaszLocalLemma}^{\uparrow}$ packet presents the finite bad-event dependency graph data over $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, and $\mathsf{FiniteBorelCantelli}^{\uparrow}$. It sits after the probability-space normalization rows of chapter 184, the finite-family independence rows of chapter 187, the random-variable preimage rows of chapter 185, and the finite exceptional-event ledger of chapter 7718. The packet is a finite dependency certificate for bad events; it does not import a completed measure algebra, countable choice, host product measure, selected avoiding assignment, or ambient compactness principle.

Definition 8061.1 (Lovasz local lemma carrier)**.** *A* $\mathsf{LovaszLocalLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (\Omega, E, D, R, A, B, I, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the finite probability-space normalization and event-complement surface.*
2. E *is the finite bad-event inventory, listing the displayed event rows whose simultaneous avoidance is being certified.*
3. D *is the finite dependency graph row, recording for each bad event the displayed neighbor list on which independence may fail.*
4. R *records the* $\mathsf{RandomVar}^{\uparrow}$ *rows whose cylinder or preimage events give the bad-event rows in* E*.*
5. A *is the avoidance request row, naming the finite conjunction of complements to be kept nonzero inside the packet.*
6. B *is the finite bound ledger, recording the displayed probability bounds and dependency-degree comparisons used by the local-lemma route.*
7. I *is the* $\mathsf{Independence}^{\uparrow}$ *ledger, certifying independence of each bad event from the finite outside-neighborhood family named by* D*.*
8. H *records componentwise* hsame *transport for the probability, event, dependency, random-variable, avoidance, bound, independence, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a local-lemma request through* $\Omega, E, D, R, A, B, I, H$.
10. *P is the* Pkg *provenance over* $\mathsf{LovaszLocalLemma}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{FiniteBorelCantelli}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LovaszLocalLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a completed probability space, a host dependency theorem, a global product-measure construction, a selected avoiding assignment, quotient event equality, or countable-choice data.

Lean4 (statement) `BEDC.Derived.LovaszLocalLemmaUp`

Theorem 8061.2 (Lovasz local lemma NameCert obligations)**.** *For every accepted* $\mathsf{LovaszLocalLemma}^{\uparrow}$ *carrier* $L = (\Omega, E, D, R, A, B, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LovaszLocalLemma}^{\uparrow}}$ *surface consists exactly of probability-space source admission through* Ω*, finite bad-event exposure through* E*, dependency-graph exposure through* D*, random-variable preimage exposure through* R*, avoidance request exposure through* A*, bound-ledger exposure through* B*, outside-neighborhood independence exposure through* I*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8061.1. The rows Ω, E, D, R, A, B, I expose the finite probability source, bad-event inventory, dependency graph, random-variable preimage data, avoidance request, bound ledger, and independence ledger before any avoidance-facing consumer can inspect the local certificate.

The dependency graph row D fixes the finite neighborhood for each bad event. Thus the independence row I can only certify independence from the named outside-neighborhood family, and it cannot be replaced by an unlisted host product-measure theorem.

The finite bound ledger B is read together with the finite exceptional-event discipline of $\mathsf{FiniteBorelCantelli}^{\uparrow}$. Transport through H, replay through C, provenance through P, and local naming through N preserve the same finite route. Since the carrier has no coordinate for completed measure, quotient event equality, selected avoiding assignments, or countable choice, the listed rows exhaust the NameCert surface. □

Falsifiable prediction: A purported $\mathsf{LovaszLocalLemma}^{\uparrow}$ consumer is refuted if it reaches an avoidance conclusion while omitting any of the displayed probability-space, bad-event, dependency-graph, random-variable, avoidance, bound, independence, transport, replay, provenance, or local NameCert rows.

Independence witness: probspace, independence, randomvar, finite-borel-cantelli: no listed sibling is bijective to $\mathsf{LovaszLocalLemma}^{\uparrow}$ because this packet jointly carries bad-event inventory, finite dependency graph, random-variable preimage rows, avoidance request, probability bounds, outside-neighborhood independence, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LovaszLocalLemma}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LovaszLocalLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8061.1 and Definition 8061.2 seed the finite bad-event dependency certificate over probability-space, random-variable, independence, finite exceptional-event, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LovaszLocalLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a completed measure algebra, host product-measure theorem, selected avoiding assignment, countable-choice principle, Lean-checked obligation theorem, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bad-event exposure, dependency-graph exposure, random-variable preimage exposure, avoidance request exposure, bound-ledger exactness, outside-neighborhood independence exposure, transport, replay, provenance, and local naming for BEDC.Derived.LovaszLocalLemmaUp.

Constructive story: A LovaszLocalLemma$^{\uparrow}$ packet is generated from ProbSpaceUp source data, finite bad-event rows, dependency graph rows, RandomVarUp preimage rows, an avoidance request, probability-bound rows, IndependenceUp outside-neighborhood rows, finite exceptional-event discipline, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8062

A Concrete Naming Certificate for $\mathsf{TrotterKato}^{\uparrow}$

Following Trotter and Kato on semigroup approximation, the $\mathsf{TrotterKato}^{\uparrow}$ packet records the finite generator-window obligations that a semigroup approximation route must expose before a downstream evolution, PDE, or operator-theoretic consumer reads convergence data. It sits after the semigroup composition surface of chapter 79, the bounded-operator and functional-analysis boundary of chapter 94, the compact or idealized operator rows of chapter 213, the terminal scalar readback of chapter 38, and the regular rational observation windows of chapter 301. The packet is a finite NameCert seed for generator and resolvent approximation; it does not assert an ambient Banach-space theorem, selected graph limits, quotient operator equality, or analytic completeness outside the displayed rows.

Definition 8062.1 (Trotter-Kato generator-window carrier)**.** *A* $\mathsf{TrotterKato}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, F, O, R, Q, G, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Semigroup}^{\uparrow}$ *composition row for the approximating evolution family and the limiting evolution row inspected by the consumer.*
2. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *source row, exposing the bounded-operator, domain-window, and graph-readback coordinates available to the approximation request.*
3. *O is the* $\mathsf{OperatorIdeal}^{\uparrow}$ *or compact-operator observation row used when the approximation is read through finite-rank, compact, or ideal-controlled windows.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the inspected rational time, resolvent, and graph-window tolerances.*
5. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the scalar error bounds and convergence budgets read from R.*
6. *G records the generator-window ledger: finite source-domain rows, finite graph comparison rows, and the displayed compatibility of approximating generators with the limiting generator window.*
7. *W records the resolvent-sequence window: finite resolvent probes, rational error budgets, and the handoff order by which resolvent convergence may be consumed.*

8. *H records componentwise* hsame *transport for the semigroup, functional-analysis, operator-ideal, rational-readback, Real-seal, generator-window, resolvent-window, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a Trotter-Kato approximation request through S, F, O, R, Q, G, W, H.*
10. *P is the* Pkg *provenance over* $\mathsf{TrotterKato}^{\uparrow}$, $\mathsf{Semigroup}^{\uparrow}$, $\mathsf{FunctionalAnalysis}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TrotterKato}^{\uparrow}}$ *row naming exactly this finite approximation packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host graph-limit theorem, selected core, quotient operator equality, global PDE well-posedness, or ambient Banach-space completeness.

Theorem 8062.2 (Trotter-Kato generator-window NameCert obligations)**.** *For every accepted* $\mathsf{TrotterKato}^{\uparrow}$ *carrier*

$$T = (S, F, O, R, Q, G, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TrotterKato}^{\uparrow}}$ *surface consists exactly of semigroup composition visibility, functional-analysis source visibility, operator-window visibility, regular rational readback, Real-seal error-budget visibility, generator-window compatibility, resolvent-sequence ordering, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every downstream semigroup, PDE, or operator approximation consumer must pass through $S, F, O, R, Q, G, W, H, C, P, N$ before it reads a Trotter-Kato approximation claim.*

Proof. Carrier admission is projection from Definition 8062.1. The rows S, F, O expose the semigroup source, functional-analysis boundary, and operator-window observations before any approximation claim is read.

The numeric side is read through R and Q. The regular rational windows provide the inspected tolerances and graph or resolvent budgets, and the Real seal records the scalar error bounds available to the consumer.

The approximation-specific rows are G and W. The generator-window ledger keeps finite source-domain and graph comparisons visible, while the resolvent-sequence window fixes the order in which resolvent probes may be handed to downstream consumers.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no row for a host graph-limit theorem, selected core, quotient operator equality, global PDE well-posedness, or ambient completeness, these displayed rows exhaust the local NameCert obligations. □

Theorem 8062.3 (Trotter-Kato resolvent-sequence handoff)**.** *Let*

$$T = (S, F, O, R, Q, G, W, H, C, P, N)$$

be an accepted $\mathsf{TrotterKato}^{\uparrow}$ *carrier. Any consumer that turns resolvent-sequence convergence into a semigroup approximation read must first expose the functional-analysis row F, the operator-window row O, the regular rational readback R, the Real-seal row Q, and the resolvent-sequence window W before it can read the semigroup row S as an evolution handoff. The route is a finite handoff through the displayed generator-window packet, not a selected limit operator or an ambient completeness argument.*

Proof. Read the analytic source rows first. The functional-analysis row F supplies the operator and domain-window boundary, while O supplies the compact or ideal-controlled observation surface available to the approximation request.

Next read the finite numeric windows. The row R gives regular rational access to the inspected resolvent and graph tolerances, and Q seals those scalar bounds as the Real-facing budget available to the consumer.

Now apply the carrier rows G and W. The generator-window ledger fixes the source-domain and graph comparisons, and the resolvent-sequence window orders the resolvent probes before any semigroup approximation endpoint is read.

Only after those rows are displayed may the consumer read S as the semigroup evolution handoff. Transport through H, replay through C, provenance through P, and naming through N preserve exactly that route and add no selected limit operator, quotient operator equality, PDE well-posedness theorem, or ambient completeness principle. □

Falsifiable prediction: An accepted $\mathsf{TrotterKato}^{\uparrow}$ consumer that reads semigroup approximation without displaying the semigroup row, functional-analysis row, operator-window row, rational readback, Real seal, generator-window ledger, resolvent-window ledger, transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: semigroup, functional-analysis, operator-ideal, regseqrat, real: no listed sibling is bijective with $\mathsf{TrotterKato}^{\uparrow}$ because this packet jointly carries semigroup composition, operator-source data, finite generator windows, resolvent-sequence ordering, rational readbacks, Real error seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TrotterKato}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TrotterKato}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8062.1, Definition 8062.2, and Definition 8062.3 seed the finite generator-window and resolvent-sequence route for Trotter-Kato approximation packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TrotterKato}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Trotter-Kato theorem, selected graph limits, quotient operator equality, PDE well-posedness, Lean verification, bridge checking, or ambient functional-analytic completeness.

Upgrade path: Obligation closure requires checked carrier admission, generator-window compatibility, resolvent-window ordering, rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TrotterKatoUp.

Constructive story: A $\mathsf{TrotterKato}^{\uparrow}$ packet is generated from SemigroupUp composition data, FunctionalAnalysisUp operator-source rows, OperatorIdealUp observation windows, RegSeqRatUp rational tolerance readbacks, RealUp scalar seals, finite generator-window ledgers, resolvent-sequence ledgers, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8063

A Concrete Naming Certificate for $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$ packet records the sequential closure surface used when a displayed regular Cauchy construction is read as a completion-facing real-name packet. It sits after the dyadic tolerance core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the effective completion route of chapter 5930. The packet names the finite sequential-closure obligations for Real and Completion consumers; it does not quotient Cauchy names, select a host limit, invoke countable choice, or assert ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8063.1 (BishopCompletionSequentialClosure carrier)**.** *A* $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, A, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic precision cells and comparison budgets inspected by the closure request.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that lists the observed positions of the Cauchy name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream window and dyadic tolerance data.*
4. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, S, R have been read.*
5. *E is the* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *completion-facing route row, recording that the same finite window and tolerance data are being consumed as a sequential closure handoff.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, stream schedule, regular readback, Real seal, effective completion route, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from dyadic tolerances and finite schedules through regular readback, Real sealing, and completion-facing closure use.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopCompletionSequentialClosure}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, S, R, A, E, H, C, P, N$. No row stores quotient stream equality, a selected representative, a host limit, countable choice, trichotomy, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8063.2 (BishopCompletionSequentialClosure obligations)**.** *For every accepted* BishopCompletionSequent *carrier*

$$B = (D, S, R, A, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionSequentialClosure}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance row, StreamName finite-window schedule, RegSeqRat readback, Real seal, EffectiveCauchyCompletion route, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The sequential-closure clause requires any completion-facing read to expose D, S, R before the Real seal A and completion route E are consumed. The non-escape clause excludes quotient Cauchy equality, selected host limits, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8063.1. Its displayed rows are exactly the dyadic tolerance data, finite StreamName schedule, RegSeqRat readback, Real seal, EffectiveCauchyCompletion route, and the structural rows H, C, P, N.

The sequential-closure route starts with D and S. These rows determine which dyadic budgets and observed positions are public before any regular rational or real-facing read is available.

The regular readback row R is then consumed before the terminal seal A. Only after this readback has displayed the same finite window and tolerance data may the completion-facing row E read the packet as a sequential closure handoff.

Transport through H, replay through C, and naming through P, N preserve the same displayed route. Since the carrier contains no quotient stream equality, selected representative, host limit, countable-choice row, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, every completion-facing consumer remains inside the finite certificate. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$ read is refuted if it reaches an $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer without displaying the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, $\mathsf{StreamName}^{\uparrow}$ finite-window schedule, $\mathsf{RegSeqRat}^{\uparrow}$ readback row, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: dyadicratcore, streamname, regseqrat, real, effective-cauchy-completion: $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic precision cells, finite stream windows, regular rational readback, a Real seal, an effective completion route, transport, replay, provenance, and local naming as one sequential closure packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionSequentialClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionSequentialClosure}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a Real seal, an EffectiveCauchyCompletion route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionSequentialClosure}^{\uparrow}}$, seed)

Scope closed: Definition 8063.1 and Definition 8063.2 seed the sequential closure route from dyadic finite windows and regular rational readback into Real and EffectiveCauchyCompletion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionSequentialClosure}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy equality, selected host limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, finite StreamName schedule exactness, RegSeqRat readback exactness, Real seal handoff, EffectiveCauchyCompletion routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionSequentialClosureUp.

Chapter 8064

A Concrete Naming Certificate for $\mathsf{RiemannSumCriterion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RiemannSumCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed family of tagged Riemann sums may be consumed as integration-facing data only after partition, mesh, sample, sum, refinement, rational readback, and Real sealing rows have appeared. It sits beside the Riemann-sum carrier of chapter 1615, the mesh discipline of chapter 7944, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite criterion carrier for constructive integration; it does not assert open-cover compactness, selected gauges, quotient equality of functions, host supremum principles, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8064.1 (Riemann sum criterion carrier)**.** *A* $\mathsf{RiemannSumCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (P, M, A, S, R, H, K, G, N)$$

with the following displayed rows:

1. *P is the partition row: a finite tagged-partition ledger whose adjacent interval endpoints are read through the Riemann-sum source.*
2. *M is the mesh row: a finite mesh-bound and refinement-budget record consumed from* $\mathsf{RiemannSumMesh}^{\uparrow}$*.*
3. *A is the sample row: the finite sample-point and evaluation-window data attached to the tagged partition.*
4. *S is the sum row: the finite Riemann-sum value ledger, with all scalar readbacks routed through* $\mathsf{RegSeqRat}^{\uparrow}$ *before any terminal* $\mathsf{Real}^{\uparrow}$ *seal is inspected.*
5. *R is the refinement row: the directed refinement comparison that records how a later partition may refine the displayed partition and preserve the inspected sum budget.*
6. *H records componentwise* hsame *transport for the partition, mesh, sample, sum, refinement, replay, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from an integration-facing request through P, M, A, S, R, H.*
8. *G is the* Pkg *provenance over* $\mathsf{RiemannSumCriterion}^{\uparrow}$*,* $\mathsf{RiemannSum}^{\uparrow}$*,* $\mathsf{RiemannSumMesh}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannSumCriterion}^{\uparrow}}$ *row naming exactly this finite criterion packet.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected limiting partition, quotient function equality, an open-cover compactness theorem, a host supremum, countable choice, or ambient real completeness.

Theorem 8064.2 (Riemann sum criterion NameCert obligations)**.** *For every accepted* $\mathsf{RiemannSumCriterion}^{\uparrow}$ *carrier*

$$C = (P, M, A, S, R, H, K, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannSumCriterion}^{\uparrow}}$ *surface consists exactly of partition visibility, mesh-bound visibility, sample-window visibility, finite sum readback, refinement comparison, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every downstream constructive-integration consumer must pass through* $P, M, A, S, R, H, K, G, N$ *before it reads a Riemann-sum criterion claim.*

Lean4 (statement) `BEDC.Derived.RiemannSumCriterionUp`

Proof. Carrier admission is projection from Definition 8064.1. The rows P, M, A expose the partition, mesh, and sample data before any integration-facing conclusion is read.

The numeric side is read through S. Its scalar observations are finite regular rational readbacks, and the terminal Real seal is available only after those readbacks have been displayed.

The refinement side is R. It records the finite comparison by which later tagged partitions refine the current packet and preserve the visible sum budget, without selecting an infinite refinement sequence.

Finally H, K, G, N transport, replay, source, and name the same finite route. Since the carrier contains no row for open-cover compactness, selected gauges, quotient equality of functions, host suprema, countable choice, or ambient completeness, these displayed rows exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{RiemannSumCriterion}^{\uparrow}$ consumer that reads a Riemann-sum criterion without displaying the partition, mesh, sample, finite sum, refinement, transport, replay, provenance, and local naming rows refutes the carrier surface.

Independence witness: riemannsum, riemann-sum-mesh, regseqrat, real: no listed sibling is bijective with $\mathsf{RiemannSumCriterion}^{\uparrow}$ because this packet jointly carries partition rows, mesh rows, sample rows, sum readbacks, refinement comparisons, regular rational observations, Real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannSumCriterion}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannSumCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8064.1 and Definition 8064.2 seed the finite Riemann-sum criterion route through partition, mesh, sample, sum, refinement, regular rational, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannSumCriterion}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close a host Riemann integration theorem, open-cover compactness, selected gauges, quotient function equality, countable choice, Lean theorem verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite partition and mesh exactness, sample-window visibility, sum readback, refinement comparison, regular rational and Real nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RiemannSumCriterionUp.

Constructive story: A $\mathsf{RiemannSumCriterion}^{\uparrow}$ packet is generated from RiemannSumUp partition data, RiemannSumMeshUp mesh budgets, finite sample windows, regular rational sum readbacks, terminal Real seals, finite refinement comparisons, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8065

A Concrete Naming Certificate for $\mathsf{FilterBasisConvergence}^{\uparrow}$

Following Kelley and Bourbaki on filters, bases, and convergence, the $\mathsf{FilterBasisConvergence}^{\uparrow}$ packet records the finite convergence-facing route that sits downstream of the filter-limit basis interface of chapter 3862. It exposes the same L10 completion corridor used by $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, but names the convergence request as finite BHist data rather than as quotient filters, ultrafilters, selected limits, countable choice, host equality, or ambient completeness.

Definition 8065.1 (FilterBasisConvergence carrier)**.** *A* $\mathsf{FilterBasisConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterLimitBasis}^{\uparrow}$ *row exposing the finite basis route already accepted by limit and completion consumers.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose accepted reads remain tied to displayed finite basis data.*
3. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *convergence-boundary row, read only after B and F have been displayed.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected by the convergence request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed convergence windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the readback at the requested precision.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after B, F, L, W, R, D have been replayed.*
8. *H records componentwise* hsame *transport for basis, filter, limit, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a convergence request through $B, F, L, W, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{FilterBasisConvergence}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FilterBasisConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, L, W, R, D, E, H, C, P, N$. There is no coordinate for quotient filters, ultrafilters, selected limits, countable-choice schedules, host filter equality, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8065.2 (FilterBasisConvergence NameCert obligations)**.** *For every accepted* $\mathsf{FilterBasisConvergence}^{\uparrow}$ *carrier $K = (B, F, L, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FilterBasisConvergence}^{\uparrow}}$ *surface consists exactly of these obligation rows:*

1. *carrier admission for the displayed filter-limit basis row, Cauchy-filter source row, convergence-boundary row, finite stream window, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming row;*
2. *basis exposure, requiring every convergence-facing read to consume B and F before it consults L, W, R, D, or E;*
3. *convergence-window compatibility, requiring the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *row L to use the same displayed basis, window, readback, and dyadic tolerance route;*
4. *Real handoff, requiring the terminal seal E to remain downstream of B, F, L, W, R, D and the structural rows H, C, P, N;*
5. *ledger refusal, excluding quotient filters, ultrafilters, selected limits, countable-choice schedules, host filter equality, host real equality, ambient completeness, and bridge certificates.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 8065.1. The displayed rows are exactly $B, F, L, W, R, D, E, H, C, P, N$, so carrier admission exposes only finite basis, filter, convergence-boundary, window, readback, tolerance, seal, transport, replay, provenance, and naming data.

The convergence route starts with B and F. The filter-limit basis row and the Cauchy-filter row force the request to pass through accepted finite basis data before any convergence-facing row can be inspected.

Next read L, W, R, D. The convergence boundary consumes the same finite stream windows, regular rational readback, and dyadic tolerance ledger, so the packet has one displayed basis-convergence route rather than two unrelated filter presentations.

Finally the terminal seal E and the structural rows H, C, P, N preserve the same route. Since quotient filters, ultrafilters, selected limits, countable-choice schedules, host equality, ambient completeness, and bridge certificates are absent from the carrier, the listed obligations exhaust the local surface. □

Theorem 8065.3 (FilterBasisConvergence L10 handoff)**.** *Every accepted convergence-facing consumer of a* $\mathsf{FilterBasisConvergence}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FilterLimitBasis}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyFilterLimit}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before terminal Real evidence is read. The route uses the displayed rows $B, F, L, W, R, D, E, H, C, P, N$ of the same packet and cannot import quotient filters, ultrafilters, selected limits, countable choice, host filter equality, host real equality, or ambient completeness.

Proof. Begin with a convergence-facing consumer of K. The carrier admits the $\mathsf{FilterLimitBasis}^{\uparrow}$ row B only together with the source filter row F and the convergence-boundary row L.

Replay the displayed continuation row C. The request consumes B and F, then passes through L, the finite windows W, the regular readback R, and the dyadic tolerance ledger D before the terminal seal E is available.

The structural rows do not create an additional convergence object. Transport through H, provenance through P, and local naming through N record the same finite route, so every accepted consumer receives only that route before the $\mathsf{Real}^{\uparrow}$ seal.

The excluded objects are not carrier rows. Consequently any consumer using quotient filters, ultrafilters, selected limits, countable choice, host equality, or ambient completeness has left the accepted $\mathsf{FilterBasisConvergence}^{\uparrow}$ packet rather than reading its L10 handoff surface. □

Falsifiable prediction: An accepted $\mathsf{FilterBasisConvergence}^{\uparrow}$ read is refuted if a convergence-facing or $\mathsf{Real}^{\uparrow}$ consumer reaches the terminal seal without displaying the FilterLimitBasis row, CauchyFilter row, CauchyFilterLimit row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FilterBasisConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{FilterBasisConvergence}^{\uparrow}$ packet is generated from a FilterLimitBasis row, a CauchyFilter source row, a CauchyFilterLimit convergence-boundary row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FilterBasisConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8065.1, Definition 8065.2, and Definition 8065.3 seed the L10 convergence route over FilterLimitBasisUp, CauchyFilterUp, CauchyFilterLimitUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FilterBasisConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient filters, ultrafilters, selected limits, countable choice, host equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, basis exposure, convergence-window compatibility, Real handoff, ledger refusal, transport preservation, replay, provenance, and local naming for BEDC.Derived.FilterBasisConvergenceUp.

Chapter 8066

A Concrete Naming Certificate for $\mathsf{RoughPath}^{\uparrow}$

Following Lyons' rough path theory, the $\mathsf{RoughPath}^{\uparrow}$ packet records an enhanced finite-variation route for paths whose iterated path-step data must be inspected before a controlled differential equation consumer may read a terminal real-name seal. It sits beside the Young integral surface of chapter 3910, the terminal Real seal of chapter 38, and the regular rational readback of chapter 301. The packet names the displayed enhancement and control-budget rows only; it is not a host rough-path quotient, selected lift, analytic existence theorem, countable-choice schedule, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8066.1 (Rough path carrier)**.** *A* $\mathsf{RoughPath}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, V, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the enhanced path-step row, listing first-level path steps, second-level iterated path-step witnesses, Chen-composition checks, and the finite interval ledger on which they are read.*
2. *V is the p-variation and control-budget row, recording the admissible variation exponent, control windows, superadditive budget checks, and the finite margins used by downstream integration requests.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for the inspected time windows and endpoint requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational observations of path-step data, iterated path-step data, and control budgets.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, V, S, R have been displayed.*
6. *H records componentwise* hsame *transport for enhanced path-step data, variation budgets, stream observations, readback rows, the Real seal, provenance, and the local name.*
7. *C records displayed* Cont *replay from a rough-path request through enhanced path-step data, variation control, stream windows, regular rational readback, and the Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{RoughPath}^{\uparrow}$, $\mathsf{YoungIntegral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RoughPath}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, V, S, R, E, H, C, P, N$. It has no coordinate for a host enhancement quotient, a selected lift, a hidden area process, countable choice, an analytic existence theorem for differential equations, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8066.2 (Rough path NameCert obligations)**.** *For every accepted* $\mathsf{RoughPath}^{\uparrow}$ *carrier* $X = (I, V, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RoughPath}^{\uparrow}}$ *surface is exhausted by enhanced path-step data, p-variation and control-budget checks,* $\mathsf{StreamName}^{\uparrow}$ *observation,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No accepted consumer may replace those rows by a host rough-path quotient, a selected lift, an unrecorded area process, countable choice, an analytic existence theorem, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier of Definition 8066.1. The row I exposes the first-level and iterated path-step data together with the displayed Chen-composition checks, and V exposes the finite p-variation and control budget used to read that path-step data.

The observation and readback route is then fixed. The row S records the inspected endpoint windows, R gives the regular rational readback for the same displayed windows, and E is available only after those rows have been consumed.

Transport and replay preserve the route. The rows H and C carry componentwise hsame transport and displayed Cont replay for the same path-step, budget, observation, readback, and seal rows, while P and N record provenance and local naming.

Since the excluded objects have no coordinate in $I, V, S, R, E, H, C, P, N$, a consumer using one of them has left the accepted packet rather than reading the local NameCert surface. □

Theorem 8066.3 (Rough path p-variation handoff)**.** *Every accepted* $\mathsf{RoughPath}^{\uparrow}$ *read that is later consumed by a controlled integration or controlled differential equation interface first factors through*

$$\mathsf{YoungIntegral}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the displayed rows $I, V, S, R, E, H, C, P, N$. The handoff exposes enhanced path-step data and a p-variation control budget before any Real-facing read, and it exports no host lift, quotient rough path, selected area representative, countable-choice schedule, or ambient Real-completeness theorem.

Proof. Start with the enhancement and variation rows. The row I supplies the finite path-step and iterated path-step ledger, while V records the control windows and p-variation margins needed by a Young-style controlled integral request.

Next read the finite observations. The $\mathsf{StreamName}^{\uparrow}$ row S fixes the endpoint windows inspected by the consumer, and the $\mathsf{RegSeqRat}^{\uparrow}$ row R attaches rational readback to the same windows before the $\mathsf{Real}^{\uparrow}$ seal E is exposed.

Finally use H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same finite route, so any downstream controlled-equation interface receives the enhanced path-step and control-budget data without importing a host lift, quotient rough path, selected area representative, countable choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RoughPath}^{\uparrow}$ packet is refuted if a consumer reaches the $\mathsf{Real}^{\uparrow}$ seal while omitting the enhanced path-step row I, the p-variation control row V, the $\mathsf{StreamName}^{\uparrow}$ observation row S, or the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R.

Independence witness: YoungIntegral, StreamName, RegSeqRat, Real: none is bijective with $\mathsf{RoughPath}^{\uparrow}$ because the packet jointly carries enhanced path-step data, variation control, finite

observations, regular rational readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RoughPath}\uparrow}$.

Constructive story: A $\mathsf{RoughPath}^{\uparrow}$ packet is generated from enhanced path-step data, p-variation control budgets, StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RoughPath}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8066.1, Definition 8066.2, and Definition 8066.3 seed the finite enhanced path-step route for rough paths.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RoughPath}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host rough-path quotients, selected lifts, hidden area processes, controlled differential equation existence, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked enhanced path-step admission, p-variation control exactness, StreamName observation, RegSeqRat readback, Real-seal nonescape, and structural transport for BEDC.Derived.RoughPathUp.

Chapter 8067

A Concrete Naming Certificate for $\mathsf{BaireOneUniformOscillation}^{\uparrow}$

Following Baire and Bishop–Bridges, $\mathsf{BaireOneUniformOscillation}^{\uparrow}$ records the finite observation surface by which a Baire-one pointwise-limit row is inspected through uniform oscillation windows before a Real-and-Completion consumer reads a terminal real seal. The packet sits after the Baire-one function surface of chapter 1604, the real oscillation surface of chapter 1839, the compact uniform-continuity route of chapter 388, the finite stream-name windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It names only the finite row discipline for oscillation windows over a pointwise-limit presentation; it does not assert uniform convergence, choose a subsequence, form quotient function equality, import compactness by open covers, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8067.1 (Baire-one uniform oscillation carrier)**.** *A* $\mathsf{BaireOneUniformOscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, O, K, W, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireOneFunction}^{\uparrow}$ *pointwise-limit row naming the approximating sequence and the inspected input windows.*
2. *O is the* $\mathsf{RealOscillation}^{\uparrow}$ *row carrying lower and upper oscillation probes for the same displayed real-valued data.*
3. *K is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *row that bounds which compact-window and uniform-modulus requests may be replayed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for the pointwise approximants and oscillation probes.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerances attached to those windows.*
6. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the pointwise-limit, oscillation, uniform-window, stream, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transports for B, O, K, W, Q, T and the structural rows.*
8. *C records the displayed* Cont *replay route through the same finite window data.*
9. *P is the* Pkg *provenance over* $\mathsf{BaireOneUniformOscillation}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BaireOneUniformOscillation}^{\uparrow}}$ *row.*
The carrier has no coordinate for host function equality, selected subsequences, uniform convergence of the approximating sequence, open-cover compactness, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8067.2 (Baire-one uniform oscillation obligations)**.** *For an accepted* $\mathsf{BaireOneUniformOscillation}^{\uparrow}$ *carrier* $U = (B, O, K, W, Q, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BaireOneUniformOscillation}^{\uparrow}}$ *surface consists exactly of six finite obligations: carrier formation over the displayed rows; classifier stability under componentwise* hsame *transport; pointwise-limit source compatibility with the* $\mathsf{BaireOneFunction}^{\uparrow}$ *row; oscillation-window compatibility with the* $\mathsf{RealOscillation}^{\uparrow}$ *row; compact uniform-window replay through* $\mathsf{CompactUniformContinuity}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$*; and terminal* $\mathsf{Real}^{\uparrow}$ *seal non-escape.*

Proof. Carrier formation is projection from Definition 8067.1. The packet displays the pointwise-limit source, oscillation probes, compact uniform-window row, stream schedule, regular-rational readback, terminal Real seal, transports, replay, provenance, and local name.

Classifier stability is rowwise. Transport along H may replace the visible rows only by rows with the same pointwise-limit source, oscillation probes, uniform-window requests, stream windows, rational tolerances, terminal seal, replay order, provenance, and local name.

The source and oscillation obligations are the compatibility rows B and O. A consumer cannot inspect oscillation width without first displaying the Baire-one pointwise-limit row and the real oscillation probes over the same finite windows.

The uniform-window obligation is the route through K, W, Q. It confines compact-uniform requests to the displayed window schedule and rational readback, so the packet exports a finite uniform oscillation window rather than open-cover compactness or uniform convergence of the approximants.

Finally, T is terminal. Since no carrier row stores a selected subsequence, quotient function equality, quotient stream equality, or ambient completeness principle, the $\mathsf{Real}^{\uparrow}$ seal is the only value-facing endpoint exported by the packet. □

Theorem 8067.3 (Baire-one uniform oscillation window route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BaireOneUniformOscillation}^{\uparrow}$ *packet reads the rows*

$$B, O, K, W, Q, T, H, C, P, N$$

in that order before treating a Baire-one pointwise-limit surface as controlled by finite uniform oscillation windows. In particular, the consumer must pass through the $\mathsf{BaireOneFunction}^{\uparrow}$ *source,* $\mathsf{RealOscillation}^{\uparrow}$ *probe row,* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *window row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal before exporting any oscillation-window conclusion.*

Proof. Begin with the source row B. It is the only displayed entry point for the Baire-one pointwise-limit presentation, so an oscillation-window consumer has no independent host function from which to read the limit.

Next read O, K, W, Q. The oscillation probes are tied to the same finite stream windows, and the compact-uniform row only bounds replay through those windows and rational tolerances.

Only after those rows have been displayed may the consumer read T. The structural rows H, C, P, N then transport, replay, source, and name the same route, so no quotient stream equality, selected subsequence, open-cover compactness proof, uniform-convergence assertion, or ambient $\mathsf{Real}^{\uparrow}$ completeness row can replace the finite window route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOneUniformOscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireOneUniformOscillation}^{\uparrow}$ packet is generated from a BaireOneFunction pointwise-limit row, RealOscillation probes, CompactUniformContinuity window data, StreamName schedules, RegSeqRat tolerance readbacks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BaireOneUniformOscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8067.1, Definition 8067.2, and Definition 8067.3 seed the finite uniform-oscillation window route for Baire-one pointwise-limit rows over the L10 Real route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BaireOneUniformOscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, uniform convergence of the approximating sequence, selected subsequences, quotient function equality, quotient stream equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, source compatibility, oscillation-window compatibility, compact uniform-window replay, and terminal Real seal non-escape for the displayed packet.

Chapter 8068

McShaneIntegralUp NameCert construction

Following McShane's gauge integral formulation, the $\mathsf{McShaneIntegral}^{\uparrow}$ packet records the finite tagged-partition and gauge-refinement ledger by which a displayed real-valued integrand is read as having a McShane integral candidate. It sits after the terminal real-name seal of chapter 38, the regular rational tolerance route of chapter 301, the finite tagged-partition carrier of chapter 7449, and the gauge-integral boundary of chapter 8045. The packet names a finite gauge-integration certificate only; it does not import measure-theoretic integration, selected gauges, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a host equality of functions.

Definition 8068.1 (McShaneIntegral carrier)**.** *A* $\mathsf{McShaneIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, I, F, G, T, S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the integration-domain row, carrying the bounded interval or displayed finite-measure cell family over which tags may be chosen.*
2. *I is the integrand row, exposing only finite* $\mathsf{Real}^{\uparrow}$ *value reads of the displayed real-valued function.*
3. *F is the finite tagged-partition row, read through* $\mathsf{TaggedPartition}^{\uparrow}$*, whose entries record cells, tags, and coverage data.*
4. *G is the gauge-admissibility row, assigning to each displayed tag a positive local radius and checking that every cell in F is subordinate to that radius.*
5. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row, giving the Cauchy-style comparison budget for two admissible tagged partitions.*
6. *S is the Real-valued sum row, recording finite sums of cell-size data multiplied by the corresponding integrand reads and sealed through* $\mathsf{Real}^{\uparrow}$*.*
7. *R is the refinement ledger, relating two admissible tagged partitions by a common gauge-refinement surface rather than by a selected infinite refinement procedure.*
8. *Q is the integral-candidate row, a regular rational name whose finite windows are checked against S, T, R.*

9. *H, C, P, N are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance over* McShaneIntegral$^{\uparrow}$, TaggedPartition$^{\uparrow}$, GaugeIntegral$^{\uparrow}$, HenstockKurzweilGaugeIntegral$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, *and* NameCert, *and the local* NameCert$_{\text{McShaneIntegral}^{\uparrow}}$ *row.*

Theorem 8068.2 (McShaneIntegral NameCert obligations)**.** *For every accepted* McShaneIntegral$^{\uparrow}$ *carrier $M = (D, I, F, G, T, S, R, Q, H, C, P, N)$, the local* NameCert$_{\text{McShaneIntegral}^{\uparrow}}$ *surface consists exactly of domain admission, integrand finite-read admission, tagged-partition coverage, gauge admissibility, regular-rational tolerance comparison, Real-valued finite-sum sealing, common-refinement ledger exposure, integral-candidate readback, componentwise transport, displayed replay, provenance, and local naming.*

The obligation surface may cite the real seal of chapter 38, the regular-rational tolerance source of chapter 301, the finite tagged-partition carrier of chapter 7449, and the gauge-integral boundary of chapter 8045. It cannot add a measure space, a selected gauge, a countable refinement sequence, a quotient equality of functions, or an ambient completeness theorem.

Proof. Project the carrier rows. The domain, integrand, tagged-partition, gauge, tolerance, sum, refinement, and candidate rows are displayed before the local naming row can be read.

The tagged-partition row supplies only finite cells and tags, and the gauge row checks admissibility cell by cell. The Real-valued sum row is therefore a finite read through Real$^{\uparrow}$, while the tolerance row keeps the comparison budget in RegSeqRat$^{\uparrow}$.

Finally the refinement ledger mediates comparisons between admissible tagged partitions. Since the carrier has no coordinate for a measure space, selected gauge, countable refinement sequence, quotient function equality, or ambient completeness argument, the local NameCert row exports exactly the finite obligation surface listed above. □

Theorem 8068.3 (McShaneIntegral gauge-refinement stability)**.** *Let $M = (D, I, F, G, T, S, R, Q, H, C, P, N)$ be an accepted* McShaneIntegral$^{\uparrow}$ *carrier. If a consumer replaces the displayed tagged partition F by another finite tagged partition that is admitted by the same gauge row G and related to F through the common-refinement ledger R, then the integral-candidate readback Q is consumed through the same tolerance and finite-sum surface*

$$T, S, R, Q, H, C, P, N.$$

The stability claim is internal to the finite gauge-refinement ledger. It is not a proof of measure-theoretic integrability, not a selected refining sequence, not a global convergence theorem for arbitrary partitions, and not a host function-equality principle.

Proof. Start with the two displayed tagged partitions and the shared gauge row. Gauge admissibility is checked by the finite row G, so each partition contributes only the cells and tags that the carrier already exposes.

Next read the common-refinement ledger R. It records the finite comparison surface between the two admissible partitions and sends their Real-valued finite sums through the same tolerance row T and sum row S.

The candidate row Q is then reached only through T, S, R and the structural rows H, C, P, N. Thus a consumer may transport the partition read inside the displayed ledger, but cannot reinterpret the result as a measure-theoretic integral, a selected refinement sequence, unrestricted partition convergence, or host equality of functions. □

Falsifiable prediction: An accepted McShaneIntegral$^{\uparrow}$ consumer that reaches the integral-candidate row without first reading the tagged-partition row, gauge-admissibility row, regular-rational tolerance row, Real-valued finite-sum row, and common-refinement ledger refutes the carrier surface.

Independence witness: real, regseqrat, tagged-partition, henstock-kurzweil-gauge-integral: no listed sibling supplies the full twelve-row packet $M = (D, I, F, G, T, S, R, Q, H, C, P, N)$, because each sibling contributes only a real seal, regular-rational tolerance route, finite tagged-partition carrier, or gauge-integral boundary while this chapter binds them into one McShane integral NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{McShaneIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{McShaneIntegral}^{\uparrow}$ packet is generated from a displayed integration domain, finite real-valued integrand reads, a finite tagged-partition row, a gauge-admissibility row, a regular-rational tolerance row, a Real-valued finite-sum row, a common-refinement ledger, an integral-candidate readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{McShaneIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8068.1, Definition 8068.2, and Definition 8068.3 seed the finite McShane gauge-integration certificate over tagged partitions, gauge-admissibility rows, Real-valued sums, regular-rational tolerance, and common-refinement ledgers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{McShaneIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim measure-theoretic integration, selected gauges, countable refinement procedures, full convergence for arbitrary partition nets, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, tagged-partition coverage, gauge admissibility, finite-sum sealing, regular-rational tolerance comparison, refinement-ledger stability, and a Lean carrier/obligation formalization for BEDC.Derived.McShaneIntegralUp.

Chapter 8069

A Concrete Naming Certificate for $\mathsf{MengerTheorem}^{\uparrow}$

Following Menger on finite graph connectivity, the $\mathsf{MengerTheorem}^{\uparrow}$ packet records the cut-path duality surface as finite BEDC data. It sits after the finite graph source of chapter 118, the flow certificate route of chapter 233, the matching certificate route of chapter 234, the finite list accounting surface of chapter 36, and the natural-number ledger of chapter 28. The packet names the displayed vertex pair, internally disjoint path family, separator row, cardinality comparison, flow/matching handoff, transport, replay, provenance, and local certificate; it is not a host max-flow theorem, not a selected infinite path family, not quotient graph equality, and not an ambient compactness or choice principle.

Definition 8069.1 (Menger theorem carrier)**.** *A* $\mathsf{MengerTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (G, s, t, \Pi, S, K, F, Q, L, A, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *source row, carrying the finite vertex inventory, edge inventory, incidence data, and endpoint-adjacency checks.*
2. *s and t are the two distinguished vertex rows, with the endpoint-separation witness that keeps the cut-path question nontrivial inside G.*
3. *Π is the internally disjoint path-family row, represented by finite* $\mathsf{List}^{\uparrow}$ *data whose entries are paths from s to t and whose internal vertex ledgers are pairwise disjoint.*
4. *S is the separator row, recording a finite vertex cut that meets every displayed s–t path while excluding the two distinguished endpoints.*
5. *K is the* $\mathsf{Nat}^{\uparrow}$ *cardinality ledger, recording the common finite size comparison between the path family and the separator.*
6. *F is the* $\mathsf{NetworkFlow}^{\uparrow}$ *handoff row, reading the path and cut data through the finite unit-capacity flow boundary rather than through a host max-flow theorem.*
7. *Q is the* $\mathsf{Matching}^{\uparrow}$ *handoff row, recording the auxiliary bipartite matching view used by finite alternating-route consumers.*
8. *L records the* $\mathsf{List}^{\uparrow}$ *accounting discipline for path inventories, separator inventories, and duplicate checks.*

9. *A records the* $\mathsf{Nat}^{\uparrow}$ *accounting discipline for lengths, family size, separator size, and equality of the two displayed finite cardinals.*
10. *H records componentwise* hsame *transport for graph source, endpoints, path-family, separator, cardinality, flow, matching, list, natural-number, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a cut-path duality query through $G, s, t, \Pi, S, K, F, Q, L, A, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{MengerTheorem}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MengerTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite graph, a host max-flow/min-cut theorem, quotient equality of paths, selected path families outside the packet, or choice over separators.

Theorem 8069.2 (Menger theorem NameCert obligations)**.** *For every accepted* $\mathsf{MengerTheorem}^{\uparrow}$ *carrier $M = (G, s, t, \Pi, S, K, F, Q, L, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MengerTheorem}^{\uparrow}}$ *surface consists exactly of graph source admission through G, endpoint exposure through s, t, internally disjoint path-family exposure through Π, separator exposure through S, cardinality-ledger exposure through K, network-flow handoff through F, matching handoff through Q, list accounting through L, natural-number accounting through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8069.1. The graph and endpoint rows G, s, t fix the finite source of the cut-path question before either side of the duality can be read.

The path-family row Π and separator row S are the two visible witnesses. The list ledger L records path inventories, duplicate checks, and separator enumeration, while the natural-number ledger A records the finite sizes inspected by the cardinality row K.

The handoff rows F and Q keep the same data readable by network-flow and matching consumers. They do not replace the packet by an ambient max-flow/min-cut theorem or by a selected matching oracle; they replay the displayed graph, path, cut, and counting rows.

Transport, continuation replay, provenance, and local naming are exactly H, C, P, N. Since no further coordinate stores infinite graph data, quotient path equality, a choice-selected path family, or a host theorem, the listed rows exhaust the NameCert obligations. □

Theorem 8069.3 (Menger theorem cut-path duality handoff)**.** *Every cut-path duality consumer of an accepted* $\mathsf{MengerTheorem}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Graph}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{Nat}^{\uparrow},\ \mathsf{NetworkFlow}^{\uparrow},\ \mathsf{Matching}^{\uparrow} \longmapsto G, s, t, \Pi, S, K, F, Q, L, A, H, C, P, N.$$

The handoff states only that the displayed internally disjoint path-family row and displayed separator row meet in the same finite cardinality ledger. It does not export a theorem for infinite graphs, quotient equality of path objects, selected witnesses outside the packet, arbitrary host max-flow/min-cut, or countable choice.

Proof. Begin with Definition 8069.2. A consumer must expose the finite graph source and the two endpoint rows before it can inspect either the internally disjoint path family or the separator.

Next read the list and natural-number ledgers. The path-family row Π is a finite $\mathsf{List}^{\uparrow}$ inventory of paths, the separator row S is a finite $\mathsf{List}^{\uparrow}$ inventory of vertices, and K, A record the $\mathsf{Nat}^{\uparrow}$ equality between their displayed sizes.

Finally read the flow and matching handoffs. The $\mathsf{NetworkFlow}^{\uparrow}$ row presents the same data as a unit-capacity cut-flow boundary, while the $\mathsf{Matching}^{\uparrow}$ row presents the same finite incidence discipline to alternating-route consumers. Both handoffs remain attached to G, s, t, Π, S, K, L, A.

Thus the duality consumer receives a finite cut-path certificate and no stronger host theorem. The refused endpoints remain outside the carrier because no row supplies infinite graph data, quotient path equality, selected external witnesses, arbitrary max-flow/min-cut, or countable choice. □

Falsifiable prediction: A purported $\mathsf{MengerTheorem}^{\uparrow}$ consumer is refuted if it reaches a cut-path duality conclusion while omitting any of the displayed graph source, endpoint, internally disjoint path-family, separator, cardinality, network-flow, matching, list, natural-number, transport, replay, provenance, or local NameCert rows.

Independence witness: graph, networkflow, matching, list, nat: no listed sibling is bijective to $\mathsf{MengerTheorem}^{\uparrow}$ because this packet jointly carries a distinguished graph source, two endpoint rows, internally disjoint path-family rows, separator rows, cardinality equality, flow handoff, matching handoff, finite list accounting, natural-number accounting, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MengerTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MengerTheorem}^{\uparrow}$ packet is generated from a GraphUp source row, two distinguished vertex rows, an internally disjoint path-family row, a separator row, a NatUp cardinality ledger, NetworkFlowUp and MatchingUp handoff rows, ListUp and NatUp accounting rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MengerTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8069.1, Definition 8069.2, and Definition 8069.3 seed the finite graph cut-path duality certificate over graph, path-family, separator, counting, flow, matching, list, natural-number, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MengerTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite graph Menger theorems, quotient path equality, selected external witnesses, arbitrary host max-flow/min-cut, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, internally disjoint path-family exposure, separator exposure, cardinality-ledger exactness, NetworkFlow and Matching handoff exposure, List and Nat accounting, transport, replay, provenance, and local naming for BEDC.Derived.MengerTheoremUp.

Chapter 8070

A Concrete Naming Certificate for $\mathsf{FiniteTailSeries}^{\uparrow}$

Following Hardy and Bishop–Bridges, $\mathsf{FiniteTailSeries}^{\uparrow}$ records the finite tail ledger by which a displayed series is read as Cauchy-facing data before any completion consumer asks for a real value. The packet sits beside the dyadic tolerance arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback row of chapter 301, the terminal real-name seal of chapter 38, and the reusable tail envelope $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$. It gives Real-and-Completion consumers a finite series-tail handoff without importing an infinite sum object, a selected limit, quotient sequence equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8070.1 (FiniteTailSeries carrier)**.** *A* $\mathsf{FiniteTailSeries}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, W, D, R, E, H, C, P, N)$$

with the following five-row NameCert surface:

1. *The source row S names the displayed finite series ledger and the tail interval being inspected.*
2. *The observation row W records the* $\mathsf{StreamName}^{\uparrow}$ *windows of terms and partial sums available on that finite tail.*
3. *The tolerance row D records the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic budgets assigned to the tail comparison.*
4. *The readback row R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational comparison by which the finite tail is handed to Cauchy consumers.*
5. *The seal row E records the terminal* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegularCauchyTailEnvelope}^{\uparrow}$ *handoff reached only after S, W, D, R have been displayed.*

The structural rows H, C, P, N carry componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{FiniteTailSeries}^{\uparrow}}$ *row for the same surface. The carrier has no coordinate for an infinite sum object, selected limit, quotient sequence equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8070.2 (FiniteTailSeries Cauchy handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{FiniteTailSeries}^{\uparrow}$ *packet must read the finite source ledger S, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, the terminal seal E, componentwise* hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N before treating the tail as Cauchy-series data.*

Proof. Project the carrier of Definition 8070.1. The analytic rows are S, W, D, R, E, and the structural rows are H, C, P, N.

The source row fixes the finite tail interval. The StreamName row then exposes the term and partial-sum windows, and the DyadicRatCore row attaches the rational tolerance budgets to those same windows.

The RegSeqRat readback row is downstream from the windows and tolerance ledger. It is therefore the first point at which the finite tail may be consumed as regular Cauchy data, and the terminal seal E remains behind that readback route.

The structural rows transport, replay, source, and name the same ordered route. Since no carrier coordinate stores an infinite sum object, selected limit, quotient sequence equality, countable choice, or ambient real-completeness principle, the Cauchy-series handoff is exactly the displayed finite tail ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTailSeries}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTailSeries}^{\uparrow}$ packet is generated from a finite series-tail source ledger, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp or RegularCauchyTailEnvelopeUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTailSeries}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8070.1 and Definition 8070.2 seed the finite tail Cauchy-series ledger used by Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTailSeries}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not provide Lean verification, an infinite sum object, a selected limit, quotient sequence equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, StreamName window exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, terminal seal handoff, transport, replay, provenance, and local naming for $\mathsf{FiniteTailSeries}^{\uparrow}$.

Chapter 8071

A Concrete Naming Certificate for $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$ packet records the finite Real-and-Completion route by which two regular Cauchy names may be interleaved and read as one completion-facing Bishop real name. It sits beside the regular rational carrier of chapter 301, the finite window surface of chapter 126, the terminal Real seal of chapter 38, the parity substream route of chapter 5876, and the interleaving criterion of chapter 3405. The packet is a finite-means certificate for manipulating regular Cauchy real names; it is not a quotient representative, selected limit, countable-choice schedule, host equality of reals, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8071.1 (Bishop real Cauchy interleaving carrier)**.** *A* $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S_0, S_1, W_0, W_1, D_0, D_1, J, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two source* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, each carrying a regular Cauchy name before any Real-facing seal is read.*
2. *W_0 and W_1 are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows that expose the inspected even-side and odd-side observation windows.*
3. *D_0 and D_1 are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers attached to the two source rows.*
4. *J is the* $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ *row, recording the finite selector and common-window comparison that licenses the interleaving.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the interleaved regular Cauchy name produced from the two source rows and the common-window criterion.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after $S_0, S_1, W_0, W_1, D_0, D_1, J, R$ have been displayed.*
7. *H records componentwise* hsame *transport for the two source rows, the two window rows, the two tolerance ledgers, the interleaving criterion, the interleaved readback, the Real seal, provenance, and local naming.*
8. *C records displayed* Cont *replay from any Real or Completion request through exactly the same finite rows.*

9. *P is the* Pkg *provenance over* BishopRealCauchyInterleaving$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyEvenOddSubstreams$^{\uparrow}$, CauchyInterleavingCriterion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopRealCauchyInterleaving}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed coordinates. It contains no coordinate for quotient-name equality, selected representatives, countable choice, host real equality, or ambient Real completeness.

Theorem 8071.2 (Bishop real Cauchy interleaving NameCert obligations)**.** *For every accepted* BishopRealCauchyInterleaving$^{\uparrow}$ *carrier*

$$I = (S_0, S_1, W_0, W_1, D_0, D_1, J, R, E, H, C, P, N),$$

the local NameCert$_{\text{BishopRealCauchyInterleaving}^{\uparrow}}$ *surface consists exactly of two regular Cauchy source rows, two finite window rows, two dyadic tolerance ledgers, one interleaving criterion row, the interleaved regular readback row, the terminal Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every Real or Completion consumer must pass through these rows before reading the interleaved Bishop real name.*

Lean4 ✓ `BEDC.Derived.BishopRealCauchyInterleavingUp.BishopRealCauchyInterleavingCarrier namecert obligations`

Proof. Project the carrier of Definition 8071.1. The rows S_0, S_1 expose the two regular Cauchy names, while W_0, W_1 restrict the read to finite stream windows and D_0, D_1 attach the visible dyadic tolerance budgets.

The interleaving step is then forced through J. That row is the finite CauchyInterleavingCriterion$^{\uparrow}$ comparison, so the interleaved readback R can be consumed only after the common-window selector and the two source tolerance ledgers have been displayed.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no row for quotient-name equality, selected representatives, countable choice, host real equality, or ambient completeness, these displayed coordinates exhaust the local NameCert obligations. □

Theorem 8071.3 (Bishop real Cauchy interleaving window route)**.** *Let*

$$I = (S_0, S_1, W_0, W_1, D_0, D_1, J, R, E, H, C, P, N)$$

be an accepted BishopRealCauchyInterleaving$^{\uparrow}$ *carrier. Any finite Real or Completion request that reads the interleaved name factors through the sibling route*

RegularCauchyEvenOddSubstreams$^{\uparrow}$, CauchyInterleavingCriterion$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, Real$^{\uparrow}$

on the same BHist, hsame, Cont, Pkg, *and* NameCert *rows. The route exposes the even and odd source windows before the interleaved readback and exports no quotient stream, selected representative, countable-choice schedule, host real equality, or ambient Real-completeness theorem.*

Proof. Start with the parity-facing sibling. The RegularCauchyEvenOddSubstreams$^{\uparrow}$ route supplies the standard even and odd window discipline, so any request for the interleaved name first reads finite windows W_0, W_1 over the two displayed source rows.

Next apply the interleaving criterion row J. It binds the two window routes to one common finite comparison before the interleaved RegSeqRat$^{\uparrow}$ readback R and terminal Real$^{\uparrow}$ seal E are consumed.

The structural rows H, C, P, N preserve this route inside the same BHist packet. Therefore every accepted request remains on the displayed Bishop real Cauchy interleaving surface and cannot import any of the excluded global objects. □

Falsifiable prediction: An accepted $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$ consumer is refuted if it reaches the $\mathsf{Real}^{\uparrow}$ seal without first displaying both $\mathsf{RegSeqRat}^{\uparrow}$ source rows, both $\mathsf{StreamName}^{\uparrow}$ window rows, both $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, the $\mathsf{CauchyInterleavingCriterion}^{\uparrow}$ row, the interleaved readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: regseqrat, streamname, real, regular-cauchy-even-odd-substreams, cauchy-interleaving-criterion: no listed sibling is bijective with $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$ because this packet jointly carries two source regular Cauchy names, two finite window rows, two dyadic tolerance ledgers, one common interleaving criterion, one interleaved readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealCauchyInterleaving}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealCauchyInterleaving}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two StreamName finite-window rows, two DyadicRatCore tolerance ledgers, a CauchyInterleavingCriterion row, an interleaved RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealCauchyInterleaving}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8071.1, Definition 8071.2, and Definition 8071.3 seed the finite Bishop real Cauchy interleaving route over regular Cauchy sources, finite windows, dyadic tolerance ledgers, interleaving criteria, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealCauchyInterleaving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient-name equality, selected representatives, countable-choice schedules, host real equality, ambient Real completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-row visibility, finite-window exactness, dyadic tolerance compatibility, interleaving criterion stability, interleaved readback nonescape, Real-seal boundary control, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealCauchyInterleavingUp.

Chapter 8072

A Concrete Naming Certificate for $\mathsf{ConditionalConvergence}^{\uparrow}$

Following Bishop and Bridges on constructive real series, the $\mathsf{ConditionalConvergence}^{\uparrow}$ packet records the finite route for a real series whose displayed partial sums converge while the absolute-value series is kept as a separate refused branch. It sits over the $\mathsf{RealSeries}^{\uparrow}$ source of chapter 1581, the absolute convergence boundary of chapter 1700, the alternating-test sibling of chapter 1483, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names conditional convergence as a convergence-with-refusal certificate, not as absolute convergence, an alternating-test proof, a selected infinite sum, quotient equality of series, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8072.1 (Conditional convergence carrier)**.** *A* $\mathsf{ConditionalConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, C, A, W, Q, D, E, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing only finite term and partial-sum windows.*
2. *C is the convergence row, recording the shared Cauchy-tail threshold and partial-sum comparison route for S.*
3. *A is the absolute-branch refusal row: it records that any* $\mathsf{AbsoluteConvergence}^{\uparrow}$ *read must enter through the separate absolute-value series route and is not supplied by K.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected terms, partial sums, and absolute-value probes.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed partial-sum windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by both the convergence row and the absolute-branch refusal.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after C, W, Q, D have been displayed.*
8. *H records componentwise* hsame *transport for source, convergence, refusal, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from series windows through convergence and refusal checks to the readback and seal rows.*

10. *P is the* Pkg *provenance over* $\mathsf{ConditionalConvergence}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{AbsoluteConvergence}^{\uparrow}$, $\mathsf{AlternatingSeriesTest}^{\uparrow}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConditionalConvergence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, C, A, W, Q, D, E, H, T, P, N$. It has no coordinate for an absolute-convergence proof, an alternating-series-test derivation, a host infinite sum, selected limits, quotient stream equality, countable choice, or ambient real completeness.

Theorem 8072.2 (Conditional convergence NameCert obligations)**.** *For every accepted* $\mathsf{ConditionalConvergence}^{\uparrow}$ *carrier $K = (S, C, A, W, Q, D, E, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConditionalConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure, convergence-row exposure, absolute-branch refusal, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 8072.1. The convergence side exposes only the real-series row S, the Cauchy-tail route C, the finite windows W, the regular readback Q, the dyadic ledger D, and the seal E.

Read the refusal row A separately. It does not provide an $\mathsf{AbsoluteConvergence}^{\uparrow}$ witness; it records that any absolute-value series read must be supplied by the sibling absolute-convergence chapter and cannot be recovered from the conditional packet alone.

The alternating-test sibling is likewise only a possible producer of examples or routes, not a coordinate of this carrier. The packet may cite $\mathsf{AlternatingSeriesTest}^{\uparrow}$ provenance when the source came from that route, but the public conditional-convergence certificate remains the displayed convergence-with-refusal surface.

Finally H, T, P, N transport, replay, source, and name the same rows. Since the carrier has no coordinate for absolute convergence, selected sums, quotient series equality, countable choice, or real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8072.3 (Conditional convergence sibling separation)**.** *Every Real-facing read of an accepted* $\mathsf{ConditionalConvergence}^{\uparrow}$ *carrier factors through*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}$$

and keeps the $\mathsf{AbsoluteConvergence}^{\uparrow}$ *and* $\mathsf{AlternatingSeriesTest}^{\uparrow}$ *routes as distinct sibling routes. A consumer may not replace the absolute-branch refusal by an absolute-convergence proof, nor replace the conditional carrier by an alternating-test proof unless that proof is supplied as an external provenance row.*

Proof. Start with an accepted carrier and a Real-facing request. The request reaches E only after the real-series source, convergence row, finite windows, regular readback, and dyadic ledger have been displayed.

The absolute branch is controlled by A. Because A is a refusal row rather than a convergence row for the absolute-value series, the request cannot read an $\mathsf{AbsoluteConvergence}^{\uparrow}$ certificate from the conditional packet.

The alternating-test route is separated by provenance. It can explain a source of examples, but it is not part of the classifier coordinates $S, C, A, W, Q, D, E, H, T, P, N$ unless explicitly recorded as provenance, and it does not erase the absolute-branch refusal.

Thus the public read is conditional convergence: convergence of the displayed real series together with separation from absolute convergence and from a specific alternating-test derivation. □

Falsifiable prediction: An accepted $\mathsf{ConditionalConvergence}^{\uparrow}$ read is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the RealSeries source, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, absolute-branch refusal, transport, replay, provenance, and local NameCert rows.

Independence witness: realseries, absoluteconvergence, alternating-series-test, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{ConditionalConvergence}^{\uparrow}$, because only this packet jointly carries a convergent RealSeries route and a separate refusal of the AbsoluteConvergence route while retaining StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ConditionalConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{ConditionalConvergence}^{\uparrow}$ packet is generated from a RealSeries source row, convergence-tail row, absolute-branch refusal row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConditionalConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8072.1, Definition 8072.2, and Definition 8072.3 seed the finite convergence-with-refusal route distinguishing conditional convergence from absolute convergence and alternating-test provenance.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConditionalConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close absolute convergence, alternating-series-test correctness, selected infinite sums, quotient series equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, convergence-row exposure, absolute-branch refusal, window and readback exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConditionalConv

Chapter 8073

A Concrete Naming Certificate for $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ packet records the finite diagonal schedule that synchronizes compact-net centers, pointwise modulus rows, rational lower-bound folds, and Real-facing readback windows. It realizes the compact-uniform finite-net route of chapter 9237 beside the compact metric source of chapter 129, the continuous-map carrier of chapter 130, the uniform-modulus boundary of chapter 369, the finite Lebesgue-number ledger of chapter 452, the stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite schedule, not an open-cover compactness theorem, selected subcover, host diagonal argument, countable choice principle, or ambient completeness theorem.

Definition 8073.1 (Compact uniform diagonal net carrier)**.** *A* $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, L, U, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, including inspected centers, coverage windows, and metric source data.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus row over the same compact source and target metric surface.*
3. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *or rational lower-bound ledger that turns the displayed finite cover into a positive radius budget.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row reached only after K, F, L have been displayed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *diagonal schedule row listing the finite source windows, center indices, target tolerances, and output windows inspected together.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled windows and uniform-modulus handoff.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for Real-facing reads of the scheduled outputs.*
8. *H records componentwise* hsame *transport for compact-net, continuous-map, radius-ledger, uniform-modulus, stream-schedule, readback, seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a tolerance request through K, F, L, U, S, Q, E.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalNet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, F, L, U, S, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected subcovers outside K, host diagonal choice, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8073.2 (Compact uniform diagonal net NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ *carrier $G = (K, F, L, U, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalNe}}$ *surface consists exactly of carrier admission, compact finite-net exposure, continuous-map pointwise-modulus exposure, finite radius-ledger exposure, uniform-modulus handoff, diagonal StreamName schedule exposure, RegSeqRat readback, Real-seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 8073.1. The compact finite-net row K, continuous-map row F, radius ledger L, and uniform-modulus row U are the only compact-uniform source data available to the classifier.

Read the diagonal schedule row S. It lists the finite windows inspected together, so the schedule is a StreamName row rather than a host diagonal choice over infinitely many requests.

The readback row Q and seal row E are downstream of that schedule. They can inspect only the windows and tolerances already displayed by S and the uniform-modulus handoff U.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for open-cover compactness, selected subcovers, host diagonal choice, quotient stream equality, selected limits, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8073.3 (Compact uniform diagonal net schedule handoff)**.** *Every Real-facing read of an accepted* $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{FiniteLebesgueNumber}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},$$

The read first displays the compact-net and pointwise-modulus rows, then the finite radius ledger and uniform-modulus handoff, then the StreamName diagonal schedule, regular rational readback, and Real seal.

Proof. Start with the carrier rows $K, F, L, U, S, Q, E, H, C, P, N$. The uniform-modulus handoff U is downstream of the compact metric row, pointwise modulus row, and finite radius ledger.

Next read the diagonal schedule. The schedule row S synchronizes center indices, source windows, tolerances, and output windows inside one finite $\mathsf{StreamName}^{\uparrow}$ surface.

The regular readback Q and Real seal E consume only that displayed schedule and the handoff U. The structural rows preserve the same finite path under transport, replay, provenance, and local naming.

Thus every Real-facing read remains inside the compact-uniform finite-net diagonal schedule and cannot add an open-cover compactness theorem, selected subcover, host diagonal selector, quotient stream equality, selected limit, or ambient real completeness. □

Falsifiable prediction: An accepted $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ read is refuted if a RealUp seal is reached without displaying the CompactMetricUp finite-net row, ContinuousMapUp pointwise-modulus row, FiniteLebesgueNumberUp radius ledger, UniformModulusUp handoff, StreamNameUp diagonal schedule, RegSeqRatUp readback, transport, replay, provenance, and local NameCert rows.

Independence witness: compactmetric, continuousmap, uniformmodulus, finite-lebesgue-number, streamname, regseqrat, real: none is bijective to $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$, because only this packet binds compact finite-net coverage, pointwise moduli, finite radius ledgers, a uniform-modulus handoff, a diagonal StreamName schedule, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming into one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalNet}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformDiagonalNet}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise-modulus rows, FiniteLebesgueNumber radius ledgers, UniformModulus handoff rows, StreamName diagonal schedules, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8073.1, Definition 8073.2, and Definition 8073.3 seed the compact-uniform finite-net diagonal schedule over compact metric, continuous-map, finite-radius, uniform-modulus, stream, regular readback, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformDiagonalNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host diagonal choice, quotient stream equality, selected limits, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, pointwise-modulus exposure, finite-radius exposure, uniform-modulus handoff, diagonal StreamName scheduling, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformDiagonalNetUp.

Chapter 8074

A Concrete Naming Certificate for $\mathsf{RealOpenBall}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RealOpenBall}^{\uparrow}$ packet records a $\mathsf{Real}^{\uparrow}$ open ball by finite centre data, a positive dyadic radius, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, and terminal Real seal rows. It consumes the real-name surface of chapter 38, the stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic core ledger of chapter 291, and the general neighbourhood boundary of chapter 2191. The packet gives later $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, and $\mathsf{ContinuousMap}^{\uparrow}$ consumers a finite real-neighbourhood row without importing host topology, quotient real equality, selected limits, open-cover compactness, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8074.1 (Real open ball carrier)**.** *A* $\mathsf{RealOpenBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (c, r, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *c is the centre* $\mathsf{Real}^{\uparrow}$ *seal row, already exposed through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
2. *r is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, with its positivity witness and tolerance ledger displayed before any neighbourhood membership read is consumed.*
3. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows opened from the centre and tested real names at the requested precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the windows in W.*
5. *D is the dyadic comparison ledger for the distance-from-centre estimate, recording the finite rational inequality needed to certify membership inside the radius row r.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the tested name after the windows, readback, and dyadic comparison have been displayed.*
7. *H records componentwise* hsame *transport for centre, radius, windows, readback, comparison, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-neighbourhood query through c, r, W, R, D, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RealOpenBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{OpenBall}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RealOpenBall}^\uparrow}$ *row.*
The classifier compares accepted packets only through $c, r, W, R, D, E, H, C, P, N$. It has no coordinate for host topology, quotient real equality, selected limits, open-cover compactness, real-order trichotomy, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8074.2 (Real open ball NameCert obligations)**.** *For every accepted* $\mathsf{RealOpenBall}^\uparrow$ *carrier $B = (c, r, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealOpenBall}^\uparrow}$ *surface consists exactly of carrier admission, positive dyadic radius admission, finite-window membership, classifier transport, Real-seal handoff, displayed replay, provenance, and local naming for the rows $c, r, W, R, D, E, H, C, P, N$.*

Proof. Carrier admission projects the finite packet of Definition 8074.1. The only real source rows are the centre seal c, the terminal tested seal E, and the window-readback route W, R between them.

The radius obligation is the positive dyadic row r. Its positivity and tolerance ledger are visible before the comparison row D can certify that the tested name lies inside the displayed neighbourhood.

Finite-window membership is therefore exhausted by W, R, D. The StreamName windows expose the requested finite observations, the RegSeqRat row reads those observations back as regular rational data, and the DyadicRatCore comparison row records the strict radius test.

Finally H, C, P, N transport, replay, source, and name exactly the same route. Since no further coordinate is present, the carrier cannot export host topology, quotient real equality, selected limits, open-cover compactness, real-order trichotomy, or ambient $\mathsf{Real}^\uparrow$ completeness. □

Theorem 8074.3 (Real open ball dyadic radius stability)**.** *Let $B = (c, r, W, R, D, E, H, C, P, N)$ be an accepted* $\mathsf{RealOpenBall}^\uparrow$ *carrier. If r' is a positive* $\mathsf{DyadicRatCore}^\uparrow$ *radius row whose displayed tolerance ledger refines the ledger of r, and the same comparison row D certifies the tested name inside r', then the packet*

$$B' = (c, r', W, R, D, E, H, C, P, N)$$

uses the same finite route and remains a $\mathsf{RealOpenBall}^\uparrow$ *carrier with the same centre, StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.*

Proof. Project the accepted carrier B. All non-radius coordinates are already fixed by the finite route from centre and tested Real seals through StreamName windows, RegSeqRat readback, and the dyadic comparison row.

Replace only the radius row by the displayed positive refinement r'. The hypothesis says that the refined tolerance ledger is still a $\mathsf{DyadicRatCore}^\uparrow$ row and that the same comparison row D certifies membership inside that radius.

The structural rows need no new data. Componentwise transport H, replay C, provenance P, and local naming N are read over the same coordinates after substituting r' for r in the radius slot.

Thus B' exposes the same finite neighbourhood route. The stability statement does not supply a chosen smaller radius outside the packet, a quotient-real equality, a trichotomy decision, or any ambient completeness theorem. □

Theorem 8074.4 (Real open ball StreamName–Real handoff)**.** *Every neighbourhood consumer of an accepted* $\mathsf{RealOpenBall}^\uparrow$ *carrier reaches* $\mathsf{Real}^\uparrow$ *only through the finite route*

$$\mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

recorded by $W, R, D, c, E, H, C, P, N$. In particular, a consumer cannot bypass the StreamName windows, detach the RegSeqRat readback, replace the DyadicRatCore radius test by host real equality, or obtain ambient $\mathsf{Real}^{\uparrow}$ *completeness from the neighbourhood row.*

Proof. Begin with the finite windows W. A neighbourhood request is allowed to inspect only the displayed StreamName windows for the centre and tested real names.

The row R is then the only regular rational readback available to the consumer. It converts those windows into the rational data used by the dyadic comparison ledger.

The radius test is exactly the $\mathsf{DyadicRatCore}^{\uparrow}$ row D together with the positive radius row r. Only after that finite comparison is displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed beside the centre seal c.

The remaining rows H, C, P, N preserve and name this order of access. Therefore every Real-facing read factors through StreamName, RegSeqRat, and DyadicRatCore rows, and no host topology, quotient real equality, selected limit, open-cover compactness, trichotomy, or ambient completeness row is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOpenBall}^{\uparrow}}$.

Constructive story: A $\mathsf{RealOpenBall}^{\uparrow}$ packet is generated from a RealUp centre seal, a positive DyadicRatCoreUp radius row, StreamName windows, RegSeqRat readback, a dyadic comparison ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealOpenBall}^{\uparrow}}$, seed)

Scope closed: Definition 8074.1, Definition 8074.2, Definition 8074.3, and Definition 8074.4 seed the finite real-neighbourhood route from displayed Real seals through StreamName, RegSeqRat, and DyadicRatCore rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealOpenBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host topology, quotient real equality, selected limits, open-cover compactness, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive dyadic radius admission, finite-window membership, classifier transport, Real-seal handoff, displayed replay, provenance, and local naming for BEDC.Derived.RealOpenBallUp.

Chapter 8075

A Concrete Naming Certificate for $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ packet records the finite L10 comparison surface used when two displayed real-name routes must be compared before a Real or Completion consumer can read an order-facing conclusion. It sits after the observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real seal of chapter 38, and the Bishop real comparison surface of chapter 1381. The packet names a located comparison route over finite rows; it does not import trichotomy, quotient equality, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8075.1 (BishopLTenComparisonPrinciple carrier)**.** *A* $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the inspected source positions for the two comparison routes.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the dyadic scales, endpoint cells, and comparison budgets consumed by the readback.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the stream, regular-rational, and dyadic rows have been displayed.*
5. *Q is the located comparison evidence row. It records a displayed separating witness or overlap certificate for the inspected window, tied to the sibling* $\mathsf{BishopRealComparison}^{\uparrow}$ *route.*
6. *H records componentwise* hsame *transport for the stream schedule, regular readback, dyadic ledger, Real seal, located comparison evidence, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from finite observation and dyadic tolerance data through regular readback, Real sealing, and located comparison use.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopRealComparison}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, R, D, E, Q, H, C, P, N$. No coordinate stores a global trichotomy branch, quotient real equality, selected representative, host equality test, countable-choice schedule, or ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8075.2 (BishopLTenComparisonPrinciple NameCert obligations)**.** *For every accepted* $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ *carrier*

$$K = (S, R, D, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}}$ *surface consists exactly of carrier admission for the StreamName finite-window row, RegSeqRat readback row, DyadicRatCore tolerance ledger, terminal Real seal, located comparison evidence, componentwise transport, displayed replay, package provenance, and local naming. Every comparison-facing consumer must expose S, R, D before reading the Real seal E or the located comparison row Q.*

Proof. Project the carrier of Definition 8075.1. Its analytic rows are exactly the finite StreamName window, regular rational readback, dyadic tolerance ledger, Real seal, and located comparison evidence.

The route begins with S. The observed source positions determine which finite prefixes of the two real-name routes are public. The readback row R and the dyadic ledger D then provide the rational and tolerance data on which the comparison evidence can be interpreted.

Only after those rows have been displayed may the terminal seal E and the located comparison row Q be consumed. The structural rows H, C, P, N transport, replay, source, and name the same finite route.

The excluded principles are absent by coordinate inspection. Since the carrier has no row for global trichotomy, quotient equality, selected representatives, host equality, countable choice, or ambient Real completeness, the local certificate cannot export any of them. □

Theorem 8075.3 (BishopLTenComparisonPrinciple Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ *packet receives located comparison evidence only through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BishopRealComparison}^{\uparrow}.$$

Thus the handoff may use the inspected window, regular readback, dyadic tolerance ledger, terminal Real seal, and located comparison row, but it exports no trichotomy principle, quotient equality of real names, host equality, selected representative, countable-choice functional, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8075.2. They force each comparison-facing consumer to read S, R, D before the Real seal E or located comparison evidence Q is available.

The Real-facing part of the handoff is therefore downstream of the finite observation and tolerance rows. The Completion-facing part receives the same route: it may replay the inspected comparison through H, C, P, N, but it cannot replace the displayed rows by quotient names or host equality.

The sibling route through $\mathsf{BishopRealComparison}^{\uparrow}$ records only located evidence for the inspected window. Since global trichotomy, selected representatives, countable choice, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not coordinates of K, no Real or Completion consumer can project them from the handoff. □

Falsifiable prediction: An accepted $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ read is refuted if it reaches a Real or Completion comparison consumer without displaying the $\mathsf{StreamName}^{\uparrow}$ finite-window row, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, terminal $\mathsf{Real}^{\uparrow}$ seal, located $\mathsf{BishopRealComparison}^{\uparrow}$ evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: streamname, regseqrat, dyadicratcore, real, bishop-real-comparison: $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite observation windows, regular rational readback, dyadic tolerance data, a Real seal, located comparison evidence, transport, replay, provenance, and local naming as one L10 comparison packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance data, a Real seal, located BishopRealComparison evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8075.1, Definition 8075.2, and Definition 8075.3 seed the L10 located comparison packet over StreamName, RegSeqRat, DyadicRatCore, Real, and BishopRealComparison rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLTenComparisonPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, trichotomy, quotient real equality, host equality, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, located comparison exactness, Real handoff, Completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopLTenComparisonPrincipleUp.

Chapter 8076

A Concrete Naming Certificate for $\mathsf{DirichletJordanTest}^{\uparrow}$

Following Jordan and Dirichlet on bounded variation and trigonometric series, the $\mathsf{DirichletJordanTest}^{\uparrow}$ packet records the finite BEDC surface needed to hand a bounded-variation row to a Fourier partial-sum consumer through a Dirichlet-kernel window. It sits between the bounded-variation carrier of chapter 398, the Fourier row of chapter 124, the kernel window of chapter 2311, the regular rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names the classical test as finite NameCert data without claiming host pointwise convergence, chosen representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8076.1 (Dirichlet–Jordan test carrier)**.** *A* $\mathsf{DirichletJordanTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, K, F, O, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the bounded-variation row read from* $\mathsf{BoundedVariation}^{\uparrow}$*, naming the finite partition-variation ledger available to the test.*
2. *K is the* $\mathsf{DirichletKernel}^{\uparrow}$ *window row, listing the displayed trigonometric-kernel indices and dyadic tail window under inspection.*
3. *F is the* $\mathsf{Fourier}^{\uparrow}$ *partial-sum row, exposing only the finite coefficient and summation data consumed with K.*
4. *O is the dyadic oscillation-budget row that bounds the inspected jump and adjacent-window oscillation data for the same bounded-variation ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the coefficient, kernel, and oscillation windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed real-valued reads.*
7. *H records componentwise* hsame *transport for the bounded-variation, kernel-window, Fourier partial-sum, oscillation-budget, readback, Real-seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a test request through B, K, F, O, R, E.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and sibling* $\mathsf{NameCert}$ *packets.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DirichletJordanTest}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, K, F, O, R, E, H, C, P, N$. It has no coordinate for a host limit of Fourier partial sums, a selected representative of the underlying real function, countable choice over partitions, or ambient real completeness.

Theorem 8076.2 (Dirichlet–Jordan test NameCert obligations)**.** *For every accepted* $\mathsf{DirichletJordanTest}^{\uparrow}$ *carrier* $D = (B, K, F, O, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DirichletJordanTest}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded-variation ledger exposure, Dirichlet-kernel window exposure, Fourier partial-sum exposure, dyadic oscillation-budget exactness, regular rational readback, Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8076.1. The displayed rows expose the bounded-variation ledger, the Dirichlet-kernel window, the Fourier partial-sum row, the dyadic oscillation budget, the regular rational readback, and the Real seal before any consumer can replay the test.

The row order fixes the obligation surface. A Fourier-facing read first consumes the $\mathsf{BoundedVariation}^{\uparrow}$ row, then the $\mathsf{DirichletKernel}^{\uparrow}$ and $\mathsf{Fourier}^{\uparrow}$ rows for the inspected partial sum, and only then reads the oscillation and regular-rational budgets through O and R.

The structural rows H, C, P, N transport, replay, source, and name the same finite data. Since no carrier coordinate stores a host convergence theorem, a selected representative, countable choice over partitions, or ambient real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8076.3 (Dirichlet–Jordan Fourier handoff)**.** *Every Fourier consumer of an accepted* $\mathsf{DirichletJordanTest}^{\uparrow}$ *carrier reads the bounded-variation ledger of chapter 398, the kernel window of chapter 2311, the partial-sum row of chapter 124, and the regular readback and Real seal of chapter 301 and chapter 38 through the single finite route*

$$B, K, F, O, R, E, H, C, P, N.$$

The handoff exports only the displayed finite test surface; it does not assert pointwise convergence of the Fourier series in the host theory.

Proof. Begin with an accepted carrier. By Definition 8076.2, the Fourier consumer receives the bounded-variation row B before it reaches the kernel and partial-sum rows K and F.

The oscillation-budget row O and the regular readback row R keep the inspected jump, adjacent-window, coefficient, and kernel data finite. The Real seal E is therefore read only after those displayed rational windows have been exposed.

Finally H, C, P, N preserve the handoff as one named BEDC packet. No row in that packet selects a Fourier-series limit, quotients real-valued functions, chooses a representative, or imports ambient completeness, so the handoff remains a finite sibling route rather than a host convergence theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{DirichletJordanTest}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DirichletJordanTest}^{\uparrow}$ packet is generated from a bounded-variation row, Dirichlet-kernel window, Fourier partial-sum row, dyadic oscillation budget, regular rational readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DirichletJordanTest}^{\uparrow}}$, seed)

Scope closed: Definition 8076.1, Definition 8076.2, and Definition 8076.3 seed the finite Dirichlet–Jordan test surface at the bounded-variation and Fourier boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DirichletJordanTest}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host pointwise Fourier convergence, quotient equality of real-valued functions, selected representatives, countable choice over partitions, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation ledger exposure, Dirichlet-kernel window exposure, Fourier partial-sum exposure, oscillation-budget exactness, regular readback, Real sealing, transport, replay, provenance, and local naming for the same finite packet.

Chapter 8077

A Concrete Naming Certificate for $\mathsf{RealClosedBall}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley's boundary language, the $\mathsf{RealClosedBall}^{\uparrow}$ packet records a closed real ball by finite center data, a positive dyadic radius, StreamName windows, RegSeqRat readback, a non-strict dyadic distance ledger, and terminal Real seal rows. It consumes the real-name surface of chapter 38, the stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic core ledger of chapter 291, the strict real-neighbourhood surface of chapter 8074, the finite-window real ball carrier of chapter 317, and the metric closed-ball boundary of chapter 1451. The packet gives located interval, compact interval, and metric boundary consumers a non-strict real-neighbourhood row without importing open-cover compactness, trichotomy, quotient real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8077.1 (Real closed ball carrier)**.** *A* $\mathsf{RealClosedBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (c, r, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *c is the center* $\mathsf{Real}^{\uparrow}$ *seal row, exposed through finite* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any boundary comparison is read.*
2. *r is the positive* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius row, including its positivity witness and tolerance ledger.*
3. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows opened from the center and tested real names at the requested precision.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows.*
5. *D is the non-strict dyadic distance ledger, recording the finite rational comparison that certifies the tested name at distance at most the radius row r.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the tested name after W, R, D have been displayed.*
7. *H records componentwise* hsame *transport for center, radius, windows, readback, non-strict comparison, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a closed-neighbourhood query through c, r, W, R, D, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{RealClosedBall}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealOpenBall}^{\uparrow}$, $\mathsf{RealBall}^{\uparrow}$, $\mathsf{MetricClosedBall}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{RealClosedBall}^\uparrow}$ *row.*
The classifier compares accepted packets only through $c, r, W, R, D, E, H, C, P, N$. It has no coordinate for open-cover compactness, trichotomy, quotient real equality, selected limits, host topology closure, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8077.2 (Real closed ball NameCert obligations)**.** *For every accepted* $\mathsf{RealClosedBall}^\uparrow$ *carrier $B = (c, r, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealClosedBall}^\uparrow}$ *surface consists exactly of carrier admission, positive dyadic radius admission, finite-window non-strict membership, classifier transport, Real-seal handoff, displayed replay, provenance, and local naming for the rows $c, r, W, R, D, E, H, C, P, N$.*

Proof. Carrier admission projects the finite packet of Definition 8077.1. The only Real-facing source rows are the center seal c, the tested seal E, and the window-readback route W, R connecting them.

The radius obligation is the positive dyadic row r. Its positivity and tolerance ledger are visible before the non-strict comparison row D can certify closed-ball membership.

Finite-window membership is exhausted by W, R, D. The StreamName windows expose finite observations, the RegSeqRat row reads those observations as regular rational data, and the DyadicRatCore row records the at-most-radius comparison.

Finally H, C, P, N transport, replay, source, and name the same route. Since no further coordinate is present, the packet cannot export open-cover compactness, trichotomy, quotient real equality, selected limits, host topology closure, or ambient $\mathsf{Real}^\uparrow$ completeness. □

Theorem 8077.3 (Real open and closed boundary duality)**.** *Every boundary consumer that compares an accepted* $\mathsf{RealClosedBall}^\uparrow$ *carrier with a strict* $\mathsf{RealOpenBall}^\uparrow$ *or finite-window* $\mathsf{RealBall}^\uparrow$ *carrier must read both sides through the shared route*

$$\mathsf{StreamName}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The closed side exports only the non-strict dyadic distance row D, while the open side exports the strict radius row of chapter 8074. A metric-facing consumer may pass this boundary to chapter 1451, but it receives no open-cover compactness, trichotomy, quotient real equality, selected limit, host topology closure, or ambient $\mathsf{Real}^\uparrow$ *completeness theorem.*

Proof. Start with the closed carrier. Its rows c, r, W, R, D, E display the center, radius, finite windows, rational readback, non-strict comparison, and tested Real seal before any boundary read is available.

Read the open side through the same finite source route. The $\mathsf{RealOpenBall}^\uparrow$ and $\mathsf{RealBall}^\uparrow$ packets expose StreamName windows, RegSeqRat readback, DyadicRatCore radius data, and terminal Real seals; they differ from the closed packet only in the strict comparison row exported to the consumer.

The duality is therefore a boundary routing statement. Closed reads keep the non-strict ledger D, open reads keep the strict radius ledger, and both are replayed through H, C, P, N rather than through host real topology.

Finally, a metric boundary consumer can consume the non-strict row through the $\mathsf{MetricClosedBall}^\uparrow$ surface, but the row remains the displayed finite comparison. No carrier coordinate selects limits, decides trichotomy, quotients real names, proves open-cover compactness, or imports ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealClosedBall}^\uparrow}$.

Constructive story: A RealClosedBall$^{\uparrow}$ packet is generated from a RealUp center seal, a positive DyadicRatCoreUp radius row, StreamName windows, RegSeqRat readback, a non-strict dyadic distance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RealClosedBall}\uparrow}$, seed)

Scope closed: Definition 8077.1, Definition 8077.2, and Definition 8077.3 seed the finite closed real-neighbourhood route from displayed Real seals through StreamName, RegSeqRat, DyadicRatCore, RealOpenBall, RealBall, and MetricClosedBall rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealClosedBall}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient real equality, selected limits, host topology closure, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive dyadic radius admission, finite-window non-strict membership, classifier transport, Real-seal handoff, displayed replay, provenance, and local naming for BEDC.Derived.RealClosedBallUp.

Chapter 8078

A Concrete Naming Certificate for $\mathsf{BishopCut}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCut}^{\uparrow}$ packet records a constructive two-sided cut as finite located lower and upper information before any quotient-real completion or Dedekind completeness principle is available. It consumes the located-cut surface of chapter 404, the lower-real row of chapter 1446, the upper-real envelope of chapter 5121, the dyadic tolerance core of chapter 291, the stream-name windows of chapter 126, the regular-rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter names only the finite cut carrier and its local handoffs; it does not claim a completed real quotient, trichotomy, countable choice, or a Dedekind-completeness theorem.

Definition 8078.1 (BishopCut carrier)**.** *A* $\mathsf{BishopCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, U, E, D, S, R, X, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedCut}^{\uparrow}$ *row recording the finite located lower and upper tests visible in the current window.*
2. *U is the paired* $\mathsf{LowerReal}^{\uparrow}$ *and* $\mathsf{UpperRealEnvelope}^{\uparrow}$ *row that separates lower information from upper-refusal information.*
3. *E is the envelope-consistency row linking the located-cut ledger to the lower and upper presentations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used for rational comparison inside the displayed window.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational handoff row assembled from D and S.*
7. *X is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after L, U, E, D, S, R have been replayed.*
8. *H records componentwise* hsame *transport for the located cut, lower-real row, upper-envelope row, dyadic tolerance row, stream window, regular readback, real seal, replay, provenance, and local naming row.*
9. *C records displayed* Cont *replay from a cut request through $L, U, E, D, S, R, X, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LowerReal}^{\uparrow}$, $\mathsf{UpperRealEnvelope}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCut}^{\uparrow}}$ *row.*

The accepted carrier has no coordinate for quotient reals, global Dedekind cuts, trichotomy, countable choice, selected decimal expansions, or host completeness.

Lean4 (statement) `BEDC.Derived.BishopCutUp`

Theorem 8078.2 (BishopCut NameCert obligations)**.** *For every accepted* $\mathsf{BishopCut}^{\uparrow}$ *carrier* $K = (L, U, E, D, S, R, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCut}^{\uparrow}}$ *surface consists of carrier admission for the displayed located-cut row, lower-real and upper-envelope rows, dyadic tolerance ledger, stream window, regular-rational handoff, terminal real seal, transport, replay, provenance, and local naming row. Every accepted read factors through those rows and refuses quotient reals, global Dedekind completeness, trichotomy, countable choice, selected decimal expansions, and host-completeness data.*

Proof. Project the carrier of Definition 8078.1. The visible rows are exactly $L, U, E, D, S, R, X, H, C, P, N$, so the local NameCert can admit only those finite rows.

The analytic part begins with the located-cut row L and the lower-real and upper-envelope row U. The envelope-consistency row E binds those presentations before dyadic tolerance data in D and stream-window data in S are read.

The Real-facing part is downstream. The row R repacks the displayed window as regular-rational readback, and X seals only that readback. The structural rows H, C, P, N transport, replay, source, and name the same route without adding a quotient, choice, trichotomy, decimal-selection, or completeness coordinate. □

Theorem 8078.3 (BishopCut located window)**.** *Every located-window read of an accepted* $\mathsf{BishopCut}^{\uparrow}$ *packet exposes the route*

$$\mathsf{LocatedCut}^{\uparrow} \longrightarrow \mathsf{LowerReal}^{\uparrow}, \mathsf{UpperRealEnvelope}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

The read is therefore local to $L, U, E, D, S, R, X, H, C, P, N$ and cannot bypass the located-cut ledger by invoking a quotient real, a completed Dedekind cut, trichotomy, countable choice, or host completeness.

Proof. Begin with a located-window request. By Definition 8078.1, the request must first inspect L and the paired lower and upper rows in U.

The finite comparison data is then forced through E, D, S. The envelope-consistency row keeps the lower and upper presentations attached to the located-cut ledger, while the dyadic and stream rows determine the precision window actually in scope.

Finally the handoff row R and the seal row X supply regular-rational and Real-facing readback. Apply Definition 8078.2 to see that H, C, P, N preserve this route and that no refused host object has a carrier coordinate. □

Theorem 8078.4 (BishopCut Real handoff)**.** *For every accepted* $\mathsf{BishopCut}^{\uparrow}$ *packet, any* $\mathsf{Real}^{\uparrow}$ *consumer receives a terminal seal only after the located-cut row, lower-real row, upper-real envelope, dyadic tolerance ledger, stream-name window, and regular-rational readback have all been displayed. The handoff is a finite NameCert route from constructive cut data to a real-name seal, not a claim of Dedekind completeness or quotient-real equality.*

Proof. Read the terminal seal request. The carrier definition makes X the only $\mathsf{Real}^{\uparrow}$ row, and it is listed after L, U, E, D, S, R.

Use Definition 8078.3 to identify the required upstream route. A Real-facing consumer has already passed through the located-cut ledger, lower and upper rows, dyadic tolerance data, stream window, and regular readback before it sees X.

The structural rows cannot strengthen the result. They only transport, replay, source, and name the same finite handoff, so the theorem exports a real-name seal while leaving completeness, quotient equality, trichotomy, and choice outside the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCut}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCut}^{\uparrow}$ packet is generated from a located-cut row, lower-real row, upper-real envelope, dyadic tolerance ledger, StreamName window, RegSeqRat handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCut}^{\uparrow}}$, seed)

Scope closed: Definition 8078.1, Definition 8078.2, Definition 8078.3, and Definition 8078.4 bind the finite two-sided constructive cut seed over the Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCut}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.BishopCutUp`

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient real equality, trichotomy, countable choice, selected decimal expansions, host completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, located-window routing, Real handoff, classifier stability, ledger exactness, and bridge eligibility for BEDC.Derived.BishopCutUp.

Chapter 8079

A Concrete Naming Certificate for FiniteCandidateDiamond$^{\uparrow}$

The FiniteCandidateDiamond$^{\uparrow}$ packet realizes the recursor-as-authorized-generator audit route of chapter 9373 as a finite candidate-diamond ledger for MetaCIC confluence work. It sits after the authorized-generator recursor surface of chapter 525, the recursor-generator packet of chapter 534, the MetaCIC critical path of chapter 765, the parallel diamond frontier of chapter 4238, and the candidate strong-normalization boundary of chapter 2274. The packet records only finite local-join candidates, branch-audit rows, and route handoffs; it does not assert full confluence, normalization, global Church–Rosser, or host equality reflection.

Definition 8079.1 (FiniteCandidateDiamond carrier)**.** *A* FiniteCandidateDiamond$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, R, M, F, S, J, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the* AuthorizedGeneratorRecursor$^{\uparrow}$ *row certifying that the inspected generator call is tied to an accepted constructor signature and branch package.*
2. *R is the* RecursorGenerator$^{\uparrow}$ *row recording the finite motive, branch, and output route.*
3. *M is the* MetaCICCriticalPath$^{\uparrow}$ *row naming the local term-shape and reduction-frontier context.*
4. *F is the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *row exposing the two candidate one-step fronts.*
5. *S is the* CandidateSNConfluenceBoundary$^{\uparrow}$ *row recording the normalization-facing candidate boundary consumed by the audit.*
6. *J is the finite local-join candidate ledger, storing only displayed joins between the two frontier rows.*
7. *T is the TasteGate-expectation row for a Nontrivial carrier and FieldFaithful readback of the displayed rows.*
8. *H records componentwise* hsame *transport for authorized-generator, recursor-generator, critical-path, frontier, boundary, join-ledger, TasteGate, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a candidate-diamond audit through $A, R, M, F, S, J, T, H, P, N$.*
10. *P is the* Pkg *provenance over* FiniteCandidateDiamond$^{\uparrow}$, AuthorizedGeneratorRecursor$^{\uparrow}$, RecursorGenerator$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, CandidateSNConfluenceBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCandidateDiamond}^{\uparrow}}$ *row.*
The accepted carrier has no coordinate for global confluence, full normalization, quotient equality, proof irrelevance, host equality reflection, or an unrestricted search oracle.

Lean4 (statement) `BEDC.Derived.FiniteCandidateDiamondUp`

Theorem 8079.2 (FiniteCandidateDiamond local-join obligation)**.** *For every accepted* $\mathsf{FiniteCandidateDiamond}^{\uparrow}$ *packet $D = (A, R, M, F, S, J, T, H, C, P, N)$, each local-join obligation is read through the authorized-generator row A, recursor-generator row R, MetaCIC critical-path row M, parallel diamond frontier F, candidate strong-normalization boundary S, finite join ledger J, TasteGate-expectation row T, and the structural rows H, C, P, N. The obligation is local to the displayed candidate diamond and does not claim full confluence, normalization, global Church–Rosser, quotient equality, or host equality reflection.*

Proof. Project the carrier of Definition 8079.1. The generator authorization and recursor generator rows A, R are the only rows that can justify the branch package being audited.

Read the MetaCIC rows next. The critical-path row M fixes the term-shape context, the frontier row F exposes the two candidate one-step fronts, and the boundary row S records the normalization-facing candidate boundary in scope.

The local join is then finite. The ledger J stores the displayed candidate joins, while T states the expected Nontrivial and FieldFaithful TasteGate surface for the carrier. The structural rows H, C, P, N preserve and name the same route, so no unrestricted global confluence or host equality principle enters the obligation. □

Theorem 8079.3 (FiniteCandidateDiamond MetaCIC handoff)**.** *Every MetaCIC consumer of an accepted* $\mathsf{FiniteCandidateDiamond}^{\uparrow}$ *packet receives candidate-diamond evidence only through the route*

$$\mathsf{AuthorizedGeneratorRecursor}^{\uparrow} \longrightarrow \mathsf{RecursorGenerator}^{\uparrow} \longrightarrow \mathsf{MetaCICCriticalPath}^{\uparrow} \longrightarrow \mathsf{MetaCICParallelDiamondFronti}$$

The handoff exposes a finite audit packet for candidate-mediated joins, not a proof of unrestricted confluence, normalization, quotient equality, or host equality reflection.

Proof. Start with a MetaCIC consumer. The carrier forces the consumer to inspect A and R before it may treat any recursor-produced branch as an authorized generator output.

The consumer then reads M, F, S. These rows tie the audit to a critical-path term context, a displayed parallel frontier, and a candidate strong-normalization boundary rather than to an ambient reduction universe.

Finally apply Definition 8079.2. The finite ledger J, TasteGate-expectation row T, and structural rows H, C, P, N exhaust the handoff. Since the refused principles have no carrier row, the exported packet remains a finite MetaCIC audit route. □

Falsifiable prediction: An accepted $\mathsf{FiniteCandidateDiamond}^{\uparrow}$ audit is refuted if a candidate local join is exposed without displaying authorizedgeneratorrecursor, recursorgenerator, metaciccriticalpath, metacic-parallel-diamond-frontier, candidate-sn-confluence-boundary, finite join-ledger, TasteGate expectation, replay, provenance, and local naming rows.

Independence witness: authorizedgeneratorrecursor, recursorgenerator, metaciccriticalpath, metacic-parallel-diamond-frontier, candidate-sn-confluence-boundary: none alone is bijective with $\mathsf{FiniteCandidateDiamond}^{\uparrow}$ because the packet jointly records generator authorization, recursor branch

data, critical-path context, parallel frontier, candidate boundary, local join ledger, TasteGate expectation, transport, replay, provenance, and NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCandidateDiamond}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCandidateDiamond}^{\uparrow}$ packet is generated from authorized-generator recursor data, recursor-generator branch data, MetaCIC critical-path rows, parallel diamond frontier rows, candidate strong-normalization boundary rows, a finite local-join ledger, TasteGate expectation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCandidateDiamond}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8079.1, Definition 8079.2, and Definition 8079.3 bind the finite candidate-diamond audit seed for recursor-generator MetaCIC work.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCandidateDiamond}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FiniteCandidateDiamondUp`

Bridge status: none

Not claimed: This chapter does not claim full confluence, normalization, global Church–Rosser, quotient equality, proof irrelevance, host equality reflection, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, local-join obligation routing, MetaCIC handoff, TasteGate Nontrivial and FieldFaithful expectations, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCandidateDiamon

Chapter 8080

A Concrete Naming Certificate for $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$

Following Birkhoff and von Neumann on doubly stochastic matrices, the $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ packet records the finite permutation-flow route by which a displayed doubly stochastic matrix is read as a convex ledger of permutation matrices. It sits after the finite matrix surface of chapter 49, the certified finite-position action rows of chapter 116, the capacity route of chapter 233, the finite matching surface of chapter 234, and the affine membership rows of chapter 208. The packet names only the finite BEDC route from matrix rows to permutation-flow rows and convex-combination ledgers; it is not the full Birkhoff polytope theorem over arbitrary host matrices.

Definition 8080.1 (Birkhoff–von Neumann finite carrier)**.** *A* $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, R, C, F, K, E, W, T, Q, H, J, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *source row, recording the finite square matrix entries and the finite index spine on which all row and column reads occur.*
2. *R is the row-stochastic ledger, displaying each finite row sum and nonnegative-entry read.*
3. *C is the column-stochastic ledger, displaying each finite column sum and the same nonnegative-entry boundary.*
4. *F is the* $\mathsf{NetworkFlow}^{\uparrow}$ *support route, naming the bipartite residual graph whose positive entries are available for decomposition.*
5. *K is the* $\mathsf{Matching}^{\uparrow}$ *row that exposes one finite perfect-matching or permutation-support step inside the currently displayed residual support.*
6. *E is the extraction row that records the scalar weight removed from the residual matrix along the displayed matching.*
7. *W is the convex-combination ledger, listing the finite weights, their total-one certificate, and the permutation-matrix rows they weight.*
8. *T is the transport row taking each matching row into a* $\mathsf{Permutation}^{\uparrow}$ *matrix exposure over the same finite index spine.*
9. *Q is the* $\mathsf{ConvexSet}^{\uparrow}$ *affine-membership row witnessing that the displayed convex combination remains inside the matrix carrier surface.*

10. *H records componentwise* hsame *transport for matrix, stochastic, flow, matching, extraction, convex-ledger, permutation-exposure, affine-membership, replay, provenance, and local naming rows.*
11. *J records displayed* Cont *replay from finite stochastic rows through support flow, matching exposure, extraction, convex ledger, and permutation-matrix exposure.*
12. *P is the* Pkg *provenance over* $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Permutation}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these thirteen displayed rows. It does not read a host polytope, an arbitrary matrix space, an ambient linear-programming theorem, quotient matrix equality, choice-selected decompositions, or an infinite compactness argument.

Theorem 8080.2 (Birkhoff–von Neumann NameCert obligations)**.** *For every accepted* $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ *packet*

$$B = (M, R, C, F, K, E, W, T, Q, H, J, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}}$ *obligation surface consists exactly of finite matrix admission, row-stochastic exposure, column-stochastic exposure, finite network-flow support, matching extraction, scalar residual extraction, convex-combination ledger, permutation-matrix exposure, convex-set affine membership, componentwise transport, displayed replay, provenance, and local naming. Every downstream consumer must display $M, R, C, F, K, E, W, T, Q$ before reading a decomposition-facing or convexity-facing conclusion.*

Proof. Project the carrier of Definition 8080.1. The matrix-facing data are exactly M, R, C: the finite square matrix entries, the row sums, the column sums, and the nonnegative-entry boundary.

The decomposition-facing data are F, K, E, W, T. The support graph is read through the finite $\mathsf{NetworkFlow}^{\uparrow}$ route, a displayed $\mathsf{Matching}^{\uparrow}$ row supplies one permutation support, the extraction row records the removed scalar weight, and the ledger W records the resulting finite convex combination. The transport row T turns each matching into the corresponding $\mathsf{Permutation}^{\uparrow}$ matrix exposure over the same index spine.

The convex-facing data are then Q, H, J, P, N. The $\mathsf{ConvexSet}^{\uparrow}$ row reads the finite weight ledger and permutation-matrix exposures, while transport, replay, provenance, and local naming keep the same rows attached to the public certificate.

No excluded principle is a coordinate of the carrier. Since there is no row for a host polytope, arbitrary matrix space, ambient linear-programming theorem, quotient matrix equality, choice-selected decomposition, or infinite compactness argument, the local NameCert surface cannot export any of them. □

Theorem 8080.3 (Birkhoff–von Neumann permutation-flow route)**.** *Every decomposition-facing read exported by an accepted* $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Mat}^{\uparrow} \longmapsto \mathsf{NetworkFlow}^{\uparrow} \longmapsto \mathsf{Matching}^{\uparrow} \longmapsto \mathsf{Permutation}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow}.$$

The route first displays the finite doubly stochastic matrix rows, then reads the residual support as a network-flow surface, exposes matching rows as permutation matrices, records the convex-combination ledger, and transports the result through replay, provenance, and the local NameCert *row. It does not claim the full Birkhoff polytope theorem over arbitrary host matrices.*

Proof. Start with the NameCert obligations of Definition 8080.2. They require every decomposition-facing consumer to inspect the matrix row M, the row-stochastic ledger R, and the column-stochastic ledger C before any matching or convex ledger can be read.

Next read the support route. The $\mathsf{NetworkFlow}^{\uparrow}$ row F exposes only the finite residual support graph, and the $\mathsf{Matching}^{\uparrow}$ row K supplies the displayed perfect-matching step used by the extraction row E.

The transport row T converts that matching support into a $\mathsf{Permutation}^{\uparrow}$ matrix exposure on the same finite index spine. The convex ledger W and affine row Q then record the weighted finite list through $\mathsf{ConvexSet}^{\uparrow}$.

The structural rows H, J, P, N replay and name the same route. Because every stage is tied to the displayed finite rows, the read cannot be replaced by a host polytope theorem, quotient matrix equality, selected decomposition oracle, or ambient compactness principle. □

Falsifiable prediction: An accepted $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ read is refuted if it exports a permutation-matrix convex decomposition without displaying the $\mathsf{Mat}^{\uparrow}$ source row, row-stochastic ledger, column-stochastic ledger, $\mathsf{NetworkFlow}^{\uparrow}$ support route, $\mathsf{Matching}^{\uparrow}$ extraction row, scalar residual extraction row, convex-combination ledger, $\mathsf{Permutation}^{\uparrow}$ matrix exposure, $\mathsf{ConvexSet}^{\uparrow}$ affine-membership row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: matrix, permutation, networkflow, matching, convexset: $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite doubly stochastic matrix rows, residual support flow, matching extraction, scalar residual weights, permutation-matrix exposure, convex-combination membership, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}}$.

Constructive story: A $\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}$ packet is generated from finite MatrixUp source rows, row-stochastic and column-stochastic ledgers, NetworkFlowUp support rows, MatchingUp extraction rows, scalar residual extraction, convex-combination ledgers, PermutationUp matrix exposures, ConvexSetUp affine-membership rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8080.1, Definition 8080.2, and Definition 8080.3 seed the finite permutation-flow certificate over MatrixUp, NetworkFlowUp, MatchingUp, PermutationUp, and ConvexSetUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BirkhoffVonNeumannFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, the full Birkhoff polytope theorem over arbitrary host matrices, host matrix equality, selected decompositions, linear-programming duality, or compactness.

Upgrade path: Obligation closure requires checked carrier admission, stochastic ledger exposure, finite support-flow routing, matching extraction, scalar residual extraction, permutation-matrix exposure, convex-combination membership, transport, replay, provenance, and local naming for BEDC.Derived.BirkhoffVonNeumannFiniteUp.

Chapter 8081

A Concrete Naming Certificate for $\mathsf{FareyApproximation}^{\uparrow}$

Following Hardy–Wright on rational approximation through Farey neighbors, the $\mathsf{FareyApproximation}^{\uparrow}$ packet records the finite rational-density route that passes from denominator-bounded Farey rows to real-name approximation consumers. It sits between the ordered neighbor surface of chapter 1759, the branch-address surface of chapter 1704, the rational readback window of chapter 1668, the regular rational sequence route of chapter 301, and the terminal real-name interface of chapter 38. The packet names finite inspection data for a displayed real input and tolerance budget; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, a global choice of best approximants, or a quotient-real equality theorem.

Definition 8081.1 (FareyApproximationUp carrier)**.** *A* $\mathsf{FareyApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (E, Q, B, F, S, R, W, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *input name whose finite rational window is being inspected.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the rational samples available at the requested budget.*
3. *B is the denominator and tolerance bound row.*
4. *F is the* $\mathsf{FareySequence}^{\uparrow}$ *neighbor row, recording the adjacent rational endpoints selected at the displayed denominator level.*
5. *S is the* $\mathsf{SternBrocot}^{\uparrow}$ *branch row that replays the same endpoints as a finite left-right address.*
6. *R is the rational output row admitted by the Farey bracket.*
7. *W is the finite error-window row witnessing that R lies inside the displayed tolerance read from B and Q.*
8. *H records componentwise* hsame *transports for the real name, readback, bound, neighbor, branch, rational output, window, provenance, and local certificate rows.*
9. *C records the displayed* Cont *replays by which consumers read the finite approximation window.*
10. *P is the* Pkg *provenance over* $\mathsf{FareyApproximation}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{RealRationalApproximation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{FareyApproximation}^\uparrow}$ *row.*
No coordinate supplies a selected best approximation, an infinite Farey process, a real-completeness proof, or a countable-choice selector.

Theorem 8081.2 (FareyApproximationUp NameCert obligations)**.** *For every accepted* $\mathsf{FareyApproximation}^\uparrow$ *carrier A, the local* $\mathsf{NameCert}_{\mathsf{FareyApproximation}^\uparrow}$ *surface consists exactly of carrier admission for*

$$E, Q, B, F, S, R, W, H, C, P, N,$$

Farey-neighbor exposure, Stern–Brocot branch replay, rational readback from the displayed real-name samples, finite tolerance-window exactness, componentwise transport, continuation replay, provenance, and nonescape from selected-best-approximant or $\mathsf{Real}^\uparrow$ *completeness claims.*

Proof. Project the carrier of Definition 8081.1. The rows E, Q, B, F, S, R, W are the whole mathematical surface: a displayed real name, a finite rational readback, a denominator and tolerance budget, the Farey neighbor bracket, the matching Stern–Brocot branch address, a rational output row, and the finite window check.

The route through chapter 1759 supplies the ordered neighbor inspection, while chapter 1704 supplies the branch replay for the same bracket. The rows H and C keep these reads componentwise and displayed.

The provenance row P and local row N record that no other obligation is available. Since no coordinate carries a selector for best approximants or a real-completeness witness, the NameCert surface stops at the finite rational-density window. □

Theorem 8081.3 (FareyApproximationUp real-density handoff)**.** *Every accepted* $\mathsf{FareyApproximation}^\uparrow$ *carrier exposes a finite rational-density handoff*

$$\mathsf{Real}^\uparrow \longleftarrow \mathsf{RegSeqRat}^\uparrow \longleftarrow \mathsf{FareySequence}^\uparrow \longleftrightarrow \mathsf{SternBrocot}^\uparrow \longrightarrow \mathsf{RealRationalApproximation}^\uparrow$$

for the displayed input row E and budget row B. The handoff gives downstream consumers the rational output R together with the finite error window W, but it does not select a denominator-optimal approximant and does not close the ambient completeness of $\mathsf{Real}^\uparrow$*.*

Proof. Read Q from the displayed real-name input E at the budget B. This produces only the finite rational samples admitted by the regular rational sequence route.

Next read the Farey neighbor row F and the Stern–Brocot branch row S. These two rows identify the same finite rational bracket: F as an ordered neighbor inspection and S as a branch-address replay. The rational output row R and window row W are consumed through that bracket.

Finally, the continuation row C exposes the resulting finite approximation window to the $\mathsf{RealRationalApproximation}^\uparrow$ consumer. Because the carrier contains neither a best-approximant selector nor a completeness construction for all Cauchy data, the handoff remains a finite rational-density packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FareyApproximation}^\uparrow}$**.**

Constructive story: A $\mathsf{FareyApproximation}^\uparrow$ packet is generated from a displayed RealUp name, RegSeqRat finite readback, denominator and tolerance budget, FareySequence neighbor row, SternBrocot branch replay, rational output row, finite error-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FareyApproximation}^\uparrow}$, seed)

Scope closed: Definition 8081.1, Definition 8081.2, and Definition 8081.3 bind the finite carrier, NameCert obligation surface, and rational-density handoff route for the displayed budget.

Formal verification: FormalStatus(NameCert$_{\text{FareyApproximation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim RealUp completeness, selected best approximants, global rational-density choice, quotient-real equality, countable choice, or a checked Lean certificate.

Upgrade path: Obligation closure requires checked carrier admission, Farey-neighbor exposure, Stern–Brocot branch replay, rational-window exactness, transport, replay, provenance, and local naming for BEDC.Derived.FareyApproximationUp.

Chapter 8082

A Concrete Naming Certificate for $\mathsf{CauchyUniformCriterion}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria and regular real names, the $\mathsf{CauchyUniformCriterion}^{\uparrow}$ packet records the finite route by which one displayed uniform tail threshold serves a family of regular Cauchy reads before a Real-completion consumer asks for a seal. It sits beside the stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the existing uniform criterion packet of chapter 5823. The packet names the uniform Cauchy handoff as finite rows; it does not form quotient streams, choose a limit, import countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8082.1 (Cauchy uniform criterion carrier)**.** *A* $\mathsf{CauchyUniformCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, M, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *family of inspected tail windows.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by all displayed windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback obtained from those windows and tolerances.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal-facing row exposed only after S, D, R, M, F have been read.*
5. *M is the common modulus row naming the uniform threshold discipline.*
6. *F is the finite family-index row recording which displayed windows are covered by the same threshold.*
7. *H records componentwise* hsame *transport for the stream, dyadic, regular-readback, real-seal, modulus, family, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P records* Pkg *provenance over* $\mathsf{CauchyUniformCriterion}^{\uparrow}$, $\mathsf{CauchyCriterionUniform}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N records the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a quotient Cauchy class, selected limit, global choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Theorem 8082.2 (Cauchy uniform criterion NameCert obligations)**.** *For an accepted* $\mathsf{CauchyUniformCriterion}^{\uparrow}$ *carrier* $U = (S, D, R, E, M, F, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyUniformCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission, finite window-family exposure, dyadic tolerance exactness, regular rational readback, real-seal non-escape, common-modulus visibility, family-index coverage, componentwise transport, displayed replay, package provenance, and local naming for the carrier of Definition 8082.1.*

Proof. Project the carrier. The rows S and F expose the inspected family of windows, and the row M supplies the common threshold discipline used by every displayed member of that family.

The dyadic ledger D is then read before the regular readback row R. The real-seal-facing row E is downstream of both the tolerance ledger and the regular readback, so it cannot be used as an independent limit selector.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no further coordinate, the NameCert surface is exhausted by the listed rows and cannot export quotient streams, selected limits, choice, host real equality, or ambient completeness. □

Theorem 8082.3 (Cauchy uniform criterion Real-completion handoff)**.** *Every Real-completion consumer of an accepted* $\mathsf{CauchyUniformCriterion}^{\uparrow}$ *carrier must read the finite route*

$$S, F, M, D, R \longmapsto E \longmapsto H, C, P, N.$$

Thus the consumer receives a displayed family of StreamName windows, one common modulus, the shared dyadic tolerance ledger, the RegSeqRat readback, and only then the RealUp seal-facing row. The handoff exports no quotient Cauchy class, selected limit, host equality of real names, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the carrier inventory of Definition 8082.1. The family row F and common modulus row M are visible before the tolerance ledger is consumed, so the route records uniformity as displayed finite data.

Next read D and R. These rows are the only tolerance and regular-rational readback surfaces available to the consumer, and the seal-facing row E appears only after them.

Finally replay H, C, P, N. The same transport, continuation, provenance, and local naming rows preserve the finite route, preventing a consumer from replacing it by a quotient completion, selected endpoint, host equality theorem, choice schedule, or ambient completeness assertion. □

Falsifiable prediction: A claimed $\mathsf{CauchyUniformCriterion}^{\uparrow}$ consumer is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ seal while omitting the displayed StreamName family, common modulus, dyadic tolerance ledger, RegSeqRat readback, transport, replay, provenance, or local NameCert row.

Independence witness: cauchy-criterion-uniform, streamname, dyadicratcore, regseqrat, real: $\mathsf{CauchyUniformCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the family-index row, common threshold discipline, shared tolerance ledger, regular readback, Real seal-facing row, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyUniformCriterion}^{\uparrow}}$.

Constructive story: A CauchyUniformCriterion$^{\uparrow}$ packet is generated from a finite StreamName family, a DyadicRatCore tolerance ledger, a RegSeqRat readback row, a RealUp seal-facing row, a common modulus row, a family-index coverage row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyUniformCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 8082.1, Definition 8082.2, and Definition 8082.3 seed the finite uniform Cauchy handoff from displayed windows and a common threshold to RegSeqRat readback and RealUp seal-facing rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyUniformCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy classes, selected limits, host real equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite family coverage, common-modulus visibility, dyadic tolerance exactness, regular readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyUniformCriterionUp.

Chapter 8083

A Concrete Naming Certificate for MetaCICDecidableTypecheckingHandoff$^{\uparrow}$

The MetaCICDecidableTypecheckingHandoff$^{\uparrow}$ packet realizes the MetaCIC decidability audit map of chapter 9379 as a finite boundary between checked type inference and bounded beta-conversion evidence. It reads the checker budget of chapter 5949, the decidability boundary of chapter 749, the typed frontier of chapter 3616, and the bounded normal-equality checker of chapter 752. The packet keeps `inferTypeCtx` soundness and completeness separate from the conditional closed-normal comparison route; it does not claim unrestricted conversion decidability.

Definition 8083.1 (MetaCIC decidable typechecking handoff carrier)**.** *A* MetaCICDecidableTypecheckingHandoff$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\Gamma, T, S, Q, B, F, R, H, C, P, N)$$

with the following displayed rows:

1. Γ *is the represented MetaCIC context row.*
2. T *is the* `inferTypeCtx` *checker row, including the context-indexed input and option-valued output.*
3. S *is the checked soundness and completeness row for the type-inference surface.*
4. Q *is the structural same-term checker row used before any normal comparison is requested.*
5. B *is the bounded normal-equality row, carrying displayed fuel and bounded normal forms.*
6. F *is the finished closed-normal boundary row required before a bounded comparison is promoted to the stronger closed-normal statement.*
7. R *is the refusal row recording that the packet does not export fuel-erased beta-conversion decidability when* F *is absent.*
8. H *records componentwise* hsame *transport for the context, checker, soundness-completeness, same-term, bounded-normal, finished-boundary, refusal, replay, provenance, and local naming rows.*
9. C *records displayed* Cont *replay through the same checker and conversion-boundary route.*
10. P *records* Pkg *provenance over* MetaCICDecidableTypecheckingHandoff$^{\uparrow}$, BoundedTypecheckingBudget$^{\uparrow}$, MetaCICDecidableTypingFrontier$^{\uparrow}$, BoundedNormalEqualityChecker$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N records the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host typechecker, proof-irrelevant term equality, unrestricted beta-conversion decider, hidden fuel, or external closedness oracle.

Theorem 8083.2 (MetaCIC decidable typechecking handoff obligations)**.** *For every accepted* $\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}$ *carrier* $K = (\Gamma, T, S, Q, B, F, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICDecid}}$ *surface consists exactly of context admission,* `inferTypeCtx` *exposure, checked soundness-completeness exposure, structural same-term exposure, bounded normal-equality exposure, finished-boundary exposure when available, refusal-boundary retention, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier. The context row Γ, checker row T, and theorem row S form the typechecking side of the packet; they expose the checked `inferTypeCtx` interface without introducing a host typechecker.

The equality side is separate. The row Q supplies structural same-term readback, while B supplies bounded normal-equality data at displayed fuel.

The row F is the boundary required before a bounded comparison can be used as closed-normal endpoint evidence. If F is absent, the refusal row R remains part of the same NameCert route and blocks any unrestricted conversion claim.

Transport H, replay C, provenance P, and local naming N preserve this separation. No remaining coordinate can erase fuel, add a closedness oracle, or turn bounded beta conversion into global decidability. □

Theorem 8083.3 (MetaCIC decidable typechecking closed-normal boundary)**.** *Every consumer of an accepted* $\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}$ *packet factors through the finite route*

$$\Gamma, T, S, Q, B, F, R \longmapsto H, C, P, N.$$

The rows Γ, T, S make checked type inference public; the rows Q, B make structural and bounded normal equality public; the row F is required for a closed-normal endpoint read; and the row R remains visible whenever that endpoint boundary is not supplied. The packet therefore separates checked type inference from conditional bounded beta conversion.

Proof. Start with the typechecking route. The checker row T is read in context Γ, and the row S records the checked soundness and completeness surface for `inferTypeCtx`.

Move to the conversion route. Structural same-term data Q and bounded normal-equality data B are finite checker rows; they do not by themselves state that fuel has reached finished closed normal forms.

The endpoint condition is exactly F. When a consumer has F, it may use the bounded comparison as a closed-normal endpoint read; without F, it must keep the refusal row R in scope.

The replay rows H, C, P, N carry no further oracle. Hence the public handoff is the displayed separation between checked type inference and conditional bounded beta conversion. □

Falsifiable prediction: A claimed $\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}$ consumer is refuted if it exports unrestricted beta-conversion decidability while omitting the finished closed-normal boundary row F and refusal row R.

Independence witness: bounded-typechecking-budget, metacic-decidable-boundary, metacic-decidable-typing-frontier, bounded-normal-equality-checker: no listed sibling is bijective to $\mathsf{MetaCICDecidableTypec}$

because this packet jointly carries the type-inference theorem row, bounded conversion boundary, refusal row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}$ packet is generated from a represented context, inferTypeCtx checker row, checked soundness-completeness row, same-term row, bounded normal-equality row, finished closed-normal boundary row, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8083.1, Definition 8083.2, and Definition 8083.3 seed the finite handoff separating checked type inference from conditional bounded beta conversion.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unrestricted beta-conversion decidability, fuel-erased normalization, a host typechecker, proof-irrelevant term equality, external closedness decision, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inferTypeCtx soundness-completeness exposure, same-term exactness, bounded normal-equality exactness, finished-boundary retention, refusal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICDecidableTypecheckingHandoffUp.

Chapter 8084

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyFilter}^{\uparrow}$

Following Kelley and Bishop–Bridges on Cauchy filters, regular real names, and finite moduli, the $\mathsf{RegulatedCauchyFilter}^{\uparrow}$ packet records the completion-facing filter object whose basis, modulus, regular readback, dyadic tolerance, and Real seal are all visible as BEDC rows. It sits after the filter-limit basis of chapter 3862, the completion surface of chapter 1569, the Cauchy-filter source of chapter 333, the filter-limit handoff of chapter 1558, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet narrows filter completion to displayed finite basis and regular-readback data; it does not assert quotient filters, selected limits, countable choice, host filter equality, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8084.1 (Regulated Cauchy filter carrier)**.** *A* $\mathsf{RegulatedCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, F, Q, L, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{FilterLimitBasis}^{\uparrow}$ *row exposing the finite basis used by completion and limit consumers.*
2. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose accepted reads remain tied to the displayed basis row B.*
3. *Q is the* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion-facing row available only through the same displayed basis and source filter.*
4. *L is the* $\mathsf{CauchyFilterLimit}^{\uparrow}$ *boundary row that records the limit-facing handoff without selecting a limit.*
5. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the regulated read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row attached to the same windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and modulus ledger controlling the requested precision.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after B, F, Q, L, W, R, D have been displayed.*
9. *H records componentwise* hsame *transport for basis, source filter, completion row, limit row, windows, readback, tolerance, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a regulated completion request through $B, F, Q, L, W, R, D, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyFilter}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{CauchyFilterCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{CauchyFilterLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, Q, L, W, R, D, E, H, C, P, N$. It has no coordinate for quotient filters, ultrafilters, selected limits, countable-choice schedules, host filter equality, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8084.2 (Regulated Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{RegulatedCauchyFilter}^{\uparrow}$ *carrier $G = (B, F, Q, L, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, finite basis exposure, Cauchy-filter source admission, completion-row handoff, filter-limit boundary admission, finite stream-window inspection, regular rational read-back, dyadic tolerance regulation, terminal Real-seal ordering, componentwise transport, displayed replay, provenance, and local naming for the rows $B, F, Q, L, W, R, D, E, H, C, P, N$.*

Proof. Project the carrier of Definition 8084.1. The only available rows are $B, F, Q, L, W, R, D, E, H, C, P, N$, so carrier admission exposes finite basis, source filter, completion, limit boundary, window, read-back, tolerance, seal, transport, replay, provenance, and naming data.

The regulated completion route begins with B and F. The filter-limit basis and Cauchy-filter source force a completion-facing request to consume finite basis data before it can inspect Q or L.

Next read the window and regularity rows W, R, D. The StreamName window is finite, the RegSeqRat row reads that window as regular rational data, and the DyadicRatCore row records the displayed tolerance budget for the requested precision.

Finally E, H, C, P, N order and preserve the same route. Since the excluded quotient, selection, choice, host-equality, and ambient-completeness objects are absent from the carrier, the listed rows exhaust the local NameCert surface. □

Theorem 8084.3 (Regulated completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{RegulatedCauchyFilter}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FilterLimitBasis}^{\uparrow},\ \mathsf{CauchyFilter}^{\uparrow},\ \mathsf{CauchyFilterCompletion}^{\uparrow},\ \mathsf{CauchyFilterLimit}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Dyac}$$

before terminal Real evidence is read. The route uses the displayed rows $B, F, Q, L, W, R, D, E, H, C, P, N$ of the same packet and cannot import quotient filters, selected limits, countable choice, host filter equality, quotient real equality, or ambient completeness.

Proof. Start with an accepted completion-facing consumer of G. The carrier admits a completion row Q only together with the displayed basis row B and source Cauchy-filter row F.

The limit-facing row L is read on the same route. It records a boundary handoff, but it does not select a limit or identify quotient filters.

The consumer then opens the finite window W, reads it through R, and checks the requested precision through D. Only after those rows are displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed.

Transport, replay, provenance, and local naming are confined to H, C, P, N. Hence every accepted consumer remains inside the displayed finite packet rather than entering host filter equality, quotient real equality, countable choice, selected limits, or ambient completeness. □

Theorem 8084.4 (Regulated Cauchy filter basis terminal seal)**.** *Every accepted terminal* $\mathsf{Real}^{\uparrow}$ *seal read through a* $\mathsf{RegulatedCauchyFilter}^{\uparrow}$ *packet must first display the* $\mathsf{FilterLimitBasis}^{\uparrow}$ *row B, the*

CauchyFilter$^{\uparrow}$ *source row* F*, the* CauchyFilterCompletion$^{\uparrow}$ *row* Q*, the* CauchyFilterLimit$^{\uparrow}$ *boundary row* L*, the* StreamName$^{\uparrow}$ *window* W*, the* RegSeqRat$^{\uparrow}$ *readback* R*, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger* D*, and the structural rows* H, C, P, N*. The terminal seal* E *is therefore read only as the endpoint of the displayed finite basis route, not as ambient* Real$^{\uparrow}$ *completeness, a selected limit, quotient filter equality, host filter equality, or quotient real equality.*

Proof. Project the carrier of Definition 8084.1. The terminal seal row E appears only in the same packet as $B, F, Q, L, W, R, D, H, C, P, N$.

Use the NameCert obligations of Definition 8084.2. They force carrier admission, finite basis exposure, source-filter admission, completion handoff, limit-boundary admission, finite window inspection, regular readback, dyadic tolerance regulation, transport, replay, provenance, and local naming to be read together.

Finally apply the completion route of Definition 8084.3. That route orders the basis, source filter, completion row, limit boundary, stream window, regular readback, and tolerance ledger before terminal Real evidence is consumed, so the seal cannot be detached from the finite basis route. □

Falsifiable prediction: An accepted RegulatedCauchyFilter$^{\uparrow}$ read is refuted if a completion-facing or Real$^{\uparrow}$ consumer reaches the terminal seal without displaying the FilterLimitBasis row, CauchyFilter row, CauchyFilterCompletion row, CauchyFilterLimit row, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{RegulatedCauchyFilter}^{\uparrow}}$.

Constructive story: A RegulatedCauchyFilter$^{\uparrow}$ packet is generated from a FilterLimitBasis row, CauchyFilter source row, CauchyFilterCompletion completion row, CauchyFilterLimit boundary row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegulatedCauchyFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8084.1, Definition 8084.2, and Definition 8084.3 seed the finite regulated completion route over FilterLimitBasisUp, CauchyFilterCompletionUp, CauchyFilterUp, CauchyFilterLimitUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RegulatedCauchyFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, ultrafilters, selected limits, countable choice, host filter equality, quotient real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite basis exposure, source-filter admission, completion-row handoff, filter-limit boundary admission, finite-window inspection, regular readback, dyadic tolerance regulation, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedCauchyFilterUp.

Chapter 8085

A Concrete Naming Certificate for $\mathsf{FiniteOpenBallCover}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis, the $\mathsf{FiniteOpenBallCover}^{\uparrow}$ packet records a finite family of displayed open balls that covers the inspected metric rows by explicit membership witnesses. It sits over the metric source of chapter 57, the real open-ball carrier of chapter 8074, the compact-metric finite-net surface of chapter 129, the total-boundedness route of chapter 127, and the finite epsilon-net witness of chapter 1767. The packet names a finite open-ball cover certificate only; it does not assert open-cover compactness, choose a subcover, prove total boundedness, or import ambient completeness.

Definition 8085.1 (Finite open-ball cover carrier)**.** *A* $\mathsf{FiniteOpenBallCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, \rho, B, I, M, W, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row whose point and distance classifiers are used by every ball and membership witness.*
2. *ρ is the positive tolerance or radius schedule, read through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows before any cover claim is consumed.*
3. *B is the finite closed* $\mathsf{ProbeBundle}$ *of open-ball names. Each entry is a displayed* $\mathsf{OpenBall}^{\uparrow}$ *or* $\mathsf{RealOpenBall}^{\uparrow}$ *row with its centre, radius, and membership comparison ledger.*
4. *I is the index and center-admission ledger, recording that every named ball in B has its center admitted by the metric source row X.*
5. *M is the membership ledger. For each inspected source point it displays a ball of B and a metric-distance comparison witnessing membership in that ball.*
6. *W is the finite readback window that exposes the ball, center, radius, and membership rows to compact-metric, total-bounded, and uniform-continuity consumers.*
7. *H records componentwise* hsame *transport for the source, radius schedule, ball bundle, index ledger, membership ledger, readback window, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a cover request through X, ρ, B, I, M, W, H.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteOpenBallCover}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{OpenBall}^{\uparrow}$, $\mathsf{RealOpenBall}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteOpenBallCover}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $X, \rho, B, I, M, W, H, C, P, N$. It has no coordinate for an arbitrary open cover, a host compactness theorem, a selected subcover, a countable choice schedule, quotient metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8085.2 (Finite open-ball cover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOpenBallCover}^{\uparrow}$ *carrier $U = (X, \rho, B, I, M, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOpenBallCover}^{\uparrow}}$ *surface consists exactly of carrier admission, positive radius admission, finite ball-bundle visibility, center admission, membership coverage, finite readback, classifier transport, displayed replay, provenance, and local naming for the rows $X, \rho, B, I, M, W, H, C, P, N$.*

Proof. Project the carrier of Definition 8085.1. The only cover-facing rows are the metric source X, radius schedule ρ, finite ball bundle B, center ledger I, membership ledger M, and readback window W.

The ball rows are visible before coverage is read. Each ball in B exposes a centre and radius through the open-ball rows, while I admits the centre as a point of the same metric source X.

Membership coverage is then the row M. Each inspected point is paired with one displayed ball of B and one metric-distance comparison read through X and the radius schedule ρ.

The structural rows preserve this finite route. Componentwise transport H, replay C, provenance P, and local naming N can only move and name X, ρ, B, I, M, W; they do not add an arbitrary open cover, a selected subcover, compactness, countable choice, quotient metric equality, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOpenBallCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteOpenBallCover}^{\uparrow}$ packet is generated from a MetricUp source row, a positive rational or dyadic radius schedule, a finite ProbeBundle of open-ball rows, center admissions, membership witnesses, finite readback windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteOpenBallCover}^{\uparrow}}$, seed)

Scope closed: Definition 8085.1 and Definition 8085.2 seed the finite open-ball cover packet over displayed metric sources, open-ball rows, explicit membership witnesses, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteOpenBallCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, total boundedness, compactness, countable choice, quotient metric equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive radius admission, finite ball-bundle visibility, center admission, membership coverage, finite readback, classifier transport, replay, provenance, and local naming for BEDC.Derived.FiniteOpenBallCoverUp.

Chapter 8086

A Concrete Naming Certificate for $\mathsf{LocatedLowerCut}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedLowerCut}^{\uparrow}$ packet records the lower-cut face of a bounded real family by finite lower-bound ledgers, located approximation windows, and regular-rational readback, before any ambient completeness principle for $\mathsf{Real}^{\uparrow}$ is available. It is the constructive lower-cut companion to the located-infimum route of chapter 1452 and the upper-bound sibling route of chapter 1427, with the bounded-family source supplied by chapter 1449.

Definition 8086.1 (LocatedLowerCut carrier)**.** *A* $\mathsf{LocatedLowerCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, L, A, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded-family source row, read through the finite family window and the common-bound data of* $\mathsf{BoundedRealFamily}^{\uparrow}$*.*
2. *L is the lower-bound ledger. It stores the finite comparisons certifying that inspected family values lie above the proposed lower surface.*
3. *A is the located approximation ledger. For each displayed precision request, it gives a finite family-side approximation that separates accepted lower reads from rejected stronger lower candidates at that precision.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that fixes the finite observations of F, L, A admitted by the packet.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for the windowed rational readback.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, L, A, W, R have been read.*
7. *H records componentwise* hsame *transport for the bounded-family row, lower-bound ledger, located approximation ledger, window, handoff, real seal, replay, provenance, and local naming row.*
8. *C records displayed* Cont *replay for lower-bound reads, located approximation reads, classifier transport, regular-rational handoff, and real-seal readback.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedLowerCut}^{\uparrow}$, $\mathsf{LocatedInfimum}^{\uparrow}$, $\mathsf{LocatedSupremum}^{\uparrow}$, $\mathsf{BoundedRealFamily}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedLowerCut}^{\uparrow}}$ *row.*

The carrier has no coordinate for Dedekind completeness, quotient real equality, trichotomy, arbitrary infimum, countable choice, or host completeness.

Theorem 8086.2 (LocatedLowerCut NameCert obligations)**.** *For every accepted* $\mathsf{LocatedLowerCut}^{\uparrow}$ *packet* $K = (F, L, A, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedLowerCut}^{\uparrow}}$ *obligation surface is exhausted by the bounded-family source, lower-bound ledger, located approximation ledger,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming rows. A consumer asking for Dedekind completeness, quotient real equality, trichotomy, arbitrary infimum, countable choice, host completeness, or a standard bridge asks for data outside the packet.*

Proof. Project the carrier of Definition 8086.1. The analytic rows are exactly F, L, A, W, R, E: the family source, lower-bound ledger, located approximation ledger, finite observation window, regular-rational handoff, and real seal.

Read the lower-cut obligations through those rows. The lower-bound part is sourced by L over F, while the located approximation part is sourced by A inside the finite window W. The rows R and E only repack and seal the displayed windowed observations.

The structural rows do not add analytic strength. The transports in H, replays in C, provenance in P, and local name row N preserve the same finite route. Since none of the displayed rows contains Dedekind completeness, quotient equality, trichotomy, arbitrary infimum, countable choice, host completeness, or a standard bridge coordinate, none can be exported by the certificate. □

Theorem 8086.3 (LocatedLowerCut window induction)**.** *For every accepted* $\mathsf{LocatedLowerCut}^{\uparrow}$ *packet* $K = (F, L, A, W, R, E, H, C, P, N)$*, induction over the finite* $\mathsf{StreamName}^{\uparrow}$ *window* W *constructs the displayed located approximation ledger* A *from the bounded-family source* F*, lower-bound ledger* L*, handoff row* R*, real seal* E*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*. The induction does not use Dedekind completeness, quotient real equality, trichotomy, arbitrary infimum, countable choice, or host completeness.*

Proof. Proceed over the finite window row W. The empty window has no precision request, so no located approximation entry is required.

For a successor window, read the next precision request together with the bounded-family source F and the lower-bound ledger L. The carrier requires the corresponding located approximation entry in A, and the induction hypothesis handles the remaining window entries.

After the window ledger is built, R repacks those entries as regular-rational readback and E seals only that readback. The rows H, C, P, N transport, replay, source, and name the same finite construction. No step asks for a completed Dedekind cut, quotient equality of real names, trichotomy, arbitrary infimum, countable-choice selector, or host-completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedLowerCut}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedLowerCut}^{\uparrow}$ packet is generated from a bounded-family source row, a lower-bound ledger, a located approximation ledger, a StreamName window, a RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedLowerCut}^{\uparrow}}$, seed)

Scope closed: Definition 8086.1, Definition 8086.2, and Definition 8086.3 bind the finite lower-cut seed over the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedLowerCut}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Dedekind completeness, quotient real equality, trichotomy, arbitrary infimum, countable choice, host completeness, or a standard bridge.

Upgrade path: Formal verification can encode carrier admission, lower-bound readback, located approximation witnessing, window induction, handoff stability, and real-seal factorization for BEDC.Derived.LocatedLowerCutUp.

Chapter 8087

A Concrete Naming Certificate for $\mathsf{ConfigurationSpace}^{\uparrow}$

Following the classical configuration-space treatment of ordered collision-free point tuples, the $\mathsf{ConfigurationSpace}^{\uparrow}$ packet records the finite inspection surface for n displayed points in an ambient space before any quotient by permutations, compactification, or path-space completion is available. It sits after the ambient open-set discipline of chapter 88, the distance and separation rows of chapter 57, the finite index spine of chapter 112, and the membership provenance of chapter 3668. It also exposes the finite ordered-strand boundary consumed by chapter 305, but it does not claim braid isotopy completeness or unordered configuration quotients.

Definition 8087.1 (ConfigurationSpace carrier)**.** *A* $\mathsf{ConfigurationSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, M, T, U, Q, A, D, W, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{FinSet}^{\uparrow}$ *index row naming the finite ordered tuple positions.*
2. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row and T is the compatible* $\mathsf{Topology}^{\uparrow}$ *row used for open-neighbourhood reads.*
3. *U is the tuple row, assigning each displayed index in I a point admitted by the ambient carrier.*
4. *Q is the* $\mathsf{SetLike}^{\uparrow}$ *membership row recording that every tuple coordinate belongs to the ambient space and to the displayed configuration window.*
5. *A is the pairwise apartness row: for each distinct pair of indices in I, it displays positive separation or an equivalent collision-refusal witness.*
6. *D is the diagonal-refusal row, recording that no admitted read of U factors through the collision diagonal.*
7. *W is the finite observation-window row exposing the open neighbourhoods and separation thresholds read by downstream consumers.*
8. *H records componentwise* hsame *transport for the finite index row, ambient metric and topology rows, tuple row, membership row, apartness row, diagonal-refusal row, window row, provenance row, and local naming row.*
9. *C records displayed* Cont *replay of the same finite configuration rows.*

10. *P is the* Pkg *provenance over* $\mathsf{ConfigurationSpace}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{BraidGroup}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConfigurationSpace}^{\uparrow}}$ *row.*

No coordinate supplies an unordered quotient, a completed path space, compactification boundary, global section of a covering map, or host equality of point tuples.

Theorem 8087.2 (ConfigurationSpace NameCert obligations)**.** *For every accepted* $\mathsf{ConfigurationSpace}^{\uparrow}$ *carrier* $X = (I, M, T, U, Q, A, D, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ConfigurationSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite index row, ambient metric and topology rows, tuple row, set-membership row, pairwise apartness row, collision-diagonal refusal row, observation window, componentwise transport, continuation replay, provenance, and local naming row. Every consumer-facing read must display* I, M, T, U, Q, A, D, W *before the structural rows* H, C, P, N *are consumed.*

Proof. Project the carrier of Definition 8087.1. The finite mathematical surface is exhausted by the displayed rows I, M, T, U, Q, A, D, W; the remaining rows only transport, replay, source, and name that surface.

The index and membership obligations are finite. The row I supplies the tuple positions through $\mathsf{FinSet}^{\uparrow}$, while Q records ambient and window membership through $\mathsf{SetLike}^{\uparrow}$, so no host powerset or infinite family of coordinates is available.

The topology and metric obligations are likewise displayed. The rows M, T, W expose only the neighbourhood and separation data read in the current window, and A, D record the pairwise apartness and diagonal refusal used by the configuration read. Thus the NameCert surface stops at the finite collision-free tuple packet. □

Theorem 8087.3 (ConfigurationSpace collision nonescape)**.** *Every accepted* $\mathsf{ConfigurationSpace}^{\uparrow}$ *read refuses collision escape through the finite route*

$$\mathsf{FinSet}^{\uparrow}, \mathsf{Met}^{\uparrow}, \mathsf{Topology}^{\uparrow}, \mathsf{SetLike}^{\uparrow} \longrightarrow U, Q, A, D, W \longrightarrow H, C, P, N.$$

In particular, if two displayed indices are distinct in I*, every downstream read of their coordinates must pass through the apartness row* A *and the diagonal-refusal row* D *before it can be replayed as a configuration-space observation.*

Proof. Begin with a read of two displayed tuple positions. Distinctness is visible only through the finite index row I, and the corresponding coordinate membership is visible only through the tuple and membership rows U, Q.

The collision-refusal step is forced by the carrier order. The pairwise apartness row A supplies the separation witness for the two indices, and D records that the read does not factor through the collision diagonal.

Finally replay through W, H, C, P, N. These rows can expose neighbourhoods, transport the same finite evidence, and name the packet, but they cannot add a missing collision witness or replace A, D by host tuple equality. □

Theorem 8087.4 (ConfigurationSpace finite product route)**.** *Every product-facing consumer of an accepted* $\mathsf{ConfigurationSpace}^{\uparrow}$ *packet receives the ordered finite tuple through the* $\mathsf{FinSet}^{\uparrow}$ *index spine and the ambient* $\mathsf{Met}^{\uparrow}$ *and* $\mathsf{Topology}^{\uparrow}$ *rows, with* $\mathsf{SetLike}^{\uparrow}$ *membership and pairwise apartness displayed before any* $\mathsf{BraidGroup}^{\uparrow}$ *strand-boundary read is available. The route exports a finite ordered configuration packet and does not claim unordered quotient configurations, braid isotopy completeness, compactification, or path lifting.*

Proof. Read the product request through I and U. The finite index spine determines the ordered tuple slots, and the tuple row supplies the coordinate reads without constructing an ambient host product object.

Next expose the ambient rows. The metric and topology data in M, T and the membership row Q place each coordinate inside the displayed ambient window; the apartness and diagonal-refusal rows A, D then certify collision-free status for every displayed pair.

Only after those rows are visible can a strand-boundary consumer read the packet through the $\mathsf{BraidGroup}^{\uparrow}$ provenance in P. That boundary sees ordered, collision-free strands, not an unordered quotient, a completed braid isotopy theorem, or a compactified configuration space. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConfigurationSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{ConfigurationSpace}^{\uparrow}$ packet is generated from a FinSet index row, ambient Metric and Topology rows, finite point tuple row, SetLike membership row, pairwise apartness and collision-refusal rows, observation window, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConfigurationSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8087.1, Definition 8087.2, Definition 8087.3, and Definition 8087.4 bind the finite ordered collision-free point tuple seed and its ambient topology, metric, membership, and braid-boundary route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConfigurationSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unordered configuration quotients, compactification, path-space completion, braid isotopy completeness, covering-space lifting, Lean verification, or any standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, pairwise apartness exactness, collision-diagonal refusal, finite product routing, transport, replay, provenance, and local naming for BEDC.Derived.ConfigurationSpaceUp.

Chapter 8088

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompactSet}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ packet records located compact subsets through finite-net locator data rather than through open-cover compactness. It sits over the compact metric source of chapter 129, the total-bounded finite-net route of chapter 127, the finite epsilon-net surface of chapter 1767, the metric readback of chapter 57, the regular rational handoff of chapter 301, and the finite stream-window surface of chapter 126. The packet names a located compact-set certificate for downstream finite-net and compact-continuity arguments; it does not assert open-cover compactness, countable choice, quotient equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8088.1 (Bishop located compact set carrier)**.** *A* $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (K_0, T, E, M, R, S, L, H, C, P, N)$$

with the following displayed rows:

1. K_0 *is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, naming the compact-metric interface inspected by the packet.*
2. T *is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net data row for displayed tolerances, centers, coverage witnesses, and refinement comparisons.*
3. E *is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row recording the finite epsilon-net center list and coverage ledger at each inspected scale.*
4. M *is the* $\mathsf{Met}^{\uparrow}$ *distance-readback row used by locator requests.*
5. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row for rational distance and tolerance reads.*
6. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which inspected compact-set names and candidate centers are read.*
7. L *is the locatedness locator row, recording finite lower and upper distance windows for the compact subset at each query and displayed tolerance.*
8. H *records componentwise* hsame *transport for the compact metric source, total-bounded data, epsilon-net row, metric readback, regular rational handoff, stream windows, locator row, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a located compact-set request through* K_0, T, E, M, R, S, L, H.
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompactSet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompactSet}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K_0, T, E, M, R, S, L, H, C, P, N$. It has no coordinate for open-cover compactness, countable-choice selection of nets, quotient equality of names, host subset equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8088.2 (Bishop located compact set NameCert obligations)**.** *For every accepted* BishopLocatedCompactS *carrier*

$$K = (K_0, T, E, M, R, S, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedCompactSet}^{\uparrow}}$ *surface consists exactly of compact-metric source admission, total-bounded finite-net data, finite epsilon-net row exposure, metric distance readback, regular rational handoff, finite stream-window exposure, locatedness locator admission, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8088.1. The analytic rows are exactly K_0, T, E, M, R, S, L.

The compact metric source is read before finite-net data. The total-bounded row and finite epsilon-net row display centers, tolerances, and coverage ledgers, while M, R, S, L provide distance readback, rational handoff, stream windows, and locatedness locator data.

The rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for open covers, countable-choice net selection, quotient equality, host subset equality, or ambient completeness, these rows exhaust the local NameCert surface. □

Theorem 8088.3 (Bishop located compact set finite-net locator)**.** *Every locatedness read exported by an accepted* $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ *packet factors through the compact-metric row K_0, the total-bounded finite-net row T, the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row E, the metric readback row M, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, the* $\mathsf{StreamName}^{\uparrow}$ *row S, and the locator row L before it reaches transport, replay, provenance, and local naming. The locator is therefore a finite-net route, not an open-cover compactness theorem or a selected ambient subset.*

Proof. Start with the NameCert obligations. They require the compact-metric source and both finite-net rows before any locator read can be certified.

Read the metric-facing side next. Distance requests pass through M, rational tolerance and comparison data pass through R, and inspected names or center windows pass through S before the locatedness locator row L is available.

Finally transport and replay the same route through H, C, P, N. No coordinate remains for open-cover compactness, countable-choice selection, quotient equality, host subset equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, so the finite-net locator is the complete exported surface. □

Falsifiable prediction: Any accepted $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ read that reaches locatedness data without displaying the compact metric source, total-bounded finite-net row, finite epsilon-net row, metric readback, RegSeqRat handoff, StreamName windows, hsame transport, Cont replay, Pkg provenance, and local NameCert row refutes the carrier.

Independence witness: compactmetric, totallybounded, finite-epsilon-net, metric, regseqrat, streamname: none is bijective with $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ because this packet jointly binds compact-metric source data, total-bounded finite-net ledgers, finite epsilon-net coverage, metric

distance readback, rational handoff, stream windows, locatedness locator data, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompactSet}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ packet is generated from CompactMetric source data, TotallyBounded finite-net rows, FiniteEpsilonNet coverage rows, Metric distance readback, RegSeqRat handoff, StreamName windows, a locatedness locator, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompactSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8088.1, Definition 8088.2, and Definition 8088.3 seed the located compact-set route over compact metric, finite-net, distance, rational-readback, stream-window, locator, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompactSet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, countable choice, quotient equality, host subset equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net locator exactness, metric readback, RegSeqRat handoff, StreamName window exposure, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCompact

Chapter 8089

A Concrete Naming Certificate for $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$

The $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ packet realizes the observer-expansion symbolic-shadow route as finite Markov partition, transition, boundary, metric, transport, provenance, and NameCert rows. It sits after the finite symbolic partition surface of chapter 4074, the metric route of chapter 3474, the Gromov boundary of chapter 6470, the visual-boundary packet of chapter 4181, and the shadowing route of chapter 6707. The packet names symbolic shadow data only as finite BEDC rows; it does not import global Anosov dynamics, invariant measures, completed shift spaces, orbit quotients, or measure-theoretic coding.

Definition 8089.1 (Hyperbolic Markov partition carrier)**.** *A* $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, Q, A, B, V, S, T, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FiniteMarkovPartition}^{\uparrow}$ *row, exposing finite atoms, cylinder blocks, adjacency rows, and refinement data.*
2. *Q is the transition ledger, recording allowed symbolic moves between displayed atoms and refusing unlisted moves.*
3. *A is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric row used to read expansion and separation budgets.*
4. *B is the* $\mathsf{GromovBoundary}^{\uparrow}$ *boundary row attached to the shadow endpoints.*
5. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *visual-boundary row used for finite visual-shadow readback.*
6. *S is the* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *row, displaying the finite fellow-traveller or shadow route consumed by the symbolic read.*
7. *T is the symbolic-shadow transport row binding partition atoms, transitions, metric budgets, boundary endpoints, visual readbacks, and shadowing data as one route.*
8. *H records componentwise* hsame *transport for partition, transition, metric, boundary, visual-boundary, shadowing, symbolic-shadow transport, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a symbolic-shadow request through F, Q, A, B, V, S, T, H.*

10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$, $\mathsf{FiniteMarkovPartition}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicShadowing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicMarkovPartition}^{\uparrow}}$ *row.*

The classifier reads only $F, Q, A, B, V, S, T, H, C, P, N$. It has no coordinate for global Anosov dynamics, measure-theoretic coding, invariant measures, completed shift spaces, orbit quotients, or host boundary equality.

Theorem 8089.2 (Hyperbolic Markov partition NameCert obligations)**.** *For every accepted* HyperbolicMarkovParti *carrier*

$$M = (F, Q, A, B, V, S, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicMarkovPartition}^{\uparrow}}$ *surface consists exactly of finite Markov partition admission, transition-ledger exposure, hyperbolic metric budgeting, Gromov-boundary handoff, visual-boundary readback, shadowing-route admission, symbolic-shadow transport, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8089.1. The visible symbolic rows are F, Q, and the visible hyperbolic rows are A, B, V, S.

The symbolic-shadow transport row T binds those rows before replay. Transport through H and continuation through C preserve the same finite route, while P, N source and name it.

Since the carrier has no coordinate for global Anosov dynamics, measure-theoretic coding, invariant measures, completed shift spaces, orbit quotients, or host boundary equality, the listed rows are exactly the local NameCert obligation surface. □

Theorem 8089.3 (Hyperbolic Markov partition symbolic shadow route)**.** *Every symbolic-shadow read exported by an accepted* $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ *packet factors through the finite Markov partition row F, the transition ledger Q, the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row A, the* $\mathsf{GromovBoundary}^{\uparrow}$ *row B, the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row V, the* $\mathsf{HyperbolicShadowing}^{\uparrow}$ *row S, and the symbolic-shadow transport row T before it reaches H, C, P, N. A read that bypasses the transition ledger is not a read of this carrier.*

Proof. Begin with the finite symbolic side. The row F supplies atoms, cylinder blocks, adjacency rows, and refinements, while Q records the allowed transitions between the displayed atoms.

Read the hyperbolic side next. Metric budgets, boundary endpoints, visual-boundary readbacks, and shadowing routes are carried by A, B, V, S and then bound to the symbolic rows by T.

Finally replay the same data through H, C, P, N. Without Q the symbolic word has no displayed transition ledger, and without A, B, V, S, T it has no hyperbolic shadow route, so any bypass changes the packet rather than exporting an accepted symbolic-shadow read. □

Falsifiable prediction: Any symbolic-shadow read that bypasses the transition ledger Q refutes the $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ carrier.

Independence witness: finite-markov-partition, hyperbolic-metric, gromov-boundary, hyperbolic-visual-boundary, hyperbolic-shadowing: none is bijective with $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ because the packet jointly carries finite Markov partition atoms, a transition ledger, hyperbolic metric budgets, Gromov-boundary endpoints, visual-boundary readback, shadowing data, symbolic-shadow transport, replay, provenance, and local naming.

The Lean follow-up must provide `Nontrivial HyperbolicMarkovPartitionUp` and `FieldFaithful HyperbolicMarkovPartitionUp` instances in `lean4/BEDC/Derived/HyperbolicMarkovPartitionUp/TasteGate`.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicMarkovPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ packet is generated from FiniteMarkovPartition rows, transition ledgers, HyperbolicMetric budgets, GromovBoundary endpoints, HyperbolicVisualBoundary readback, HyperbolicShadowing data, symbolic-shadow transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicMarkovPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8089.1, Definition 8089.2, and Definition 8089.3 seed the finite symbolic-shadow route over Markov partition, transition, metric, boundary, visual-boundary, shadowing, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicMarkovPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global Anosov dynamics, measure-theoretic coding, invariant measures, completed shift spaces, orbit quotients, host boundary equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-ledger exactness, metric and boundary handoff, shadowing readback, symbolic-shadow transport, replay, provenance, local naming, and TasteGate instances for BEDC.Derived.HyperbolicMarkovPartitionUp.

Chapter 8090

A Concrete Naming Certificate for $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$ packet records the finite comparison surface by which two regular Cauchy real names are judged equivalent through located windows and dyadic tolerances. It sits after the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Bishop L10 comparison route of chapter 8075. The packet names located equivalence as displayed finite data only; it does not quotient regular names, import host equality, assert trichotomy, choose representatives, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8090.1 (Located regular Cauchy equivalence carrier)**.** *A* $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (L, R, W_L, W_R, D, C, V, H, A, P, N)$$

with the following displayed rows:

1. *L and R are the left and right regular-name rows read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *surface;*
2. *W_L and W_R are the finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected on the two sides;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the located comparison;*
4. *C is the finite comparison row licensed by the Bishop L10 comparison surface;*
5. *V is the located verdict row saying that the inspected windows agree within the displayed dyadic budget;*
6. *H records componentwise* hsame *transport for the two names, windows, tolerance, comparison, verdict, replay, provenance, and local naming rows;*
7. *A records displayed* Cont *replay through the same finite comparison route;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BishopLTenComparisonPrinciple}$ BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of regular names, host equality of completed reals, trichotomy, selected representatives, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.LocatedRegularCauchyEquivalenceUp`

Theorem 8090.2 (Located regular Cauchy equivalence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$ *carrier* $E = (L, R, W_L, W_R, D, C, V, H, A, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, two regular-name exposures through* L, R*, finite window exposure through* W_L, W_R*, dyadic tolerance exposure through* D*, Bishop L10 comparison exposure through* C*, located verdict exposure through* V*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* A*, provenance through* P*, and local naming through* N*.*

Consequently, an accepted consumer may read equivalence only as the finite located comparison of the two displayed regular Cauchy names. It cannot detach the verdict from the windows and tolerance ledger, convert the verdict into quotient equality, choose a representative, decide trichotomy, or appeal to ambient completion of $\mathsf{Real}^{\uparrow}$*.*

Proof. Project the carrier of Definition 8090.1. The only exposed rows are $L, R, W_L, W_R, D, C, V, H, A, P, N$, so the naming surface begins with two regular-name rows, their inspected windows, and the dyadic budget used by the comparison.

Read the comparison row next. The Bishop L10 comparison route licenses C only after the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ data have been inspected, so the verdict V remains a located finite-window statement.

Finally inspect the structural rows. Componentwise transport, displayed replay, provenance, and local naming preserve the same rows and add no quotient equality, selected representative, host equality, trichotomy, countable-choice schedule, selected limit, or ambient completeness coordinate. □

Theorem 8090.3 (Located regular Cauchy equivalence Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$ *verdict must first display the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows* L, R*, the* $\mathsf{StreamName}^{\uparrow}$ *windows* W_L, W_R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* D*, the Bishop L10 comparison row* C*, the located verdict row* V*, and the structural rows* H, A, P, N*. The handoff reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through those rows and does not assert quotient real equality, selected limits, trichotomy, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with an accepted located-equivalence packet. By Definition 8090.2, a verdict is accepted only with the two regular names, their finite windows, the dyadic tolerance ledger, and the comparison row still present.

Now read the terminal seal. A $\mathsf{Real}^{\uparrow}$ consumer may use the verdict as a displayed handoff because P ties the packet to the real-name seal and A replays the same finite route.

No excluded object is produced by this route. Since the carrier lacks quotient equality, selected representatives, trichotomy, host equality, selected limits, and ambient completeness rows, the Real handoff remains a finite located comparison rather than a completed equality principle. □

Falsifiable prediction: A located regular Cauchy equivalence read is rejected if the verdict row is accepted without both StreamName windows, both RegSeqRat rows, the DyadicRatCore tolerance ledger, the Bishop L10 comparison row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}$ packet is generated from two regular Cauchy name rows, two finite StreamName windows, a DyadicRatCore tolerance ledger, a Bishop L10 comparison row, a located verdict, componentwise hsame transport, displayed Cont replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRegularCauchyEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8090.1, Definition 8090.2, and Definition 8090.3 seed the finite located equivalence route over StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BishopLTenComparisonPrincipleUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRegularCauchyEquivalence}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient equality of regular names, host real equality, trichotomy, selected representatives, selected limits, countable choice, ambient RealUp completeness, Lean verification of the theorem surface, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located verdict stability, tolerance-ledger nonescape, Real handoff ordering, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRegularCauchyEquivalenceUp.

Chapter 8091

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ packet records the finite-window induction surface used by regular Cauchy real-name arguments. It sits over the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the located regular-Cauchy sibling of chapter 2376. The packet supplies Real and Completion consumers with a displayed induction route for finite regular-Cauchy windows; it does not assert quotient stream equality, selected limits, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8091.1 (Regular Cauchy window induction carrier)**.** *A* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Q, W_0, D_0, R_0, S, W, D, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the regular Cauchy name row whose observations are accessed only through finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *Q is the requested dyadic tolerance row in* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
3. *W_0, D_0, R_0 are the base window, base dyadic tolerance, and base* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows.*
4. *S is the finite successor schedule listing the displayed one-step window extensions.*
5. *W, D, R are the accumulated window, dyadic-budget, and regular-readback rows produced along the schedule S.*
6. *T is the tail-stability row saying that each accepted successor window preserves the already displayed regular-Cauchy tolerance obligation.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the finite induction route has exposed W, D, R, T.*
8. *H records componentwise* hsame *transport for the name, tolerance request, windows, dyadic budgets, readbacks, tail-stability rows, Real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a tolerance request through the base row, each successor window, the readback row, the tail-stability row, and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowInduction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for an infinite stream quotient, a selected limit, countable choice, host real equality, or an ambient completeness theorem.

Theorem 8091.2 (Regular Cauchy window induction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *carrier*

$$K = (X, Q, W_0, D_0, R_0, S, W, D, R, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowInduction}^{\uparrow}}$ *surface consists exactly of regular-name admission, dyadic tolerance admission, base-window admission, finite successor-window admission, accumulated* $\mathsf{StreamName}^{\uparrow}$ *window replay,* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget replay,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback stability, tail-stability preservation, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8091.1. The analytic data are the regular Cauchy name X, the requested tolerance Q, the base rows W_0, D_0, R_0, the successor schedule S, the accumulated rows W, D, R, the tail-stability row T, and the Real seal E.

The base step is displayed by W_0, D_0, R_0. It reads one finite window through the dyadic budget and records the corresponding regular rational readback before any Real-facing seal is available.

The successor schedule S contains only finitely many one-step window extensions. Each extension adds a displayed $\mathsf{StreamName}^{\uparrow}$ observation, transports its dyadic tolerance row through D, and refreshes the $\mathsf{RegSeqRat}^{\uparrow}$ readback in R.

The row T records the induction invariant: after each displayed successor step, the same regular-Cauchy tail obligation remains available for the accumulated window. Finally E, H, C, P, N seal, transport, replay, source, and name exactly that finite route, so the listed rows exhaust the NameCert obligations. □

Theorem 8091.3 (Regular Cauchy finite-tail closure)**.** *Let*

$$K = (X, Q, W_0, D_0, R_0, S, W, D, R, T, E, H, C, P, N)$$

be an accepted $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *carrier. Any finite extension of the displayed successor schedule S by accepted one-step* $\mathsf{StreamName}^{\uparrow}$ *observations remains within the same regular-Cauchy tail route, provided each new dyadic budget row transports through the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. The accepted packet therefore supplies a finite induction principle for the displayed tail windows without identifying quotient streams or selecting a limiting real.*

Proof. Proceed by induction on the finite list of displayed successor observations. The base case is W_0, D_0, R_0, which already exposes the requested window, dyadic budget, and readback rows.

For the successor step, append one displayed $\mathsf{StreamName}^{\uparrow}$ observation to the accumulated window row W. The transported dyadic budget row enters D, and the matching $\mathsf{RegSeqRat}^{\uparrow}$ readback enters R.

The tail-stability row T is then replayed for the enlarged finite window. Since T is componentwise transported by H and replayed by C, the accepted route remains the same local NameCert route after the one-step extension.

Because the induction ranges only over the displayed finite schedule, no quotient stream equality, selected limit, countable-choice sequence, host real equality, or ambient completeness principle is introduced. □

Theorem 8091.4 (Regular Cauchy window induction Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion consumer of an accepted* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{RegularCauchyWindowInduction}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer may use the displayed finite-window induction route to extend regular-Cauchy tail evidence, but it cannot extract quotient stream equality, a selected limit, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness from the packet.*

Proof. Start with a Real or Completion consumer of the accepted packet. The carrier exposes no Real-facing row before the base finite window, dyadic budget, and regular readback rows have been displayed.

The consumer then follows the finite successor schedule S. Each successor step passes through the same window, dyadic-budget, readback, and tail-stability rows, so the induction route remains finite and displayed.

Only after that route has been replayed does the seal row E expose a $\mathsf{Real}^{\uparrow}$ endpoint. The structural rows H, C, P, N preserve this ordering under transport, replay, provenance, and naming.

Thus the Real-facing output is a seal for the displayed finite regular-Cauchy window induction route, not a source of quotient equality, selected limits, countable choice, host real equality, trichotomy, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowInduction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ packet is generated from a regular Cauchy name row, a dyadic tolerance request, base StreamName windows, finite successor window extensions, dyadic budget rows, RegSeqRat readbacks, tail-stability rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8091.1, Definition 8091.2, Definition 8091.3, and Definition 8091.4 seed the finite-window induction route for regular Cauchy names through displayed StreamName windows, dyadic budgets, RegSeqRat readbacks, tail stability, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped treatment asks for checked carrier admission, finite successor-window induction, dyadic budget transport, regular readback stability, Real-seal nonescape, transport, replay, provenance, and local naming.

Chapter 8092

A Concrete Naming Certificate for $\mathsf{DyadicRealBracketRefinement}^{\uparrow}$

Following Bishop and Bridges on constructive real approximation by nested rational intervals, the $\mathsf{DyadicRealBracketRefinement}^{\uparrow}$ packet records the finite bracket-refinement step by which a displayed real-name read is replaced by a smaller dyadic bracket before any completion-facing consumer reads a terminal Real seal. It sits after the Archimedean window surface of chapter 7489, the dyadic arithmetic core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a local radius-refinement certificate; it is not Real completeness, trichotomy, quotient stream equality, a selected limit, or open-cover compactness.

Definition 8092.1 (DyadicRealBracketRefinement carrier)**.** *A* $\mathsf{DyadicRealBracketRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, S, Q, D, E, E', \rho, \rho', I, J, H, C, P, N)$$

with the following displayed rows:

1. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row whose finite observation is being bracketed.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite requests through which the current bracket may inspect the real-name data.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying endpoint arithmetic, midpoint arithmetic, containment checks, and the displayed halving comparison.*
5. *E and E' are the current and refined dyadic bracket rows; E' keeps the same real-name source and is read only after E, S, Q, D are visible.*
6. *ρ and ρ' are positive radius rows over* $\mathsf{PositiveReal}^{\uparrow}$*, with ρ' displayed as the halved radius before the refined bracket may be exported.*
7. *I is the inclusion row saying that the inspected regular readback stays inside the current bracket E.*
8. *J is the refinement row saying that the refined bracket E' stays inside E and uses the halved radius ρ'.*

9. *H records componentwise* hsame *transport for the Real seal, StreamName window, RegSeqRat readback, dyadic ledger, both brackets, both radius rows, inclusion, refinement, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a bracket request through finite window inspection, regular rational readback, dyadic arithmetic, radius halving, bracket inclusion, bracket refinement, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicRealBracketRefinement}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRealBracketRefinement}^{\uparrow}}$ *row.*

The carrier contains no coordinate for Real completeness, trichotomy, quotient stream equality, selected limits, open-cover compactness, or an ambient host order oracle.

Theorem 8092.2 (DyadicRealBracketRefinement NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRealBracketRefinement}^{\uparrow}$ *carrier*

$$B = (R, S, Q, D, E, E', \rho, \rho', I, J, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRealBracketRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission, finite window exposure, regular readback exposure, dyadic arithmetic exposure, positive-radius exposure, inclusion of the inspected readback in E, halved-radius refinement from ρ to ρ', containment of E' in E, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8092.1. The rows $R, S, Q, D, E, E', \rho, \rho', I, J, H, C, P, N$ are the only rows made public by the packet.

The window and readback obligations are the route through S and Q. A bracket request first opens the finite StreamName window and then reads the regular rational data supplied by $\mathsf{RegSeqRat}^{\uparrow}$.

The dyadic and radius obligations are the route through D, ρ, ρ'. The ledger D records the endpoint, midpoint, containment, and halving checks, while ρ' is exposed as a positive halved radius before the refined bracket is exported.

The inclusion and refinement obligations are the rows I and J. They keep the inspected readback inside E and the refined bracket E' inside E. The structural rows H, C, P, N transport, replay, source, and name exactly this route, so none of the refused endpoints is introduced. □

Theorem 8092.3 (DyadicRealBracketRefinement radius halving)**.** *For every accepted* DyadicRealBracketRefinemen *carrier $B = (R, S, Q, D, E, E', \rho, \rho', I, J, H, C, P, N)$, any consumer that reads the refined bracket row E' must first read the positive radius rows ρ, ρ', the* $\mathsf{DyadicRatCore}^{\uparrow}$ *halving ledger D, and the containment row J. Thus the radius-halving step is a finite dyadic ledger route, not a completeness argument or a selected limiting process.*

Proof. Start from the carrier definition. The refined bracket row E' is not standalone; it is paired with the current bracket E, the two positive radius rows, the dyadic ledger, and the refinement row J.

Use the NameCert obligations of Definition 8092.2. They force radius exposure and dyadic arithmetic exposure before the refined bracket may be consumed.

Finally read J. This row is the displayed containment and halving handoff from E to E'. Since no row stores a limit selector, quotient stream equality, trichotomy proof, or completeness theorem, the halving step remains a finite bracket-refinement route. □

Theorem 8092.4 (DyadicRealBracketRefinement scope)**.** *Every public* DyadicRealBracketRefinement$^{\uparrow}$ *read factors through*

$$R, S, Q, D, E, E', \rho, \rho', I, J, H, C, P, N.$$

It may be consumed by Real and Completion chapters only as a finite bracket-refinement packet over the displayed Real seal, StreamName window, RegSeqRat readback, DyadicRatCore ledger, positive-radius rows, transport, replay, provenance, and local NameCert. It does not assert Real completeness, trichotomy, quotient stream equality, selected limits, open-cover compactness, or host real equality.

Proof. Apply the carrier projection and the NameCert obligation surface. Together they expose the exact finite route from the Real seal through window inspection, regular readback, dyadic ledger checks, bracket inclusion, radius halving, and bracket refinement.

Apply radius halving from Definition 8092.3. The only refinement export is the displayed containment row J after D, ρ, ρ' have been read.

The rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Because the carrier has no further coordinate, downstream Real or Completion consumers receive only the finite bracket-refinement packet. □

Closure status for NameCert$_{\text{DyadicRealBracketRefinement}^{\uparrow}}$**.**

Constructive story: A DyadicRealBracketRefinement$^{\uparrow}$ packet is generated from a Real seal, a StreamName window, a RegSeqRat readback, a DyadicRatCore endpoint and halving ledger, current and refined bracket rows, positive radius rows, inclusion and refinement rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicRealBracketRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 8092.1, Definition 8092.2, Definition 8092.3, and Definition 8092.4 seed the finite dyadic bracket-refinement route over RealUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, PositiveRealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicRealBracketRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, quotient stream equality, selected limits, open-cover compactness, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite window exposure, regular readback exposure, dyadic halving exposure, positive-radius exposure, inclusion, refinement containment, transport, replay, provenance, and local NameCert field faithfulness for BEDC.Derived.DyadicRealBracketRefinementUp.

Chapter 8093

A Concrete Naming Certificate for $\mathsf{KleeneRealizability}^{\uparrow}$

Following Kleene's realizability interpretation, the $\mathsf{KleeneRealizability}^{\uparrow}$ packet records realizer evidence as displayed finite computation rows before any constructive consumer may use it as proof content. It sits after the bounded computation surface of chapter 199, the lambda-term carrier of chapter 200, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies choice-free L10 reasoning with finite witness readback data; it does not assert countable choice, quotient equality of programs, host evaluation, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8093.1 (Kleene realizability carrier)**.** *A* $\mathsf{KleeneRealizability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (e, I, O, T, R, H, C, P, N)$$

with the following displayed rows:

1. *e is the code/index row, read through the* $\mathsf{Computable}^{\uparrow}$ *bounded computation surface and, when the realizer is term-facing, through the* $\mathsf{LambdaCalc}^{\uparrow}$ *syntax surface.*
2. *I is the input packet row, consisting only of finite argument data such as* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback requests, or already displayed BEDC witnesses.*
3. *O is the output packet row returned by the finite computation trace.*
4. *T is the computation trace row, recording the inspected step sequence from the index e and input packet I to the output packet O.*
5. *R is the realizer-relation row saying that the displayed trace realizes the requested predicate or construction only through e, I, O, T.*
6. *H records componentwise* hsame *transport for the code/index, input packet, output packet, trace, realizer relation, replay, provenance, and local name rows.*
7. *C records displayed* Cont *replay from a consumer request through the input packet, computation trace, output packet, and realizer-relation row.*
8. *P is the* Pkg *provenance over* $\mathsf{KleeneRealizability}^{\uparrow}$*,* $\mathsf{Computable}^{\uparrow}$*,* $\mathsf{LambdaCalc}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KleeneRealizability}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only by the displayed rows $e, I, O, T, R, H, C, P, N$. It has no coordinate for host execution, function extensionality, quotient equality of programs, countable choice, a selected infinite stream, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.KleeneRealizabilityUp.KleeneRealizabilityTasteGate single carrier alignment`

Theorem 8093.2 (Kleene realizability finite witness readback)**.** *For every accepted* $\mathsf{KleeneRealizability}^{\uparrow}$ *carrier*

$$K = (e, I, O, T, R, H, C, P, N),$$

any witness read exported to a choice-free L10 consumer factors through the finite code/index row e, the input packet I, the output packet O, the computation trace T, the realizer relation R, componentwise hsame *transport H, displayed* Cont *replay C,* Pkg *provenance P, and the local* NameCert *row N. The read may consume* $\mathsf{Computable}^{\uparrow}$, $\mathsf{LambdaCalc}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows named by P, but it cannot extract a choice function, quotient program equality, host evaluator, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Project the carrier of Definition 8093.1. The possible witness data are exactly the code/index row e, the input row I, the output row O, the computation trace T, and the realizer relation R.

The computation row T is finite. It records the inspected route by which e acts on the displayed input packet I and reaches the output packet O, so the realizer relation can be read without invoking host execution.

The structural rows H, C, P, N then transport, replay, source, and name the same finite route. Provenance may cite the bounded computation, lambda-term, stream-window, regular rational, and real-name siblings, but it adds no further selection coordinate.

Thus every exported witness remains a finite NameCert readback. Since no carrier row contains a choice function, quotient program equality, host evaluator, selected limit, or ambient completeness principle, no consumer can recover one from the packet. □

Theorem 8093.3 (Kleene realizability L10 nonescape)**.** *Every L10 read of an accepted* $\mathsf{KleeneRealizability}^{\uparrow}$ *packet preserves the finite witness boundary*

$$\mathsf{Computable}^{\uparrow} \longmapsto \mathsf{LambdaCalc}^{\uparrow} \longmapsto \mathsf{KleeneRealizability}^{\uparrow} \longmapsto (\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}).$$

The route may pass finite stream windows and regular rational readbacks to a real-facing consumer, but it never promotes realizability evidence into countable choice, quotient equality of programs, unrestricted beta-conversion, host-level evaluation, selected limits, or a global real-completeness assertion.

Proof. Begin with the realizer witness readback of Definition 8093.2. It forces every consumer to expose e, I, O, T, R before any real-facing or stream-facing row can be consumed.

If the consumer requests stream or real data, the provenance row routes that request through the finite $\mathsf{StreamName}^{\uparrow}$ windows, the $\mathsf{RegSeqRat}^{\uparrow}$ readback row, and the terminal $\mathsf{Real}^{\uparrow}$ seal. These rows are consumed as displayed packet data, not as selected representatives of an infinite object.

The replay rows H and C preserve only the visible computation trace and its realizer relation. They do not add quotient equality of programs, unrestricted beta-conversion, host execution, or an external choice operator.

Therefore the L10 route remains a finite readback surface for constructive witness data and cannot escape to the global principles excluded by the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{KleeneRealizability}^{\uparrow}}$.

Constructive story: A $\mathsf{KleeneRealizability}^{\uparrow}$ packet is generated from a code/index row, finite input and output packets, a displayed computation trace, a realizer-relation row, componentwise hsame transport, displayed Cont replay, Pkg provenance over ComputableUp, LambdaCalcUp, StreamNameUp, RegSeqRatUp, and RealUp, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KleeneRealizability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8093.1, Definition 8093.2, and Definition 8093.3 seed the finite realizer-witness route for choice-free L10 reasoning through displayed computation, input, output, trace, relation, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KleeneRealizability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient equality of programs, host execution, unrestricted beta-conversion, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Scoped treatment asks for checked carrier admission, finite trace readback, realizer-relation exactness, L10 nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KleeneRealizabilityUp.

Chapter 8094

A Concrete Naming Certificate for $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ packet records a finite sequence of located compact interval certificates through displayed locator, finite-net, and regular-Cauchy window data. It sits over the compact-interval locator of chapter 1891, the Bishop located compact-set surface of chapter 8088, the finite-window induction route of chapter 8091, the stream-name interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names a located and finite-net sequence surface for L10 compact-interval arguments; it does not use open-cover compactness, selected subsequential limits, countable choice, quotient equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8094.1 (Located compact interval sequence carrier)**.** *A* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, L, B, F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval row, listing the compact rational or dyadic interval names inspected by the packet.*
2. *L is the* $\mathsf{CompactIntervalLocator}^{\uparrow}$ *row, recording left and right endpoint locator data, metric-distance requests, and displayed interval containment checks.*
3. *B is the* $\mathsf{BishopLocatedCompactSet}^{\uparrow}$ *row, storing the located compact-set finite-net reading attached to the same interval sequence.*
4. *F is the finite-net ledger, recording the finite centers, coverage witnesses, and refinement comparisons used at each displayed tolerance.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which interval names, locator requests, and net centers are read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint, radius, and distance comparisons.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for denominator budgets, dyadic radii, and interval-overlap inequalities.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, L, B, F, W, R, D have been displayed.*

9. *H records componentwise* hsame *transport for interval rows, locator rows, located compact-set rows, finite-net ledgers, stream windows, regular rational readbacks, dyadic tolerance rows, Real seals, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a compact-interval sequence request through $I, L, B, F, W, R, D, E, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$, $\mathsf{CompactIntervalLocator}^{\uparrow}$, BishopLocatedCompac RegularCauchyWindowInduction$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, B, F, W, R, D, E, H, C, P, N$. It has no coordinate for open-cover compactness, selected subsequential limits, countable-choice net selection, quotient equality of interval names, trichotomy of endpoints, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8094.2 (Located compact interval sequence NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ *carrier*

$$K = (I, L, B, F, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSequence}^{\uparrow}}$ *surface consists exactly of interval-row admission, compact-interval locator exposure, Bishop located compact-set handoff, finite-net ledger coverage,* $\mathsf{StreamName}^{\uparrow}$ *finite-window exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8094.1. The accepted packet displays the interval row I, locator row L, located compact-set row B, finite-net ledger F, window row W, readback row R, tolerance row D, and Real seal E.

The compactness-facing data are finite. Locator reads pass through L, locatedness reads pass through B, and finite-net coverage passes through F before any Real-facing seal is available.

The regular-Cauchy side is W, R, D. A consumer reads stream windows, rational readback, and dyadic tolerance budgets before using E.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the classifier has no coordinate for open covers, selected subsequential limits, countable-choice schedules, quotient equality, endpoint trichotomy, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 8094.3 (Located compact interval sequence extraction)**.** *Every Real or Completion-facing read exported by an accepted* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ *carrier factors through the finite route*

$$I \longmapsto L, B, F \longmapsto W, R, D \longmapsto E \longmapsto H, C, P, N.$$

Thus a consumer can extract located interval data, finite-net coverage, regular rational readback, and a terminal $\mathsf{Real}^{\uparrow}$ *seal only by displaying the locator and finite-window schedules that precede them.*

Proof. Start with the obligation theorem. It requires every accepted read to keep $I, L, B, F, W, R, D, E, H, C, P, N$ as one finite packet.

The locator stage reads I, L, B, F. The interval names are exposed before the compact-interval locator and Bishop located compact-set rows, and the finite-net ledger records the centers and coverage witnesses used by the located read.

The finite-window stage reads W, R, D. The $\mathsf{StreamName}^{\uparrow}$ windows expose the inspected names, the $\mathsf{RegSeqRat}^{\uparrow}$ row reads endpoint and radius data, and the $\mathsf{DyadicRatCore}^{\uparrow}$ row records the tolerance comparisons.

Only after those rows are displayed may E be read as a terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows preserve the same route, so no hidden open-cover theorem, selected limit, countable-choice selection, quotient equality, trichotomy, or ambient completeness principle can replace the displayed extraction path. □

Theorem 8094.4 (Located compact interval sequence ledger)**.** *Every accepted* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ *carrier exposes a single finite ledger joining compact-interval locator data, located compact-set finite nets, regular-Cauchy finite windows, rational readback, and dyadic tolerance comparisons. The ledger is stable under componentwise* hsame *transport and displayed* Cont *replay, and it exports no open-cover compactness, sequential compactness without displayed finite nets, countable choice, quotient equality, trichotomy, selected limits, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Read the carrier named in Definition 8094.1. Its finite ledger is precisely the tuple $I, L, B, F, W, R, D, E, H, C$

The compact-interval part is I, L, B, F. These rows bind interval names, locator requests, located compact-set data, and finite-net coverage witnesses into one displayed packet.

The finite-window part is W, R, D, E. These rows record the inspected stream windows, regular rational readbacks, dyadic tolerance comparisons, and the terminal Real seal.

Componentwise transport H and displayed replay C preserve the same rows, while provenance P and local naming N keep the ledger attached to $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$. The excluded principles are absent from the classifier, so the ledger cannot export them. □

Falsifiable prediction: An accepted $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal or finite-net compact-interval read without displaying $I, L, B, F, W, R, D, E, H, C, P, N$ refutes the carrier surface.

Independence witness: compactintervallocator, bishoplocatedcompactset, regularcauchywindowinduction, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the joint finite packet containing compact interval locator data, located compact-set finite nets, regular-Cauchy finite windows, rational readback, dyadic tolerance accounting, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$ packet is generated from finite interval rows, CompactIntervalLocator rows, BishopLocatedCompactSet finite-net rows, RegularCauchyWindowInduction schedules, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8094.1, Definition 8094.2, Definition 8094.3, and Definition 8094.4 seed the located compact interval sequence route from compact-interval locator data through finite nets, finite windows, rational readback, dyadic tolerance accounting, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactIntervalSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness without displayed finite nets, countable choice, quotient equality, trichotomy, selected limits, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-interval locator exactness, located finite-net coverage, finite-window induction, rational readback, dyadic tolerance accounting, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactIntervalSequenceUp.

Chapter 8095

A Concrete Naming Certificate for $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$

Following Bishop–Bridges regular real analysis, the $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ packet records the finite inspection window that turns regular-Cauchy oscillation control into a $\mathsf{Real}^{\uparrow}$-facing seal. It sits after the dyadic tolerance core of chapter 291, the finite stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name surface of chapter 38, and the oscillation ledger of chapter 6026. The chapter names only the displayed finite-window certificate; it does not claim quotient real equality, selected representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8095.1 (Regular-Cauchy oscillation window carrier)**.** *A* $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (O, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{RegularCauchyOscillation}^{\uparrow}$ *source row recording the accepted oscillation bounds for the inspected regular-Cauchy name.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that names the requested precision and the dyadic comparison cells used by the window.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite window row, exposing the stage range inspected before a readback is available.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same stream window and tolerance ledger.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after O, D, S, R are visible.*
6. *H records componentwise* hsame *transport for the oscillation, tolerance, window, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the route*

$$O, D, S \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$, $\mathsf{RegularCauchyOscillation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationWindow}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only by the displayed rows $O, D, S, R, E, H, C, P, N$. It has no coordinate for quotient real equality, selected representatives, countable choice, host real equality, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8095.2 (Regular-Cauchy oscillation window NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ *carrier*

$$W = (O, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegularCauchyOscillation}^{\uparrow}$ *source row, dyadic tolerance exposure through* $\mathsf{DyadicRatCore}^{\uparrow}$*, finite window exposure through* $\mathsf{StreamName}^{\uparrow}$*, regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, Real sealing through* $\mathsf{Real}^{\uparrow}$*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and ledger nonescape for the excluded quotient, selection, choice, host-equality, trichotomy, and ambient-completeness coordinates.*

Proof. Project the carrier of Definition 8095.1. The projection exposes the regular-Cauchy oscillation source, dyadic tolerance row, finite stream window, regular rational readback, Real seal, and structural rows.

The local NameCert obligations are then read row by row. Carrier admission names O; tolerance exposure names D; finite inspection names S; readback names R; and sealing names E.

The remaining rows H, C, P, N transport, replay, source, and name the same route. Since no excluded coordinate occurs in the carrier, the listed obligations exhaust the accepted packet. □

Theorem 8095.3 (Regular-Cauchy oscillation window Real-seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer admitted by an accepted* $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ *packet first reads the oscillation bounds in* $\mathsf{RegularCauchyOscillation}^{\uparrow}$*, the dyadic tolerance row in* $\mathsf{DyadicRatCore}^{\uparrow}$*, the finite window row in* $\mathsf{StreamName}^{\uparrow}$*, and the regular rational readback row in* $\mathsf{RegSeqRat}^{\uparrow}$*. Only after those rows are displayed may the consumer read the* $\mathsf{Real}^{\uparrow}$ *seal. The route is a finite* BHist/Cont/Pkg *certificate and not a quotient-real construction, selected-limit operation, countable-choice schedule, trichotomy argument, or ambient completeness theorem.*

Proof. Start with an accepted carrier $W = (O, D, S, R, E, H, C, P, N)$ and project its displayed rows. The only oscillation source is O, the only tolerance data are in D, and the only window schedule is S.

The regular rational readback is therefore forced through R before the seal row E can be consumed. Componentwise transport through H preserves the row roles, and replay through C preserves the order of the displayed route.

Provenance and local naming through P, N attach the route to the packet without adding analytic content. Since the carrier contains no quotient, selection, choice, trichotomy, host-equality, or ambient-completeness coordinate, the Real-facing seal is reached only through the finite rows named above. □

Falsifiable prediction: Every $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ Real-facing read factors through one $\mathsf{RegularCauchyOscillation}^{\uparrow}$ source row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, one $\mathsf{StreamName}^{\uparrow}$ finite window row, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: regularcauchyoscillation, dyadicratcore, streamname, regseqrat, real: $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries oscillation bounds, dyadic tolerance, finite window inspection, regular readback, Real sealing, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOscillationWindow}^{\uparrow}$ packet is generated from regular-Cauchy oscillation bounds, a DyadicRatCore tolerance row, a StreamName finite window, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8095.1, Definition 8095.2, and Definition 8095.3 seed the finite-window route from regular-Cauchy oscillation control to Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient reals, selected representatives, countable choice, host real equality, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite window coverage, regular readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyOscillationWindowU

Chapter 8096

A Concrete Naming Certificate for $\mathsf{EllInftySequenceSpace}^{\uparrow}$

Following Banach and Bourbaki on bounded sequence spaces, the $\mathsf{EllInftySequenceSpace}^{\uparrow}$ packet records the finite NameCert surface for bounded real sequence data inspected through stream schedules, regular rational readback, and a uniform bound ledger. It sits after the terminal real-name seal of chapter 38, the finite stream window interface of chapter 126, the regular rational readback of chapter 301, the bounded sequence carrier of chapter 1415, and the Cauchy sequence-space route of chapter 406. The packet names the classical ℓ^∞ surface as bounded sequence inspection data, not as a quotient Banach space, selected representative, countable-choice family, host supremum, or ambient completeness theorem.

Definition 8096.1 (Ell-infinity sequence-space carrier)**.** *An* $\mathsf{EllInftySequenceSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, W, R, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the inspected sequence coordinates and finite prefixes.*
2. *W is the finite sequence-window ledger consumed from S.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback route that turns displayed windows into terminal real-name seals.*
4. *B is the uniform bound ledger, recording the displayed bound used by every inspected coordinate before the corresponding Real seal is exported.*
5. *H records componentwise* hsame *transport for the schedule, windows, readback, bound ledger, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a consumer request through S, W, R, B, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{EllInftySequenceSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{EllInftySequenceSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, W, R, B, H, C, P, N. There is no coordinate for quotient sequence equality, selected representatives, countable-choice schedules, host suprema, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8096.2 (Ell-infinity sequence-space NameCert obligations)**.** *For every accepted* $\mathsf{EllInftySequenceSpace}^{\uparrow}$ *carrier* $E = (S, W, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{EllInftySequenceSpace}^{\uparrow}}$ *surface consists exactly of five obligation rows:*

1. *carrier admission for the displayed schedule, finite windows, regular rational and Real readback, uniform bound ledger, transport, replay, provenance, and local naming rows;*
2. *sequence-window exposure, requiring every consumer to read* S *and* W *before it can inspect coordinate readback;*
3. *Real readback ordering, requiring* R *to remain downstream of the displayed finite windows and regular rational rows;*
4. *uniform bound exactness, requiring* B *to be read before any exported Real seal is treated as part of the bounded sequence-space packet;*
5. *ledger refusal, excluding quotient sequence equality, selected representatives, countable-choice schedules, host suprema, ambient Real completeness, and bridge certificates.*

No local NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 8096.1. Its displayed rows are exactly S, W, R, B, H, C, P, N, so carrier admission exposes only finite sequence schedules, windows, readback, a uniform bound ledger, transport, replay, provenance, and local naming.

The sequence-window and readback obligations follow the route through S, W, R. A consumer first reads the finite schedule and windows, then the regular rational and Real readback attached to those windows.

The bound row is independent of host suprema. It is a displayed ledger row B tied to the inspected windows and readback, so boundedness is consumed as packet data rather than inferred from an ambient function space.

Finally the structural rows H, C, P, N preserve the same finite packet. Since the carrier has no coordinate for quotient sequence equality, selected representatives, choice schedules, host suprema, ambient completeness, or bridge certificates, the five rows exhaust the local NameCert surface. □

Theorem 8096.3 (Ell-infinity sequence-space uniform bound ledger)**.** *Every consumer read of an accepted* $\mathsf{EllInftySequenceSpace}^{\uparrow}$ *carrier reaches a* $\mathsf{Real}^{\uparrow}$ *seal only after reading the uniform bound ledger* B *for the same displayed schedule and finite window route. In carrier notation, any exported coordinate read factors through*

$$S, W, R, B, H, C, P, N$$

with B *visible before the coordinate is consumed as bounded sequence-space data.*

Proof. Begin with the finite schedule S and the window ledger W. These rows determine which sequence coordinates and prefixes are available to the consumer.

Read the regular rational and Real route R next. The route is attached to those displayed windows, so a terminal Real seal is not a detached representative of a quotient sequence.

Now inspect the uniform bound ledger B. By the NameCert obligations of Definition 8096.2, B is read before the Real seal is exported as bounded sequence-space evidence.

The structural rows H, C, P, N replay the same route and do not add a host supremum or completeness row. Thus every consumer sees the bound ledger before it can use the Real seal as an $\mathsf{EllInftySequenceSpace}^{\uparrow}$ coordinate. □

Theorem 8096.4 (Ell-infinity sequence-space L10 nonescape)**.** *For every accepted* $\mathsf{EllInftySequenceSpace}^{\uparrow}$ *carrier* $E = (S, W, R, B, H, C, P, N)$*, the local ledger refuses quotient sequence equality, selected representatives, countable choice, host suprema, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any request for one of those objects leaves the accepted packet rather than reading the finite bounded sequence-space certificate.*

Proof. Inspect the carrier definition. The only coordinates are the schedule, finite windows, readback route, uniform bound ledger, transport, replay, provenance, and local naming rows.

Apply the NameCert obligations and the uniform bound ledger theorem. They force consumer reads through the displayed finite route and place boundedness in B, not in a host supremum or ambient completeness principle.

Because no carrier row stores quotient sequence equality, a selected representative, a choice schedule, a host supremum, or a Real completeness theorem, no replay through H, C, P, N can export those objects. □

Falsifiable prediction: An accepted $\mathsf{EllInftySequenceSpace}^{\uparrow}$ read is refuted if a consumer reaches bounded sequence-space data without displaying a StreamName schedule, finite sequence windows, RegSeqRat and Real readback, a uniform bound ledger, transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, real, boundedrealsequence, cauchysequencespace: none alone is bijective with $\mathsf{EllInftySequenceSpace}^{\uparrow}$ because the packet jointly carries schedule, finite windows, readback, a uniform bound ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EllInftySequenceSpace}^{\uparrow}}$**.**

Constructive story: An $\mathsf{EllInftySequenceSpace}^{\uparrow}$ packet is generated from a StreamName schedule, finite sequence windows, RegSeqRat and Real readback, a uniform bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EllInftySequenceSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8096.1, Definition 8096.2, and Definition 8096.3 seed the finite bounded sequence-space route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{CauchySequenceSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EllInftySequenceSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Banach-space equality, selected representatives, countable choice, host suprema, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sequence-window exposure, Real readback ordering, uniform bound exactness, ledger refusal, transport, replay, provenance, and local naming for BEDC.Derived.EllInftySequenceSpaceUp.

Chapter 8097

A Concrete Naming Certificate for $\mathsf{CompactCauchyFilter}^{\uparrow}$

Following Kelley, Bourbaki, and Bishop–Bridges on compactness, filters, and constructive completion, the $\mathsf{CompactCauchyFilter}^{\uparrow}$ packet records the finite compact-generated Cauchy-filter surface used by the Real and Completion route. It sits after the compact metric carrier of chapter 129, the filter-base interface of chapter 1601, the Cauchy-filter surface of chapter 333, the StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, the DyadicRatCore tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names only displayed compact finite-net and Cauchy-filter data; it does not select a limit, quotient filters, use countable choice, import open-cover compactness, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8097.1 (Compact Cauchy filter carrier)**.** *A* $\mathsf{CompactCauchyFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, B, Q, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *or compact finite-net row, exposing the finite compact source windows and net witnesses consumed by the filter route.*
2. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *row, listing the finite filter-base packets and directed-refinement witnesses visible to completion consumers.*
3. *Q is the* $\mathsf{CauchyFilter}^{\uparrow}$ *row, recording the displayed Cauchy requests over the same base and compact source.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when the compact filter route is inspected by sequential or real-facing consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite windows and tolerance requests.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, bounding every displayed Cauchy request before the terminal seal is read.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reachable only after K, B, Q, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the compact-source, filter-base, Cauchy-filter, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a compact filter request through K, B, Q, W, R, D, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactCauchyFilter}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, B, Q, W, R, D, E, H, C, P, N$. It has no coordinate for a selected limit, quotient filter equality, quotient real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8097.2 (Compact Cauchy filter NameCert obligations)**.** *For every accepted* $\mathsf{CompactCauchyFilter}^{\uparrow}$ *carrier $F = (K, B, Q, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactCauchyFilter}^{\uparrow}}$ *surface consists exactly of compact-source admission, filter-base admission, Cauchy-filter admission, finite-window exposure, regular-rational readback, dyadic tolerance exposure, Real sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8097.1. The analytic rows are precisely K, B, Q, W, R, D, E: compact finite-net data, filter-base data, Cauchy evidence, finite windows, regular-rational readback, dyadic tolerances, and the terminal Real seal.

The structural rows H, C, P, N preserve, replay, source, and name the same displayed data. They do not add a second filter object, a quotient relation, a selected limit, or an ambient compactness theorem.

Thus every local NameCert obligation is one of the displayed rows, and the excluded completion and compactness principles cannot be obligations of the carrier. □

Theorem 8097.3 (Compact Cauchy filter finite-net handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactCauchyFilter}^{\uparrow}$ *carrier reads the compact finite-net row K, the* $\mathsf{FilterBase}^{\uparrow}$ *row B, the* $\mathsf{CauchyFilter}^{\uparrow}$ *row Q, the* $\mathsf{StreamName}^{\uparrow}$ *row W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D before the* $\mathsf{Real}^{\uparrow}$ *seal E is available. The handoff exports compact-generated Cauchy-filter data only through finite BEDC rows, not through selected limits, quotient filter equality, countable choice, open-cover compactness, or ambient Real completeness.*

Proof. Start with the compact source row. The finite-net data in K supply the compact windows that a completion-facing filter consumer may inspect.

Next read the filter route. The base row B exposes the finite directed interface, and the Cauchy row Q records the Cauchy requests only over that displayed base.

The real-facing portion is downstream. The rows W, R, D translate the inspected filter requests into finite windows, regular-rational readback, and dyadic tolerance accounting before E can be read.

Finally use the structural rows H, C, P, N. They preserve and name the same finite handoff, so no selected limit, quotient filter, choice schedule, open-cover compactness proof, or ambient completeness row is available to a consumer. □

Falsifiable prediction: Every accepted $\mathsf{CompactCauchyFilter}^{\uparrow}$ completion read must expose compact finite-net data, a FilterBase row, a CauchyFilter row, StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a Real-facing consumer may inspect the result.

Independence witness: compactmetric, filterbase, cauchyfilter, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{CompactCauchyFilter}^{\uparrow}$ because this packet jointly

carries compact finite-net data, filter-base refinements, Cauchy-filter requests, finite windows, rational readback, dyadic tolerances, Real sealing, transport, replay, provenance, and local naming as one completion-facing surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCauchyFilter}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCauchyFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8097.1, Definition 8097.2, and Definition 8097.3 seed the compact-generated Cauchy-filter route over CompactMetric, FilterBase, CauchyFilter, StreamName, RegSeqRat, DyadicRatCore, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCauchyFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient filter equality, quotient real equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net admission, filter-base routing, Cauchy-filter routing, finite-window readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactCauchyFilterUp.

Constructive story: A $\mathsf{CompactCauchyFilter}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, FilterBase rows, CauchyFilter rows, StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8098

A Concrete Naming Certificate for $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$

Following Hadamard, Morse, and Bowen on geodesic dynamics and symbolic coding for hyperbolic systems, the $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ packet records the finite Markov-partition coding surface used by the hyperbolic observer-expansion vision of chapter 9463. It sits after the Markov partition carrier of chapter 8089, the geodesic-flow carrier of chapter 3856, the subshift carrier of chapter 2107, and the boundary-shadow carrier of chapter 3813. The packet names a finite symbolic coding route only; it does not import invariant measures, completed shift spaces, orbit quotients, global Anosov theorems, or host boundary equality.

Definition 8098.1 (Hyperbolic symbolic coding carrier)**.** *A* $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, G, Q, B, T, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ *row, exposing finite atoms, transition ledgers, and partition refinements.*
2. *G is the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row, exposing the finite flow window to be coded.*
3. *Q is the* $\mathsf{Subshift}^{\uparrow}$ *code row, recording the finite symbolic word or cylinder data admitted by the Markov transition ledger.*
4. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, binding the coded flow window to displayed boundary-shadow data.*
5. *T is the transport row from Markov partition atoms and geodesic-flow windows to subshift code rows and boundary shadows.*
6. *A is the adjacency and admissibility ledger, recording the exact finite transition checks used before a code row is accepted.*
7. *H records componentwise* hsame *transport for Markov partition, geodesic-flow, subshift-code, boundary-shadow, adjacency, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a coding request through M, G, Q, B, T, A, H.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$, $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$, $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$, $\mathsf{Subshift}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicSymbolicCoding}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, G, Q, B, T, A, H, C, P, N$. It has no coordinate for invariant measures, completed shift spaces, orbit quotients, global Anosov dynamics, measure-theoretic coding, or host boundary equality.

Theorem 8098.2 (Hyperbolic symbolic coding NameCert obligations)**.** *For every accepted* HyperbolicSymbolicCodi *carrier $S = (M, G, Q, B, T, A, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSymbolicCoding}^{\uparrow}}$ *surface consists exactly of Markov-partition admission, geodesic-flow admission, subshift-code admission, boundary-shadow admission, coding transport, adjacency and admissibility checking, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8098.1. The rows M, G, Q, B supply the finite Markov partition, the finite geodesic-flow window, the symbolic code row, and the boundary-shadow row.

The rows T, A bind those data as a coding route. They record how partition atoms and flow windows are transported to code rows and which finite adjacency checks are required before the code is admitted.

The structural rows H, C, P, N preserve, replay, source, and name the same finite route. Since invariant measures, completed shift spaces, orbit quotients, global Anosov dynamics, measure-theoretic coding, and host boundary equality are absent from the carrier, they cannot be local NameCert obligations. □

Theorem 8098.3 (Hyperbolic symbolic coding flow-partition handoff)**.** *Every coding-facing consumer of an accepted* $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ *packet reads the* $\mathsf{HyperbolicMarkovPartition}^{\uparrow}$ *row M, the* $\mathsf{HyperbolicGeodesicFlow}^{\uparrow}$ *row G, the* $\mathsf{Subshift}^{\uparrow}$ *row Q, and the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row B through the same finite transport and admissibility rows T, A before the coding route reaches replay, provenance, and local naming. A read that bypasses either the Markov transition ledger or the geodesic-flow window is outside this carrier.*

Proof. Begin with the Markov partition row. It supplies the finite atoms, transition ledger, and refinement data that make the code admissible.

Read the flow row next. The geodesic-flow window is the dynamic object being coded, so the symbolic row Q cannot be consumed before G has been displayed.

Now bind the boundary and code rows. The boundary-shadow row B keeps the code attached to the displayed hyperbolic boundary data, while T, A record the finite transport and transition checks from M, G to Q, B.

Finally replay the same route through H, C, P, N. Without the Markov transition ledger or the geodesic-flow window, a consumer has a different object, not an accepted $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ handoff. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ read must expose HyperbolicMarkovPartition, HyperbolicGeodesicFlow, Subshift, HyperbolicBoundaryShadow, transport, adjacency, hsame, Cont, Pkg, and local NameCert rows before a coding-facing consumer may inspect the symbolic route.

Independence witness: hyperbolic-markov-partition, hyperbolic-geodesic-flow, subshift, hyperbolic-boundary-shadow: no listed sibling is bijective to $\mathsf{HyperbolicSymbolicCoding}^{\uparrow}$ because this packet jointly carries Markov atoms, geodesic-flow windows, symbolic code rows, boundary shadows, transport, admissibility, replay, provenance, and local naming as one coding surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSymbolicCoding}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicSymbolicCoding}^{\uparrow}}$, seed)

Scope closed: Definition 8098.1, Definition 8098.2, and Definition 8098.3 seed the finite symbolic coding route over HyperbolicMarkovPartition, HyperbolicGeodesicFlow, Subshift, HyperbolicBoundaryShadow, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicSymbolicCoding}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close invariant measures, completed shift spaces, orbit quotients, global Anosov dynamics, measure-theoretic coding, host boundary equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Markov-partition admission, geodesic-flow admission, subshift-code admission, boundary-shadow admission, transport, adjacency checking, replay, provenance, and local naming for BEDC.Derived.HyperbolicSymbolicCodingUp.

Constructive story: A HyperbolicSymbolicCoding$^{\uparrow}$ packet is generated from HyperbolicMarkovPartition rows, HyperbolicGeodesicFlow windows, Subshift code rows, HyperbolicBoundaryShadow rows, transport rows, adjacency ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8099

Tug-of-war game NameCert construction

Following Peres–Schramm–Sheffield–Wilson on tug-of-war games and infinity-harmonic limits, the $\mathsf{TugOfWarGame}^{\uparrow}$ packet records a finite alternating-play game as displayed BEDC data before any metric or PDE-facing consumer may read its value. It sits beside the viscosity-solution boundary of chapter 2177, the metric and compact-metric sources of chapter 57 and chapter 129, the finite real-cover packet of chapter 2377, and the fixed-point discipline around chapter 3529. The packet names finite play, legal moves, strategy/payoff classification, stopping, transport, replay, provenance, and local naming; it does not assert comparison, uniqueness, measurable strategy selection, martingale convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8099.1 (Tug-of-war game carrier)**.** *A* $\mathsf{TugOfWarGame}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, A, B, L, S, V, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose inspected positions and distance comparisons constrain every move.*
2. *A and B are the two finite action rows, recording the legal alternatives available to the first and second player at each inspected position.*
3. *L is the legal-move ledger. It records the metric or finite-cover witness that each displayed action remains inside the admitted neighbour set.*
4. *S is the strategy/payoff classifier row. It records only finite response tables, payoff comparisons, and player-role tags visible in the packet.*
5. *V is the value-readback row, exposing the finite dynamic-programming value requested by a viscosity-solution or fixed-point consumer.*
6. *T is the payoff and stopping ledger, recording terminal positions, stopping flags, terminal payoff rows, and the finite horizon at which a replay stops.*
7. *H records componentwise* hsame *transport for the source, action, legal-move, strategy/payoff, value, stopping, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for legal moves: a consumer request must replay X, A, B, L, S, V, T, H before a value row is exported.*

9. *P is the* Pkg *provenance over* $\mathsf{TugOfWarGame}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteRealCover}^{\uparrow}$, $\mathsf{ViscositySolution}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{DynamicProgramming}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TugOfWarGame}^{\uparrow}}$ *row.*

The classifier has no coordinate for host strategies, measurable selectors, infinite plays, optional-stopping theorems, quotient value functions, comparison principles, or ambient real completeness.

Definition 8099.2 (Tug-of-war strategy and payoff classifier)**.** *Two accepted* $\mathsf{TugOfWarGame}^{\uparrow}$ *carriers*

$$G = (X, A, B, L, S, V, T, H, C, P, N)$$

and

$$G' = (X', A', B', L', S', V', T', H', C', P', N')$$

are classified together exactly when the stored hsame *rows transport the source positions, both action rows, the legal-move ledger, the strategy/payoff table, the value-readback row, the payoff and stopping ledger, the provenance, and the local name, and when C and C' replay the same legal-move route. The comparison is finite-observation equality of the displayed game packet, not equality of host strategies or of an ambient value function.*

Theorem 8099.3 (Tug-of-war game carrier obligation)**.** *For every accepted* $\mathsf{TugOfWarGame}^{\uparrow}$ *carrier $G = (X, A, B, L, S, V, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TugOfWarGame}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *finite play carrier admission through X, A, B, L;*
2. *strategy/payoff classifier admission through S and Definition 8099.2;*
3. *componentwise* hsame *stability through H;*
4. *displayed* Cont *replay for legal moves through C;*
5. *payoff and stopping ledger admission through T, with value readback through V and provenance/local naming through P, N.*

Proof. Project the carrier of Definition 8099.1. The finite play data are precisely the source row, the two action rows, and the legal-move ledger.

The classifier row S and Definition 8099.2 compare only displayed response tables and payoff comparisons. Componentwise transport H preserves those rows, while C replays the same legal moves before any value row is read.

The remaining game-specific information is the payoff and stopping ledger T, together with value readback, provenance, and local naming. Since no host strategy, infinite play, measurable selector, optional-stopping theorem, quotient value function, comparison principle, or ambient completeness row is stored in G, the five displayed rows exhaust the local NameCert surface. □

Theorem 8099.4 (Tug-of-war game payoff ledger)**.** *Every payoff or value read exported by an accepted* $\mathsf{TugOfWarGame}^{\uparrow}$ *packet factors through*

$$X, A, B, L \longmapsto S \longmapsto V \longmapsto T \longmapsto H, C, P, N.$$

Thus a viscosity-solution, finite-cover, compact-metric, metric, or Banach-contraction neighbour receives only the displayed finite game ledger: legal moves, finite strategy/payoff classification, value readback, stopping data, transport, replay, provenance, and local naming.

Proof. Begin with a payoff-facing consumer. Carrier projection exposes X, A, B, L before any player-role, payoff, or value row is available, so legal moves are certified before they are scored.

Next read the finite classifier and value rows. The row S records the response table and payoff comparison visible at the inspected positions, while V records the value read requested by the downstream consumer.

Finally the stopping ledger T seals the terminal positions and horizon, and H, C, P, N transport, replay, source, and name the same route. The exported read therefore remains a finite game-value ledger and cannot become a host strategy selector, infinite-play value theorem, optional-stopping argument, viscosity comparison theorem, fixed-point existence theorem, quotient equality, or ambient real-completeness claim. □

Falsifiable prediction: Any accepted $\mathsf{TugOfWarGame}^{\uparrow}$ value read that omits the metric or compact-metric source, both action rows, the legal-move ledger, the strategy/payoff classifier, the value-readback row, the payoff and stopping ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row refutes the carrier.

Independence witness: viscosity-solution, compactmetric, metric, finite-real-cover, banach-contraction: none is bijective with $\mathsf{TugOfWarGame}^{\uparrow}$ because this packet jointly binds alternating finite play, two action rows, legal-move replay, payoff classification, stopping data, value readback, transport, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TugOfWarGame}\uparrow}$.

Constructive story: A $\mathsf{TugOfWarGame}^{\uparrow}$ packet is generated from metric or compact-metric position rows, two finite action rows, a legal-move ledger, finite strategy/payoff classification, value readback, a payoff and stopping ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TugOfWarGame}\uparrow}$, seed)

Scope closed: Definition 8099.1, Definition 8099.2, Definition 8099.3, and Definition 8099.4 seed the finite game-value route over legal moves, payoff classification, stopping, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TugOfWarGame}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close viscosity comparison, game-value existence or uniqueness, measurable strategy selection, infinite-play convergence, optional stopping, quotient value equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite play admission, strategy/payoff classifier stability, legal-move replay, payoff and stopping ledger exactness, value-readback nonescape, transport, provenance, and local naming for BEDC.Derived.TugOfWarGameUp.

Chapter 8100

A Concrete Naming Certificate for $\mathsf{LinearBoundedAutomaton}^{\uparrow}$

Following Hopcroft–Ullman and the Chomsky hierarchy presentation of bounded machine computation, the $\mathsf{LinearBoundedAutomaton}^{\uparrow}$ packet names finite accepting computations whose tape cells stay inside the input-length bound. It sits between the pushdown-automaton surface of chapter 6018, the context-sensitive grammar route of chapter 6178, the context-sensitive language carrier of chapter 7749, and the machine-code surface of chapter 280. The packet records bounded tape windows, transition rows, accepting histories, and the accepted-word classifier; it is not an unrestricted machine semantics, a host language set, complement theorem, grammar quotient, or ambient decidability principle.

Definition 8100.1 (Linear bounded automaton carrier)**.** *A* $\mathsf{LinearBoundedAutomaton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (Q, \Sigma, \Gamma, W, B, T, H_{\mathrm{run}}, F, M, S, C, P, N)$$

with the following displayed rows:

1. *Q is the finite state row.*
2. *Σ is the finite input-alphabet row and Γ is the finite tape-alphabet row.*
3. *W is the input word row, read through* $\mathsf{List}^{\uparrow}$ *and* $\mathsf{Nat}^{\uparrow}$ *length data.*
4. *B is the linear tape-bound ledger, naming the finite tape interval admitted for the input word.*
5. *T is the finite transition row over states, tape symbols, head moves, and boundary checks.*
6. *H_{run} is the accepting-history ledger, listing each configuration window, applied transition, head position, and tape-bound witness.*
7. *F is the final-state row.*
8. *M records sibling comparison to* $\mathsf{ContextSensitiveGrammar}^{\uparrow}$*,* $\mathsf{ContextSensitiveLanguage}^{\uparrow}$*, and* $\mathsf{PushdownAutomaton}^{\uparrow}$ *consumers.*
9. *S is the accepted-word classifier, available only after $Q, \Sigma, \Gamma, W, B, T, H_{\mathrm{run}}, F, M$ have been replayed.*
10. *C records displayed* Cont *replay from an acceptance query through the finite machine, tape-bound, transition, history, final-state, comparison, classifier, provenance, and naming rows.*

11. *P is the* Pkg *provenance over* LinearBoundedAutomaton$^{\uparrow}$, ContextSensitiveGrammar$^{\uparrow}$, ContextSensitiveLanguage$^{\uparrow}$, PushdownAutomaton$^{\uparrow}$, List$^{\uparrow}$, Nat$^{\uparrow}$, BHist, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an unbounded tape, a host language set, quotient configuration equality, selected infinite computation, global complement closure, or a general Turing-machine decision oracle.

Theorem 8100.2 (Linear bounded automaton NameCert obligations)**.** *For every accepted* LinearBoundedAutomato *carrier*

$$A = (Q, \Sigma, \Gamma, W, B, T, H_{\mathrm{run}}, F, M, S, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}$ *surface consists exactly of finite state admission, input and tape alphabet admission, input-word admission, linear tape-bound replay, transition-row admission, accepting-history replay, final-state admission, sibling comparison, accepted-word classification, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No accepted packet exports unrestricted Turing-machine computation, host language equality, quotient configuration equality, complement closure, an infinite accepting trace, or ambient decidability.

Proof. Project the carrier of Definition 8100.1. The rows Q, Σ, Γ, W fix the finite machine alphabet and input word, while B fixes the only tape interval a computation may inspect.

The transition and history rows are downstream. The row T lists the permitted finite moves, and H_{run} records each configuration window together with its transition row and tape-bound witness.

The classifier S is exposed only after the final-state row F and comparison row M have been read. Thus a context-sensitive grammar or language consumer may use the accepted-word route, but it cannot replace the route by a host language object or an unrestricted machine semantics.

Finally C, P, N replay, source, and name the same finite route. Since the excluded objects are not carrier coordinates, the listed obligations exhaust the local NameCert surface. □

Theorem 8100.3 (Linear bounded automaton bounded tape route)**.** *Every accepted-word read exported by a* LinearBoundedAutomaton$^{\uparrow}$ *packet factors through the input row W, the linear tape-bound ledger B, the transition row T, and the accepting-history ledger H_{run} before the final-state row F or accepted-word classifier S is available. The comparison route to* ContextSensitiveGrammar$^{\uparrow}$, ContextSensitiveLanguage$^{\uparrow}$, *and* PushdownAutomaton$^{\uparrow}$ *preserves only that finite bounded-tape computation surface; it exports no unbounded tape semantics, host language set, quotient configuration equality, selected infinite run, complement theorem, or global decidability result.*

Proof. Start with the input. By Definition 8100.1, the word row W and bound ledger B are read before any transition history can be inspected.

Apply Definition 8100.2. The accepting-history row H_{run} lists only transition applications from T whose configuration windows stay within B, so neither the final-state row F nor the classifier S can bypass the bounded-tape ledger.

The comparison row M carries this same finite route to the context-sensitive and pushdown siblings. It does not contain a host language set, quotient configuration equality, or unbounded machine oracle.

Replay and provenance through C, P, N preserve the order of the displayed rows. Hence every accepted-word read remains a bounded-tape computation certificate and no stronger semantic object is exported. □

Falsifiable prediction: Every $\mathsf{LinearBoundedAutomaton}^{\uparrow}$ read factors through finite state, input alphabet, tape alphabet, input word, tape-bound, transition, accepting-history, final-state, sibling comparison, accepted-word classifier, displayed Cont, Pkg, and local $\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}$ rows.

Independence witness: pushdownautomaton, contextsensitivegrammar, contextsensitivelanguage: $\mathsf{LinearBoundedAutomaton}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries bounded tape windows, transition rows, accepting histories, and an accepted-word classifier, while the siblings separately record stack computation, noncontracting grammar syntax, or accepted context-sensitive language rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}$.

Constructive story: A $\mathsf{LinearBoundedAutomaton}^{\uparrow}$ packet is generated from finite state rows, input and tape alphabet rows, an input-word row, a linear tape-bound ledger, transition rows, accepting-history rows, a final-state row, sibling comparison, accepted-word classification, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8100.1, Definition 8100.2, and Definition 8100.3 seed the bounded tape computation surface over finite machine rows, input windows, tape bounds, transition histories, sibling comparison, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LinearBoundedAutomaton}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted Turing-machine semantics, host language equality, quotient configuration equality, selected infinite runs, complement closure, or global decidability.

Upgrade path: Obligation closure requires checked finite-state admission, alphabet admission, bounded tape replay, transition-row exactness, accepting-history replay, classifier transport, sibling comparison, provenance, and local naming for BEDC.Derived.LinearBoundedAutomatonUp.

Chapter 8101

A Concrete Naming Certificate for $\mathsf{IrrationalReal}^{\uparrow}$

Following Euclid and Bishop–Bridges, the $\mathsf{IrrationalReal}^{\uparrow}$ packet records a Real-and-Completion name whose rational-candidate exclusion route is visible as finite BEDC data. It sits over the rational and integer rows of chapter 37 and chapter 31, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the finite obstruction packet of chapter 1983. The packet names a rational-exclusion interface for Real-facing consumers; it does not assert trichotomy, quotient real equality, selected representatives, a global rational-or-irrational decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8101.1 (IrrationalReal carrier)**.** *An* $\mathsf{IrrationalReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (R, Q, Z, D, W, T, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source row, recording the Real-and-Completion seal whose rational-exclusion surface is being named.*
2. *Q is the* $\mathsf{Rat}^{\uparrow}$ *candidate row, listing the inspected rational names that a consumer asks to compare with R.*
3. *Z is the* $\mathsf{Int}^{\uparrow}$ *numerator and denominator row attached to the displayed rational candidates.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the finite comparison budgets between R and the candidates in Q.*
5. *W is the* $\mathsf{IrrationalWitness}^{\uparrow}$ *obstruction row, recording the finite witness packet that refuses the displayed rational candidate route.*
6. *T is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which rational approximations to the Real seal are exposed.*
7. *E is the terminal rational-exclusion seal, reached only after R, Q, Z, D, W, T have been displayed.*
8. *H records componentwise* hsame *transport for the Real source, rational candidates, integer data, dyadic ledger, witness row, regular rational readback, exclusion seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a Real-and-Completion rational-exclusion request through R, Q, Z, D, W, T, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{IrrationalReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{IrrationalWitness}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{IrrationalReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient real equality, trichotomy, selected representatives, a host rationality decision, or ambient Real completeness.

Theorem 8101.2 (IrrationalReal NameCert obligations)**.** *For every accepted* $\mathsf{IrrationalReal}^{\uparrow}$ *carrier*

$$I = (R, Q, Z, D, W, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{IrrationalReal}^{\uparrow}}$ *surface consists exactly of Real-source admission, rational-candidate exposure, integer numerator and denominator readback, dyadic tolerance accounting,* $\mathsf{IrrationalWitness}^{\uparrow}$ *obstruction routing,* $\mathsf{RegSeqRat}^{\uparrow}$ *approximation readback, terminal rational-exclusion sealing, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8101.1. The accepted packet displays the Real source R, rational candidate row Q, integer row Z, dyadic ledger D, witness row W, regular rational readback T, terminal seal E, and structural rows H, C, P, N.

The rational-candidate side is finite. The rows Q and Z expose only the inspected rational names and their integer numerator-denominator data, while D records the dyadic comparison budgets used by those inspections.

The exclusion side is routed through W and T. The witness row supplies the finite obstruction packet of $\mathsf{IrrationalWitness}^{\uparrow}$, and the regular rational readback row supplies only the $\mathsf{RegSeqRat}^{\uparrow}$ observations visible before the terminal seal.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no row stores quotient equality, trichotomy, selected representatives, a host rationality decision, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8101.3 (IrrationalReal rational-exclusion route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{IrrationalReal}^{\uparrow}$ *packet must read*

$$\mathsf{Real}^{\uparrow}, \mathsf{Rat}^{\uparrow}, \mathsf{Int}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{IrrationalWitness}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}$$

through the displayed rows $R, Q, Z, D, W, T, H, C, P, N$ before the terminal rational-exclusion seal E is available. The route exports a finite refusal surface for the displayed rational candidates only; it does not export trichotomy, quotient real equality, selected representatives, a global rationality classifier, or Real completeness.

Proof. Begin with the carrier rows of Definition 8101.1. The Real source R is displayed before any rational-exclusion seal, and the candidate data Q, Z are the only rational and integer rows available to the consumer.

Next read the dyadic and regular-rational ledgers. The row D stores the tolerance budgets for candidate comparison, while T stores the $\mathsf{RegSeqRat}^{\uparrow}$ readback used by the Real-facing route.

Use the witness row W. It imports the finite obstruction discipline of chapter 1983 without adding a new coordinate for quotient equality, trichotomy, selected representatives, or a host rationality theorem.

The terminal seal E is therefore downstream of R, Q, Z, D, W, T. Componentwise transport, replay, provenance, and local naming preserve exactly this route, so every Real-and-Completion consumer receives only the displayed rational-exclusion packet. □

Falsifiable prediction: An accepted $\mathsf{IrrationalReal}^{\uparrow}$ consumer that reaches the rational-exclusion seal E without displaying $R, Q, Z, D, W, T, H, C, P, N$ refutes the carrier surface.

Independence witness: real, rat, int, dyadicratcore, regseqrat, irrational-witness: no listed sibling alone supplies the joint Real source, rational candidate, integer numerator-denominator, dyadic tolerance, finite irrational-witness obstruction, regular rational readback, transport, replay, provenance, and local NameCert rows bound in $\mathsf{IrrationalReal}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{IrrationalReal}^{\uparrow}}$.

Constructive story: An $\mathsf{IrrationalReal}^{\uparrow}$ packet is generated from a RealUp source row, Rat candidate rows, Int numerator-denominator rows, a DyadicRatCore tolerance ledger, an IrrationalWitness obstruction row, a RegSeqRat readback row, a terminal rational-exclusion seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{IrrationalReal}^{\uparrow}}$, seed)

Scope closed: Definition 8101.1, Definition 8101.2, and Definition 8101.3 seed the finite rational-exclusion interface from a Real source through rational candidates, dyadic tolerances, witness obstruction, regular rational readback, and terminal sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{IrrationalReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient real equality, selected representatives, a global rationality decision, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, rational-candidate exposure, dyadic tolerance exactness, witness-obstruction routing, regular rational readback, rational-exclusion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.IrrationalRealUp.

Chapter 8102

A Concrete Naming Certificate for $\mathsf{StreamDiagonalization}^{\uparrow}$

Following Bishop–Bridges diagonal arguments, the $\mathsf{StreamDiagonalization}^{\uparrow}$ packet records only the finite diagonal-window surface that can be inspected before any countable choice principle, quotient stream equality, or ambient completeness theorem is claimed. It sits over the stream naming layer of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the real seal of chapter 38, and the finite diagonal-selection route of chapter 4080. The certificate names a displayed diagonal window over finite stream observations; it does not select an infinite host sequence or assert convergence outside the listed rows.

Definition 8102.1 (Stream diagonalization carrier)**.** *A* $\mathsf{StreamDiagonalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, R, T, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window family, naming the finite stream observations and the visible stream indices inspected by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational values available at the displayed windows.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, accounting for dyadic tolerances used when adjacent window readings are compared.*
4. *W is the diagonal-window row, retaining the finite index-window schedule through which the packet reads the stream family.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal over the displayed diagonal readback, not a host limit of the surrounding stream family.*
6. *H records componentwise* hsame *transport for the stream-name windows, regular readback, dyadic tolerances, diagonal window, real seal, provenance, and local naming rows.*
7. *C records the displayed* Cont *replay routes by which consumers read S, R, T, W, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{StreamDiagonalization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyDiagonalSelection}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamDiagonalization}^{\uparrow}}$ *row.*

The carrier contains no row for countable choice, quotient stream equality, a selected host limit, or ambient completeness of the surrounding sequence space.

Theorem 8102.2 (Stream diagonalization NameCert obligations)**.** *For every accepted* $\mathsf{StreamDiagonalization}^{\uparrow}$ *carrier* $D = (S, R, T, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{StreamDiagonalization}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *window exposure, requiring the* $\mathsf{StreamName}^{\uparrow}$ *row* S *and diagonal-window row* W *to display the finite stream observations being read;*
2. *diagonal selection, requiring* W *to identify the finite diagonal path before the real seal* E *is consumed;*
3. *regular readback stability, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *to preserve the displayed rational readings under the transport row* H*;*
4. *dyadic tolerance control, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* T *to account for every tolerance used by the diagonal-window comparison;*
5. *ledger non-escape, requiring* H, C, P, N *to transport, replay, source, and name the same finite route without exporting any unlisted stream or limit principle.*

No obligation is stored outside $S, R, T, W, E, H, C, P, N$*.*

Proof. Project the carrier of Definition 8102.1. The accepted packet displays exactly the stream-name window family, regular rational readback, dyadic tolerance ledger, diagonal window, real seal, transport, replay, provenance, and local naming rows.

The window and selection obligations are read through S and W. The stream family is inspected only at the displayed finite windows, and the diagonal route is named before any consumer reaches the real seal row E.

The stability and tolerance obligations are read through R and T. Regular rational readback supplies the finite values, while the dyadic ledger accounts for the tolerances used in comparing those values along the diagonal window.

Finally H, C, P, N preserve the same displayed route. Since the carrier has no additional coordinate, the local NameCert surface is exhausted by the listed rows and cannot export a countable-choice selector, quotient stream equality, host limit, or ambient completeness claim. □

Theorem 8102.3 (Stream diagonalization window non-escape)**.** *Every consumer read of an accepted* $\mathsf{StreamDiagonalization}^{\uparrow}$ *packet factors through the finite route*

$$S, R, T, W, E, H, C, P, N.$$

The packet may expose StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a diagonal window, a Real seal, componentwise transport, displayed replay, provenance, and local naming. It exports no countable choice principle, no quotient stream equality, no selected host limit, and no ambient completeness theorem.

Proof. Start with Definition 8102.2. It makes the window family, diagonal route, regular readback, dyadic ledger, real seal, transport, replay, provenance, and local name the complete obligation surface.

A consumer reading the diagonal window must therefore pass through S, W, R, T before E is available. The rows are finite NameCert data, so they do not supply a global selector for all streams or an equality relation on quotient streams.

The support rows H, C, P, N preserve and name the same route. They do not add a host sequence, a chosen limit, or a completeness endpoint, so the visible window cannot escape into any of the excluded claims. □

Falsifiable prediction: Every $\mathsf{StreamDiagonalization}^{\uparrow}$ diagonal-window read factors through StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a displayed diagonal window, a Real seal, hsame transport, Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, cauchy-diagonal-selection, real: $\mathsf{StreamDiagonalization}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries stream windows, regular readback, tolerance accounting, diagonal-window routing, real sealing, transport, replay, provenance, and local naming while refusing countable choice and quotient stream equality.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamDiagonalization}^{\uparrow}}$.

Constructive story: A $\mathsf{StreamDiagonalization}^{\uparrow}$ packet is generated from a StreamName window family, RegSeqRat readback, DyadicRatCore tolerance ledger, diagonal-window row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamDiagonalization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8102.1, Definition 8102.2, and Definition 8102.3 seed the finite diagonal-window NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamDiagonalization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, quotient stream equality, selected host limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, diagonal selection, regular readback stability, dyadic tolerance control, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.StreamDiagonalizationUp.

Chapter 8103

A Concrete Naming Certificate for BackwardDifferentiationFormula$^{\uparrow}$

Following Gear and the classical backward differentiation formula tradition, the BackwardDifferentiationFormula$^{\uparrow}$ packet records an implicit linear multistep update as finite BEDC rows. It sits after the one-step Euler carrier of chapter 6231, the staged Runge–Kutta route of chapter 6764, the finite-difference stencil of chapter 5135, the ODE naming surface of chapter 193, the terminal real seal of chapter 38, the regular rational readback of chapter 301, the finite StreamName window of chapter 126, and the dyadic tolerance row of chapter 291. The packet names a finite implicit step window; it does not claim global ODE existence, convergence order, selected limits, a solved nonlinear equation, or ambient Real$^{\uparrow}$ completeness.

Definition 8103.1 (Backward differentiation formula carrier)**.** *A* BackwardDifferentiationFormula$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (O, W, C, D, R, S, H, K, P, N)$$

with the following displayed rows:

1. *O is the* Ode$^{\uparrow}$ *source row naming the inspected right-hand side and the finite step request.*
2. *W is the* StreamName$^{\uparrow}$ *history window containing the displayed past solution values used by the multistep stencil.*
3. *C is the coefficient row for the selected backward differentiation stencil, including the current implicit coefficient and the finite list of past coefficients.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row for the step size, residual budget, and finite comparison windows.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for every rational coefficient, history value, and residual budget consumed by the step.*
6. *S is the* Real$^{\uparrow}$ *seal row for the current implicit residual after O, W, C, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the ODE source, history window, coefficient row, tolerance row, readback row, seal row, replay row, provenance row, and local naming row.*
8. *K records displayed* Cont *replay from a finite step request through the same history, coefficient, tolerance, readback, and seal rows.*

9. *P records* Pkg *provenance over* $\mathsf{BackwardDifferentiationFormula}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{RungeKuttaFiniteStep}^{\uparrow}$, $\mathsf{EulerMethodFiniteStep}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N records the local* $\mathsf{NameCert}_{\mathsf{BackwardDifferentiationFormula}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a chosen exact solution, a selected implicit root, global convergence, a host real-completeness theorem, or an infinite time grid.

Lean4 (definition) `BEDC.Derived.BackwardDifferentiationFormulaUp`

Theorem 8103.2 (Backward differentiation formula NameCert obligations)**.** *For every accepted* $\mathsf{BackwardDifferentiationFormula}^{\uparrow}$ *carrier* $B = (O, W, C, D, R, S, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BackwardDifferentiationFo}}$ *surface consists exactly of ODE source admission, finite history-window coverage, backward-stencil coefficient exposure, dyadic step and residual budget exposure, regular rational readback, terminal Real seal admission, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier rows. The ODE source O, history window W, and coefficient row C provide the finite implicit multistep stencil; no solution curve is present outside these rows.

Read the numerical boundary through D, R, S. The dyadic row supplies the step and residual budget, the RegSeqRat row supplies rational readback for the displayed data, and the Real row seals only the displayed residual comparison.

Transport and replay are then forced through H and K. Provenance P and local naming N preserve the same finite packet, so the NameCert obligations are exactly the listed finite rows and not a convergence theorem or selected implicit solve. □

Theorem 8103.3 (Backward differentiation formula window stability)**.** *Let* $B = (O, W, C, D, R, S, H, K, P, N)$ *and* $B' = (O', W', C', D', R', S', H', K', P', N')$ *be accepted* $\mathsf{BackwardDifferentiationFormula}^{\uparrow}$ *carriers. If the source, history, coefficient, tolerance, readback, and seal rows are componentwise transported by the displayed* hsame *data and replayed through the displayed* Cont *routes, then every finite-step consumer sees the same backward-stencil window and the same residual-budget ledger. The stable surface is the finite step packet; it exposes no selected exact solution, host implicit-root choice, infinite grid, global convergence theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project both carriers. A finite-step consumer can inspect only O, W, C, D, R, S before it reaches transport, replay, provenance, and local naming.

Use the displayed hsame data to identify the corresponding ODE source, history window, coefficient row, dyadic budget, regular readback, and Real seal rows. The replay rows K and K' then route the same step request through the transported finite packet.

Finally read P, N and P', N'. These rows name and source the same finite backward-stencil window, so stability holds at the packet boundary and cannot be promoted to a selected solution, an implicit-root oracle, an infinite grid, convergence, or completeness. □

Falsifiable prediction: A claimed $\mathsf{BackwardDifferentiationFormula}^{\uparrow}$ consumer is refuted if it reads an implicit step while omitting the history window W, coefficient row C, dyadic residual budget D, RegSeqRat readback row R, or Real seal row S.

Closure status for $\mathsf{NameCert}_{\mathsf{BackwardDifferentiationFormula}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BackwardDifferentiationFormula}^{\uparrow}$ packet is generated from an ODE source row, finite history window, backward-stencil coefficient row, dyadic step and residual budget, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BackwardDifferentiationFormula}^{\uparrow}}$, seed)

Scope closed: Definition 8103.1, Definition 8103.2, and Definition 8103.3 seed the finite implicit multistep NameCert surface.

Formal verification: FormalStatus(NameCert$_{\text{BackwardDifferentiationFormula}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.BackwardDifferentiationFormulaUp`

Bridge status: none

Not claimed: This chapter does not close global ODE existence, convergence order, selected limits, implicit-root choice, infinite time grids, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient-window exactness, residual-budget replay, transport, provenance, and local naming for BEDC.Derived.BackwardDifferentiationFormulaUp.

Chapter 8104

A Concrete Naming Certificate for $\mathsf{TypecheckTraceDecider}^{\uparrow}$

The $\mathsf{TypecheckTraceDecider}^{\uparrow}$ packet realizes the MetaCIC decidability audit map of chapter 9379 as finite checker-trace data. It reads `inferTypeCtx`, `checkSameTerm`, `normalizeBounded`, and bounded normal-equality comparison as displayed rows, then keeps refusal and provenance visible before any NameCert consumer can replay the trace. The packet is adjacent to chapter 8083, chapter 3616, chapter 752, and chapter 3889; it does not claim unrestricted conversion decidability or fuel-erased normalization.

Definition 8104.1 (Type-check trace decider carrier)**.** *A* $\mathsf{TypecheckTraceDecider}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (G, I, Q, B, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the represented MetaCIC context row consumed by* `inferTypeCtx`*.*
2. *I is the type-check trace row, recording the checker input, option-valued output, and the local soundness-completeness witness surface.*
3. *Q is the same-term row exposed by* `checkSameTerm` *before a typing trace compares represented terms.*
4. *B is the bounded-normal comparison row, carrying* `normalizeBounded` *fuel and the corresponding bounded normal-equality check.*
5. *R is the refusal row recording that the packet does not export unrestricted beta-conversion decidability, host definitional equality, or a hidden normalizer endpoint.*
6. *H records componentwise* hsame *transport for the context, checker trace, same-term row, bounded-normal row, refusal row, replay row, provenance row, and local naming row.*
7. *C records displayed* Cont *replay through the same checker, comparison, refusal, transport, provenance, and local naming route.*
8. *P records* Pkg *provenance over* $\mathsf{TypecheckTraceDecider}^{\uparrow}$, $\mathsf{MetaCICDecidableTypecheckingHandoff}^{\uparrow}$, $\mathsf{MetaCICDecidableTypingFrontier}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N records the local* $\mathsf{NameCert}_{\mathsf{TypecheckTraceDecider}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host typechecker, proof-irrelevant term equality, fuel-erased normalization, unrestricted conversion, or an external closedness oracle.

Lean4 (definition) `BEDC.Derived.TypecheckTraceDeciderUp`

Theorem 8104.2 (Type-check trace decider obligations)**.** *For every accepted* $\mathsf{TypecheckTraceDecider}^{\uparrow}$ *carrier* $T = (G, I, Q, B, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TypecheckTraceDecider}^{\uparrow}}$ *surface consists exactly of context admission,* `inferTypeCtx` *trace exposure,* `checkSameTerm` *exposure, bounded-normal comparison exposure, refusal-boundary retention, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier. The rows G and I expose the finite checker trace for `inferTypeCtx`; they do not add a host typechecker.

Read the comparison side through Q and B. Structural same-term data and bounded-normal comparison data are displayed as finite rows with their fuel and outputs still visible.

The refusal row R remains part of the NameCert route whenever a consumer asks for unrestricted conversion, fuel-erased normalization, or external closedness. Transport H, replay C, provenance P, and local naming N preserve the same finite trace and add no hidden oracle. □

Theorem 8104.3 (Type-check trace decider replay boundary)**.** *Every consumer of an accepted* $\mathsf{TypecheckTraceDecider}^{\uparrow}$ *packet factors through*

$$G, I, Q, B, R \longmapsto H, C, P, N.$$

The rows G, I *make the checked typing trace public,* Q *makes structural same-term checking public,* B *makes bounded normal comparison public, and* R *keeps the conversion refusal visible. Thus the packet supplies a finite trace decider surface, not an unrestricted conversion or normalization theorem.*

Proof. Start from a consumer read and project the context and checker trace rows G, I. The typing decision surface is the displayed `inferTypeCtx` trace.

Next project the equality rows. The same-term row Q is structural, while B is bounded by the displayed `normalizeBounded` fuel and comparison output.

Finally route the read through R, H, C, P, N. The refusal row blocks stronger conversion readings, and transport, replay, provenance, and local naming preserve only the finite trace packet. □

Falsifiable prediction: A claimed $\mathsf{TypecheckTraceDecider}^{\uparrow}$ consumer is refuted if it promotes `normalizeBounded` to fuel-erased conversion or omits the refusal row R while reading bounded normal-equality data.

Independence witness: metacic-decidable-typechecking-handoff, metacic-decidable-typing-frontier, bounded-normal-equality-checker, metacic-fuel-trace: no listed sibling is bijective to $\mathsf{TypecheckTraceDecider}^{\uparrow}$ because this packet jointly carries checked typing traces, same-term checks, bounded-normal comparison, refusal, transport, replay, provenance, and local naming.

The Lean follow-up is finite: the carrier declaration should support ‘Nontrivial TypecheckTraceDeciderUp‘ and ‘FieldFaithful TypecheckTraceDeciderUp‘ instances by encoding the rows $G, I, Q, B, R, H, C, P, N$ into a displayed event-flow route.

Closure status for $\mathsf{NameCert}_{\mathsf{TypecheckTraceDecider}^{\uparrow}}$.

Constructive story: A TypecheckTraceDecider$^{\uparrow}$ packet is generated from a represented context, inferTypeCtx trace row, checkSameTerm row, normalizeBounded comparison row, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{TypecheckTraceDecider}^{\uparrow}}$, seed)

Scope closed: Definition 8104.1, Definition 8104.2, and Definition 8104.3 seed the finite trace-decider NameCert surface.

Formal verification: FormalStatus(NameCert$_{\text{TypecheckTraceDecider}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.TypecheckTraceDeciderUp`

Bridge status: none

Not claimed: This chapter does not close unrestricted beta-conversion decidability, fuel-erased normalization, host typechecking, proof-irrelevant term equality, external closedness decision, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, inferTypeCtx trace exactness, same-term exactness, bounded-normal comparison exactness, refusal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.TypecheckTraceDeciderUp.

Chapter 8105

A Concrete Naming Certificate for $\mathsf{JordanOscillationDecomposition}^{\uparrow}$

Following Jordan's bounded-variation decomposition theorem, the $\mathsf{JordanOscillationDecomposition}^{\uparrow}$ packet records the finite oscillation route by which a bounded-variation real function is read as two monotone variation ledgers before completion-facing consumers inspect any real output. It sits after the bounded-variation surface of chapter 398, the finite oscillation partition row of chapter 3800, the finite oscillation variation handoff of chapter 7175, the Darboux-sum boundary of chapter 1880, and the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback endpoints of chapter 301 and chapter 38. The packet names only displayed partitions, positive and negative variation rows, finite oscillation ledgers, certified numeric readback, structural transport, replay, provenance, and local naming data; it does not assert host function equality, a quotient measure, a selected supremum over all partitions, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8105.1 (Jordan oscillation decomposition carrier)**.** *A* $\mathsf{JordanOscillationDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (I, B, P, O, V_+, V_-, D, R, E, H, C, S, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *interval and endpoint source row.*
2. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *source ledger over the same endpoint row.*
3. *P is the accepted* $\mathsf{FiniteOscillationPartition}^{\uparrow}$ *row, including the displayed cells and refinement witnesses used by the packet.*
4. *O is the finite oscillation ledger, recording the oscillation budget visible on each displayed cell.*
5. *V_+ is the positive-variation row, listing the finite upward adjacent-difference reads along P.*
6. *V_- is the negative-variation row, listing the finite downward adjacent-difference reads along P.*
7. *D is the Darboux-facing comparison row, present only after P, O, V_+, V_- have been displayed.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite variation and oscillation budgets.*
9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for endpoint, value, oscillation, and variation reads.*
10. *H records componentwise* hsame *transport for interval, bounded-variation, partition, oscillation, two variation, Darboux, readback, seal, replay, provenance, and naming rows.*

11. *C records displayed* Cont *replay through the same finite rows.*

12. *S is the* Pkg *provenance over* $\mathsf{JordanOscillationDecomposition}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{FiniteOscillationPartition}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{JordanOscillationDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, B, P, O, V_+, V_-, D, R, E, H, C, S, N$. Its stability predicate is componentwise: refinement of P may split an oscillation cell only by appending finite rows to O, V_+, V_- and by replaying the same D, R, E, H, C, S, N boundary. There is no coordinate for host function equality, quotient measure, external variation supremum, selected refinement family, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8105.2 (Jordan oscillation decomposition NameCert obligations)**.** *For every accepted* $\mathsf{JordanOscillationDecomposition}^{\uparrow}$ *carrier $J = (I, B, P, O, V_+, V_-, D, R, E, H, C, S, N)$, the local* $\mathsf{NameCert}_{\mathsf{JordanOscillati}}$ *surface consists exactly of carrier admission, interval and endpoint exposure through I, bounded-variation source exposure through B, finite oscillation partition exposure through P, oscillation-ledger exactness through O, positive and negative variation-ledger exactness through V_+ and V_-, Darboux-facing comparison through D, regular-rational readback through R, terminal Real seal through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through S, and local naming through N.*

Proof. Project the carrier of Definition 8105.1. The visible rows are precisely the interval, bounded-variation source, finite oscillation partition, oscillation ledger, positive and negative variation ledgers, Darboux comparison, readback, Real seal, transport, replay, provenance, and local name.

The partition row P is the sole route to local oscillation data. Refining a cell replaces one finite oscillation row by finitely many displayed subcell rows and appends the corresponding adjacent-difference entries to V_+ and V_-.

The two variation rows are finite BHist data. Positive variation records upward adjacent differences and negative variation records downward adjacent differences, both read against the same displayed partition and bounded-variation source row B.

The Darboux, readback, and Real rows are downstream. Row D can compare only the displayed finite ledgers, R reads only their certified regular-rational budgets, and E seals only those readback values as Real-facing output. Thus no hidden host equality, quotient measure, selected supremum, choice principle, or ambient completeness coordinate enters the NameCert surface. □

Theorem 8105.3 (Finite-variation scope of Jordan oscillation decomposition)**.** *Every completion-facing or Darboux-facing read of an accepted* $\mathsf{JordanOscillationDecomposition}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{BoundedVariation}^{\uparrow} \longmapsto \mathsf{FiniteOscillationPartition}^{\uparrow} \longmapsto (V_+, V_-) \longmapsto \mathsf{DarbouxSum}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exposes a Jordan-style positive and negative variation decomposition over displayed oscillation partitions, not a host equality between functions, a quotient measure construction, an external total-variation supremum, a choice-selected partition net, or ambient real completeness.

Proof. Begin with the bounded-variation row B and the displayed interval row I. They give the packet a finite source ledger before any decomposition rows are visible.

Next use the oscillation partition row P. Each refinement step is a finite ledger operation: oscillation entries in O are subdivided, and the upward and downward adjacent-difference entries are appended to V_+ and V_-.

The Darboux row D reads only that finite partition and the two variation ledgers. It can compare upper and lower finite sums, but it has no row for quotient equality of functions, measure completion, or a selected family of refinements.

Finally, $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback occurs only through R and E. Since those rows are downstream of the certified finite classifiers P, O, V_+, V_-, D, every completion-facing output remains inside the displayed finite-variation scope. □

Closure status for $\mathsf{NameCert}_{\mathsf{JordanOscillationDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{JordanOscillationDecomposition}^{\uparrow}$ packet is generated from a Real interval row, bounded-variation source ledger, finite oscillation partition, oscillation budget rows, positive and negative variation ledgers, Darboux comparison, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{JordanOscillationDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8105.1, Definition 8105.2, and Definition 8105.3 seed the finite Jordan decomposition route from bounded-variation ledgers through oscillation partitions to Real and RegSeqRat readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{JordanOscillationDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host function equality, quotient measure construction, external total-variation suprema, selected partition nets, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, bounded-variation source exposure, finite oscillation partition exposure, positive and negative variation-ledger exactness, Darboux comparison, regular-rational readback, Real seal exactness, transport, replay, provenance, and local naming for BEDC.Derived.JordanOscillationDecompositionUp.

Chapter 8106

A Concrete Naming Certificate for $\mathsf{BaireOneModulus}^{\uparrow}$

Following Baire's function hierarchy and Bishop–Bridges constructive analysis, the $\mathsf{BaireOneModulus}^{\uparrow}$ packet records finite oscillation-window moduli for displayed Baire-one pointwise-limit names. It sits after the pointwise-limit carrier of chapter 1604, the continuous approximant rows of chapter 130, the finite stream schedules of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the lower-semicontinuous handoff of chapter 1536, and the source prefix context of chapter 334. The packet names a finite oscillation-modulus companion to the Baire-one function ledger; it is not an ambient space of functions, not a selected approximating sequence, not quotient equality of real names, not a full measurability theorem, and not a completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8106.1 (Baire-one modulus carrier)**.** *A* $\mathsf{BaireOneModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, S, O, M, Q, R, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{BaireSpace}^{\uparrow}$ *source-context row naming the inspected source points and finite prefix information;*
2. *F is the finite family ledger of* $\mathsf{ContinuousMap}^{\uparrow}$ *approximants read by the companion* $\mathsf{BaireOneFunction}^{\uparrow}$ *packet;*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite approximant and source windows inspected by the modulus request;*
4. *O records the finite oscillation windows over the selected source and approximant rows;*
5. *M records modulus witnesses that turn each displayed oscillation window into a tolerance-controlled finite read;*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerances and approximant-value windows selected by S, O, M;*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after the displayed modulus windows and readbacks have been inspected;*
8. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *handoff row receiving the same finite oscillation-modulus ledger;*

9. *H records componentwise* hsame *transport for the source, approximant, schedule, oscillation, modulus, readback, real-seal, handoff, replay, provenance, and local naming rows;*
10. *C records displayed* Cont *replay from a source-point and tolerance request through X, F, S, O, M, Q, R, L;*
11. *P is the* Pkg *provenance over* $\mathsf{BaireOneModulus}^{\uparrow}$, $\mathsf{BaireOneFunction}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BaireOneModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for an ambient function space, arbitrary approximant choice, quotient real equality, full measurability, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*
