Theorem 8106.2 (Baire-one modulus NameCert obligations)**.** *For every accepted* $\mathsf{BaireOneModulus}^{\uparrow}$ *carrier*

$$K = (X, F, S, O, M, Q, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BaireOneModulus}^{\uparrow}}$ *surface consists exactly of carrier admission, continuous approximant admission, pointwise schedule exposure, oscillation-window induction, modulus witness exposure, real-seal nonescape, lower-semicontinuous handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission projects the twelve displayed rows of Definition 8106.1. The source row X, approximant ledger F, and schedule row S are the only entries by which a consumer reaches the Baire-one pointwise-limit surface.

Oscillation-window induction is finite because O is indexed by the displayed schedule. Each step exposes a selected source window and approximant window before the modulus row M may answer the tolerance request.

The readback and value rows Q, R are downstream of the same finite route, and the lower-semicontinuous handoff L consumes only that route. The structural rows H, C, P, N transport, replay, source, and name this packet, so no excluded ambient function-space, choice, quotient, measurability, or completeness principle is available. □

Falsifiable prediction: Every accepted $\mathsf{BaireOneModulus}^{\uparrow}$ read exposes BaireSpace source data, ContinuousMap approximant rows, StreamName schedules, oscillation windows, modulus witnesses, RegSeqRat tolerance readbacks, RealUp seals, LowerSemicontinuous handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any oscillation-modulus consumer receives the packet.

Independence witness: baireonefunction, bairespace, continuousmap, streamname, regseqrat, real, lowersemicontinuous: no listed sibling supplies the full twelve-row packet $K = (X, F, S, O, M, Q, R, L, H, C, P,$ because each sibling contributes only the pointwise-limit ledger, source context, approximant admission, finite schedule, rational readback, real seal, or lower-semicontinuous handoff while this chapter binds oscillation windows and modulus witnesses into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{BaireOneModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BaireOneModulus}^{\uparrow}$ packet is generated from a BaireSpace source row, ContinuousMap approximant rows, StreamName schedules, finite oscillation windows, modulus witnesses, RegSeqRat tolerance readbacks, RealUp seals, a LowerSemicontinuous handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BaireOneModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8106.1 and Definition 8106.2 seed the finite oscillation-modulus companion to the Baire-one pointwise-limit packet over displayed source, approximant, schedule, oscillation, modulus, readback, seal, handoff, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{BaireOneModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close ambient function spaces, arbitrary approximant choice, quotient real equality, full measurability, Real$^{\uparrow}$ completeness, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, continuous approximant admission, pointwise schedule exposure, oscillation-window induction, modulus witness exposure, real-seal nonescape, lower-semicontinuous handoff, transport, replay, provenance, and local naming for BEDC.Derived.BaireOneModulusUp.

Chapter 8107

A Concrete Naming Certificate for $\mathsf{FiniteMeasureDensity}^{\uparrow}$

Following Radon–Nikodym finite-density practice in constructive measure theory, the $\mathsf{FiniteMeasureDensity}^{\uparrow}$ packet records the finite-partition case where an absolutely continuous measure is read cellwise against a displayed base measure before any integration or probability consumer inspects a density. It sits after the finite measure surface of chapter 92, the probability package of chapter 184, the distribution ledger of chapter 186, and the regular rational readback route of chapter 301. The packet names only finite partition cells, base-measure rows, absolutely-continuous measure rows, density ratios, certified $\mathsf{RegSeqRat}^{\uparrow}$ readback, terminal $\mathsf{Real}^{\uparrow}$ seals, structural transport, replay, provenance, and local naming; it does not claim sigma-completion, quotient measure classes, countable choice, or a general Radon–Nikodym theorem.

Definition 8107.1 (Finite measure density carrier)**.** *A* $\mathsf{FiniteMeasureDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (P, M, A, Z, Q, R, E, H, C, G, N)$$

with the following displayed rows:

1. *P is the finite partition row, listing the cells and refinement witnesses inspected by the density request.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *base-measure row, displaying the base value of each cell of P.*
3. *A is the absolutely-continuous measure row, displaying the second measure on the same cells and recording zero-base cells as zero-target cells.*
4. *Z is the density ledger, with one finite row for each cell carrying the rational ratio or the zero-cell witness used by the packet.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite base, target, and density values listed by M, A, Z.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed cell measures and cellwise densities.*
7. *E is the finite expectation or distribution handoff row consumed by* $\mathsf{ProbSpace}^{\uparrow}$ *and* $\mathsf{Distribution}^{\uparrow}$ *requests.*
8. *H records componentwise* hsame *transport for partition, measure, absolute-continuity, density, readback, seal, handoff, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a finite density query through P, M, A, Z, Q, R, E, H.*

10. *G is the* Pkg *provenance over* $\mathsf{FiniteMeasureDensity}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteMeasureDensity}^{\uparrow}}$ *row.*

The carrier has no coordinate for sigma-algebra completion, quotient measure classes, countable choice, non-finite partitions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8107.2 (Finite measure density NameCert obligations)**.** *For every accepted* $\mathsf{FiniteMeasureDensity}^{\uparrow}$ *carrier*

$$D = (P, M, A, Z, Q, R, E, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteMeasureDensity}^{\uparrow}}$ *surface consists exactly of carrier admission, finite partition exposure through P, base-measure exposure through M, absolutely-continuous measure exposure through A, cellwise density exactness through Z, regular-rational readback through Q, terminal Real sealing through R, probability and distribution handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8107.1. The rows $P, M, A, Z, Q, R, E, H, C, G, N$ are the complete visible packet.

The finite partition row P is the only route to cells. The base-measure row M and absolutely-continuous row A are read on the same cells, so a zero-base cell can only be consumed through the displayed zero-target witness in A.

The density ledger Z is finite and cellwise. Each nonzero base cell carries its displayed ratio, while each zero-base cell carries the corresponding zero-target witness rather than a quotient or completion argument.

The readback and seal rows Q, R are downstream of P, M, A, Z, and the probability or distribution handoff E consumes only that sealed finite route. The structural rows H, C, G, N transport, replay, source, and name the same packet, so no sigma-completion, quotient measure class, countable choice, non-finite partition, or ambient completeness coordinate is available. □

Theorem 8107.3 (Finite Radon–Nikodym handoff)**.** *Every* $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, *or integration-facing consumer that reads an accepted* $\mathsf{FiniteMeasureDensity}^{\uparrow}$ *packet receives the finite route*

$$\mathsf{Measure}^{\uparrow} \longmapsto (P, M, A) \longmapsto Z \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route is a Radon–Nikodym density handoff for a displayed finite partition: it exports cellwise base values, absolutely-continuous target values, density rows, certified regular-rational readback, and Real seals, not a sigma-completed measure space, quotient density class, countable-choice selector, or general measure-class derivative.

Proof. Start with the finite partition row P. It fixes the cells on which the base and target measures are compared, so the consumer cannot replace the packet by an unlisted partition or a completed sigma-algebra.

Read the rows M and A cell by cell. Absolute continuity is represented only by the finite zero-cell witnesses in A, and nonzero cells are passed to the density ledger Z as displayed arithmetic data.

Now use the readback route. Row Q gives the $\mathsf{RegSeqRat}^{\uparrow}$ values for the base, target, and density rows, while R seals those displayed values as $\mathsf{Real}^{\uparrow}$ data. The handoff row E passes the same sealed rows to probability and distribution consumers.

Since the carrier has no quotient-density coordinate, no choice schedule over a countable partition, and no sigma-completion row, every accepted Radon–Nikodym-facing read remains the finite cellwise handoff stated above. □

Falsifiable prediction: Every accepted $\mathsf{FiniteMeasureDensity}^{\uparrow}$ read exposes finite partition cells, MeasureUp base rows, absolutely-continuous target rows, density ledger rows, RegSeqRat readback, RealUp seals, probability or distribution handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any density consumer receives the packet.

Independence witness: measure, probspace, distribution, regseqrat, real: no listed sibling supplies the full eleven-row packet $D = (P, M, A, Z, Q, R, E, H, C, G, N)$, because the siblings contribute measure rows, probability packaging, distribution readback, regular rational values, or Real seals separately while this chapter binds them into one finite density NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteMeasureDensity}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteMeasureDensity}^{\uparrow}$ packet is generated from finite partition cells, base-measure rows, absolutely-continuous target-measure rows, density ledger rows, RegSeqRat readback, RealUp seals, probability or distribution handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteMeasureDensity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8107.1, Definition 8107.2, and Definition 8107.3 seed the finite partition density route from displayed measure rows through RegSeqRat readback and Real seals to probability and distribution consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteMeasureDensity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, sigma-completed measure spaces, quotient density classes, countable-choice selectors, non-finite partitions, or a general Radon–Nikodym theorem.

Upgrade path: Obligation closure requires checked carrier admission, finite partition exposure, base-measure exposure, absolute-continuity exposure, density-ledger exactness, regular-rational readback, Real seal exactness, probability and distribution handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteMeasureDensityUp.

Chapter 8108

A Concrete Naming Certificate for $\mathsf{SchreierRefinement}^{\uparrow}$

Following Schreier and the Zassenhaus refinement route used in Jordan–Holder group theory, the $\mathsf{SchreierRefinement}^{\uparrow}$ packet records a finite refinement comparison between two displayed normal-series rows. It sits after the group carrier of chapter 41, the subgroup carrier of chapter 80, the normal-subgroup route carried by the subgroup chapter, the quotient-group carrier of chapter 82, and the composition-series consumer of chapter 6694. The packet names the finite row data needed by a refinement consumer; it does not assert Jordan–Holder uniqueness, group classification, a selected refinement outside the displayed rows, or quotient equality of host groups.

Definition 8108.1 (Schreier refinement carrier)**.** *A* $\mathsf{SchreierRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (G, A, B, I, Q, R, T, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Group}^{\uparrow}$ *source row whose operation, unit, inverse, and classifier are read by both series.*
2. *A and B are the two normal-series rows, each exposing a finite chain of* $\mathsf{Subgroup}^{\uparrow}$ *rows with normality read through the subgroup chapter's normal-subgroup route.*
3. *I is the subgroup-inclusion ledger comparing adjacent entries and cross-intersections in the two displayed rows.*
4. *Q is the* $\mathsf{QuotientGroup}^{\uparrow}$ *factor row attached to the adjacent quotients and intersection quotients exposed by the refinement.*
5. *R records the refinement maps that send each displayed factor row to its paired comparison factor.*
6. *T records componentwise* hsame *transport for the group source, series rows, inclusion ledger, quotient-factor rows, refinement maps, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a normal-series comparison request through G, A, B, I, Q, R, T.*
8. *P is the* Pkg *provenance over* $\mathsf{SchreierRefinement}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Subgroup}^{\uparrow}$, $\mathsf{NormalSubgroup}^{\uparrow}$, $\mathsf{QuotientGroup}^{\uparrow}$, $\mathsf{JordanHolder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SchreierRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host subgroup lattice, quotient primitive, selected refinement oracle, Jordan–Holder uniqueness, or finite-group classification.

Theorem 8108.2 (Schreier refinement NameCert obligations)**.** *For every accepted* $\mathsf{SchreierRefinement}^{\uparrow}$ *carrier*

$$S = (G, A, B, I, Q, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchreierRefinement}^{\uparrow}}$ *surface consists exactly of group-source admission, two normal-series row admissions, subgroup-inclusion accounting, quotient-factor exposure, refinement-map exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8108.1. The group row G is the only ambient algebraic source, while A and B are the only normal-series rows available to the packet.

The comparison surface is finite. The inclusion ledger I records only displayed subgroup inclusions and intersections, and the quotient row Q records only the adjacent and refinement-factor rows read through $\mathsf{QuotientGroup}^{\uparrow}$.

The refinement maps R are then interpreted over those visible rows. Transport, replay, provenance, and local naming are supplied by T, C, P, N, so the listed obligations exhaust the local certificate surface without adding a quotient primitive, selected refinement oracle, host subgroup lattice, or classification theorem. □

Theorem 8108.3 (Schreier refinement normal-series lattice route)**.** *Every* $\mathsf{JordanHolder}^{\uparrow}$ *or composition-series consumer that reads a* $\mathsf{SchreierRefinement}^{\uparrow}$ *packet must first expose the* $\mathsf{Group}^{\uparrow}$ *source, both* $\mathsf{Subgroup}^{\uparrow}$ *normal-series rows, the normal-subgroup inclusion ledger, the* $\mathsf{QuotientGroup}^{\uparrow}$ *factor rows, the refinement maps, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The route supplies a finite normal-series refinement carrier only; it does not prove Jordan–Holder uniqueness, classify groups, select canonical series, or identify quotient factors by host equality.*

Proof. Begin with the group and series rows. The carrier requires G, A, B before a refinement comparison can be consumed, so every downstream read is already tied to the displayed algebra and subgroup surfaces.

Next read the lattice-facing rows I, Q, R. These rows expose subgroup inclusions, normal-series intersection data, quotient factors, and refinement maps as finite packet coordinates, with quotient-facing data routed through chapter 82.

Finally apply the structural rows T, C, P, N. They transport, replay, source, and name the same packet for $\mathsf{JordanHolder}^{\uparrow}$ consumers, while the refused endpoints remain absent from the carrier. Thus the normal-series lattice route is a displayed finite handoff rather than a uniqueness theorem or classification result. □

Falsifiable prediction: A $\mathsf{SchreierRefinement}^{\uparrow}$ consumer that reaches a refinement-map row without first displaying $G, A, B, I, Q, T, C, P, N$ refutes the carrier surface.

Independence witness: group, subgroup, normal-subgroup, quotientgroup, jordan-holder: no listed sibling alone supplies the joint two-series refinement packet $S = (G, A, B, I, Q, R, T, C, P, N)$, because each sibling contributes only the ambient group rows, subgroup rows, normality route, quotient-factor rows, or composition-series consumer boundary.

Closure status for $\mathsf{NameCert}_{\mathsf{SchreierRefinement}^{\uparrow}}$.

Constructive story: A SchreierRefinement$^{\uparrow}$ packet is generated from a GroupUp source row, two normal-series rows, subgroup-inclusion and intersection rows, quotient-factor rows, refinement maps, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SchreierRefinement}^{\uparrow}}$, seed)

Scope closed: Definition 8108.1, Definition 8108.2, and Definition 8108.3 seed the finite normal-series refinement carrier over displayed group, subgroup, normality, quotient-factor, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{SchreierRefinement}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim full Jordan–Holder uniqueness, group classification, selected canonical refinements, quotient primitive construction, Lean verification, bridge checking, or host quotient equality.

Upgrade path: Obligation closure asks for checked carrier admission, two normal-series row admissions, subgroup-inclusion accounting, quotient-factor exposure, refinement-map exposure, transport, replay, provenance, and local naming for BEDC.Derived.SchreierRefinementUp.

Chapter 8109

A Concrete Naming Certificate for ConstructiveClosedIntervalLocator$^{\uparrow}$

Following Bishop and Bridges on located real intervals, the ConstructiveClosedIntervalLocator$^{\uparrow}$ packet records closed-interval location as finite endpoint, enclosure, membership, and completion-handoff data. It refines the located interval carrier of chapter 394, consumes rational locator cells from chapter 4202, reads dyadic tolerance arithmetic from chapter 291, takes finite observation windows through chapter 301, and seals the endpoint route at chapter 38. The packet is an L10 Real and Completion locator surface; it is not an appeal to order trichotomy, quotient completion, chosen endpoint representatives, or ambient closed-interval compactness.

Definition 8109.1 (Constructive closed interval locator carrier)**.** *A* ConstructiveClosedIntervalLocator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (L, U, A, D, M, S, R, E, H, K, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint admission row, read as a located real endpoint already named in the surrounding interval history.*
2. *U is the upper endpoint admission row, read as the corresponding located real endpoint in the same history.*
3. *A is the endpoint-order admission row, recording the finite evidence that the displayed lower endpoint is admitted before the displayed upper endpoint for this closed-interval read.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *enclosure ledger of dyadic cells and radii used to shrink rational endpoint windows.*
5. *M is the located membership readback row, recording which rational-interval locator query is accepted, rejected outside the displayed enclosure, or deferred to a smaller dyadic cell.*
6. *S is the finite* StreamName$^{\uparrow}$ *observation surface for endpoint and membership windows.*
7. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to those finite windows and dyadic tolerance cells.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row for the closed-interval endpoint pair and the accepted membership read.*
9. *H records componentwise* hsame *transport for endpoint admission, dyadic enclosure, membership readback, finite windows, regular rational readback, and terminal seal.*

10. *K records displayed* Cont *replay from endpoint windows and locator cells to dyadic enclosure, located membership, regular readback, and terminal sealing.*

11. *P is the* Pkg *provenance over* $\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{RationalIntervalLocator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}}$ *row naming exactly this finite closed-interval locator packet.*

The classifier compares packets only through the displayed endpoint admission, dyadic enclosure, membership readback, regular-rational handoff, real seal, transport, replay, provenance, and local naming rows. It has no coordinate for trichotomy on real endpoints, quotient real equality, selected representatives, countable choice, host compactness, or an ambient closed-interval object.

Theorem 8109.2 (Constructive closed interval locator NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}$ *carrier*

$$C = (L, U, A, D, M, S, R, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}}$ *obligation surface consists of five finite rows:*

1. *endpoint admission, requiring the lower and upper endpoint rows L, U and the endpoint-order admission row A to be displayed before any locator read is exported;*

2. *dyadic enclosure, requiring every closed-interval refinement to pass through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D and the finite* $\mathsf{StreamName}^{\uparrow}$ *windows S;*

3. *located membership readback, requiring every accepted membership read to be one of the rational locator reads in M, interpreted through the same D, S, R route;*

4. *Real-seal handoff, requiring any endpoint-pair or membership consumer to reach the terminal* $\mathsf{Real}^{\uparrow}$ *row E only after L, U, A, D, M, S, R have been displayed;*

5. *nonescape from trichotomy, choice, and quotient equality, requiring every consumer to remain inside $L, U, A, D, M, S, R, E, H, K, P, N$ and forbidding real-order trichotomy, quotient completion, host equality of real names, countable choice, selected endpoint representatives, and ambient compactness.*

These rows are exactly the NameCert surface for constructive closed-interval location over the L10 Real and Completion route.

Proof. Project the carrier of Definition 8109.1. Endpoint admission is supplied by the rows L, U, A, so the packet exposes a lower endpoint, an upper endpoint, and their displayed finite ordering admission before any locator read can be consumed.

The enclosure and membership rows are read next. The dyadic ledger D records the finite tolerances and cells, while M records the rational locator answers accepted at those cells. The finite windows S and regular-rational row R are the only route from these cells to endpoint and membership observations.

The handoff to real names is terminal. A consumer reaches E through the displayed continuation route K and the package provenance P, with componentwise transport supplied by H and local naming by N.

Since no coordinate of the carrier stores a trichotomy oracle, quotient completion, selected endpoint representative, countable-choice functional, host equality of real names, or ambient compactness theorem, the five displayed rows exhaust the obligation surface. □

Theorem 8109.3 (Constructive closed interval locator Real-completion handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}$ *packet must read the route*

$$\mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{RationalIntervalLocator}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows $L, U, A, D, M, S, R, E, H, K, P, N$*. The handoff exports a finite closed-interval locator readback, not an ambient real interval, a quotient completion, a trichotomy decision on real endpoints, a countable-choice selector, or a chosen completed endpoint pair.*

Proof. Start with the interval surface. The endpoint rows L, U and the admission row A place the closed-interval read inside the surrounding $\mathsf{LocatedInterval}^{\uparrow}$ history, while the rational locator row M records the finite membership question being answered.

Then read the completion-facing rows in order. The dyadic ledger D and finite windows S determine the inspected tolerance cells, the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies regular rational readback, and only then may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed.

Transport, replay, provenance, and local naming are structural: H, K, P, N preserve and expose the same finite route. Because the route has no additional coordinate, the consumer receives exactly the displayed closed-interval locator handoff and no ambient order, quotient, choice, or compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}$ packet is generated from endpoint admission, dyadic enclosure, located membership readback, StreamName windows, RegSeqRat handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8109.1, Definition 8109.2, and Definition 8109.3 seed the L10 closed-interval locator route over endpoint admission, dyadic enclosure, membership readback, regular-rational handoff, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveClosedIntervalLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim real-order trichotomy, quotient completion, selected endpoint representatives, countable choice, host equality of real names, ambient compactness, public closure, or a standard bridge.

Upgrade path: Formalization can encode BEDC.Derived.ConstructiveClosedIntervalLocatorUp as carrier admission, dyadic enclosure, located membership readback, Real-seal handoff, nonescape, transport, replay, provenance, and local naming obligations.

Chapter 8110

A Concrete Naming Certificate for $\mathsf{CantorBendixsonDerivative}^{\uparrow}$

Following Cantor and Bendixson, the $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ packet records one finite derivative step for a displayed closed real-set row before any rank, located, or decomposition-facing consumer reads it. It sits between the broader $\mathsf{CantorBendixson}^{\uparrow}$ packet of chapter 2024, the located derivative route of chapter 6393, and the finite rank budget of chapter 7197. The carrier also cites the closed-set boundary of chapter 4229, the stream-name windows of chapter 126, the regular rational readback of chapter 301, the dyadic comparison core of chapter 291, and the real-name seal of chapter 38. It names only a finite derivative-step operation on displayed data; it does not claim a transfinite rank, a full scattered-perfect decomposition, a selected enumeration of isolated points, quotient closed-set equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8110.1 (Cantor–Bendixson derivative carrier)**.** *A* $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, A, I, F', W, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the input* $\mathsf{ClosedSet}^{\uparrow}$ *row, recording the closed real-set observations whose derivative is being inspected.*
2. *A is the finite accumulation-test row, listing the displayed neighborhood and non-isolation tests used to decide whether an inspected point remains in the derivative row.*
3. *I is the isolated-rejection row, recording only displayed separating intervals, dyadic radii, and membership failures that remove a point from the next derivative row.*
4. *F' is the output* $\mathsf{ClosedSet}^{\uparrow}$ *row, read as the derivative-step closed set produced from F, A, I.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which the input row, accumulation tests, isolated rejections, and output row are exposed to finite consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same windows and stage-local derivative observations.*
7. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger for the radii, interval separations, containment checks, and neighborhood comparisons used by F, A, I, F', W, R.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal boundary for the displayed real-name reads.*
9. *H records componentwise* hsame *transport for F, A, I, F', W, R, Q, E and for the replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of every derivative-step request through*

$$F, A, I \longmapsto F' \longmapsto W, R, Q, E.$$

11. *P is the* Pkg *provenance over* $\mathsf{CantorBendixsonDerivative}^{\uparrow}$, $\mathsf{CantorBendixson}^{\uparrow}$, $\mathsf{LocatedCantorBendixson}^{\uparrow}$, $\mathsf{CantorBendixsonRank}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CantorBendixsonDerivative}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for transfinite derivative chains, selected isolated-point enumerations, quotient closed-set equality, countable choice, host closed-set equality, or ambient completeness outside the displayed real-name route.

Theorem 8110.2 (Cantor–Bendixson derivative NameCert obligations)**.** *For every accepted* CantorBendixsonDeriva *carrier*

$$D = (F, A, I, F', W, R, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CantorBendixsonDerivative}^{\uparrow}}$ *surface is exhausted by the following finite obligation rows:*

1. *carrier admission for the displayed input closed set, accumulation tests, isolated-rejection row, output closed set, StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, Real seal, transport, replay, provenance, and local naming rows;*
2. *derivative-step classifier stability, requiring componentwise* hsame *transport to preserve the same input row, tested neighborhoods, rejected isolated rows, and output row;*
3. *isolated-rejection exactness, requiring each removed point to carry a displayed separating interval, dyadic radius, and membership check inside I and Q;*
4. *output closed-set handoff, requiring F' to be downstream of F, A, I before any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer reads it;*
5. *structural nonescape, requiring W, R, Q, E, H, C, P, N to export no transfinite rank, full decomposition, hidden selector, quotient equality, countable-choice schedule, or ambient closed-set theorem.*

No derivative-step obligation is stored outside these rows.

Proof. Project the carrier of Definition 8110.1. The packet displays exactly the input closed-set row, accumulation tests, isolated-rejection row, output closed-set row, observation windows, rational readback, dyadic comparison ledger, Real seal, and structural rows.

The derivative work is a single finite step. Row A records the inspected neighborhoods, while I records the displayed isolating data that prevents a rejected point from remaining in F'.

The output row is therefore read only after the input and rejection rows have been displayed. The windows W, readback R, dyadic ledger Q, and Real seal E expose that same step to finite consumers without adding a further derivative stage.

Finally H, C, P, N transport, replay, source, and name those rows. Since the carrier has no coordinate for transfinite chains, selected enumerations, quotient closed-set equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8110.3 (Cantor–Bendixson derivative closed-set handoff)**.** *Every accepted* $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ *consumer that asks for the derivative-step closed set must first display the route*

$$F, A, I \longmapsto F' \longmapsto W, R, Q, E \longmapsto H, C, P, N.$$

Thus the exported closed-set row F' is a finite BEDC handoff over the $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *surfaces. The consumer receives no host transfinite derivative chain, no selected list of isolated points, no quotient closed-set equality, no countable-choice schedule, and no ambient compactness or completeness theorem.*

Proof. Begin with the input and test rows. The closed-set row F and accumulation-test row A are the only data from which a derivative-step read may decide whether an inspected point remains.

Next read the isolated-rejection row. Each rejection in I is accompanied by the displayed interval, radius, and membership data recorded through the dyadic comparison ledger Q.

The output closed-set row F' is downstream of those rows. The StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, and Real seal expose F' only through the same finite route.

The transport, replay, provenance, and local naming rows preserve that route and add no mathematical coordinate for the excluded host-level data. Hence the closed-set handoff factors through the displayed derivative-step packet. □

Falsifiable prediction: Every accepted $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ consumer that reads the output closed-set row while omitting the input closed set, accumulation tests, isolated-rejection data, stream windows, rational readback, dyadic comparisons, Real seal, transport, replay, provenance, or local name has left the packet.

Independence witness: cantorbendixson, locatedcantorbendixson, cantorbendixsonrank, closedset, streamname, regseqrat, dyadicratcore, real: $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ is not bijective with any listed sibling because it isolates one derivative-step operator with input and output closed-set rows, accumulation tests, isolated rejections, finite windows, arithmetic readback, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CantorBendixsonDerivative}^{\uparrow}}$.

Constructive story: A $\mathsf{CantorBendixsonDerivative}^{\uparrow}$ packet is generated from an input ClosedSetUp row, finite accumulation tests, isolated-rejection data, an output ClosedSetUp row, StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CantorBendixsonDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8110.1, Definition 8110.2, and Definition 8110.3 seed the finite one-step derivative operator for closed real-set packets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CantorBendixsonDerivative}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the full Cantor–Bendixson decomposition, host ordinal rank, selected isolated-point enumeration, quotient closed-set equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-step classifier stability, isolated-rejection exactness, output closed-set handoff, structural nonescape, and route replay for BEDC.Derived.CantorBendixsonDerivativeUp.

Chapter 8111

A Concrete Naming Certificate for MetaCICResidualDiamondFrontier$^{\uparrow}$

The MetaCICResidualDiamondFrontier$^{\uparrow}$ packet realizes the residual-diamond frontier of chapter 9378 as finite confluence-facing NameCert data. It sits beside the parallel-diamond frontier of chapter 4238, the residual-substitution boundary of chapter 2181, the confluence critical-pair boundary of chapter 2212, and the closed-normal confluence seal of chapter 741. The packet records candidate residual diamonds as bounded finite evidence while keeping BetaParallelSubstitutionCompatibility, BetaParallelDiamondClosed, arbitrary closed-term Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency outside the carrier.

Falsifiable prediction: Every accepted MetaCICResidualDiamondFrontier$^{\uparrow}$ read exposes the residual-substitution premise and obstruction rows before any residual-diamond handoff is consumed.

Independence witness: metacic-parallel-diamond-frontier, metacic-residual-substitution-boundary, metacic-confluence-critical-pair-boundary, closednormalconfluenceseal: the parallel-diamond frontier records a conditional parallel handoff without this packet's residual-diamond candidate grid; the residual-substitution boundary names the missing compatibility premise without candidate residual joins; the critical-pair boundary records local peak rows without the residual-diamond handoff; and the closed-normal confluence seal supplies normal-source joins without residual substitution. None is bijective to MetaCICResidualDiamondFrontier$^{\uparrow}$.

Definition 8111.1 (MetaCIC residual-diamond frontier carrier)**.** *A* MetaCICResidualDiamondFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, R, J, B, O, X, H, C, P, N)$$

with the following displayed rows:

1. *K is the finite critical-pair row, recording the inspected peak, branch labels, and local source window.*
2. *R is the residual-substitution premise row retained from the residual-substitution boundary.*
3. *J is the candidate-join row, recording the proposed residual-diamond common target and branch-local join routes.*
4. *B is the bounded-checker row, recording the finite checker budget for residual descendants, closedness, support, and branch compatibility.*

5. *O is the obstruction row naming every endpoint not discharged by the packet: residual-substitution compatibility, premise-free parallel diamond, arbitrary closed-term Church–Rosser, subject reduction, evaluator equality, quotient term equality, and kernel consistency.*
6. *X is the residual-diamond handoff row exposed only after K, R, J, B, O have all been displayed.*
7. *H records componentwise* hsame *transport for critical-pair, residual-substitution, candidate-join, bounded-checker, obstruction, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a confluence query through K, R, J, B, O and then to X.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, $\mathsf{MetaCICConfluenceCriticalPairBoundary}^{\uparrow}$, $\mathsf{ClosedNormalConfluenceSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, R, J, B, O, X, H, C, P, N$. It has no coordinate for a discharged substitution-compatibility theorem, a premise-free parallel diamond, an arbitrary closed Church–Rosser theorem, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 8111.2 (MetaCIC residual-diamond frontier obligations)**.** *For every accepted* MetaCICResidualDiamondF *carrier $F = (K, R, J, B, O, X, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}}$ *surface consists exactly of finite critical-pair exposure through K, residual-substitution premise retention through R, candidate-join exposure through J, bounded-checker accounting through B, obstruction retention through O, residual-diamond handoff non-escape through X, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

The Lean-side TasteGate surface must provide `Nontrivial` $\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}$ *and* `FieldFaithful` $\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}$ *instances in* `TasteGate.lean`*: the first separates genuine frontier packets from the empty carrier, and the second asserts that the classifier reads every displayed field $K, R, J, B, O, X, H, C, P, N$.*

Proof. Project the carrier of Definition 8111.1. The projection exposes exactly the critical-pair, residual-substitution, candidate-join, bounded-checker, obstruction, handoff, transport, replay, provenance, and local naming rows.

Read the confluence rows in order. The critical-pair row K fixes the inspected peak, the residual-substitution row R remains visible as a retained premise, the candidate-join row J records the proposed residual diamond, and the bounded checker B accounts for the finite branch checks.

The obstruction row O is retained before X can be consumed. Thus the residual-diamond handoff is a bounded frontier row, not a discharge of residual substitution, a premise-free parallel diamond, or a closed Church–Rosser endpoint.

Finally H, C, P, N transport, replay, source, and locally name the same finite route. The stated TasteGate obligations are precisely the classifier-readiness conditions for nonempty, field-faithful packet data. □

Theorem 8111.3 (MetaCIC residual-diamond frontier confluence handoff)**.** *Every confluence consumer of an accepted* $\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}$ *packet must display the route*

$$K \longmapsto R \longmapsto J \longmapsto B \longmapsto O \longmapsto X \longmapsto H, C, P, N$$

before consuming the residual-diamond handoff. The handoff may feed the conditional confluence boundary of chapter 9378, but it does not prove BetaParallelSubstitutionCompatibility*, does not*

prove BetaParallelDiamondClosed*, and does not prove arbitrary closed-term Church–Rosser for* BetaStarStep*.*

Proof. Let $F = (K, R, J, B, O, X, H, C, P, N)$ be accepted. By Definition 8111.1, the handoff row X is downstream of critical-pair exposure, residual-substitution premise retention, candidate-join exposure, bounded checking, and obstruction retention.

Apply the obligation surface of Definition 8111.2. It forces every residual-diamond read to keep K, R, J, B, O visible before the handoff row is available.

The structural rows preserve the same route. Componentwise transport through H, replay through C, provenance through P, and local naming through N do not add any of the omitted confluence endpoints. Therefore the handoff remains a finite residual-diamond frontier certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondFrontier}\uparrow}$.

Constructive story: A $\mathsf{MetaCICResidualDiamondFrontier}^{\uparrow}$ packet is generated from critical-pair rows, residual-substitution premise retention, candidate-join rows, bounded-checker rows, obstruction retention, a residual-diamond handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondFrontier}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8111.1, Definition 8111.2, and Definition 8111.3 seed the residual-diamond frontier over critical-pair, residual-substitution, candidate-join, bounded-checker, obstruction, handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualDiamondFrontier}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim residual-substitution compatibility, premise-free parallel diamond, arbitrary closed-term Church–Rosser, subject reduction, evaluator equality, quotient term equality, kernel consistency, public closure, or a standard bridge.

Upgrade path: Formalization can encode BEDC.Derived.MetaCICResidualDiamondFrontierUp as carrier admission, residual-diamond obligation rows, confluence handoff non-escape, Nontrivial TasteGate evidence, FieldFaithful TasteGate evidence, transport, replay, provenance, and local naming.

Chapter 8112

A Concrete Naming Certificate for $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$ packet records the finite criterion by which two displayed regular rational names are accepted as the same real-name seal. It sits after the regular rational readback of chapter 301, the finite observation surface of chapter 126, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the comparison-window route of chapter 411. The packet is a criterion surface: it names the displayed comparison windows that force the same $\mathsf{Real}^{\uparrow}$ seal, without quotienting streams, choosing representatives, invoking trichotomy, using countable choice, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8112.1 (Regular Cauchy equivalence criterion carrier)**.** *A* $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, R, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational names being compared.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule on which the comparison is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the displayed windows.*
4. *Q is the* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *comparison row witnessing that every displayed tolerance window closes along the same route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after L, R, W, D, Q have been displayed.*
6. *H records componentwise* hsame *transport for the two names, window schedule, dyadic ledger, comparison row, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the same finite comparison route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through the displayed rows $L, R, W, D, Q, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8112.2 (Regular Cauchy equivalence criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$ *carrier* $K = (L, R, W, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ *comparison row, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. The obligation surface may use the criterion only after the comparison windows and dyadic ledger have been displayed.*

Proof. Project the carrier of Definition 8112.1. The two candidate real names enter only as $\mathsf{RegSeqRat}^{\uparrow}$ rows L, R, and every consumer-visible comparison request must first pass through the finite window schedule W.

Read the tolerance and comparison rows. The dyadic ledger D supplies the displayed budgets, while the $\mathsf{RegularCauchyComparisonPrinciple}^{\uparrow}$ row Q records that the inspected windows close under those budgets before the terminal seal is consumed.

Finally replay and transport the same route through H, C, P, N. These rows preserve the displayed comparison surface and add no quotient-stream equality, representative selector, trichotomy branch, countable-choice schedule, host real equality test, or ambient completeness coordinate. □

Theorem 8112.3 (Regular Cauchy equivalence criterion Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$ *packet reaches seal equality only through the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow} \times \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyComparisonPrinciple}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

Thus the criterion can certify that the two regular Cauchy names present the same real seal inside the finite comparison surface, but it does not export quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the NameCert obligations of Definition 8112.2. They force the consumer to keep both regular rational rows, the shared finite window, the dyadic tolerance ledger, and the comparison row visible before the Real seal is read.

The terminal seal E is therefore downstream of a displayed comparison route. Any accepted seal read is replayed by C, transported by H, sourced by P, and locally named by N along the same finite packet.

The excluded objects cannot be projected from the carrier. Since K stores no quotient stream equality, representative selector, trichotomy branch, countable-choice schedule, host real equality test, or ambient completeness row, the real-seal conclusion remains a finite criterion rather than a quotient or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}$ packet is generated from two RegSeqRat names, a shared StreamName finite-window schedule, a DyadicRatCore tolerance ledger, a RegularCauchyComparisonPrinciple row, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 8112.1, Definition 8112.2, and Definition 8112.3 seed the finite equivalence criterion linking RegSeqRat comparison windows to RealUp seal equality.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyEquivalenceCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, trichotomy, countable choice, host real equality, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-window exactness, dyadic tolerance stability, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyEquivalenceCriterionUp.

Chapter 8113

A Concrete Naming Certificate for DescriptionComplexity$^{\uparrow}$

The DescriptionComplexity$^{\uparrow}$ packet realizes the explanation-complexity information surface of section 9462.10 as finite source-description, score-vector, public-weight, debt, classifier-novelty, minimal-witness, replay, provenance, and NameCert rows. It sits beside the existing ExplanationComplexityInformation$^{\uparrow}$ packet of chapter 6181, the KolmogorovComplexity$^{\uparrow}$ compression boundary of chapter 5989, the Hash$^{\uparrow}$ certificate of chapter 242, the finite prefix stream certificate of chapter 7253, and the classifier-novelty witness of chapter 6138. The packet measures displayed descriptions inside a public protocol; it does not identify minimal text with Kolmogorov optimality, recover hidden source equality from hashes, infer classifier novelty from score motion alone, or certify positive discovery without a later TasteGate.

Definition 8113.1 (Description complexity carrier)**.** *A* DescriptionComplexity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (S, V, W, B, R, J, M, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-description row naming the finite explanation text, feature list, circuit record, classifier specification, ledger summary, and verification surface.*
2. *V is the score-vector row refining the explanation-complexity coordinates of Definition 9462.233.*
3. *W is the public weight row used by the scalar score of Definition 9462.234.*
4. *B is the benefit and debt row recording coverage, prediction, transfer, intervention, verification, unification, and the debt components of Definition 9462.238.*
5. *R is the replay row tying the description to finite prefix evidence through* FinitePrefixStream$^{\uparrow}$ *and to visible digest discipline through* Hash$^{\uparrow}$*.*
6. *J is the* ClassifierNoveltyWitness$^{\uparrow}$ *row, present only when the description claims classifier novelty rather than a score-only improvement.*
7. *M is the minimal-witness row: it records a displayed lower-bound boundary for the accepted description under W, not an absolute Kolmogorov minimum.*
8. *F is the comparison row to* KolmogorovComplexity$^{\uparrow}$ *and* ExplanationComplexityInformation$^{\uparrow}$*, separating source-description cost from compression optimality and net explanation information.*

9. *H records componentwise* hsame *transport for S, V, W, B, R, J, M, F.*
10. *C records displayed* Cont *replay through source description, score-vector accounting, public weights, debt, classifier novelty, minimal-witness boundary, sibling comparison, provenance, and local naming.*
11. *P is the* Pkg *provenance over* $\mathsf{DescriptionComplexity}^{\uparrow}$, $\mathsf{ExplanationComplexityInformation}^{\uparrow}$, $\mathsf{KolmogorovComplexity}$ $\mathsf{Hash}^{\uparrow}$, $\mathsf{FinitePrefixStream}^{\uparrow}$, $\mathsf{ClassifierNoveltyWitness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DescriptionComplexity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, V, W, B, R, J, M, F, H, C, P, N$. It has no coordinate for hidden semantic truth, host compression optimality, hash preimage recovery, undisplayed weights, classifier novelty without J, positive discovery without a separate gate, or a minimal witness detached from the displayed public protocol.

Theorem 8113.2 (Description complexity NameCert obligations)**.** *For every accepted* $\mathsf{DescriptionComplexity}^{\uparrow}$ *carrier $D = (S, V, W, B, R, J, M, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DescriptionComplexity}^{\uparrow}}$ *surface consists exactly of carrier admission for source description, score-vector coordinates, public weights, benefit and debt accounting, finite replay and digest discipline, classifier-novelty witnessing when claimed, minimal-witness boundary, comparison to explanation-complexity and Kolmogorov-complexity siblings, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8113.1. The description itself is S, while V and W expose the coordinate vector and public weights before any scalar score can be read.

Read benefit and debt through B. This keeps the score from being interpreted as an explanation-quality verdict by itself, because debt and benefit remain visible in the same packet.

The rows R, J, M, F supply the boundary data. The replay row R ties the source description to finite prefix and hash-visible evidence; J records classifier novelty only when present; M states a protocol-relative minimal-witness boundary; and F separates description cost from Kolmogorov optimality and net explanation information.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for the excluded objects, the listed rows exhaust the local NameCert surface. □

Theorem 8113.3 (Description complexity minimal-witness boundary)**.** *An accepted* $\mathsf{DescriptionComplexity}^{\uparrow}$ *packet may use its minimal-witness row M only relative to the displayed source-description row S, score vector V, public weights W, benefit and debt row B, replay row R, classifier-novelty row J when present, and sibling-comparison row F. It does not certify an absolute Kolmogorov minimum, a hidden source recovered from a hash, a classifier shift without J, or a positive discovery verdict without a later TasteGate.*

Proof. Apply the NameCert obligations of Definition 8113.2. They force M to be read together with the public protocol rows S, V, W, B and with the replay and sibling-comparison rows R, F.

The Kolmogorov comparison is therefore only a boundary comparison. The packet may record that a description is minimal among displayed candidates under the public protocol, but it cannot project absolute compression optimality or hidden source equality.

Classifier novelty is likewise explicit. If the row J is absent, the packet has no classifier-shift witness; if J is present, it is still only a row of this description-complexity packet and not a positive-discovery gate.

Thus the minimal witness remains protocol-relative and finite. A later Lean file `TasteGate.lean` must provide Nontrivial $\mathsf{DescriptionComplexity}^{\uparrow}$ and FieldFaithful $\mathsf{DescriptionComplexity}^{\uparrow}$ instances

before any checked TasteGate theorem can certify that these rows are distinct and nondegenerate. □

Falsifiable prediction: Every accepted $\mathsf{DescriptionComplexity}^{\uparrow}$ minimal-witness read exposes the source description, score vector, public weights, benefit and debt accounting, finite-prefix replay, hash-visible provenance, classifier novelty when claimed, sibling comparison, transport, replay, provenance, and local NameCert naming.

Independence witness: explanation-complexity-information, kolmogorov-complexity, hash, name-cert, finite-prefix-stream-certificate: none is bijective to $\mathsf{DescriptionComplexity}^{\uparrow}$ because this packet jointly carries source-description rows, score-vector rows, public weights, debt and benefit accounting, classifier-novelty witnessing, protocol-relative minimal-witness boundaries, finite replay, digest-visible provenance, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DescriptionComplexity}^{\uparrow}}$.

Constructive story: A $\mathsf{DescriptionComplexity}^{\uparrow}$ packet is generated from source-description rows, score-vector rows, public weights, benefit and debt accounting, finite replay, hash-visible provenance, classifier-novelty witnessing, protocol-relative minimal-witness boundaries, sibling comparison, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DescriptionComplexity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8113.1, Definition 8113.2, Definition 8113.3, the falsifiable prediction, and the independence witness seed the finite description-complexity packet for explanation-complexity information.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DescriptionComplexity}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close absolute Kolmogorov optimality, hidden semantic truth, hash preimage recovery, classifier novelty without the displayed witness row, positive discovery, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-description exposure, score-vector and public-weight accounting, debt and benefit exposure, classifier-novelty row separation, minimal-witness boundary exactness, replay, provenance, local naming, and Nontrivial and FieldFaithful instances for BEDC.Derived.DescriptionComplexityUp.

Chapter 8114

A Concrete Naming Certificate for $\mathsf{MarkovBlanket}^{\uparrow}$

Following Pearl, *Causality*, 2009, the $\mathsf{MarkovBlanket}^{\uparrow}$ packet records the finite causal-inference boundary around one displayed variable in a Bayesian network. It sits after the do-calculus surface of chapter 453, the intervention rows of chapter 1290, the normalized probability source of chapter 184, the random-variable carrier of chapter 185, and the conditional-independence rows of chapter 187. The packet names the parent, child, spouse, separating-set, d-separation, transport, replay, provenance, and local NameCert rows as BEDC data; it does not assert a host Bayesian-network semantics, global graph faithfulness, positivity, probabilistic completeness, or a selected causal model.

Definition 8114.1 (Markov blanket carrier)**.** *A* $\mathsf{MarkovBlanket}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (V, G, P, C, S, B, D, I, H, R, Q, N)$$

with the following displayed rows:

1. *V is the focused* $\mathsf{RandomVar}^{\uparrow}$ *row whose local boundary is being named.*
2. *G is the finite directed-neighborhood row, exposing only the displayed parent, child, and co-parent incidences used by the certificate.*
3. *P is the parent row of V, read through the same probability source as* $\mathsf{ProbSpace}^{\uparrow}$*.*
4. *C is the child row of V, recording the visible outgoing incidences.*
5. *S is the spouse row, containing the displayed co-parents of children in C.*
6. *B is the blanket row P, C, S packaged as one finite boundary before any query consumer reads it.*
7. *D is the d-separation boundary row, recording that variables outside B are screened from V only through the displayed conditional-independence surface.*
8. *I is the* $\mathsf{Independence}^{\uparrow}$ *row used by the query consumer, with conditioning restricted to the displayed blanket row.*
9. *H records componentwise* hsame *transport for V, G, P, C, S, B, D, I and the local naming row.*
10. *R records displayed* Cont *replay from a causal or probabilistic query through the finite blanket rows.*

11. *Q is the* Pkg *provenance over* $\mathsf{MarkovBlanket}^{\uparrow}$, $\mathsf{DoCalculus}^{\uparrow}$, $\mathsf{CausalIntervention}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MarkovBlanket}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $V, G, P, C, S, B, D, I, H, R, Q, N$. It has no coordinate for a full Bayesian network, graph-faithfulness theorem, global factorization, positivity assumption, selected interventional model, host conditional-probability equality, or completed probability semantics.

Theorem 8114.2 (Markov blanket NameCert obligations)**.** *For every accepted* $\mathsf{MarkovBlanket}^{\uparrow}$ *carrier $M = (V, G, P, C, S, B, D, I, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{MarkovBlanket}^{\uparrow}}$ *surface consists exactly of focused-variable admission, directed-neighborhood exposure, parent row exposure, child row exposure, spouse row exposure, blanket packaging, d-separation boundary admission, conditional-independence query admission, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8114.1. The focused variable and finite neighborhood are displayed as V, G, while the three boundary components are displayed as P, C, S and repackaged by B.

The causal and probabilistic dependencies are then read through the sibling rows named in the carrier. The probability source, random-variable row, causal-intervention surface, do-calculus surface, and independence row are all cited by Q before a query can consume the boundary.

Finally H, R, Q, N transport, replay, source, and name only the same finite rows. Since no carrier coordinate stores a full Bayesian network semantics, graph-faithfulness theorem, global factorization, positivity assumption, selected interventional model, host conditional-probability equality, or completed probability semantics, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8114.3 (Markov blanket d-separation boundary)**.** *Every accepted d-separation read exported by a* $\mathsf{MarkovBlanket}^{\uparrow}$ *packet factors through the finite route*

$$V, G \longmapsto P, C, S \longmapsto B \longmapsto D \longmapsto I \longmapsto H, R, Q, N.$$

The read can condition on the displayed blanket row B and can cite $\mathsf{Independence}^{\uparrow}$ *through I, but it cannot replace the route by a global Bayesian-network factorization, faithfulness assumption, positivity condition, or host conditional-probability equality.*

Proof. Start with the focused random variable V and the directed-neighborhood row G. The parent, child, and spouse rows P, C, S are the only displayed contributors to the blanket row B.

The d-separation row D is read after B has been exposed. It does not store a global graph theorem; it records only the finite screening boundary consumed by the conditional-independence row I.

The structural rows H, R, Q, N then preserve, replay, source, and name this route. Because the carrier has no coordinate for global factorization, faithfulness, positivity, or host conditional-probability equality, the d-separation read remains a finite boundary route. □

Theorem 8114.4 (Markov blanket nonescape)**.** *No accepted* $\mathsf{MarkovBlanket}^{\uparrow}$ *consumer can export a selected causal model, completed probability semantics, full Bayesian-network object, global graph-faithfulness theorem, positivity assumption, quotient equality of random variables, or host conditional-probability equality from the blanket packet. Every exported read is confined to the displayed rows $V, G, P, C, S, B, D, I, H, R, Q, N$.*

Proof. Inspect the carrier coordinates in Definition 8114.1. They display one focused variable, one finite directed-neighborhood row, three blanket components, one packaged blanket row, one d-separation boundary, one conditional-independence query row, and the structural transport, replay, provenance, and naming rows.

The dependency chapters named in the introduction supply only sibling surfaces: do-calculus rows, intervention rows, probability rows, random-variable rows, and independence rows. None of those rows is copied into this packet as a selected global model or as completed probability semantics.

Thus every accepted read is routed through $V, G, P, C, S, B, D, I, H, R, Q, N$. Since the refused objects have no displayed coordinate, no continuation, package, or local certificate row can export them. □

Falsifiable prediction: A consumer that obtains a full Bayesian-network factorization or host conditional-probability equality from B alone refutes the $\mathsf{MarkovBlanket}^{\uparrow}$ carrier.

Independence witness: do-calculus, causal-intervention, probspace, randomvar, independence: none is bijective with $\mathsf{MarkovBlanket}^{\uparrow}$ because the packet jointly carries a focused variable, finite neighborhood, parent, child, spouse, blanket, d-separation, conditional-independence, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MarkovBlanket}^{\uparrow}}$.

Constructive story: A $\mathsf{MarkovBlanket}^{\uparrow}$ packet is generated from one focused RandomVar row, finite directed-neighborhood data, parent rows, child rows, spouse rows, a packaged blanket boundary, a d-separation boundary, an Independence query row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarkovBlanket}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8114.1, Definition 8114.2, Definition 8114.3, and Definition 8114.4 seed the finite causal-inference blanket packet over focused-variable, neighborhood, boundary, d-separation, independence, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarkovBlanket}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a full Bayesian-network semantics, global graph faithfulness, positivity, probabilistic completeness, selected causal model, quotient equality of random variables, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite blanket component exposure, d-separation boundary routing, conditional-independence query admission, transport, replay, provenance, local naming, and nonescape for BEDC.Derived.MarkovBlanketUp.

Chapter 8115

A Concrete Naming Certificate for $\mathsf{BinarySignedDigit}^{\uparrow}$

Following Bishop and Bridges on signed-digit real representations, the $\mathsf{BinarySignedDigit}^{\uparrow}$ packet records the finite binary signed-digit substrate used before a signed-digit real name is read as a regular rational or sealed as a $\mathsf{Real}^{\uparrow}$ object. It sits below the signed-digit real expansion of chapter 6684, the dyadic signed-digit stream of chapter 6915, the dyadic arithmetic core of chapter 291, the finite window interface of chapter 126, the regular rational handoff of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite digit rows and dyadic readback data; it is not a quotient of infinite streams, a selected expansion, trichotomy, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8115.1 (BinarySignedDigit carrier)**.** *A* $\mathsf{BinarySignedDigit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, W, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the binary signed-digit row, listing only finite words over the digit alphabet $\{-1, 0, 1\}$ and the dyadic place attached to each displayed digit.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that schedules the visible signed-digit prefixes.*
3. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *signed dyadic readback ledger, recording the finite partial sum, carry normalization, endpoint value, and tolerance radius for each displayed prefix.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reading the signed dyadic ledger as regular rational data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the digit, window, dyadic, and regular-readback rows have been displayed.*
6. *H records componentwise* hsame *transport for digit rows, windows, signed dyadic readback, regular readback, Real sealing, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a digit-window request through dyadic readback, regular rational handoff, and Real sealing.*
8. *P is the* Pkg *provenance over* $\mathsf{BinarySignedDigit}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SignedDigitRealExpansion}^{\uparrow}$, $\mathsf{DyadicSignedDigitStream}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BinarySignedDigit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, W, Q, R, E, H, C, P, N$. It contains no coordinate for quotient stream equality, selected infinite expansions, host real equality, trichotomy, countable choice, or ambient completeness.

Theorem 8115.2 (BinarySignedDigit NameCert obligations)**.** *For every accepted* $\mathsf{BinarySignedDigit}^{\uparrow}$ *carrier*

$$B = (D, W, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BinarySignedDigit}^{\uparrow}}$ *surface consists exactly of digit-row admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *signed dyadic readback,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8115.1. Its analytic rows are precisely the finite digit row D, the stream-window row W, the signed dyadic readback ledger Q, the regular rational handoff R, and the Real seal E.

The digit and window obligations are the route through D and W. A consumer can inspect only the displayed finite signed-digit prefixes, with each digit attached to its dyadic place.

The arithmetic and readback obligations are the route through Q and R. The dyadic ledger records partial sums, carry normalization, endpoint values, and tolerance radii before the regular rational handoff is available.

The rows H, C, P, N transport, replay, source, and name exactly the same finite route. Since no other coordinate is present, the refused endpoints cannot be projected from an accepted packet. □

Theorem 8115.3 (BinarySignedDigit window induction)**.** *Let*

$$B = (D, W, Q, R, E, H, C, P, N)$$

be an accepted $\mathsf{BinarySignedDigit}^{\uparrow}$ *carrier. Every accepted extension of a displayed binary signed-digit prefix by one digit remains in the same carrier route only after the enlarged prefix is recorded in D, the enlarged window is recorded in W, and the corresponding signed dyadic readback is recorded in Q. Thus prefix growth is a finite window induction through displayed rows, not a selected infinite expansion or quotient stream equality.*

Proof. Proceed by induction on the finite displayed prefix window. The base window reads the empty prefix through D and W, and its signed dyadic readback is the base row in Q.

For the successor step, append one admitted digit to the visible prefix. The digit row D records the digit and dyadic place, while W records the enlarged inspection window.

The dyadic readback ledger Q then normalizes the enlarged partial sum and records its endpoint and radius. Transport through H and replay through C keep the route inside the same finite carrier.

Finally R, E, P, N read the resulting regular rational handoff, Real seal, provenance, and local name. No step introduces an infinite representative, quotient equality, choice schedule, trichotomy branch, host real equality, or completeness theorem. □

Theorem 8115.4 (BinarySignedDigit dyadic readback)**.** *Every* $\mathsf{SignedDigitRealExpansion}^{\uparrow}$, $\mathsf{DyadicSignedDigitStrea}$ $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BinarySignedDigit}^{\uparrow}$ *packet reads the finite route*

$$D, W \longmapsto Q \longmapsto R \longmapsto E, H, C, P, N.$$

The row Q is the unique local passage from binary signed-digit windows to signed dyadic endpoint and tolerance data, so downstream signed-digit and completion-facing consumers receive a finite dyadic readback packet rather than a host real, quotient stream class, selected expansion, or ambient completeness principle.

Proof. Start from the obligation surface of Definition 8115.2. It requires the digit row and StreamName window before any signed dyadic readback can be consumed.

Use the window induction theorem Definition 8115.3. Each finite prefix extension reaches Q only through the displayed digit and window rows, so Q is attached to a visible finite prefix.

The regular rational row R and the Real seal row E are downstream of Q. The signed-digit real expansion and dyadic signed-digit stream chapters can therefore consume the packet only as the same finite dyadic readback route.

The structural rows H, C, P, N preserve this route under transport, replay, provenance, and naming. Since the carrier has no coordinate for the excluded endpoints, no downstream consumer can recover them from the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BinarySignedDigit}\uparrow}$.

Constructive story: A $\mathsf{BinarySignedDigit}^{\uparrow}$ packet is generated from finite binary signed-digit rows, StreamName windows, a DyadicRatCore signed dyadic readback ledger, RegSeqRat handoff rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BinarySignedDigit}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8115.1, Definition 8115.2, Definition 8115.3, and Definition 8115.4 seed the finite binary signed-digit substrate route from digit windows to signed dyadic, regular rational, and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BinarySignedDigit}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected infinite expansions, trichotomy, countable choice, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, digit-row induction, signed dyadic readback exactness, RegSeqRat handoff, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BinarySignedDigitUp.

Chapter 8116

A Concrete Naming Certificate for $\mathsf{RationalBallFilter}^{\uparrow}$

Following Bishop and Bridges on neighborhood filters and constructive real approximation, the $\mathsf{RationalBallFilter}^{\uparrow}$ packet records a finite rational-ball request route for Real and Completion consumers. It sits after the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric-completion boundary of chapter 1506. The packet names rational-neighborhood evidence through displayed finite rows only; it does not quotient real names, select representatives, invoke trichotomy, use countable choice, assert open-cover compactness, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8116.1 (RationalBallFilter carrier)**.** *A* $\mathsf{RationalBallFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational center request row, recording the requested center and comparison budget as finite rational data.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *dyadic radius and tolerance ledger attached to the same request.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the request.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that reads the stream window as regular rational approximation data.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the rational center, dyadic ledger, stream window, and regular readback rows have been displayed.*
6. *H records componentwise* hsame *transport for the rational request, dyadic ledger, stream window, readback, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a rational-ball request through Q, D, W, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RationalBallFilter}^{\uparrow}$*, rational center data,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalBallFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $Q, D, W, R, E, H, C, P, N$. It has no coordinate for quotient real equality, selected representatives, trichotomy, countable-choice schedules, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8116.2 (RationalBallFilter NameCert obligations)**.** *For every accepted* $\mathsf{RationalBallFilter}^{\uparrow}$ *carrier $F = (Q, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalBallFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, rational center request exposure, ball-window coverage, dyadic refinement stability, regular rational readback, Real-seal nonescape, ledger exhaustion, componentwise transport, displayed replay, provenance, and local naming for the rows $Q, D, W, R, E, H, C, P, N$.*

Proof. Project the carrier of Definition 8116.1. The only available rows are $Q, D, W, R, E, H, C, P, N$, so carrier admission exposes the rational request, dyadic ledger, stream window, regular readback, terminal seal, transport, replay, provenance, and local naming data.

The ball-window coverage clause is read through Q, W, R. The rational center request opens only the stored finite StreamName windows, and the RegSeqRat row reads those windows as regular rational approximation data.

Dyadic refinement stability and ledger exhaustion are read through D. Refining a radius or tolerance budget changes only the displayed DyadicRatCore ledger row, and every accepted request must spend the ledger before the terminal seal can be inspected.

Finally E, H, C, P, N preserve the same route. The Real-seal row is downstream of Q, D, W, R, while transport, replay, provenance, and local naming keep the packet inside the displayed finite data. The excluded quotient, selection, trichotomy, choice, compactness, and ambient-completeness objects are absent from the carrier, so the listed clauses exhaust the local NameCert surface. □

Theorem 8116.3 (RationalBallFilter finite-window handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RationalBallFilter}^{\uparrow}$ *carrier must read the rational ball request through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

before terminal Real evidence is consumed. The handoff uses the displayed rows $Q, D, W, R, E, H, C, P, N$ of the same packet and cannot import quotient real equality, selected representatives, trichotomy, countable choice, open-cover compactness, or ambient completeness.

Proof. Start with an accepted $\mathsf{Real}^{\uparrow}$ or completion-facing consumer of F. The carrier admits a rational center request Q only together with the dyadic radius and tolerance ledger D.

The consumer then opens the finite window W and reads it through R. These rows are the only route from the rational-ball request to regular rational approximation data.

Only after Q, D, W, R have been displayed can the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed. Thus a completion-facing consumer receives rational-neighborhood evidence through finite dyadic, stream, and regular-readback rows before any terminal Real evidence is available.

Transport, replay, provenance, and local naming are confined to H, C, P, N. Since the carrier contains no quotient equality, representative selector, trichotomy branch, choice schedule, open-cover compactness row, or ambient-completeness row, the handoff remains a finite rational-ball route. □

Falsifiable prediction: An accepted $\mathsf{RationalBallFilter}^{\uparrow}$ read is refuted if a $\mathsf{Real}^{\uparrow}$ or completion-facing consumer reaches the terminal seal without displaying the rational center request, DyadicRatCore tolerance ledger, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBallFilter}^{\uparrow}}$.

Constructive story: A RationalBallFilter$^{\uparrow}$ packet is generated from a rational center request, a DyadicRatCore radius and tolerance ledger, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RationalBallFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8116.1, Definition 8116.2, and Definition 8116.3 seed the finite rational-ball route over rational request, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{RationalBallFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected representatives, trichotomy, countable choice, open-cover compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ball-window coverage, dyadic refinement stability, Real-seal nonescape, ledger exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.RationalBallFilterUp.

Chapter 8117

A Concrete Naming Certificate for $\mathsf{RationalBallCover}^{\uparrow}$

Following Bishop and Bridges on rational covers and constructive real neighborhoods, the $\mathsf{RationalBallCover}^{\uparrow}$ packet records finite rational-ball cover evidence for Real and Completion consumers. It sits after the request route of chapter 8116, the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite cover evidence through displayed rows only; it does not select a subcover by choice, quotient real names, invoke trichotomy, assert compactness, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8117.1 (Choice-free RationalBallCover source)**.** *A* $\mathsf{RationalBallCover}^{\uparrow}$ *source packet is a finite* BHist *record*

$$U = (F, L, D, W, R, M, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{RationalBallFilter}^{\uparrow}$ *request row that supplies the rational center and ball-request surface.*
2. *L is the finite cover ledger, listing the displayed rational-ball entries and their finite indices.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius-refinement and tolerance ledger attached to the cover entries.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the cover request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that reads the stream windows as regular rational approximation data.*
6. *M is the cover-modulus handoff row, recording the finite modulus by which a consumer reads enough cover entries for the requested window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the filter request, cover ledger, dyadic refinement, stream window, regular readback, and modulus rows have been displayed.*
8. *H records componentwise* hsame *transport for the filter request, finite cover ledger, dyadic ledger, stream windows, readback, modulus, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the rational-ball filter request through $F, L, D, W, R, M, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{RationalBallCover}^{\uparrow}$, $\mathsf{RationalBallFilter}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalBallCover}^\uparrow}$ *row.*

The five NameCert rows are carrier admission, finite cover ledger, dyadic refinement stability, cover-modulus handoff, and Real-seal nonescape. The carrier has no coordinate for countable choice, selected subcovers, open-cover compactness, quotient real equality, trichotomy, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8117.2 (Choice-free RationalBallCover finite subcover)**.** *Every accepted* $\mathsf{RationalBallCover}^\uparrow$ *packet $U = (F, L, D, W, R, M, E, H, C, P, N)$ exposes a finite subcover surface by reading the* $\mathsf{RationalBallFilter}^\uparrow$ *request row F, the finite ledger L, the* $\mathsf{DyadicRatCore}^\uparrow$ *refinement row D, the* $\mathsf{StreamName}^\uparrow$ *window W, and the* $\mathsf{RegSeqRat}^\uparrow$ *readback R before any terminal* $\mathsf{Real}^\uparrow$ *seal is consumed. The subcover is the displayed finite ledger in L transported through H, C, P, N; it is not selected by countable choice, compactness, quotient equality, trichotomy, or ambient completeness.*

Proof. Project the source packet of Definition 8117.1. Carrier admission exposes only $F, L, D, W, R, M, E, H, C, P, N$.

The finite cover ledger L is downstream of the $\mathsf{RationalBallFilter}^\uparrow$ request F. Thus a cover-facing consumer first reads the rational-ball request route and then the finite list of displayed rational-ball entries.

Dyadic refinement and window coverage are supplied by D, W, R. The cover entries are read through the same dyadic tolerance, stream-window, and regular-rational readback surface used by the Real and Completion route.

Finally H, C, P, N transport, replay, source, and name the same finite ledger. Since the carrier has no coordinate for choice, compactness, quotient equality, trichotomy, selected subcovers, or ambient completeness, the exported subcover surface is exactly the displayed finite ledger. □

Theorem 8117.3 (Choice-free RationalBallCover modulus)**.** *Every* $\mathsf{Real}^\uparrow$ *or Completion consumer of an accepted* $\mathsf{RationalBallCover}^\uparrow$ *packet reads the cover-modulus handoff through*

$$\mathsf{RationalBallFilter}^\uparrow,\ \mathsf{DyadicRatCore}^\uparrow,\ \mathsf{StreamName}^\uparrow,\ \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{Real}^\uparrow.$$

The modulus row M may be consumed only after the finite cover ledger L, dyadic refinement row D, stream window W, and regular rational readback R have been displayed, and before the terminal seal E is read. The handoff exports no countable-choice schedule, compactness theorem, selected limit, quotient real equality, trichotomy branch, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Start with an accepted $\mathsf{Real}^\uparrow$ or Completion consumer of U. The consumer receives the rational-ball request from F and the finite cover entries from L.

Next consume D, W, R. The dyadic ledger controls radius refinement, the stream window fixes the finite observation surface, and the regular rational readback interprets that window as approximation data.

Only then can the modulus row M be read. It records how much of the displayed finite cover ledger is needed for the requested window, without adding a selector or choice schedule.

The terminal seal E is downstream of F, L, D, W, R, M. Transport, replay, provenance, and local naming remain confined to H, C, P, N, so the Real and Completion handoff reaches only the displayed finite-cover route and none of the excluded compactness, quotient, trichotomy, choice, selected-limit, or completeness principles. □

Falsifiable prediction: An accepted $\mathsf{RationalBallCover}^\uparrow$ read is refuted if a $\mathsf{Real}^\uparrow$ or Completion consumer reaches the terminal seal without displaying the RationalBallFilter request, finite cover ledger, DyadicRatCore refinement row, StreamName window, RegSeqRat readback, cover-modulus handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBallCover}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalBallCover}^{\uparrow}$ packet is generated from a RationalBallFilter request, finite rational-ball cover ledger, DyadicRatCore radius refinement, StreamName windows, RegSeqRat readback, cover-modulus handoff, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalBallCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8117.1, Definition 8117.2, and Definition 8117.3 seed the finite rational-ball cover surface over RationalBallFilterUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalBallCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, selected subcovers, open-cover compactness, selected limits, quotient real equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover ledger exposure, dyadic refinement stability, cover-modulus handoff, Real-seal nonescape, ledger exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.RationalBallCoverUp.

Chapter 8118

A Concrete Naming Certificate for CompactUniformFinalTriangleClosure$^{\uparrow}$

Following Bishop and Bridges on the Heine–Cantor compact metric argument, the CompactUniformFinalTriangleClos packet records the last source-and-target triangle closure in the compact-uniform-continuity route of chapter 9237. It sits after the epsilon-triangle handoff of chapter 1257, the source-target triangle ledger of chapter 7260, and the metric-triangle uniform estimate of chapter 1159. The packet names a finite compact-net, pointwise-modulus, tolerance-budget, UniformModulus, and Real-seal closure route; it is not a host compactness theorem, an external modulus selector, quotient equality, choice of hidden centers, or ambient completeness principle.

Definition 8118.1 (Compact-uniform final triangle closure carrier)**.** *A* CompactUniformFinalTriangleClosure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, S, T, D, U, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-net source-distance row, recording the selected finite center, the source distance from the first point to that center, and the source distance between the two compared points.*
2. *M is the pointwise modulus row consumed at the selected center.*
3. *S is the source triangle estimate row, keeping the second point inside the same local source ball.*
4. *T is the target triangle estimate row, joining the two pointwise target estimates through the selected center image.*
5. *D is the dyadic tolerance budget row, carrying the finite split of the requested tolerance among source, pointwise, and target triangle contributions.*
6. *U is the* UniformModulus$^{\uparrow}$ *handoff row produced after K, M, S, T, D have been displayed.*
7. *E is the* Real$^{\uparrow}$ *seal row available only after the uniform-modulus handoff has been read.*
8. *H records componentwise* hsame *transport for compact-net source distances, pointwise modulus rows, source triangle rows, target triangle rows, dyadic tolerance budgets, uniform-modulus handoffs, Real seals, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from compact-net coverage through pointwise modulus, source triangle, target triangle, dyadic tolerance budget, UniformModulus handoff, and Real sealing.*

10. *P is the* Pkg *provenance over* CompactUniformFinalTriangleClosure$^{\uparrow}$, UniformModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert, *together with the compact-uniform triangle sibling rows cited above.*

11. *N is the local* NameCert$_{\text{CompactUniformFinalTriangleClosure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, S, T, D, U, E, H, C, P, N$. It has no coordinate for host compactness, a hidden center choice, quotient equality, selected subsequences, semantic continuity, or ambient completeness.

Theorem 8118.2 (Compact-uniform final triangle closure carrier)**.** *Every accepted* CompactUniformFinalTriangleCl *packet exposes exactly the finite carrier rows of Definition 8118.1. In particular, a public read of the packet must factor through compact-net source distances, a pointwise modulus row, source and target triangle estimates, a dyadic tolerance budget, a* UniformModulus$^{\uparrow}$ *handoff, a* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The rows $K, M, S, T, D, U, E, H, C, P, N$ are the whole public surface of the accepted packet.

The analytic rows are K, M, S, T, D, U, E. They record the compact-net source distances, the pointwise modulus at the selected center, the two triangle estimates, the dyadic tolerance budget, the uniform-modulus handoff, and the Real seal.

The structural rows H, C, P, N transport, replay, source, and name exactly that route. Since the carrier has no additional coordinate, no host compactness theorem, hidden center choice, quotient equality, selected subsequence, semantic continuity theorem, or ambient completeness principle can be exported. □

Theorem 8118.3 (Compact-uniform final triangle closure NameCert obligations)**.** *For every accepted* CompactUniformFinalTriangleClosure$^{\uparrow}$ *carrier*

$$F = (K, M, S, T, D, U, E, H, C, P, N),$$

the local NameCert$_{\text{CompactUniformFinalTriangleClosure}^{\uparrow}}$ *surface consists exactly of compact-net source-distance admission, pointwise modulus admission, source triangle admission, target triangle admission, dyadic tolerance-budget admission,* UniformModulus$^{\uparrow}$ *handoff,* Real$^{\uparrow}$ *seal routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Read compact-net source-distance admission from K. This row fixes the selected center and the two source distances used by the source triangle estimate.

Read pointwise modulus admission from M and source triangle admission from S. The source triangle keeps the second point inside the selected local radius, so the same pointwise modulus row may be consumed for both compared source points.

Read target triangle admission from T and dyadic tolerance-budget admission from D. The target triangle combines the two pointwise target estimates, while the dyadic budget records the finite tolerance split that makes the estimate fit the requested bound.

Finally read the handoff and seal rows U and E. The rows H, C, P, N preserve this source-and-target triangle route under transport, replay, provenance, and local naming, and no further NameCert obligation is available. □

Theorem 8118.4 (Compact-uniform final triangle closure handoff)**.** *Every* UniformModulus$^{\uparrow}$ *or* Real$^{\uparrow}$ *consumer of an accepted* CompactUniformFinalTriangleClosure$^{\uparrow}$ *packet receives only the finite route*

$$K, M, S, T, D \longmapsto U \longmapsto E, H, C, P, N.$$

The handoff is the closure of the displayed compact-net source distance, pointwise-modulus, source-triangle, target-triangle, and dyadic-budget rows, not an external modulus selector, host compactness argument, quotient equality, selected subsequence, or ambient Real completeness theorem.

Proof. Start with the carrier theorem Definition 8118.2. It identifies K, M, S, T, D as the only estimate rows available before the $\mathsf{UniformModulus}^{\uparrow}$ handoff.

Use the NameCert obligations of Definition 8118.3. They force the source triangle and target triangle to be read through the same compact-net center and the same dyadic tolerance budget.

The row U is therefore a handoff from those displayed rows, and the Real seal E is downstream of U. Transport, replay, provenance, and local naming keep the same route through H, C, P, N.

Since no excluded coordinate occurs in the carrier, the consumer receives a finite closure packet rather than an outside compactness or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformFinalTriangleClosure}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformFinalTriangleClosure}^{\uparrow}$ packet is generated from compact-net source-distance rows, pointwise modulus rows, source and target triangle estimates, a dyadic tolerance budget, a UniformModulus handoff, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformFinalTriangleClosure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8118.1, Definition 8118.2, Definition 8118.3, and Definition 8118.4 seed the finite source-and-target triangle closure route from compact-net and pointwise-modulus data to UniformModulus and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformFinalTriangleClosure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host compactness, external modulus selection, quotient equality, selected subsequences, semantic continuity, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-net source-distance admission, pointwise modulus admission, source and target triangle admission, dyadic tolerance-budget exactness, UniformModulus handoff, RealUp seal routing, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformFinalTriangleClosureUp.

Chapter 8119

A Concrete Naming Certificate for $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$

Following Bishop and Troelstra–van Dalen, the $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ packet records the finite located read by which a choice-sequence prefix is consumed by Bishop-style real analysis without importing a selected infinite choice function. It sits after the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the located choice-sequence surface of chapter 5958. The packet supplies an L10 boundary object for located choice-sequence reads; it is not a countable-choice selector, quotient stream equality, host real endpoint, selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8119.1 (Bishop located choice sequence carrier)**.** *A* $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, S, W, D, L, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the choice-sequence prefix row, recording only the inspected finite portion of the input sequence.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that names the finite observation window available to the read.*
3. *W is the located-window row, binding the inspected prefix to an explicit finite interval of observations.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the located comparison.*
5. *L is the local locatedness row, saying that each displayed tolerance request is answered by finite prefix evidence.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from Q, S, W, D, L.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the prefix, window, tolerance, locatedness, and regular readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the prefix, schedule, window, tolerance, locatedness, readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through exactly the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$, $\mathsf{LocatedRealChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedChoiceSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, S, W, D, L, R, E, H, C, P, N$. It has no coordinate for a completed choice function, countable choice, quotient stream equality, selected endpoint, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8119.2 (Bishop located choice sequence NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ *carrier*

$$B = (Q, S, W, D, L, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedChoiceSequence}^{\uparrow}}$ *surface consists exactly of prefix exposure through Q, finite schedule exposure through S, located-window exposure through W, dyadic tolerance exposure through D, locatedness exposure through L, regular-rational readback through R, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. Every Real or Completion consumer of the packet must pass through these rows before it reads a located choice-sequence endpoint.*

Proof. Project the carrier of Definition 8119.1. The rows Q, S, W expose only the finite prefix and observation window available to the consumer, while D records the dyadic tolerance budget attached to that window.

Read locatedness next. The row L answers tolerance requests by displayed prefix evidence, so the regular readback R can be consumed only after the finite window and tolerance ledger have been inspected.

Finally consume the terminal seal and structural rows. The Real seal E, componentwise transport H, replay C, provenance P, and local name N preserve the same finite route. Since no carrier coordinate supplies countable choice, quotient stream equality, a selected endpoint, host real equality, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8119.3 (Bishop located choice sequence window exhaustion)**.** *Every accepted* BishopLocatedChoiceSeque *read that reaches a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback or* $\mathsf{Real}^{\uparrow}$ *seal factors through the displayed route*

$$\mathsf{LocatedRealChoiceSequence}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

on the same $Q, S, W, D, L, R, E, H, C, P, N$ rows. The route exhausts the available finite windows and exports no countable-choice schedule, quotient stream equality, hidden infinite branch, selected limit, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Start with an accepted carrier $B = (Q, S, W, D, L, R, E, H, C, P, N)$. By Definition 8119.2, any Real-facing read must first display the prefix row, schedule row, located window, dyadic tolerance ledger, and locatedness row.

The regular readback is then forced through R. It is produced from the displayed prefix-window route and cannot be replaced by a host stream, quotient equality, or selected infinite branch.

The terminal seal E is reached only after this readback, and H, C, P, N preserve the same packet. Hence every downstream read exhausts the displayed windows and cannot introduce countable choice, selected limits, host real equality, or ambient completeness. □

Falsifiable prediction: A $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ read is rejected if it reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without displaying the choice-sequence prefix, StreamName schedule, located window, DyadicRatCore tolerance ledger, locatedness row, transport, replay, provenance, and local naming.

Independence witness: located-real-choice-sequence, streamname, regseqrat, dyadicratcore, real: $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a choice-sequence prefix, a finite observation schedule, a located window, a dyadic tolerance ledger, a locatedness row, regular readback, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedChoiceSequence}^{\uparrow}$ packet is generated from a choice-sequence prefix, StreamName finite schedule, located window, DyadicRatCore tolerance ledger, locatedness row, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8119.1, Definition 8119.2, and Definition 8119.3 seed the finite located choice-sequence route over prefix, window, tolerance, locatedness, readback, Real sealing, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BishopLocatedChoiceSequenceUp`

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient stream equality, hidden infinite branches, selected limits, host real equality, ambient RealUp completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-window visibility, tolerance-ledger exposure, locatedness nonescape, RegSeqRat readback ordering, RealUp seal boundary control, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedChoiceSequenceUp.

Chapter 8120

A Concrete Naming Certificate for BoundedRealUniformContinuityModulus$^{\uparrow}$

Following Bishop and Bridges and the Heine–Cantor theorem for compact intervals, the BoundedRealUniformContinu packet records the finite modulus surface for a displayed continuous map on a bounded real interval. It sits after the terminal real-name seal of chapter 38, the compact metric source of chapter 129, the pointwise continuity rows of chapter 130, the uniform-modulus consumer of chapter 369, and the dyadic tolerance ledger of chapter 291. The packet names the bounded Real and Completion modulus route; it is not a host Heine–Cantor theorem, an open-cover compactness principle, a quotient of real functions, a selected subcover, or ambient Real$^{\uparrow}$ completeness.

Definition 8120.1 (Bounded real uniform-continuity modulus carrier)**.** *A* BoundedRealUniformContinuityModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, K, F, U, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the bounded* Real$^{\uparrow}$ *interval row, recording endpoints, membership, and the displayed closed-bounded interval source;*
2. *K is the* CompactMetric$^{\uparrow}$ *finite-net row over the same interval source, with a finite family of centers and mesh histories;*
3. *F is the* ContinuousMap$^{\uparrow}$ *pointwise-modulus row for the displayed map on the interval;*
4. *U is the* UniformModulus$^{\uparrow}$ *extraction row obtained only after the finite-net and pointwise-modulus rows have been replayed;*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, recording positive target tolerance, center radii, mesh bounds, slack, and the exported source precision;*
6. *E is the terminal* Real$^{\uparrow}$ *seal row for all endpoint, value, and tolerance reads used by the packet;*
7. *H records componentwise* hsame *transport for the interval, finite-net, pointwise-modulus, uniform-modulus, dyadic-ledger, real-seal, provenance, and naming rows;*
8. *C records displayed* Cont *replay routes for reading the same rows in consumer order;*
9. *P is the* Pkg *provenance over* BoundedRealUniformContinuityModulus$^{\uparrow}$, Real$^{\uparrow}$, CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRealUniformContinuityModulus}^{\uparrow}}$ *row.*
The carrier has no coordinate for host compactness, open-cover compactness, a selected subcover, quotient equality of functions, trichotomy of reals, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached semantic continuity theorem.*

Theorem 8120.2 (Bounded real uniform-continuity modulus NameCert obligations)**.** *For the carrier of Definition 8120.1, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealUniformContinuityModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$M = (I, K, F, U, D, E, H, C, P, N),$$

bounded real interval exposure through I, compact finite-net exposure through K, $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus exposure through F,* $\mathsf{UniformModulus}^{\uparrow}$ *extraction through U, dyadic tolerance exactness through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from the displayed packet M. The rows $I, K, F, U, D, E, H, C, P, N$ list the bounded interval, finite-net source, pointwise continuity data, uniform-modulus extraction, tolerance ledger, Real seal, transports, replay routes, provenance, and local name.

The positive modulus route is finite. A consumer first reads I as the bounded $\mathsf{Real}^{\uparrow}$ interval, then K as the finite compact-metric net over that source, then F as the pointwise $\mathsf{ContinuousMap}^{\uparrow}$ modulus row at the displayed centers.

The output row U is exposed only after the dyadic ledger D records the target tolerance, mesh, slack, and source precision, and after E, H, C, P, N seal, transport, replay, source, and name those rows. Since no further coordinate is present, the local NameCert surface is exhausted by the displayed packet. □

Theorem 8120.3 (Bounded real uniform-continuity modulus consumer handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BoundedRealUniformContinuityModulus}^{\uparrow}$ *carrier reads a uniform-continuity modulus only through the finite route*

$$I, K, F, D, E, H, C, P, N \longmapsto U.$$

The handoff may cite the compact finite-net source, the $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-modulus rows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it exports no host Heine–Cantor theorem, open-cover compactness principle, selected subcover, quotient equality of real functions, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8120.2. They identify $I, K, F, U, D, E, H, C, P, N$ as the complete local certificate surface for the modulus packet.

Read the consumer route in order. The interval row I and compact finite-net row K supply the source coverage; the pointwise-modulus row F supplies local target control at the displayed centers; and the dyadic ledger D records the finite tolerance calculation that feeds the output row U.

Finally use the structural rows E, H, C, P, N. They seal the Real-facing reads, transport the rows componentwise, replay the displayed route, record provenance, and name the packet. None of these rows adds host compactness, a selected subcover, function quotient equality, countable choice, or ambient Real completeness, so the handoff is exactly the finite uniform-modulus route. □

Falsifiable prediction: Every accepted BoundedRealUniformContinuityModulusUp consumer that exports a uniform-continuity modulus without displaying a bounded Real interval row, compact finite-net row, ContinuousMap pointwise-modulus row, DyadicRatCore tolerance ledger, RealUp seal, transport, replay, provenance, and local NameCert row refutes the packet.

Independence witness: real, compactmetric, continuousmap, uniformmodulus, dyadicratcore: none is bijective to BoundedRealUniformContinuityModulusUp because the packet jointly carries the bounded interval source, finite-net coverage, pointwise-modulus data, uniform-modulus extraction, dyadic tolerance accounting, terminal Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealUniformContinuityModulus}\uparrow}$.

Constructive story: A $\mathsf{BoundedRealUniformContinuityModulus}^{\uparrow}$ packet is generated from a bounded Real interval row, compact finite-net row, ContinuousMap pointwise-modulus row, UniformModulus extraction row, DyadicRatCore tolerance ledger, Real seal, componentwise hsame transports, Cont replay routes, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedRealUniformContinuityModulus}\uparrow}, \mathsf{obligation})$

Scope closed: Definition 8120.1, Definition 8120.2, and Definition 8120.3 bind the finite bounded-Real uniform-modulus surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedRealUniformContinuityModulus}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Heine–Cantor, open-cover compactness, selected subcovers, quotient equality of real functions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires checked source coverage, pointwise-modulus replay, dyadic tolerance exactness, Real sealing, transport, provenance, and non-escape for the same finite packet.

Chapter 8121

A Concrete Naming Certificate for $\mathsf{SetValuedMap}^{\uparrow}$

Following Aubin–Frankowska set-valued analysis and Berge's compact-value route, the $\mathsf{SetValuedMap}^{\uparrow}$ packet records a multifunction interface as finite graph, fibre, closed-boundary, and compact-image rows. It sits between the topological and metric sources of chapter 88 and chapter 57, the terminal real seal of chapter 38, the closed-set boundary of chapter 4229, and the compact-image closed consumer of chapter 4162. The packet names a finite correspondence surface; it is not a host powerset-valued function, selected-value operator, quotient graph equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness claim.

Definition 8121.1 (Set-valued map carrier)**.** *A* $\mathsf{SetValuedMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, G, F, L, K, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Topology}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *row whose finite probes name the domain windows.*
2. *Y is the target* $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *row whose finite probes name the value windows.*
3. *G is the graph ledger, recording displayed source probes, target probes, and membership rows for the correspondence graph.*
4. *F is the fibre ledger, recording the finite rows that expose each displayed value fibre over a source probe.*
5. *L is the* $\mathsf{ClosedSet}^{\uparrow}$ *row used to read closed-graph or closed-fibre boundaries.*
6. *K is the* $\mathsf{CompactImageClosed}^{\uparrow}$ *consumer row used when compact-source image data must be read as a closed target boundary.*
7. *H records componentwise* hsame *transport for X, Y, G, F, L, K and the structural rows.*
8. *C records displayed* Cont *replay from source probes through graph membership, fibre exposure, closed-boundary readback, and compact-image consumption.*
9. *P is the* Pkg *provenance over* $\mathsf{SetValuedMap}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{CompactImageClosed}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SetValuedMap}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, G, F, L, K, H, C, P, N$. It has no coordinate for an ambient multifunction object, host powerset of values, pointwise value selection, quotient equality of graphs, open-cover compactness, or detached closedness theorem.

Theorem 8121.2 (Set-valued map NameCert obligations)**.** *For every accepted* $\mathsf{SetValuedMap}^{\uparrow}$ *carrier*

$$M = (X, Y, G, F, L, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SetValuedMap}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, source-window exposure through X, target-window exposure through Y, graph membership exposure through G, fibre exposure through F, closed-boundary readback through L, compact-image closed consumption through K, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The source and target rows X, Y determine the only windows in which the correspondence can be inspected, while G records graph membership and F records fibre exposure.

Read the boundary rows next. The closed-set row L is the only route to closed-graph or closed-fibre information, and the compact-image row K is the only route by which compact-source image data reaches a closed target consumer.

Finally inspect the structural rows H, C, P, N. They transport, replay, source, and name the same finite packet. Since no carrier coordinate stores an ambient multifunction, host powerset, selected value, graph quotient, open-cover proof, or detached closedness theorem, the listed rows exhaust the NameCert surface. □

Theorem 8121.3 (Closed-graph and compact-image handoff)**.** *Every closed-graph or compact-image consumer of an accepted* $\mathsf{SetValuedMap}^{\uparrow}$ *carrier must read the route*

$$\mathsf{Topology}^{\uparrow}/\mathsf{Met}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto G \longmapsto F \longmapsto \mathsf{ClosedSet}^{\uparrow} \longmapsto \mathsf{CompactImageClosed}^{\uparrow} \longmapsto H, C, P, N.$$

In particular, closed-graph reasoning and compact-image closedness are handed to consumers as finite NameCert rows, not as host semantics for a multifunction.

Proof. Begin with the source and target rows. Any consumer first receives the finite source probes in X and target probes in Y before it can inspect graph membership or fibre data.

The graph and fibre rows then expose the correspondence surface. Closed-graph reads pass through the $\mathsf{ClosedSet}^{\uparrow}$ row L, while compact-image reads pass through the $\mathsf{CompactImageClosed}^{\uparrow}$ row K.

The transport, replay, provenance, and local naming rows keep this handoff attached to the same packet. Thus downstream closed-set and compact-image consumers receive finite certificate data, with no ambient multifunction semantics or selected-value principle added by the packet. □

Falsifiable prediction: Every accepted $\mathsf{SetValuedMap}^{\uparrow}$ consumer read must display source, target, graph, fibre, closed-boundary, compact-image, transport, replay, provenance, and local naming rows before using closed-graph or compact-image reasoning.

Independence witness: closedset and compact-image-closed: neither is bijective to $\mathsf{SetValuedMap}^{\uparrow}$ because the closed-set packet isolates a boundary row, the compact-image packet isolates a compact-source closed-target consumer, and the set-valued-map packet binds source, target, graph, fibre, closed-boundary, compact-image, transport, replay, provenance, and local naming rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SetValuedMap}^{\uparrow}}$.

Constructive story: A $\mathsf{SetValuedMap}^{\uparrow}$ packet is generated from source windows, target windows, graph membership rows, fibre rows, closed-boundary readback, compact-image closed consumption, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SetValuedMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8121.1, Definition 8121.2, and Definition 8121.3 seed the finite multifunction interface for closed-graph and compact-image consumers over $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, and $\mathsf{CompactImageClosed}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SetValuedMap}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host powerset semantics, pointwise value selection, quotient graph equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph and fibre exposure, closed-boundary readback, compact-image handoff, transport and replay stability, and local NameCert provenance for BEDC.Derived.SetValuedMapUp.

Chapter 8122

A Concrete Naming Certificate for $\mathsf{AbelPoissonSummability}^{\uparrow}$

Following Abel, Poisson, and Zygmund, the $\mathsf{AbelPoissonSummability}^{\uparrow}$ packet records the finite radial summability handoff by which Abel summability rows and Poisson-kernel rows feed the L10 Real and Completion route through displayed radius windows. It sits after the Abel summability route of chapter 6420, the positive Poisson-kernel boundary surface of chapter 2293, the Abel theorem radial boundary of chapter 6058, the regular rational readback of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The chapter names a finite radial ledger, not a host boundary limit, selected harmonic extension, quotient series equality, countable choice, or ambient Real completeness.

Definition 8122.1 (Abel–Poisson summability carrier)**.** *An* $\mathsf{AbelPoissonSummability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (A, K, T, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelSummability}^{\uparrow}$ *row exposing the Abel summability source, radial-window readback, and existing finite Real-seal ordering.*
2. *K is the* $\mathsf{PoissonKernel}^{\uparrow}$ *row exposing the positive radius row, angle-window row, denominator ledger, numerator ledger, kernel-value readback, and Fejer/Dirichlet comparison surface.*
3. *T is the* $\mathsf{AbelTheorem}^{\uparrow}$ *row recording the radial-boundary handoff used by the same radius ledger.*
4. *D is the dyadic radial ledger, storing finite radii, dyadic tolerances, kernel denominators, and comparison margins.*
5. *W records the finite radius windows, coefficient windows, angle windows, and kernel-value windows inspected by A, K, T, D.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the displayed Abel and Poisson windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row visible only after A, K, T, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the Abel, Poisson, theorem, dyadic-ledger, window, readback, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from each finite radial request through A, K, T, D, W to R and then to E.*

10. *P is the* Pkg *provenance over* $\mathsf{AbelPoissonSummability}^{\uparrow}$, $\mathsf{AbelSummability}^{\uparrow}$, $\mathsf{PoissonKernel}^{\uparrow}$, $\mathsf{AbelTheorem}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelPoissonSummability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, K, T, D, W, R, E, H, C, P, N$. It has no coordinate for host boundary limits, harmonic-function equality, selected sums, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8122.2 (Abel–Poisson summability NameCert obligations)**.** *For every accepted* $\mathsf{AbelPoissonSummability}^{\uparrow}$ *carrier $Q = (A, K, T, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AbelPoissonSummability}^{\uparrow}}$ *surface consists exactly of Abel summability admission through A, Poisson-kernel admission through K, Abel theorem radial-boundary admission through T, dyadic radial tolerance accounting through D, finite radius and angle-window exhaustion through W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal ordering through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8122.1. The tuple displays exactly the Abel summability row, Poisson-kernel row, Abel theorem row, dyadic radial ledger, finite windows, regular rational readback, Real seal, and structural support rows.

The analytic data remain finite. Rows A, K, T, D, W name the summability, kernel, radial-boundary, tolerance, radius, coefficient, angle, and kernel-value windows that the packet may inspect, while R repacks those displayed rows as regular rational data.

The terminal seal row E is downstream from R. Transport through H and replay through C preserve the same displayed route, and P, N only source and name it. Since no further coordinate exists in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8122.3 (Abel–Poisson summability Real-seal route)**.** *Every Real or Completion consumer of an accepted* $\mathsf{AbelPoissonSummability}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{AbelSummability}^{\uparrow}, \quad \mathsf{PoissonKernel}^{\uparrow}, \quad \mathsf{AbelTheorem}^{\uparrow}, \quad D, W, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the same packet rows $A, K, T, D, W, R, E, H, C, P, N$. Thus the Abel–Poisson handoff is a displayed radial-window readback and not a host boundary limit, selected harmonic extension, quotient series equality, countable-choice selector, or ambient Real-completeness principle.

Proof. Begin with an accepted carrier and project the route rows A, K, T, D, W, R, E. The rows A and T supply the Abel summability and radial theorem faces, while K supplies the positive Poisson-kernel comparison surface over the same displayed radius requests.

Read the finite radial ledger through D and W. These rows fix the dyadic tolerances, radius parameters, coefficient windows, angle windows, and kernel-value windows that determine the regular rational readback R.

Finally pass through E, H, C, P, N. The seal row receives its analytic input from R, and the structural rows transport, replay, source, and name that same path. Therefore a downstream Real or Completion consumer obtains only the displayed finite handoff. □

Falsifiable prediction: An accepted $\mathsf{AbelPoissonSummability}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading the $\mathsf{AbelSummability}^{\uparrow}$ row, $\mathsf{PoissonKernel}^{\uparrow}$ row, $\mathsf{AbelTheorem}^{\uparrow}$ row, dyadic radial ledger, finite radius windows, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: abel-summability, poisson-kernel, abel-theorem, regseqrat, real: AbelPoissonSummability is not bijective to any listed sibling because it binds Abel radial summability, Poisson kernel data, dyadic radius ledgers, regular readback, and Real sealing into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelPoissonSummability}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelPoissonSummability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8122.1, Definition 8122.2, and Definition 8122.3 seed the finite Abel–Poisson summability route over Abel summability rows, Poisson-kernel windows, Abel theorem radial boundaries, regular rational readback, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelPoissonSummability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host boundary limits, harmonic-function equality, selected sums, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Abel summability admission, Poisson-kernel admission, Abel theorem radial-boundary admission, dyadic radial tolerance accounting, finite radius-window exhaustion, regular readback, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.AbelPoissonSummabilityUp.

Constructive story: An $\mathsf{AbelPoissonSummability}^{\uparrow}$ packet is generated from Abel summability data, Poisson-kernel data, Abel theorem radial-boundary data, dyadic radial tolerances, finite radius and angle windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8123

A Concrete Naming Certificate for $\mathsf{StepIndexedTrace}^{\uparrow}$

The $\mathsf{StepIndexedTrace}^{\uparrow}$ packet realizes the total-host/substrate bridge of chapter 9370 as one finite trace object. It sits beside the total-host boundary of chapter 964, the bounded MetaCIC replay of chapter 3889, the bounded universal trace of chapter 944, the cellular substrate of chapter 934, and the MetaCIC strong-normalization boundary of chapter 3954. Those siblings expose totality, bounded replay, universal finite traces, local cellular rows, or normalization boundaries separately; this packet binds fuel, prefix, endpoint, refusal, replay, provenance, and local naming as one NameCert trace.

Definition 8123.1 (Step-indexed trace carrier)**.** *A* $\mathsf{StepIndexedTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, S, Q, E, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite fuel row read by the total host.*
2. *S is the substrate row, either a* $\mathsf{CellularAutomaton}^{\uparrow}$ *local rule/orbit source or a MetaCIC bounded evaluator source.*
3. *Q is the finite prefix row containing the trace segment produced at fuel F.*
4. *E is the endpoint row reached at the end of the prefix, including normal-form or timeout readback when such a row is displayed.*
5. *R is the refusal row for every read that asks for global halting, an infinite orbit, a fuel-erased endpoint, a hidden normalizer, or an unbounded substrate theorem.*
6. *H records componentwise* hsame *transport for F, S, Q, E, R and the structural rows.*
7. *C records displayed* Cont *replay from fuel to substrate source, from source to prefix, from prefix to endpoint, and from absent global claims to the refusal row.*
8. *P is the* Pkg *provenance over* $\mathsf{StepIndexedTrace}^{\uparrow}$*,* $\mathsf{StepIndexedTotalHost}^{\uparrow}$*,* $\mathsf{MetaCICFuelTrace}^{\uparrow}$*,* $\mathsf{BoundedUniversalTrace}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*,* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{StepIndexedTrace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, Q, E, R, H, C, P, N$. It has no coordinate for fuel-free halting, an all-time cellular orbit, unrestricted MetaCIC normalization, host evaluator equality, substrate theorem content, or quotient equality of traces.

Theorem 8123.2 (Step-indexed trace NameCert obligations)**.** *For every accepted* $\mathsf{StepIndexedTrace}^{\uparrow}$ *carrier*

$$T = (F, S, Q, E, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StepIndexedTrace}^{\uparrow}}$ *surface consists exactly of fuel exposure through F, substrate-source exposure through S, finite prefix exposure through Q, endpoint readback through E, refusal exactness through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The fuel row F is the first public coordinate, and the substrate source S is only read at that displayed fuel.

The trace body is Q, E. The prefix row Q records the finite segment, and the endpoint row E records the finite readback reached by that segment.

The refusal row R is part of the same carrier, not an external convention. It rejects global halting, infinite orbit, fuel-erased endpoint, hidden normalizer, and unbounded theorem reads.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no additional coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 8123.3 (Total-host substrate handoff)**.** *Every total-host or substrate consumer of an accepted* $\mathsf{StepIndexedTrace}^{\uparrow}$ *packet must read the route*

$$\mathsf{StepIndexedTotalHost}^{\uparrow} \longmapsto F \longmapsto S \longmapsto Q \longmapsto E \longmapsto R \longmapsto H, C, P, N.$$

The route may pass through $\mathsf{MetaCICFuelTrace}^{\uparrow}$*,* $\mathsf{BoundedUniversalTrace}^{\uparrow}$*,* $\mathsf{CellularAutomaton}^{\uparrow}$*, and* $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ *as sibling evidence, but no consumer may erase F and treat the prefix or endpoint as a global halting read.*

Proof. Start with the total-host boundary. A host consumer reaches this packet only through the fuel discipline already exposed by $\mathsf{StepIndexedTotalHost}^{\uparrow}$, so every trace read begins with F.

Read the substrate side next. The row S identifies the finite cellular or MetaCIC source, Q records the prefix generated at the displayed fuel, and E records the endpoint visible at that prefix.

The sibling rows provide comparison evidence without replacing the packet. $\mathsf{MetaCICFuelTrace}^{\uparrow}$ accounts for bounded evaluator replay, $\mathsf{BoundedUniversalTrace}^{\uparrow}$ accounts for universal finite prefixes, $\mathsf{CellularAutomaton}^{\uparrow}$ accounts for local cellular rows, and $\mathsf{MetaCICStrongNormalizationBoundary}^{\uparrow}$ accounts for the normal-form boundary.

The refusal row R then blocks the fuel-erased read. Transport, replay, provenance, and naming preserve the same packet, so no consumer can convert Q or E into global halting or unbounded substrate content. □

Falsifiable prediction: Any accepted $\mathsf{StepIndexedTrace}^{\uparrow}$ packet that admits a global halting read without displaying fuel and prefix rows is rejected by the NameCert surface.

Independence witness: stepindexedtotalhost, metacic-fuel-trace, bounded-universal-trace, cellularautomaton, metacic-strong-normalization-boundary: none is bijective to $\mathsf{StepIndexedTrace}^{\uparrow}$ because this carrier binds the finite fuel, substrate source, prefix, endpoint, refusal, transport, replay, provenance, and local naming rows in one packet.

The Lean follow-up namespace BEDC.Derived.StepIndexedTraceUp must provide Nontrivial StepIndexedTrace$^{\uparrow}$ and FieldFaithful StepIndexedTrace$^{\uparrow}$ instances for the displayed fuel, source, prefix, endpoint, refusal, transport, replay, provenance, and naming rows.

Closure status for NameCert$_{\text{StepIndexedTrace}^{\uparrow}}$.

Constructive story: A StepIndexedTrace$^{\uparrow}$ packet is generated from finite fuel, a substrate source, a finite trace prefix, endpoint readback, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{StepIndexedTrace}^{\uparrow}}$, seed)

Scope closed: Definition 8123.1, Definition 8123.2, and Definition 8123.3 seed the finite trace packet for total-host and substrate consumers over StepIndexedTotalHost$^{\uparrow}$, MetaCICFuelTrace$^{\uparrow}$, BoundedUniversalTrace$^{\uparrow}$, CellularAutomaton$^{\uparrow}$, and MetaCICStrongNormalizationBoundary$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{StepIndexedTrace}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global halting, all-time cellular orbits, unrestricted MetaCIC normalization, host evaluator equality, substrate theorem content, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fuel-prefix endpoint exposure, refusal exactness, transport and replay stability, Nontrivial and FieldFaithful instances, and local NameCert provenance for BEDC.Derived.StepIndexedTraceUp.

Chapter 8124

A Concrete Naming Certificate for $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$

Following Kurzweil, Henstock, and Stieltjes, the $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ packet records a finite gauge-controlled Stieltjes integration surface in which a displayed integrand is read against a bounded-variation integrator through tagged gauges and regulated handoff rows. It sits after the Riemann–Stieltjes packet of chapter 1637, the gauge-integral surface of chapter 1999, the bounded-variation ledger of chapter 398, the regulated-integral handoff of chapter 1557, and the terminal real seal of chapter 38. The packet names only a finite gauge-variation carrier; it does not assert measure completion, host quotient equality of integrands, a selected primitive, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8124.1 (Kurzweil–Stieltjes integral carrier)**.** *A* $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (G, R, A, T, I, E, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{GaugeIntegral}^{\uparrow}$ *row exposing the finite gauge cover, tagged cells, and admissible local radii.*
2. *R is the* $\mathsf{RiemannStieltjes}^{\uparrow}$ *row supplying the tagged Stieltjes sum surface already accepted by the Riemann–Stieltjes certificate.*
3. *A is the* $\mathsf{BoundedVariation}^{\uparrow}$ *integrator ledger, including transported endpoint jumps and finite variation bounds for the displayed cells.*
4. *T is the gauge-tagged refinement row tying the cells of G to the Stieltjes tags read by R.*
5. *I is the* $\mathsf{RegulatedIntegral}^{\uparrow}$ *handoff row reached only after the gauge, Stieltjes, variation, and refinement rows are present.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the accepted integral value.*
7. *H records componentwise* hsame *transport for the gauge, Stieltjes, variation, refinement, handoff, real seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from gauge cells to tags, from bounded-variation jumps to Stieltjes sums, from refinement rows to the regulated handoff, and from the handoff to the* $\mathsf{Real}^{\uparrow}$ *seal.*
9. *P is the* Pkg *provenance over* $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$, $\mathsf{RiemannStieltjes}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{RegulatedIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{KurzweilStieltjesIntegral}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $G, R, A, T, I, E, H, C, P, N$. It has no coordinate for measure spaces, completed variation objects, host quotient equality of functions, selected antiderivatives, or ambient real completeness.

Lean4 (statement) `BEDC.Derived.KurzweilStieltjesIntegralUp`

Theorem 8124.2 (Kurzweil–Stieltjes integral NameCert obligations)**.** *For an accepted* $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ *carrier $K = (G, R, A, T, I, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{KurzweilStieltjesIntegral}^{\uparrow}}$ *surface consists exactly of gauge admission, accepted Riemann–Stieltjes readback, bounded-variation integrator control, gauge-tagged refinement, regulated-integral handoff, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed continuation replay, package provenance, and local naming through $G, R, A, T, I, E, H, C, P, N$.*

Proof. Project the carrier of Definition 8124.1. The rows $G, R, A, T, I, E, H, C, P, N$ are the complete public packet, so every accepted read is first a finite gauge read, then a Riemann–Stieltjes tagged-sum read, then a bounded-variation and refinement read.

The regulated handoff row I is downstream of those rows. Transport through H and replay through C preserve the displayed order, while P and N only record provenance and local naming. Since the carrier contains no measure, quotient, selected primitive, or ambient completeness coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 8124.3 (Kurzweil–Stieltjes gauge-variation handoff)**.** *Every accepted* $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ *consumer of a terminal* $\mathsf{Real}^{\uparrow}$ *value must read the route*

$$\mathsf{GaugeIntegral}^{\uparrow},\ \mathsf{RiemannStieltjes}^{\uparrow},\ \mathsf{BoundedVariation}^{\uparrow},\ \mathsf{RegulatedIntegral}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameC}$$

through $G, R, A, T, I, E, H, C, P, N$ before it treats the output as an integral value. The route consumes existing gauge and bounded-variation rows and does not assert measure completion, host quotient equality, selected primitives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $K = (G, R, A, T, I, E, H, C, P, N)$. The gauge row G supplies the only admissible local cells, and the Riemann–Stieltjes row R supplies the only tagged Stieltjes sum surface.

The bounded-variation row A controls the integrator contribution on the same displayed cells. The refinement row T ties the gauge tags to the Stieltjes tags, so a downstream consumer cannot bypass either the gauge surface or the variation ledger.

The handoff row I then exposes the regulated-integral route, and the terminal seal E is available only after that handoff. Structural transport, continuation replay, provenance, and local naming preserve the same order through H, C, P, N, leaving no coordinate for the excluded host objects. □

Falsifiable prediction: Every accepted $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ read is refuted if a consumer reaches a $\mathsf{Real}^{\uparrow}$ integral value without displaying the gauge row, accepted Riemann–Stieltjes row, bounded-variation ledger, regulated-integral handoff, and local NameCert row.

Independence witness: Riemann–Stieltjes, gauge-integral, bounded-variation, regulated-integral, and Real packets: the Riemann–Stieltjes packet records tagged Stieltjes sums without owning a gauge cell ledger, the gauge-integral packet records local gauge admission without Stieltjes variation control, the bounded-variation packet records integrator variation without naming an integral value, the regulated-integral packet records a handoff surface without a Stieltjes integrator, and the Real packet supplies only the terminal seal. None is bijective to $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{KurzweilStieltjesIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{KurzweilStieltjesIntegral}^{\uparrow}$ packet is generated from finite gauge rows, accepted Riemann–Stieltjes rows, bounded-variation integrator ledgers, gauge-tagged refinement rows, regulated-integral handoff rows, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KurzweilStieltjesIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8124.1, Definition 8124.2, and Definition 8124.3 seed the finite gauge-variation Stieltjes readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KurzweilStieltjesIntegral}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.KurzweilStieltjesIntegralUp`

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, measure completion, host quotient equality of integrands or integrators, selected primitives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked gauge admission, accepted Riemann–Stieltjes readback, bounded-variation control, regulated handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.KurzweilStieltjesIntegralUp

Chapter 8125

A Concrete Naming Certificate for $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$

Following Bishop and Bridges on located real numbers and finite real-name comparisons, the $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$ packet records the binary separation surface read before a later $\mathsf{RealNameClassifier}^{\uparrow}$ decision is exposed. It sits over the dyadic rational core of chapter 291, the finite window interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the classifier packet of chapter 1517. The packet names only the finite located separator rows by which two regular real names are inspected; it is not a proof of full real trichotomy, quotient-real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8125.1 (Located real binary separator carrier)**.** *A* $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, B, W, T, R, D, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two displayed real-name source rows whose located separation is being inspected.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the requested observation stages for both sources.*
3. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the shared window.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that serves the displayed rational observations on the same window.*
5. *D is the finite binary decision row, recording only the accepted left/right separator outcome read from W, T, R after the terminal* $\mathsf{Real}^{\uparrow}$ *seal row is available.*
6. *H records componentwise* hsame *transport for source rows, windows, dyadic tolerance rows, regular readbacks, terminal real sealing, binary decision rows, provenance, replay, and local naming.*
7. *C records displayed* Cont *replay from a separator request through A, B, W, T, R, D and back to the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealNameClassifier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealBinarySeparator}^{\uparrow}}$ *row.*

The carrier exports only this finite located binary separator surface. It has no coordinate for quotient real equality, host equality of completed reals, selected representatives, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8125.2 (Located real separator dyadic decision)**.** *For every accepted* $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$ *carrier*

$$S = (A, B, W, T, R, D, H, C, P, N),$$

the binary decision row D *can be read only after the shared* $\mathsf{StreamName}^{\uparrow}$ *row* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger* T*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal route have been displayed. Thus a later* $\mathsf{RealNameClassifier}^{\uparrow}$ *consumer receives a finite decision surface, not an ambient equality or order oracle on completed real numbers.*

Proof. Project the carrier of Definition 8125.1. The source rows A, B are inspected through the common finite window W, so a separator request has no independent host-level observation route.

Read the dyadic and regular rows next. The tolerance ledger T supplies the displayed dyadic comparison data, and R exposes the regular rational readback on the same finite window.

Only after that route is visible may the decision row D be consumed. The sibling chapters provide the surfaces in the order $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, and $\mathsf{RealNameClassifier}^{\uparrow}$, so the classifier-facing decision is a finite packet row.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient-real equality, selected representative, selected limit, trichotomy, countable-choice schedule, or ambient completeness coordinate, none of those principles is exported. □

Theorem 8125.3 (Located real separator NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$ *carrier*

$$S = (A, B, W, T, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealBinarySeparator}^{\uparrow}}$ *surface consists exactly of source-row admission through* A, B*, shared finite-window exposure through* W*, dyadic tolerance exposure through* T*, regular rational readback through* R*, finite binary decision exposure through* D*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the tuple in Definition 8125.1. Its analytic rows are precisely A, B, W, T, R, D, and its structural rows are precisely H, C, P, N.

Apply the dyadic decision theorem. It orders the decision-facing read through the shared window, dyadic ledger, regular readback, terminal seal route, and only then the finite binary decision row.

The remaining rows account for transport, replay, provenance, and local naming. No additional carrier coordinate remains from which a consumer could recover full trichotomy, quotient real equality, selected representatives, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealBinarySeparator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealBinarySeparator}^{\uparrow}$ packet is generated from two displayed real-name source rows, one shared StreamNameUp window, a DyadicRatCoreUp tolerance ledger, a RegSeqRatUp readback row, a finite binary decision row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealBinarySeparator}^{\uparrow}}$, seed)

Scope closed: Definition 8125.1, Definition 8125.2, and Definition 8125.3 seed the finite binary separator route consumed by RealNameClassifier-facing reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealBinarySeparator}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close full real trichotomy, quotient reals, selected representatives, selected limits, countable choice, ambient $\mathrm{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-window exposure, dyadic tolerance exposure, regular rational readback, terminal seal routing, decision-row exposure, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealBinarySeparatorUp.

Chapter 8126

A Concrete Naming Certificate for $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$

The $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as a finite residual-overlap matrix for typed MetaCIC redexes. It sits beside the critical-path packet of chapter 765, the parallel-diamond frontier of chapter 4238, the typed normal-form readback surface of chapter 562, the subject-reduction boundary of chapter 483, and the residual-diamond frontier of chapter 8111. The packet records only finite typed-redex, residual-row, join-candidate, closedness, substitution-boundary, transport, replay, provenance, and local naming data; it is not a broad confluence assertion.

Falsifiable prediction: Every accepted $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ consumer must expose both residual rows and one join-candidate row before a parallel-diamond read is available.

Independence witness: metacic-parallel-diamond-frontier, metaciccriticalpath, typedreduction-normalform, subjectreduction: the parallel-diamond frontier records a conditional diamond handoff without this packet's typed overlap matrix; the critical-path packet records routing pressure without residual-row adjacency; the typed normal-form packet records endpoint readback without paired residual overlaps; and the subject-reduction packet records preservation boundaries without candidate joins. None is bijective to $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$.

Definition 8126.1 (MetaCIC residual join frontier carrier)**.** *A* $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, L, R, J, K, S, O, H, C, P, N)$$

with the following displayed rows:

1. *Q is the typed critical-pair row, recording the source term, typing boundary, redex labels, and inspected overlap window.*
2. *L and R are the two residual rows, one for each branch descending from the overlap.*
3. *J is the join-candidate row, recording the proposed common target and the two branch-local routes to it.*
4. *K is the closedness and finite-support row for the inspected source and residual descendants.*
5. *S is the substitution-boundary row retaining the residual-substitution premise and any obstruction that remains outside the packet.*

6. *O is the parallel-diamond read row, exposed only after Q, L, R, J, K, S have all been displayed.*
7. *H records componentwise* hsame *transport for typed critical pairs, residual rows, join candidates, closedness rows, substitution-boundary rows, parallel-diamond reads, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a confluence query through Q, L, R, J, K, S before O is read.*
9. *P is the* Pkg *provenance over* $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{SubjectReduction}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}}$ *row.*

The carrier exports no coordinate for premise-free confluence, unrestricted subject reduction, global normalization, evaluator equality, quotient syntax equality, or kernel consistency.

Theorem 8126.2 (MetaCIC residual join frontier diamond consumer)**.** *Every parallel-diamond consumer of an accepted* $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ *packet first factors through the typed critical-pair row Q, both residual rows L, R, one join-candidate row J, the closedness row K, and the substitution-boundary row S before the parallel-diamond read row O is exposed. The resulting read is a finite residual-join consumer for the confluence audit map, not a proof of unrestricted MetaCIC confluence.*

Proof. Project the carrier of Definition 8126.1. The parallel-diamond read row O is downstream of Q, L, R, J, K, S by construction.

Read the overlap rows first. The typed critical-pair row Q fixes the source, typing boundary, redex labels, and inspected overlap window; the two residual rows L, R record the branch-local descendants; and J supplies the candidate common target.

Next read the boundary rows. The closedness row K keeps the source and residual descendants inside the finite inspected support, while S retains the substitution premise or obstruction rather than discharging it silently.

Finally use H, C, P, N for transport, replay, provenance, and local naming. These structural rows preserve the same finite matrix and add no premise-free confluence theorem, unrestricted subject reduction theorem, global normalization oracle, evaluator equality, quotient syntax equality, or kernel-consistency claim. □

Theorem 8126.3 (MetaCIC residual join frontier NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ *carrier*

$$M = (Q, L, R, J, K, S, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}}$ *surface consists exactly of typed critical-pair exposure through Q, two residual-row exposures through L, R, join-candidate exposure through J, closedness and finite-support exposure through K, substitution-boundary retention through S, parallel-diamond read exposure through O, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the tuple in Definition 8126.1. The carrier lists exactly the matrix rows Q, L, R, J, K, S, O and the structural rows H, C, P, N.

Apply the diamond-consumer theorem. It forces every confluence-facing read through the typed pair, both residual rows, a join candidate, closedness data, and the retained substitution boundary before the parallel-diamond row can be used.

The structural rows account for all remaining obligations. Since the carrier has no other coordinate, its local NameCert cannot export unrestricted confluence, subject reduction, global normalization, evaluator equality, quotient syntax equality, or kernel consistency. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}$ packet is generated from a typed critical-pair row, two residual rows, one join-candidate row, closedness and finite-support data, a retained substitution-boundary row, a parallel-diamond read row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8126.1, Definition 8126.2, and Definition 8126.3 seed the finite residual-overlap matrix consumed by MetaCIC parallel-diamond reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted MetaCIC confluence, premise-free parallel diamond, unrestricted subject reduction, global normalization, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed critical-pair exposure, two residual-row exposures, join-candidate exposure, closedness exposure, substitution-boundary retention, diamond-read non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICCriticalPairResidualMatrixUp.

Chapter 8127

A Concrete Naming Certificate for $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$

Following Hardy and Bishop–Bridges on Cauchy's condensation test, the $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$ packet records the harmonic-block face of a monotone real-series comparison as finite BEDC NameCert data. It sits after the condensation-test surface of chapter 1478, the real-series carrier of chapter 1581, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives downstream condensation and tail-modulus consumers a displayed block route; it is not a selected infinite sum, a quotient series equality, a countable-choice schedule, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8127.1 (Cauchy condensation harmonic block carrier)**.** *A* $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (S, B, D, T, R, E, Hs, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing the monotone nonnegative term stream and partial-sum windows only through the series packet.*
2. *B is the harmonic block schedule, listing the dyadic block indices, the harmonic weights inside each block, and the finite block endpoints used by the condensation read.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic precision cells, comparison slack, and block-budget conversions used by B.*
4. *T is the tail comparison ledger, recording the finite inequalities between source tails, harmonic block sums, and condensed comparison rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after S, B, D, T have displayed the block schedule and tail ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback is displayed.*
7. *Hs records componentwise* hsame *transport for the source, block schedule, tolerance, tail ledger, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a harmonic-block request through $S, B, D, T, R, E, Hs, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{CauchyCondensationTest}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for a host infinite sum, quotient series equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8127.2 (Cauchy condensation harmonic block obligations)**.** *For every accepted* CauchyCondensationHarm *carrier $H = (S, B, D, T, R, E, Hs, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}}$ *surface consists exactly of carrier admission, harmonic block schedule exactness, dyadic tolerance exactness, tail comparison ledger exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8127.1. Carrier admission is the display of $S, B, D, T, R, E, Hs, C, P, N$ as one finite BHist packet.

Read the block rows next. The schedule B lists the dyadic block indices, harmonic weights, and endpoints, while D supplies the dyadic precision cells and comparison slack used to certify those finite blocks.

The comparison row T then records only displayed inequalities between the source tails, harmonic block sums, and condensed comparison rows. The readback row R is downstream of this ledger, and the seal row E is downstream of R.

Finally Hs, C, P, N transport, replay, source, and locally name the same route. Since no carrier coordinate names selected infinite sums, quotient series equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8127.3 (Cauchy condensation harmonic block Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing harmonic-block read of an accepted* $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{CauchyCondensationTest}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports the displayed source series, condensation block schedule, dyadic tolerance ledger, regular rational readback, terminal Real seal, transport, replay, provenance, and local naming rows, but no selected infinite sum, quotient series equality, countable-choice schedule, detached Real seal, or ambient completeness principle.

Proof. Start with the source row S. It exposes the real-series terms and partial-sum windows before any block consumer can inspect a harmonic schedule.

The condensation-facing read then passes through B, T and the sibling condensation-test surface. The block schedule and tail comparison ledger are the only rows that connect the source series to condensed block data.

Next read the dyadic and regular rational boundary. The row D supplies the tolerance budget before R can be consumed as a $\mathsf{RegSeqRat}^{\uparrow}$ readback, and the terminal seal E is downstream of R.

The structural rows Hs, C, P, N preserve this order under transport, replay, provenance, and local naming. Thus every Real-facing read factors through the stated finite route and has no coordinate for selected infinite sums, quotient equality, countable choice, detached Real data, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$ Real-facing read factors through a RealSeries source row, CauchyCondensationTest block schedule, DyadicRatCore tolerance row, RegSeqRat readback, RealUp seal, transport, replay, provenance, and local NameCert row.

Independence witness: realseries, cauchy-condensation-test, dyadicratcore, regseqrat, real: no listed sibling supplies the whole harmonic-block packet $H = (S, B, D, T, R, E, Hs, C, P, N)$, because each sibling contributes only the source series, condensation-test block surface, dyadic tolerance, regular readback, or endpoint seal while this chapter binds them as one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}$ packet is generated from a RealSeries source row, harmonic block schedule, DyadicRatCore tolerance row, tail comparison ledger, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8127.1, Definition 8127.2, and Definition 8127.3 seed the finite harmonic-block condensation route from RealSeries data through dyadic block scheduling, regular rational readback, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationHarmonicBlock}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite sums, quotient series equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, block schedule exactness, dyadic tolerance exactness, tail comparison ledger exposure, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationHarmonicBlockUp.

Chapter 8128

A Concrete Naming Certificate for $\mathsf{SchauderBasisProjection}^{\uparrow}$

Following Schauder and Banach basis theory, the $\mathsf{SchauderBasisProjection}^{\uparrow}$ packet records finite coordinate projections licensed by displayed Schauder basis data. It sits after the basis packet of chapter 3669, the bounded coordinate readback of chapter 7494, the vector-space carrier of chapter 47, the norm row of chapter 89, the Banach completion surface of chapter 90, the regular rational scalar route of chapter 301, and the terminal real-name seal of chapter 38. The certificate names the projection window and its norm-controlled finite sum without invoking Hamel bases, arbitrary dual vectors, Hahn–Banach extension, quotient functionals, or choice.

Definition 8128.1 (Schauder basis projection carrier)**.** *A* $\mathsf{SchauderBasisProjection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (B, I, Q, C, V, N, R, H, T, S, L)$$

with the following displayed rows:

1. *B is the* $\mathsf{SchauderBasis}^{\uparrow}$ *source row naming the basis-vector stream, partial-sum route, coordinate requests, tail estimates, and reconstruction data.*
2. *I is the finite index-window row, recording the initial segment or finite coordinate set on which the projection is read.*
3. *Q is the* $\mathsf{CoordinateFunctional}^{\uparrow}$ *row family for the displayed coordinate reads licensed by B and indexed by I.*
4. *C is the* $\mathsf{RegSeqRat}^{\uparrow}$ *coefficient row, naming the rational scalar approximants used by the coordinate reads in Q.*
5. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row naming finite linear-combination syntax, vector addition, scalar action, and the zero vector used to assemble the projected vector.*
6. *N is the* $\mathsf{Norm}^{\uparrow}$ *and* $\mathsf{Banach}^{\uparrow}$ *budget row, recording the bound that treats the finite projection as a norm-controlled operation on the displayed Banach-space carrier.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the projection norm estimate, tail estimate, and completion-facing tolerance.*
8. *H records componentwise* hsame *transport for the Schauder source, index window, coordinate functional rows, coefficient names, vector operations, norm and Banach budget, real readback, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a projection request through B, I, Q, C, V, N, R.*
10. *S records* Pkg *provenance over* $\mathsf{SchauderBasisProjection}^{\uparrow}$, $\mathsf{SchauderBasis}^{\uparrow}$, $\mathsf{CoordinateFunctional}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{SchauderBasisProjection}^{\uparrow}}$ *row.*

The classifier compares packets only through $B, I, Q, C, V, N, R, H, T, S, L$. It has no coordinate for a Hamel basis selector, an arbitrary dual-space element, a Hahn–Banach extension, a quotient functional, countable choice, unconditional convergence, or a projection outside the displayed finite window.

Theorem 8128.2 (Schauder basis projection NameCert obligations)**.** *For every accepted* $\mathsf{SchauderBasisProjection}^{\uparrow}$ *carrier $P = (B, I, Q, C, V, N, R, H, T, S, L)$, the local* $\mathsf{NameCert}_{\mathsf{SchauderBasisProjection}^{\uparrow}}$ *surface consists exactly of carrier admission, Schauder basis source exposure through B, finite window exposure through I, coordinate-functional exposure through Q, regular rational coefficient exposure through C, vector assembly through V, norm and Banach budget exposure through N, real readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through T,* Pkg *provenance through S, and local naming through L.*

Proof. Carrier admission is projection from Definition 8128.1. The accepted packet exposes exactly the tuple $B, I, Q, C, V, N, R, H, T, S, L$.

The analytic route is fixed by B, I, Q, C, V, N, R. The Schauder row supplies the basis source, the index row supplies the finite projection window, the coordinate-functional rows supply the licensed coefficient reads, the regular rational row names the scalar approximants, the vector row assembles the finite linear combination, and the norm and real rows display the boundedness and tolerance data.

The structural rows H, T, S, L preserve that same route under transport, replay, provenance, and naming. Since no carrier coordinate stores a Hamel selector, arbitrary dual vector, Hahn–Banach extension, quotient functional, choice schedule, unconditional convergence proof, or off-window projection, none of those objects becomes a local NameCert obligation. □

Theorem 8128.3 (Schauder basis projection real completion handoff)**.** *Let $P = (B, I, Q, C, V, N, R, H, T, S, L)$ be an accepted* $\mathsf{SchauderBasisProjection}^{\uparrow}$ *carrier. A downstream Real or completion-facing consumer may read the finite projection only after the* $\mathsf{SchauderBasis}^{\uparrow}$ *source row B, the* $\mathsf{CoordinateFunctional}^{\uparrow}$ *rows Q, the coefficient names C, the vector assembly row V, the norm and Banach budget row N, and the real readback row R have all been exposed along the same transport and replay route. The handoff exports a bounded finite coordinate projection and its displayed tolerance data, but no Hamel basis, no arbitrary functional, no quotient functional, no Hahn–Banach extension, and no choice-selected projection.*

Proof. Begin with a projection request. The finite window I determines which coordinate rows in Q are read from the Schauder source B, and the regular rational row C names the scalar approximants for those reads.

Assemble the projected vector through V. The vector-space row supplies the finite linear-combination syntax for the selected basis vectors and coefficients, while N supplies the norm and Banach budget that lets the projection be treated as a bounded finite operation.

Expose the Real-facing estimate through R. The real readback row names the norm and tolerance data that a completion consumer receives, and the transport, replay, provenance, and local naming rows H, T, S, L keep that read tied to the same finite packet.

Therefore the completion-facing handoff is exactly the displayed route through $B, I, Q, C, V, N, R, H, T, S, L$. The omitted principles have no carrier coordinate, so they cannot be exported by the projection certificate. □

Falsifiable prediction: Every accepted $\mathsf{SchauderBasisProjection}^{\uparrow}$ projection read factors through a SchauderBasis source row, finite index window, CoordinateFunctional rows, RegSeqRat coefficient names, VecSpace finite linear-combination syntax, Norm and Banach budget rows, Real tolerance readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Independence witness: schauder-basis, coordinate-functional, vecspace, norm, banach, regseqrat, real: no listed sibling supplies the whole packet $P = (B, I, Q, C, V, N, R, H, T, S, L)$, because the projection carrier binds a displayed Schauder source, finite window, coordinate reads, scalar names, vector assembly, norm budget, completion-facing Real tolerance, transport, replay, provenance, and local naming in one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderBasisProjection}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderBasisProjection}^{\uparrow}$ packet is generated from a SchauderBasis source row, finite index-window row, CoordinateFunctional row family, RegSeqRat coefficient row, VecSpace finite linear-combination row, Norm and Banach budget row, Real readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderBasisProjection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8128.1, Definition 8128.2, and Definition 8128.3 seed the finite coordinate-projection route licensed by displayed Schauder basis and coordinate-functional data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderBasisProjection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hamel bases, arbitrary dual vectors, Hahn–Banach extension, quotient functionals, countable choice, unconditional convergence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, coordinate-readback exactness, vector assembly, norm-budget exposure, Real completion handoff, transport, replay, provenance, and local naming for the displayed Schauder basis projection packet.

Chapter 8129

A Concrete Naming Certificate for $\mathsf{SearchableSpace}^{\uparrow}$

Following Escardo on searchable spaces and selection functionals, the $\mathsf{SearchableSpace}^{\uparrow}$ packet records the finite route by which a displayed decidable predicate is inspected through a search schedule before a witness row or compact-search handoff is exposed. It sits after the stream-window route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the fan-functional selector surface of chapter 1525, the compact metric finite-net surface of chapter 129, the searchable compact sibling of chapter 6618, and the terminal real-name seal of chapter 38. The packet names searchability as finite NameCert data; it is not an ambient choice functional, not an open-cover compactness theorem, and not a selected real outside the displayed route.

Definition 8129.1 (Searchable space carrier)**.** *A* $\mathsf{SearchableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, Q, F, K, H, C, P, N)$$

with the following displayed rows:

1. *W is the search schedule row, read through* $\mathsf{StreamName}^{\uparrow}$ *finite windows and bounded fan-functional branches when the source is fan-like.*
2. *Q is the predicate readback row, opening only the displayed decidable predicate observations requested by W.*
3. *F is the finite witness row, recording the retained candidate list, the accepted witness when one is displayed, and the refusal of a hidden global selector.*
4. *K is the compact-search handoff row, allowing* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SearchableCompact}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *consumers to read the same finite search route.*
5. *H records componentwise* hsame *transport for W, Q, F, K and the structural rows.*
6. *C records displayed* Cont *replay from schedule to predicate readback, from predicate readback to finite witness, and from finite witness to compact-search handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{SearchableSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SearchableCompact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{SearchableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through W, Q, F, K, H, C, P, N. It has no coordinate for a detached selection functional, an unbounded search over an ambient set, quotient equality of predicates, open-cover compactness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8129.2 (Searchable space NameCert obligations)**.** *For every accepted* $\mathsf{SearchableSpace}^{\uparrow}$ *carrier*

$$S = (W, Q, F, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SearchableSpace}^{\uparrow}}$ *surface consists exactly of five obligation rows: schedule exposure through W, predicate readback through Q, finite witness or refusal exposure through F, compact-search handoff through K, and structural certification through H, C, P, N.*

Proof. Project the displayed carrier of Definition 8129.1. The schedule row W is the only source of search windows, so every predicate read is bounded by the displayed stream or fan-functional route.

Read the predicate and witness rows next. The predicate row Q exposes only the decidable observations requested by W, while F records either the retained finite witness boundary or the refusal of a hidden selector.

Now hand the finite search route to compact and real-facing consumers through K. This handoff may cite $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SearchableCompact}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, but it carries only the same schedule, predicate, and witness rows.

Finally H, C, P, N transport, replay, source, and name the packet. Since the carrier has no coordinate for detached selection, unbounded ambient search, quotient predicate equality, open-cover compactness, countable choice, or ambient real completeness, the five listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{SearchableSpace}^{\uparrow}$ consumer read must display the search schedule, predicate readback, finite witness row, compact-search handoff, transport, replay, provenance, and local naming before consuming a selected witness.

Independence witness: streamname, regseqrat, dyadicratcore, fanfunctional, compactmetric, searchable-compact, real: none is bijective to $\mathsf{SearchableSpace}^{\uparrow}$ because this carrier binds predicate readback and finite witness exposure to the same search schedule, compact handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SearchableSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SearchableSpace}^{\uparrow}$ packet is generated from a search schedule, predicate readback rows, finite witness or refusal rows, compact-search handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SearchableSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8129.1 and Definition 8129.2 seed the finite searchable-space route over $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FanFunctional}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SearchableCompact}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SearchableSpace}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.SearchableSpaceUp`

Bridge status: none

Not claimed: This chapter does not close detached selection functionals, unbounded ambient search, quotient equality of predicates, open-cover compactness, countable choice, Lean verification of the NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule-bounded predicate readback, finite witness exactness, compact-search handoff, transport and replay stability, and local NameCert provenance for BEDC.Derived.SearchableSpaceUp.

Chapter 8130

A Concrete Naming Certificate for $\mathsf{BishopUniformGauge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopUniformGauge}^{\uparrow}$ packet records the finite gauge-radius object used to pass from Bishop uniform-structure data to finite cover and tagged-partition consumers. It sits after the dyadic arithmetic surface of chapter 291, the terminal real-name surface of chapter 38, the real uniform-structure surface of chapter 1624, the Cousin cover source of chapter 3426, and the tagged-partition consumer of chapter 7449. The packet names a finite radius gauge carrier only; it is not an open-cover compactness theorem, a selected limiting process, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8130.1 (Bishop uniform gauge carrier)**.** *A* $\mathsf{BishopUniformGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (D, R, U, Q, F, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, listing the dyadic radius codes and comparison tests inspected by the gauge.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *source row, exposing the real-name endpoints or centers on which the gauge is read.*
3. *U is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *row, carrying entourage and uniform-neighborhood data in a Bishop-readable form.*
4. *Q is the local gauge-radius row. For each displayed source point and entourage request, it stores a positive dyadic radius history admitted by the uniform-structure row.*
5. *F is the* $\mathsf{CousinCover}^{\uparrow}$ *handoff row, reading the displayed gauge radii as local cover cells without turning them into an open-cover compactness proof.*
6. *T is the* $\mathsf{TaggedPartition}^{\uparrow}$ *consumer row, available only after the finite gauge cells have been named.*
7. *H records componentwise* hsame *transport for dyadic tolerances, real source rows, uniform-structure rows, gauge radii, Cousin cover handoff, tagged-partition consumption, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an entourage request through dyadic radius choice, Cousin cover handoff, and tagged-partition consumption.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopUniformGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CousinCover}^{\uparrow}$, $\mathsf{TaggedPartition}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformGauge}^{\uparrow}}$ *row.*

The classifier compares accepted gauges only through $D, R, U, Q, F, T, H, C, P, N$. It has no coordinate for host open-cover compactness, selected limits, countable choice, quotient cover equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8130.2 (Bishop uniform gauge NameCert obligations)**.** *For every accepted* $\mathsf{BishopUniformGauge}^{\uparrow}$ *carrier*

$$G = (D, R, U, Q, F, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopUniformGauge}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission through D, real source exposure through R, Bishop uniform-structure admission through U, displayed positive gauge-radius exactness through Q, Cousin cover handoff through F, tagged-partition consumption through T, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. No obligation is discharged by host open-cover compactness, selected limits, countable choice, quotient cover equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8130.1. The tuple displays the dyadic tolerance row, real source row, uniform-structure row, gauge-radius row, Cousin cover handoff, tagged-partition consumer, transport, replay, provenance, and local naming rows.

The gauge-radius row is downstream of the uniform-structure row. The row D supplies dyadic radius codes, R supplies the finite real-name surface being inspected, and U supplies the Bishop uniform-neighborhood request.

The row Q then records the positive radius histories admitted for that displayed request. Because Q is a finite carrier row, it does not select a limiting process, quantify over an ambient open cover, or call a countable-choice schedule.

Finally F, T, H, C, P, N export, consume, transport, replay, source, and name exactly the same finite route. Since the excluded compactness, choice, quotient, limit, and completeness objects are absent from the carrier, they cannot appear in the local NameCert obligations. □

Theorem 8130.3 (Bishop uniform gauge finite-cover route)**.** *Every* $\mathsf{CousinCover}^{\uparrow}$ *or* $\mathsf{TaggedPartition}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopUniformGauge}^{\uparrow}$ *packet reads gauge data only through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{RealUniformStructure}^{\uparrow},\ Q,\ \mathsf{CousinCover}^{\uparrow},\ \mathsf{TaggedPartition}^{\uparrow}.$$

The route exports finite Bishop gauge-radius data for cover and partition consumers; it exports no open-cover compactness proof, selected limiting process, countable-choice selector, quotient cover equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the accepted carrier $G = (D, R, U, Q, F, T, H, C, P, N)$. A cover-facing read must expose the dyadic tolerance row D, the real source row R, and the Bishop uniform-structure row U before any local gauge radius is visible.

Use the gauge-radius row Q. This row stores the displayed positive radius histories for the finite source surface, so a downstream consumer cannot replace the route by an unrecorded open-cover compactness argument or an external selector.

The Cousin cover row F reads those radii as local cover cells, and the tagged-partition row T is downstream of that handoff. Componentwise transport and replay through H, C preserve the same order, while P, N source and name it.

Thus every cover or partition read factors through the finite Bishop uniform-gauge route. The excluded compactness, limit, choice, quotient, and completeness principles have no carrier row from which to enter. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformGauge}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopUniformGauge}^{\uparrow}$ packet is generated from dyadic tolerance rows, Real source rows, RealUniformStructure rows, positive gauge-radius rows, CousinCover handoff, TaggedPartition consumption, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformGauge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8130.1, Definition 8130.2, and Definition 8130.3 seed the finite Bishop uniform-gauge route for cover and tagged-partition consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformGauge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host open-cover compactness, selected limiting processes, countable choice, quotient cover equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic tolerance admission, Real source exposure, RealUniformStructure admission, gauge-radius exactness, CousinCover handoff, TaggedPartition consumption, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformGaugeUp.

Chapter 8131

A Concrete Naming Certificate for $\mathsf{BishopCompletionReflector}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopCompletionReflector}^{\uparrow}$ packet records the finite reflector data that sends a regular Cauchy presentation into its separated completion object. It sits after the regular rational sequence surface of chapter 301, the terminal real-name seal of chapter 38, and the Cauchy completion criterion of chapter 1476. The packet names a finite completion reflector only; it does not import quotient completions, selected limits, choice sequences, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Definition 8131.1 (BishopCompletionReflector carrier)**.** *A* $\mathsf{BishopCompletionReflector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, S, E, A, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the regular Cauchy input row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *finite windows and the Cauchy criterion route.*
2. *S is the separated identity row, recording when two regular Cauchy inputs have the same separated completion readback.*
3. *E is the completion seal row, exposing the terminal* $\mathsf{Real}^{\uparrow}$ *name reached from the regular Cauchy input.*
4. *A is the reflector arrow row, sending the accepted regular Cauchy input to the separated completion seal.*
5. *L is the finite ledger recording the order in which regular input, separated identity, completion seal, and reflector arrow are consumed.*
6. *H records componentwise* hsame *transport for Q, S, E, A, L, C, P, N.*
7. *C records displayed* Cont *replay for the same finite route.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionReflector}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionReflector}^{\uparrow}}$ *row.*

Two accepted carriers are classified together only by the displayed rows $Q, S, E, A, L, H, C, P, N$. The classifier has no coordinate for quotient real equality, a chosen completion point, countable choice, host completion functoriality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8131.2 (BishopCompletionReflector NameCert obligations)**.** *For every accepted* BishopCompletionReflec *carrier* $R = (Q, S, E, A, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionReflector}^{\uparrow}}$ *surface consists exactly of regular Cauchy input admission through* Q*, separated identity exposure through* S*, completion seal exposure through* E*, reflector arrow admission through* A*, finite ledger order through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. No obligation is supplied by quotient completion semantics, selected limits, countable choice, host functorial completions, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 8131.1. The tuple displays the regular input, separated identity, completion seal, reflector arrow, ledger, transport, replay, provenance, and local naming rows.

The local NameCert reads these rows in the order recorded by L. Regular Cauchy input is consumed through Q, separated identity through S, terminal completion naming through E, and the reflector arrow through A.

Transport and replay are supplied by H and C, while P and N record provenance and local naming. Since the carrier has no coordinate for quotient completion semantics, selected limits, countable choice, host functorial completions, or ambient Real completeness, the listed rows exhaust the local obligation surface. □

Theorem 8131.3 (BishopCompletionReflector universal arrow)**.** *Every accepted* $\mathsf{BishopCompletionReflector}^{\uparrow}$ *packet exports a finite universal-arrow route from regular Cauchy input to separated completion readback:*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{CauchyCompletionCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The route states that a completion-facing consumer must read the regular Cauchy input, separated identity, completion seal, reflector arrow, ledger, transport, replay, provenance, and local naming rows before treating the reflected object as sealed. It does not assert a quotient universal property, choose a limit representative, or use countable choice.

Proof. Start from an accepted carrier $R = (Q, S, E, A, L, H, C, P, N)$. The source of the arrow is the regular Cauchy input row Q, and the target is the completion seal E read after the separated identity row S.

The reflector arrow row A records the finite handoff from Q through S to E. The ledger L fixes the order of this handoff, so the consumer cannot inspect the terminal seal before the regular input and separated identity rows have been displayed.

The structural rows H, C, P, N transport, replay, name, and package the same route. Because no accepted row stores quotient completion semantics, selected representatives, choice schedules, or host completeness, the universal arrow is exactly the finite BEDC reflector route stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionReflector}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopCompletionReflector}^{\uparrow}$ packet is generated from regular Cauchy input, separated identity, completion seal, reflector arrow, finite ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopCompletionReflector}^{\uparrow}}$, seed)

Scope closed: Definition 8131.1, Definition 8131.2, and Definition 8131.3 record the seed reflector carrier, local NameCert obligation surface, and finite universal-arrow route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopCompletionReflector}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion semantics, selected limits, countable choice, host functorial completions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked regular Cauchy input admission, separated identity exposure, completion seal exposure, reflector arrow admission, ledger order, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionReflectorUp.

Chapter 8132

A Concrete Naming Certificate for $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$

Following Bishop and Bridges and Kelley, the $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ packet records a family-level Cauchy route whose members share one displayed finite control surface before any completion-facing consumer reads a Real seal. It sits between the subbasis generation of chapter 4232, the filter-limit basis of chapter 3862, the stream-window schedule of chapter 126, the regular rational handoff of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real carrier of chapter 38. The packet names uniform Cauchy behavior across a displayed family; it is not a quotient filter, not a selected pointwise limit, and not an appeal to countable choice.

Definition 8132.1 (Uniformly Cauchy filter family carrier)**.** *A* $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, B, L, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite family index schedule naming the members currently visible to the certificate.*
2. *B is the* $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ *generation row, recording the subbasic filter requests shared by the visible family.*
3. *L is the* $\mathsf{FilterLimitBasis}^{\uparrow}$ *row that exposes only the basis requests through which family convergence is tested.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to read the same request across the indexed family.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational handoff for the displayed windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the common dyadic thresholds and comparison rows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *completion-facing seal row available after the shared subbasis, limit-basis, stream, regular-rational, and dyadic rows have been displayed.*
8. *H stores componentwise* hsame *transport for the family index, subbasis, limit-basis, stream, handoff, dyadic, seal, continuation, provenance, and naming rows.*
9. *C stores displayed* Cont *replay from the family index to the subbasis and limit-basis rows, from those rows to stream windows and regular-rational handoff, and from the dyadic tolerance ledger to the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$, $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eleven rows. It has no coordinate for quotient filters, selected pointwise limits, countable-choice enumeration of members, ambient completeness, or host real equality.

Theorem 8132.2 (Uniformly Cauchy filter family NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ *carrier* $U = (I, B, L, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilterFamily}}$ *surface consists exactly of five obligations:*

1. *family-index exposure through the finite schedule I;*
2. *shared subbasis generation through B and limit-basis testing through L;*
3. *uniform stream-window and regular-rational handoff through S and R;*
4. *common dyadic tolerance accounting through D before the Real seal row E is visible;*
5. *structural transport, continuation replay, provenance, and local naming through H, C, P, N.*

Proof. Project the displayed carrier of Definition 8132.1. The family index I is the only visible source of members, so every family read is bounded by the same finite schedule.

Read the subbasis and limit-basis rows next. The row B generates the shared Cauchy filter requests, while L records the basis tests through which those requests are observed. These rows connect the family route to $\mathsf{CauchyFilterSubbasis}^{\uparrow}$ and $\mathsf{FilterLimitBasis}^{\uparrow}$ without adding a quotient filter.

Now pass to the stream and rational rows. The schedule S and handoff R make the same request visible through finite windows and regular rational data, and the dyadic ledger D supplies the common tolerance route before E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for selected pointwise limits, countable-choice enumeration, host equality, or ambient completeness, the five listed obligations exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ consumer read must display the family index schedule, shared Cauchy subbasis, filter-limit basis, stream windows, regular rational handoff, dyadic tolerance ledger, Real seal row, transport, replay, provenance, and local naming before consuming a family-level completion route.

Independence witness: cauchy-filter-subbasis, filterlimitbasis, streamname, regseqrat, dyadicratcore, real: none is bijective to $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ because this carrier binds a shared family index and uniform tolerance route to the same subbasis, limit-basis, stream, rational, dyadic, seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}$ packet is generated from a finite family index schedule, shared Cauchy filter subbasis, filter-limit basis tests, stream windows, regular rational handoff, dyadic tolerance ledger, Real seal row, componentwise transport, displayed continuation replay, package provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}}$, seed)

Scope closed: Definition 8132.1 and Definition 8132.2 seed the family-level uniform Cauchy route over $\mathsf{CauchyFilterSubbasis}^{\uparrow}$, $\mathsf{FilterLimitBasis}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformlyCauchyFilterFamily}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected pointwise limits, countable-choice enumeration, ambient completeness, host real equality, Lean verification of the NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared subbasis generation, limit-basis testing, uniform window handoff, dyadic tolerance accounting, transport and replay stability, and local NameCert provenance for BEDC.Derived.UniformlyCauchyFilterFamilyUp.

Chapter 8133

A Concrete Naming Certificate for $\mathsf{ModulusToRegularCauchy}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ packet records the finite route from an explicit Cauchy modulus schedule to a regular Cauchy rational name and then to the terminal real-name seal. It sits over the modulus schedule of chapter 292, the finite stream-window interface of chapter 126, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet is a finite Real and Completion bridge from schedules to regular names; it does not import quotient equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8133.1 (Modulus-to-regular-Cauchy carrier)**.** *A* $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CauchyModulus}^{\uparrow}$ *schedule row assigning every requested regular precision to a finite source-window request.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the source observations named by S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that checks the scheduled window against the requested dyadic error budget.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row assembled from S, W, D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the regular readback row has been displayed.*
6. *H records componentwise* hsame *transport for the schedule, window, dyadic tolerance, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Real and Completion consumer request through S, W, D, R, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{ModulusToRegularCauchy}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusToRegularCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, a chosen completed limit, countable choice, a host Cauchy-completion operator, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8133.2 (Modulus-to-regular-Cauchy NameCert obligations)**.** *For every accepted* ModulusToRegularCauch *carrier*

$$M = (S, W, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusToRegularCauchy}^{\uparrow}}$ *surface consists exactly of Cauchy-modulus schedule admission through S, finite window exposure through W, dyadic tolerance checking through D, regular rational readback through R, terminal real-name sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8133.1. The schedule row S is the only coordinate that assigns requested precisions to finite source-window requests, and the window row W is the only coordinate that exposes the corresponding source observations.

The dyadic row D checks those observations against the requested tolerance. The regular rational row R is therefore downstream of S, W, D, and the terminal real-name seal E is downstream of R.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no quotient-equality coordinate, selected-limit coordinate, countable-choice schedule, host completion operator, or ambient completeness field, the listed rows exhaust the local NameCert surface. □

Theorem 8133.3 (Modulus-to-regular-Cauchy window induction)**.** *Every finite precision-window read exported by an accepted* $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ *packet is obtained by induction over the requests named by the* $\mathsf{CauchyModulus}^{\uparrow}$ *row S: each step exposes one* $\mathsf{StreamName}^{\uparrow}$ *window row, checks the corresponding* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, extends the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, and only then permits the* $\mathsf{Real}^{\uparrow}$ *seal row to be read. The induction exports no quotient stream equality, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Proceed by induction over the displayed finite request window. The empty window exposes no source observation and therefore has no regular readback or Real seal to export.

For a successor window, read the next request from the modulus schedule row S. The stream window row W supplies exactly the finite observations demanded by that request.

Now consume the dyadic tolerance row D. Once the scheduled observations meet the requested dyadic budget, the regular rational readback row R is extended for that finite stage.

Finally use H, C, P, N to transport, replay, source, and name the same stage before the terminal seal E is read. Because no excluded principle is a row of the carrier, the induction remains a finite schedule-to-regular-name construction rather than a quotient, selector, choice, or completeness argument. □

Falsifiable prediction: Every accepted $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ read exposes the CauchyModulus schedule row, StreamName finite-window row, DyadicRatCore tolerance row, RegSeqRat readback row, RealUp seal row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a Real and Completion consumer may use the regular name.

Independence witness: cauchymodulus, streamname, dyadicratcore, regseqrat, real: $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a modulus schedule, finite window observations, dyadic tolerance checks, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one finite bridge.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusToRegularCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ModulusToRegularCauchy}^{\uparrow}$ packet is generated from a CauchyModulus schedule row, a StreamName finite-window row, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ModulusToRegularCauchy}\uparrow}$, seed)

Scope closed: Definition 8133.1, Definition 8133.2, and Definition 8133.3 seed the finite schedule-to-regular-Cauchy bridge for the L10 Real and Completion route.

Formal verification: FormalStatus(NameCert$_{\text{ModulusToRegularCauchy}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host Cauchy completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, schedule exposure, finite-window exactness, dyadic tolerance checking, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ModulusToRegular

Chapter 8134

A Concrete Naming Certificate for MetaCICResidualJoinMatrix$^{\uparrow}$

The MetaCICResidualJoinMatrix$^{\uparrow}$ packet realizes the residual-substitution conditional boundary of section 9378.3 as a finite matrix of retained premise rows, local residual branches, candidate joins, and audit consumers. It sits beside the parallel-diamond frontier of chapter 4238, the finite-window confluence packet of chapter 6027, the residual local-join packet of chapter 5126, the candidate-normalization confluence handoff of chapter 5547, and the confluence audit packet of chapter 735. The matrix is a concrete NameCert object for the confluence audit boundary; it is not an unconditional confluence theorem.

Definition 8134.1 (MetaCIC residual-join matrix carrier)**.** *A* MetaCICResidualJoinMatrix$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (P, F, L, R, K, S, A, O, H, C, G, N)$$

with the following displayed rows:

1. *P is the residual-substitution premise row retained by the confluence audit boundary.*
2. *F is the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *row exposing the finite frontier of local peaks, residual premises, and obstruction rows.*
3. *L and R are the left and right residual-branch rows, each read through* ParallelDiamondResidual$^{\uparrow}$ *data.*
4. *K is the finite candidate-join row, recording the proposed common target and the branch-local routes to it.*
5. *S is the finite-window confluence row, read through* FiniteWindowConfluence$^{\uparrow}$ *before any matrix row is exported.*
6. *A is the candidate-normalization confluence handoff row, read through* MetacicCandidateNormalizationConfluence *when normalization-facing consumers inspect the same matrix.*
7. *O is the confluence-audit consumer row, read through* MetaCICConfluenceAuditPacket$^{\uparrow}$ *after P, F, L, R, K, S, A remain visible.*
8. *H records componentwise* hsame *transport for premise, frontier, residual-branch, candidate-join, finite-window, handoff, audit-consumer, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a confluence query through $P, F, L, R, K, S, A, O, H$.*

10. *G is the* Pkg *provenance over* MetaCICResidualJoinMatrix$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, FiniteWindowConfluence$^{\uparrow}$, ParallelDiamondResidual$^{\uparrow}$, MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$, MetaCICConfluenceAuditPacket$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MetaCICResidualJoinMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, F, L, R, K, S, A, O, H, C, G, N$. It has no coordinate for premise-free parallel diamond, unrestricted closed Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, global normalization, or kernel consistency.

Theorem 8134.2 (MetaCIC residual-join matrix NameCert obligations)**.** *For every accepted* MetaCICResidualJoinMatrix$^{\uparrow}$ *carrier*

$$J = (P, F, L, R, K, S, A, O, H, C, G, N),$$

the local NameCert$_{\text{MetaCICResidualJoinMatrix}^{\uparrow}}$ *surface consists exactly of residual-substitution premise retention through P, frontier exposure through F, two residual-branch exposures through L, R, candidate-join exposure through K, finite-window confluence exposure through S, candidate-normalization confluence handoff through A, confluence-audit consumption through O, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through G, and local naming through N.*

Proof. Project the carrier of Definition 8134.1. Its matrix rows are P, F, L, R, K, S, A, O, and its structural rows are H, C, G, N.

The retained premise row P is read before the frontier row F can be consumed. The two residual rows L, R and the candidate row K then record the local join matrix under the same finite frontier.

The finite-window row S and candidate-normalization handoff row A keep the matrix bounded for confluence and normalization-facing consumers. The audit row O receives the matrix only after those rows remain visible.

Finally H, C, G, N transport, replay, source, and name the same packet. Since no excluded global endpoint is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8134.3 (MetaCIC residual-join matrix candidate-diamond boundary)**.** *Every candidate-diamond consumer of an accepted* MetaCICResidualJoinMatrix$^{\uparrow}$ *packet must expose the residual-substitution premise row P, the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *row F, both* ParallelDiamondResidual$^{\uparrow}$ *branch rows L, R, the candidate-join row K, the* FiniteWindowConfluence$^{\uparrow}$ *row S, the* MetacicCandidateNormalization *row A, and the* MetaCICConfluenceAuditPacket$^{\uparrow}$ *row O before any local diamond read is public. The read is a bounded audit-matrix route, not a premise-free parallel diamond or closed Church–Rosser theorem.*

Proof. Apply the NameCert obligations of Definition 8134.2. They force every accepted matrix read through the retained premise, frontier, two residual branches, candidate join, finite window, normalization handoff, audit consumer, and structural rows.

Read the residual side first. The row P keeps the substitution premise visible, while F, L, R, K display the finite local peak, its two residual descendants, and the candidate common target.

Read the bounded-audit side next. The row S restricts the read to a finite confluence window, A records the candidate-normalization handoff for the same matrix, and O supplies the confluence-audit consumer row.

The rows H, C, G, N only preserve that displayed route. Therefore the matrix cannot be cited as a premise-free parallel diamond, closed Church–Rosser theorem, subject-reduction theorem,

evaluator equality, quotient syntax equality, global normalization theorem, or kernel-consistency certificate. □

Falsifiable prediction: If the residual-substitution premise row P is omitted, the $\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}$ classifier rejects the matrix even when the frontier, residual-branch, candidate-join, finite-window, candidate-normalization handoff, and confluence-audit rows are present.

Independence witness: metacic-parallel-diamond-frontier, finite-window-confluence, parallel-diamond-residual, metacic-candidate-normalization-confluence-handoff, metacicconfluenceauditpacket: none is bijective to $\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}$ because this packet jointly carries retained residual-substitution premise data, frontier rows, two residual branches, one candidate join, finite-window confluence, candidate-normalization handoff, confluence-audit consumption, transport, replay, provenance, and local naming.

The Lean file `lean4/BEDC/Derived/MetaCICResidualJoinMatrixUp/TasteGate.lean` later supplies explicit Nontrivial $\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}$ and FieldFaithful $\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}$ instances, with field-projection witnesses keeping $P, F, L, R, K, S, A, O, H, C, G, N$ separate.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}$ packet is generated from a retained residual-substitution premise row, a parallel-diamond frontier row, two residual branch rows, a candidate-join row, a finite-window confluence row, a candidate-normalization confluence handoff row, a confluence-audit consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}}$, obligation)

Scope closed: Definition 8134.1, Definition 8134.2, and Definition 8134.3 expose the finite carrier rows, NameCert duties, and candidate-diamond boundary that form the residual-join matrix obligation surface for MetaCIC confluence audit boundaries.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinMatrix}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close premise-free parallel diamond, unrestricted closed Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, global normalization, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, premise retention, frontier exposure, residual-branch exposure, candidate-join exposure, finite-window confluence exposure, candidate-normalization handoff, audit-consumer non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualJoinMatrixUp.

Chapter 8135

A Concrete Naming Certificate for $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy completions and uniformly continuous extension, the $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$ packet records the finite modulus data by which a uniformly continuous map on displayed regular-Cauchy dense input extends to a separated complete target. It sits after the regular rational readback of chapter 301, the finite stream windows of chapter 126, the terminal real-name seal of chapter 38, the unit row of chapter 1527, the uniform-continuity surface of chapter 391, and the universal-property packet of chapter 2319. The packet names the completion-extension handoff as displayed BEDC rows; it does not quotient Cauchy names, select representatives, import countable choice, or use ambient completeness outside the target metric row.

Definition 8135.1 (RegularCauchyExtensionModulus carrier)**.** *A* $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (R, S, X, U, T, M, G, L, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row carrying the regular rational readback of the dense input name.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording exactly which source observations are inspected before an extension value is requested.*
3. *X is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the displayed regular Cauchy input.*
4. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row embedding the dense source into the completion-facing surface.*
5. *T is the separated target metric row, read through* $\mathsf{SeparatedMetric}^{\uparrow}$ *and the target's displayed complete-metric evidence.*
6. *M is the* $\mathsf{UniformContinuity}^{\uparrow}$ *modulus row for the source map on the displayed dense data.*
7. *G is the extension graph row, pairing completion-input windows with target values using only R, S, X, U, T, M.*
8. *L is the uniqueness row, comparing two extension graph rows over the same source, unit, target, and modulus data by separatedness of T.*

9. *H records componentwise* hsame *transport for $R, S, X, U, T, M, G, L, C, P, N$.*
10. *C records displayed* Cont *replay of dense-input reading, unit handoff, modulus use, graph construction, and uniqueness comparison.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, $\mathsf{SeparatedMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, S, X, U, T, M, G, L, H, C, P, N$. It has no coordinate for quotient completion equality, selected limits, host function equality, countable-choice schedules, or ambient completeness outside the displayed separated target metric row.

Theorem 8135.2 (RegularCauchyExtensionModulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$ *carrier $E = (R, S, X, U, T, M, G, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyExte}}$ *surface consists exactly of regular Cauchy source admission, finite stream-window inspection, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, Cauchy-completion unit handoff, separated target metric exposure, uniform-continuity modulus use, extension graph construction, separated uniqueness comparison, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Carrier exposure is projection from Definition 8135.1. The tuple displays the source name, inspected finite windows, terminal Real seal, completion unit, separated target metric, modulus, graph, uniqueness, transport, replay, provenance, and local naming rows.

The dense input is read through R, S, X, U. The regular rational row and stream windows are visible before the terminal Real seal and before the completion unit can be consumed by an extension request.

The target-facing part is read through T, M, G, L. The separated target metric supplies the comparison surface, the uniform-continuity modulus bounds how finite source windows determine target windows, the graph row records the extension values, and the uniqueness row compares graph rows only over the same displayed data.

The structural boundary is fixed by H, C, P, N. These rows transport, replay, source, and name the same finite packet, while the carrier lists no quotient completion equality, selected limit, host function equality, countable-choice schedule, or ambient completeness coordinate outside T. □

Theorem 8135.3 (RegularCauchyExtensionModulus factorization)**.** *Every extension consumer of an accepted* $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletionUnit}^{\uparrow} \longmapsto \mathsf{UniformContinuity}^{\uparrow},\ \mathsf{SeparatedMetric}^{\uparrow} \longmapsto \mathsf{BHist}$$

The consumer receives a finite extension graph and a separated uniqueness row only after the source regular Cauchy data, inspected stream windows, completion unit, target metric, and uniform-continuity modulus are displayed. It obtains no quotient completion equality, selected representative, host function equality, countable-choice schedule, or ambient completeness principle.

Proof. Begin with an extension request for an accepted carrier $E = (R, S, X, U, T, M, G, L, H, C, P, N)$. The request can first inspect only the regular rational source row R, the finite window row S, and the terminal seal row X.

The completion handoff is then forced through U. This row is the only displayed passage from the dense regular-Cauchy data to the completion-facing input, so the request cannot substitute a quotient representative or selected limit.

Next the request reads T, M, G, L. The target metric row supplies separated comparison, the modulus row explains how finite source windows control target windows, the graph row records the extension values, and the uniqueness row compares only graph rows over the same visible source, unit, target, and modulus data.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier row stores host function equality, countable-choice schedules, or an ambient completeness principle, every extension consumer factors through the displayed route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyExtensionModulus}^{\uparrow}$ packet is generated from RegSeqRat source data, StreamName finite windows, a RealUp seal, a CauchyCompletionUnit row, separated target metric evidence, a UniformContinuity modulus, an extension graph, separated uniqueness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8135.1, Definition 8135.2, and Definition 8135.3 seed the finite completion-extension route over regular Cauchy, stream, Real, completion-unit, uniform-modulus, separated-target, graph, uniqueness, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyExtensionModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient completion equality, selected representatives, host function equality, countable-choice schedules, or ambient completeness outside the displayed target metric row.

Upgrade path: Obligation closure requires checked carrier admission, finite-window inspection, unit handoff, uniform-modulus use, extension graph construction, separated uniqueness, transport replay, provenance nonescape, and local naming for BEDC.Derived.RegularCauchyExtensionModulusUp.

Chapter 8136

A Concrete Naming Certificate for $\mathsf{RegularCauchySubdivision}^{\uparrow}$

Following Bishop and Bridges, finite subdivision arguments for regular Cauchy data are useful only after the mesh, tolerance ledger, window reads, rational readback, and real-name seal are all visible as finite data. The $\mathsf{RegularCauchySubdivision}^{\uparrow}$ packet sits after the dyadic tolerance core of chapter 291, the finite stream interface of chapter 126, the regular rational sequence boundary of chapter 301, the terminal real-name seal of chapter 38, and the rational scaling route of chapter 465. It records a finite subdivision induction surface rather than a selected limit, a quotient real equality, or an ambient compactness theorem.

Definition 8136.1 (Regular Cauchy subdivision carrier)**.** *A* $\mathsf{RegularCauchySubdivision}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite subdivision mesh row, listing the inspected subintervals, endpoints, adjacency witnesses, and boundary cells;*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying the dyadic mesh width, endpoint tolerances, and local error budgets used on each mesh cell;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family, exposing the finite stream windows inspected on each subdivision cell;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, reading every inspected window as regular rational data over the displayed dyadic ledger;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the mesh, dyadic tolerance ledger, StreamName windows, and RegSeqRat readback rows have been displayed;*
6. *H records componentwise* hsame *transport for M, D, W, R, E, C, P, N;*
7. *C records displayed* Cont *replay for the subdivision route;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySubdivision}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyScale}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubdivision}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for selected limits, quotient real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8136.2 (Regular Cauchy subdivision NameCert obligations)**.** *For every accepted* RegularCauchySubdivisi *carrier* $S = (M, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySubdivision}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite mesh, mesh compatibility between adjacent cells, readback stability through the displayed* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows,* $\mathsf{Real}^{\uparrow}$ *seal nonescape through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The row M supplies the finite mesh and its adjacency witnesses, while D supplies the dyadic width and tolerance ledger used on every mesh cell.

Read the window and rational rows next. The family W exposes only finitely many StreamName windows, and R reads those windows as regular rational data over the same dyadic ledger. Mesh compatibility is therefore checked by comparing adjacent displayed rows, not by selecting a limit.

Finally replay the seal and structural rows. The row E is downstream of the mesh, tolerance, window, and readback data, while H, C, P, N only transport, replay, source, and name that same finite route. These projections exhaust the local NameCert obligations and leave no selected limits, quotient real equality, countable choice, open-cover compactness, or ambient completeness coordinate. □

Theorem 8136.3 (Regular Cauchy subdivision regular-window induction)**.** *Every induction over an accepted* $\mathsf{RegularCauchySubdivision}^{\uparrow}$ *packet is finite induction over the displayed mesh row* M*. The base cells read their tolerance data through* D*, their inspected windows through* W*, and their regular rational data through* R*; each adjacent step preserves the same* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* C*, provenance* P*, and local naming row* N*. Consequently the induction route exports only finite subdivision data and never exports selected limits, quotient real equality, countable choice, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Induct over the finite list of mesh cells carried by M. In the base cell, the tolerance ledger D, window family W, and readback row R provide the inspected regular Cauchy data before any Real-facing seal is available.

For an adjacent cell, use the mesh compatibility row inside M together with the dyadic ledger D. The next window read remains inside W, the regular rational read remains inside R, and the terminal seal is still the displayed row E.

The structural rows are copied componentwise along the induction. The rows H, C, P, N transport, replay, source, and name the same finite subdivision route, so the induction closes inside the carrier projections and cannot introduce selected limits, quotient real equality, countable choice, open-cover compactness, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySubdivision}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySubdivision}^{\uparrow}$ packet is generated from a finite subdivision mesh, dyadic tolerance ledger, StreamName window family, RegSeqRat readback rows, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySubdivision}^{\uparrow}}$, seed)

Scope closed: Definition 8136.1, Definition 8136.2, and Definition 8136.3 seed the finite subdivision induction route between regular rational windows and Real-name sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySubdivision}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close selected limits, quotient real equality, countable choice, open-cover compactness, ambient $\mathrm{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh compatibility, readback stability, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySubdivisionUp.

Chapter 8137

A Concrete Naming Certificate for $\mathsf{BoundedLipschitzDomain}^{\uparrow}$

Following Evans and Adams–Fournier, the $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ packet records the finite boundary-chart data needed before Sobolev trace, PDE boundary estimates, Lipschitz extension, and compact metric arguments may read a domain as bounded with Lipschitz boundary. It sits over the metric carrier of chapter 57, the topology carrier of chapter 88, the Lipschitz-function carrier of chapter 3762, the Lipschitz-modulus carrier of chapter 3724, the compact-metric carrier of chapter 129, and the terminal real-name seal of chapter 38. The packet names a finite boundary-domain certificate only; it does not import host open-set equality, selected boundary charts, quotient metric equality, countable choice, or ambient compactness.

Definition 8137.1 (Bounded Lipschitz domain carrier)**.** *A* $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (O, M, F, L, R, H, C, P, N)$$

with the following displayed rows:

1. *O is the open-set and topology row, naming the domain membership tests, boundary-neighbourhood windows, and local topology data read through* $\mathsf{Topology}^{\uparrow}$*.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row, naming the distance comparisons used by the boundedness and boundary-chart reads.*
3. *F is the finite boundary-chart cover row. Each chart names a displayed neighbourhood, a local coordinate window, and the finite overlap data needed to compare adjacent chart reads.*
4. *L is the Lipschitz constant and modulus row, read through* $\mathsf{LipschitzFunction}^{\uparrow}$ *and* $\mathsf{LipschitzModulus}^{\uparrow}$ *for every boundary chart and overlap comparison in F.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance row, recording the finite radius, height, and boundedness tolerances used by M, F, L before any real-valued boundary estimate is sealed.*
6. *H records componentwise* hsame *transport for the topology, metric, chart-cover, Lipschitz, tolerance, replay, provenance, and local certificate rows.*
7. *C records displayed* Cont *replay from a domain or boundary request through O, M, F, L, R, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedLipschitzDomain}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{LipschitzFunction}^{\uparrow}$*,* $\mathsf{LipschitzModulus}^{\uparrow}$*,* $\mathsf{CompactMetric}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{BoundedLipschitzDomain}^{\uparrow}}$ *row.*
The carrier predicate asserts that the finite chart cover in F covers the displayed boundary windows from O, that each chart is read with the Lipschitz data in L, that boundedness and chart tolerances are sealed through R, and that all downstream reads pass through H, C, P, N. It has no coordinate for host open-set equality, a selected atlas outside F, quotient metric equality, countable choice, or ambient compactness.

Theorem 8137.2 (Bounded Lipschitz domain NameCert obligations)**.** *For every accepted* $\mathsf{BoundedLipschitzDomain}$ *carrier $D = (O, M, F, L, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BoundedLipschitzDomain}^{\uparrow}}$ *surface consists exactly of carrier admission, displayed topology and open-set exposure through O, metric distance exposure through M, finite boundary-chart cover exposure through F, Lipschitz constant and modulus exposure through L, real tolerance sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows O, M, F, L, R are the only analytic coordinates, and they respectively expose the topology, metric, boundary-chart cover, Lipschitz data, and real tolerance data.

Read the structural rows next. The row H transports those analytic coordinates componentwise, C replays a domain or boundary request through the displayed route, P records the allowed sibling sources, and N names the local certificate.

Since the carrier contains no further coordinate, every NameCert obligation is one of the listed rows. Host open-set equality, selected atlases, quotient metric equality, countable-choice schedules, and ambient compactness cannot be exported by the packet. □

Theorem 8137.3 (Bounded Lipschitz domain finite-chart handoff)**.** *Every Sobolev trace, PDE boundary, Lipschitz extension, or compact metric consumer of an accepted* $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ *carrier must read the finite boundary-chart cover F after the topology and metric rows O, M and before the Lipschitz row L and real tolerance row R are consumed. The handoff route exposes only finite chart windows, finite overlap comparisons, Lipschitz constants and moduli, real tolerances, transport, replay, provenance, and local naming.*

Proof. Begin with a consumer request. The domain membership and boundary-neighbourhood data are read through O, and the distance comparisons needed by boundedness and chart windows are read through M.

The finite chart row F is then the only boundary-cover coordinate available to the consumer. Its overlap data are finite packet data, so a downstream trace, PDE, extension, or compactness read cannot replace them by a host atlas or selected cover.

After F is displayed, the Lipschitz constants and moduli in L and the real tolerances in R can be read. The structural rows H, C, P, N preserve the same finite route, so the handoff exports no host open-set equality, quotient metric equality, countable-choice schedule, or ambient compactness theorem. □

Falsifiable prediction: Every accepted $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ boundary read exposes topology, metric, finite boundary-chart cover, Lipschitz constant and modulus, Real tolerance, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: metric, topology, lipschitz-function, lipschitz-modulus, compactmetric, real: $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries displayed open-set topology rows, metric rows, finite boundary-chart cover rows, Lipschitz constant and modulus rows, Real tolerance rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedLipschitzDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ packet is generated from displayed open-set and topology rows, metric rows, finite boundary-chart cover rows, Lipschitz constant and modulus rows, Real tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedLipschitzDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8137.1, Definition 8137.2, and Definition 8137.3 seed the finite boundary-domain packet for bounded Lipschitz domains.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedLipschitzDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Sobolev trace, PDE regularity, Lipschitz extension, compactness, host open-set equality, selected boundary charts, quotient metric equality, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite boundary-chart cover exposure, Lipschitz constant and modulus exposure, Real tolerance sealing, transport, replay, provenance, and local naming for BEDC.Derived.BoundedLipschitzDomainUp.

Chapter 8138

A Concrete Naming Certificate for KolmogorovRieszCriterion$^{\uparrow}$

Following Kolmogorov and Riesz, the KolmogorovRieszCriterion$^{\uparrow}$ packet records the finite L10 compactness criterion by which translation tightness, compact-source control, equicontinuous sequence data, rational readback, and terminal real seals are named before any function-space compactness consumer may inspect the route. It sits after the compact metric source of chapter 129, the regular rational comparison surface of chapter 301, the terminal real-name seal of chapter 38, the shared-modulus sequence surface of chapter 4356, and the finite compactness route of chapter 3846. The criterion carrier names only displayed finite windows, translation-tightness rows, readback rows, and the Frechet–Kolmogorov handoff; it does not assert an ambient compact embedding theorem, selected subsequence, quotient function equality, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8138.1 (Kolmogorov-Riesz criterion carrier)**.** *A* KolmogorovRieszCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, Q, S, R, V, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the* CompactMetric$^{\uparrow}$ *source row whose finite net interface fixes the inspected compact metric support.*
2. *T is the finite translation-tightness row, listing the shifts, radii, and tolerance windows visible to the criterion request.*
3. *Q is the* EquicontinuousSequence$^{\uparrow}$ *row that supplies the shared sequence modulus consumed by compactness-facing reads.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row for inspected sequence entries, translation requests, and compact net cells.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for rational tolerance comparisons.*
6. *V is the* Real$^{\uparrow}$ *seal row for the displayed norm, distance, and translation estimates.*
7. *F is the* FrechetKolmogorovCompactness$^{\uparrow}$ *handoff row, packaging M, T, Q, S, R, V as one L10 finite compactness criterion.*
8. *H records componentwise* hsame *transport for compact metric, translation-tightness, equicontinuity, window, readback, Real, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a compactness request through the same finite rows.*
10. *P is the* Pkg *provenance over* KolmogorovRieszCriterion$^{\uparrow}$, CompactMetric$^{\uparrow}$, EquicontinuousSequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, FrechetKolmogorovCompactness$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{KolmogorovRieszCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, T, Q, S, R, V, F, H, C, P, N$.

Theorem 8138.2 (Kolmogorov-Riesz criterion NameCert obligations)**.** *For every accepted* KolmogorovRieszCriterio *carrier*

$$K = (M, T, Q, S, R, V, F, H, C, P, N),$$

the local NameCert$_{\text{KolmogorovRieszCriterion}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure, finite translation-tightness exposure, shared equicontinuous sequence modulus exposure, finite window visibility, regular rational readback, Real sealing, Frechet–Kolmogorov handoff exactness, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier rows of Definition 8138.1. The compact metric row M, translation row T, equicontinuous sequence row Q, window row S, readback row R, Real seal V, and Frechet–Kolmogorov handoff F are the only analytic coordinates.

Read the finite compactness criterion in order. Compact-source data come from M, translation tightness is displayed by T, and the common modulus needed by sequence consumers is supplied by Q before any window, rational, or real-facing read is inspected.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for selected subsequences, quotient equality of functions, countable choice, open-cover compactness, or ambient Real$^{\uparrow}$ completeness, the listed rows exhaust the local certificate surface. □

Theorem 8138.3 (Kolmogorov-Riesz translation tightness route)**.** *Every compactness-facing read of an accepted* KolmogorovRieszCriterion$^{\uparrow}$ *carrier factors through the finite route*

$$M, T, Q, S, R, V \longmapsto F, H, C, P, N.$$

Thus translation tightness is consumed only after compact metric support, equicontinuous sequence control, finite StreamName windows, RegSeqRat readback, and Real sealing have been displayed, and the final handoff is the Frechet–Kolmogorov compactness row rather than an ambient compact embedding theorem.

Proof. Start with a compactness-facing consumer and project the accepted carrier. The consumer first sees the compact metric source M and the translation-tightness row T, so the inspected shifts, radii, and tolerances are finite data of the packet.

Next read the equicontinuous sequence row Q and the finite window row S. This keeps shared-modulus information attached to the inspected sequence entries and compact net cells before any numerical comparison is exported.

The readback rows R, V then seal the rational and real-facing comparisons. Only after those rows are visible may the Frechet–Kolmogorov compactness handoff F be consumed.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Because no row stores an ambient compact embedding theorem, selected subsequence, quotient function equality, countable-choice selector, or ambient completeness principle, the compactness-facing read is exactly the displayed translation-tightness route. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovRieszCriterion}\uparrow}$.

Constructive story: A $\mathsf{KolmogorovRieszCriterion}^{\uparrow}$ packet is generated from a CompactMetric source row, finite translation-tightness windows, an EquicontinuousSequence shared-modulus row, StreamName finite windows, RegSeqRat readback, Real sealing, FrechetKolmogorovCompactness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovRieszCriterion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8138.1, Definition 8138.2, and Definition 8138.3 seed the finite Kolmogorov–Riesz compactness criterion over compact metric, translation-tightness, equicontinuous sequence, readback, Real, handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovRieszCriterion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient compact embedding, open-cover compactness, selected subsequences, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite translation-tightness exactness, equicontinuous sequence modulus exposure, StreamName window visibility, RegSeqRat readback, Real sealing, Frechet–Kolmogorov handoff, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovRieszCriterionUp.

Chapter 8139

A Concrete Naming Certificate for $\mathsf{RegularCauchyBisimulation}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyBisimulation}^{\uparrow}$ packet records equality-facing comparison of two regular Cauchy real names by finite paired windows rather than by quotient real equality. It sits after the regular rational source of chapter 301, the finite stream-window route of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the uniqueness route of chapter 3390. The packet names a non-quotient comparison surface for Real and Completion consumers; it does not select representatives, collapse names by quotient equality, import countable choice, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8139.1 (Regular Cauchy bisimulation carrier)**.** *A* $\mathsf{RegularCauchyBisimulation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, Y, W_X, W_Y, D_X, D_Y, M, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose regular rational approximants are being compared.*
2. *W_X and W_Y are paired* $\mathsf{StreamName}^{\uparrow}$ *windows exposing the finite observations of X and Y at the same inspected precisions.*
3. *D_X and D_Y are* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers recording the error budgets and comparison radii used for the two source rows.*
4. *M is the finite matching relation pairing inspected windows whose dyadic distance is below the displayed joint tolerance.*
5. *H records componentwise* hsame *transport for $X, Y, W_X, W_Y, D_X, D_Y, M, C, P, N$.*
6. *C records displayed* Cont *replay of each paired-window comparison through the source rows, stream windows, tolerance ledgers, matching relation, provenance, and local naming row.*
7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyBisimulation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBisimulation}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one symmetric paired-window comparison certificate. It has no coordinate for quotient real equality, selected representatives, infinite branch selection, countable choice, host equality of real numbers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8139.2 (Regular Cauchy bisimulation NameCert obligations)**.** *For every accepted* RegularCauchyBisimula *carrier* $B = (X, Y, W_X, W_Y, D_X, D_Y, M, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyBisimulation}^{\uparrow}}$ *surface consists exactly of carrier admission, paired-window exposure, dyadic tolerance comparison, symmetric step matching,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise transport, displayed replay, provenance, and local naming. In particular, every comparison read remains inside the displayed route*

$$X, Y \longmapsto W_X, W_Y \longmapsto D_X, D_Y \longmapsto M$$

before a Real-facing consumer may use the comparison.

Proof. Project the carrier of Definition 8139.1. The rows $X, Y, W_X, W_Y, D_X, D_Y, M$ expose exactly two regular rational source rows, their paired stream windows, their dyadic tolerance ledgers, and the finite matching relation.

The matching relation is symmetric because every admitted comparison step is stored as a paired-window relation between the two displayed sources. Reading the pair in the opposite direction uses the same windows and the same dyadic tolerance data, so no quotient-real equality or selected representative is introduced.

The Real-facing seal is downstream of the displayed source rows. The $\mathsf{Real}^{\uparrow}$ consumer can only receive a comparison after the $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows have been replayed through C and transported through H.

Finally P and N source and name the same finite packet. Since the carrier has no coordinate for host equality, branch selection, choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyBisimulation}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyBisimulation}^{\uparrow}$ packet is generated from two $\mathsf{RegSeqRat}^{\uparrow}$ source rows, paired $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledgers, a finite symmetric matching relation, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyBisimulation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8139.1 and Definition 8139.2 seed the paired-window comparison surface over RegSeqRat, StreamName, DyadicRatCore, Real, and regular-Cauchy uniqueness rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyBisimulation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, representative selection, countable choice, infinite branch selection, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, paired-window exposure, dyadic tolerance comparison, symmetric step matching, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyBisim

Chapter 8140

A Concrete Naming Certificate for $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$

The $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$ packet realizes the reversible transport trace surface of section 9463.2 as finite NameCert data. It sits beside the Cayley operator route of chapter 7887, the holonomy surface of chapter 6385, the metric route of chapter 3474, the reversible transport certificate of chapter 219, and the terminal Real seal of chapter 38. The packet names an operator trace only after reversible disk transport, classifier preservation, boundary refusal, and Real-seal readout have all been displayed.

Definition 8140.1 (Hyperbolic operator trace carrier)**.** *A* $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, O, U, L, B, R, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite disk-transport row recording the inspected Poincare-disk or hyperbolic disk windows and the reversible route between them.*
2. *O is the operator row whose finite action is read only on the displayed disk-transport window.*
3. *U is the reversible classifier-preservation row, recording the transport witness that preserves the relevant phase or inner-product classifier.*
4. *L is the trace ledger row, recording the finite trace read, normalization, visible source ledger, and comparison budget.*
5. *B is the boundary-refusal row excluding unlogged boundary collapse, hidden ambient Hilbert-space operators, global spectral measures, and unbounded functional calculus.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal readout row for the trace value or trace comparison exposed by L.*
7. *H records componentwise* hsame *transport for disk transport, operator, reversible classifier preservation, trace ledger, boundary refusal, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through disk transport, operator read, classifier preservation, trace ledger inspection, boundary refusal, Real-seal readout, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$, $\mathsf{HyperbolicOperatorCayley}^{\uparrow}$, $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{UnitaryGroup}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorTrace}^{\uparrow}}$ *row.*
The Lean-side follow-up for this carrier must provide `Nontrivial HyperbolicOperatorTraceUp` *and* `FieldFaithful HyperbolicOperatorTraceUp` *TasteGate instances in* `lean4/BEDC/Derived/HyperbolicOpe`

Theorem 8140.2 (Hyperbolic operator trace NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$ *carrier* $T = (D, O, U, L, B, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorTrace}^{\uparrow}}$ *surface consists exactly of finite disk-transport exposure, operator-row admission, reversible classifier-preservation exposure, trace-ledger readout, boundary-refusal exposure,* $\mathsf{Real}^{\uparrow}$ *seal readout, componentwise transport, displayed replay, provenance, and local naming. A trace read that omits* U*,* L*, or* B *is not an accepted trace read of this packet.*

Proof. Project the carrier of Definition 8140.1. The rows D, O, U, L, B, R expose the disk transport, operator window, reversible classifier-preservation witness, trace ledger, boundary refusal, and Real-seal readout.

The trace row is not read in isolation. It is admitted only after the reversible transport row U preserves the displayed classifier over the disk route D, and the ledger row L records the finite trace value together with its source and comparison budget.

The boundary-refusal row B blocks unlogged operator reads, boundary collapse, global spectral measures, and host Hilbert-space constructions. The Real-seal row R is therefore a readout of the displayed trace ledger, not a substitute for the transport and refusal rows.

Finally H, C, P, N preserve, replay, source, and name the same packet. Since no additional coordinate stores an ambient operator trace, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$ packet that exposes a trace read without the reversible transport row, boundary-refusal row, and trace ledger refutes the classifier.

Independence witness: hyperbolic-operator-cayley, hyperbolic-phase-holonomy, hyperbolic-metric, unitarygroup, real: HyperbolicOperatorTraceUp is not bijective to any listed sibling because it binds reversible disk transport, operator trace, boundary refusal, and Real-seal readout in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicOperatorTrace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicOperatorTrace}^{\uparrow}$ packet is generated from finite disk transport, an operator row, reversible classifier preservation, a trace ledger, a boundary-refusal row, a Real-seal readout, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicOperatorTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8140.1 and Definition 8140.2 seed the reversible disk-transport trace surface over hyperbolic operator, holonomy, metric, unitary, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicOperatorTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global spectral traces, host Hilbert-space operators, unbounded functional calculus, boundary collapse, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, reversible disk transport, operator-trace ledger exactness, boundary refusal, Real-seal readout, Nontrivial and FieldFaithful TasteGate instances, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicOperatorTraceUp.

Chapter 8141

A Concrete Naming Certificate for $\mathsf{LowerTopology}^{\uparrow}$

Following Scott and Lawson domain theory, the $\mathsf{LowerTopology}^{\uparrow}$ packet records the lower-topology component of an ordered carrier as finite NameCert data. It sits between the specialization discipline of chapter 52 and chapter 53, the indexed-open surface of chapter 88, the observable-open classifier of chapter 1860, and the domain-topology neighbours chapter 5950 and chapter 5162. The packet names lower-open reads through displayed order and observable-open rows; it does not import a host powerset topology, a selected family of all opens, quotient point equality, choice over down-closed witnesses, or an ambient compactness theorem.

Definition 8141.1 (Lower topology carrier)**.** *A* $\mathsf{LowerTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, Q, T, S, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Preorder}^{\uparrow}$ *specialization source row, carrying the finite comparison reads used by lower-open inspection.*
2. *Q is the* $\mathsf{Poset}^{\uparrow}$ *separated-order row when the lower topology is read over a displayed antisymmetric order surface.*
3. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open row that records the finite lower-open neighbourhood requests admitted by the packet.*
4. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-open row, reading membership in each displayed lower-open request as a finite truth observation.*
5. *H records componentwise* hsame *transport for the order, topology, observable-open, replay, provenance, and naming rows.*
6. *C records displayed* Cont *replay from an order comparison request through the indexed-open row and then through the observable-open classifier.*
7. *P is the* Pkg *provenance over* $\mathsf{LowerTopology}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerTopology}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these eight rows. It has no coordinate for a host family of all lower opens, arbitrary powersets, selected bases, quotient point equality, countable choice, or a compactness principle.

Theorem 8141.2 (Lower topology NameCert obligations)**.** *For every accepted* $\mathsf{LowerTopology}^{\uparrow}$ *carrier* $L = (R, Q, T, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LowerTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the preorder or poset row, lower-open topology row, observable-open row, transport row, replay row, provenance row, and local naming row; lower-open membership inspection through* T *and* S*; order compatibility through* R *and, when present,* Q*; and provenance exhaustion through* P, N*. No obligation is discharged by a host powerset topology, selected lower-open basis, quotient point equality, countable-choice schedule, Scott-open completeness, or Lawson compactness.*

Proof. Project the displayed carrier of Definition 8141.1. The only order-facing data are R and Q, so every lower-open read must begin with the finite preorder or poset comparisons already present in the packet.

Read the topology and observable-open rows next. The row T records the indexed lower-open requests, while S turns each membership read into displayed Sierpinski truth data. Thus the topology route remains a finite observation surface rather than a host powerset of opens.

Finally use H, C, P, N. Componentwise transport, displayed replay, provenance, and local naming preserve the same row order from comparison data to observable-open data. Since none of the excluded host objects has a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8141.3 (Lower topology specialization scope)**.** *Every accepted* $\mathsf{LowerTopology}^{\uparrow}$ *consumer that reads specialization information must factor through the finite route*

$$\mathsf{Preorder}^{\uparrow} \longmapsto \mathsf{Poset}^{\uparrow} \longmapsto \mathsf{Topology}^{\uparrow} \longmapsto \mathsf{SierpinskiSpace}^{\uparrow}.$$

The preorder row supplies comparison data, the optional poset row supplies separated-order data, the topology row names lower-open neighbourhood requests, and the Sierpinski row exposes membership observations. The route may be consumed by $\mathsf{ScottTopology}^{\uparrow}$ *and* $\mathsf{LawsonTopology}^{\uparrow}$ *as their lower-topology component, but it exports no host powerset topology, selected open basis, quotient order, choice principle, or compactness theorem.*

Proof. Start with the order rows of Definition 8141.1. A specialization-facing request first reads R, and when a separated order surface is present it reads Q as the displayed $\mathsf{Poset}^{\uparrow}$ handoff.

The request then passes to T. Lower-open neighbourhoods are indexed rows in the $\mathsf{Topology}^{\uparrow}$ surface, so the consumer sees only the finite lower-open requests carried by the packet.

The final observable read is S. Membership in those indexed opens is exposed through $\mathsf{SierpinskiSpace}^{\uparrow}$ truth data, after which H, C, P, N transport, replay, source, and name the same route. The Scott and Lawson neighbours may consume this component only through the displayed rows, so no external topology or choice object is exported. □

Falsifiable prediction: Every accepted $\mathsf{LowerTopology}^{\uparrow}$ read must display Preorder, Poset, Topology, SierpinskiSpace, hsame, Cont, Pkg, and local NameCert rows before it can serve as the lower-topology component for a ScottTopologyUp or LawsonTopologyUp consumer.

Independence witness: preorder, poset, topology, sierpinski-space, scott-topology, lawson-topology: none is bijective to $\mathsf{LowerTopology}^{\uparrow}$ because this carrier alone binds comparison data, separated-order data, lower-open requests, observable-open truth, transport, replay, provenance, and local naming as one lower-topology packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LowerTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{LowerTopology}^{\uparrow}$ packet is generated from Preorder comparison rows, optional Poset separated-order rows, Topology lower-open rows, SierpinskiSpace observable-open rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8141.1, Definition 8141.2, and Definition 8141.3 seed the finite lower-topology route over $\mathsf{Preorder}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host powerset topology, selected basis of lower opens, quotient point equality, countable choice, Scott-topology completeness, Lawson compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, order compatibility, lower-open inspection, observable-open exactness, transport, replay, provenance, and local naming for BEDC.Derived.LowerTopologyUp.

Chapter 8142

A Concrete Naming Certificate for $\mathsf{DescentData}^{\uparrow}$

Following Grothendieck on descent and SGA-style gluing, the $\mathsf{DescentData}^{\uparrow}$ packet records local objects, restriction isomorphisms, cocycle comparisons, and effectivity rows as finite BEDC data. It sits over the coverage surface of chapter 6718, the restriction surface of chapter 150, the locality and gluing surface of chapter 151, the groupoid-valued descent surface of chapter 260, and the object-arrow carrier of chapter 61. The packet names only the displayed descent rows and does not export a host quotient stack, selected gluing object, global representative choice, or ambient sheaf equality.

8142.1 Descent Carrier

Definition 8142.1 (Descent data carrier)**.** *A* $\mathsf{DescentData}^{\uparrow}$ *carrier is a tuple* $(U, L, R, C, E, H, T, P, N)$ *with the following rows.*

1. *U is a cover row over the displayed* $\mathsf{GrothendieckTopology}^{\uparrow}$ *site, naming the finite cover or covering sieve from which the descent packet is read.*
2. *L is the family of local-object rows, one row for each certified member of U, read through the* $\mathsf{PreSheaf}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, *or* $\mathsf{Stack}^{\uparrow}$ *restriction surface relevant to the target consumer.*
3. *R is the restriction-isomorphism row, assigning to each certified overlap a displayed comparison between the two restrictions of the corresponding local-object rows.*
4. *C is the cocycle row, asserting that on each displayed triple overlap the two composite restriction-isomorphism routes have the same classifier read.*
5. *E is the effectivity and gluing row, naming the accepted global row or gluing-readback surface that may be consumed after C has been checked.*
6. *H is componentwise* hsame *transport for covers, local objects, restriction isomorphisms, cocycle witnesses, and effectivity witnesses.*
7. *T is displayed* Cont *replay for the route that reads U, then L, then R, then C, then E.*
8. *P is* Pkg *provenance for the site, cover, local-object source, overlap restriction source, cocycle source, and effectivity source.*
9. *N is a local* $\mathsf{NameCert}$ *row naming the accepted descent packet and every exported row.*

No component of the carrier is a host quotient of objects, a selected representative of a gluing class, a global choice function for local objects, or an equality of ambient sheaf sections outside the displayed classifier rows.

Theorem 8142.2 (Descent data NameCert obligations)**.** *Every accepted* $\mathsf{DescentData}^{\uparrow}$ *packet exposes exactly the carrier, cover, local-object, restriction, cocycle, effectivity, transport, replay, provenance, and naming obligations listed in Definition 8142.1. A consumer may inspect the cover row* U*, local-object rows* L*, restriction-isomorphism rows* R*, cocycle row* C*, effectivity row* E*, componentwise* hsame *transport* H*, displayed* Cont *replay* T*,* Pkg *provenance* P*, and local* NameCert *row* N*, but obtains no host quotient stack, selected global gluing, global choice of representatives, ambient sheaf equality, or standard bridge.*

Proof. Project the tuple $(U, L, R, C, E, H, T, P, N)$ from Definition 8142.1. The first five coordinates give the analytic descent data: a displayed cover, local objects over that cover, restriction isomorphisms on overlaps, a cocycle witness on triple overlaps, and the effectivity or gluing row.

The remaining coordinates give the BEDC certificate discipline. Componentwise hsame moves each displayed row without replacing it by host equality, Cont replays the read order, Pkg records the site and gluing provenance, and NameCert names the packet and its exported rows.

The exclusions follow by absence of carrier coordinates. A host quotient stack, a selected global gluing, a representative-choice operation, ambient sheaf equality, and a standard bridge would each require an additional row not present in the tuple, so they are outside the accepted certificate. □

Theorem 8142.3 (Descent cocycle and effectivity route)**.** *Every stack or sheaf gluing consumer of a* $\mathsf{DescentData}^{\uparrow}$ *packet must read the cocycle rows before the effectivity rows. The exported route is*

$$U \longrightarrow L \longrightarrow R \longrightarrow C \longrightarrow E,$$

then H, T, P, N *transport, replay, source, and name the same route. This export supplies no host quotient of objects, no global choice of representatives, and no ambient sheaf equality.*

Proof. Start with the carrier order of Definition 8142.1. The cover row U determines the displayed local indices, L supplies the local objects on those indices, and R supplies the overlap restriction-isomorphism rows.

The effectivity row E is certified only after the cocycle row C has checked the triple-overlap composites. Thus a sheaf or stack gluing consumer reaches E through the finite route U, L, R, C rather than by an ambient existence principle.

Finally apply the structural rows H, T, P, N. They transport the route componentwise, replay the same read order, record provenance, and name the resulting packet. Since none of these rows is a quotient, representative selector, choice function, or host equality witness, the exported route does not supply those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{DescentData}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DescentData}^{\uparrow}$ packet is generated from a Grothendieck-topology cover row, local-object rows, restriction-isomorphism rows, a cocycle row, an effectivity or gluing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DescentData}^{\uparrow}}$, seed)

Scope closed: Definition 8142.1, Definition 8142.2, and Definition 8142.3 bind the finite descent-data carrier and the cocycle-before-effectivity route for sheaf and stack consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DescentData}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host quotient stacks, selected gluings, global choice of representatives, ambient sheaf equality, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, cocycle-before-effectivity read order, componentwise transport, provenance, naming, and the absence of quotient, choice, and ambient-equality exports for BEDC.Derived.DescentDataUp.

Chapter 8143

A Concrete Naming Certificate for $\mathsf{LipschitzExtensionDomain}^{\uparrow}$

Following Jones, Stein, and Adams–Fournier, the $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ packet names the finite domain-side admissibility data needed before a Lipschitz, Sobolev, trace, compact, or real-valued extension consumer may read a domain as extension-ready. It sits between the bounded-domain certificate of chapter 8137, the operator route of chapter 3650, the Sobolev extension surface of chapter 7326, and the metric, topology, compact, and real rows used by those neighbours. The packet is a domain-level gate, not a selected extension operator, a host trace theorem, a quotient equality of function spaces, or a choice principle.

Definition 8143.1 (Lipschitz extension domain carrier)**.** *A* $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ *carrier is a finite packet*

$$D = (D_0, M, T, L, E, H, C, P, N)$$

with the following displayed rows:

1. D_0 *is the* $\mathsf{BoundedLipschitzDomain}^{\uparrow}$ *row, naming the finite boundary-chart, boundedness, and local domain data.*
2. M *is the* $\mathsf{Met}^{\uparrow}$ *row, recording the distance comparisons used by local extension and trace reads.*
3. T *is the* $\mathsf{Topology}^{\uparrow}$ *row, recording membership, neighbourhood, and boundary-open reads.*
4. L *is the Lipschitz bound row, read through* $\mathsf{LipschitzExtension}^{\uparrow}$ *and the sibling Lipschitz rows for every admissible extension request.*
5. E *is the extension-route row, recording the allowed handoff to* $\mathsf{SobolevExtensionOperator}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *support data without selecting a global operator.*
6. H *records componentwise* hsame *transport for* D_0, M, T, L, E, C, P, N.
7. C *records displayed* Cont *replay from an extension or trace request through the domain, metric, topology, Lipschitz, and extension-route rows.*
8. P *is the* Pkg *provenance over* $\mathsf{LipschitzExtensionDomain}^{\uparrow}$, $\mathsf{BoundedLipschitzDomain}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{SobolevExtensionOperator}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}$ *row.*

The carrier predicate asserts that every admissible extension-domain read first exposes the bounded Lipschitz domain row D_0, then the metric and topology rows M, T, then the Lipschitz bound and extension-route rows L, E, and finally the transport, replay, provenance, and local naming rows H, C, P, N. It has no coordinate for a selected extension operator, host open-set equality, quotient metric equality, completed trace space, or countable choice.

Theorem 8143.2 (Lipschitz extension domain NameCert obligations)**.** *For every accepted* $\mathsf{LipschitzExtensionDomai}$ *carrier*

$$D = (D_0, M, T, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the bounded Lipschitz domain, metric, topology, Lipschitz bound, extension route, transport, replay, provenance, and local naming rows;*
2. *metric-topology compatibility, requiring distance, membership, neighbourhood, and boundary reads to pass through M and T after D_0 is displayed;*
3. *Lipschitz bound exposure, requiring every extension-ready request to expose the row L before any extension consumer reads a function bound;*
4. *extension-route admissibility, requiring the row E to route only to displayed* $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{SobolevExtensionOperator}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *support rows;*
5. *structural stability under H, C, P, N, which transports, replays, sources, and names only the displayed finite route.*

No domain-level extension obligation is stored outside these rows.

Proof. Project the carrier of Definition 8143.1. The domain row D_0 is the only bounded Lipschitz domain coordinate, and the rows M, T are the only metric and topology coordinates available to a consumer.

Next read the Lipschitz and extension-route rows. The row L records the bound surface that an extension request may inspect, while E records the admissible handoff to the displayed Lipschitz, Sobolev, compact, and real support rows.

Finally attach the structural rows H, C, P, N. They transport, replay, source, and name the same finite route, so the carrier has no remaining coordinate from which a selected operator, host open-set equality, quotient metric equality, completed trace space, or choice schedule could be exported. □

Theorem 8143.3 (Lipschitz extension domain extension-trace route)**.** *Every extension or trace consumer of an accepted* $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ *carrier must pass through the displayed domain row D_0, the metric and topology rows M, T, the Lipschitz bound row L, the extension-route row E, componentwise transport H, displayed replay C, provenance P, and the local* $\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}$ *row N before receiving any extension-domain conclusion. The route may cite the bounded-domain surface of chapter 8137 and the Sobolev extension surface of chapter 7326, but it exports no host extension operator, trace theorem, quotient function-space equality, ambient compactness, or choice principle.*

Proof. Begin with an accepted extension or trace request. Carrier admission forces the request to display D_0 first, so the bounded Lipschitz boundary and domain data are read through the sibling bounded-domain certificate rather than a host domain predicate.

The request then reads the metric and topology rows M, T. These rows provide the distance, membership, neighbourhood, and boundary-open data that the extension-domain route may use before any Lipschitz estimate is inspected.

Next expose the Lipschitz bound row L and the extension-route row E. Together they keep the request inside the displayed Lipschitz and Sobolev extension neighbours, with compact and real support rows available only as named finite packet data.

Finally apply H, C, P, N. Transport and replay preserve the same row order, provenance records the permitted sibling sources, and the local NameCert names the domain-level gate. Since no carrier coordinate remains for a selected operator, host trace theorem, quotient equality, ambient compactness, or choice schedule, every accepted consumer must follow the stated route. □

Falsifiable prediction: Every accepted $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ extension-domain read exposes BoundedLipschitzDomainUp, MetricUp, TopologyUp, LipschitzExtensionUp, SobolevExtensionOperatorUp, CompactMetricUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows before any extension or trace consumer receives a domain admissibility conclusion.

Independence witness: bounded-lipschitz-domain, metric, topology, lipschitz-extension, sobolev-extension-operator, compactmetric, real: $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries domain admissibility, metric and topology readback, Lipschitz bound exposure, extension-route admissibility, transport, replay, provenance, and local naming in one finite gate.

Closure status for $\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{LipschitzExtensionDomain}^{\uparrow}$ packet is generated from a bounded Lipschitz domain row, metric row, topology row, Lipschitz bound row, extension-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8143.1, Definition 8143.2, and Definition 8143.3 seed the finite extension-domain admissibility packet over bounded-domain, metric, topology, Lipschitz, Sobolev extension, compact, and real neighbours.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LipschitzExtensionDomain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a selected host extension operator, unrestricted trace theorem, quotient function-space equality, ambient compactness, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-topology compatibility, Lipschitz bound exposure, extension-route admissibility, transport, replay, provenance, and local naming for BEDC.Derived.LipschitzExtensionDomainUp.

Chapter 8144

A Concrete Naming Certificate for $\mathsf{LinearRecurrence}^{\uparrow}$

Following Stanley and Graham–Knuth–Patashnik on linear recurrence sequences, the $\mathsf{LinearRecurrence}^{\uparrow}$ packet records a finite recurrence-stream NameCert for the L10 $\mathsf{StreamName}^{\uparrow}$–$\mathsf{RegSeqRat}^{\uparrow}$–$\mathsf{Real}^{\uparrow}$ route. It sits after the unary index discipline of chapter 28, the rational coefficient rows of chapter 37, the dyadic tolerance core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names finite lawlike stream data only; it does not import host sequence equality, selected infinite streams, closed-form solutions, characteristic roots, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8144.1 (Linear recurrence carrier)**.** *A* $\mathsf{LinearRecurrence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (C, I, N, S, Q, R, H, P, A)$$

with the following displayed rows:

1. *C is the coefficient row over* $\mathsf{Rat}^{\uparrow}$ *and* $\mathsf{DyadicRatCore}^{\uparrow}$*, listing the finite recurrence order, rational coefficients, and dyadic tolerance tags used by later reads.*
2. *I is the initial finite window, giving the seed values needed before the recurrence rule can be replayed.*
3. *N is the unary* $\mathsf{Nat}^{\uparrow}$ *index schedule naming which finite indices and successor steps are inspected.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row, exposing the inspected stream entries and recurrence replay windows.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational values generated by the coefficient row and initial window.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for those readback values when a Real or Completion consumer asks for terminal scalar output.*
7. *H records componentwise* hsame *transport for coefficient, initial-window, index, stream, readback, and seal rows.*
8. *P is the* Pkg *provenance over* $\mathsf{Nat}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*, and* Cont *rows.*
9. *A is the local* $\mathsf{NameCert}_{\mathsf{LinearRecurrence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $C, I, N, S, Q, R, H, P, A$.

Theorem 8144.2 (Linear recurrence NameCert obligations)**.** *For every accepted* $\mathsf{LinearRecurrence}^{\uparrow}$ *carrier*

$$L = (C, I, N, S, Q, R, H, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{LinearRecurrence}^{\uparrow}}$ *surface consists exactly of coefficient-row exposure, initial-window exposure, unary index scheduling, finite stream observation, regular rational readback, Real sealing, componentwise transport, provenance, and local naming.*

Proof. Project the carrier of Definition 8144.1. The recurrence rule is not an ambient function on host sequences; it is the finite row C together with the initial window I and the unary index schedule N.

Read the numeric rows through the sibling chapters. The index schedule is supplied by chapter 28, the rational coefficients by chapter 37, and the dyadic tolerance tags by chapter 291.

Finally route observations through chapter 126, readback through chapter 301, and terminal sealing through chapter 38. The remaining rows H, P, A only transport, source, and name the same finite packet, so the listed rows exhaust the local certificate surface. □

Theorem 8144.3 (Linear recurrence stream handoff)**.** *Every stream-facing read of an accepted* $\mathsf{LinearRecurrence}^{\uparrow}$ *carrier factors through the finite route*

$$C, I, N \longmapsto S \longmapsto Q.$$

The consumer first sees the recurrence coefficients, initial window, and unary index schedule, then the $\mathsf{StreamName}^{\uparrow}$ *observation row, and only then the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. No stream read may replace this route by host sequence equality, an uninspected tail, a selected closed-form solution, or an infinite recurrence oracle.*

Proof. Begin with the coefficient, initial-window, and index rows. By chapter 37 and chapter 291, the coefficient row is finite rational-and-dyadic data; by chapter 28, the schedule row names only unary inspected indices.

Pass next to the stream observation row of chapter 126. It exposes the requested entries and replay windows, not a quotient of infinite streams.

The regular rational readback of chapter 301 consumes exactly those displayed windows. Since the route has no coordinate for host sequence equality, uninspected tails, selected closed forms, or infinite recurrence oracles, every stream-facing read factors through C, I, N, S, Q. □

Theorem 8144.4 (Linear recurrence Real seal boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{LinearRecurrence}^{\uparrow}$ *packet may read the terminal scalar row only through*

$$C, I, N, S, Q, R, H, P, A.$$

The $\mathsf{Real}^{\uparrow}$ *seal R records a terminal boundary for displayed recurrence readback values; it does not assert convergence of the whole recurrence stream, completeness of the ambient real line, characteristic-root solvability, or equality with a host sequence.*

Proof. Use Definition 8144.3 to force the consumer through the finite coefficient, initial-window, index, observation, and regular-readback rows. The construction therefore reaches the real-facing surface only after $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ rows have been exposed through chapter 28, chapter 37, chapter 291, chapter 126, and chapter 301.

Apply the terminal seal boundary of chapter 38. The $\mathsf{Real}^{\uparrow}$ row R seals displayed readback values; it is not a convergence theorem for all indices, a completeness principle, or a host-sequence equality test.

The transport, provenance, and local naming rows H, P, A preserve only the same route. Hence the Real or Completion consumer receives exactly the displayed recurrence-readback boundary and no stronger analytic structure. □

Closure status for $\mathsf{NameCert}_{\mathsf{LinearRecurrence}^{\uparrow}}$.

Constructive story: A $\mathsf{LinearRecurrence}^{\uparrow}$ packet is generated from finite rational and dyadic coefficient data, an initial window, a unary Nat index schedule, StreamName observations, RegSeqRat readback, a Real seal, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LinearRecurrence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8144.1, Definition 8144.2, Definition 8144.3, and Definition 8144.4 seed the finite recurrence-stream carrier, stream handoff, and Real seal boundary for the L10 StreamName–RegSeqRat–Real route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LinearRecurrence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host sequence equality, closed-form recurrence solving, characteristic-root theory, convergence of all recurrence streams, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient exactness, initial-window coverage, unary index scheduling, StreamName observation, RegSeqRat readback, Real sealing, transport, provenance, and local naming for BEDC.Derived.LinearRecurrenceUp.

Chapter 8145

A Concrete Naming Certificate for $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$

Following Bishop–Bridges on constructive Cauchy comparison and Mac Lane on functorial packaging, the $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$ packet records tail-comparison transport between regular Cauchy presentations as finite BEDC data. It sits after the objectwise comparison surface of chapter 387, the regular comparison route of chapter 2146, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet names comparison transport and composition as a finite functorial boundary; it does not quotient streams, select representatives, compare host real values, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8145.1 (CauchyTailComparisonFunctor carrier)**.** *A* $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, B, W_A, W_B, D_A, D_B, T, R, E, H, C, P, N)$$

with the following displayed coordinates:

1. *A and B are the source and target* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback rows;*
2. *W_A and W_B are the* $\mathsf{StreamName}^{\uparrow}$ *windows that select the compared source and target tails;*
3. *D_A and D_B are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance rows read through those windows;*
4. *T is the local* $\mathsf{CauchyTailComparison}^{\uparrow}$ *or* $\mathsf{RegularCauchyTailComparison}^{\uparrow}$ *comparison row over the displayed windows;*
5. *R is the transported* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced by the comparison;*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row visible only after the comparison readback has been exposed;*
7. *H stores componentwise* hsame *transports for the source, target, window, dyadic, comparison, readback, and seal rows;*
8. *C stores the displayed* Cont *replay routes for reading the windows, applying the comparison, transporting readback, and exposing the real seal;*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$, $\mathsf{CauchyTailComparison}^{\uparrow}$, $\mathsf{RegularCauchyTailCompari}$ $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparisonFunctor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for quotient stream equality, selected limits, host real equality, or ambient completeness.

Theorem 8145.2 (CauchyTailComparisonFunctor NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{CauchyTailComparisonFu}}$ *surface for the carrier of Definition 8145.1 consists of five finite obligations:*

1. *carrier admission: the accepted object is exactly the displayed packet F with source and target* $\mathsf{RegSeqRat}^{\uparrow}$ *rows, paired* $\mathsf{StreamName}^{\uparrow}$ *windows, paired* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint rows, a comparison row, a transported readback row, a* $\mathsf{Real}^{\uparrow}$ *seal, transport rows, continuation rows, provenance, and local naming data;*
2. *window functoriality: every comparison read first exposes W_A, W_B, D_A, D_B before the row T is consumed;*
3. *regular readback transport: the transported row R is obtained from the comparison row and remains inside the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback surface;*
4. *classifier stability: componentwise* hsame *transport preserves the same comparison packet and its displayed* Cont *replay routes;*
5. *real seal handoff: every* $\mathsf{Real}^{\uparrow}$ *consumer sees $A, B, W_A, W_B, D_A, D_B, T, R, H, C, P, N$ before the seal row E is readable.*

Proof. Carrier admission is projection from the tuple in Definition 8145.1. The source and target regular rows, windows, dyadic endpoint rows, comparison row, transported readback, seal, transports, replays, package row, and local naming row are explicit coordinates.

Window functoriality follows from the sibling comparison chapters. The objectwise comparison row of chapter 387 and the regular comparison row of chapter 2146 both read finite $\mathsf{StreamName}^{\uparrow}$ windows and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance rows before exposing any comparison result.

The transported readback and classifier clauses then use the same finite route. The $\mathsf{RegSeqRat}^{\uparrow}$ row R is obtained only after T has been read, and componentwise hsame transport keeps the source, target, windows, endpoint rows, comparison row, and readback row in the displayed packet.

Finally the $\mathsf{Real}^{\uparrow}$ seal handoff is a consumer boundary. Since E is reached only after the readback row and its visible provenance have been exposed, no quotient stream, selected limit, host real equality, or ambient completeness coordinate can be projected from the carrier. □

Theorem 8145.3 (CauchyTailComparisonFunctor composition law)**.** *Let*

$$F_{AB} = (A, B, W_A, W_B, D_A, D_B, T_{AB}, R_{AB}, E_{AB}, H_{AB}, C_{AB}, P_{AB}, N_{AB})$$

and

$$F_{BC} = (B, C, W_B, W_C, D_B, D_C, T_{BC}, R_{BC}, E_{BC}, H_{BC}, C_{BC}, P_{BC}, N_{BC})$$

be accepted $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$ *packets whose middle* $\mathsf{RegSeqRat}^{\uparrow}$ *row,* $\mathsf{StreamName}^{\uparrow}$ *window, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row agree as displayed carrier rows. Then any composite comparison from A to C factors through the finite route*

$$W_A,\ W_B,\ W_C,\ D_A,\ D_B,\ D_C,\ T_{AB},\ T_{BC},\ R_{AB},\ R_{BC}$$

and reaches a $\mathsf{Real}^{\uparrow}$ *seal only after the combined* hsame, Cont, Pkg, *and local* $\mathsf{NameCert}$ *rows of the two packets have been exposed. The composite exports no quotient stream equality, selected representative, host real equality, or ambient completeness object.*

Proof. First expose the two accepted carriers. The shared middle row B, window W_B, and endpoint row D_B are common displayed coordinates, so both comparison reads use the same middle tail rather than a hidden equality class.

Apply the NameCert obligations of Definition 8145.2 to F_{AB} and F_{BC}. The first packet reads W_A, W_B, D_A, D_B before T_{AB} and R_{AB}; the second reads W_B, W_C, D_B, D_C before T_{BC} and R_{BC}.

The composite route is therefore the concatenation of two displayed comparison reads with the middle rows identified by the carrier data. Componentwise hsame transport and displayed Cont replay preserve the same windows, endpoint rows, comparison rows, and readback rows across the concatenation.

Finally the two $\mathsf{Real}^{\uparrow}$ seal rows are consumer boundaries. A composite seal can be read only after the visible readback, transport, replay, provenance, and local naming rows have been exposed, so the composition law is a finite functorial boundary and not a quotient-stream, selected-limit, host-equality, or ambient-completeness assertion. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailComparisonFunctor}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyTailComparisonFunctor}^{\uparrow}$ packet is generated from source and target RegSeqRat rows, paired StreamName windows, paired DyadicRatCore endpoint rows, CauchyTailComparison or RegularCauchyTailComparison rows, a transported RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyTailComparisonFunctor}^{\uparrow}}, \mathsf{seed})$

Scope closed: The chapter names the finite carrier, obligation surface, and composition boundary for regular-Cauchy tail-comparison transport.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyTailComparisonFunctor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, quotient equality of streams, selected limits, host real equality, ambient RealUp completeness, or standard bridge checking.

Upgrade path: Obligation closure requires a checked carrier and NameCert obligation theorem for the displayed tail-comparison functor packet.

Chapter 8146

A Concrete Naming Certificate for $\mathsf{BishopLocatedDiagonal}^{\uparrow}$

Following Bishop and Bridges on constructive analysis, the $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ packet records the finite route by which a located diagonal subsequence is read from displayed rational and stream data. It sits over the dyadic core of chapter 291, the stream naming surface of chapter 126, the regular rational sequence carrier of chapter 301, and the terminal real seal of chapter 38. The packet also consumes diagonal-extraction sibling rows such as $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ and $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$ before it exports a located diagonal read. It is a finite naming certificate, not countable choice, quotient stream equality, selected host subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

8146.1 Carrier definition

Definition 8146.1 (BishopLocatedDiagonal carrier)**.** *A* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (Q, W, R, E, X, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the diagonal error budgets, comparison cells, and slack conversions.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected source stream entries and their chosen diagonal indices.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the dyadic tolerances and stream windows have been displayed.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the located real endpoint read from the regular rational diagonal.*
5. *X is the diagonal-extraction sibling row, read through* $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$ *and* $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$*, that records the finite extraction handoff.*
6. *L is the locatedness ledger, recording the displayed lower and upper rational comparisons used by the diagonal request.*
7. *H records componentwise* hsame *transport for Q, W, R, E, X, L.*
8. *C records displayed* Cont *replay of the same finite diagonal route.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *the diagonal-extraction siblings,* BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$ *row.*

The classifier accepts exactly packets exposing these rows and compares them componentwise through the inherited classifiers. It has no coordinate for countable choice, quotient stream equality, host-level subsequence identity, hidden real completeness, or an unrecorded diagonal selector.

Lean4 ✓ `BEDC.Derived.BishopLocatedDiagonalUp.TasteGate.BishopLocatedDiagonalTasteGate single carrier alignment`

8146.2 Certificate obligations

Theorem 8146.2 (BishopLocatedDiagonal NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ *carrier $D = (Q, W, R, E, X, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$ *surface consists exactly of dyadic tolerance exposure through Q, finite stream-window exposure through W, regular rational readback through R, real seal non-escape through E, diagonal-extraction handoff through X, locatedness comparison through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $Q, W, R, E, X, L, H, C, P, N$ are the full visible inventory, so any consumer of the diagonal read must begin with the dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, extraction row, and locatedness ledger.

The inherited dependencies fix the numeric route. The dyadic row is read through chapter 291, the stream windows through chapter 126, the regular readback through chapter 301, and the final seal through chapter 38.

The sibling row X then records which finite diagonal-extraction handoff is being consumed. Since the structural rows H, C, P, N only transport, replay, source, and name the same displayed route, no countable choice principle, quotient stream equality, selected host subsequence, or ambient completeness row is introduced. □

Theorem 8146.3 (BishopLocatedDiagonal window handoff)**.** *Every* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ *consumer that reads a located diagonal endpoint must pass through the finite window route*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalExtraction}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalizati}$

The handoff exports a located diagonal ledger over finite windows and dyadic budgets; it does not export a global selector, countable choice, quotient stream equality, or a real-completeness theorem.

Proof. Read the carrier of Definition 8146.1. The dyadic row Q and stream-window row W are exposed before any regular rational readback can be consumed.

Next consume the regular sequence and real seal rows R, E. These rows only state that the displayed finite window and tolerance route reaches the named real boundary; they do not supply host equality of streams or selected representatives.

Finally read the extraction sibling row X together with the locatedness row L and structural rows H, C, P, N. The consumer therefore receives only the finite BEDC handoff shown in the theorem. □

Theorem 8146.4 (BishopLocatedDiagonal real seal non-escape)**.** *In an accepted* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ *packet, the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E *can be consumed only after the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* Q*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* R*, diagonal-extraction row* X*, and locatedness ledger* L *have all been displayed. No consumer may bypass these rows to obtain ambient* $\mathsf{Real}^{\uparrow}$ *completeness, quotient equality of real names, or a hidden limit selector.*

Proof. The carrier places E after the tolerance, window, readback, extraction, and locatedness rows. Projection therefore exposes E only as the endpoint of that finite route.

The window handoff of Definition 8146.3 records the same dependency order for consumers. Since the accepted packet contains no coordinate for ambient completeness, quotient real equality, or hidden selection, the real seal cannot be read as any of those stronger objects. □

Theorem 8146.5 (BishopLocatedDiagonal transport stability)**.** *If an accepted* $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ *packet is transported by* hsame *or replayed by* Cont*, then the rows* Q, W, R, E, X, L *remain attached to the same local* $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$ *route. Thus transport preserves the finite diagonal ledger while refusing countable choice, quotient stream equality, host subsequence identity, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the transport row H and replay row C of the carrier. They act componentwise on the dyadic tolerance, stream-window, regular readback, real seal, extraction, and locatedness rows.

The provenance row P and local name row N record the same dependency anchors after transport. Hence a transported packet still factors through the four dependency certificates and the diagonal-extraction sibling rows before exposing the diagonal ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedDiagonal}^{\uparrow}$ packet is generated from DyadicRatCore tolerance rows, StreamName finite windows, RegSeqRat readback, a RealUp seal, diagonal-extraction sibling rows, locatedness comparisons, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$, seed)

Scope closed: Definition 8146.1, Definition 8146.2, Definition 8146.3, Definition 8146.4, and Definition 8146.5 seed the finite Bishop-style located diagonal packet over dyadic, stream, regular rational, real, and diagonal-extraction rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedDiagonal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, countable choice, quotient stream equality, selected host subsequences, hidden real completeness, or global diagonal compactness.

Upgrade path: Obligation closure requires a Lean carrier for BEDC.Derived.BishopLocatedDiagonalUp and checked rows for tolerance exposure, window handoff, real-seal non-escape, transport, replay, provenance, and local naming.

Chapter 8147

A Concrete Naming Certificate for $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$

Following Crandall and Liggett on nonlinear semigroups generated by accretive operators, the $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ packet records the resolvent–Euler construction surface as finite BEDC data. It sits over the complete-metric carrier of chapter 128, the metric-space carrier of chapter 4230, the ODE and PDE consumer surfaces of chapter 193 and chapter 194, the regular rational readback of chapter 301, the finite stream interface of chapter 126, and the terminal real-name seal of chapter 38. The packet names the displayed nonlinear evolution route; it does not assert host Banach-space completeness, maximal-accretive generation, selected limits, quotient trajectories, or ambient real analysis outside the displayed rows.

Definition 8147.1 (Crandall–Liggett semigroup carrier)**.** *A* $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (X, M, A, R, E, S, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompleteMetric}^{\uparrow}$ *state-space row, read together with the underlying* $\mathsf{Met}^{\uparrow}$ *distance comparisons used by every resolvent and Euler step.*
2. *M is the metric-accretive operator row, recording the displayed graph windows, range probes, accretive comparison data, and domain entries available to the packet.*
3. *A is the admissible step-size row, recording the positive rational time steps and their finite subdivision schedule.*
4. *R is the resolvent row, storing the finite resolvent reads $(I + \lambda M)^{-1}$ as named graph-window data rather than as a host inverse operator.*
5. *E is the Euler product row, recording finite products of resolvent steps along the displayed subdivision schedule.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the inspected time windows, initial-state probes, and requested precision windows.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the time-step, resolvent, and Euler-product ledgers.*
8. *T is the* $\mathsf{Real}^{\uparrow}$ *seal row for the inspected semigroup time and state-coordinate readbacks.*

9. *H records componentwise* hsame *transport for complete-metric, metric, operator, step-size, resolvent, Euler-product, stream-window, regular-readback, real-seal, replay, provenance, and local-name rows.*
10. *C records displayed* Cont *replay from an initial-state and time request through X, M, A, R, E, S, Q, T.*
11. *P is the* Pkg *provenance over* $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CrandallLiggettSemigroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, M, A, R, E, S, Q, T, H, C, P, N$. It has no coordinate for a host nonlinear semigroup, selected trajectory limit, quotient curve equality, unbounded-operator domain completion, countable choice over step schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8147.2 (Crandall–Liggett semigroup NameCert obligations)**.** *For every accepted* CrandallLiggettSemigrou *carrier $G = (X, M, A, R, E, S, Q, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CrandallLiggettSemigroup}^{\uparrow}}$ *surface consists exactly of carrier admission for the complete-metric state row, underlying metric comparisons, metric-accretive operator row, admissible step-size row, resolvent row, Euler-product row, finite stream windows, regular rational readback, terminal real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation may replace those rows by a host semigroup, selected limit curve, quotient trajectory equality, unlogged domain closure, countable-choice schedule, or external PDE/ODE well-posedness theorem.*

Proof. Project the carrier of Definition 8147.1. The analytic rows are X, M, A, R, E, S, Q, T: complete-metric and metric state data, operator graph data, admissible rational step sizes, resolvent reads, finite Euler products, stream windows, regular rational readback, and the terminal real seal.

Read the resolvent data before the Euler product. The row R supplies only displayed resolvent graph windows for the step sizes in A, and the row E records finite products of those displayed rows. Thus the packet does not introduce a host inverse operator or a selected infinite product.

The ODE/PDE-facing read is downstream of the finite windows. The $\mathsf{StreamName}^{\uparrow}$ row S fixes inspected times and state probes, the $\mathsf{RegSeqRat}^{\uparrow}$ row Q records the rational readback, and the $\mathsf{Real}^{\uparrow}$ row T seals only the displayed read.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for a host semigroup, selected trajectory, quotient curve equality, unlogged domain completion, choice schedule, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8147.3 (Crandall–Liggett resolvent–Euler route)**.** *Every ODE- or PDE-facing consumer of an accepted* $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ M,\ A,\ R,\ E,\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The route exposes the complete-metric state row, metric comparisons, accretive operator windows, rational step-size schedule, resolvent rows, finite Euler products, stream windows, regular rational readback, real seal, transport, replay, provenance, and local naming before any evolution read is public. It exports no ambient nonlinear semigroup theorem, selected limit, quotient trajectory equality, countable choice, or hidden complete state space.

Proof. Start with an evolution request from an ODE or PDE consumer. The request first reads the complete-metric and metric state rows in X, then the operator graph and accretive comparison data in M.

The time discretization is finite. The admissible step-size row A names the rational subdivisions, R supplies the displayed resolvent rows for those steps, and E records the finite Euler product available at the inspected window.

Only after that finite product is displayed may the consumer read S, Q, T. These rows expose the stream window, regular rational readback, and terminal real seal for the inspected semigroup value.

The structural rows H, C, P, N preserve the same order by componentwise transport, displayed replay, provenance, and local naming. Therefore the public route is the resolvent–Euler NameCert surface, not a host generation theorem or selected trajectory limit. □

Falsifiable prediction: An accepted $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ packet that exports an ODE/PDE evolution read while omitting the resolvent row, Euler-product row, stream-window row, regular rational readback, or terminal $\mathsf{Real}^{\uparrow}$ seal refutes the carrier.

Independence witness: complete-metric, metricspace, ode, pde, streamname, regseqrat, real: $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ is not bijective to any listed sibling because it binds an accretive-operator row, rational step-size schedule, resolvent rows, Euler products, finite windows, readback, real seal, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CrandallLiggettSemigroup}^{\uparrow}}$.

Constructive story: A $\mathsf{CrandallLiggettSemigroup}^{\uparrow}$ packet is generated from a complete-metric state row, metric comparisons, accretive operator graph windows, admissible rational step sizes, resolvent rows, finite Euler products, finite stream windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CrandallLiggettSemigroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8147.1, Definition 8147.2, and Definition 8147.3 seed the finite resolvent–Euler NameCert surface for nonlinear semigroup consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CrandallLiggettSemigroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close maximal-accretive generation, host nonlinear semigroup existence, uniqueness of trajectories, selected limits, quotient curve equality, countable choice over subdivisions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, resolvent-row exactness, Euler-product exactness, finite-window visibility, regular-readback boundary, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.CrandallLiggettSemigroupUp.

Chapter 8148

A Concrete Naming Certificate for $\mathsf{CompactRegularCauchyCriterion}^{\uparrow}$

Following Bishop and Bridges on compact metric sources through finite nets and explicit Cauchy moduli, the $\mathsf{CompactRegularCauchyCriterion}^{\uparrow}$ packet records the finite-window criterion used by Real and Completion consumers before any ambient compactness theorem is available. It sits over the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the compact regular-Cauchy criterion as explicit finite data; it does not identify compactness with open-cover compactness, quotient real equality, trichotomy, or selected limits.

Theorem 8148.1 (Compact regular-Cauchy criterion NameCert obligations)**.** *A local* $\mathsf{NameCert}_{\mathsf{CompactRegularCauchyC}}$ *packet is accepted exactly when it displays a finite carrier*

$$K = (G, W, D, R, E, H, C, P, N)$$

where G is a finite compactness grid row, W is the $\mathsf{StreamName}^{\uparrow}$ *family of sampled windows, D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for those windows, R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback produced by the grid, E is the downstream* $\mathsf{Real}^{\uparrow}$ *seal, H is componentwise* hsame *transport, C is displayed* Cont *replay, P is* Pkg *provenance, and N is the local naming row. The classifier compares accepted packets only through these rows.*

Proof. Carrier admission is projection from the displayed tuple. The compactness grid G is not a host compact set; it is the finite list of centers, dyadic radii, and grid-cover incidence data that the packet exposes.

The stream and dyadic rows then determine the visible read. For each grid cell, W names the sampled finite windows and D gives the corresponding dyadic tolerance checks, so the regular rational row R is downstream of finite observations and budgets.

The real seal and structural rows are consumer boundaries. The row E is read only after R, and H, C, P, N transport, replay, source, and name the same finite route. No quotient real equality, open-cover compactness principle, trichotomy, selected subsequence, or ambient completeness coordinate can be projected from the carrier. □

Theorem 8148.2 (Compact regular-Cauchy modulus window)**.** *For every accepted* $\mathsf{CompactRegularCauchyCriterior}$ *packet and every requested regular precision m, there is a displayed finite window budget*

$$B_m = (\Gamma_m, \rho_m, \omega_m)$$

such that Γ_m is a finite grid of dyadic centers, ρ_m is a DyadicRatCore$^{\uparrow}$ *radius row, and ω_m is a* StreamName$^{\uparrow}$ *read schedule. Any two sampled regular names in the same grid cell are transported by* hsame *to a common* RegSeqRat$^{\uparrow}$ *readback within the dyadic budget for m before any* Real$^{\uparrow}$ *seal is exposed.*

Proof. Fix the requested precision m. The packet reads the compactness grid coordinate G at precision m and obtains the finite grid Γ_m, dyadic radius row ρ_m, and stream-window schedule ω_m.

Each cell is checked by the dyadic ledger. The row D supplies the tolerance comparison for the sampled endpoints, while W supplies exactly the finite observations named by ω_m.

Now use componentwise hsame transport. If two sampled names land in the same cell, the transport row identifies their displayed window data and dyadic budget data, so the RegSeqRat$^{\uparrow}$ readback is common at precision m.

Only after this finite route has been exposed may the Real$^{\uparrow}$ seal row be read. The argument is a finite-window construction and not a proof by open covers, quotient reals, trichotomy, or choice. □

Theorem 8148.3 (Compact regular-Cauchy L10 scope)**.** *The* CompactRegularCauchyCriterion$^{\uparrow}$ *packet belongs to the L10 Real and Completion scope as a criterion surface over* DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$. *It supplies finite grids, dyadic budgets, regular readback, and seal order for downstream completion arguments, but it does not assert ambient* Real$^{\uparrow}$ *completeness, open-cover compactness, sequential compactness without explicit data, trichotomy, quotient reals, Lean verification, or bridge checking.*

Proof. The dependency surface is exactly the displayed route named in the theorem. Dyadic budgets come from DyadicRatCore$^{\uparrow}$, finite reads come from StreamName$^{\uparrow}$, regular rational names come from RegSeqRat$^{\uparrow}$, and the public completion-facing boundary is the Real$^{\uparrow}$ seal.

The L10 scope is therefore a finite criterion packet. A downstream consumer may ask for the grid and window budget at a requested precision, then use hsame transport to keep the regular readback stable across the displayed cell data.

Nothing in the packet supplies the excluded coordinates listed in the statement. Completeness, open-cover compactness, data-free sequential compactness, trichotomy, quotient-real equality, Lean verification, and bridge checking remain outside the named scope. □

Closure status for NameCert$_{\text{CompactRegularCauchyCriterion}^{\uparrow}}$.

Constructive story: A CompactRegularCauchyCriterion$^{\uparrow}$ packet is generated from finite compactness grids, StreamName sample windows, DyadicRatCore tolerance ledgers, RegSeqRat regular readback rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{CompactRegularCauchyCriterion}^{\uparrow}}$, seed)

Scope closed: Definition 8148.1, Definition 8148.2, and Definition 8148.3 seed the finite compact regular-Cauchy criterion packet for the L10 Real and Completion route.

Formal verification: FormalStatus(NameCert$_{\text{CompactRegularCauchyCriterion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, RealUp completeness, sequential compactness without explicit data, trichotomy, quotient reals, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite grid exposure, dyadic window budgets, regular readback, hsame transport, Real sealing, replay, provenance, and local naming for BEDC.Derived.CompactRegularCauchyCriterionUp.

Chapter 8149

A Concrete Naming Certificate for $\mathsf{BishopEffectiveRealName}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopEffectiveRealName}^{\uparrow}$ packet records an effective real name as explicit dyadic approximation, precision and modulus visibility, finite StreamName windows, RegSeqRat readback, and RealUp seal rows. It sits over the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational sequence handoff of chapter 301, the terminal real-name surface of chapter 38, and the fast threshold discipline of chapter 1781. The packet is a finite L10 real-name interface; it does not assert quotient equality of streams or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8149.1 (Bishop effective real-name carrier)**.** *A* $\mathsf{BishopEffectiveRealName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation ledger, storing the dyadic approximants and tolerance accounts exposed to the consumer.*
2. *M is the visible precision and modulus row that tells which dyadic tolerance is requested and which finite window may be opened.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened at the precision displayed by M.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the dyadic approximants and the opened stream windows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after D, M, S, R have been displayed.*
6. *H records componentwise* hsame *transport for the approximation ledger, precision and modulus row, finite window, regular rational readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the effective name from a precision query through D, M, S, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopEffectiveRealName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopEffectiveRealName}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, S, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge data.*

Theorem 8149.2 (Bishop effective real-name NameCert obligations)**.** *For every accepted* $\mathsf{BishopEffectiveRealName}$ *carrier*

$$B = (D, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopEffectiveRealName}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{DyadicRatCore}^{\uparrow}$ *approximation ledger, precision and modulus row,* $\mathsf{StreamName}^{\uparrow}$ *finite window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming rows;*
2. *approximation-row exactness, requiring D to display the dyadic approximants and tolerance accounts consumed by the readback;*
3. *modulus visibility, requiring M to expose the precision request and the finite threshold before any stream window is opened;*
4. *finite-window exactness, requiring S to be precisely the finite StreamName window opened by the visible row M;*
5. *RegSeqRat handoff, requiring R to read D, M, S before exporting a regular rational name;*
6. *Real seal nonescape, requiring E to consume D, M, S, R before any Real-facing row is public;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same displayed rows through H, C, P, N.*

No Bishop effective real-name obligation is stored outside these rows.

Proof. Project the carrier of Definition 8149.1. The only approximation-bearing coordinates are the dyadic ledger D, the precision and modulus row M, the finite window S, and the regular rational readback R.

The approximation-row exactness and modulus visibility clauses are read before any Real-facing seal is available. The row M supplies the precision query and threshold, while D supplies the dyadic tolerance account for that same query.

The finite-window and handoff clauses then force the consumer through S and R. The window S is opened from the visible threshold, and R reads the displayed dyadic data and window data as a regular rational name.

Finally E, H, C, P, N preserve the same finite route as a Real-facing seal, componentwise transport, replay, provenance, and local naming. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8149.3 (Bishop effective real-name Real seal handoff)**.** *Every Real-facing read of an accepted* $\mathsf{BishopEffectiveRealName}^{\uparrow}$ *carrier first exposes the displayed route*

$$D, M, S, R, E, H, C, P, N.$$

The handoff exports no quotient stream equality, selected limit, countable choice, trichotomy, host real equality, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge datum.*

Proof. Start from an accepted carrier $B = (D, M, S, R, E, H, C, P, N)$. The Real seal row E is listed downstream of the dyadic approximation ledger, precision and modulus row, finite StreamName window, and RegSeqRat readback.

Apply Definition 8149.2. Its RegSeqRat handoff and Real seal nonescape clauses require R to consume D, M, S and require E to consume D, M, S, R before a Real-facing row is public.

The structural rows H, C, P, N replay and name the same finite path. No separate coordinate supplies quotient stream equality, a selected limit, choice, trichotomy, host equality, ambient completeness, Lean verification, or bridge data, so the seal cannot bypass the displayed Bishop-style real-name interface. □

Falsifiable prediction: Every $\mathsf{BishopEffectiveRealName}^{\uparrow}$ Real-facing read factors through a DyadicRatCore approximation ledger, a visible precision and modulus row, a finite StreamName window, a RegSeqRat readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, fastcauchymodulus: BishopEffectiveRealNam is not bijective to any listed sibling because it jointly carries dyadic approximation, precision visibility, finite-window opening, regular rational readback, and Real-facing seal data as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopEffectiveRealName}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopEffectiveRealName}^{\uparrow}$ packet is generated from a DyadicRatCoreUp approximation ledger, a visible precision and modulus row, a StreamNameUp finite window, a RegSeqRatUp readback, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopEffectiveRealName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8149.1, Definition 8149.2, and Definition 8149.3 seed the finite Bishop-style effective real-name route from dyadic approximation evidence to the RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopEffectiveRealName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximation-row exactness, modulus visibility, finite-window exactness, RegSeqRat handoff, Real seal nonescape, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.BishopEffectiveRealNameUp.

Chapter 8150

A Concrete Naming Certificate for ProjectionValuedMeasure$^{\uparrow}$

Following von Neumann and the Reed–Simon treatment of spectral families, the ProjectionValuedMeasure$^{\uparrow}$ packet isolates the finite projection-family interface used between SpectralMeasure$^{\uparrow}$ and spectral-theorem consumers. It sits after the spectral-measure carrier of chapter 298, the Hilbert carrier of chapter 91, the bounded self-adjoint operator source of chapter 5160, the event-measure rows of chapter 92, and the consumer statement of chapter 214. Those siblings provide scalar measure windows, Hilbert endpoints, operator sources, event rows, and theorem-facing demand separately; this packet names the projection-valued family before any spectral theorem, functional calculus, or selected decomposition is read.

Definition 8150.1 (Projection-valued measure carrier)**.** *A* ProjectionValuedMeasure$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (H, A, E, \Pi, O, F, S, T, C, K, N)$$

with the following displayed rows:

1. *H is the* Hilbert$^{\uparrow}$ *endpoint on which all projection rows act.*
2. *A is the* BoundedSelfAdjointOperator$^{\uparrow}$ *source row whose spectral projections are being requested.*
3. *E is the* Measure$^{\uparrow}$ *event-family row, recording only the displayed finite event requests.*
4. *Π is the projection-family row, assigning each displayed event in E a projection endpoint over H.*
5. *O is the orthogonality row for disjoint displayed event pairs.*
6. *F is the finite-additivity row for displayed finite unions.*
7. *S is the scalar-window handoff row linking the projection family to the* SpectralMeasure$^{\uparrow}$ *scalar measure windows.*
8. *T stores componentwise* hsame *transport for Hilbert, operator, event, projection, orthogonality, additivity, and scalar-window rows.*
9. *C stores displayed* Cont *replay from event requests through projection endpoints and scalar-window handoff.*
10. *K is the* Pkg *provenance over* ProjectionValuedMeasure$^{\uparrow}$, SpectralMeasure$^{\uparrow}$, Hilbert$^{\uparrow}$, BoundedSelfAdjointOperator Measure$^{\uparrow}$, SpectralTheorem$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProjectionValuedMeasure}^{\uparrow}}$ *row.*
The carrier contains no coordinate for host sigma-additivity, quotient event equality, selected spectral decomposition, eigenbasis choice, unrestricted functional calculus, or a proof of the spectral theorem.

Definition 8150.2 (Projection-valued measure classifier)**.** *For accepted* $\mathsf{ProjectionValuedMeasure}^{\uparrow}$ *packets P and P', the classifier $P \sim_{\mathsf{ProjectionValuedMeasure}^{\uparrow}} P'$ holds exactly when their displayed Hilbert rows, bounded self-adjoint operator rows, measure-event rows, projection endpoints, orthogonality ledgers, finite-additivity ledgers, scalar-window handoffs, continuation routes, package provenance, and local naming rows compare componentwise by the recorded* hsame *witnesses. The classifier does not compare completed measurable spaces, host projection-valued functions, countable projection families, or spectral theorem objects.*

Theorem 8150.3 (Projection-valued measure NameCert obligations)**.** *For the carrier of Definition 8150.1, the local* $\mathsf{NameCert}_{\mathsf{ProjectionValuedMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for $P = (H, A, E, \Pi, O, F, S, T, C, K, N)$, Hilbert endpoint exposure through H, bounded self-adjoint source exposure through A, event-family exposure through E, projection-family exposure through Π, orthogonality through O, finite additivity through F, scalar-window handoff through S, componentwise transport through T, displayed replay through C, package provenance through K, and local naming through N.*

Proof. Project the finite packet $P = (H, A, E, \Pi, O, F, S, T, C, K, N)$. The first three rows supply the Hilbert endpoint, bounded self-adjoint source, and finite event family on which the projection-valued read is typed.

Read the projection rows next. The projection-family row Π assigns displayed events to projection endpoints, while O and F record orthogonality and finite additivity only for displayed event pairs and finite unions.

The scalar-window handoff S connects the projection ledger to $\mathsf{SpectralMeasure}^{\uparrow}$ without importing a completed measure space. Transport, replay, provenance, and local naming then preserve the same displayed rows, so the listed coordinates exhaust the NameCert obligations. □

Theorem 8150.4 (Projection-valued measure spectral-measure handoff)**.** *Every* $\mathsf{SpectralMeasure}^{\uparrow}$ *or* $\mathsf{SpectralTheorem}^{\uparrow}$ *consumer that reads projection-valued data from an accepted* $\mathsf{ProjectionValuedMeasure}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{Hilbert}^{\uparrow},\ \mathsf{BoundedSelfAdjointOperator}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \Pi,\ O,\ F,\ \mathsf{SpectralMeasure}^{\uparrow}$$

before local naming. The route exposes the projection family, orthogonality, finite additivity, and scalar-window handoff, but it does not expose host sigma-additivity, a quotient event space, an eigenbasis selector, an unrestricted functional calculus, or a spectral theorem proof.

Proof. Start with the carrier and classifier. They expose only the Hilbert row, bounded self-adjoint source row, displayed event family, projection endpoints, orthogonality and finite-additivity ledgers, scalar-window handoff, transport, replay, provenance, and local naming.

The $\mathsf{SpectralMeasure}^{\uparrow}$ sibling is reached through S, the scalar-window handoff row. This keeps scalar measure reads downstream of the projection ledger, rather than letting the spectral-measure chapter carry both the projection family and scalar window roles at once.

Finally the $\mathsf{SpectralTheorem}^{\uparrow}$ consumer reads the same finite package through K and N. Since the packet has no coordinate for completed measurable spaces, selected decompositions, functional calculus, or theorem proof data, the handoff is exhausted by the displayed projection-valued measure route. □

Falsifiable prediction: A spectral-theorem consumer that reads projection-valued data without displaying Hilbert, bounded self-adjoint operator, event-family, projection, orthogonality, finite-additivity, scalar-window, transport, replay, provenance, and local NameCert rows refutes the $\mathsf{ProjectionValuedMeasure}^{\uparrow}$ carrier.

Independence witness: spectralmeasure, hilbert, boundedselfadjointoperator, measure, spectraltheorem: none is bijective to ProjectionValuedMeasureUp because this packet alone binds finite event rows to projection endpoints with orthogonality, finite additivity, scalar-window handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ProjectionValuedMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{ProjectionValuedMeasure}^{\uparrow}$ packet is generated from a Hilbert endpoint, bounded self-adjoint source, displayed measure-event rows, projection endpoints, orthogonality ledgers, finite-additivity ledgers, scalar-window handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProjectionValuedMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8150.1, Definition 8150.2, Definition 8150.3, and Definition 8150.4 seed the finite projection-family interface consumed by SpectralMeasureUp and SpectralTheoremUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProjectionValuedMeasure}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.ProjectionValuedMeasureUp`

Bridge status: none

Not claimed: This chapter does not close host sigma-additivity, completed measurable spaces, quotient event equality, selected spectral decompositions, eigenbasis choices, unrestricted functional calculus, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, projection-family exposure, orthogonality, finite additivity, scalar-window handoff, transport, replay, provenance, and local naming for BEDC.Derived.ProjectionValuedMeasur

Chapter 8151

A Concrete Naming Certificate for $\mathsf{PeterWeyl}^{\uparrow}$

Following Peter and Weyl on compact-group representation theory, the $\mathsf{PeterWeyl}^{\uparrow}$ packet records the finite BEDC surface by which matrix coefficients of finite-dimensional unitary representations approximate compact-group functions. It sits after the topological-group rows of chapter 204, the invariant-measure surface of chapter 7873, the finite Grothendieck-ledger rows of chapter 246, the Hilbert carrier of chapter 91, the matrix readback of chapter 49, and the finite Fourier observation interface of chapter 124. The packet names the displayed coefficient-density route; it does not import a host compact group, ambient L^2 completion, selected irreducible list, quotient function equality, or analytic Peter–Weyl theorem as a primitive.

Definition 8151.1 (Peter–Weyl carrier)**.** *A* $\mathsf{PeterWeyl}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (G, M, R, H, F, A, D, T, C, Q, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{TopGroup}^{\uparrow}$ *compact-group source row, exposing multiplication, inversion, unit, continuity, and compact-readback windows used by the coefficient route.*
2. *M is the* $\mathsf{HaarMeasure}^{\uparrow}$ *row, recording the invariant integration surface and finite measure readbacks consumed by coefficient pairing.*
3. *R is the* $\mathsf{RepresentationRing}^{\uparrow}$ *row, listing the finite representation endpoints, direct-sum rows, tensor rows, and Grothendieck ledger entries available to the packet.*
4. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *row carrying the finite inner-product and norm windows over which coefficient functions are compared.*
5. *F is the* $\mathsf{Fourier}^{\uparrow}$ *finite-observation row for coefficient windows, transform samples, truncation bounds, and integration witnesses.*
6. *A is the* $\mathsf{Mat}^{\uparrow}$ *coefficient row, naming the inspected matrix entries of the displayed representation endpoints.*
7. *D is the density ledger, recording the finite coefficient span, requested tolerance row, approximation witness, and error readback.*
8. *T records componentwise* hsame *transport for group, measure, representation, Hilbert, Fourier, matrix, density, replay, provenance, and local-name rows.*

9. *C records displayed* Cont *replay from a compact-group probe and tolerance request through G, M, R, H, F, A, D.*
10. *Q is the* Pkg *provenance over* $\mathsf{PeterWeyl}^{\uparrow}$, $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{HaarMeasure}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PeterWeyl}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, M, R, H, F, A, D, T, C, Q, N$. It has no coordinate for a host compact group, a selected complete irreducible basis, quotient function equality, completed L^2 space, ambient Haar integration theorem, or external density proof.

Theorem 8151.2 (Peter–Weyl NameCert obligations)**.** *For every accepted* $\mathsf{PeterWeyl}^{\uparrow}$ *carrier*

$$P = (G, M, R, H, F, A, D, T, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{PeterWeyl}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact topological-group row, Haar-measure row, representation-ring row, Hilbert row, finite Fourier-observation row, matrix-coefficient row, density ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8151.1. The analytic source rows are G, M, R, H, F, A, D: compact-group operations, invariant measure readback, finite representation endpoints, Hilbert comparison windows, Fourier finite observations, matrix entries, and the coefficient-density ledger.

Read the rows in dependency order. The representation row R is interpreted over the group source G, the coefficient row A is read through the displayed representation endpoints, and the Hilbert and Fourier rows H, F provide only finite pairing and finite-observation windows.

The density ledger D is downstream from those rows. It records a finite coefficient span, a tolerance request, an approximation witness, and an error readback, without adding an ambient basis or a completed L^2 object.

Finally the structural rows T, C, Q, N transport, replay, package, and name the same finite surface. Since no excluded coordinate occurs in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8151.3 (Peter–Weyl matrix-coefficient density route)**.** *Every density read exported by an accepted* $\mathsf{PeterWeyl}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{TopGroup}^{\uparrow},\ \mathsf{HaarMeasure}^{\uparrow},\ \mathsf{RepresentationRing}^{\uparrow},\ \mathsf{Hilbert}^{\uparrow},\ \mathsf{Fourier}^{\uparrow},\ \mathsf{Mat}^{\uparrow},\ D,\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

The route exposes compact group operations, invariant-measure readback, finite representation endpoints, Hilbert comparison windows, finite Fourier observations, inspected matrix entries, and the density ledger before any approximation claim is public. It exports no selected irreducible basis, quotient function equality, completed L^2 carrier, or host Peter–Weyl theorem.

Proof. Start with a density request. The carrier first exposes the compact-group row G and the Haar-measure row M, so every coefficient comparison is attached to the displayed topological-group and invariant-measure surfaces.

Next read the representation and coefficient rows. The finite endpoints in R determine the representation data under inspection, and the matrix row A names only the selected coefficient entries of those endpoints.

The Hilbert and Fourier rows then provide the comparison surface. The row H supplies finite inner-product and norm windows, while F supplies finite coefficient or transform observations with their truncation and integration witnesses.

Only after these rows are displayed may the density ledger D be consumed. The replay, provenance, and local-name rows preserve that same order, so any public density read factors through the stated finite route and not through an ambient analytic theorem. □

Theorem 8151.4 (Peter–Weyl non-escape)**.** *An accepted* $\mathsf{PeterWeyl}^{\uparrow}$ *carrier exports only the rows* $G, M, R, H, F, A, D, T, C, Q, N$ *of Definition 8151.1. It exports no host compact group, selected complete list of irreducible representations, quotient equality of functions, completed Hilbert-space carrier, external Haar-integration theorem, or analytic Peter–Weyl density theorem.*

Proof. Inspect the carrier inventory. Its mathematical rows are the topological-group source, Haar-measure source, representation-ring source, Hilbert comparison row, Fourier finite-observation row, matrix-coefficient row, and density ledger.

Apply the NameCert obligations of Definition 8151.2. Every accepted read remains inside those rows and their structural transport, replay, provenance, and local naming.

Apply the density route of Definition 8151.3. Approximation-facing consumers must read through the finite coefficient route before they may inspect the density ledger. The excluded analytic objects have no carrier coordinate and no continuation route, so they cannot be recovered from the packet. □

Falsifiable prediction: An accepted $\mathsf{PeterWeyl}^{\uparrow}$ packet that exports a density read while omitting the compact-group row, Haar-measure row, representation-ring row, Hilbert comparison row, Fourier finite-observation row, matrix-coefficient row, density ledger, transport, replay, provenance, or local NameCert row refutes the carrier.

Independence witness: topgroup, haarmeasure, representationring, hilbert, fourier, matrix: $\mathsf{PeterWeyl}^{\uparrow}$ is not bijective to any listed sibling because it binds compact-group operations, invariant measure, finite representation endpoints, Hilbert comparison windows, Fourier finite observations, matrix coefficients, and a density ledger in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{PeterWeyl}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PeterWeyl}^{\uparrow}$ packet is generated from compact topological-group rows, Haar-measure readback, finite representation-ring endpoints, Hilbert comparison windows, Fourier finite observations, matrix-coefficient rows, a coefficient-density ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PeterWeyl}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8151.1, Definition 8151.2, Definition 8151.3, and Definition 8151.4 seed the finite matrix-coefficient density route over displayed $\mathsf{TopGroup}^{\uparrow}$, $\mathsf{HaarMeasure}^{\uparrow}$, $\mathsf{RepresentationRing}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, and $\mathsf{Mat}^{\uparrow}$ rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PeterWeyl}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the analytic Peter–Weyl theorem, selected irreducible basis, quotient function equality, completed L^2 carrier, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, matrix-coefficient exactness, density-ledger exactness, Hilbert and Fourier readback boundaries, transport, replay, provenance, and local naming for BEDC.Derived.PeterWeylUp.

Chapter 8152

A Concrete Naming Certificate for $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$

Following Leibniz and Bishop–Bridges, the $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$ packet records differentiation under a Riemann integral as finite BEDC analysis rows rather than as a host analytic principle. It sits beside the Riemann-integral route of chapter 1526, the uniform convergence route of chapter 3417, the completion-modulus route of chapter 6156, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names the finite window in which a parameter derivative and an integral readback share the same displayed modulus ledger before a Real-facing consumer may compare the two rows.

Definition 8152.1 (Differentiation under integral carrier)**.** *A* $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, I, R, \Delta, M, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the parameter row, naming the finite parameter window and the parameter probe at which the derivative is requested.*
2. *I is the interval row, naming the compact interval over which the Riemann integral is read.*
3. *R is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row, containing the finite tagged-partition and integral-readback data.*
4. *Δ is the derivative row, naming the finite difference-window data for the parameter derivative of the displayed integrand.*
5. *M is the shared modulus row governing both the integral approximation and the derivative-window comparison.*
6. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row listing the inspected parameter, interval, partition, and tolerance windows.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to R, Δ, M, S.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the readback row Q and the shared modulus row M have been displayed.*
9. *H records componentwise* hsame *transport for parameter, interval, Riemann-integral, derivative, shared-modulus, stream-window, readback, real-seal, replay, provenance, and local-name rows.*
10. *C records displayed* Cont *replay from a finite parameter-tolerance request through $A, I, R, \Delta, M, S, Q, E$.*

11. *P is the* Pkg *provenance over* $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, I, R, \Delta, M, S, Q, E, H, C, P, N$. It has no coordinate for measure-theoretic dominated convergence, host function extensionality, quotient equality of functions or streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a detached derivative theorem outside the finite window.*

Theorem 8152.2 (Differentiation under integral NameCert obligations)**.** *For every accepted* DifferentiationUnderIn *carrier $D = (A, I, R, \Delta, M, S, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission for the parameter, interval, Riemann-integral, derivative, shared-modulus, stream-window, regular-readback, real-seal, transport, replay, provenance, and local naming rows; shared-modulus exactness requiring R and Δ to consume the same M row; finite-window exactness through S; readback exactness through Q; and non-escape from measure-theoretic dominated convergence, host extensionality, quotient equality, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and detached derivative data.*

Proof. Project the carrier. The only analytic rows visible to the classifier are the parameter row A, interval row I, Riemann-integral row R, derivative row Δ, shared-modulus row M, stream-window row S, readback row Q, and real-seal row E.

The shared-modulus clause is read before the derivative and integral rows can be compared. The packet therefore treats the requested Leibniz-style equality as a finite window route through R, Δ, M, S, Q, E, not as an ambient theorem about all functions.

Rows H, C, P, N transport, replay, source, and name that same route. Since the carrier has no coordinate for dominated convergence, host extensionality, quotient equality, countable choice, ambient completeness, or detached derivative data, the listed obligations exhaust the local NameCert surface. □

Theorem 8152.3 (Differentiation under integral finite-window route)**.** *Every Real-facing read of an accepted* $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$ *carrier factors through the finite route*

$\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{RiemannIntegralCompletionModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, E

The route supplies a finite parameter window, compact interval data, Riemann-integral approximation, derivative-window comparison, shared modulus, regular rational readback, and terminal real-name seal. It exports no measure-theoretic dominated-convergence theorem, host function extensionality, quotient equality, countable-choice schedule, or ambient real-completeness principle.

Proof. Start with the NameCert obligations of Definition 8152.2. They identify the integral and derivative rows as displayed carrier rows that must share the same modulus before a Real-facing comparison is public.

The consumer next opens only the finite stream windows in S. Those windows determine the regular rational readback Q from the Riemann-integral and derivative rows under the shared modulus M, and only then can the terminal seal E be consumed.

The completion-modulus, transport, replay, provenance, and local naming rows preserve that same order. Thus the read remains a finite BEDC analysis route through the displayed rows and never becomes a host dominated-convergence, extensionality, quotient, choice, or completeness principle. □

Theorem 8152.4 (Differentiation under integral L10 seal nonescape)**.** *An accepted* $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$ *packet reaches* $\mathsf{Real}^{\uparrow}$ *only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and shared-modulus rows. Any consumer that asks for a real equality without exposing* M, S, Q, E *has left the packet surface and cannot cite the local* $\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$ *row.*

Proof. Use the finite-window route of Definition 8152.3. The route places the stream windows before regular rational readback and places the readback before the Real seal.

Apply the obligation surface of Definition 8152.2. It keeps the shared modulus visible throughout the Riemann-integral and derivative comparison, so a consumer that omits M, S, Q, E lacks the rows required for local naming.

Therefore the L10 seal is a nonescape boundary. The packet can export only the finite readback-and-seal route displayed in the carrier, not a detached real-equality theorem or an ambient completeness argument. □

Closure status for $\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$.

Constructive story: A $\mathsf{DifferentiationUnderIntegral}^{\uparrow}$ packet is generated from parameter, interval, Riemann-integral, derivative, shared-modulus, finite StreamName window, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$, seed)

Scope closed: Definition 8152.1, Definition 8152.2, Definition 8152.3, and Definition 8152.4 seed the finite-window differentiation-under-integral packet for Real-facing readback consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DifferentiationUnderIntegral}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure-theoretic dominated convergence, host function extensionality, quotient equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exactness, finite-window exactness, regular-readback boundary, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.DifferentiationUnderInt

Chapter 8153

A Concrete Naming Certificate for $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$

Following Bishop and Bridges on metric completions, the $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ packet records the terminal finite seal by which a uniformly controlled map between displayed metric sources is read as a completion-facing functorial handoff. It sits after the metric-completion carrier of chapter 1506, the functoriality packet of chapter 3755, the dense-embedding surface of chapter 3351, the finite stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a single finite terminal-seal object; it does not assert quotient completion equality, selected representatives, countable choice, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8153.1 (Metric completion functorial seal carrier)**.** *A* $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source-completion row, naming the displayed source and target completion boundaries.*
2. *F is the* $\mathsf{MetricCompletionFunctor}^{\uparrow}$ *functoriality row, recording the map graph and the finite continuity control used by the completion handoff.*
3. *D is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row, exposing the dense source embeddings that must be read before the completed map is sealed.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the source and target approximation requests.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, repacking the opened windows as regular rational source and target names.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal, visible only after M, F, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the completion, functoriality, dense-embedding, window, readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same completion-facing functorial route.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{MetricCompletionFunctor}^{\uparrow}$, $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, F, D, W, R, E, H, C, P, N$. It has no coordinate for quotient completion equality, selected representatives, countable choice, host function equality, global extension uniqueness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8153.2 (Metric completion functorial seal NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ *carrier*

$$S = (M, F, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}}$ *surface consists exactly of completion-boundary admission, functorial map-row admission, dense-embedding exposure, finite StreamName window inspection, RegSeqRat readback, terminal Real seal discipline, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming. Every completion-facing consumer must read the displayed route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletionFunctor}^{\uparrow} \longmapsto \mathsf{MetricCompletionDenseEmbedding}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Re}$$

before the functorial seal is public.

Proof. Project the carrier of Definition 8153.1. The completion boundary, functorial map row, dense embedding row, finite stream window, regular rational readback, and Real seal are the only analytic coordinates.

The completion consumer first reads M, F, D. These rows display the source and target completion boundaries, the map graph with its continuity control, and the dense embeddings whose images are being sealed.

The finite observation rows then mediate the Real-facing read. The window row W and readback row R expose only inspected stream fragments and regular rational names before E becomes visible.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no coordinate for quotient completion equality, selected representatives, countable choice, host function equality, global extension uniqueness, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8153.3 (Metric completion functorial seal dense readback)**.** *Every dense-source read of an accepted* $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ *carrier must expose the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row before the* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal are consumed. Thus the completed map is available only through the displayed dense embedding and regular readback route, not through a selected completion representative, quotient stream equality, host function equality, or ambient completeness theorem.*

Proof. Start with the NameCert obligations of Definition 8153.2. They place the dense-embedding row D between the functorial completion row F and the window/readback rows W, R.

The dense row controls the public source of the readback. A consumer may inspect the completed map only after the source embedding has been displayed, and the subsequent StreamName and RegSeqRat rows record the finite approximation data actually read.

The terminal seal E and structural rows H, C, P, N preserve that same route. No carrier coordinate supplies a selected representative, quotient stream equality, host function equality, or ambient completeness principle, so the dense readback remains the displayed finite handoff. □

Falsifiable prediction: Every $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ completion-facing read exposes MetricCompletionUp, MetricCompletionFunctorUp, MetricCompletionDenseEmbeddingUp, StreamNameUp, RegSeqRatUp, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the functorial seal is public.

Independence witness: metriccompletion, metric-completion-functoriality, metric-completion-dense-embedding, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ because this packet jointly carries the completion boundary, functorial map row, dense embedding row, finite observation window, regular rational readback, and terminal Real seal as one NameCert object.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}$ packet is generated from MetricCompletionUp source and target boundaries, a MetricCompletionFunctorUp map row, a MetricCompletionDenseEmbeddingUp dense-source row, StreamNameUp windows, RegSeqRatUp readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8153.1, Definition 8153.2, and Definition 8153.3 seed the finite terminal-seal route for metric-completion functorial reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricCompletionFunctorialSeal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, countable choice, host function equality, global extension uniqueness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, functorial map-row exactness, dense-embedding exposure, StreamName window inspection, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionFunctorialSealUp.

Chapter 8154

A Concrete Naming Certificate for $\mathsf{HermiteFunction}^{\uparrow}$

Following Hermite and Fourier analysis, the $\mathsf{HermiteFunction}^{\uparrow}$ packet records the finite normalized Hermite-function surface built from the Hermite polynomial recurrence, a Gaussian envelope ledger, Schwartz-space admission, Fourier-transform handoff, and tempered-distribution action rows. It sits beside the polynomial recurrence packet of chapter 6236, the transform surface of chapter 4025, the rapidly decreasing test-space carrier of chapter 5877, and the distributional action route of chapter 2310. The packet names the finite certificate interface only; it does not assert Hilbert-space completeness, spectral decomposition, quotient equality of functions, or a selected ambient basis.

Definition 8154.1 (Hermite-function carrier)**.** *A* $\mathsf{HermiteFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (P, G, S, T, D, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{HermitePolynomial}^{\uparrow}$ *source row, exposing the finite polynomial seed and recurrence window that supplies the displayed Hermite polynomial.*
2. *G is the Gaussian envelope row, recording the finite decay and normalization budget attached to the polynomial source.*
3. *S is the* $\mathsf{SchwartzSpace}^{\uparrow}$ *admission row, opened only after P and G display the rapid-decay budget consumed by the test-space carrier.*
4. *T is the* $\mathsf{FourierTransform}^{\uparrow}$ *handoff row, recording the finite transform-read route for the displayed Hermite-function window.*
5. *D is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *action row, exposing only the distribution-facing read obtained from the same Schwartz and transform rows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *scalar readback row for normalization, phase, and finite coefficient data.*
7. *H records componentwise* hsame *transport for the polynomial source, Gaussian envelope, Schwartz admission, transform handoff, distribution action, scalar readback, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route from P, G through S, T, D, R, H, Q, N.*

9. *Q is the* Pkg *provenance over* $\mathsf{HermiteFunction}^{\uparrow}$, $\mathsf{HermitePolynomial}^{\uparrow}$, $\mathsf{FourierTransform}^{\uparrow}$, $\mathsf{SchwartzSpace}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HermiteFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, G, S, T, D, R, H, C, Q, N$. It has no coordinate for a completed L^2 basis, global spectral theorem, quotient function equality, distribution dual completeness, selected representatives, Lean verification, or standard-bridge data.

Theorem 8154.2 (Hermite-function NameCert obligations)**.** *For every accepted* $\mathsf{HermiteFunction}^{\uparrow}$ *carrier*

$$F = (P, G, S, T, D, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{HermiteFunction}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the* $\mathsf{HermitePolynomial}^{\uparrow}$ *source, Gaussian envelope,* $\mathsf{SchwartzSpace}^{\uparrow}$ *admission,* $\mathsf{FourierTransform}^{\uparrow}$ *handoff,* $\mathsf{TemperedDistribution}^{\uparrow}$ *action, scalar readback, transport, replay, provenance, and local naming rows;*
2. *polynomial-source exactness, requiring P to expose the same Hermite recurrence window consumed by the envelope row G;*
3. *Schwartz admission, requiring S to read P and G before a rapidly decreasing function-space row is public;*
4. *Fourier handoff, requiring T to consume the displayed polynomial, envelope, and Schwartz rows before any transform-facing read is exported;*
5. *tempered-distribution nonescape, requiring D to read the same S, T route before any distributional action is public;*
6. *scalar readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming for the same rows through R, H, C, Q, N.*

No Hermite-function obligation is stored outside these rows.

Proof. Project the carrier of Definition 8154.1. The only analytic source rows are the Hermite polynomial window P, the Gaussian envelope G, the Schwartz admission row S, the transform handoff T, and the distribution action row D.

The polynomial-source and envelope clauses force the recurrence data to be visible before any function-space read is available. The Schwartz admission row can therefore expose rapid decay only through the displayed P, G pair.

The Fourier and tempered-distribution rows then use the same path. The row T reads P, G, S before exporting a transform-facing observation, and D reads S, T before exposing a distributional action.

Finally R, H, C, Q, N preserve the same finite route as scalar readback, componentwise transport, replay, provenance, and local naming. Since the excluded objects have no carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8154.3 (Hermite-function Fourier-transform handoff)**.** *Every Fourier-facing or tempered-distribution-facing read of an accepted* $\mathsf{HermiteFunction}^{\uparrow}$ *carrier first exposes the finite route*

$$P, G, S, T, D, R, H, C, Q, N.$$

The handoff exports no completed L^2 basis, global spectral theorem, quotient function equality, distribution dual completeness, selected representative, Lean verification, or standard-bridge datum.

Proof. Start from an accepted carrier $F = (P, G, S, T, D, R, H, C, Q, N)$. The transform row T is listed downstream of the Hermite polynomial source, Gaussian envelope, and Schwartz admission rows.

Apply Definition 8154.2. Its Schwartz admission and Fourier handoff clauses require S to consume P, G and require T to consume P, G, S before a transform-facing observation is public.

The tempered-distribution row D is downstream of the same route, and R, H, C, Q, N replay and name that route without adding any extra analytic coordinate. Thus every Fourier-facing or distribution-facing read factors through the displayed Hermite-function packet. □

Falsifiable prediction: Every accepted $\mathsf{HermiteFunction}^{\uparrow}$ Fourier-facing or tempered-distribution-facing read factors through a HermitePolynomialUp source row, a Gaussian envelope ledger, a SchwartzSpaceUp admission row, a FourierTransformUp handoff, a TemperedDistributionUp action row, scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: hermite-polynomial, fourier-transform, schwartz-space, tempered-distribution: $\mathsf{HermiteFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries polynomial recurrence, Gaussian envelope, function-space admission, transform handoff, distribution action, scalar readback, transport, replay, provenance, and local naming in one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{HermiteFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{HermiteFunction}^{\uparrow}$ packet is generated from a HermitePolynomialUp source row, a Gaussian envelope ledger, a SchwartzSpaceUp admission row, a FourierTransformUp handoff, a TemperedDistributionUp action row, scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HermiteFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8154.1, Definition 8154.2, and Definition 8154.3 seed the finite Hermite-function route from polynomial recurrence and Gaussian decay to Fourier and tempered-distribution reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HermiteFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hilbert-space completeness, spectral decomposition, quotient equality of functions, completed distribution duality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, polynomial-source exactness, Schwartz admission, Fourier handoff, tempered-distribution nonescape, scalar readback, componentwise transport, displayed replay, provenance, and local naming for BEDC.Derived.HermiteFunctionUp.

Chapter 8155

A Concrete Naming Certificate for $\mathsf{WeierstrassMTestWindow}^{\uparrow}$

Following Bishop and Bridges constructive analysis and the standard Weierstrass M-test, the $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ packet records the finite majorant-window data needed before a function-series consumer may read a regular Cauchy handoff or terminal real-name seal. It sits beside the M-test carrier of chapter 399, the real-series source of chapter 1581, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the constructive majorant-window route as finite BEDC rows; it does not import countable choice, arbitrary infinite sums, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8155.1 (Weierstrass M-test finite-window carrier)**.** *A* $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (F, M, B, T, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite function-series window, listing only the summand windows and source indices inspected by this packet.*
2. *M is the displayed positive majorant sequence for the same inspected indices, written as a finite read of positive comparison rows rather than as an ambient infinite sum.*
3. *B is the finite domination ledger matching each inspected summand window in F to its corresponding positive majorant row in M.*
4. *T is the finite partial-tail budget obtained from B and the displayed majorant tail route.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window surface through which the source summand windows and partial-tail requests are observed.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced after the partial-tail budget has been exposed.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only through R.*
8. *H records componentwise* hsame *transport for source windows, majorant rows, domination ledgers, partial-tail budgets, stream windows, regular readbacks, real seals, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay of the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{WeierstrassMTestWindow}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{WeierstrassMTestWindow}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, M, B, T, S, R, E, H, C, P, N$. It has no coordinate for countable choice, an arbitrary infinite sum object, quotient real equality, selected limits, host equality of functions, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8155.2 (Weierstrass M-test finite-window NameCert obligations)**.** *For every accepted* $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ *carrier*

$$W = (F, M, B, T, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WeierstrassMTestWindow}^{\uparrow}}$ *surface consists exactly of finite function-series window exposure through F, positive majorant-row exposure through M, domination ledger exposure through B, finite partial-tail budgeting through T, StreamName observation through S, RegSeqRat readback through R, RealUp sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8155.1. The rows F, M, B, T expose the source windows, positive majorant sequence rows, domination ledger, and finite partial-tail budget before any convergence-facing read can be served.

Use the sibling surfaces in order. The source series is the real-series surface of chapter 1581; the majorant route is the M-test packet of chapter 399; the finite observations are StreamName windows from chapter 126; and the regular readback is the $\mathsf{RegSeqRat}^{\uparrow}$ surface of chapter 301.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for countable choice, arbitrary infinite sums, quotient real equality, selected limits, host function equality, or ambient Real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8155.3 (Weierstrass M-test finite-window Cauchy-bound route)**.** *Every Cauchy-bound or Real-facing consumer of an accepted* $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RealSeries}^{\uparrow},\ \mathsf{WeierstrassMTest}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The partial-tail budget is therefore read as a finite majorant-window certificate before the terminal real seal is consumed. The route exports no countable-choice schedule, arbitrary infinite sum, quotient real equality, selected limit, host function equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 8155.2. It forces every consumer read through the source window, positive majorant rows, domination ledger, finite partial-tail budget, StreamName observation, RegSeqRat readback, and RealUp seal before the local certificate can be inspected.

The $\mathsf{WeierstrassMTest}^{\uparrow}$ sibling supplies the majorant-tail route, while $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ keep each observation and tolerance request finite. Thus the Cauchy-bound read is a displayed finite-window route, not an appeal to an unrecorded infinite summation theorem.

The terminal row E is only the $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The absence of countable-choice, arbitrary-sum, quotient-real, selector, host-equality, and ambient-completeness coordinates prevents any such object from entering the exported route. □

Falsifiable prediction: Every accepted $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ read exposes finite function-series windows, positive majorant rows, finite domination ledgers, partial-tail budgets, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any Cauchy-bound or Real-facing consumer is served.

Independence witness: realseries, weierstrassmtest, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ because this packet alone binds the finite source window, positive majorant window, domination ledger, partial-tail budget, observation route, readback, seal, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{WeierstrassMTestWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{WeierstrassMTestWindow}^{\uparrow}$ packet is generated from finite function-series windows, displayed positive majorant rows, a finite domination ledger, a partial-tail budget, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{WeierstrassMTestWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8155.1, Definition 8155.2, and Definition 8155.3 seed the finite majorant-window route for the Weierstrass M-test.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{WeierstrassMTestWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, arbitrary infinite sums, quotient real equality, selected limits, host function equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite source-window exposure, positive majorant-row exposure, domination-ledger exactness, partial-tail budgeting, StreamName observation, RegSeqRat readback, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.WeierstrassMTestWindowUp.

Chapter 8156

A Concrete Naming Certificate for GaussDivergenceTheorem$^{\uparrow}$

Following Gauss and Stokes, the GaussDivergenceTheorem$^{\uparrow}$ packet records the finite flux-boundary route by which a displayed vector field, its divergence row, an oriented boundary, and compatible integration readbacks are named as one boundary-flux certificate. It sits beside the differential-form surface of chapter 136, the manifold carrier of chapter 96, the tagged integration boundary of chapter 1526, the terminal scalar seal of chapter 38, and the graph/readback discipline of chapter 130. The packet is a finite BEDC route for the classical divergence theorem; it does not import measure completion, host vector calculus, selected representatives, quotient equality of fields, or ambient completeness of Real$^{\uparrow}$.

Definition 8156.1 (Gauss divergence theorem carrier)**.** *A* GaussDivergenceTheorem$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, V, D, B, W, I, T, R, P, N)$$

with the following displayed rows:

1. *M is the manifold and chart-window row, read through* Manifold$^{\uparrow}$ *and carrying only the finite domain windows visible to the certificate;*
2. *V is the vector-field row, read through* ContinuousMap$^{\uparrow}$ *and the differential-form interface* DiffForm$^{\uparrow}$ *without adding a host vector-field object;*
3. *D is the divergence row obtained from the same displayed vector-field and chart rows;*
4. *B is the oriented-boundary row for the domain window, including incidence, normal-orientation, and boundary-chart data;*
5. *W is the domain-window row that keeps the interior integration request and the boundary integration request tied to the same finite region;*
6. *I is the integral and readback row, routing both the divergence integral and the boundary flux integral through* RiemannIntegral$^{\uparrow}$ *and the terminal* Real$^{\uparrow}$ *seal;*
7. *T records componentwise* hsame *transport for the manifold, vector-field, divergence, boundary, window, and integration rows;*
8. *R records displayed* Cont *replay from a chart-window request through the vector-field, divergence, boundary, and integral readback rows;*

9. *P is the* Pkg *provenance over* $\mathsf{GaussDivergenceTheorem}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and sibling* NameCert *rows;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{GaussDivergenceTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host divergence theorem, a completed measure space, a selected boundary parametrization, quotient equality of vector fields, or ambient real completeness.

Theorem 8156.2 (Gauss divergence theorem NameCert obligations)**.** *For every accepted* GaussDivergenceTheorem *carrier $G = (M, V, D, B, W, I, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GaussDivergenceTheorem}^{\uparrow}}$ *surface is exhausted by carrier admission for the manifold chart window, vector-field row, divergence row, oriented-boundary row, domain-window row, integral and readback row, componentwise transport, displayed replay, provenance, and local naming. The obligations are discharged only over the finite route*

$$M, V, D, B, W, I, T, R, P, N.$$

No local obligation is stored in a host vector-calculus theorem, a measure-completion carrier, a quotient field equality, a selected representative, or an ambient completeness principle.

Proof. Project the carrier of Definition 8156.1. The analytic rows are exactly M, V, D, B, W, I: the finite chart window, displayed vector field, divergence row, oriented boundary, shared domain window, and integration readback.

The divergence and boundary rows remain tied to the same source. The row D is read from V over the chart data in M, while B and W keep the boundary and interior integration requests on one finite domain window.

Finally attach T, R, P, N. These structural rows transport, replay, source, and name the same packet. Since none of the rows stores host vector calculus, measure completion, quotient equality, selected representatives, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8156.3 (Gauss divergence theorem flux-boundary route)**.** *Every* $\mathsf{GaussDivergenceTheorem}^{\uparrow}$ *consumer that reads a boundary-flux statement must first read the finite route*

$\mathsf{Manifold}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, NameCert

through the rows $M, V, D, B, W, I, T, R, P, N$ of Definition 8156.1. The divergence integral and the oriented boundary flux are therefore two readbacks of the same displayed finite window, not a host vector-calculus theorem, a completed measure-space comparison, a selected boundary parametrization, or a quotient equality of vector fields.

Proof. Begin with the carrier inventory. The manifold row M and domain-window row W make the finite region visible before either integral read is public.

Next read the vector-field and divergence rows. The vector-field row V is routed through $\mathsf{ContinuousMap}^{\uparrow}$ and $\mathsf{DiffForm}^{\uparrow}$, and the divergence row D is a displayed row over the same chart data. The boundary row B supplies the oriented boundary needed by the flux read.

The integral row I then routes the interior divergence read and the boundary flux read through $\mathsf{RiemannIntegral}^{\uparrow}$ and the terminal $\mathsf{Real}^{\uparrow}$ seal. The structural rows T, R, P, N preserve that route and add no host theorem, measure completion, quotient equality, selected representative, or ambient completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{GaussDivergenceTheorem}^{\uparrow}$ packet whose oriented-boundary row or domain-window row is removed loses the displayed flux-boundary route; with both rows present, every flux read factors through the same finite carrier.

Independence witness: diffform, manifold, riemannintegral, real, continuousmap: none is bijective with $\mathsf{GaussDivergenceTheorem}^{\uparrow}$ because the packet jointly carries vector-field, divergence, oriented-boundary, domain-window, integral readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{GaussDivergenceTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{GaussDivergenceTheorem}^{\uparrow}$ packet is generated from a displayed manifold chart window, vector-field row, divergence row, oriented-boundary row, domain-window row, integral and readback row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GaussDivergenceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8156.1, Definition 8156.2, and Definition 8156.3 seed the finite flux-boundary packet over displayed manifold, vector-field, divergence, oriented-boundary, domain-window, integration, readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GaussDivergenceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, measure completion, host vector calculus, selected representatives, quotient equality of vector fields, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, divergence-row exactness, oriented-boundary compatibility, domain-window stability, integral readback, transport, replay, provenance, and ledger non-escape for BEDC.Derived.GaussDiverge

Chapter 8157

A Concrete Naming Certificate for $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ packet records the finite stability handoff by which a displayed dyadic absolute-value row remains usable when a regular rational or real-name consumer replays the same tolerance windows. It sits after the dyadic source surface of chapter 291, the rational source of chapter 37, the stream-window carrier of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite absolute-value endpoint packet of chapter 293. The packet names a stability route for absolute-value tolerance rows; it is not a host rational absolute value, quotient equality, a selected representative, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8157.1 (Dyadic absolute-value stability carrier)**.** *A* $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, A, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row whose dyadic endpoint and tolerance ledger are being inspected.*
2. *A is the* $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ *endpoint-and-tolerance row attached to D.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which downstream observers request dyadic endpoint approximations.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same stream windows and absolute-value tolerance ledger.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, A, S, Q have been displayed.*
6. *H records componentwise* hsame *transport for the dyadic source, absolute-value row, stream windows, regular readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a stability request through*

$$D, A, S, Q, E \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicAbsoluteValue}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{DyadicAbsoluteValueStability}^{\uparrow}}$ *row.*
The carrier contains no host rational absolute-value function, quotient equality of rational or real names, selected representative, trichotomy witness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 8157.2 (Dyadic absolute-value stability NameCert obligations)**.** *For every accepted* $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ *carrier* $T = (D, A, S, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicAbsoluteValueStability}^{\uparrow}}$ *surface consists exactly of dyadic-source admission through D, absolute-value row exposure through A, StreamName window exposure through S, RegSeqRat readback through Q, Real seal non-escape through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8157.1. The analytic rows are the dyadic source D, absolute-value row A, stream-window row S, regular readback Q, and terminal seal E; the structural rows are H, C, P, N.

The dyadic-source and absolute-value obligations are inherited as displayed rows. A consumer first opens D as the dyadic endpoint and tolerance ledger, then opens A as the finite absolute-value endpoint-and-tolerance row attached to that same source.

The readback obligations are finite. The row S supplies the inspected windows, Q records the regular rational readback obtained from those windows, and E is downstream of D, A, S, Q rather than an independent completed real.

Transport, replay, provenance, and local naming are exactly H, C, P, N. Since the carrier has no coordinate for host rational absolute value, quotient equality, selected representatives, trichotomy, or ambient completeness, no local NameCert obligation can project one of those objects. □

Theorem 8157.3 (Dyadic absolute-value stability RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ *packet reads the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{DyadicAbsoluteValue}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto H, C, P, N.$$

The handoff preserves the displayed absolute-value tolerance ledger from the dyadic source through the stream windows and regular readback before any terminal real seal is consumed. It exports no host rational absolute value, quotient equality, selected representative, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8157.2. The accepted consumer must expose D, A, S, Q, E and the structural rows before the packet can be read.

Read D through $\mathsf{DyadicRatCore}^{\uparrow}$ and the rational source surface of $\mathsf{Rat}^{\uparrow}$. The absolute-value endpoint and tolerance ledger are then supplied by A, the accepted $\mathsf{DyadicAbsoluteValue}^{\uparrow}$ row attached to the same displayed dyadic source.

Next read the finite windows S and the regular rational handoff Q. This is the only route by which a $\mathsf{RegSeqRat}^{\uparrow}$ consumer sees the absolute-value tolerance data, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is downstream of that regular readback.

Therefore the handoff is stable under the displayed hsame transport and Cont replay rows. The absent carrier coordinates rule out any hidden host absolute value, quotient equality, selected representative, trichotomy, or ambient completeness principle. □

Falsifiable prediction: Any accepted $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without displaying the dyadic source, absolute-value row, StreamName windows, transport, replay, provenance, and local naming rows refutes the packet.

Independence witness: dyadicratcore, rat, streamname, regseqrat, real, dyadicabsolutevalue: no listed sibling supplies the whole nine-row packet $T = (D, A, S, Q, E, H, C, P, N)$, because each sibling contributes only source, window, readback, seal, or absolute-value rows while this chapter binds their stability route with transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicAbsoluteValueStability}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{DyadicAbsoluteValueStability}^{\uparrow}$ packet is generated from a DyadicRatCore source row, a DyadicAbsoluteValue endpoint-and-tolerance row, finite StreamName windows, a RegSeqRat readback row, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicAbsoluteValueStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8157.1, Definition 8157.2, and Definition 8157.3 seed the finite stability handoff from dyadic absolute-value tolerance rows to RegSeqRat and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicAbsoluteValueStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host rational absolute value, Real completeness, trichotomy, quotient equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked dyadic-source admission, absolute-value row exposure, StreamName window exposure, RegSeqRat readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicAbsoluteValueStabilityUp.

Chapter 8158

A Concrete Naming Certificate for MonotoneRealFunction$^{\uparrow}$

Following Bishop and Bridges on constructive real functions of bounded variation, the MonotoneRealFunction$^{\uparrow}$ packet records a displayed monotone real-function route as finite NameCert data. It reads endpoint and value names through Real$^{\uparrow}$ and chapter 38, finite approximation windows through StreamName$^{\uparrow}$ and chapter 126, rational readback through RegSeqRat$^{\uparrow}$ and chapter 301, order comparisons through TotalOrder$^{\uparrow}$ and chapter 54, bounded-window control through BoundedRealSequence$^{\uparrow}$ and chapter 1415, and cumulative variation handoff through TotalVariationFunction$^{\uparrow}$ and chapter 2257. The packet names the finite monotonicity and variation ledger; it is not a selected-limit theorem, a trichotomy principle for arbitrary reals, a quotient of functions, or a use of ambient real completeness.

Definition 8158.1 (Monotone real function carrier)**.** *A* MonotoneRealFunction$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, W, V, O, B, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the source interval and finite window schedule, including the displayed endpoint names and the inspected input rows.*
2. *W is the* StreamName$^{\uparrow}$ *window row for the inspected source positions and value requests.*
3. *V is the* Real$^{\uparrow}$ *value row for the displayed function values reached from I and W.*
4. *O is the* TotalOrder$^{\uparrow}$ *comparison ledger witnessing monotonicity for each displayed ordered pair of source windows.*
5. *B is the* BoundedRealSequence$^{\uparrow}$ *bounded-window row attached to the finite value sequence read by the packet.*
6. *L is the variation-bound ledger, recording the finite nonnegative steps permitted by the monotone comparison rows and the handoff boundary toward* TotalVariationFunction$^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for interval, window, value, order-comparison, bounded-window, variation-ledger, replay, provenance, and local-name rows.*
8. *C records displayed* Cont *replay from an inspected source pair through the window row, value row, order comparison, bounded-window row, and variation ledger.*

9. *P is the* Pkg *provenance over* MonotoneRealFunction$^\uparrow$, Real$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, TotalOrder$^\uparrow$, BoundedRealSequence$^\uparrow$, TotalVariationFunction$^\uparrow$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MonotoneRealFunction}^\uparrow}$ *row.*

The classifier compares accepted packets only through $I, W, V, O, B, L, H, C, P, N$. It has no coordinate for selected limits, real trichotomy, quotient equality of functions, countable choice, an external variation supremum, or ambient Real$^\uparrow$ *completeness.*

Theorem 8158.2 (Monotone real function NameCert obligations)**.** *For every accepted* MonotoneRealFunction$^\uparrow$ *carrier $M = (I, W, V, O, B, L, H, C, P, N)$, the local* NameCert$_{\text{MonotoneRealFunction}^\uparrow}$ *surface consists exactly of carrier admission for the displayed interval and window rows,* StreamName$^\uparrow$ *windows,* Real$^\uparrow$ *value rows,* TotalOrder$^\uparrow$ *monotonicity comparisons,* BoundedRealSequence$^\uparrow$ *bounded-window row, variation-bound ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Each monotonicity read must use the same source-window row I, W and the same value row V before it may consume the comparison ledger O or the variation ledger L.*

Proof. Project the carrier of Definition 8158.1. The only analytic rows exposed by the packet are I, W, V, O, B, L.

The monotonicity clause is finite. For each displayed ordered pair of source windows, the source interval and stream rows determine the two value rows, and the order comparison is then read from O as a TotalOrder$^\uparrow$ row over those displayed Real$^\uparrow$ values.

The remaining rows do not add analytic content. They transport, replay, source, and name the same finite packet through H, C, P, N, so the listed rows exhaust the local NameCert surface. □

Theorem 8158.3 (Monotone real function Real seal boundary)**.** *Every* Real$^\uparrow$ *value read exported by an accepted* MonotoneRealFunction$^\uparrow$ *carrier factors through the finite route*

$$\text{StreamName}^\uparrow,\ \text{RegSeqRat}^\uparrow,\ \text{Real}^\uparrow,\ \text{TotalOrder}^\uparrow,\ \text{BHist},\ \text{hsame},\ \text{Cont},\ \text{Pkg},\ \text{NameCert}.$$

The route exposes source windows, rational readback, real-value seals, and displayed order comparisons before any monotone-function consumer can read the value. It exports no selected limit, quotient function equality, countable-choice schedule, trichotomy premise, or ambient real-completeness object.

Proof. Start from an accepted carrier $M = (I, W, V, O, B, L, H, C, P, N)$. A value read first opens the source interval and stream windows I, W, then reads the rational approximation and terminal real seal represented by V.

Only after the value rows are displayed may a monotone consumer inspect O. The transport and continuation rows keep this order attached to the same local name, while provenance records the visible dependency surface.

Since no row of the carrier stores selected limits, quotient functions, countable choice, trichotomy, or ambient completeness, the public Real-facing seal boundary is exactly the displayed finite route. □

Theorem 8158.4 (Monotone real function variation-ledger handoff)**.** *Every* TotalVariationFunction$^\uparrow$ *or bounded-variation consumer of an accepted* MonotoneRealFunction$^\uparrow$ *carrier receives the finite variation-bound ledger L only after the displayed source windows,* Real$^\uparrow$ *value rows,* TotalOrder$^\uparrow$ *monotonicity comparisons, and* BoundedRealSequence$^\uparrow$ *bounded-window row have been exposed. Thus the variation handoff is a finite monotone ledger over displayed rows, not a supremum over all partitions, quotient equality of real-valued functions, selected endpoint limit, countable-choice schedule, or ambient* Real$^\uparrow$ *completeness theorem.*

Proof. The variation ledger is downstream of the monotonicity comparisons. The carrier first supplies I, W, V, then O records the finite order comparisons for displayed source pairs, and B records the bounded window of values used by the ledger.

The handoff row L can therefore be consumed only as a finite ledger attached to those rows. The continuation and provenance rows route this ledger toward $\mathsf{TotalVariationFunction}^{\uparrow}$ without adding an external partition supremum or host function object.

The exclusions follow from the carrier boundary: selected limits, quotient function equality, countable choice, ambient completeness, and unrestricted variation suprema are absent from $I, W, V, O, B, L, H, C, P, N$. □

Closure status for $\mathsf{NameCert}_{\mathsf{MonotoneRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{MonotoneRealFunction}^{\uparrow}$ packet is generated from source interval windows, StreamName request rows, RealUp value rows, TotalOrderUp comparison rows witnessing monotonicity, a BoundedRealSequenceUp bounded-window row, a finite variation-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MonotoneRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8158.1, Definition 8158.2, Definition 8158.3, and Definition 8158.4 seed the finite monotone real-function packet for Real and variation-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MonotoneRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, real trichotomy, quotient function equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, displayed monotonicity comparisons, Real-seal boundary, bounded-window routing, variation-ledger handoff, transport, replay, provenance, and local naming for BEDC.Derived.MonotoneRealFunctionUp.

Chapter 8159

A Concrete Naming Certificate for $\mathsf{RegularCauchySheaf}^{\uparrow}$

Following Godement's sheaf gluing viewpoint and Bishop–Bridges regular Cauchy names, $\mathsf{RegularCauchySheaf}^{\uparrow}$ records finite cover-indexed local regular-Cauchy windows whose compatible overlaps glue to a $\mathsf{Real}^{\uparrow}$ seal without quotient representatives or countable choice. The packet sits after the finite gluing surface of chapter 5899, the stream-name interface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the reindexing route of chapter 1568.

Definition 8159.1 (Regular Cauchy sheaf carrier)**.** *A* $\mathsf{RegularCauchySheaf}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, R, O, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the finite cover-window ledger. It lists the cover indices, the displayed refinements between windows, and the finite overlap pairs on which local regular Cauchy data are compared.*
2. *R is the restriction-map row. For each displayed refinement in U, it records the finite restriction route that transports a local* $\mathsf{StreamName}^{\uparrow}$ *observation and its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback to the smaller window.*
3. *O is the overlap ledger. It records the pairwise compatibility witnesses consumed by* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *and the finite overlap-induction route used when several refinements are chained.*
4. *Q is the glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row. It is obtained by reading all local regular rational rows through U, R, O, H, C and not by selecting representatives of a quotient.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the finite cover windows, restrictions, overlap ledgers, and glued readback have been displayed.*
6. *H records componentwise* hsame *transport for the cover ledger, restriction maps, overlap ledgers, glued readback, real seal, replay, provenance, and local certificate.*
7. *C records displayed* Cont *replay of the same finite descent route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchySheaf}^{\uparrow}$, $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySheaf}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that the local windows in U restrict through R, agree on every displayed overlap in O, glue to Q, and then seal as E. It has no coordinate for quotient sheaves, selected global representatives, countable choice, global completeness of $\mathsf{Real}^{\uparrow}$*, Lean verification, or bridge checking.*

Lean4 ✓ `BEDC.Derived.RegularCauchySheafUp.RegularCauchySheafTasteGate single carrier alignment`

Theorem 8159.2 (Regular Cauchy sheaf NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySheaf}^{\uparrow}$ *carrier* $S = (U, R, O, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySheaf}^{\uparrow}}$ *surface consists exactly of finite cover-window admission through* U*, restriction-map exactness through* R*, pairwise overlap compatibility and finite overlap induction through* O*, glued* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The cover windows are finite because U displays the inspected indices, their refinements, and the overlap pairs consumed by the descent route.

For a single overlap, apply the $\mathsf{RegularCauchyGluing}^{\uparrow}$ surface named in P. It compares the local $\mathsf{StreamName}^{\uparrow}$ observations and $\mathsf{RegSeqRat}^{\uparrow}$ readbacks through the displayed overlap data and preserves the glued readback row.

For a finite chain of overlaps, induct on the displayed refinement list in O. The empty chain reads the local row already present in U, and the step composes the next restriction row from R with the induction hypothesis before applying the gluing classifier to the next overlap.

The rows H and C transport and replay the same finite route, while P records the route through $\mathsf{CauchyReindexing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyGluing}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$. Repacking these projections gives the listed local NameCert obligations, with no quotient sheaf, representative selector, countable choice, global completeness principle, Lean verification, or bridge claim. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySheaf}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySheaf}^{\uparrow}$ packet is generated from finite cover windows, displayed restriction maps, finite overlap ledgers, a glued $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySheaf}^{\uparrow}}$, seed)

Scope closed: Definition 8159.1 and Definition 8159.2 seed the finite sheaf-style descent carrier and its local NameCert obligation surface over BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySheaf}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient sheaves, selected global representatives, countable choice, global completeness of $\mathsf{Real}^{\uparrow}$, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked finite cover-window admission, restriction-map exactness, overlap compatibility, finite overlap induction, glued RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchySheafUp.

Chapter 8160

A Concrete Naming Certificate for $\mathsf{SphericallyCompleteUltrametric}^{\uparrow}$

Following Schikhof on non-Archimedean functional analysis, the $\mathsf{SphericallyCompleteUltrametric}^{\uparrow}$ packet records the finite NameCert surface for a nested-ball completeness condition in an ultrametric setting. It sits after the strong-triangle carrier of chapter 1535, the non-Archimedean metric route of chapter 7609, the complete-ultrametric service of chapter 3879, the nested closed-ball ledger of chapter 3526, and the constructive ultrametric completion boundary of chapter 5204. The packet names displayed ball-chain rows and finite intersection obligations; it does not choose centers, assert ambient completeness, or identify spherical completeness with ordinary metric completeness.

Definition 8160.1 (Spherically complete ultrametric carrier)**.** *A* $\mathsf{SphericallyCompleteUltrametric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, A, C, B, D, I, R, H, T, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UltrametricSpace}^{\uparrow}$ *row carrying the strong max-radius triangle comparison.*
2. *A is the* $\mathsf{NonArchimedeanMetric}^{\uparrow}$ *row exposing the non-Archimedean metric route used by every ball comparison.*
3. *C is the* $\mathsf{CompleteUltrametric}^{\uparrow}$ *service row available as a displayed dependency, not as an ambient completeness theorem.*
4. *B is the* $\mathsf{NestedClosedBall}^{\uparrow}$ *row naming the nested family of closed ultrametric balls and their finite containment witnesses.*
5. *D is the* $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$ *boundary row for completion-facing consumers.*
6. *I records the finite intersection-obligation row: every displayed nested family read must retain a nonempty-intersection request before any center read is public.*
7. *R is the radius and containment ledger, recording the inspected ball radii, reverse-inclusion order, and late-radius comparisons.*
8. *H records componentwise* hsame *transport for the ultrametric, non-Archimedean, complete-ultrametric, nested-ball, completion-boundary, intersection, radius-ledger, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a nested-ball request through U, A, C, B, D, I, R.*
10. *P is the* Pkg *provenance over* SphericallyCompleteUltrametric$^{\uparrow}$, UltrametricSpace$^{\uparrow}$, NonArchimedeanMetric$^{\uparrow}$, CompleteUltrametric$^{\uparrow}$, NestedClosedBall$^{\uparrow}$, ConstructiveUltrametricCompletion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{SphericallyCompleteUltrametric}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, A, C, B, D, I, R, H, T, P, N$. It has no coordinate for a choice-selected center, quotient completion, global compactness theorem, host-valued equality of balls, countable choice, or ambient completeness.

Theorem 8160.2 (Spherically complete ultrametric NameCert obligations)**.** *For every accepted* SphericallyCompleteUltrametric$^{\uparrow}$ *carrier*

$$S = (U, A, C, B, D, I, R, H, T, P, N),$$

the local NameCert$_{\text{SphericallyCompleteUltrametric}^{\uparrow}}$ *surface consists exactly of carrier admission for the ultrametric row, non-Archimedean metric row, complete-ultrametric service row, nested closed-ball row, constructive ultrametric completion boundary, intersection-obligation row, radius and containment ledger, componentwise transport, displayed continuation replay, package provenance, and local naming. A consumer may read the spherical-completeness handoff only after $U, A, C, B, D, I, R, H, T, P, N$ have all been displayed, and the handoff exports no choice-selected center, ambient completeness theorem, quotient completion, compactness principle, or host equality of ball families.*

Proof. Project the accepted carrier of Definition 8160.1. The rows U, A, C, B, D place the packet inside the existing ultrametric, non-Archimedean metric, complete-ultrametric, nested closed-ball, and constructive completion chapters.

The spherical row is I together with the radius ledger R. It records the finite obligation that a nested closed-ball family has an intersection request available before any center-facing consumer reads the handoff; it does not select a center or replace the displayed nested-ball route by host completeness.

Transport, replay, provenance, and local naming are exactly H, T, P, N. Since every read of the handoff must pass through those rows, the local NameCert surface is exhausted by $U, A, C, B, D, I, R, H, T, P, N$, and all excluded choice, quotient, compactness, and ambient-completeness claims remain outside the packet. □

Falsifiable prediction: Every SphericallyCompleteUltrametric$^{\uparrow}$ consumer must expose the ultrametric row, non-Archimedean metric row, complete-ultrametric service row, nested closed-ball row, constructive ultrametric completion boundary, intersection-obligation row, radius ledger, transport, replay, provenance, and local naming before it reads a spherical-completeness handoff.

Independence witness: ultrametricspace, nonarchimedean-metric, complete-ultrametric, nestedclosedball, constructive-ultrametric-completion: none alone is bijective to SphericallyCompleteUltrametric$^{\uparrow}$ because the packet jointly carries strong-triangle, non-Archimedean metric, complete-ultrametric service, nested-ball, completion-boundary, intersection-obligation, radius-ledger, transport, replay, provenance, and local NameCert rows while excluding selected centers and ambient completeness.

Closure status for NameCert$_{\text{SphericallyCompleteUltrametric}^{\uparrow}}$.

Constructive story: A SphericallyCompleteUltrametric$^{\uparrow}$ packet is generated from an ultrametric row, a non-Archimedean metric row, a complete-ultrametric service row, a nested closed-ball row, a constructive ultrametric completion boundary, an intersection-obligation row, a radius and containment ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{SphericallyCompleteUltrametric}\uparrow}$, seed)

Scope closed: Definition 8160.1 and Definition 8160.2 seed the finite nested-ball completeness carrier and local NameCert obligation surface over ultrametric, non-Archimedean, complete-ultrametric, nested-ball, and constructive completion rows.

Formal verification: FormalStatus(NameCert$_{\text{SphericallyCompleteUltrametric}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close choice-selected centers, ambient completeness, quotient completions, compactness principles, host equality of ball families, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ultrametric route exposure, non-Archimedean metric exposure, complete-ultrametric service exposure, nested-ball exactness, completion-boundary routing, intersection-obligation coverage, radius-ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.SphericallyCompleteUltrametricU

Chapter 8161

A Concrete Naming Certificate for $\mathsf{BishopSpread}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopSpread}^{\uparrow}$ packet records spread data as a finite-prefix carrier rather than as a completed choice sequence. It sits beside the binary prefix surfaces of $\mathsf{CantorSpace}^{\uparrow}$ in chapter 1475, the fan restriction of $\mathsf{FanSpace}^{\uparrow}$ in chapter 1962, the finite observation windows of $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the regular rational readback rows of $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, and the bar-modulus rows of $\mathsf{BishopBarInductionModulus}^{\uparrow}$ in chapter 5132. The packet supplies countable-name discipline for later $\mathsf{Real}^{\uparrow}$ and completion consumers without assuming a selected infinite branch, countable choice, or an ambient space of completed sequences.

8161.1 Carrier and obligations

Definition 8161.1 (Bishop spread carrier)**.** *A* $\mathsf{BishopSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, A, W, R, B, H, C, G, N)$$

with the following displayed rows:

1. *P is the finite-prefix tree row, whose nodes are finite natural-number lists and whose admissibility predicate is decidable on displayed prefixes.*
2. *A is the apartness and compatibility row saying that two prefixes are compared only by the first displayed coordinate at which both rows are defined, or by prefix extension when no split is displayed.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected prefixes and requests.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row available only when the prefix data is consumed by a regular-Cauchy or real-name consumer.*
5. *B is the* $\mathsf{BishopBarInductionModulus}^{\uparrow}$ *bar-modulus handoff row for finite bars over the same prefix surface.*
6. *H records componentwise* hsame *transport for prefix, apartness, window, readback, bar, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay of the same finite-prefix route.*

8. *G is the* Pkg *provenance over* $\mathsf{BishopSpread}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{FanSpace}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{BishopBarInductionModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopSpread}^{\uparrow}}$ *row.*

The classifier compares two carriers only through $P, A, W, R, B, H, C, G, N$. It has no coordinate for a selected infinite branch, a completed choice-sequence object, host equality of sequences, countable choice, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8161.2 (Bishop spread NameCert obligations)**.** *For every accepted* $\mathsf{BishopSpread}^{\uparrow}$ *carrier $S = (P, A, W, R, B, H, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopSpread}^{\uparrow}}$ *surface consists exactly of finite-prefix admission, apartness and prefix-compatibility admission, finite-window exposure, regular rational readback handoff, bar-modulus handoff, componentwise transport, displayed replay, provenance, and local naming. Every downstream* $\mathsf{Real}^{\uparrow}$ *or completion consumer must read the prefix rows through W before it can inspect R or B.*

Proof. Project the carrier of Definition 8161.1. The rows P and A expose the finite-prefix substrate and its displayed apartness discipline before any branch-facing read is possible.

Next read the countable-name route through W and R. The $\mathsf{StreamName}^{\uparrow}$ row supplies only finite windows, and the $\mathsf{RegSeqRat}^{\uparrow}$ row is reached only as a displayed readback for regular-Cauchy or real-name consumers.

Finally use B, H, C, G, N to carry the bar handoff, transport, replay, provenance, and local naming rows. Since no coordinate stores a selected infinite branch, completed choice sequence, host sequence equality, countable choice, quotient stream equality, or ambient completeness principle, the listed rows exhaust the NameCert surface. □

Theorem 8161.3 (Bishop spread finite-prefix induction)**.** *Every induction or bar-style consumer of an accepted* $\mathsf{BishopSpread}^{\uparrow}$ *packet must factor through the finite prefix rows P, A, W and the displayed bar-modulus row B. The consumer may extend a prefix, inspect a finite bar, or pass the read to* $\mathsf{RegSeqRat}^{\uparrow}$*, but it cannot infer a completed branch, a chosen path through the spread, countable choice, host-level sequence equality, or a global continuity theorem from the packet alone.*

Proof. Begin with the obligation surface of Definition 8161.2. It forces every consumer to expose the prefix row, apartness row, and finite-window row before the bar or readback rows are inspected.

For an induction read, extend only the displayed prefix in P and transport the apartness row A componentwise. This keeps the step inside the same finite-prefix carrier.

For a bar-style read, use the $\mathsf{BishopBarInductionModulus}^{\uparrow}$ handoff row B. The handoff names finite bar coverage over the displayed prefixes, not a selected infinite path or a global theorem about all completed choice sequences.

For a completion-facing read, pass through W before R. The regular rational handoff therefore consumes finite windows and exports no branch selector, countable-choice schedule, quotient stream equality, host sequence equality, or ambient real completeness row. □

Falsifiable prediction: Every accepted $\mathsf{BishopSpread}^{\uparrow}$ read exposes finite-prefix admission, prefix apartness, StreamName windows, RegSeqRat readback when requested, BishopBarInductionModulus handoff, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any RealUp or completion consumer is served.

Independence witness: cantorspace, fan-space, streamname, regseqrat, bishop-bar-induction-modulus: none is bijective with $\mathsf{BishopSpread}^{\uparrow}$ because this packet alone binds spread-prefix admission, apartness, finite observation windows, regular-Cauchy readback, bar-modulus handoff, transport, replay, provenance, and local naming as one countable-name substrate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSpread}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopSpread}^{\uparrow}$ packet is generated from finite-prefix tree rows, apartness and prefix-compatibility rows, StreamName finite windows, optional RegSeqRat readback, BishopBarInductionModulus bar handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSpread}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8161.1, Definition 8161.2, and Definition 8161.3 seed the finite-prefix spread substrate for countable-name and regular-Cauchy consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSpread}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed choice sequences, selected infinite branches, countable choice, quotient stream equality, host sequence equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-apartness stability, finite-window coverage, RegSeqRat readback, bar-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.BishopSpreadUp.

Chapter 8162

A Concrete Naming Certificate for HyperbolicPhaseHolonomyIndex$^{\uparrow}$

The HyperbolicPhaseHolonomyIndex$^{\uparrow}$ packet realizes the hyperbolic observer phase route of chapter 9463 as a finite index surface for closed phase-transport classes. It is distinct from the carrier-level HyperbolicPhaseHolonomy$^{\uparrow}$ packet of chapter 6385: the holonomy packet records an accepted closed reversible transport row, while the index packet records the finite comparison class, boundary anchor, disk-metric readback, observer groupoid route, and provenance rows that allow consumers to compare such closed transports without importing a host holonomy group. It sits beside ObserverPhaseGroupoid$^{\uparrow}$ in chapter 6146, HyperbolicMetric$^{\uparrow}$ in chapter 3474, PoincareDiskMetric$^{\uparrow}$ in chapter 6209, and HyperbolicBoundaryShadow$^{\uparrow}$ in chapter 3813.

8162.1 Carrier and vision route

Definition 8162.1 (Hyperbolic phase-holonomy index carrier)**.** *A* HyperbolicPhaseHolonomyIndex$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, B, M, O, L, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* PoincareDiskMetric$^{\uparrow}$ *disk-metric readback row for the finite disk observations used by the closed transport.*
2. *B is the* HyperbolicBoundaryShadow$^{\uparrow}$ *boundary-anchor row saying which visible boundary shadow is preserved or crossed by the transport loop.*
3. *M is the* HyperbolicMetric$^{\uparrow}$ *comparison row attached to the same displayed disk and boundary observations.*
4. *O is the* ObserverPhaseGroupoid$^{\uparrow}$ *reversible phase-route row, including source, target, inverse, and composition evidence for the observer-facing phase surface.*
5. *L is the accepted* HyperbolicPhaseHolonomy$^{\uparrow}$ *closed transport row whose finite loop data is being indexed.*
6. *Q is the holonomy-index row, comparing two accepted loops only by D, B, M, O, L and by the displayed classifier rows already present in those packets.*

7. *H records componentwise* hsame *transport for disk, boundary, metric, groupoid, holonomy, index, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$, $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$, ObserverPhaseGroupo $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}}$ *row.*

The classifier compares accepted index carriers only through $D, B, M, O, L, Q, H, C, P, N$. It has no coordinate for a host holonomy group, quotient loop space, global curvature invariant, selected representative loop, physical observer law, or completed hyperbolic boundary.

Theorem 8162.2 (Hyperbolic phase-holonomy index obligations)**.** *For every accepted* HyperbolicPhaseHolonomyIn *carrier $I = (D, B, M, O, L, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}}$ *surface consists exactly of disk-metric readback, boundary-shadow anchoring, hyperbolic metric comparison, observer phase-groupoid routing, closed holonomy-row exposure, finite index comparison, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8162.1. The disk, boundary, metric, groupoid, and holonomy rows D, B, M, O, L must be displayed before the index row can be consumed.

The row Q compares accepted closed transports only through those displayed rows. It therefore records a finite index surface rather than a host quotient of loops or a global holonomy group.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no host holonomy group, quotient loop space, global curvature invariant, selected representative loop, physical observer law, or completed boundary coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 8162.3 (Hyperbolic phase-holonomy index vision route)**.** *The* $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$ *packet realizes the observer-expansion holonomy-index route only as finite disk, boundary, metric, observer-groupoid, closed-holonomy, index, transport, replay, provenance, and NameCert rows. Every consumer of the index must first read* $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, *and* $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ *rows; the consumer receives no generic phase-transport packet, host holonomy group, quotient loop space, global curvature invariant, physical observer law, selected representative loop, or completed boundary object.*

Proof. Use the obligation surface of Definition 8162.2. It orders every index read through the disk, boundary, metric, observer-groupoid, and closed-holonomy rows before Q is exposed.

The vision route is therefore a concrete finite ledger for comparing closed phase transports. It refines $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ by adding the comparison index and its boundary and metric anchors, but it does not duplicate the underlying holonomy carrier.

Finally project the refusal coordinates from Definition 8162.1. Since the packet has no host quotient, global holonomy group, curvature invariant, physical observer law, selected loop, or completed-boundary coordinate, no consumer can extract those objects from the index route. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$ read exposes PoincareDiskMetric, HyperbolicBoundaryShadow, HyperbolicMetric, ObserverPhaseGroupoid, HyperbolicPhaseHolonomy, index comparison, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before any holonomy-index consumer is served.

Independence witness: hyperbolic-phase-holonomy, observer-phase-groupoid, hyperbolic-metric, poincare-disk-metric, hyperbolic-boundary-shadow: $\mathsf{HyperbolicPhaseHolonomy}^{\uparrow}$ carries a closed transport without the index row, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$ carries reversible phase routing without the closed holonomy comparison, $\mathsf{HyperbolicMetric}^{\uparrow}$ and $\mathsf{PoincareDiskMetric}^{\uparrow}$ carry metric readback without the phase loop, and $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ carries the boundary anchor without the index comparison. None is bijective to $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$ packet is generated from PoincareDiskMetric disk rows, HyperbolicBoundaryShadow boundary anchors, HyperbolicMetric comparison rows, ObserverPhaseGroupoid reversible phase-route rows, HyperbolicPhaseHolonomy closed transport rows, a finite index comparison row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8162.1, Definition 8162.2, and Definition 8162.3 seed the finite holonomy-index route for hyperbolic observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host holonomy groups, quotient loop spaces, global curvature invariants, physical observer laws, selected representative loops, completed hyperbolic boundaries, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, disk and boundary row exposure, metric comparison, observer-groupoid routing, closed-holonomy handoff, index comparison, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseHolonomyIndexUp.

Chapter 8163

A Concrete Naming Certificate for $\mathsf{FiniteModulusBundle}^{\uparrow}$

Following Bishop and Bridges on constructive uniform continuity and explicit moduli, the $\mathsf{FiniteModulusBundle}^{\uparrow}$ packet records the finite L10 data that lets a Real and Completion consumer read one displayed uniform modulus together with the finite windows, regular rational readback, and terminal seal it controls. It sits beside the uniform-modulus certificate of chapter 369, the uniformly continuous sequence route of chapter 4287, the stream-window interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names shared finite modulus data; it is not a host function, a quotient stream equality, a choice of infinitely many witnesses, or an ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8163.1 (FiniteModulusBundle carrier)**.** *A* $\mathsf{FiniteModulusBundle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, Q, W, R, E, S, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row carrying the requested uniform modulus schedule.*
2. *Q is the query ledger that lists the finite precision requests and source-window requests served by U.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the observations named by Q.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback assembled from the displayed modulus requests and stream windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the finite readback row has been displayed.*
6. *S is the* $\mathsf{UniformlyContinuousSequence}^{\uparrow}$ *handoff row that records which sequence-facing consumer may reuse the same modulus bundle.*
7. *H records componentwise* hsame *transport for the modulus, query, window, readback, seal, handoff, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an L10 consumer request through U, Q, W, R, E, S, H.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusBundle}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{UniformlyContinuousSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusBundle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, Q, W, R, E, S, H, C, P, N$. It has no coordinate for a host function, quotient equality of streams, a selected infinite witness family, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.FiniteModulusBundleUp`

Theorem 8163.2 (FiniteModulusBundle NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusBundle}^{\uparrow}$ *carrier*

$$B = (U, Q, W, R, E, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteModulusBundle}^{\uparrow}}$ *surface consists exactly of uniform-modulus schedule admission through U, finite request listing through Q, stream-window exposure through W, regular rational readback through R, terminal real-name sealing through E, uniformly continuous sequence handoff through S, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8163.1. The row U is the only coordinate that stores the uniform modulus schedule, and Q is the only coordinate that lists the finite consumer requests governed by that schedule.

The stream and numeric rows are downstream of those requests. The row W exposes exactly the named finite observations, R records the regular rational readback obtained from those observations, and E seals that readback as the terminal real-facing row.

The sequence handoff and structural rows do not add hidden analytic data. The row S records the sequence-facing reuse boundary, while H, C, P, N transport, replay, source, and name the same displayed packet. Since the carrier lists no host function, quotient stream equality, infinite selected witness family, countable-choice schedule, or ambient completeness coordinate, the displayed rows exhaust the local NameCert surface. □

Theorem 8163.3 (FiniteModulusBundle uniform-sequence handoff)**.** *Every uniformly continuous sequence consumer of an accepted* $\mathsf{FiniteModulusBundle}^{\uparrow}$ *packet factors through*

$$\mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformlyContinuousSequence}^{\uparrow} \longmapsto \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{F}$$

The consumer may reuse the displayed modulus schedule only after the finite request ledger, stream-window rows, regular rational readback, and terminal Real seal have been exposed. It obtains no host function equality, quotient stream equality, selected infinite witness family, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with a consumer read of $B = (U, Q, W, R, E, S, H, C, P, N)$. The read first exposes the uniform modulus row U and the finite request ledger Q, so the consumer sees a displayed schedule and a finite list of requests rather than an external function.

Next the consumer reads W, R, E. The stream row supplies the requested windows, the regular rational row records their finite readback, and the Real row seals only that displayed readback.

Finally the handoff row S records the uniformly continuous sequence boundary that may reuse the schedule. The structural rows H, C, P, N transport, replay, source, and name the same route, so the consumer cannot project any of the excluded host, quotient, choice, or completeness data from the packet. □

Falsifiable prediction: Every accepted $\mathsf{FiniteModulusBundle}^{\uparrow}$ read exposes the UniformModulus schedule row, finite request ledger, StreamName finite-window row, RegSeqRat readback row,

RealUp seal row, UniformlyContinuousSequence handoff row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a sequence-facing L10 consumer may reuse a modulus.

Independence witness: uniformmodulus, uniformly-continuous-sequence, streamname, regseqrat, real: $\mathsf{FiniteModulusBundle}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a shared uniform-modulus schedule, finite request ledger, stream windows, regular rational readback, terminal Real sealing, sequence handoff, transport, replay, provenance, and local naming as one finite L10 packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusBundle}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusBundle}^{\uparrow}$ packet is generated from a UniformModulus schedule row, a finite request ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, a UniformlyContinuousSequence handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusBundle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8163.1, Definition 8163.2, and Definition 8163.3 seed the shared finite-modulus packet for the L10 Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusBundle}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FiniteModulusBundleUp`

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, host function equality, quotient stream equality, selected infinite witness families, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite request exactness, stream-window exactness, regular readback, Real sealing, sequence handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusBundle

Chapter 8164

A Concrete Naming Certificate for $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$ packet records the finite common-window lattice by which left and right regular Cauchy readings can share one dyadic refinement route before any $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits after the dyadic arithmetic of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the common-modulus meet route of chapter 462.

Definition 8164.1 (Regular Cauchy window lattice carrier)**.** *A* $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (L, R, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right regular-Cauchy window rows. Each row exposes the requested precision, the finite source indices, and the local regularity budget visible to a* $\mathsf{RegSeqRat}^{\uparrow}$ *readback.*
2. *D is the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger. It records the shared dyadic radii, endpoint comparisons, radius meets, and refinement witnesses used by both windows.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row listing exactly the source observations inspected on the left window, right window, and overlap.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after L, R, D, S have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through the displayed common-window route.*
6. *H records componentwise* hsame *transport for the two windows, common dyadic ledger, finite observations, regular readback, real seal, replay, provenance, and local certificate.*
7. *C records displayed* Cont *replay of the same finite common-window route.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyModulusMeet}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowLattice}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that the two windows share the displayed refinement ledger before either downstream readback is consumed. It has no coordinate for quotient equality of regular sequences, selected representatives, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8164.2 (Regular Cauchy window lattice NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$ *carrier*

$$W = (L, R, D, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowLattice}^{\uparrow}}$ *surface consists exactly of left and right regular-Cauchy window admission, common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement through* D*, finite* $\mathsf{StreamName}^{\uparrow}$ *observation through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The analytic rows before the seal are the two window rows L, R, the common dyadic ledger D, the finite observation row S, and the regular readback row Q.

The common-window condition is finite. The row D stores the radius meets and endpoint comparisons, while S records exactly the observations used to inspect both windows. Thus Q reads a single shared refinement route rather than two unrelated regular-sequence witnesses.

The remaining rows H, C, P, N transport, replay, source, and name this same route. Since quotient equality, selected representatives, countable choice, host equality, and ambient completeness are absent from the carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 8164.3 (Regular Cauchy window lattice RegSeqRat handoff)**.** *Every accepted* RegularCauchyWindowLatt *carrier exposes its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q *only after the left and right regular-Cauchy windows* L, R*, the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger* D*, and the finite* $\mathsf{StreamName}^{\uparrow}$ *observation row* S *have been displayed. The handoff exports the common-window packet to* $\mathsf{RegSeqRat}^{\uparrow}$ *consumers without exporting quotient equality of regular sequences or a selected representative.*

Proof. Read the carrier rows in order. The two source windows L, R provide the local regular-Cauchy requests, but neither is a complete readback route for a downstream consumer on its own.

The ledger D and observation row S form the common refinement surface. They display the dyadic meets, overlap comparisons, and inspected indices that make the two window reads compatible inside one finite packet.

Only then is the readback row Q available. The structural rows H, C, P, N preserve and name this handoff, and the carrier has no coordinate from which a quotient equality or selected representative could be read. □

Theorem 8164.4 (Regular Cauchy window lattice Real seal nonescape)**.** *Let* $W = (L, R, D, S, Q, E, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$ *carrier. Any downstream* $\mathsf{Real}^{\uparrow}$ *read of the seal row* E *must first expose the common dyadic ledger* D*, the finite observation row* S*, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row* Q*. Consequently the Real-facing route cannot bypass the finite common-window lattice by appealing to host real equality, quotient sequence equality, countable choice, selected representatives, or ambient completeness.*

Proof. Project the displayed carrier. The seal row E is listed after the two window rows, the common dyadic ledger, the finite observation row, and the regular readback row.

The $\mathsf{RegSeqRat}^{\uparrow}$ handoff of Definition 8164.3 keeps D, S, Q visible before a Real-facing consumer can inspect E. The same route is transported by H and replayed by C with provenance P and local naming N.

No excluded principle is stored in W. Thus a $\mathsf{Real}^{\uparrow}$ seal read is a read of the finite common-window lattice, not an escape to host equality, quotient equality, choice, representatives, or completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyWindowLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyWindowLattice}^{\uparrow}$ packet is generated from left and right regular-Cauchy windows, a common $\mathsf{DyadicRatCore}^{\uparrow}$ refinement ledger, finite $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowLattice}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8164.1, Definition 8164.2, Definition 8164.3, and Definition 8164.4 seed the finite common-window lattice route for regular Cauchy readbacks and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyWindowLattice}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of regular sequences, selected representatives, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common dyadic-refinement exactness, finite observation exposure, RegSeqRat handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyWindowLatticeUp.

Chapter 8165

A Concrete Naming Certificate for $\mathsf{CauchyTailInterleaving}^{\uparrow}$

Following Bishop–Bridges constructive Cauchy-sequence practice, the $\mathsf{CauchyTailInterleaving}^{\uparrow}$ packet records the finite route by which two regular Cauchy tails are fused into one displayed tail schedule without choosing representatives of completed real names. It sits after the regular rational source of chapter 301, the finite window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the monotone selector corridor of chapter 5902. The packet is a choice-free fusion carrier for Real and Completion consumers; it is not a quotient of tails, a selected limit, a countable-choice functional, host real equality, or ambient completeness.

Definition 8165.1 (Cauchy tail interleaving carrier)**.** *A* $\mathsf{CauchyTailInterleaving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R_0, R_1, S_0, S_1, M, W, D, E, H, C, P, N)$$

with the following displayed rows:

1. R_0 *and* R_1 *are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows whose Cauchy tails are being fused.*
2. S_0 *and* S_1 *are the* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows used to inspect the two tails.*
3. M *is the* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *monotone corridor that records the displayed tail schedules used by the fusion.*
4. W *is the interleaving window row, recording for each inspected output window whether it reads the left tail, the right tail, or the shared comparison window.*
5. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the two tail reads at the displayed windows.*
6. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal exposed only after* $R_0, R_1, S_0, S_1, M, W, D$ *have been read.*
7. H *records componentwise* hsame *transport for the two sources, two window rows, selector corridor, interleaving row, tolerance ledger, seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a fusion request through* $R_0, R_1, S_0, S_1, M, W, D, E, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{CauchyTailInterleaving}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySubsequenceSelector}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyTailInterleaving}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for quotient stream equality, selected representatives, a host limit, countable choice, real trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8165.2 (Cauchy tail interleaving NameCert obligations)**.** *For every accepted* $\mathsf{CauchyTailInterleaving}^{\uparrow}$ *carrier* $T = (R_0, R_1, S_0, S_1, M, W, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyTailInterleaving}^{\uparrow}}$ *surface consists exactly of carrier admission, left-tail and right-tail source admission, finite-window admission, selector-corridor monotonicity, interleaving-window exactness, dyadic tolerance compatibility,* $\mathsf{Real}^{\uparrow}$ *seal non-escape, componentwise transport, displayed replay, package provenance, and local naming. Every obligation is read through the finite route*

$$R_0, R_1, S_0, S_1, M, W, D \longrightarrow E \longrightarrow H, C, P, N.$$

Proof. Carrier admission is projection from Definition 8165.1. The two regular rational sources, the two finite window rows, the selector corridor, the interleaving window, the dyadic tolerance ledger, and the terminal seal are all visible coordinates of the same packet.

The selector-corridor obligation is supplied by M. It keeps the two tail schedules monotone and finite, while W records which source tail each output window reads before any fused consumer receives a seal.

The tolerance obligation is read from D over the displayed windows. It compares only the inspected regular rational rows R_0, R_1 through S_0, S_1, M, W, so the certificate has no need for a quotient-tail equality or a selected representative.

Transport through H, replay through C, provenance P, and local naming N preserve the same route. Since the excluded quotient, choice, limit, trichotomy, host equality, and completeness objects are absent from the carrier coordinates, no NameCert obligation can discharge through them. □

Theorem 8165.3 (Cauchy tail interleaving Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing consumer of an accepted* $\mathsf{CauchyTailInterleaving}^{\uparrow}$ *packet must expose the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows* R_0, R_1*, the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows* S_0, S_1*, the* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ *corridor* M*, the interleaving window row* W*, and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D *before it reads the terminal seal* E*. The fused tail reaches Real and Completion consumers only through this displayed window-and-tolerance route, not through quotient tails, countable choice, selected limits, host real equality, or ambient completeness.*

Proof. Project the accepted carrier $T = (R_0, R_1, S_0, S_1, M, W, D, E, H, C, P, N)$. The terminal seal E is downstream of the two source rows, the two finite-window rows, the selector corridor, the interleaving row, and the dyadic tolerance ledger.

Apply Definition 8165.2. It forces carrier admission, source admission, finite-window admission, selector monotonicity, interleaving-window exactness, and dyadic tolerance compatibility before any consumer can read E.

The structural rows H, C, P, N transport, replay, source, and name the same data. Therefore the handoff cannot bypass $R_0, R_1, S_0, S_1, M, W, D$, and the absent quotient, choice, selected-limit, host-equality, and completeness principles remain outside the public route. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyTailInterleaving}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyTailInterleaving}^{\uparrow}$ packet is generated from two RegSeqRat source rows, two finite StreamName window rows, a CauchySubsequenceSelector corridor, an interleaving window row, a DyadicRatCore tolerance ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyTailInterleaving}\uparrow}$, seed)

Scope closed: Definition 8165.1, Definition 8165.2, and Definition 8165.3 seed the finite choice-free fusion surface for two regular Cauchy tails before Real and Completion consumers read a terminal seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyTailInterleaving}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient tail equality, selected representatives, countable choice, selected limits, trichotomy, host real equality, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, left-tail and right-tail source admission, finite-window admission, selector-corridor monotonicity, interleaving-window exactness, dyadic tolerance compatibility, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyTailInterleavingUp.

Chapter 8166

A Concrete Naming Certificate for BishopRegularCauchyMetric$^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the BishopRegularCauchyMetric$^{\uparrow}$ packet records the metric interface on regular Cauchy rational names as finite BEDC NameCert data. It sits after the dyadic arithmetic of chapter 291, the finite observation schedules of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the common-window lattice of chapter 8164. The packet names the regular-Cauchy distance read only through displayed dyadic windows and readback ledgers; it is not a quotient of streams, a selected host real representative, a trichotomy principle, or an ambient completeness theorem.

Definition 8166.1 (Bishop regular-Cauchy metric carrier)**.** *A* BishopRegularCauchyMetric$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, D, S, Q, E, B, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the left and right regular-Cauchy rational-name rows whose finite windows are being compared.*
2. *D is the* DyadicRatCore$^{\uparrow}$ *distance ledger, recording the dyadic tolerance, absolute-difference row, radius comparison, and common refinement budget.*
3. *S is the* StreamName$^{\uparrow}$ *observation row listing exactly the source indices inspected on the two names.*
4. *Q is the* RegSeqRat$^{\uparrow}$ *readback row obtained after the dyadic ledger and finite observations have been displayed.*
5. *E is the terminal* Real$^{\uparrow}$ *seal for the distance value read from the same regular-Cauchy route.*
6. *B is the Bishop metric-bound row, storing positivity, symmetry, triangle-window, and zero-distance readback clauses only as finite regular-Cauchy obligations.*
7. *H records componentwise* hsame *transport for the two source names, dyadic ledger, stream observations, regular readback, Real seal, metric-bound row, replay, provenance, and local certificate.*
8. *C records displayed* Cont *replay of the finite route from regular-Cauchy names to the distance seal.*
9. *P is the* Pkg *provenance over* BishopRegularCauchyMetric$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, RegularCauchyWindowLattice$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyMetric}^{\uparrow}}$ *row.*
The carrier predicate asserts that every metric read factors through the displayed dyadic common-window route. It has no coordinate for quotient equality of sequences, a selected completion representative, excluded middle over order comparisons, countable choice, or host metric completion.

Theorem 8166.2 (Bishop regular-Cauchy metric NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyMetric}^{\uparrow}$ *carrier*

$$M = (L, R, D, S, Q, E, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyMetric}^{\uparrow}}$ *surface consists exactly of regular-name exposure for L, R, dyadic distance-ledger exposure through D, finite stream-window exposure through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through Q,* $\mathsf{Real}^{\uparrow}$ *sealing through E, Bishop metric-bound ledger exposure through B, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, local naming through N, and non-escape from quotient, choice, order-trichotomy, or host completion principles.*

Proof. Project the accepted carrier. The only analytic input rows are L, R, D, S, Q, E, B together with the structural rows H, C, P, N.

The distance ledger is finite. The dyadic row D records the requested tolerance and absolute-difference comparison, while S records the inspected indices. Thus the readback row Q and seal row E are reached through displayed regular-Cauchy data rather than through a semantic quotient of streams.

The Bishop metric-bound row B names positivity, symmetry, triangle-window, and zero-distance clauses as ledgers over the same route. Componentwise transport and replay preserve those displayed rows, and the excluded principles have no carrier coordinate. Hence the listed rows exhaust the NameCert obligations. □

Theorem 8166.3 (Bishop regular-Cauchy metric Real-completion handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopRegularCauchyMetric}^{\uparrow}$ *packet must first read*

$$L, R, D, S, Q, E, B, H, C, P, N$$

in the displayed order before treating the sealed row E as a regular-Cauchy distance in $\mathsf{Real}^{\uparrow}$*. The handoff therefore passes through* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*, and the common-window lattice of chapter 8164; it exports no host equality of Cauchy names, selected representative, countable-choice schedule, trichotomy oracle, or ambient completion operator.*

Proof. Start with a completion-facing read. The carrier exposes two regular-Cauchy source rows L, R before any distance row can be consumed.

The dyadic and stream stages are D and S. They record the common tolerance budget, absolute-difference comparison, and inspected windows that license the regular readback Q.

Only after this readback does the terminal Real seal E become visible, and the Bishop metric-bound row B is a ledger over the same displayed route. The structural rows H, C, P, N transport, replay, source, and name that route without adding coordinates.

Since quotient equality of names, selected representatives, countable choice, trichotomy, and host completion are absent from the packet, every completion-facing distance read remains inside the finite regular-Cauchy metric handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyMetric}^{\uparrow}$ packet is generated from two regular-Cauchy rational-name rows, a DyadicRatCore distance ledger, finite StreamName observations, RegSeqRat readback, a RealUp seal, a Bishop metric-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8166.1, Definition 8166.2, and Definition 8166.3 seed the finite metric route from regular Cauchy rational names to a Real-facing distance seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of Cauchy names, selected representatives, countable choice, trichotomy of reals, ambient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic distance-ledger exactness, finite stream-window exposure, RegSeqRat readback, Real seal ordering, Bishop metric-bound rows, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyMetricUp.

Chapter 8167

A Concrete Naming Certificate for $\mathsf{CompactUniformModulusSelector}^{\uparrow}$

Following Bishop and Bridges compact metric analysis, the $\mathsf{CompactUniformModulusSelector}^{\uparrow}$ packet records the finite selector that turns compact finite-net data and pointwise continuity rows into a tolerance-only uniform-modulus ledger. It realizes the compact-uniform-continuity route of chapter 9237 through the compact source of chapter 60, the metric rows of chapter 57, the continuity surface of chapter 59, the rational finite-minimum readback of chapter 54, the $\mathsf{Rat}^{\uparrow}$ arithmetic of chapter 37, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ packet of chapter 369. The packet names only a displayed finite ProbeBundle fold; it is not an open-cover compactness theorem, a host modulus function, a selected Lebesgue number, a sequential compactness argument, or an ambient completeness principle.

Definition 8167.1 (Compact uniform-modulus selector carrier)**.** *A* $\mathsf{CompactUniformModulusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, K, F, T, B, R, L, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the shared* $\mathsf{Met}^{\uparrow}$ *source row.*
2. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-net row, exposing the bundled centers and coverage radii inspected by the selector.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row over the same source.*
4. *T is the positive* $\mathsf{Rat}^{\uparrow}$ *tolerance request.*
5. *B is the finite* ProbeBundle *ledger whose entries contain centers, local pointwise-modulus rows, subordinate radius rows, and half-radius cover data.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, using the finite-order selector from* $\mathsf{TotalOrder}^{\uparrow}$ *to produce a displayed radius below every bundled radius.*
7. *L is the metric-triangle ledger joining compact coverage, pointwise moduli, and the selected radius.*
8. *U is the terminal* $\mathsf{UniformModulus}^{\uparrow}$ *row exposed only after B, R, L have been displayed.*

9. *H records componentwise* hsame *transport for the metric, compact, continuous, tolerance, bundle, rational fold, triangle ledger, uniform-modulus output, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay for the finite selector route.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformModulusSelector}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{TotalOrder}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusSelector}^{\uparrow}}$ *row.*

The carrier predicate compares accepted selectors only through these rows. It has no coordinate for an arbitrary open cover, selected point outside the bundle, host minimum, sequence extraction, quotient metric equality, countable choice, or ambient compactness.

Theorem 8167.2 (Compact uniform-modulus selector NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformModulusSelector}^{\uparrow}$ *carrier* $S = (X, K, F, T, B, R, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformModulusSelector}^{\uparrow}}$ *obligations are exactly carrier admission, shared metric-source lock, compact finite-net exposure, pointwise-modulus exposure, positive rational tolerance exposure, finite* ProbeBundle *admission, rational lower-bound fold exactness, metric-triangle ledger replay,* $\mathsf{UniformModulus}^{\uparrow}$ *output admission, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from open-cover, choice, quotient, or ambient-completeness principles.*

Proof. Carrier admission projects the displayed rows of Definition 8167.1. The source side is X, K, F, T, so the compact and continuous rows are locked to one metric carrier before the finite bundle is opened.

The selector stage is B, R, L. The bundle row lists the inspected centers and local radius data, the rational row folds those finitely many radii through $\mathsf{Rat}^{\uparrow}$ and $\mathsf{TotalOrder}^{\uparrow}$, and the ledger row records the metric-triangle replay needed by the uniform-modulus consumer.

The output and structural stage is U, H, C, P, N. These rows expose, transport, replay, source, and name the same finite route. Since the excluded open-cover, host-minimum, choice, quotient, and completeness objects are absent from the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8167.3 (Compact uniform-modulus selector finite-fold handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{CompactUniformModulusSelector}^{\uparrow}$ *packet factors through the finite route*

$$X, K, F, T \longmapsto B, R, L \longmapsto U, H, C, P, N.$$

Thus the selector first reads the common metric source, compact finite-net data, pointwise-modulus rows, and rational tolerance; then folds the displayed ProbeBundle *radius ledger; and only then exposes the tolerance-only uniform-modulus output.*

Proof. Begin with the source rows X, K, F, T. They fix the metric carrier, compact finite-net coverage, pointwise-modulus entries, and tolerance request available to the selector.

The finite fold is carried by B and R. The row B displays every bundled radius and center, while R records the rational lower-bound selected by the finite order readback. No entry outside the bundle is available to the fold.

The metric-triangle ledger L is then replayed before U is public. The structural rows H, C, P, N preserve that same route, so a $\mathsf{UniformModulus}^{\uparrow}$ consumer receives only the finite selector package and no host compactness, selected Lebesgue number, arbitrary open cover, quotient equality, countable choice, or ambient completeness row. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformModulusSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformModulusSelector}^{\uparrow}$ packet is generated from a MetricUp source, CompactUp finite-net rows, ContinuousUp pointwise-modulus rows, a RatUp tolerance, a finite ProbeBundle ledger, a RatUp lower-bound fold, a metric-triangle ledger, a UniformModulusUp output, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8167.1, Definition 8167.2, and Definition 8167.3 seed the finite selector from compact finite-net and pointwise-modulus rows to a UniformModulus output.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, sequence extraction, host modulus functions, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source lock, compact finite-net exposure, pointwise-modulus exposure, rational fold exactness, metric-triangle replay, UniformModulus output admission, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformModulusSelectorUp.

Chapter 8168

A Concrete Naming Certificate for $\mathsf{AlexanderDuality}^{\uparrow}$

Following Hatcher and Spanier, the $\mathsf{AlexanderDuality}^{\uparrow}$ packet records the finite simplicial complement route behind Alexander duality as BEDC NameCert data. It sits after the simplicial-complex carrier of chapter 238, the homology and cohomology rows of chapter 98 and chapter 99, the compact metric support of chapter 129, and the circle boundary carrier of chapter 58. The chapter names the finite complement-window and boundary rows used by the duality read; it does not import a classical point-set complement, open-cover compactness, selected deformation retracts, quotient homology equality, choice, or ambient local compactness.

Definition 8168.1 (Alexander duality carrier)**.** *An* $\mathsf{AlexanderDuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, L, H, C, M, S, W, B, D, T, R, P, N)$$

with the following displayed rows:

1. *K is the finite* $\mathsf{SimplicialComplex}^{\uparrow}$ *row naming the inspected subcomplex and its face-incidence ledger.*
2. *L is the finite ambient sphere or compact support row, read through* $\mathsf{CompactMetric}^{\uparrow}$ *and the boundary discipline of* $\mathsf{S}^{1\uparrow}$ *when the inspected window is one-dimensional.*
3. *H is the* $\mathsf{Homology}^{\uparrow}$ *row for the displayed complement window.*
4. *C is the* $\mathsf{Cohomology}^{\uparrow}$ *row for the displayed subcomplex window.*
5. *M is the compact-metric witness row that keeps complement membership and boundary reads finite.*
6. *S is the sphere-boundary row, recording the visible boundary orientation and the inspected sphere coordinate windows.*
7. *W is the complement-window ledger, listing the finite faces and boundary cells whose complement is available to the duality read.*
8. *B is the boundary-link row, pairing each inspected face of K with the corresponding complement-window boundary cell.*
9. *D is the duality-degree ledger, recording the inspected degree shift and the finite source and target windows.*

10. *T records componentwise* hsame *transport for the simplicial, homology, cohomology, compact-support, sphere-boundary, complement-window, boundary-link, and degree rows.*
11. *R records displayed* Cont *replay for consumers that ask for the same finite duality route.*
12. *P is the* Pkg *provenance over* $\mathsf{AlexanderDuality}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AlexanderDuality}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient point-set complement, an arbitrary sphere model, a selected deformation retract, quotient homology equality, open-cover compactness, countable choice, or external excision.

Theorem 8168.2 (Alexander duality NameCert obligations)**.** *For every accepted* $\mathsf{AlexanderDuality}^{\uparrow}$ *carrier $A = (K, L, H, C, M, S, W, B, D, T, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AlexanderDuality}^{\uparrow}}$ *surface consists exactly of carrier admission for the simplicial-complex row K, compact sphere-support row L, complement homology row H, subcomplex cohomology row C, compact-metric row M, sphere-boundary row S, complement-window ledger W, boundary-link row B, degree ledger D, componentwise transport T, displayed replay R, provenance P, and local naming N. A consumer may read the displayed duality window from these rows, but it receives no unrestricted Alexander duality theorem outside the finite carrier.*

Proof. Project the carrier of Definition 8168.1. The rows $K, L, H, C, M, S, W, B, D, T, R, P, N$ are the entire accepted inventory, so every local certificate obligation must be read from those rows.

The topological input is finite. The simplicial row K, compact support row L, compact-metric witness M, sphere-boundary row S, and complement-window ledger W expose only the inspected faces, boundary cells, and complement windows.

The algebraic input is finite as well. The homology row H, cohomology row C, boundary-link row B, and degree ledger D identify the inspected duality source and target windows without introducing quotient representatives or a global exactness principle.

Finally the structural rows T, R, P, N transport, replay, source, and name exactly that packet. Hence the local certificate cannot export an ambient point-set complement, selected deformation retract, quotient homology equality, open-cover compactness, choice, or external excision. □

Theorem 8168.3 (Alexander duality simplicial complement route)**.** *Every homology or cohomology consumer of an accepted* $\mathsf{AlexanderDuality}^{\uparrow}$ *packet must first read the finite route*

$$\mathsf{SimplicialComplex}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{S}^{1\uparrow} \longmapsto W, S, B, D \longmapsto \mathsf{Homology}^{\uparrow},\ \mathsf{Cohomology}^{\uparrow}.$$

The route exposes a displayed complement window, sphere-boundary row, boundary-link ledger, and degree-shift row before the homology and cohomology windows are consumed. It is a finite simplicial complement route, not a classical point-set complement, a host duality isomorphism, a selected deformation retract, quotient homology equality, or a choice principle.

Proof. Begin with the NameCert obligations of Definition 8168.2. They force every consumer to read K, L, M, S, W, B, D before the algebraic windows H and C are available.

The complement route is then determined by W, S, B, D. The window ledger W lists the complement cells, the sphere-boundary row S fixes the inspected boundary support, the boundary-link row B pairs subcomplex faces with complement cells, and the degree ledger D records the finite shift read by the algebraic rows.

It remains to pass the route to homology and cohomology consumers. The transport and replay rows T, R preserve the displayed route, while P, N source and name it. Since no other coordinate is present, the consumer receives only the finite simplicial complement route and not an ambient complement theorem, selected deformation retract, quotient equality, or choice datum. □

Falsifiable prediction: If the complement-window ledger W is read without the displayed $\mathsf{SimplicialComplex}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, sphere-boundary, boundary-link, and degree rows, an accepted $\mathsf{AlexanderDuality}^{\uparrow}$ consumer must refuse the homology/cohomology handoff rather than treating the complement as a host point-set object.

Independence witness: simplicialcomplex, homology, cohomology, compactmetric, s1: $\mathsf{AlexanderDuality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries complement-window rows, sphere-boundary rows, boundary-link ledgers, degree-shift rows, homology/cohomology windows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AlexanderDuality}^{\uparrow}}$.

Constructive story: An $\mathsf{AlexanderDuality}^{\uparrow}$ packet is generated from a finite SimplicialComplexUp source row, compact sphere-support rows, complement HomologyUp rows, subcomplex CohomologyUp rows, CompactMetricUp finite support, SOneUp boundary windows when present, complement-window ledgers, boundary-link rows, a degree ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AlexanderDuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8168.1, Definition 8168.2, and Definition 8168.3 seed the finite simplicial complement route for Alexander duality packets over simplicial, homology, cohomology, compact-metric, and sphere-boundary rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AlexanderDuality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, unrestricted Alexander duality, classical point-set complements, selected deformation retracts, quotient homology equality, open-cover compactness, countable choice, or external excision.

Upgrade path: Obligation closure requires checked carrier admission, complement-window exactness, sphere-boundary exactness, boundary-link stability, degree-ledger readback, homology/cohomology handoff, transport, replay, provenance, and local naming for BEDC.Derived.AlexanderDualityUp.

Chapter 8169

A Concrete Naming Certificate for $\mathsf{BishopRealLocatedness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRealLocatedness}^{\uparrow}$ packet records located real evidence as finite regular-Cauchy witness data rather than as real trichotomy, quotient-real equality, or ambient completeness. It sits after the dyadic core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric comparison surface of chapter 57. The packet names the finite evidence by which a regular real name can answer located interval requests.

Definition 8169.1 (Bishop real locatedness carrier)**.** *A* $\mathsf{BishopRealLocatedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, E, M, Q, H, C, P, N)$$

over $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *with the following displayed rows:*

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger naming exactly the real-name observations inspected by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and interval-comparison ledger used to compare the readback with displayed rational bounds.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the stream, regular-readback, and dyadic rows have been exposed.*
5. *M is the* $\mathsf{Met}^{\uparrow}$ *comparison row that records the located-distance request against rational interval endpoints.*
6. *Q is the locatedness query ledger. Each row names a pair of rational endpoints $a < b$ and records which side of the displayed interval is witnessed by the finite readback and dyadic comparison rows.*
7. *H records componentwise* hsame *transport for the stream, readback, dyadic, real-seal, metric, query, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a locatedness request through Q, S, R, D, E, M, H.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealLocatedness}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{BishopRealLocatedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host real trichotomy, quotient-real equality, a selected Dedekind cut, a completed Cauchy quotient, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8169.2 (Bishop real locatedness NameCert obligations)**.** *For every accepted* $\mathsf{BishopRealLocatedness}^{\uparrow}$ *carrier* $L = (S, R, D, E, M, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopRealLocatedness}^{\uparrow}}$ *surface consists exactly of stream-window admission, regular-rational readback, dyadic tolerance comparison, real-seal nonescape, metric interval comparison, locatedness query admission, componentwise transport, displayed replay, provenance, and local naming. Every locatedness answer must cite the visible* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows of the same packet.*

Proof. Project the carrier of Definition 8169.1. The stream row S, regular readback R, dyadic ledger D, real seal E, metric row M, and query ledger Q are all visible coordinates of one finite packet.

Read a locatedness request through Q. The requested rational interval is compared only after the packet exposes the finite stream windows, the regular rational readback, and the dyadic tolerance ledger, so the answer is a finite witness row rather than a host real-order decision.

The structural rows H, C, P, N transport, replay, source, and name the same displayed coordinates. Since the carrier has no coordinate for trichotomy, quotient-real equality, a selected cut, a completed Cauchy quotient, countable choice, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8169.3 (Bishop real locatedness RegSeqRat witness route)**.** *Every locatedness witness exported by an accepted* $\mathsf{BishopRealLocatedness}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow}.$$

Thus a consumer may read a located interval answer only after it has displayed the finite stream windows, the regular rational readback, the dyadic tolerance comparison, the real-name seal, and the metric comparison row. The route does not export real trichotomy, quotient-real equality, selected cuts, selected limits, countable choice, or ambient completeness.

Proof. Begin with a consumer of a locatedness answer. Carrier admission exposes the query row Q together with S, R, D, E, M, so the answer is attached to the same finite witness tuple.

Replay the request through C. The consumer first reads the finite $\mathsf{StreamName}^{\uparrow}$ windows, then the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback, then the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance comparison. Only after those rows are visible may the terminal $\mathsf{Real}^{\uparrow}$ seal and the $\mathsf{Met}^{\uparrow}$ comparison row be inspected.

Transport by H preserves this order componentwise. The package and local NameCert rows cite only the displayed route, so no excluded real-order, quotient, choice, selected-limit, or completeness datum can be projected from the packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealLocatedness}^{\uparrow}$ read exposes StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance comparison, RealUp seal, MetricUp interval comparison, locatedness query admission, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before a located interval answer is served.

Independence witness: streamname, regseqrat, dyadicratcore, real, metric: $\mathsf{BishopRealLocatedness}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries finite windows, regular readback,

dyadic interval comparison, real sealing, metric comparison, locatedness queries, transport, replay, provenance, and local naming as one witness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealLocatedness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealLocatedness}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance comparison, a RealUp seal, MetricUp interval comparison, locatedness query rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealLocatedness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8169.1, Definition 8169.2, and Definition 8169.3 seed the located-real witness route from regular Cauchy names to finite interval answers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealLocatedness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close real trichotomy, quotient-real equality, selected cuts, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-query exactness, RegSeqRat readback, DyadicRatCore comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealLocatednessUp

Chapter 8170

A Concrete Naming Certificate for $\mathsf{CompactModulusComposition}^{\uparrow}$

Following Bishop–Bridges constructive metric analysis and the compact-uniform-continuity route of chapter 9237, the $\mathsf{CompactModulusComposition}^{\uparrow}$ packet records the finite cover-level step that turns compact finite-cover rows and pointwise modulus rows into one uniform-modulus ledger. It sits beside compact data from chapter 60, continuous rows from chapter 59, metric comparison rows from chapter 57, rational tolerance rows from chapter 37 and chapter 38, and the uniform handoff of chapter 391. The packet is narrower than a composition theorem for already uniform maps: it names the finite compact-cover fold itself.

Definition 8170.1 (Compact modulus composition carrier)**.** *A* $\mathsf{CompactModulusComposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, B, L, Q, R, T, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Compact}^{\uparrow}$ *row carrying the displayed finite cover or finite-net packet at the requested tolerance.*
2. *F is the* $\mathsf{Continuous}^{\uparrow}$ *row whose pointwise modulus evidence is read at the cover centers named by X.*
3. *B is the finite cover bundle row. Its entries name centers, radii, membership certificates, and the cover incidence relation used by the compact row.*
4. *L is the local modulus ledger assigning to each displayed cover entry a pointwise rational precision row.*
5. *Q is the* $\mathsf{Rat}^{\uparrow}$ *rational fold row that compares the finitely many local precision and radius rows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance and seal row consumed by the final uniform ledger.*
7. *T is the* $\mathsf{Met}^{\uparrow}$ *triangle and distance-comparison row that transports a source pair through the chosen cover center.*
8. *U is the* $\mathsf{UniformContinuity}^{\uparrow}$ *handoff row produced from the finite cover, local modulus, rational fold, real tolerance, and metric rows.*
9. *H records componentwise* hsame *transport for compact cover, continuity, local modulus, rational fold, real seal, metric comparison, uniform handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a uniform-modulus request through $X, F, B, L, Q, R, T, U, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactModulusComposition}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Continuous}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusComposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for a host finite-subcover selection theorem, a selected global modulus, quotient point equality, open-cover compactness, choice over cover entries, or ambient completeness.

Theorem 8170.2 (Compact modulus composition NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusComposition}^{\uparrow}$ *carrier $K = (X, F, B, L, Q, R, T, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactModulusComp}}$ *surface consists exactly of compact finite-cover admission through X, B, pointwise continuous-modulus admission through F, L, rational finite-fold exactness through Q, real tolerance sealing through R, metric triangle transport through T, uniform-continuity export through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8170.1. The compact cover rows X, B, continuous row F, local modulus row L, rational fold Q, real seal R, metric row T, and uniform handoff U are visible coordinates of the same finite packet.

The local modulus rows are read only along the displayed cover entries. The rational fold Q compares those finitely many local rows and radius rows, so the packet produces a single tolerance-facing ledger without selecting a host-level global modulus.

The metric row T transports a source pair through the cover center chosen by the finite cover row, and U records the resulting uniform-continuity handoff. The rows H, C, P, N transport, replay, source, and name this same route.

Since the carrier has no coordinate for open-cover compactness, quotient point equality, cover-entry choice outside B, a selected global modulus, host finite-subcover selection, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8170.3 (Compact modulus composition uniform route)**.** *Every uniform-continuity consumer of an accepted* $\mathsf{CompactModulusComposition}^{\uparrow}$ *packet reaches its tolerance-only ledger through the finite route*

$$\mathsf{Compact}^{\uparrow},\ \mathsf{Continuous}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformContinuity}^{\uparrow}.$$

More precisely, it must read the compact finite-cover rows X, B, the pointwise-modulus rows F, L, the rational finite-fold row Q, the real tolerance seal R, and the metric triangle row T before the uniform handoff U is exported.

Proof. Start with a uniform-modulus request. The replay row C routes the request first to the compact finite-cover data X, B, so a displayed cover entry is available before any local modulus row is consumed.

At the selected cover entry, the continuous row F and local ledger L expose the pointwise precision data. The rational fold row Q then supplies a finite lower-bound row across all displayed cover entries, and the real seal R records the tolerance being served.

Finally the metric row T gives the source and target triangle estimate needed by the uniform handoff U. Transport, provenance, and local naming preserve the same rows, so the consumer receives a finite compact-cover composition route rather than a host compactness theorem or a selected global modulus. □

Falsifiable prediction: Every accepted $\mathsf{CompactModulusComposition}^{\uparrow}$ read exposes compact finite-cover rows, continuous pointwise-modulus rows, a RatUp finite-fold row, RealUp tolerance sealing, MetricUp triangle transport, a UniformContinuity handoff, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before a tolerance-only uniform ledger is served.

Independence witness: compact, continuous, metric, rat, real, uniformcontinuity: $\mathsf{CompactModulusComposition}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries compact finite-cover rows, pointwise modulus rows, a rational fold, real tolerance sealing, metric triangle transport, uniform handoff, transport, replay, provenance, and local naming as one finite composition packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusComposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusComposition}^{\uparrow}$ packet is generated from compact finite-cover rows, Continuous pointwise-modulus rows, a RatUp finite-fold ledger, RealUp tolerance sealing, MetricUp triangle transport, a UniformContinuityUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusComposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8170.1, Definition 8170.2, and Definition 8170.3 seed the finite compact-cover composition route from pointwise moduli to a uniform ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusComposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected global moduli, quotient point equality, cover-entry choice outside the displayed finite cover, host finite-subcover selection, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-cover admission, pointwise-modulus admission, rational fold exactness, real tolerance sealing, metric triangle transport, uniform handoff, replay stability, provenance exhaustion, and local naming for BEDC.Derived.CompactModulusCompositionUp.

Chapter 8171

A Concrete Naming Certificate for $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$

Following Sierpinski and continuum theory, the $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ packet records the planar universal-curve boundary as finite compact-metric and square-refinement NameCert data. It sits after the compact-metric source of chapter 129, the Peano-continuum interface of chapter 2160, the planar retained-square surface of chapter 3960, the universal one-dimensional comparison packet of chapter 7789, and the terminal real readback of chapter 38. The packet names a finite planar curve boundary for downstream compact-continuum consumers; it does not assert a host hyperspace equality, open-cover compactness, selected branch points, quotient continua, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8171.1 (Sierpinski universal curve carrier)**.** *A* $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, P, S, M, G, W, R, H, C, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row supplying compact metric coverage before any planar boundary row is consumed;*
2. *P is the* $\mathsf{PeanoContinuum}^{\uparrow}$ *row recording compact connected locally connected continuum data;*
3. *S is the* $\mathsf{SierpinskiCarpet}^{\uparrow}$ *planar retained-square sibling row;*
4. *M is the* $\mathsf{MengerCurve}^{\uparrow}$ *universal one-dimensional comparison row;*
5. *G is the finite square-refinement row naming the retained and deleted planar-window stages;*
6. *W is the planar-window row exposing finite boundary arcs and hole-adjacency reads;*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *readback row for the finite coordinate windows used by G and W;*
8. *H records componentwise* hsame *transports for the compact, continuum, planar, square-refinement, readback, replay, provenance, and local naming rows;*
9. *C is the displayed* Cont *replay route for extending the finite square-refinement ledger;*
10. *Q is the* Pkg *provenance over* $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{SierpinskiCarpet}^{\uparrow}$, $\mathsf{MengerCurve}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SierpinskiUniversalCurve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, P, S, M, G, W, R, H, C, Q, N$. It has no coordinate for host hyperspace equality, open-cover compactness, selected planar continua, quotient point equality, choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8171.2 (Sierpinski universal curve NameCert obligations)**.** *For every accepted* $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ *carrier*

$$U = (K, P, S, M, G, W, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{SierpinskiUniversalCurve}^{\uparrow}}$ *surface consists exactly of compact-metric exposure through K, Peano-continuum exposure through P, Sierpinski-carpet planar comparison through S, Menger-curve universal comparison through M, finite square-refinement exposure through G, planar-window boundary exposure through W, real readback through R, componentwise transport through H, displayed continuation replay through C, provenance through Q, and local naming through N.*

Proof. Project the accepted carrier through Definition 8171.1. The rows K, P, S, M expose the compact, continuum, planar-carpet, and universal-curve sibling data that a consumer may cite.

The finite planar boundary data are held by G, W, R. The square-refinement row records retained and deleted stages, the planar-window row records boundary arcs and adjacency reads, and the real readback row seals only those finite coordinate windows.

Finally use H, C, Q, N for transport, replay, source, and local naming. Since no carrier coordinate supplies host hyperspace equality, open-cover compactness, selected branch points, quotient continua, choice, or ambient completeness, those obligations cannot enter the local NameCert surface. □

Theorem 8171.3 (Sierpinski universal curve planar curve boundary)**.** *Every compact-planar-continuum consumer of an accepted* $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{PeanoContinuum}^{\uparrow},\ \mathsf{SierpinskiCarpet}^{\uparrow},\ \mathsf{MengerCurve}^{\uparrow} \longmapsto G, W, R \longmapsto H, C, Q, N.$$

The route may use the Sierpinski-carpet sibling as a planar retained-square boundary and the Menger-curve sibling as a universal one-dimensional comparison surface, but it exports no host hyperspace equality, no open-cover compactness theorem, no selected universal embedding, no quotient equality of continua, no choice principle, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the carrier rows K, P, S, M. These rows place the packet inside the existing compact metric, Peano continuum, Sierpinski carpet, and Menger curve surfaces without identifying the new packet with any sibling.

Read the planar boundary through G, W, R. The square-refinement and planar-window rows are finite BHist data, and the $\mathsf{Real}^{\uparrow}$ row is only the coordinate readback for those displayed windows.

Transport and replay are then forced through H, C, Q, N. The packet has no row for a host hyperspace, an open-cover proof, a selected embedding, quotient continuum equality, choice, or ambient completeness, so a consumer cannot extract any of those principles from the boundary route. □

Falsifiable prediction: Every accepted $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ compact-planar-continuum read factors through $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{PeanoContinuum}^{\uparrow}$, $\mathsf{SierpinskiCarpet}^{\uparrow}$, $\mathsf{MengerCurve}^{\uparrow}$, finite square-refinement rows, planar-window rows, $\mathsf{Real}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ before using the curve boundary.

Independence witness: sierpinski-carpet, menger-curve, peano-continuum, compactmetric, real: $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ is not bijective to any listed sibling because it binds compact metric,

continuum, planar retained-square, universal-curve comparison, square-refinement, planar-window, real readback, transport, replay, provenance, and local naming rows into one planar universal-curve certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{SierpinskiUniversalCurve}^{\uparrow}}$.

Constructive story: A $\mathsf{SierpinskiUniversalCurve}^{\uparrow}$ packet is generated from a CompactMetricUp source row, a PeanoContinuumUp row, a SierpinskiCarpetUp planar sibling row, a MengerCurveUp universal comparison row, finite square-refinement rows, planar-window boundary rows, RealUp readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SierpinskiUniversalCurve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8171.1, Definition 8171.2, and Definition 8171.3 seed the compact-planar-continuum route over CompactMetricUp, PeanoContinuumUp, SierpinskiCarpetUp, MengerCurveUp, finite square-refinement, planar-window, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SierpinskiUniversalCurve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host hyperspace equality, open-cover compactness, selected universal embeddings, quotient equality of continua, choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric exposure, continuum exposure, planar sibling exposure, universal-curve comparison, finite square-refinement exposure, planar-window readback, transport, replay, provenance, and local naming for BEDC.Derived.SierpinskiUniversalCurveUp.

Chapter 8172

A Concrete Naming Certificate for $\mathsf{LowerSemicontinuousRegularization}^{\uparrow}$

Following Bourbaki and Bishop-style constructive analysis, the $\mathsf{LowerSemicontinuousRegularization}^{\uparrow}$ packet records the finite BEDC surface by which a real-valued metric datum is replaced by its displayed lower-semicontinuous envelope. It sits after the metric carrier of chapter 57, the regular-rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the lower-semicontinuity packet of chapter 1536. The packet names only displayed finite windows and refusals; it does not import host infima, selected limits, quotient functions, countable choice, or ambient completion.

Definition 8172.1 (Semicontinuous envelope carrier)**.** *A* $\mathsf{LowerSemicontinuousRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, M, R, D, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{Real}^{\uparrow}$ *row naming the real-valued datum whose lower envelope is being read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *row naming the displayed neighbourhood or ball requests over which the envelope is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational approximants attached to those metric windows.*
4. *D is the dyadic lower-bound window row, carrying the finite lower estimates that a consumer may inspect.*
5. *L is the* $\mathsf{LowerSemicontinuous}^{\uparrow}$ *row stating that accepted reads preserve lower-window stability under displayed metric refinement.*
6. *H records componentwise* hsame *transport for the source, metric, readback, dyadic-window, lower-stability, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from source data through metric windows, regular-rational readback, dyadic lower bounds, and the lower-semicontinuity row.*
8. *P is the* Pkg *provenance over* $\mathsf{LowerSemicontinuousRegularization}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{LowerSemicontinuous}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LowerSemicontinuousRegularization}^{\uparrow}}$ *row.*

The classifier compares accepted envelopes only through these nine rows. It has no coordinate for hidden infima, selected minimizing sequences, quotient functions, host real equality, countable choice, or ambient lower-completion principles.

Theorem 8172.2 (Semicontinuous envelope NameCert obligations)**.** *For every accepted* LowerSemicontinuousRegul *carrier*

$$E = (S, M, R, D, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LowerSemicontinuousRegularization}^{\uparrow}}$ *surface consists exactly of source-real exposure through* S*, metric-window exposure through* M*, regular-rational readback through* R*, dyadic lower-bound exposure through* D*, lower-semicontinuity stability through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8172.1. The source row, metric row, readback row, dyadic lower-window row, and lower-semicontinuity row are all displayed before the local name is admitted.

Read the analytic route in dependency order. The source real datum is inspected only through S; metric refinement requests are named by M; regular-rational witnesses are read back through R; and the dyadic lower-bound ledger D records the finite estimates available to consumers.

Finally use L, H, C, P, N. Lower-semicontinuity is a displayed stability row, and transport, replay, provenance, and local naming preserve the same packet. Since the carrier has no hidden infimum or selected-limit coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 8172.3 (Semicontinuous envelope lower-upper stability)**.** *Every accepted* LowerSemicontinuousRegulariza *consumer must preserve the dyadic lower-bound windows* D *together with the source, metric, readback, and lower-semicontinuity rows* S, M, R, L*. The packet may export lower-envelope stability under displayed metric refinement, but it cannot be consumed as a selected pointwise infimum, a hidden upper regularity theorem, a quotient-function equality, or a final real-name oracle.*

Proof. Start from the NameCert obligations of Definition 8172.2. They place D in the same packet as S, M, R, L, so lower bounds are not detachable annotations.

Apply the classifier clause in Definition 8172.1. Accepted comparison sees the dyadic window row and the lower-semicontinuity row together with componentwise transport and displayed replay. A consumer that drops D or L therefore leaves the accepted envelope surface.

The exclusions follow from the absent coordinates. The carrier contains no selected infimum, no hidden upper envelope, no quotient-function equality, and no final real-name oracle, while H, C, P, N only transport, replay, source, and name the displayed rows already present. □

Falsifiable prediction: A lower-envelope consumer that asks for a selected infimum or a quotient-function representative without displaying the dyadic lower-bound window row is rejected by the LowerSemicontinuousRegularizationUp classifier.

Independence witness: real, metric, regseqrat, lowersemicontinuous: none is bijective because the regularization packet binds source real data, metric windows, regular-rational readback, dyadic lower bounds, lower-semicontinuity stability, transport, replay, provenance, and local NameCert rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LowerSemicontinuousRegularization}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LowerSemicontinuousRegularization}^{\uparrow}$ packet is generated from source Real rows, Metric window rows, RegSeqRat readback rows, dyadic lower-bound windows, a LowerSemicontinuous stability row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LowerSemicontinuousRegularization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8172.1, Definition 8172.2, and Definition 8172.3 seed the finite lower-semicontinuous regularization route over $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LowerSemicontinuous}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LowerSemicontinuousRegularization}^{\uparrow}}, \text{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected infima, quotient functions, countable choice, ambient completion, hidden upper regularity, or final real-name oracle behavior.

Upgrade path: Obligation closure requires checked carrier admission, dyadic lower-window exposure, lower-semicontinuity stability, transport, replay, provenance, and local naming for BEDC.Derived.LowerSemicontinuousRegularizationUp.

Chapter 8173

A Concrete Naming Certificate for $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$

The $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$ packet realizes the compact-uniform-modulus direction of chapter 9237 as finite law-facing NameCert data. It sits after the compact source of chapter 129, the continuous-map row of chapter 130, the tolerance-only modulus handoff of chapter 369, the law-certificate surface of chapter 1155, and the terminal real-name seal of chapter 38. The packet binds compact source, continuous map, modulus, lawlike claim, failure surface, transport, replay, provenance, and local naming before a compact law can be consumed.

Definition 8173.1 (Compact law failure-envelope carrier)**.** *A* $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, F, U, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, naming the compact finite-net or compact-window surface on which the law is offered.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row, naming the continuous map or observable transformation whose lawlike behavior is being inspected.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row, naming the tolerance-only modulus handoff extracted from compact and continuous data.*
4. *L is the* $\mathsf{LawCertificate}^{\uparrow}$ *row, recording the lawlike equation, invariant, or classifier claim attached to the compact-uniform route.*
5. *E is the failure-envelope row, listing compact windows, modulus refinements, source observations, or Real-facing reads that would defeat the law claim.*
6. *H records componentwise* hsame *transport for the compact source, continuous map, modulus, law-certificate, failure-envelope, replay, provenance, and naming rows.*
7. *C records displayed* Cont *replay from compact-source admission through continuous-map inspection, uniform-modulus handoff, law-certificate reading, and failure-envelope exposure.*
8. *P is the* Pkg *provenance over* $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{LawCertificate}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactLawFailureEnvelope}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a compact law without a modulus row, a law certificate without a failure envelope, a total prediction over all compact refinements, hidden compactness, selected real limits, or ledger-free law status.

Theorem 8173.2 (Compact law failure-envelope NameCert obligations)**.** *For every accepted* $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$ *carrier*

$$K = (S, F, U, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactLawFailureEnvelope}^{\uparrow}}$ *surface consists exactly of compact-source exposure through* S*, continuous-map exposure through* F*, uniform-modulus exposure through* U*, law-certificate exposure through* L*, failure-envelope exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8173.1. The compact source, continuous map, uniform modulus, law certificate, and failure envelope are all displayed rows before the local name is public.

Read the compact-uniform route in order. The compact row supplies the source surface, the continuous-map row supplies the observable transformation, and the uniform-modulus row supplies the tolerance-only handoff. The law-certificate row then attaches the lawlike claim only after those rows are visible.

The failure-envelope row is part of the same NameCert surface. Componentwise transport, displayed replay, provenance, and local naming preserve this packet rather than replacing it by a compactness theorem or equation-only law, so the listed rows exhaust the local obligations. □

Theorem 8173.3 (Compact law failure-envelope classifier boundary)**.** *Every accepted* $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$ *consumer must preserve* $S, F, U, L, E, H, C, P, N$ *together. In particular, a compact law packet with a uniform modulus but no failure-envelope row is outside the classifier, and a route that keeps the law-certificate row while dropping compact source, continuous-map, modulus, or failure-surface data cannot export compact-law status.*

Proof. Use the NameCert obligations of Definition 8173.2. They make E a required row alongside the compact source, continuous-map, uniform-modulus, and law-certificate rows.

Apply the classifier clause in Definition 8173.1. Accepted comparison preserves the displayed packet through H, C, P, N, so a consumer that omits E or detaches L from S, F, U has left the accepted row surface.

The refusal clauses follow from absent coordinates. There is no hidden compactness row, selected real limit, total prediction, or ledger-free equation route from which the missing failure envelope could be reconstructed. □

The future Lean TasteGate surface for $\mathsf{CompactLawFailureEnvelope}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial}\ \mathsf{CompactLaw}$ and $\mathsf{FieldFaithful}\ \mathsf{CompactLawFailureEnvelope}^{\uparrow}$ instances preserving $S, F, U, L, E, H, C, P, N$ as separate displayed rows.

Falsifiable prediction: A compact law packet with a uniform modulus but no failure-envelope row is rejected by the classifier.

Independence witness: compactmetric, continuousmap, uniformmodulus, lawcertificate: none is bijective because the new packet binds compact source, continuous map, modulus, lawlike claim, failure surface, and provenance rows in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactLawFailureEnvelope}^{\uparrow}}$ **.**

Constructive story: A CompactLawFailureEnvelope$^{\uparrow}$ packet is generated from CompactMetric source rows, ContinuousMap rows, UniformModulus handoff rows, LawCertificate rows, explicit failure-envelope rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactLawFailureEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 8173.1, Definition 8173.2, and Definition 8173.3 seed the compact law failure-envelope route over CompactMetric$^{\uparrow}$, ContinuousMap$^{\uparrow}$, UniformModulus$^{\uparrow}$, LawCertificate$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactLawFailureEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, total compact-law prediction, hidden compactness, selected real limits, ledger-free equation status, or failure-envelope-free law export.

Upgrade path: Obligation closure requires checked carrier admission, compact source exposure, continuous-map exposure, uniform-modulus handoff, law-certificate exposure, failure-envelope exactness, transport, replay, provenance, and local naming for BEDC.Derived.CompactLawFailureEnvelopeUp.

Chapter 8174

A Concrete Naming Certificate for $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ packet records finite-net compactness data for a displayed family of continuous maps over a compact metric source. It sits beside the compact source of chapter 129, the equicontinuity surface of chapter 4076, the continuous-map graph rows of chapter 130, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite data consumed by compact-uniform and Arzela–Ascoli routes; it does not assert open-cover compactness, selected subsequences, quotient function-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Falsifiable prediction: Any compact-family consumer that reads a $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ packet while bypassing its compact source row, continuous-map family row, equicontinuity modulus row, finite-net row, RegSeqRat/Real readback rows, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the classifier.

Independence witness: compactmetric, equicontinuity, continuousmap, streamname, regseqrat, real: $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ is not bijective to any listed sibling because it binds compact source inspection, a continuous-map family ledger, equicontinuity modulus data, finite totally-bounded nets, regular rational readback, Real endpoint seals, transport, replay, provenance, and local naming in one packet.

Definition 8174.1 (Compact totally bounded function-family carrier)**.** *A* $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, F, E, B, W, R, V, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the compact finite-net windows used to inspect source points.*
2. *F is the finite* $\mathsf{ContinuousMap}^{\uparrow}$ *family ledger whose graph rows expose the admissible maps on the source windows.*
3. *E is the* $\mathsf{Equicontinuity}^{\uparrow}$ *modulus row, recording one displayed source-radius response for the family at each requested target tolerance.*

4. *B is the totally-bounded finite-net row for the image family, including the finite list of net centers and radius budgets visible to compact-family consumers.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation row through which source windows, family indices, and value samples are requested.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *value-readback row obtained from the displayed windows and dyadic tolerance ledgers.*
7. *V is the* $\mathsf{Real}^{\uparrow}$ *value-seal row reached only after the regular readback is exposed.*
8. *H records componentwise* hsame *transport for compact source rows, continuous-map rows, equicontinuity rows, finite-net rows, stream windows, readbacks, Real seals, replay rows, provenance, and local naming.*
9. *C records displayed* Cont *replay from a family compactness request through compact source inspection, graph evaluation, equicontinuity radius use, finite-net comparison, regular readback, and Real sealing.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Equicontinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, E, B, W, R, V, H, C, P, N$. No coordinate names open-cover compactness, selected subsequences, quotient function-space equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CompactTotallyBoundedFunctionFamilyUp.CompactTotallyBoundedFunctionFamilyTasteGate`
`single carrier alignment`

Theorem 8174.2 (Compact totally bounded function-family NameCert obligations)**.** *For every accepted* $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ *carrier $K = (X, F, E, B, W, R, V, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the compact source, continuous-map family, equicontinuity modulus, totally-bounded finite-net, stream-window, regular-readback, Real-seal, transport, replay, provenance, and local naming rows;*
2. *compact source visibility, requiring every sampled source point to enter through the* $\mathsf{CompactMetric}^{\uparrow}$ *row X and the observation row W;*
3. *family graph visibility, requiring every sampled value to be read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *ledger F before regular readback;*
4. *equicontinuity stability, requiring the modulus row E to mediate tolerance changes before a finite-net comparison is read;*
5. *finite-net exactness, requiring the totally-bounded row B to supply the only admissible net centers and radius budgets for the family image;*
6. *value readback, requiring every terminal value to pass through W, R, V before any Real-facing consumer reads it;*
7. *non-escape, requiring H, C, P, N to preserve the same displayed rows and to export no open-cover compactness, selected subsequence, quotient function-space equality, countable-choice selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation for the compact function family is stored outside these rows.

Proof. Project the carrier of Definition 8174.1. Its analytic coordinates are exactly the compact source row, the continuous-map family ledger, the equicontinuity modulus row, the totally-bounded finite-net row, the stream windows, the regular readback, and the Real seal.

Compact source visibility comes from X and W. A sampled source point has no independent coordinate, so it must be requested through the displayed observation row and then interpreted by the compact-metric source packet.

Family graph visibility comes from F. The carrier stores graph reads only as continuous-map rows, hence a sampled value cannot be read before the relevant family graph row is displayed.

Equicontinuity stability and finite-net exactness are the rows E and B. The modulus row translates tolerance requests into source-window control, and the finite-net row is the only place where net centers and radius budgets are named.

Finally inspect H, C, P, N. These rows transport, replay, record provenance for, and name exactly the displayed packet, so the excluded principles have no row from which a local certificate could read them. □

Theorem 8174.3 (Compact totally bounded function-family finite-net consumer)**.** *Every compact-uniform or Arzela–Ascoli-facing consumer of an accepted* $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{Equicontinuity}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

The route exposes compact source windows, graph samples, equicontinuity moduli, finite totally-bounded net centers, regular value readbacks, and terminal Real seals. It exports no open-cover compactness, selected subsequence, quotient function-space equality, countable-choice selector, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted carrier $K = (X, F, E, B, W, R, V, H, C, P, N)$. A compact-uniform consumer first reads the source windows through X and W, because the packet has no host source-point selector.

The value side then reads F, R, and V. The continuous-map family ledger supplies graph samples, the regular-rational row records their finite readback, and the Real seal is reached only after that readback is visible.

The compact-family comparison is confined by E and B. Equicontinuity supplies the tolerance-to-window handoff, while the finite-net row supplies the displayed centers and radius budgets consumed by the downstream compactness route.

The structural rows H, C, P, N preserve exactly this route. Since the carrier has no row for open covers, selected subsequences, quotient function-space equality, countable choice, or ambient Real completeness, the consumer cannot export any of those objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}$ packet is generated from a CompactMetricUp source row, ContinuousMapUp family rows, an EquicontinuityUp modulus row, a totally-bounded finite-net row, StreamNameUp observation rows, RegSeqRatUp value readback rows, RealUp value seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8174.1, Definition 8174.2, and Definition 8174.3 seed the finite-net compactness data for displayed continuous-map families.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactTotallyBoundedFunctionFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequences, quotient function-space equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source visibility, family graph visibility, equicontinuity stability, finite-net exactness, value readback, transport, replay, and non-escape rows for BEDC.Derived.CompactTotallyBounded

Chapter 8175

A Concrete Naming Certificate for $\mathsf{RealSegment}^{\uparrow}$

Following Bishop and Bridges on located intervals in constructive real analysis, the $\mathsf{RealSegment}^{\uparrow}$ packet records a closed real segment by finite endpoint, located-order, apartness, and tolerance rows rather than by a host subset of an ambient real line. It sits after the terminal real-name seal of chapter 38, the regular rational readback surface of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance core of chapter 291. The packet gives compact-interval and uniform-modulus consumers a local interval object without importing Heine–Borel, open-cover compactness, sequential compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8175.1 (RealSegment carrier)**.** *A* $\mathsf{RealSegment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, O, A, D, R, W, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower endpoint* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *U is the upper endpoint* $\mathsf{Real}^{\uparrow}$ *seal.*
3. *O is the located order row witnessing that the endpoint comparison is read as displayed constructive order data.*
4. *A is the located apartness row that separates exterior probes from the accepted closed segment boundary.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-window ledger for interval enclosures, endpoint budgets, and refinement thresholds.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for endpoint approximants and accepted subinterval endpoints.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that exposes only bounded endpoint and tolerance observations.*
8. *H records componentwise* hsame *transport for endpoint seals, located order, apartness, dyadic windows, regular readback, finite windows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a segment request through L, U, O, A, D, R, W.*
10. *P is the* Pkg *provenance over* $\mathsf{RealSegment}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSegment}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for Heine–Borel compactness, open-cover compactness, sequential compactness, a selected midpoint process, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8175.2 (RealSegment NameCert obligations)**.** *For every accepted* $\mathsf{RealSegment}^{\uparrow}$ *carrier*

$$S = (L, U, O, A, D, R, W, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSegment}^{\uparrow}}$ *surface consists exactly of the following five rows of obligations:*

1. *endpoint admission for the lower and upper* $\mathsf{Real}^{\uparrow}$ *seals L, U;*
2. *located boundary evidence through the order row O and apartness row A;*
3. *finite tolerance exposure through the dyadic ledger D, regular rational readback R, and stream window W;*
4. *componentwise transport and displayed replay through H, C;*
5. *source provenance and local naming through P, N.*

Every accepted interval read is therefore routed through $L, U, O, A, D, R, W, H, C, P, N$, and no certificate obligation is stored outside those rows.

Proof. Project the carrier of Definition 8175.1. The endpoint seals L, U are the only terminal real-name rows, while O, A are the only rows that can witness located order and apartness at the boundary.

The finite tolerance rows are D, R, W. They expose dyadic budgets, regular rational endpoint approximants, and finite observation windows before any downstream compact-interval or modulus consumer reads the segment.

The structural rows H, C, P, N transport, replay, source, and name exactly the same packet. Since no excluded coordinate occurs in the carrier, the five listed obligation groups exhaust the local NameCert surface and do not export compactness or ambient completeness. □

Theorem 8175.3 (RealSegment located subinterval transport)**.** *Let $S = (L, U, O, A, D, R, W, H, C, P, N)$ be an accepted* $\mathsf{RealSegment}^{\uparrow}$ *carrier. If a subinterval request refines the endpoint classifier through transported* hsame *rows and a smaller dyadic tolerance window, then the accepted subinterval row remains inside the same displayed route*

$$L, U, O, A, D, R, W, H, C, P, N.$$

Endpoint classifier transport and dyadic tolerance refinement therefore preserve accepted subinterval rows without introducing Heine–Borel compactness, open-cover compactness, sequential compactness, selected witnesses, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the endpoint rows L, U and the located boundary rows O, A. Transport along H preserves the componentwise endpoint classifier data, so the subinterval request still reads the same lower and upper real-name seals together with the same located order and apartness evidence.

Next refine the tolerance window. The dyadic ledger D records the smaller budget, while R and W expose the corresponding regular rational endpoints and finite observation windows. Thus the refined subinterval is admitted through the same tolerance rows rather than through a new compactness principle.

Finally replay the transported request through C and source it through P, N. The accepted subinterval row is still a row of the original finite packet, so no excluded compactness, quotient, choice, or ambient completeness endpoint is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealSegment}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSegment}^{\uparrow}$ packet is generated from two RealUp endpoint seals, located order and apartness evidence, dyadic tolerance windows, regular rational readback, finite stream windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSegment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8175.1, Definition 8175.2, and Definition 8175.3 seed the located closed real interval route over endpoint, order, apartness, dyadic, readback, window, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSegment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Heine–Borel, open-cover compactness, sequential compactness, selected subinterval witnesses, quotient real equality, countable choice, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint locatedness, apartness transport, dyadic-window refinement, regular-rational readback, finite-window replay, provenance, and local naming for BEDC.Derived.RealSegmentUp.

Chapter 8176

A Concrete Naming Certificate for $\mathsf{ResidueTheorem}^{\uparrow}$

Following Ahlfors and Conway, the $\mathsf{ResidueTheorem}^{\uparrow}$ packet records the finite contour-residue surface by which a holomorphic-domain read with a displayed finite pole window is routed to a contour-integral ledger. It sits after the complex carrier of chapter 39, the holomorphic source of chapter 68, the contour-integral operation of chapter 521, the point-evaluation route of chapter 4136, and the winding-count ledger of chapter 7193. The packet names only a finite contour, a displayed holomorphic-domain row outside the recorded pole window, residue rows, winding-index rows, contour-integral rows, transport, replay, provenance, and local naming; it does not import analytic continuation, unrestricted meromorphic function theory, selected roots, quotient contours, or classical choice.

Definition 8176.1 (Residue theorem carrier)**.** *A* $\mathsf{ResidueTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (G, D, P, Z, W, I, L, T, C, Q, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{PLContour}$ *row with* $\mathsf{Complex}^{\uparrow}$ *endpoint, segment, orientation, and non-boundary incidence data.*
2. *D is the* $\mathsf{Holomorphic}^{\uparrow}$ *domain row on the displayed neighbourhood of the contour image after the finite pole window has been removed.*
3. *P is the finite pole-window row, listing the inspected pole names, local punctured neighbourhood rows, and exclusion evidence from the contour image.*
4. *Z is the residue row, giving one local* $\mathsf{Residue}^{\uparrow}$ *datum for each displayed pole in P.*
5. *W is the winding-index ledger, read through the* $\mathsf{ArgumentPrinciple}^{\uparrow}$ *counting surface when the contour winds around a displayed pole.*
6. *I is the* $\mathsf{ContourIntegralOperation}^{\uparrow}$ *row for the contour integral of the displayed holomorphic-domain input around G.*
7. *L is the residue-sum ledger, pairing the contour-integral row I with the finite sum of the indexed residue rows Z weighted by W.*
8. *T records componentwise* hsame *transport for the contour, holomorphic-domain, pole-window, residue, winding-index, contour-integral, and residue-sum rows.*

9. *C records displayed* Cont *replay for the same finite contour-residue route.*
10. *Q is the* Pkg *provenance over* ResidueTheorem$^{\uparrow}$, Complex$^{\uparrow}$, Holomorphic$^{\uparrow}$, ContourIntegralOperation$^{\uparrow}$, CauchyIntegralFormula$^{\uparrow}$, ArgumentPrinciple$^{\uparrow}$, Residue$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ResidueTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $G, D, P, Z, W, I, L, T, C, Q, N$. The carrier has no coordinate for analytic continuation, unrestricted meromorphic function theory, selected roots, quotient contours, ambient path homotopy, or classical choice.

Theorem 8176.2 (Residue theorem NameCert obligations)**.** *For every accepted* ResidueTheorem$^{\uparrow}$ *carrier*

$$R = (G, D, P, Z, W, I, L, T, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{ResidueTheorem}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the contour row, holomorphic-domain row, finite pole-window row, residue rows, winding-index ledger, contour-integral operation row, residue-sum ledger, transport, replay, provenance, and local naming;*
2. *contour exposure, requiring all integral and index reads to begin with the displayed* PLContour *row G over* Complex$^{\uparrow}$ *endpoints and segments;*
3. *holomorphic-domain exposure, requiring D to display the function domain away from the finite pole window P before any residue row is read;*
4. *local residue exposure, requiring every row of Z to be attached to an inspected pole of P and to the point-evaluation discipline of* CauchyIntegralFormula$^{\uparrow}$*;*
5. *winding-index exposure, requiring W to be read through the finite counting surface of* ArgumentPrinciple$^{\uparrow}$ *before the residue-sum ledger is public;*
6. *contour-integral exposure, requiring I to be the displayed* ContourIntegralOperation$^{\uparrow}$ *row for the same contour and domain data;*
7. *residue-sum exactness, requiring L to pair only the displayed contour-integral row with the finite indexed residue rows;*
8. *componentwise transport, displayed replay, provenance, and local naming through T, C, Q, N;*
9. *nonescape, excluding analytic continuation, unrestricted meromorphic function theory, selected roots, quotient contours, ambient path homotopy, and classical choice.*

No residue-theorem obligation is stored outside these rows.

Proof. Project the accepted carrier of Definition 8176.1. The contour row G, holomorphic-domain row D, pole-window row P, residue rows Z, winding ledger W, contour-integral row I, and residue-sum ledger L are the only analytic rows available to the local certificate.

The local residue part is finite. Each residue row in Z is indexed by a displayed pole in P, and the Cauchy-integral formula dependency is read only as the point-evaluation and local kernel discipline attached to those displayed neighbourhoods.

The contour side is finite as well. The winding ledger W is read through the argument-principle counting surface for the same contour, and the integral row I is the contour-integral operation row for G and D.

Finally the ledger L pairs only those displayed rows, while T, C, Q, N transport, replay, source, and name the same packet. Since none of the excluded objects occurs as a carrier coordinate, the

local NameCert surface cannot export analytic continuation, unrestricted meromorphic function theory, selected roots, quotient contours, ambient path homotopy, or classical choice. □

Falsifiable prediction: An accepted $\mathsf{ResidueTheorem}^{\uparrow}$ read is refuted if it omits the displayed contour row, holomorphic-domain row, finite pole window, residue rows, winding-index ledger, contour-integral row, residue-sum ledger, transport row, replay row, provenance row, or local NameCert row.

Independence witness: complex, holomorphic, contourintegraloperation, cauchy-integral-formula, argument-principle: $\mathsf{ResidueTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds contour rows, holomorphic-domain rows, finite pole-window rows, local residue data, winding-index ledgers, contour-integral rows, residue-sum ledgers, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ResidueTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{ResidueTheorem}^{\uparrow}$ packet is generated from a displayed PLContour row over ComplexUp endpoints, a HolomorphicUp domain row away from a finite pole window, residue rows, winding-index rows, a ContourIntegralOperationUp row, a residue-sum ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ResidueTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8176.1 and Definition 8176.2 seed the finite contour-residue NameCert surface over $\mathsf{Complex}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{ContourIntegralOperation}^{\uparrow}$, $\mathsf{CauchyIntegralFormula}^{\uparrow}$, $\mathsf{ArgumentPrinciple}^{\uparrow}$, $\mathsf{Residue}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ResidueTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, analytic continuation, unrestricted meromorphic function theory, selected roots, quotient contours, ambient path homotopy, or classical choice.

Upgrade path: Obligation closure requires checked carrier admission, contour exposure, holomorphic-domain exposure, finite pole-window exposure, local residue exposure, winding-index exactness, contour-integral routing, residue-sum exactness, transport, replay, provenance, and local naming for BEDC.Derived.ResidueTheoremUp.

Chapter 8177

A Concrete Naming Certificate for $\mathsf{ZTransform}^{\uparrow}$

Following Widder and standard discrete transform theory, the $\mathsf{ZTransform}^{\uparrow}$ packet records a one-sided coefficient stream by finite shift, formal-power, radius, tolerance, transport, provenance, and local NameCert rows. It sits beside the coefficient-window surface of chapter 3356, the exponential-kernel transform route of chapter 3649, the positive-index series surface of chapter 70, the analytic power-series route of chapter 1583, the stream naming discipline of chapter 126, and the regular rational readback rows of chapter 301. The packet names only finite one-sided transform data; it does not assert analytic convergence, inversion, a bilateral transform, host infinite sums, quotient series, or Lean verification.

Definition 8177.1 (ZTransform carrier)**.** *A* $\mathsf{ZTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (W, S, F, R, T, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite one-sided coefficient-window row, exposing only inspected nonnegative indices and their coefficient reads.*
2. *S is the shift row, recording how a finite delay or advance request reindexes the displayed one-sided window.*
3. *F is the formal-power readback row, reading the inspected coefficients as a finite* $\mathsf{FPS}^{\uparrow}$ *or* $\mathsf{GeneratingFunction}^{\uparrow}$ *prefix.*
4. *R is the radius ledger, recording the displayed convergence-radius or subradius data available to downstream* $\mathsf{RealPowerSeries}^{\uparrow}$ *consumers.*
5. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for coefficient budgets, radius budgets, and endpoint readback requests.*
6. *H records componentwise* hsame *transport for coefficient windows, shift rows, formal-power readback, radius and tolerance ledgers, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a transform request through W, S, F, R, T, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{ZTransform}^{\uparrow}$, $\mathsf{GeneratingFunction}^{\uparrow}$, $\mathsf{LaplaceTransform}^{\uparrow}$, $\mathsf{Dirichlet}^{\uparrow}$, $\mathsf{RealPowerSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FPS}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{ZTransform}^\uparrow}$ *row.*

The classifier compares accepted carriers only through $W, S, F, R, T, H, C, P, N$. It has no coordinate for analytic convergence, inverse-transform reconstruction, bilateral negative-index data, selected infinite sums, quotient equality of series, countable choice, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8177.2 (ZTransform NameCert obligations)**.** *For every accepted* $\mathsf{ZTransform}^\uparrow$ *carrier $Z = (W, S, F, R, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ZTransform}^\uparrow}$ *surface consists exactly of one-sided coefficient-window admission, shift-row admission, formal-power readback, radius-ledger exposure, dyadic tolerance exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every transform read factors through the finite route*

$$W, S, F, R, T \longmapsto H, C, P, N.$$

It exports no analytic convergence theorem, inversion theorem, bilateral transform, host infinite sum, quotient series equality, or Lean-checked target.

Proof. Project the carrier of Definition 8177.1. The one-sided coefficient window W, shift row S, formal-power readback F, radius ledger R, and tolerance ledger T are the only transform-facing rows in the packet.

The structural rows preserve that visible route. Componentwise hsame transport can identify only displayed rows, and Cont replay can move only along the finite route from coefficient windows through local naming.

The package and local NameCert rows cite the same packet. Since no excluded coordinate occurs in Z, the certificate cannot export analytic convergence, inversion, bilateral negative-index data, selected infinite sums, quotient series equality, or Lean verification. □

Theorem 8177.3 (ZTransform generating-function handoff)**.** *Every coefficient-facing consumer of an accepted* $\mathsf{ZTransform}^\uparrow$ *carrier reaches* $\mathsf{GeneratingFunction}^\uparrow$ *or* $\mathsf{RealPowerSeries}^\uparrow$ *data only through the displayed one-sided coefficient window, shift row, formal-power readback, radius ledger, dyadic tolerance ledger, transport, replay, provenance, and local naming rows. The handoff is therefore a finite formal-power route, not an analytic inversion principle, bilateral transform, host summation, or quotient-series equality.*

Proof. Start with the coefficient window W. It exposes only the inspected one-sided coefficients, so a consumer cannot obtain negative-index or bilateral data from the packet.

Read the shift row S and formal-power row F. The shift row reindexes the displayed finite window, while F hands that same window to $\mathsf{GeneratingFunction}^\uparrow$ or $\mathsf{FPS}^\uparrow$ before any $\mathsf{RealPowerSeries}^\uparrow$ endpoint consumer can inspect radius information.

Finally use the radius and tolerance ledgers R, T together with H, C, P, N. These rows keep the handoff inside finite NameCert data, so the consumer receives no analytic inversion theorem, host infinite sum, quotient series equality, countable-choice selector, or ambient completeness witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{ZTransform}^\uparrow}$.

Constructive story: A $\mathsf{ZTransform}^\uparrow$ packet is generated from one-sided coefficient windows, shift rows, formal-power readback, radius ledgers, dyadic tolerance ledgers, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ZTransform}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 8177.1, Definition 8177.2, and Definition 8177.3 seed the finite one-sided transform route over coefficient windows, shifts, formal-power readback, radius and tolerance rows, transport, replay, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{ZTransform}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close analytic convergence, inversion theorems, bilateral transforms, host infinite sums, quotient series equality, Lean verification, bridge checking, countable choice, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, one-sided coefficient-window exactness, shift-row compatibility, formal-power readback, radius and tolerance ledger coverage, transport, replay, provenance, and local naming for BEDC.Derived.ZTransformUp.

Chapter 8178

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$

The $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$ packet realizes the observer phase-distance shell route of chapter 9463 as finite boundary-shadow, visual-boundary, observer-window, phase-distance, shell, provenance, and local NameCert rows. It sits beside the observer shell of chapter 5180, the phase-distance observer-expansion packet of chapter 6017, the phase-space packet of chapter 7108, the boundary-shadow packet of chapter 3813, and the visual-boundary packet of chapter 4181. The packet names the joint observer shell and phase-distance boundary rather than a host hyperbolic space, physical observer, quotient ideal boundary, selected geodesic ray, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8178.1 (Hyperbolic observer phase-distance shell carrier)**.** *A* $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, V, O, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row exposing the boundary-shadow window seen by the observer.*
2. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row reading the same shadow window as visual-boundary data.*
3. *O is the* $\mathsf{HyperbolicObserverShell}^{\uparrow}$ *row that records the observer-window shell over boundary and expansion data.*
4. *D is the* $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$ *row exposing the finite phase-distance comparison for the same observer window.*
5. *Q is the* $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$ *row that keeps the reversible phase-space route tied to displayed disk, boundary, refusal, and provenance rows.*
6. *R is the shell-radius and provenance ledger, recording which boundary-shadow, visual-boundary, observer-window, and phase-distance rows are jointly read.*
7. *H records componentwise* hsame *transport for boundary-shadow, visual-boundary, observer-shell, phase-distance, phase-space, ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an observer phase-distance request through $B, V, O, D, Q, R, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$, $\mathsf{HyperbolicObserverShell}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicPhaseSpace}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, HyperbolicVisualBounda BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, V, O, D, Q, R, H, C, P, N$. It has no coordinate for a completed hyperbolic space, physical observer trajectory, quotient ideal-boundary equality, selected geodesic ray, hidden visual-boundary completion, or ambient real completeness.

Theorem 8178.2 (Hyperbolic observer phase-distance shell NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$ *carrier $S = (B, V, O, D, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}}$ *surface consists exactly of boundary-shadow admission, visual-boundary readback, observer-shell admission, phase-distance comparison, hyperbolic phase-space routing, shell-radius provenance, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8178.1. The visible geometric rows are B, V, O, D, Q, R, and each is displayed before transport, replay, provenance, or local naming is consumed.

The boundary rows B, V anchor the shell at the visual boundary. The observer row O and phase-distance row D force the observer-window and distance comparison to be read together, while Q keeps the route inside the finite phase-space packet.

The structural rows H, C, P, N preserve that same finite packet. Since no excluded coordinate occurs in S, the NameCert obligations cannot export a completed hyperbolic space, physical observer trajectory, quotient ideal boundary, selected geodesic ray, hidden visual-boundary completion, or ambient real completeness. □

Theorem 8178.3 (Hyperbolic observer phase-distance shell vision handoff)**.** *The* HyperbolicObserverPhaseDistance *packet realizes the boundary-shadow, phase-distance, observer-window, and provenance rows of chapter 9463 as one finite NameCert carrier. Every consumer of the shell must first read* HyperbolicBoundaryShadow $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverShell}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, *and* HyperbolicPhaseSpace *rows, then the ledger, transport, replay, provenance, and local naming rows.*

Proof. Use the obligation surface of Definition 8178.2. It orders every shell read through the boundary-shadow, visual-boundary, observer-shell, phase-distance, phase-space, and shell-radius rows before any consumer receives a result.

This route is a vision handoff because the cited vision chapter names exactly the observer boundary, phase-distance, shell, and provenance rows that the carrier displays. The handoff is therefore concrete finite NameCert data rather than a prose-only observer geometry.

Finally inspect the refused coordinates in Definition 8178.1. The carrier contains no completed hyperbolic space, physical observer path, quotient ideal-boundary equality, selected geodesic ray, hidden visual-boundary completion, or ambient completeness row, so no such object can be exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicObserverPhaseDistanceShell}^{\uparrow}$ read exposes HyperbolicBoundaryShadow, HyperbolicVisualBoundary, HyperbolicObserverShell, PhaseDistanceObserverExpansion, HyperbolicPhaseSpace, shell-radius provenance, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before the phase-distance shell handoff is consumed.

Independence witness: hyperbolic-observer-shell, phase-distance-observer-expansion, hyperbolic-phase-space, hyperbolic-boundary-shadow, hyperbolic-visual-boundary: $\mathsf{HyperbolicObserverShell}^{\uparrow}$

lacks the phase-distance row, PhaseDistanceObserverExpansion$^{\uparrow}$ lacks the observer shell and boundary-shadow ledger, HyperbolicPhaseSpace$^{\uparrow}$ lacks the observer-window shell, HyperbolicBoundaryShadow$^{\uparrow}$ lacks the phase-distance comparison, and HyperbolicVisualBoundary$^{\uparrow}$ lacks the joint observer-shell provenance. None is bijective to HyperbolicObserverPhaseDistanceShell$^{\uparrow}$ under displayed NameCert-row preservation.

Closure status for NameCert$_{\text{HyperbolicObserverPhaseDistanceShell}^{\uparrow}}$.

Constructive story: A HyperbolicObserverPhaseDistanceShell$^{\uparrow}$ packet is generated from HyperbolicBoundaryShadow rows, HyperbolicVisualBoundary rows, HyperbolicObserverShell rows, PhaseDistanceObserverExpansion rows, HyperbolicPhaseSpace rows, a shell-radius provenance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicObserverPhaseDistanceShell}^{\uparrow}}$, seed)

Scope closed: Definition 8178.1, Definition 8178.2, and Definition 8178.3 seed the finite observer phase-distance shell over boundary-shadow, visual-boundary, observer-shell, phase-distance, phase-space, ledger, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicObserverPhaseDistanceShell}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed hyperbolic spaces, physical observer trajectories, quotient ideal-boundary equality, selected geodesic rays, hidden visual-boundary completion, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow admission, visual-boundary readback, observer-shell admission, phase-distance comparison, phase-space routing, shell-radius provenance, transport, replay, and local naming for BEDC.Derived.HyperbolicObserverPhaseDistanceShellUp.

Chapter 8179

A Concrete Naming Certificate for $\mathsf{HilbertSchmidt}^{\uparrow}$

Following Schatten and von Neumann operator-ideal theory, the $\mathsf{HilbertSchmidt}^{\uparrow}$ packet records the finite square-summable coefficient surface by which a bounded Hilbert operator may be read as Hilbert–Schmidt before compact, trace-class, or spectral consumers inspect it. It sits after the Hilbert carrier of chapter 91, the linear-map rows of chapter 48, the scalar-bound surface of chapter 3603, the finite-image route of chapter 6952, and the operator-ideal boundary of chapter 213. The packet names only displayed Hilbert rows, a bounded linear action, a finite orthonormal-basis window, a square-sum ledger, transport, replay, provenance, and local naming; it does not select an infinite basis, assert trace theory, identify host Hilbert-space equality, or import compactness from outside the displayed rows.

Definition 8179.1 (Hilbert–Schmidt carrier)**.** *A* $\mathsf{HilbertSchmidt}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (H, L, B, S_{\mathrm{sq}}, T, R, P, N)$$

with the following displayed rows:

1. *H is the Hilbert source row, carrying the source and target* $\mathsf{Hilbert}^{\uparrow}$ *endpoints together with the inner-product and norm data consumed by operator readers.*
2. *L is the bounded* $\mathsf{LinMap}^{\uparrow}$ *row for the same endpoints, read through the bounded-operator and* $\mathsf{OperatorNorm}^{\uparrow}$ *surfaces before any ideal consumer appears.*
3. *B is a finite orthonormal-basis window: a displayed finite list of source vectors, their orthonormality ledger, and the corresponding coefficient rows for the images under L.*
4. *S_{sq} is the square-summable coefficient ledger, recording the finite sum of squared image coefficients over the window B and the scalar endpoint that bounds that displayed sum.*
5. *T records componentwise* hsame *transport for the Hilbert rows, bounded linear-map row, basis window, square-sum ledger, replay, provenance, and local name.*
6. *R records displayed* Cont *replay from Hilbert-source observations through the bounded action and coefficient ledger into operator-ideal and compact-operator consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{HilbertSchmidt}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{OperatorNorm}^{\uparrow}$, $\mathsf{FiniteRankOperator}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{OperatorIdeal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HilbertSchmidt}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $H, L, B, S_{\mathrm{sq}}, T, R, P, N$. It has no coordinate for a selected infinite orthonormal basis, host Hilbert-space equality, trace-class membership, singular-value decomposition, spectral theorem, or ambient compactness principle.

Theorem 8179.2 (Hilbert–Schmidt NameCert obligations)**.** *For every accepted* $\mathsf{HilbertSchmidt}^{\uparrow}$ *carrier* $S = (H, L, B, S_{\mathrm{sq}}, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HilbertSchmidt}^{\uparrow}}$ *surface consists exactly of carrier admission for the Hilbert endpoints, bounded linear action, finite orthonormal-basis window, square-sum ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming; basis-window invariance for replacing B by a transported finite orthonormal window over the same Hilbert rows; square-sum ledger stability under the same transport; operator-ideal handoff through the bounded action and displayed square bound; and nonescape from host Hilbert-space equality, selected infinite bases, trace theory, spectral data, or ambient compactness.*

Proof. Project the carrier rows. The Hilbert endpoints, bounded linear action, finite basis window, square-sum ledger, transport, replay, provenance, and local name are the complete displayed inventory.

Basis-window invariance is a statement about transported finite windows. The row T moves the Hilbert data, the list B, and the coefficient ledger together, so a consumer may compare two displayed finite windows only through componentwise hsame transport.

Square-sum ledger stability follows from the same finite route. The scalar endpoint attached to S_{sq} is read after the bounded action and the coefficient rows have been displayed, and R replays that order for downstream consumers.

Finally, the operator-ideal handoff consumes only L and S_{sq} through P, N. Since no row stores a selected infinite basis, host equality of Hilbert spaces, trace-class membership, spectral data, or ambient compactness, those objects are refused by the local certificate. □

Theorem 8179.3 (Hilbert–Schmidt operator-norm bound)**.** *Every* $\mathsf{OperatorNorm}^{\uparrow}$ *or* $\mathsf{OperatorIdeal}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{HilbertSchmidt}^{\uparrow}$ *carrier must pass through the finite route*

$$H, L, B, S_{\mathrm{sq}}, T, R, P, N.$$

The displayed square-sum ledger supplies the finite scalar bound consumed by the operator-norm boundary for the same bounded action L, and this bound is the only Hilbert–Schmidt data available to $\mathsf{OperatorIdeal}^{\uparrow}$ *and* $\mathsf{CompactOperator}^{\uparrow}$ *consumers at this paper site.*

Proof. Start from the bounded linear-map row L over the Hilbert endpoints H. The operator-norm reader receives the action only after the same packet has displayed its finite coefficient window B.

Read the square-sum ledger next. The row S_{sq} records the finite scalar bound that dominates the displayed image coefficients, so the operator-norm consumer sees a finite bound-facing certificate rather than a host supremum.

The ideal and compact consumers then read through T, R, P, N. These rows transport, replay, source, and name the same bounded action and square ledger. They do not add trace data, selected compactness, spectral values, or equality of ambient Hilbert spaces. □

Falsifiable prediction: Every accepted $\mathsf{HilbertSchmidt}^{\uparrow}$ consumer must display Hilbert source rows, a bounded LinearMapUp action, a finite orthonormal-basis window, a square-sum ledger, componentwise hsame, displayed Cont, Pkg, and local $\mathsf{NameCert}$ rows before Hilbert–Schmidt operator data is available.

Independence witness: hilbert, linearmap, operator-norm, finite-rank-operator, operatorideal: no listed sibling is bijective to $\mathsf{HilbertSchmidt}^{\uparrow}$ because this packet jointly carries Hilbert endpoints,

bounded action, finite orthonormal coefficient windows, square-sum ledger stability, operator-ideal handoff, transport, replay, provenance, and local naming in one operator-facing surface.

Closure status for $\mathsf{NameCert}_{\mathsf{HilbertSchmidt}^{\uparrow}}$.

Constructive story: A $\mathsf{HilbertSchmidt}^{\uparrow}$ packet is generated from Hilbert source rows, a bounded LinearMapUp action, a finite orthonormal-basis window, a square-sum coefficient ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HilbertSchmidt}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8179.1, Definition 8179.2, Definition 8179.3, the falsifiable prediction, and the independence witness seed the finite Hilbert–Schmidt operator route over Hilbert, linear-map, operator-norm, finite-rank, compact-operator, operator-ideal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HilbertSchmidt}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trace-class theory, spectral decomposition, selected infinite orthonormal bases, host Hilbert-space equality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, basis-window invariance, square-sum ledger stability, operator-ideal handoff, operator-norm bound consumption, transport, replay, provenance, and local naming for BEDC.Derived.HilbertSchmidtUp.HilbertSchmidtNameCert.

Chapter 8180

A Concrete Naming Certificate for $\mathsf{WhittakerShannonSampling}^{\uparrow}$

Following Whittaker and Shannon sampling theory, the $\mathsf{WhittakerShannonSampling}^{\uparrow}$ packet records the finite BEDC boundary by which a displayed bandlimited row, a sampling grid, and a reconstruction kernel may be consumed without importing an infinite host Fourier series. It sits downstream of the finite grid discipline of chapter 451, the transform rows of chapter 4025, the observed stream interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite sampling bridge for later Fourier and Real-completion consumers; it is not a theorem asserting host-level convergence of all sinc series, quotient equality of functions, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8180.1 (Whittaker-Shannon sampling carrier)**.** *A* $\mathsf{WhittakerShannonSampling}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (B, G, K, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite bandlimit row, naming the Fourier-side cutoff, the admitted frequency window, and the aliasing exclusions read through* $\mathsf{FourierTransform}^{\uparrow}$*.*
2. *G is the sampling-grid row, displaying the finite grid points, mesh denominator, phase offsets, and the finite-grid compatibility inherited from* $\mathsf{FinitePhaseSampling}^{\uparrow}$*.*
3. *K is the reconstruction-kernel row, recording the displayed kernel values and truncation window used by the sampled reconstruction route.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *sample row, exposing exactly the observed sample stream entries consumed by the packet.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same grid, kernel, and sample entries.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal read only after B, G, K, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for the bandlimit row, grid row, kernel row, sample stream row, regular-rational readback, real seal, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a finite sampling request through B, G, K, S, Q, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{WhittakerShannonSampling}^{\uparrow}$*,* $\mathsf{FinitePhaseSampling}^{\uparrow}$*,* $\mathsf{FourierTransform}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{WhittakerShannonSampling}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite Fourier-series object, quotient equality of functions, unbounded choice of samples, host sinc convergence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8180.2 (Whittaker-Shannon sampling NameCert obligations)**.** *For every accepted* WhittakerShannonSam *carrier*

$$W = (B, G, K, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{WhittakerShannonSampling}^{\uparrow}}$ *surface consists exactly of the five analytic rows B, G, K, S, Q followed by the* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise transport H, displayed replay C, provenance P, and local naming N. A downstream consumer must therefore read the finite bandlimit row, the displayed sampling-grid row, the reconstruction-kernel row, the* $\mathsf{StreamName}^{\uparrow}$ *sample row, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row before it reaches any Real-facing handoff. The certificate refuses host infinite Fourier series, quotient function equality, unbounded sample choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8180.1. The analytic sampling surface is exactly the finite tuple B, G, K, S, Q: bandlimit data, sampling grid, reconstruction kernel, observed samples, and regular-rational readback.

The finite-grid row G is read through chapter 451, while B and K provide the Fourier-side cutoff and reconstruction kernel consumed by the same displayed route. The sample row S then binds the grid to concrete $\mathsf{StreamName}^{\uparrow}$ observations, and Q records the regular rational readback over those observations.

The rows E, H, C, P, N seal, transport, replay, source, and name the same finite packet. Since no carrier coordinate stores an infinite Fourier series, quotient equality of functions, an unbounded sample selector, or ambient Real completeness, no accepted consumer can project those objects from the local certificate. □

Falsifiable prediction: An accepted $\mathsf{WhittakerShannonSampling}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading $B, G, K, S, Q, E, H, C, P, N$ refutes the carrier surface.

Independence witness: finite-phase-sampling, fourier-transform, streamname, regseqrat, real: no listed sibling supplies the joint packet containing a finite bandlimit row, sampling grid, reconstruction kernel, stream sample row, regular-rational readback, Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{WhittakerShannonSampling}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{WhittakerShannonSampling}^{\uparrow}$ packet is generated from finite bandlimit rows, displayed sampling-grid rows, reconstruction-kernel rows, StreamName samples, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WhittakerShannonSampling}^{\uparrow}}$, seed)

Scope closed: Definition 8180.1 and Definition 8180.2 seed the finite sampling bridge from Fourier and finite phase sampling rows to StreamName, RegSeqRat, and Real-facing consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WhittakerShannonSampling}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host infinite Fourier series, quotient equality of functions, unbounded sample choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite bandlimit exposure, sampling-grid stability, reconstruction-kernel readback, StreamName and RegSeqRat handoff, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.WhittakerShannonSamplingUp.

Chapter 8181

A Concrete Naming Certificate for $\mathsf{BishopCompletionWitness}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{BishopCompletionWitness}^{\uparrow}$ packet records the finite witness data that a Real and Completion consumer must expose before treating a regular Cauchy route as completion-facing. It sits after the dyadic arithmetic of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the diagonal classifier boundary of chapter 443, and the complete-real interface of chapter 4233. The packet names a displayed witness surface only; it is not $\mathsf{Real}^{\uparrow}$ completeness, quotient Cauchy equality, countable choice, or a selected completed real.

Definition 8181.1 (Bishop completion witness carrier)**.** *A* $\mathsf{BishopCompletionWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (D, S, Q, R, L, B, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic endpoint, radius, tail-comparison, and error-budget rows used by the witness.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing exactly the finite observations and requested precisions inspected by the completion read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those displayed windows and tolerances.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, Q have appeared.*
5. *L is the accepted* $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$ *row that classifies the displayed regular-Cauchy handoff for a completion consumer.*
6. *B is the* $\mathsf{BishopCompleteReal}^{\uparrow}$ *boundary row, recording only the finite witness route by which the complete-real interface may inspect D, S, Q, R, L.*
7. *H records componentwise* hsame *transport for dyadic ledgers, stream windows, regular readbacks, Real seals, classifier rows, complete-real boundary rows, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay of the same finite witness route.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionWitness}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$, $\mathsf{BishopCompleteReal}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, Q, R, L, B, H, C, P, N$. It has no coordinate for quotient equality of Cauchy streams, selected limits, countable-choice schedules, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or an unbounded completion operator.*

Theorem 8181.2 (Bishop completion witness NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionWitness}$ *carrier*

$$W = (D, S, Q, R, L, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionWitness}^{\uparrow}}$ *surface consists exactly of dyadic tolerance-ledger exposure, finite stream-window exposure, regular rational readback, terminal Real sealing, regular-Cauchy limit-classifier admission, Bishop complete-real boundary exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read B as a completion-facing witness only after D, S, Q, R, L are displayed in the same finite packet.*

Proof. Project the carrier $W = (D, S, Q, R, L, B, H, C, P, N)$. The analytic rows D, S, Q, R, L, B list the tolerance ledger, inspected windows, regular readback, Real seal, classifier row, and complete-real boundary row.

The completion-facing row B is downstream of the classifier row L. By the public boundary of chapter 443 and the complete-real interface of chapter 4233, the consumer sees only the displayed dyadic, stream, regular-readback, and Real-seal route before the witness is offered.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the excluded principles are not carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 8181.3 (Bishop completion witness Real-completion handoff)**.** *Every Real and Completion consumer of an accepted* $\mathsf{BishopCompletionWitness}^{\uparrow}$ *packet must factor its read through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{RegularCauchyLimitClassifier}^{\uparrow} \longmapsto \mathsf{BishopComplet}$$

Thus the exported completion witness is the finite route $D, S, Q, R, L, B, H, C, P, N$ over the displayed packet. It exports no quotient Cauchy class, selected limit, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the dyadic and stream rows. The ledger D and window S determine the finite tolerance and observation data that can be inspected by a completion-facing read.

Next read the regular rational and Real rows. The row Q is the only regular readback in the carrier, and R is the only terminal Real seal available after that readback.

Now route through the classifier and complete-real boundary. The row L makes the displayed regular-Cauchy handoff visible to the limit-classifier surface, and B lets the Bishop complete-real interface consume only that classified finite witness.

Finally the rows H, C, P, N preserve the same route under transport, replay, provenance, and naming. Because no excluded endpoint is a row of W, the consumer cannot reread the witness as quotient Cauchy equality, selected completion, countable choice, host real equality, or ambient completeness. □

Falsifiable prediction: Every $\mathsf{BishopCompletionWitness}^{\uparrow}$ consumer reaches $\mathsf{BishopCompleteReal}^{\uparrow}$ only after exposing $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyLimitClassifier}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, real, regularcauchylimitclassifier, bishop-complete-real: $\mathsf{BishopCompletionWitness}^{\uparrow}$ is not bijective to any listed sibling because it

jointly carries dyadic tolerance data, finite stream windows, regular rational readback, a Real seal, a limit-classifier row, a complete-real boundary row, transport, replay, provenance, and local naming in one finite witness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionWitness}\uparrow}$.

Constructive story: A $\mathsf{BishopCompletionWitness}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, a RegularCauchyLimitClassifier row, a BishopCompleteReal boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionWitness}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8181.1, Definition 8181.2, and Definition 8181.3 seed the finite witness route for the open Real and Completion phase.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionWitness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim $\mathsf{Real}^{\uparrow}$ completeness, quotient Cauchy equality, selected limits, countable choice, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, stream-window exposure, RegSeqRat readback, Real seal ordering, classifier admission, complete-real boundary routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopCompletionWitnessUp.

Chapter 8182

A Concrete Naming Certificate for $\mathsf{StrongLawLargeNumbers}^{\uparrow}$

Following Kolmogorov and Bishop–Bridges on almost-sure convergence of independent finite-variance averages, the $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ packet names the theorem-level route from finite tail control to a BEDC strong-law certificate. It consumes the weak-law finite-average route of chapter 4373, the finite-window strong-law handoff of chapter 7364, the Chebyshev tail-bound carrier of chapter 6592, the first Borel–Cantelli event-budget carrier of chapter 2357, the normalized probability source of chapter 184, the finite random-variable rows of chapter 185, and the terminal $\mathsf{Real}^{\uparrow}$ seal. The packet records a finite certificate surface for the strong-law route; it does not import a host almost-sure quotient, countable-choice subsequence, ambient measurable completion, or external probability-limit principle.

Definition 8182.1 (Strong law large numbers carrier)**.** *A* $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (P, R, A, C, B, F, E, H, T, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row carrying the event classifier and total-event normalization.*
2. *R is the finite* $\mathsf{RandomVar}^{\uparrow}$ *family over P whose partial averages are inspected.*
3. *A is the partial-sum average row, recording the displayed finite average names and centers used by the law.*
4. *C is the* $\mathsf{ChebyshevInequality}^{\uparrow}$ *tail-budget table attached to the displayed averages.*
5. *B is the* $\mathsf{BorelCantelli}^{\uparrow}$ *finite-window schedule and repeated-hit budget for those tail rows.*
6. *F is the* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *handoff row, packaging the window schedule, Chebyshev table, and Borel–Cantelli budget as the finite strong-law precursor.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal for positive tolerances, tail-budget bounds, and terminal average names.*
8. *H records componentwise* hsame *transport for the probability source, random-variable rows, averages, tail budgets, event-budget schedules, finite-window handoff, Real seals, replay, provenance, and local naming.*
9. *T records displayed* Cont *replay of the strong-law route through $P, R, A, C, B, F, E, H, Q, N$.*

10. *Q is the* Pkg *provenance over* $\mathsf{StrongLawLargeNumbers}^{\uparrow}$, $\mathsf{StrongLawFiniteWindow}^{\uparrow}$, $\mathsf{WeakLawLargeNumbers}^{\uparrow}$, $\mathsf{ChebyshevInequality}^{\uparrow}$, $\mathsf{BorelCantelli}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{StrongLawLargeNumbers}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host almost-sure equality, selected subsequences, completed sigma-algebra quotients, central-limit normalization, or ambient real completeness.

Theorem 8182.2 (Strong law large numbers NameCert obligations)**.** *For every accepted* $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ *carrier $L = (P, R, A, C, B, F, E, H, T, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{StrongLawLargeNumbers}^{\uparrow}}$ *surface consists exactly of carrier admission for the probability source row, finite random-variable rows, partial-sum average rows, Chebyshev tail budgets, Borel–Cantelli finite-window schedules,* $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *handoff rows,* $\mathsf{Real}^{\uparrow}$ *seals, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may cite the strong law only after all rows $P, R, A, C, B, F, E, H, T, Q, N$ are visible in the carrier.*

Proof. Project the carrier. The rows P, R, A provide the probability source, displayed random variables, and finite partial-average names before any tail estimate or convergence-facing statement can be read.

The rows C, B, F, E then route the averages through Chebyshev tail budgets, Borel–Cantelli finite-window schedules, the finite-window strong-law handoff, and Real tolerance seals. This is the only convergence-facing analytic segment in the carrier.

Finally H, T, Q, N transport, replay, source, and name the same packet. Since no carrier coordinate stores an almost-sure quotient, selected subsequence, host measurable completion, or external probability-limit operator, the listed rows exhaust the local NameCert obligations. □

Theorem 8182.3 (Strong law finite-window handoff)**.** *Every accepted* $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ *read factors its convergence-facing request through the finite-window route*

$$P \longmapsto R \longmapsto A \longmapsto C \longmapsto B \longmapsto F \longmapsto E \longmapsto H, T, Q, N.$$

The handoff row F is therefore mandatory: it is the point where the weak-law finite-average surface and the $\mathsf{StrongLawFiniteWindow}^{\uparrow}$ *packet are joined before the final strong-law certificate is named.*

Proof. Begin with a strong-law consumer request. The carrier exposes only the probability source P, finite random-variable family R, and partial-average row A before any tail-control row is available.

Next the request reads C and B. The Chebyshev table supplies finite tail budgets, and the Borel–Cantelli row supplies the finite-window schedule for repeated-hit control.

The row F packages precisely the sibling handoff supplied by chapter 7364. Only after that row is displayed can the $\mathsf{Real}^{\uparrow}$ seal and structural rows E, H, T, Q, N present the local strong-law name. Thus every accepted read factors through the finite-window handoff rather than bypassing it with a host convergence theorem. □

Falsifiable prediction: A $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ consumer that exports almost-sure convergence without the ProbSpace, RandomVar, partial-average, Chebyshev, Borel–Cantelli, StrongLawFiniteWindow, Real, transport, replay, provenance, and local NameCert rows refutes this packet.

Independence witness: weak-law-large-numbers, strong-law-finite-window, chebyshev-inequality, borel-cantelli, probspace, randomvar, real: $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ is not bijective to any listed

sibling because it binds the full theorem-level handoff from finite averages and tail budgets to the local strong-law NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{StrongLawLargeNumbers}^{\uparrow}}$.

Constructive story: A $\mathsf{StrongLawLargeNumbers}^{\uparrow}$ packet is generated from a ProbSpace source row, finite RandomVar family, partial-sum average rows, Chebyshev tail budgets, BorelCantelli finite-window schedules, a StrongLawFiniteWindow handoff row, RealUp seals, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StrongLawLargeNumbers}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8182.1, Definition 8182.2, and Definition 8182.3 seed the theorem-level strong-law route through probability, random-variable, average, tail-budget, event-schedule, finite-window handoff, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StrongLawLargeNumbers}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host almost-sure quotient equality, countable-choice subsequence selection, completed sigma-algebra universes, central-limit normalization, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, tail-budget exactness, Borel–Cantelli schedule stability, finite-window handoff nonescape, Real-seal stability, transport, replay, provenance, and local naming for BEDC.Derived.StrongLawLargeNumbersUp.

Chapter 8183

A Concrete Naming Certificate for $\mathsf{ClassifierInformationBudget}^{\uparrow}$

The $\mathsf{ClassifierInformationBudget}^{\uparrow}$ packet realizes the classifier-level information distinction of chapter 9366 as finite BEDC data. It separates record growth from classifier shift by displaying before/after classifier-state rows, a SigRel handoff row, ledger-delta rows, transport, replay, provenance, and local naming. The packet is designed for discovery-classifier and TasteGate consumers that must know whether a route changes the classifier rather than merely extending a trace.

The budget packet consumes the morphism-level route discipline of chapter 590 and the boundary-exposure discipline of chapter 595 before interpreting a SigRel ledger delta as classifier-level information.

It also consumes the before/after disagreement route of chapter 6985 and feeds the positive-claim boundary of chapter 6931 together with the novelty ledger of chapter 6241.

Definition 8183.1 (Classifier information budget carrier)**.** *A* $\mathsf{ClassifierInformationBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S_0, S_1, G, D, L, H, C, P, N)$$

with the following displayed rows:

1. S_0 *is the source classifier-state row before the audited transition.*
2. S_1 *is the target classifier-state row after the audited transition.*
3. G *is the* SigRel *handoff row, recording which signature relation compares the two classifier states.*
4. D *is the ledger-delta row, separating external record growth from the classifier-shift bit read along* G*.*
5. L *is the local budget row, recording which classifier-level information budget is consumed by a downstream route.*
6. H *records componentwise* hsame *transport for the source state, target state,* SigRel *handoff, ledger delta, budget row, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the classifier-budget route through* $S_0, S_1, G, D, L, H, P, N$*.*
8. P *is the* Pkg *provenance over* $\mathsf{ClassifierInformationBudget}^{\uparrow}$*,* SigRel*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{ClassifierInformationBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, G, D, L, H, C, P, N$. It has no coordinate for equating record growth with discovery, for treating a notation change as classifier shift, or for reading a positive discovery without the displayed ledger-delta row.

Theorem 8183.2 (Classifier information budget NameCert obligations)**.** *For every accepted* ClassifierInformationBu *carrier $I = (S_0, S_1, G, D, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClassifierInformationBudget}^{\uparrow}}$ *surface consists exactly of classifier-state admission for S_0, S_1,* SigRel *handoff admission for G, ledger-delta exposure for D, local budget exposure for L, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream consumer may read classifier-level information only after it displays these rows and keeps record growth distinct from classifier shift.*

Proof. Project the carrier. The two classifier-state rows and the SigRel handoff are the only before/after comparison data available to a consumer.

The ledger-delta row D separates record growth from classifier shift before the local budget row L can be consumed. Thus a longer record is not itself a classifier-level information witness, and a notation-only presentation change is not accepted as a shift.

The structural rows H, C, P, N preserve, replay, source, and name the same route. Since the carrier has no hidden discovery bit or host classifier oracle, the listed rows exhaust the local NameCert obligations. □

Theorem 8183.3 (Classifier information budget SigRel handoff)**.** *Every accepted* $\mathsf{ClassifierInformationBudget}^{\uparrow}$ *read of classifier-level information factors through*

$$S_0 \longmapsto S_1 \longmapsto G \longmapsto D \longmapsto L \longmapsto H, C, P, N.$$

In particular, the SigRel *row G is mandatory before the ledger-delta row D may classify the transition as classifier-preserving, classifier-shifting, or budget-consuming.*

Proof. Start with a classifier-information request. The source and target classifier states S_0, S_1 are displayed before any comparison can be made.

The request next reads G. This row fixes the signature relation by which the two states are compared, so the ledger-delta row D cannot be interpreted independently of the handoff.

Finally the budget row L and the structural rows H, C, P, N present the accepted consumer surface. The route therefore records classifier-level information only through the displayed SigRel comparison and ledger delta. □

Falsifiable prediction: A $\mathsf{ClassifierInformationBudget}^{\uparrow}$ consumer that treats record growth alone as classifier-level information, or records classifier shift without a displayed SigRel handoff and ledger-delta row, refutes this packet.

Independence witness: classifier-state, sigrel, ledger-delta, transport, replay: $\mathsf{ClassifierInformationBudget}^{\uparrow}$ is not bijective to any single constituent because it binds before/after classifier rows, signature comparison, budget consumption, provenance, and local NameCert data in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierInformationBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{ClassifierInformationBudget}^{\uparrow}$ packet is generated from before/after classifier-state rows, a SigRel handoff row, ledger-delta rows separating record growth from classifier shift, a local information-budget row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ClassifierInformationBudget}^{\uparrow}}$, seed)

Scope closed: Definition 8183.1, Definition 8183.2, and Definition 8183.3 seed the classifier-level information budget through classifier-state, SigRel, ledger-delta, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ClassifierInformationBudget}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, a positive-discovery gate, a global classifier oracle, or any claim that record growth alone is classifier-level information.

Upgrade path: Obligation closure requires checked carrier admission, SigRel handoff exactness, ledger-delta separation, budget-row nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ClassifierInformationBudgetUp.

Chapter 8184

A Concrete Naming Certificate for $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$

Following Schauder's compact-map approximation method, the $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ packet records the finite BEDC carrier that sits between compact metric approximation data and the fixed-point endpoint consumers of chapter 1923, chapter 396, and the L10 compact-metric route. It uses the compact metric surface of chapter 129, the convex carrier of chapter 208, the continuous-map rows of chapter 130, and the uniform-modulus handoff of chapter 369. The packet names a finite approximation and residual ledger; it does not select a host fixed point, import open-cover compactness, or add a limiting point choice.

Definition 8184.1 (Schauder finite compact-map carrier)**.** *A* $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, Q, F, U, E, D, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, including the compact metric inspection surface and the finite cover windows used by downstream L10 compact-metric consumers.*
2. *Q is the* $\mathsf{ConvexSet}^{\uparrow}$ *row for the admitted compact convex region in which approximation points and residual tests are read.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *self-map row, carrying graph access, source membership, target membership, and displayed continuity data.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row that turns the local continuity information for F into a tolerance-facing approximation budget over K.*
5. *E is the finite* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *approximation row, listing the displayed net centers, cover witnesses, and projection choices available to the packet.*
6. *D is the displacement-budget row comparing each net approximation with its mapped image at the tolerance requested by U.*
7. *R is the fixed-point residual row, recording the finite residual comparison exported to* $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, *or another L10 compact-metric fixed-point consumer.*
8. *H stores componentwise* hsame *transport for K, Q, F, U, E, D, R and the local certificate row.*

9. *C stores displayed* Cont *replay from compact source, convex membership, continuous-map reads, uniform-modulus reads, finite net approximation, displacement budget, residual row, provenance, and local name.*

10. *P is the* Pkg *provenance over* $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SchauderFiniteCompactMap}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for an ambient compactness theorem, a selected fixed point, quotient equality of approximants, a hidden limit point, or a detached self-map outside the displayed rows.

Theorem 8184.2 (Schauder finite compact-map NameCert obligations)**.** *For every accepted* SchauderFiniteCompac *carrier $S = (K, Q, F, U, E, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SchauderFiniteCompactMap}^{\uparrow}}$ *surface consists exactly of compact metric admission through K, convex carrier admission through Q, continuous self-map admission through F, uniform-modulus accountability through U, finite epsilon-net approximation through E, displacement-budget exposure through D, fixed-point residual exposure through R, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Lean4 (statement) `BEDC.Derived.SchauderFiniteCompactMapUp`

Proof. Project the carrier of Definition 8184.1. The compact source, convex region, continuous self-map, uniform modulus, finite epsilon-net, displacement budget, residual row, transport, replay, provenance, and local naming row are all displayed before a consumer can read the packet.

The approximation side is read in fixed order. The compact metric and convex rows admit the finite domain surface, the continuous-map row supplies the self-map, and the uniform-modulus row supplies the tolerance budget. The finite epsilon-net row then lists the centers and cover witnesses available to the displacement-budget row.

The residual row is downstream-facing only after those approximation rows have been replayed. Since the remaining rows H, C, P, N only transport, replay, source, and name the same finite packet, the listed rows exhaust the local NameCert surface and exclude the host principles named in the carrier. □

Theorem 8184.3 (Schauder finite compact-map residual route)**.** *Every fixed-point consumer of an accepted* $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ConvexSet}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto R.$$

The residual row R may be consumed by $\mathsf{SchauderFixedPoint}^{\uparrow}$, $\mathsf{BanachFixedPoint}^{\uparrow}$, *or another L10 compact-metric endpoint only after the compact source, convex carrier, continuous-map row, uniform-modulus row, finite epsilon-net approximation, displacement budget, componentwise transport, replay, provenance, and local naming rows have all been displayed.*

Proof. Begin with a fixed-point consumer. The continuation row C must expose K, Q, F, U, E, D before the residual row R is available.

The compact metric and convex rows bind the finite domain surface. The continuous-map row and uniform-modulus row bind the self-map and tolerance budget. The finite epsilon-net row and displacement-budget row are then the only approximation rows available to the consumer.

Thus R is a residual read from the displayed finite approximation packet, not a selected fixed point or a host compactness theorem. The structural rows H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. □

Falsifiable prediction: An accepted $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ read is refuted if a fixed-point residual row is consumed without displaying compact metric support, convex carrier membership, continuous self-map data, uniform-modulus accountability, finite epsilon-net approximation, displacement budget, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: compactmetric, convexset, continuousmap, uniformmodulus, banach-fixed-point, schauder-fixed-point: none alone is bijective with $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ because this packet jointly records finite epsilon-net approximation, displacement-budget comparison, residual export, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SchauderFiniteCompactMap}^{\uparrow}}$.

Constructive story: A $\mathsf{SchauderFiniteCompactMap}^{\uparrow}$ packet is generated from CompactMetric rows, ConvexSet carrier rows, ContinuousMap self-map rows, UniformModulus budget rows, finite epsilon-net approximation rows, displacement-budget rows, fixed-point residual rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchauderFiniteCompactMap}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8184.1, Definition 8184.2, and Definition 8184.3 seed the finite compact-map approximation packet over compact metric, convex, continuous-map, uniform-modulus, finite-net, displacement-budget, residual, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchauderFiniteCompactMap}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.SchauderFiniteCompactMapUp`

Bridge status: none

Not claimed: This chapter does not close a host fixed-point selector, open-cover compactness, quotient equality of approximants, hidden limiting points, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact metric exposure, convex carrier exposure, continuous-map replay, uniform-modulus accountability, finite epsilon-net approximation, displacement-budget exposure, residual export, transport stability, replay stability, provenance, and local naming for BEDC.Derived.SchauderFiniteCompactMapUp.

Chapter 8185

A Concrete Naming Certificate for $\mathsf{DyadicNestedIntervalCode}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicNestedIntervalCode}^{\uparrow}$ packet records the finite nested-interval route by which dyadic brackets are read as regular rational data before any terminal real-name seal is consumed. It sits over the dyadic tolerance ledger of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. The packet names only displayed finite rows; it is not a quotient completion, a countable-choice selector, a trichotomy principle, a host equality of streams, or an appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8185.1 (Dyadic nested interval code carrier)**.** *A* $\mathsf{DyadicNestedIntervalCode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (I, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite family of nested dyadic interval rows, each row naming lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints and the containment relation to the next inspected row.*
2. *W is the width-shrink ledger, recording the dyadic denominator budget, the exact positive width row, and the displayed shrink comparison for every inspected stage.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the finite stage numbers and endpoint observations that a consumer may read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed midpoint or endpoint-selection data attached to the same windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after the rows I, W, S, R have been replayed.*
6. *H records componentwise* hsame *transport for the interval rows, width rows, stream windows, regular-rational readback, real seal, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from a finite nested-interval request through I, W, S, R, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicNestedIntervalCode}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalCode}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, W, S, R, E, H, C, P, N$. It has no coordinate for quotient streams, countable choice, trichotomy, host equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8185.2 (Dyadic nested interval code NameCert obligations)**.** *For every accepted* DyadicNestedIntervalCod *carrier*

$$D = (I, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalCode}^{\uparrow}}$ *surface consists of carrier admission, nested containment stability, width-shrink exactness, classifier transport, ledger exactness, and nonescape from quotient streams, countable choice, trichotomy, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 8185.1. The accepted object is exactly the finite packet $D = (I, W, S, R, E, H, C, P, N)$, so every visible row is one of the displayed interval, width, window, readback, seal, transport, replay, provenance, or naming coordinates.

Nested containment stability is read from I, while width-shrink exactness is read from W. Both rows are dyadic rows, so their endpoint and tolerance data are consumed through the $\mathsf{DyadicRatCore}^{\uparrow}$ surface named by chapter 291.

Classifier transport is componentwise through H and C. The same finite stage windows are exposed by S, and the regular rational readback R is attached to those windows before any consumer reaches the real seal E.

Ledger exactness and nonescape follow by inspection of the carrier. No coordinate stores quotient streams, a choice function, trichotomy, host equality of real names, or an ambient completeness theorem, so no accepted $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalCode}^{\uparrow}}$ packet can export those objects. □

Theorem 8185.3 (Dyadic nested interval code regular-Cauchy handoff)**.** *Every accepted* DyadicNestedIntervalCode *packet reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback. In particular, the route to E factors through*

$$I, W, S, R \longmapsto E,$$

with I, W supplying dyadic containment and shrink data, S supplying the inspected windows, and R supplying the regular-Cauchy rational handoff.

Proof. Start from the carrier of Definition 8185.1. The real seal coordinate E is listed after the interval rows I, width ledger W, stream windows S, and regular rational readback R.

The NameCert obligations of Definition 8185.2 force each of those rows to be exposed before any consumer reads E. The dyadic rows supply the tolerance and shrink data, the stream row supplies the finite observation windows, and the regular-rational row supplies the Cauchy readback attached to those same windows.

Thus the handoff to $\mathsf{Real}^{\uparrow}$ is routed through $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ data only. Since the packet has no quotient, choice, trichotomy, host-equality, or ambient-completeness coordinate, the terminal seal cannot be reached through any other route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalCode}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicNestedIntervalCode}^{\uparrow}$ packet is generated from nested dyadic interval rows, width-shrink rows, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicNestedIntervalCode}^{\uparrow}}$, seed)

Scope closed: Definition 8185.1, Definition 8185.2, and Definition 8185.3 seed the finite dyadic nested-interval route from tolerance rows and stream windows to regular-Cauchy readback and a Real-facing seal.

Formal verification: FormalStatus(NameCert$_{\mathsf{DyadicNestedIntervalCode}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, countable choice, trichotomy, host equality of real names, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nested containment stability, width-shrink exactness, classifier transport, ledger exactness, and regular-Cauchy handoff for BEDC.Derived.DyadicNestedIntervalCodeUp.

Chapter 8186

A Concrete Naming Certificate for $\mathsf{RegularCauchyExponential}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RegularCauchyExponential}^{\uparrow}$ packet records the exponential-series constructor on regular Cauchy names as finite BEDC data. It refines the displayed series route of chapter 7993 through the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet gives Real algebra and elementary-function consumers a non-quotient dependency anchor; it does not import host exponential functions, quotient streams, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8186.1 (RegularCauchyExponential carrier)**.** *A* $\mathsf{RegularCauchyExponential}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, W, D, A, F, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row naming the regular Cauchy input.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule used to inspect source values, powers, factorial denominators, partial sums, and tail budgets.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the requested precision window.*
4. *A is the coefficient row for the rational factorial denominators and dyadic comparison budgets of the exponential series.*
5. *F is the finite partial-sum row for the displayed exponential series over the inspected regular Cauchy windows.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the finite partial sums and tail ledger.*
7. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the regular Cauchy exponential name.*
8. *H records componentwise* hsame *transport for source, windows, dyadic budgets, coefficients, partial sums, readback, Real seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay along the same finite route.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyExponential}^{\uparrow}$, $\mathsf{CauchyExponential}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyExponential}^{\uparrow}}$ *row.*
The carrier exports only this finite regular Cauchy series surface. It stores no host exponential function, no quotient stream equality, no chosen infinite limit, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Theorem 8186.2 (RegularCauchyExponential NameCert obligations)**.** *For every accepted* RegularCauchyExponent *carrier $E = (X, W, D, A, F, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyExponential}^{\uparrow}}$ *surface consists exactly of carrier admission, regular Cauchy source exposure, finite StreamName window exposure, dyadic tolerance accounting, factorial coefficient accounting, finite partial-sum display, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, package provenance, and local naming. No local obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8186.1. The available analytic data are the source row X, the window schedule W, the dyadic budget D, the coefficient row A, the finite partial-sum row F, the readback row R, and the seal row S.

The finite series rows are ordered by the inspected windows. A consumer first reads the regular Cauchy input through X, W, D, then the factorial coefficients and partial sums through A, F, and only then the regular readback and Real seal through R, S.

The structural rows H, C, P, N preserve and name exactly that route. Since no coordinate contains a host exponential, quotient stream equality, selected infinite limit, countable-choice schedule, or ambient completeness principle, none of those objects belongs to the local NameCert surface. □

Theorem 8186.3 (RegularCauchyExponential series window)**.** *Every series-facing consumer of an accepted* $\mathsf{RegularCauchyExponential}^{\uparrow}$ *carrier must read the displayed route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto F \longmapsto \mathsf{RegSeqRat}^{\uparrow}$$

before any terminal $\mathsf{Real}^{\uparrow}$ *seal is exported. The finite row F contains only the partial sums, factorial denominator ledger, and tail estimates visible in the requested window.*

Proof. Start with the source and window rows X, W. They determine which regular Cauchy values and which partial-sum stages are available for the request.

Next read the dyadic tolerance ledger D and coefficient row A. These rows bound the inspected factorial denominators and tail estimates before the finite partial-sum row F is exposed.

Finally the readback row R repacks the displayed partial sums as regular rational data. The terminal seal can only consume that readback, so the consumer receives a finite windowed series route rather than a hidden host exponential or selected infinite limit. □

Theorem 8186.4 (RegularCauchyExponential Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{RegularCauchyExponential}^{\uparrow}$ *carrier must pass through the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row X, finite* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, coefficient and partial-sum rows A, F, regular readback R, and structural rows H, C, P, N before the seal row S is available. The export is a displayed regular Cauchy exponential name, not ambient Real completeness, quotient stream equality, a selected limit, or a host exponential function.*

Proof. Use Definition 8186.3. It forces every series read through the finite window, dyadic tolerance ledger, coefficient row, partial sums, and regular rational readback before a Real-facing row can be consumed.

The seal row S is downstream from R. Thus a $\mathsf{Real}^{\uparrow}$ consumer cannot inspect a terminal value until the regular readback has already exposed the finite series route.

Transport, replay, provenance, and local naming then preserve the same packet through H, C, P, N. These rows do not add ambient Real completeness, quotient stream equality, selected limits, or host exponential functions, so the exported seal is exactly the displayed regular Cauchy exponential name. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyExponential}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyExponential}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8186.1, Definition 8186.2, Definition 8186.3, and Definition 8186.4 seed the finite regular Cauchy exponential route over CauchyExponential, RegSeqRat, StreamName, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyExponential}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient streams, selected limits, countable choice, host exponential functions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, coefficient accounting, finite partial-sum display, dyadic tail control, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyExponentia

Constructive story: A $\mathsf{RegularCauchyExponential}^{\uparrow}$ packet is generated from a regular Cauchy source row, finite StreamName windows, a DyadicRatCore tolerance ledger, factorial coefficient data, finite partial sums, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8187

A Concrete Naming Certificate for $\mathsf{LocatednessPrinciple}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen on located predicates, the $\mathsf{LocatednessPrinciple}^{\uparrow}$ packet records the finite comparison surface by which a real or completion consumer may ask for a displayed located comparison without importing an omniscience principle. It sits beside the Ishihara trick boundary of chapter 1665, the lesser limited omniscience boundary of chapter 1977, the Markov principle boundary of chapter 1666, the located real packet of **??**, and the terminal real-name seal of chapter 38. The packet names a local locatedness service only: it does not claim LLPO, LPO, Markov principle, trichotomy, selected witnesses, quotient reals, or ambient completeness.

Definition 8187.1 (Locatedness principle carrier)**.** *A* $\mathsf{LocatednessPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (Q, A_-, A_+, I, O, B, R, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the rational comparison request row for the bounded real or completion-facing object being inspected.*
2. *A_- and A_+ are the two located approximation rows that bracket the request by negative and positive rational margins.*
3. *I is the* $\mathsf{IshiharaTrick}^{\uparrow}$ *boundary row used only to record finite inspection of a branch-shaped comparison.*
4. *O is the* $\mathsf{LesserLimitedOmniscience}^{\uparrow}$ *boundary row marking where two-alternative inspection is refused as a global rule.*
5. *B is the* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *row recording that negative evidence is named as boundary data, not accepted as a principle.*
6. *R is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row through which endpoint or cut-shaped locatedness is read.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the request, approximation, and boundary rows have been displayed.*
8. *H stores componentwise* hsame *transport for the request, approximation, boundary, located-real, real-seal, provenance, and naming rows.*

9. *C stores displayed* Cont *replay from the rational comparison request through the approximation rows, boundary rows, located-real read, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatednessPrinciple}^{\uparrow}$, $\mathsf{IshiharaTrick}^{\uparrow}$, $\mathsf{LesserLimitedOmniscience}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatednessPrinciple}^{\uparrow}}$ *row.*

The carrier has no coordinate for LLPO, LPO, Markov principle, trichotomy, selected witnesses, quotient reals, or ambient completeness.

Lean4 ✓ `BEDC.Derived.LocatednessPrincipleUp.LocatednessPrincipleTasteGate single carrier alignment`

Theorem 8187.2 (Locatedness principle NameCert obligations)**.** *For every accepted* $\mathsf{LocatednessPrinciple}^{\uparrow}$ *carrier*

$$L = (Q, A_-, A_+, I, O, B, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatednessPrinciple}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed rational comparison request, two approximation rows, boundary rows, located-real read, Real seal, transport, replay, provenance, and local naming;*
2. *approximation locatedness, requiring A_- and A_+ to be read before any* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer receives a comparison answer;*
3. *boundary discipline, requiring every branch-shaped read to pass through I, O, B as named inspection boundaries rather than as imported decision principles;*
4. *real-boundary handoff, requiring the located-real row R and terminal seal E to appear only after the comparison and boundary rows have been displayed;*
5. *nonescape for LLPO, LPO, Markov principle, trichotomy, selected witnesses, quotient reals, and ambient completeness.*

Proof. Carrier admission is projection from Definition 8187.1. The packet displays exactly one request row, two approximation rows, three boundary rows, one located-real read, one Real seal, and four structural rows.

The approximation rows provide the located comparison service. A consumer reads Q, then A_- and A_+, before any located-real or Real-facing row is available.

The branch-sensitive rows are only boundary data. The Ishihara, lesser-limited-omniscience, and Markov-boundary rows record finite inspection and refusal surfaces, so they cannot be consumed as global LLPO, LPO, Markov principle, or trichotomy.

Finally R, E, H, C, P, N transport, replay, source, and name the displayed route. Since the carrier has no coordinate for selected witnesses, quotient reals, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 8187.3 (Locatedness principle real boundary)**.** *Every* $\mathsf{LocatedReal}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{LocatednessPrinciple}^{\uparrow}$ *carrier factors through the finite route*

$$Q \longmapsto (A_-, A_+) \longmapsto (I, O, B) \longmapsto R \longmapsto E \longmapsto (H, C, P, N).$$

Thus the consumer may receive a displayed located comparison, but it receives no LLPO, LPO, Markov principle, trichotomy, selected witness, quotient-real equality, or ambient completeness principle.

Proof. Project the accepted carrier. The request row Q is the only entry point for a comparison query.

Read the approximation rows next. The rows A_- and A_+ provide the finite located margins before any endpoint, cut, or Real-seal read can occur.

The boundary rows are downstream of those approximations. They record where Ishihara-style branch inspection, lesser-limited-omniscience refusal, and Markov-sensitive negative evidence are named, without adding a decision coordinate.

The located-real and Real rows are then R and E. Transport, replay, provenance, and naming through H, C, P, N preserve the same route, so no selected witness, quotient-real equality, trichotomy, or ambient completeness row can be exported by the packet. □

Falsifiable prediction: If the boundary rows I, O, B are removed, a consumer could misread a finite located comparison as a global decision principle rather than as a displayed local route.

Independence witness: ishihara-trick, lesser-limited-omniscience, markov-principle-boundary, locatedreal, real: not bijective because the locatedness packet stores the request, the two approximation rows, three boundary refusals, a located-real read, and a terminal Real seal as one finite NameCert route.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatednessPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatednessPrinciple}^{\uparrow}$ packet is generated from a rational comparison request, two located approximation rows, Ishihara, lesser-limited-omniscience, and Markov boundary rows, a LocatedReal read, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatednessPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8187.1, Definition 8187.2, and Definition 8187.3 seed the finite locatedness route over comparison requests, approximation rows, boundary refusals, located-real reads, and Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatednessPrinciple}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.LocatednessPrincipleUp.LocatednessPrincipleTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not claim LLPO, LPO, Markov principle, trichotomy, selected witnesses, quotient reals, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, approximation locatedness, boundary discipline, located-real handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LocatednessPrincipleUp.

Chapter 8188

A Concrete Naming Certificate for $\mathsf{KolmogorovReflection}^{\uparrow}$

Following Kolmogorov's separation axiom and the Bourbaki–Kelley presentation of topological identification by indistinguishability, the $\mathsf{KolmogorovReflection}^{\uparrow}$ packet records the T_0 separation-reflection route as finite BEDC NameCert data. It sits beside the topological carrier of chapter 88, the separated metric reflector of chapter 1790, and the metric-space carrier of chapter 4230, while keeping quotient topology and host equality outside the certificate.

Definition 8188.1 (Kolmogorov reflection carrier)**.** *A* $\mathsf{KolmogorovReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, T, M, S, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source point-classifier row, carrying only the observable names whose topological indistinguishability is inspected.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-observation row, recording finite open-neighbourhood tests and their BEDC classifier readings.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *optional metric neighbourhood row used when a metric presentation supplies the same observation boundary.*
4. *S is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *comparison row, available only as a neighbouring separated-reflection route and not as a quotient object.*
5. *R is the Kolmogorov-reflected classifier row, identifying exactly the finite observation profile that distinguishes points up to T_0 separation.*
6. *H stores componentwise* hsame *transport for the source, topological, metric, separated-reflection, reflected-classifier, replay, provenance, and naming rows.*
7. *C stores displayed* Cont *replay from a finite observation query through X, T, M, S, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{KolmogorovReflection}^{\uparrow}$*,* $\mathsf{Topology}^{\uparrow}$*,* $\mathsf{SeparatedMetricReflection}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovReflection}^{\uparrow}}$ *row.*

The carrier exposes a T_0 reflection classifier only as finite observation data. It has no quotient-topology coordinate, no host equality coordinate, no sober-space reconstruction, no choice principle, and no completeness or separated-metric theorem beyond the displayed sibling route.

Lean4 ✓ `BEDC.Derived.KolmogorovReflectionUp.KolmogorovReflectionTasteGate single carrier alignment`

Theorem 8188.2 (Kolmogorov reflection NameCert obligations)**.** *For every accepted* $\mathsf{KolmogorovReflection}^{\uparrow}$ *carrier* $K = (X, T, M, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{KolmogorovReflection}^{\uparrow}}$ *surface consists exactly of carrier exposure, finite* $\mathsf{Topology}^{\uparrow}$ *observation, optional* $\mathsf{Met}^{\uparrow}$ *neighbourhood reading, neighbouring* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *comparison, reflected* T_0 *classifier output, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read the observation profile and the reflected classifier row, but it may not infer quotient topology or host equality.*

Proof. Project the displayed carrier. The rows X, T, M, S, R are the only point, topology, metric-neighbourhood, separated-reflection, and reflected-classifier rows available to a consumer.

The T_0 observation route is finite. A consumer reads open-neighbourhood evidence through T, may compare a metric presentation through M, and may inspect the neighbouring separated-reflection route through S before reaching the classifier output R.

Transport, replay, provenance, and local naming are supplied by H, C, P, N. Since quotient topology and host equality are not fields of the carrier, no NameCert obligation can export either object. □

Theorem 8188.3 (Kolmogorov reflection separation route)**.** *Every accepted* $\mathsf{KolmogorovReflection}^{\uparrow}$ *packet factors any* T_0 *separation read through the displayed route*

$$\mathsf{Topology}^{\uparrow} \to \mathsf{Met}^{\uparrow} \to \mathsf{SeparatedMetricReflection}^{\uparrow} \to \mathsf{BHist} \to \mathsf{hsame} \to \mathsf{Cont} \to \mathsf{Pkg} \to \mathsf{NameCert}.$$

The route may inspect finite open observations, metric neighbourhood rows, separated-reflection classifier comparison, transport, replay, provenance, and local naming. It does not construct a quotient topology, identify host points, or claim a separated metric reflection as an ambient equality theorem.

Proof. Begin with the carrier projection of Definition 8188.1. The topological observation row T, metric neighbourhood row M, separated-reflection row S, and reflected classifier row R are ordinary finite rows in one BHist packet.

Apply the NameCert obligations of Definition 8188.2. They force every local read to preserve the observation, comparison, classifier, transport, replay, provenance, and naming rows before the reflected classifier is consumed.

The separated metric reflector is used only as a sibling dependency. Its row S supplies comparison data, while the local packet still refuses quotient topology, host equality, and any ambient equality theorem. Thus the route remains a finite T_0 reflection certificate. □

Theorem 8188.4 (Kolmogorov reflection no-quotient boundary)**.** *Let* $K = (X, T, M, S, R, H, C, P, N)$ *be an accepted* $\mathsf{KolmogorovReflection}^{\uparrow}$ *packet. Any consumer that reads the reflected classifier row* R *must still display the original observation rows* X, T, M, S *and the structural rows* H, C, P, N*. Consequently the packet supplies no quotient topology, no host equality of points, no selected representatives, and no global separation theorem beyond the finite classifier route.*

Proof. Project the accepted packet. The reflected classifier row R is not independent of the observation rows; it is listed after X, T, M, S in the carrier and is transported and replayed only through H and C.

Use the separation route theorem. It keeps any T_0 read on the displayed route through topology, optional metric neighbourhoods, neighbouring separated reflection, history, transport, replay, provenance, and local naming.

The provenance row P names no quotient topology, host equality, selected representative, or global separation theorem. Therefore a consumer of R receives only the finite classifier route and cannot repack the packet as any of those stronger objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovReflection}^{\uparrow}$ packet is generated from a source point-classifier row, finite topological observations, optional metric neighbourhood data, a separated-reflection comparison row, a reflected T_0 classifier, componentwise transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovReflection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8188.1, Definition 8188.2, Definition 8188.3, and Definition 8188.4 seed the finite T_0 reflection route over topological, metric, separated-reflection, history, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovReflection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient topology, host equality of points, selected representatives, sober-space reconstruction, choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite topological observation exactness, separated-reflection comparison, no-quotient nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovReflectionUp.

Chapter 8189

A Concrete Naming Certificate for $\mathsf{MontelNormalFamily}^{\uparrow}$

Following Montel's theorem in classical complex analysis, the $\mathsf{MontelNormalFamily}^{\uparrow}$ packet records the finite-window handoff from local boundedness of holomorphic families to a normal-family read over displayed compact complex windows. It consumes the normal-family carrier of chapter 2186, the finite Montel route of chapter 3693, the holomorphic source rows of chapter 68, the complex coordinate rows of chapter 39, and the compact-window boundary of chapter 60. The packet names only the displayed BEDC rows: compact windows, local boundedness, holomorphic readback, complex coordinates, finite stream windows, regular rational tolerances, transport, replay, provenance, and local naming.

Definition 8189.1 (Montel normal-family carrier)**.** *A* $\mathsf{MontelNormalFamily}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (N, T, K, L, F, Z, S, R, H, C, P, A)$$

with the following visible rows:

1. *N is the* $\mathsf{NormalFamily}^{\uparrow}$ *row, exposing the family ledger, compact source data, equicontinuity route, pointwise image rows, and finite probe surface.*
2. *T is the* $\mathsf{MontelTheorem}^{\uparrow}$ *handoff row, restricted to the same family ledger and compact complex window.*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-window row for the displayed compact subset of the complex domain.*
4. *L is the local boundedness ledger for the family on K.*
5. *F is the* $\mathsf{Holomorphic}^{\uparrow}$ *readback row for the displayed family entries on the complex window.*
6. *Z is the* $\mathsf{Complex}^{\uparrow}$ *coordinate row for source points, target values, and the visible complex bounds used by L and F.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that lists the family members, compact-window probes, and tolerance requests actually inspected.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational tolerance and readback row for the finite windows named by S.*
9. *H records componentwise* hsame *transport of N, T, K, L, F, Z, S, R.*

10. *C records displayed* Cont *replay from compact-window request through local boundedness, holomorphic readback, normal-family admission, and Montel handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{MontelNormalFamily}^{\uparrow}$, $\mathsf{NormalFamily}^{\uparrow}$, $\mathsf{MontelTheorem}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{Complex}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *A is the local* $\mathsf{NameCert}_{\mathsf{MontelNormalFamily}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their displayed transport, replay, provenance, and local naming data.

Theorem 8189.2 (Montel normal-family NameCert obligations)**.** *For every accepted* $\mathsf{MontelNormalFamily}^{\uparrow}$ *carrier* $M = (N, T, K, L, F, Z, S, R, H, C, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{MontelNormalFamily}^{\uparrow}}$ *surface consists exactly of:*

1. *normal-family admission for N over the same displayed family ledger;*
2. *Montel handoff admission for T over the same compact complex window;*
3. *compact finite-window admission for K;*
4. *local boundedness admission for L over K;*
5. *holomorphic and complex readback through F and Z;*
6. *finite stream-window and regular-rational tolerance admission through S and R;*
7. *componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through H, C, P, A.*

No obligation introduces countable choice, arbitrary subsequence selection, open-cover compactness, ambient complex completeness, quotient complex equality, or a host compact-open function space.

Proof. Project the carrier in Definition 8189.1. The normal-family row N and Montel row T are the only family-compactness handoffs, and both are tied to the same compact window K and family window schedule S.

The analytic input is finite. Local boundedness is the row L, holomorphic readback is the row F, complex coordinate exposure is the row Z, and regular rational tolerance data is the row R. Each of these rows is named before the packet can be consumed as a Montel normal-family handoff.

Finally, H, C, P, A preserve exactly the displayed row inventory under transport, replay, provenance, and local naming. Since the packet has no coordinate for a choice-selected subsequence, open-cover compactness proof, ambient complex completeness theorem, quotient equality principle, or compact-open host function space, the local certificate cannot export any of those objects. □

Theorem 8189.3 (Montel compact-window handoff)**.** *Every consumer reading an accepted* $\mathsf{MontelNormalFamily}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{Compact}^{\uparrow} \longmapsto \textit{local boundedness} \longmapsto \mathsf{Holomorphic}^{\uparrow} \longmapsto \mathsf{NormalFamily}^{\uparrow} \longmapsto \mathsf{MontelTheorem}^{\uparrow} \longmapsto \mathsf{NameCert}_{\mathsf{MontelNorm}}$$

The stream schedule and regular rational rows S, R bound this route to the displayed finite compact windows, while H, C, P, A provide transport, replay, provenance, and local naming.

Proof. Begin with the compact window K. It is the only source of compact-domain information in the carrier, and the stream schedule S records the probes and tolerance requests that may be inspected.

Next read the local boundedness row L, the holomorphic row F, and the complex coordinate row Z. These rows supply the analytic input over the same compact window, with R carrying the regular rational tolerance data needed by the finite-window readback.

Now consume N and T. The normal-family row receives the family and compact-window data, while the Montel row records the finite handoff from local boundedness and holomorphic readback to the normal-family conclusion. The closing rows H, C, P, A preserve this route under transport, continuation replay, provenance, and local naming. □

Theorem 8189.4 (Montel normal-family public non-escape)**.** *An accepted* $\mathsf{MontelNormalFamily}^{\uparrow}$ *carrier exports no countable-choice principle, arbitrary subsequence selector, open-cover compactness theorem, ambient* $\mathsf{Complex}^{\uparrow}$ *completeness assertion, quotient complex equality, or host compact-open function-space object. Every public read is confined to the displayed rows* $N, T, K, L, F, Z, S, R, H, C, P, A$.

Proof. Inspect the carrier coordinates. The family-facing routes are N and T, the compact and analytic rows are K, L, F, Z, the finite-window rows are S, R, and the structural rows are H, C, P, A.

None of these coordinates names countable choice, an arbitrary subsequence selector, open-cover compactness, ambient complex completeness, quotient equality, or a compact-open host function space. Componentwise hsame transport and Cont replay can only preserve displayed rows, while Pkg provenance and local NameCert naming record the same row set. Therefore no public read can escape the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{MontelNormalFamily}^{\uparrow}}$**.**

Constructive story: A $\mathsf{MontelNormalFamily}^{\uparrow}$ packet is generated from NormalFamily and MontelTheorem handoff rows, a Compact finite-window row, local boundedness, Holomorphic and Complex readback, StreamName finite windows, RegSeqRat tolerance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MontelNormalFamily}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8189.1, Definition 8189.2, Definition 8189.3, and Definition 8189.4 seed the finite-window Montel normal-family handoff over existing complex-analysis and compact-window rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MontelNormalFamily}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, countable choice, arbitrary subsequence selection, open-cover compactness, ambient complex completeness, quotient complex equality, or a host compact-open function space.

Upgrade path: Obligation closure requires checked carrier admission, local boundedness confinement, compact-window handoff factorization, holomorphic and complex readback compatibility, finite-window tolerance replay, provenance exhaustion, and local naming for BEDC.Derived.MontelNormalFamilyUp.

Chapter 8190

A Concrete Naming Certificate for $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$

Bishop and Bridges constructive analysis treats an oscillation modulus as finite located data: a tolerance request is answered by an inspected window and a displayed rational bound, not by a selected limiting object. The $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ packet records this L10 corridor as a NameCert carrier over the pointwise oscillation surface of chapter 1839, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name boundary of chapter 38. It refines the neighboring located oscillation certificate by naming the modulus row consumed before Real or Completion consumers turn oscillation bounds into Cauchy-facing evidence.

Definition 8190.1 (Bishop located oscillation-modulus carrier)**.** *A* $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{locosc}} = (O, D, S, Q, R, W, T, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{RealOscillation}^{\uparrow}$ *source row whose inspected values and local difference bounds are read from the existing real-oscillation packet.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger carrying the requested oscillation radius, endpoint slack, and comparison budget.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the sampled source windows used for the request.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows and dyadic budget.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after O, D, S, Q have been displayed.*
6. *W is the located-window ledger recording which finite source window answers the request and which rational bound it returns.*
7. *T is the tolerance-to-window modulus row: for every displayed dyadic tolerance in D, it points to one inspected row of W and to the corresponding regular readback through Q and R.*
8. *H records componentwise* hsame *transport for O, D, S, Q, R, W, T and the local naming data.*
9. *C records displayed* Cont *replay from a tolerance request through the dyadic ledger, window row, regular readback, Real seal, located-window ledger, and modulus row.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$, $\mathsf{RealOscillation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets whose modulus row T is downstream of the displayed oscillation row O and the same dyadic-window-readback route D, S, Q, R, W. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, trichotomy, countable choice, host supremum, or a detached modulus oracle.*

Theorem 8190.2 (Bishop located oscillation-modulus NameCert obligations)**.** *For an accepted* $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ *carrier $M_{\mathrm{locosc}} = (O, D, S, Q, R, W, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocated}}$ *surface consists exactly of:*

1. *carrier admission for the real-oscillation row, dyadic tolerance ledger, stream-window row, regular rational readback, Real seal, located-window ledger, tolerance-to-window modulus row, transport, replay, provenance, and local naming rows;*
2. *oscillation-source exposure, requiring O to be read before any modulus row answers a tolerance request;*
3. *dyadic-window coverage, requiring every accepted tolerance in D to name one displayed finite window in S and one regular readback in Q before the terminal seal R is consumed;*
4. *located-modulus exactness, requiring T to point only to rows already present in W and to export no answer outside the displayed dyadic-window route;*
5. *non-escape, requiring H, C, P, N to transport, replay, source, and name no ambient completeness theorem, quotient stream equality, selected limit, trichotomy, countable-choice schedule, host supremum, or detached oracle.*

Proof. Project the accepted carrier. The source row O, tolerance ledger D, window row S, regular readback Q, Real seal R, located ledger W, and modulus row T are all displayed before the structural rows H, C, P, N can expose the packet.

The source-exposure and dyadic-window clauses are componentwise projections. A tolerance request is first read in D, then replayed through S and Q, and only then reaches the terminal seal R.

Located-modulus exactness follows from the shape of T: every answer points back into W and to the same D, S, Q, R route. Since the carrier stores no separate oracle row, T cannot answer from outside the packet.

Finally, H, C, P, N preserve and name only these displayed coordinates. None contains ambient real completeness, quotient stream equality, selected limits, trichotomy, countable choice, host suprema, or detached modulus data, so the NameCert surface has no exit to those objects. □

Theorem 8190.3 (Bishop located oscillation-modulus window route)**.** *Every Real-facing or Completion-facing consumer of an accepted* $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{RealOscillation}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ W,\ T,\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}.$$

Thus oscillation-to-Cauchy or limit-facing use receives a displayed located modulus over finite windows, not ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, trichotomy, countable choice, a host supremum, or a detached modulus oracle.*

Proof. Start with the accepted carrier of Definition 8190.1. Its only source of oscillation information is O, and its only tolerance budget is the dyadic row D.

The window route is forced by the readback rows. The stream row S names the inspected finite windows, Q gives regular rational readback for those windows, and R seals the Real-facing endpoint only after those rows are visible.

The modulus row T then reads through the located-window ledger W and cannot bypass it. Applying the NameCert obligations of Definition 8190.2 shows that every consumer-visible route is exhausted by $O, D, S, Q, R, W, T, H, C, P, N$.

The excluded objects are absent from those coordinates. Therefore an oscillation-to-Cauchy or limit-facing consumer receives exactly the displayed finite-window modulus route. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ consumer read factors through RealOscillation, DyadicRatCore, StreamName, RegSeqRat, RealUp, located-window, tolerance-to-window modulus, hsame, Cont, Pkg, and NameCert rows.

Independence witness: real-oscillation, dyadicratcore, streamname, regseqrat, real: BishopLocatedOscillationMo is not bijective to any listed sibling because it jointly carries an oscillation source row, dyadic tolerance budget, finite observation windows, regular rational readback, Real seal, located-window ledger, tolerance-to-window modulus row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedOscillationModulus}^{\uparrow}$ packet is generated from a RealOscillation source row, a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, a located-window ledger, a tolerance-to-window modulus row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8190.1, Definition 8190.2, and Definition 8190.3 seed the finite located oscillation-modulus route over RealOscillation, DyadicRatCore, StreamName, RegSeqRat, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, trichotomy, countable choice, host suprema, detached modulus oracles, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, oscillation-source exposure, dyadic-window coverage, located-modulus exactness, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedOscillationMo

Chapter 8191

A Concrete Naming Certificate for MetaCICResidualChoiceBudget$^{\uparrow}$

The MetaCICResidualChoiceBudget$^{\uparrow}$ packet realizes the bounded residual-choice frontier of section 9386.3 as finite confluence-facing NameCert data. It sits beside the residual-substitution boundary of chapter 2181, the residual checker of chapter 3827, the residual-join budget of chapter 7378, the residual-diamond budget of chapter 7407, and the parallel-diamond frontier of chapter 4238. The packet records a finite choice boundary for residual pairs without claiming full residual substitution, unrestricted Church–Rosser, subject reduction, evaluator equality, quotient term equality, or kernel consistency.

Falsifiable prediction: Every accepted MetaCICResidualChoiceBudget$^{\uparrow}$ confluence read exposes a bounded choice-boundary row before any local-join candidate can be transported to a residual-diamond or parallel-diamond consumer.

Independence witness: metacic-residual-join-budget, metacic-residual-diamond-budget, metacic-parallel-diamond-frontier, metacic-confluence-residual-checker, metacic-residual-substitution-boundary: none is bijective to MetaCICResidualChoiceBudget$^{\uparrow}$ because this packet jointly carries typed windows, residual pairs, explicit choice-boundary rows, bounded local joins, obstruction retention, transport, replay, provenance, and local naming.

Definition 8191.1 (MetaCIC residual-choice budget carrier)**.** *A* MetaCICResidualChoiceBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, R, Q, J, O, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, recording the closed term, local typing window, and bounded checker context in which a residual pair is inspected.*
2. *R is the residual-pair row, recording the two residual descendants and their branch-local exposure.*
3. *Q is the choice-boundary row, listing the finite branch choices still retained by the budget.*
4. *J is the bounded local-join row, recording candidate joins available only after T, R, Q have been displayed.*

5. *O is the obstruction-retention row, naming residual-substitution discharge, unrestricted confluence, subject reduction, evaluator equality, quotient term equality, and kernel consistency as endpoints not supplied by the packet.*
6. *H stores componentwise* hsame *transport for the typed-window, residual-pair, choice-boundary, bounded-join, obstruction, replay, provenance, and naming rows.*
7. *C stores displayed* Cont *replay from a confluence query through T, R, Q, J, O, H, P, N.*
8. *P is the* Pkg *provenance over* MetaCICResidualChoiceBudget$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceResidualChecker$^{\uparrow}$, MetaCICResidualJoinBudget$^{\uparrow}$, MetaCICResidualDiamondBudget$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* NameCert$_{\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, Q, J, O, H, C, P, N$. It has no coordinate for full residual substitution, premise-free Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, global conversion decidability, or kernel consistency.

Theorem 8191.2 (MetaCIC residual-choice budget obligations)**.** *For every accepted* MetaCICResidualChoiceBudget *carrier $B = (T, R, Q, J, O, H, C, P, N)$, the local* NameCert$_{\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}}$ *surface consists exactly of typed-window exposure through T, residual-pair exposure through R, bounded choice-boundary retention through Q, bounded local-join exposure through J, obstruction retention through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier. The confluence-facing rows are T, R, Q, J, O, and the structural rows are H, C, P, N.

The choice boundary is retained as data. Row Q is not discharged by the carrier; it records the finite branch choices that a local-join consumer must keep visible before reading J.

The obstruction row then keeps the stronger endpoints outside the packet. Transport, replay, provenance, and local naming preserve the same bounded budget rather than turning it into residual-substitution discharge or unrestricted confluence. □

Theorem 8191.3 (MetaCIC residual-choice budget frontier route)**.** *Every confluence consumer of an accepted* MetaCICResidualChoiceBudget$^{\uparrow}$ *packet must expose the typed-window row T, residual-pair row R, choice-boundary row Q, bounded local-join row J, obstruction row O, componentwise transport row H, replay row C, provenance row P, and local naming row N before it may hand the budget to a residual-join, residual-diamond, residual-checker, or parallel-diamond consumer. The route does not discharge residual substitution, prove Church–Rosser, prove subject reduction, identify evaluator equality, identify quotient term equality, or certify kernel consistency.*

Proof. Start from the obligation surface of Definition 8191.2. It makes $T, R, Q, J, O, H, C, P, N$ the visible budget rows.

Read the neighbouring MetaCIC packets through the provenance row. Residual-substitution boundary, residual checker, residual-join budget, residual-diamond budget, and parallel-diamond frontier consumers may inspect the same finite budget, but only after Q and O remain visible.

Thus the handoff is bounded and conditional. Since no carrier coordinate supplies residual-substitution compatibility, unrestricted confluence, subject reduction, evaluator equality, quotient equality, or kernel consistency, none of those endpoints can be exported by the budget route. □

The Lean TasteGate surface for this packet requires future Nontrivial and FieldFaithful instances in `lean4/BEDC/Derived/MetaCICResidualChoiceBudgetUp/TasteGate.lean`, with field-projection witnesses separating $T, R, Q, J, O, H, C, P, N$.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}$ packet is generated from a typed-window row, residual-pair row, choice-boundary row, bounded local-join row, obstruction-retention row, componentwise transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8191.1, Definition 8191.2, and Definition 8191.3 seed the finite residual-choice frontier over typed-window, residual-pair, choice-boundary, bounded local-join, obstruction, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualChoiceBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full residual substitution, unrestricted Church–Rosser, subject reduction, evaluator equality, quotient term equality, global conversion decidability, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-pair exposure, choice-boundary retention, bounded local-join exposure, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualChoiceBudgetUp.

Chapter 8192

A Concrete Naming Certificate for $\mathsf{AbelCesaroTheorem}^{\uparrow}$

Following Hardy and Bishop–Bridges constructive analysis, the $\mathsf{AbelCesaroTheorem}^{\uparrow}$ packet records the finite handoff by which an Abel summability window and a Cesaro mean window are read before a Real-and-Completion sequence endpoint is exposed. It sits after the Abel route of chapter 1763, the averaging surface of chapter 1765, and the regular rational readback of chapter 301. The packet names only displayed windows, dyadic budgets, regular readback rows, and terminal seals; it is not Real completeness, quotient series equality, a selected limit, countable choice, trichotomy, or open-cover compactness.

Definition 8192.1 (Abel–Cesaro theorem carrier)**.** *An* $\mathsf{AbelCesaroTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, H, D, R, E, K, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, exposing the Abel window inspected at the given precision.*
2. *H is the* $\mathsf{HardyCesaroMean}^{\uparrow}$ *row, exposing the Cesaro averaging window compared with L.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row that assigns the Abel–Cesaro comparison a finite tolerance ledger.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only after L, H, D have been displayed.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row handed to sequence or completion-facing consumers only through R.*
6. *K records componentwise* hsame *transport for the Abel, Cesaro, dyadic, regular-readback, real-seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through L, H, D, R, E.*
8. *P is the* Pkg *provenance over* $\mathsf{AbelCesaroTheorem}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{HardyCesaroMean}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelCesaroTheorem}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these nine rows. It contains no coordinate for Real completeness, quotient series equality, selected limits, countable choice, trichotomy, or open-cover compactness.

Theorem 8192.2 (Abel–Cesaro theorem NameCert obligations)**.** *For every accepted* $\mathsf{AbelCesaroTheorem}^{\uparrow}$ *carrier* $A = (L, H, D, R, E, K, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{AbelCesaroTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for that nine-row packet, Abel-window exposure through* L*, Cesaro-window exposure through* H*, dyadic comparison budgeting through* D*, regular rational readback through* R*, Real sealing through* E*, and transport, replay, provenance, and local naming through* K, C, P, N*.*

Lean4 ✓ `BEDC.Derived.AbelCesaroTheoremUp.AbelCesaroTheoremTasteGate single carrier alignment`

Proof. Project the carrier of Definition 8192.1. Carrier admission exposes precisely the Abel row L, the Cesaro row H, the dyadic budget D, the regular readback R, the real seal E, and the structural rows K, C, P, N.

The analytic rows are read in order. An accepted comparison first displays the Abel and Cesaro windows, then reads the dyadic tolerance ledger that licenses the finite comparison, and only then reaches the regular rational readback row.

The terminal seal is downstream of that readback. Since the remaining rows only transport, replay, source, and name the same displayed packet, the local NameCert surface is exhausted by the stated rows and cannot import the refused endpoints. □

Theorem 8192.3 (Abel–Cesaro theorem regular handoff)**.** *Every sequence endpoint or completion-facing read exported by an accepted* $\mathsf{AbelCesaroTheorem}^{\uparrow}$ *carrier factors through*

$$L, H, D, R, E, K, C, P, N.$$

Thus the handoff from Abel and Cesaro data to a terminal $\mathsf{Real}^{\uparrow}$ *seal must pass through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row, rather than through Real completeness, quotient series equality, a selected limit, countable choice, trichotomy, or open-cover compactness.*

Proof. Start with a consumer requesting the endpoint. By Definition 8192.1, the only available Abel data are in L and the only available Cesaro data are in H.

The comparison budget is the dyadic row D. No real-facing read can bypass this row, because R is the first regular rational readback row and it is declared only after L, H, D have been displayed.

Finally, the terminal seal E is reached through R, with K, C, P, N preserving and naming the same finite route. Therefore any endpoint or completion-facing consumer receives the stated handoff rather than one of the refused host principles. □

Falsifiable prediction: An accepted $\mathsf{AbelCesaroTheorem}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without first reading the $\mathsf{AbelSummation}^{\uparrow}$ row, $\mathsf{HardyCesaroMean}^{\uparrow}$ row, $\mathsf{DyadicRatCore}^{\uparrow}$ budget row, and $\mathsf{RegSeqRat}^{\uparrow}$ readback row refutes the carrier surface.

Independence witness: abel-summation, hardy-cesaro-mean, regseqrat, dyadicratcore, real: no listed sibling supplies the whole nine-row packet $A = (L, H, D, R, E, K, C, P, N)$, because each sibling contributes only a summation route, averaging route, readback surface, budget ledger, or seal face while this chapter binds the Abel–Cesaro theorem handoff into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelCesaroTheorem}^{\uparrow}}$**.**

Constructive story: An $\mathsf{AbelCesaroTheorem}^{\uparrow}$ packet is generated from an $\mathsf{AbelSummation}^{\uparrow}$ row, a $\mathsf{HardyCesaroMean}^{\uparrow}$ row, a $\mathsf{DyadicRatCore}^{\uparrow}$ budget row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AbelCesaroTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 8192.1, Definition 8192.2, and Definition 8192.3 seed the finite Abel–Cesaro theorem handoff over AbelSummation, HardyCesaroMean, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AbelCesaroTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient series equality, selected limits, countable choice, trichotomy, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the nine-row carrier and prove the finite NameCert obligation surface, regular handoff theorem, and TasteGate field faithfulness for BEDC.Derived.AbelCesaroTheoremUp.

Chapter 8193

A Concrete Naming Certificate for $\mathsf{TailWindowUniformSequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{TailWindowUniformSequence}^{\uparrow}$ packet records the finite tail-window interface used when a uniformly continuous sequence is inspected only through displayed windows and a shared modulus row. It refines the sequence route of chapter 4287 through the modulus discipline of chapter 369, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives Real and Completion consumers a tail-window surface without selected limits, quotient streams, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8193.1 (Tail-window uniformly continuous sequence carrier)**.** *A* $\mathsf{TailWindowUniformSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (I, M, W_0, W_1, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the sequence-index window row naming the finite tail interval being inspected.*
2. *M is the shared* $\mathsf{UniformModulus}^{\uparrow}$ *row used by every read in the window.*
3. *W_0 and W_1 are the paired* $\mathsf{StreamName}^{\uparrow}$ *window reads cut from the same tail interval.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the two window reads and their shared modulus budget.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, M, W_0, W_1, R have been displayed.*
6. *H records componentwise* hsame *transport for the index window, modulus, stream windows, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the index window through the shared modulus, StreamName windows, RegSeqRat readback, and Real seal.*
8. *P is the* Pkg *provenance over* $\mathsf{TailWindowUniformSequence}^{\uparrow}$, $\mathsf{UniformlyContinuousSequence}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TailWindowUniformSequence}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected limiting value, quotient equality of streams, a private modulus per side of the window, countable choice, trichotomy, or ambient completeness.

Theorem 8193.2 (Tail-window uniformly continuous sequence obligations)**.** *For every accepted* $\mathsf{TailWindowUniformSequence}^{\uparrow}$ *carrier*

$$T = (I, M, W_0, W_1, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TailWindowUniformSequence}^{\uparrow}}$ *surface consists of the following five obligation rows:*

1. *carrier admission for the displayed sequence-index window, shared modulus, paired StreamName reads, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming;*
2. *shared-modulus exposure, requiring M to be read before either window can be consumed as a uniformly continuous sequence tail;*
3. *tail-window readback, requiring W_0, W_1 and R to expose only the finite inspected tail interval named by I;*
4. *Real-seal handoff, requiring E to appear only after the shared modulus and regular readback rows have been displayed;*
5. *nonescape for selected limits, quotient streams, private side moduli, countable choice, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8193.1. The analytic coordinates are exactly the index window, shared modulus, two StreamName reads, regular readback, and terminal Real seal.

Read the shared modulus row before the window rows. Since M is common to W_0 and W_1, the two reads cannot choose separate tail thresholds or private uniform-continuity data.

The RegSeqRat row repacks only the displayed window data. Thus a Real-facing consumer reaches E through I, M, W_0, W_1, R rather than through a selected limit or quotient stream.

Finally the structural rows H, C, P, N transport, replay, source, and name the same route. They do not add countable choice, trichotomy, private moduli, or ambient completeness, so the five listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{TailWindowUniformSequence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{TailWindowUniformSequence}^{\uparrow}$ packet is generated from a finite sequence-index window, a shared UniformModulus row, paired StreamName window reads, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TailWindowUniformSequence}^{\uparrow}}$, seed)

Scope closed: Definition 8193.1 and Definition 8193.2 seed the finite tail-window route for uniformly continuous sequence consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TailWindowUniformSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, selected limits, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, shared-modulus exposure, finite tail-window readback, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.TailWindowUniformSequenceUp.

Chapter 8194

A Concrete Naming Certificate for $\mathsf{CompactModulusTailFusion}^{\uparrow}$

Following the Bishop–Bridges finite-net proof of compact uniform continuity, the $\mathsf{CompactModulusTailFusion}^{\uparrow}$ packet records the ledger that fuses a compact-source uniform modulus with the tail-window rows later consumed by Real and Completion arguments. It realizes the route of chapter 9237 through the compact modulus surface of chapter 2299, the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff of chapter 369, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite fusion row, not a host modulus function, selected cover center, quotient stream, countable-choice schedule, or ambient compactness theorem.

Definition 8194.1 (Compact modulus tail fusion carrier)**.** *A* $\mathsf{CompactModulusTailFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, U, T, W, R, E, H, C, P, L, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactUniformModulus}^{\uparrow}$ *row produced from compact finite-net and pointwise-modulus data.*
2. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row extracted from the compact modulus surface.*
3. *T is the shared tail-window ledger naming the finite sequence tail on which U is used.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window read attached to that shared tail ledger.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the window values and uniform-modulus tolerance data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after K, U, T, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the compact modulus, uniform-modulus handoff, tail ledger, window read, regular readback, Real seal, replay, provenance, fusion ledger, and local naming rows.*
8. *C records displayed* Cont *replay from the compact modulus row through the uniform-modulus handoff, tail window, StreamName read, RegSeqRat readback, and Real seal.*
9. *P is the* Pkg *provenance over* $\mathsf{CompactModulusTailFusion}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *L is the local fusion ledger recording that the compact modulus row and the tail-window readback are consumed in one route.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusTailFusion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host modulus selector, an unrecorded compact cover center, a quotient stream, countable choice, trichotomy, selected limits, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CompactModulusTailFusionUp.CompactModulusTailFusionTasteGate single carrier alignment`

Theorem 8194.2 (Compact modulus tail fusion obligations)**.** *For every accepted* $\mathsf{CompactModulusTailFusion}^{\uparrow}$ *carrier*

$$F = (K, U, T, W, R, E, H, C, P, L, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusTailFusion}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-modulus exposure through K, uniform-modulus handoff through U, shared tail-window ledgering through T, finite StreamName readback through W, RegSeqRat readback through R, Real-seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, fusion ledgering through L, local naming through N, and nonescape for host modulus selectors, hidden compact centers, quotient streams, countable choice, trichotomy, selected limits, and ambient completeness.*

Proof. Project the carrier of Definition 8194.1. The compact analytic source is K, its tolerance-only handoff is U, and the tail-facing consumer rows are T, W, R, E.

Read the compact modulus before the tail data. The row K supplies the finite compact-uniform route, and U is the displayed uniform-modulus consumer row, so the later tail window cannot replace it with a host selector or private modulus.

Read the tail rows next. The ledger T, window W, and regular readback R bind the finite sequence tail before E is exposed as a Real seal.

Finally H, C, P, L, N transport, replay, source, ledger, and name the same route. Since the carrier lacks hidden compact centers, quotient streams, countable choice, trichotomy, selected limits, and ambient completeness, the listed rows exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusTailFusion}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusTailFusion}^{\uparrow}$ packet is generated from a compact-uniform modulus row, a UniformModulus handoff, a shared tail-window ledger, finite StreamName readback, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, a fusion ledger, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactModulusTailFusion}^{\uparrow}}$, seed)

Scope closed: Definition 8194.1 and Definition 8194.2 seed the finite fusion route from compact modulus rows to tail-window Real readback.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactModulusTailFusion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host modulus selectors, hidden compact centers, quotient streams, countable choice, trichotomy, selected limits, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-modulus exposure, uniform-modulus handoff, tail-window readback, Real-seal exposure, fusion ledgering, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusTailFusionUp.

Chapter 8195

A Concrete Naming Certificate for $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$

Following Weierstrass and Bishop–Bridges, the $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ packet records the textbook route from an absolute majorant series to uniform convergence of a real-valued series. It is adjacent to the M-test surface of chapter 399, the uniform Cauchy criterion of chapter 435, the regular rational readback of chapter 301, the finite stream windows of chapter 126, and the real-name seal of chapter 38. The carrier exposes only finite majorant, absolute-value, tail-modulus, readback, transport, replay, provenance, and naming rows; it does not import host completeness, countable choice, or a selected limit function.

Definition 8195.1 (Uniform absolute convergence carrier)**.** *A* $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, W, T, S, Q, R, H, C, P, N)$$

with the following visible rows:

1. *A is the majorant-series row, displaying finitely inspected nonnegative rational or real-name bounds and the summable tail ledger consumed by the packet.*
2. *W is the absolute-value window row, recording the displayed inequalities $|f_n(x)| \leq a_n$ for the inspected indices, source probes, and tolerance requests.*
3. *T is the shared uniform-tail modulus row, read once from the majorant tail and reused for every inspected source probe.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the inspected indices, probes, partial sums, and requested tail tolerances.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the partial-sum and tail windows generated by S, W, T.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular rational readback has been displayed.*
7. *H records componentwise* hsame *transport for majorant, absolute-value, tail-modulus, stream-window, regular-readback, real-seal, replay, provenance, and local-name rows.*
8. *C records displayed* Cont *replay from a tolerance request through A, W, T, S, Q, R.*
9. *P is the* Pkg *provenance over* $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$, $\mathsf{WeierstrassMTest}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformAbsoluteConvergence}^{\uparrow}}$ *row.*

The classifier accepts a packet only when the majorant tail is displayed before the shared uniform modulus is consumed, every absolute-value window is bounded by the same majorant row, every stream window reads that common tail modulus, and the regular rational and real-name rows preserve the same finite route. It has no coordinate for host completeness of function spaces, selected pointwise limits, countable-choice schedules, quotient equality of series, or detached absolute-convergence facts.

Theorem 8195.2 (Uniform absolute convergence NameCert obligations)**.** *For every accepted* $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ *carrier* $U = (A, W, T, S, Q, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformAbsoluteConvergence}^{\uparrow}}$ *obligations are exactly carrier admission for the majorant series, absolute-value windows, shared uniform-tail modulus, finite stream windows, regular rational readback, real-name seal, componentwise transport, continuation replay, provenance, and local naming; majorant exactness requiring each displayed absolute-value window to read the same* A *row; tail-modulus exactness requiring* T *to be produced from the majorant tail before any stream window is consumed; readback exactness through* Q*; real-seal boundary through* R*; and non-escape from host completeness, selected limits, countable choice, quotient series equality, and detached absolute-convergence predicates.*

Proof. Project the carrier of Definition 8195.1. The majorant row A, the absolute-value windows W, the shared tail modulus T, the stream windows S, the regular readback Q, and the real seal R are the only analytic rows visible to the classifier.

Majorant exactness is read before any uniform tail request. Each displayed inequality in W points to the same majorant row A, so the packet cannot replace the majorant by a probe-dependent bound or by an external convergence assertion.

The shared tail modulus T is then consumed by the finite windows in S. Those windows determine the regular rational readback Q, and the $\mathsf{Real}^{\uparrow}$ row R is reached only after the displayed stream and readback rows have been exposed.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no row for host completeness, selected pointwise limits, countable choice, quotient equality of series, or detached absolute-convergence facts, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: If the shared uniform-tail modulus row is removed, a $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ consumer can still inspect majorant and absolute-value windows, but it can no longer force a single tolerance-only route to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ readback.

Independence witness: weierstrass-m-test, uniform-cauchy-criterion, regseqrat, streamname, real: $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a majorant series, absolute-value windows, a shared uniform-tail modulus, finite stream windows, regular rational readback, a Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformAbsoluteConvergence}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformAbsoluteConvergence}^{\uparrow}$ packet starts from a displayed majorant series, records absolute-value windows, extracts one shared uniform-tail modulus, routes finite StreamName windows through RegSeqRat readback, seals the result as RealUp data, and preserves the same finite route by hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformAbsoluteConvergence}^{\uparrow}}$, seed)

Scope closed: Definition 8195.1 and Definition 8195.2 seed the majorant, absolute-window, uniform-tail, finite-window, readback, and Real-seal carrier for uniform absolute convergence over real series.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UniformAbsoluteConvergence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host completeness of function spaces, selected pointwise limits, countable choice, quotient equality of series, detached absolute-convergence predicates, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, majorant exactness, tail-modulus exactness, stream-window exactness, regular-readback boundary, Real-seal boundary, transport, replay, provenance, and local naming for BEDC.Derived.UniformAbsoluteConvergenceUp.

Chapter 8196

A Concrete Naming Certificate for $\mathsf{PhaseCurvatureTransport}^{\uparrow}$

The $\mathsf{PhaseCurvatureTransport}^{\uparrow}$ packet realizes the hyperbolic phase-geometry route as finite transport and curvature-budget data. It is adjacent to the curvature-budget surface of chapter 6437, the phase-holonomy route of chapter 8162, the disk metric surface of chapter 6209, the hyperbolic metric interface of chapter 3474, and the real-name seal of chapter 38. The carrier records only finite disk, metric, boundary, phase, curvature-budget, Real-seal, transport, replay, provenance, and naming rows; it does not assert a global smooth connection, choose geodesic representatives, or identify boundary refusal with an interior phase center.

Definition 8196.1 (Phase curvature transport carrier)**.** *A* $\mathsf{PhaseCurvatureTransport}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (D, M, B, \Phi, K, R, H, T, P, N)$$

with the following visible rows:

1. *D is the finite* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *disk-window row, displaying the inspected disk probes and admissible boundary-facing routes.*
2. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *readback row consumed by the packet before any phase transport is inspected.*
3. *B is the boundary-refusal row, recording which far-end or boundary reads are preserved as boundary data and not collapsed into interior centers.*
4. *Φ is the phase-transport row, listing the finite phase windows, holonomy comparisons, and observer-expansion readbacks inspected by the packet.*
5. *K is the curvature-budget handoff row, reusing the budget discipline of chapter 6437 for the displayed phase transport.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for metric, phase, and curvature-budget readbacks reached only after D, M, B, Φ, K have been displayed.*
7. *H records componentwise* hsame *transport for disk, metric, boundary, phase, curvature-budget, real-seal, replay, provenance, and local-name rows.*
8. *T records displayed* Cont *replay from disk windows through metric readback, boundary refusal, phase transport, curvature-budget handoff, and real sealing.*

9. *P is the* Pkg *provenance over* $\mathsf{PhaseCurvatureTransport}^{\uparrow}$, $\mathsf{PoincareDiskMetric}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicPhaseCurvatureBudget}^{\uparrow}$, $\mathsf{HyperbolicPhaseHolonomyIndex}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{PhaseCurvatureTransport}^{\uparrow}}$ *row.*

The classifier accepts a packet only when disk reads pass through D, metric reads pass through M, boundary refusal is read from B, phase transport is displayed in Φ, curvature-budget constraints are carried by K, and all Real-facing outputs preserve R, H, T, P, N. It has no coordinate for a global connection form, chosen geodesic representative, quotient boundary equality, hidden smooth curvature tensor, or an identification of the boundary refusal with an interior phase center.

Theorem 8196.2 (Phase curvature transport NameCert obligations)**.** *For every accepted* $\mathsf{PhaseCurvatureTransport}^{\uparrow}$ *carrier $C = (D, M, B, \Phi, K, R, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PhaseCurvatureTransport}^{\uparrow}}$ *obligations are exactly carrier admission for the disk-window row, hyperbolic metric readback, boundary-refusal row, phase-transport row, curvature-budget handoff, real-name seal, componentwise transport, continuation replay, provenance, and local naming; metric exactness requiring all phase windows to read the same displayed disk and metric rows; boundary-refusal exactness requiring transport to preserve the boundary row before phase readback is sealed; curvature-budget exactness requiring K to be consumed before any Real-facing phase output; and non-escape from global connection forms, chosen geodesic representatives, quotient boundary equality, hidden smooth curvature tensors, and interior-center collapse.*

Proof. Project the carrier of Definition 8196.1. The finite disk row D, metric row M, boundary-refusal row B, phase-transport row Φ, curvature-budget row K, and Real seal R are the only geometric rows available to the classifier.

Metric exactness is read first. A phase window cannot be consumed until the displayed disk probes have passed through D and their hyperbolic metric readback has passed through M.

Boundary and curvature data are then checked in order. The row B keeps the far-end refusal as boundary data, while K supplies the finite curvature-budget handoff for the phase transport in Φ before any Real-facing output is sealed by R.

Finally, H, T, P, N transport, replay, source, and name the same route. Because the carrier has no row for global connection forms, chosen geodesic representatives, quotient boundary equality, hidden smooth curvature tensors, or interior-center collapse, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: If the curvature-budget row is removed, phase transport can no longer force the same boundary refusal and metric-readback route.

Independence witness: hyperbolic-phase-curvature-budget, hyperbolic-phase-holonomy, poincare-disk-metric, hyperbolic-metric, real: not bijective because $\mathsf{PhaseCurvatureTransport}^{\uparrow}$ jointly carries phase transport, curvature-budget handoff, disk metric, boundary refusal, Real seal, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{PhaseCurvatureTransport}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PhaseCurvatureTransport}^{\uparrow}$ packet starts from finite Poincare disk windows, reads hyperbolic metric data, preserves boundary refusal, transports phase windows through a curvature-budget handoff, seals Real-facing outputs, and preserves the same route by hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{PhaseCurvatureTransport}^{\uparrow}}$, seed)

Scope closed: Definition 8196.1 and Definition 8196.2 seed the disk, metric, boundary-refusal, phase-transport, curvature-budget, Real-seal, transport, replay, provenance, and naming carrier.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{PhaseCurvatureTransport}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global smooth connection data, chosen geodesic representatives, quotient boundary equality, hidden curvature tensors, interior-center collapse, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric exactness, boundary-refusal exactness, curvature-budget exactness, Real-seal boundary, transport, replay, provenance, local naming, and Nontrivial and Field-Faithful instances in lean4/BEDC/Derived/PhaseCurvatureTransportUp/TasteGate.lean.

Chapter 8197

A Concrete Naming Certificate for $\mathsf{SignedDyadicInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SignedDyadicInterval}^{\uparrow}$ packet records the finite signed dyadic interval data used before regular rational and real-name consumers inspect an enclosure. It sits after the dyadic endpoint core of chapter 291, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the interval-operation surface of chapter 1645. The packet names the signed endpoint order, containment ledger, and real-facing handoff rows without importing quotient real equality, host interval equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8197.1 (Signed dyadic interval carrier)**.** *A* $\mathsf{SignedDyadicInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L and U are lower and upper endpoint rows accepted by* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *σ_L and σ_U are the signed-endpoint rows, recording the visible sign data attached to the two dyadic endpoints.*
3. *O is the lower-before-upper order ledger, read only through dyadic comparison rows over L and U.*
4. *W is the finite window row exported to* $\mathsf{StreamName}^{\uparrow}$ *consumers.*
5. *I is the interval-arithmetic handoff row, exposing the same endpoints and containment comparisons through* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$*.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for consumers that turn the displayed interval into a regular rational enclosure.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the endpoint, sign, window, interval-arithmetic, and regular-readback rows have been displayed.*
8. *H records componentwise* hsame *transport for the endpoint, sign, order, window, containment, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through the same finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{SignedDyadicInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicInterval}^{\uparrow}}$ *row.*

The carrier predicate is exactly the assertion that these rows form one signed dyadic interval packet. It has no coordinate for quotient real equality, host interval equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8197.2 (Signed dyadic interval NameCert obligations)**.** *For every accepted* $\mathsf{SignedDyadicInterval}^{\uparrow}$ *carrier* $S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SignedDyadicInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the endpoint rows, signed-endpoint rows, endpoint-order ledger, StreamName window, interval-arithmetic handoff, RegSeqRat readback, Real seal, componentwise transport, continuation replay, provenance, and local naming;*
2. *endpoint sign exactness, requiring σ_L and σ_U to remain attached to the displayed dyadic endpoint rows L and U;*
3. *order stability, requiring O to transport along* hsame *and displayed* Cont *replay without replacing dyadic comparison by host real order;*
4. *containment handoff, requiring I to expose every interval containment row through* $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ *using the same displayed endpoints;*
5. *completion boundary, requiring W, R, E to route the finite window through* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *in that order;*
6. *ledger non-escape, excluding quotient real equality, host interval equality, trichotomy, selected representatives, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 8197.1. The projection exposes exactly the two $\mathsf{DyadicRatCore}^{\uparrow}$ endpoints, the signed-endpoint rows, the dyadic order ledger, the StreamName window, the interval-arithmetic handoff, the RegSeqRat readback, the Real seal, and the structural rows H, C, P, N.

Endpoint sign exactness and order stability are read from $\sigma_L, \sigma_U, O, H, C$. Componentwise transport and displayed replay move the named endpoint histories together with their sign and order ledgers, so no host real order or quotient equality row is introduced.

Containment handoff is the row I. It points to the existing $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ enclosure surface and uses the same displayed endpoint rows L, U rather than a detached interval object.

Finally the completion boundary is the route $W \longmapsto R \longmapsto E$. A completion-facing consumer receives finite windows, regular rational readback, and the terminal real seal only in that order. The excluded ambient principles are absent from the carrier inventory. □

Theorem 8197.3 (Signed dyadic interval containment stability)**.** *Let $S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N)$ be an accepted* $\mathsf{SignedDyadicInterval}^{\uparrow}$ *carrier. Any containment read exported through I remains stable under the componentwise* hsame *transport and displayed* Cont *replay rows H and C, and every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer receives the transported containment only after the signed dyadic endpoint rows and endpoint-order ledger have been displayed.*

Proof. Start from the containment row I in Definition 8197.1. Its endpoints are the displayed rows L, U together with their signed data σ_L, σ_U and order ledger O.

Apply the NameCert obligations of Definition 8197.2. They force the containment handoff to remain inside $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ and force H, C to transport and replay the same endpoint, sign, order, and containment rows componentwise.

The downstream completion route is then read through W, R, E. Since those rows are reached only after the displayed containment row, every listed consumer sees the same transported interval packet and cannot replace it by host interval equality, quotient real equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8197.4 (Signed dyadic interval endpoint sign exactness)**.** *Let $S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N$ be an accepted $\mathsf{SignedDyadicInterval}^{\uparrow}$ carrier. Under every transported read recorded by H and every displayed replay recorded by C, the sign rows σ_L and σ_U remain attached respectively to the displayed $\mathsf{DyadicRatCore}^{\uparrow}$ endpoint rows L and U.*

Proof. Project the carrier tuple in Definition 8197.1. The endpoint rows L, U and the sign rows σ_L, σ_U occur as named coordinates of the same finite packet, not as separately chosen representatives.

Apply the obligation surface of Definition 8197.2. Its endpoint sign exactness row is read through σ_L, σ_U, H, C, so componentwise hsame transport and displayed Cont replay move each sign row together with its endpoint row.

No quotient real equality, selected representative, host interval equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness row is available in the carrier inventory. Therefore a consumer can read only the displayed attachment of σ_L to L and σ_U to U. □

Theorem 8197.5 (Signed dyadic interval order stability)**.** *Let $S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N)$ be an accepted $\mathsf{SignedDyadicInterval}^{\uparrow}$ carrier. The lower-before-upper ledger O is preserved under the componentwise hsame transport row H and the displayed Cont replay row C; the preserved order read is the displayed dyadic comparison over L and U, not host real order or trichotomy.*

Proof. Project O, H, C from the carrier of Definition 8197.1. The order coordinate is a lower-before-upper dyadic ledger over the displayed endpoints L, U.

Use Definition 8197.2. The order-stability obligation requires the ledger O to travel through the same componentwise transport and replay rows that carry the endpoints and their signs.

Since the carrier contains no host real order, trichotomy, quotient equality, representative selector, countable-choice coordinate, or ambient completeness coordinate, the replayed order read cannot be replaced by any external comparison principle. It remains exactly the displayed dyadic ledger O over L, U. □

Theorem 8197.6 (Signed dyadic interval completion boundary)**.** *Let $S = (L, U, \sigma_L, \sigma_U, O, W, I, R, E, H, C, P, N)$ be an accepted $\mathsf{SignedDyadicInterval}^{\uparrow}$ carrier. Every $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer must read the route $W \longmapsto R \longmapsto E$ only after the signed endpoint rows σ_L, σ_U, the order ledger O, and the containment handoff I have been displayed.*

Proof. Project the completion-facing coordinates W, R, E from Definition 8197.1. They are ordered as the finite window, regular rational readback, and terminal real seal of the same signed interval packet.

Apply Definition 8197.2 together with Definition 8197.3. The obligation surface places the completion route after endpoint signs, endpoint order, and containment handoff, while containment stability ensures the handoff remains the displayed $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ row transported by H and replayed by C.

Thus a completion-facing consumer receives $W \longmapsto R \longmapsto E$ only through the displayed finite route. The carrier offers no quotient real equality, host interval equality, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness through which the consumer could bypass those rows. □

Falsifiable prediction: Every accepted $\mathsf{SignedDyadicInterval}^{\uparrow}$ read that exports containment to $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ without first exposing signed dyadic endpoints, endpoint order, the $\mathsf{DyadicIntervalArithmetic}^{\uparrow}$ containment row, componentwise transport, displayed replay, provenance, and local naming is outside the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, dyadic-interval-arithmetic: no listed sibling supplies the joint packet containing signed dyadic endpoints, endpoint order, finite StreamName windows, DyadicIntervalArithmetic containment, RegSeqRat readback, Real seal, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDyadicInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{SignedDyadicInterval}^{\uparrow}$ packet is generated from lower and upper DyadicRatCore endpoint rows, signed-endpoint rows, an endpoint-order ledger, finite StreamName windows, a DyadicIntervalArithmetic containment handoff, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDyadicInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8197.1, Definition 8197.2, Definition 8197.3, Definition 8197.4, Definition 8197.5, and Definition 8197.6 seed the finite signed dyadic interval route from DyadicRatCore endpoints through StreamName, RegSeqRat, Real, and DyadicIntervalArithmetic consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDyadicInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, host interval equality, trichotomy, selected representatives, countable choice, ambient Real completeness, Lean verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, signed-endpoint exactness, endpoint-order stability, containment handoff, completion-boundary, classifier transport, and ledger non-escape proofs for BEDC.Derived.SignedDyadicIntervalUp.

Chapter 8198

A Concrete Naming Certificate for $\mathsf{UniformLimitIntegral}^{\uparrow}$

Following Bishop and Bridges on constructive integration, the $\mathsf{UniformLimitIntegral}^{\uparrow}$ packet records the finite BEDC route by which a uniformly convergent family of Riemann-integrable real-valued names yields an integral read for the displayed limit. It sits after the uniform-limit continuity boundary of chapter 1748, the Riemann-integral carrier of chapter 1526, the regular rational readback of chapter 301, the finite stream-name window of chapter 126, and the terminal real-name seal of chapter 38. The packet names only the displayed route from uniform convergence, integral packets, regular rational readback, and Real sealing; it does not import host function equality, selected limiting partitions, countable choice, measure completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8198.1 (Uniform limit integral carrier)**.** *A* $\mathsf{UniformLimitIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (F, U, J, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite family row, listing the displayed real-valued approximants and their common interval window;*
2. *U is the uniform-limit row, read through* $\mathsf{UniformLimitContinuous}^{\uparrow}$*, recording the shared modulus and the displayed limit-name route;*
3. *J is the* $\mathsf{RiemannIntegral}^{\uparrow}$ *row for the approximants, exposing only tagged-mesh, Darboux-gap, and integral-readback data already present in the Riemann packet;*
4. *W is the finite window row through* $\mathsf{StreamName}^{\uparrow}$*, recording the observation schedule used by the approximants, the limit read, and the integral read;*
5. *Q is the regular rational readback row through* $\mathsf{RegSeqRat}^{\uparrow}$*, recording the rational Cauchy data used to compare integral values at a requested tolerance;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the limit integral value;*
7. *H records componentwise* hsame *transport for F, U, J, W, Q, E;*
8. *C records displayed* Cont *replay through the uniform-limit, Riemann-integral, stream-window, regular-rational, and Real-seal rows;*
9. *P is the* Pkg *provenance over* $\mathsf{UniformLimitIntegral}^{\uparrow}$, $\mathsf{UniformLimitContinuous}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformLimitIntegral}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host equality of functions, a selected sequence of partitions, a measure-completion object, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$*.*

Theorem 8198.2 (Uniform limit integral NameCert obligations)**.** *For the carrier of Definition 8198.1, the local* $\mathsf{NameCert}_{\mathsf{UniformLimitIntegral}^{\uparrow}}$ *surface consists exactly of carrier exposure for* $I = (F, U, J, W, Q, E, H, C, P, N)$*, uniform-limit exposure through* U*, Riemann-integral packet exposure through* J*, stream-window and regular-rational readback through* W, Q*, terminal Real sealing through* E*, structural transport through* H, C, P*, and local naming through* N*.*

Proof. Project the carrier rows of Definition 8198.1. The finite family, uniform-limit, Riemann-integral, stream-window, regular-rational, and Real-seal rows are separate displayed coordinates before the local name is consumed.

The structural rows H, C, P, N transport, replay, source, and name that same finite packet. Since the carrier has no host function-equality, selected-partition, measure-completion, choice, or ambient-completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8198.3 (Uniform limit integral Riemann handoff)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformLimitIntegral}^{\uparrow}$ *packet must read the finite route*

$$F \longmapsto U \longmapsto J \longmapsto W \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

Thus the integral of the displayed limit is available only after the uniform-limit row, the Riemann-integral row, the stream-window row, the regular-rational readback row, and the Real-seal row are all exposed.

Proof. Use the NameCert obligations of Definition 8198.2. The Riemann handoff row J is downstream of the displayed family and uniform-limit rows, while the integral value is downstream of the stream-window and regular-rational readback rows.

The continuation row C replays the route in the order shown, and the provenance row P records the allowed sibling packets. A Riemann-integral consumer therefore receives a finite BEDC handoff, not an external limiting theorem or a hidden partition-selection principle. □

Theorem 8198.4 (Uniform limit integral Real seal nonescape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{UniformLimitIntegral}^{\uparrow}$ *packet is reached only through* $F, U, J, W, Q, E, H, C, P, N$*. It cannot be read as host equality of integrals, quotient equality of functions, a selected limiting partition family, countable choice, measure completion, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier of Definition 8198.1. The Real-facing coordinate is the row E, and E is displayed only after the uniform-limit, Riemann-integral, stream-window, and regular-rational readback rows have been exposed.

Apply the Riemann handoff theorem Definition 8198.3. Any consumer that reaches E has already passed through the finite route $F, U, J, W, Q, H, C, P, N$. None of those rows contains a host equality, quotient, selected partition family, countable-choice schedule, measure-completion object, or ambient-completeness theorem, so the Real seal cannot escape the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitIntegral}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformLimitIntegral}^{\uparrow}$ packet is generated from finite family rows, a uniform-limit row, a Riemann-integral handoff row, stream-window rows, regular-rational readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformLimitIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8198.1, Definition 8198.2, Definition 8198.3, and Definition 8198.4 seed the finite uniform-limit integral route over UniformLimitContinuous$^{\uparrow}$, RiemannIntegral$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{UniformLimitIntegral}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host equality of functions, selected limiting partitions, countable choice, measure completion, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, uniform-limit exposure, Riemann-integral hand-off, stream-window readback, regular-rational comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.UniformLimitIntegralUp.

Chapter 8199

A Concrete Naming Certificate for CompactIntervalFanModulusSelector$^{\uparrow}$

Following Bishop and Bridges on compact intervals and fan-bar moduli, the CompactIntervalFanModulusSelector$^{\uparrow}$ packet records the finite selector that carries compact interval source data through fan-bar depth, dyadic tolerance, finite StreamName windows, RegSeqRat readback, and a terminal Real seal. It sits beside the located interval boundary of chapter 7165, the compact interval fan route of chapter 6946, and the finite fan-bar modulus surface of chapter 4297. The packet supplies an L10 Real and Completion route without asserting open-cover compactness, choosing branches, quotienting real names, invoking countable choice, or importing ambient Real$^{\uparrow}$ completeness.

Definition 8199.1 (Compact interval fan modulus selector carrier)**.** *A* CompactIntervalFanModulusSelector$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (I, B, D, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, read through the Bishop compact interval and located interval surfaces before any fan-bar depth is consumed.*
2. *B is the finite fan-bar depth row, read through* CompactIntervalFanBridge$^{\uparrow}$, LocatedIntervalFanBarrier$^{\uparrow}$, *and* FiniteFanBarModulus$^{\uparrow}$ *as a bounded prefix-depth certificate.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row carrying the requested precision and the finite comparison budget used by the selector.*
4. *S is the finite* StreamName$^{\uparrow}$ *window ledger opened by the depth and tolerance rows.*
5. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the regular rational approximants observed inside the displayed windows.*
6. *E is the terminal* Real$^{\uparrow}$ *seal, available only after I, B, D, S, Q have been displayed.*
7. *H records componentwise* hsame *transport for interval source, fan-bar depth, dyadic tolerance, stream windows, regular-rational readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from compact interval source data through the fan-bar depth and then through D, S, Q, E.*

9. *P is the* Pkg *provenance over* CompactIntervalFanModulusSelector$^{\uparrow}$, CompactIntervalFanBridge$^{\uparrow}$, LocatedIntervalFanBarrier$^{\uparrow}$, FiniteFanBarModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{CompactIntervalFanModulusSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, D, S, Q, E, H, C, P, N$. It has no coordinate for open-cover compactness, a selected branch, quotient real equality, countable choice, host real comparison, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8199.2 (Compact interval fan modulus selector obligations)**.** *For every accepted* CompactIntervalFanMod *carrier*

$$M = (I, B, D, S, Q, E, H, C, P, N),$$

the local NameCert$_{\text{CompactIntervalFanModulusSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, compact interval source exposure through I, finite fan-bar depth exposure through B, dyadic tolerance accounting through D, finite* StreamName$^{\uparrow}$ *window exposure through S,* RegSeqRat$^{\uparrow}$ *readback through Q, terminal* Real$^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8199.1. The accepted packet displays exactly the interval source, finite fan-bar depth, dyadic tolerance, stream-window, regular-rational, Real-seal, transport, replay, provenance, and naming rows.

The analytic route is ordered. The compact interval source row I is exposed first, the fan-bar row B supplies the finite depth bound, and the dyadic row D records the tolerance budget consumed by the selected windows.

The readback rows are downstream of that finite prefix. The window ledger S is opened from the depth and tolerance rows, Q reads regular rational data inside those windows, and E seals the Real-facing result only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite selector. Since the carrier has no coordinate for open-cover compactness, selected branches, quotient real equality, countable choice, host real comparison, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 8199.3 (Compact interval fan modulus finite route)**.** *Every L10 Real and Completion consumer of an accepted* CompactIntervalFanModulusSelector$^{\uparrow}$ *carrier factors through the finite route*

CompactIntervalFanBridge$^{\uparrow}$, LocatedIntervalFanBarrier$^{\uparrow}$, FiniteFanBarModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, Re

In carrier notation, the consumer reads I, B, D, S, Q, E before using the structural rows H, C, P, N. The route exports a displayed modulus selector from compact interval and fan-bar evidence to Real-facing readback, and it exports no open-cover compactness theorem, selected branch, quotient real equality, countable-choice row, host equality test, or ambient Real$^{\uparrow}$ *completeness theorem.*

Proof. Start with the compact interval and fan rows. The compact source row I supplies the interval data, while B records the finite fan-bar depth available through the adjacent compact interval and finite bar chapters.

The tolerance and window rows come next. The dyadic row D fixes the requested precision, and the finite window ledger S lists only the observations licensed by the displayed depth and tolerance.

The Real-facing suffix is Q, E. RegSeqRat readback is performed inside the finite windows, and the terminal Real seal is visible only after that readback has been replayed.

The structural rows H, C, P, N preserve the same order under transport, continuation replay, provenance, and local naming. Therefore every L10 consumer factors through the displayed finite route, while each excluded compactness, choice, branch, quotient, host-equality, or ambient-completeness reading lacks a carrier coordinate. □

Falsifiable prediction: Every accepted CompactIntervalFanModulusSelectorUp Real or Completion-facing read factors through compact interval source, finite fan-bar depth, dyadic tolerance, finite StreamName windows, RegSeqRat readback, Real seal, transport, replay, provenance, and local naming rows.

Independence witness: located interval fan barrier, compact interval fan bridge, finite fan bar modulus, dyadicratcore, streamname, regseqrat, real: $\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact interval source data, fan-bar depth, dyadic tolerance, finite observation windows, regular rational readback, Real sealing, and structural support while refusing open-cover compactness, selected branches, quotient real equality, countable choice, host real comparison, and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}$ packet is generated from compact interval source rows, finite fan-bar depth rows, DyadicRatCore tolerance ledgers, finite StreamName windows, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8199.1, Definition 8199.2, and Definition 8199.3 seed the compact interval fan-bar route from finite depth and dyadic tolerance to Real and Completion readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalFanModulusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected branches, quotient real equality, countable choice, host real comparison, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval source exposure, fan-bar depth exposure, dyadic tolerance accounting, stream-window readback, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalFanModulusSelectorUp.

Chapter 8200

A Concrete Naming Certificate for FiniteDimensionalBrouwerFixedPoint$^{\uparrow}$

Following Brouwer and Sperner, the FiniteDimensionalBrouwerFixedPoint$^{\uparrow}$ packet records the finite-dimensional fixed-point route in which a compact convex carrier, a continuous self-map, and a finite mesh certificate are displayed before any fixed-point-facing read is allowed. It consumes the Brouwer packet of chapter 2030, the finite labelled-simplex route of chapter 2003, the metric approximation route of chapter 5941, the compact finite-net discipline of chapter 129, the convex interval and cell discipline of chapter 6585, the self-map surface of chapter 130, and the terminal real-name seal of chapter 38. The packet names the finite-dimensional mesh route itself; it does not choose an exact host fixed point or assert an unrestricted classical theorem.

Definition 8200.1 (Finite-dimensional Brouwer fixed-point carrier)**.** *A* FiniteDimensionalBrouwerFixedPoint$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, V, M, S, L, A, R, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact finite-net row, read through* CompactMetric$^{\uparrow}$ *data and recording the finite radius, cover, and total-boundedness surface used by the argument.*
2. *V is the finite-dimensional convex-cell row, recording the listed coordinates, face incidences, convex-combination cells, and boundary faces inspected by the self-map route.*
3. *M is the* ContinuousMap$^{\uparrow}$ *self-map row, exposing only the displayed modulus and finite image data used on the mesh.*
4. *S is the* SpernerLemma$^{\uparrow}$ *handoff row, carrying the boundary-admissible finite labelling and the fully labelled simplex witness.*
5. *L is the* BrouwerFixedPoint$^{\uparrow}$ *mesh route row, tying the Sperner witness to the dyadic subdivision and approximate fixed-simplex readback.*
6. *A is the* BrouwerFixedPointMetric$^{\uparrow}$ *approximation row, recording metric residual bounds, mesh scale, and finite approximation evidence.*
7. *R is the* Real$^{\uparrow}$ *seal row reached only after the compact, convex, continuous-map, Sperner, Brouwer, and metric approximation rows have been displayed.*
8. *H records componentwise* hsame *transport for K, V, M, S, L, A, R and the structural rows.*

9. *C records displayed* Cont *replay for the finite route*

$$K, V, M, S, L, A \longmapsto R, H, P, N.$$

10. *P is the* Pkg *provenance over* $\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}$, $\mathsf{BrouwerFixedPoint}^{\uparrow}$, $\mathsf{SpernerLemma}^{\uparrow}$, $\mathsf{BrouwerFixedPointMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, M, S, L, A, R, H, C, P, N$. It has no coordinate for an exact host fixed point, a selected limit, open-cover compactness, quotient stream equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8200.2 (Finite-dimensional Brouwer fixed-point NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}$ *carrier*

$$F = (K, V, M, S, L, A, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, finite-dimensional convex-cell exposure through V, continuous self-map access through M, Sperner boundary and fully labelled simplex handoff through S, Brouwer mesh routing through L, metric residual readback through A, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8200.1. Its accepted rows are precisely the compact finite-net row, finite-dimensional convex-cell row, continuous-map row, Sperner handoff, Brouwer mesh route, metric approximation row, Real seal, and structural transport, replay, provenance, and naming rows.

The geometric part is finite. The compact row K gives only finite-net and radius data, and the convex row V gives only listed cells, faces, and convex-combination checks.

The map and fixed-point-facing part is routed. The self-map row M supplies the displayed modulus data used by the mesh, the Sperner row S supplies the labelled-simplex certificate, the Brouwer row L ties that certificate to the dyadic fixed-simplex route, and the metric row A records residual bounds at the displayed mesh scale.

Finally R, H, C, P, N seal and preserve the same finite packet. Since no excluded exact fixed point, selected limit, open-cover compactness principle, quotient equality, choice, trichotomy, ambient completeness, Lean verification, or bridge row occurs in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 8200.3 (Finite-dimensional Brouwer fixed-point Sperner mesh route)**.** *Every fixed-point-facing read of an accepted* $\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}$ *packet factors through the displayed finite route*

$$\mathsf{CompactMetric}^{\uparrow},\quad \mathsf{ContinuousMap}^{\uparrow},\quad \mathsf{SpernerLemma}^{\uparrow},\quad \mathsf{BrouwerFixedPoint}^{\uparrow},\quad \mathsf{BrouwerFixedPointMetric}^{\uparrow},\quad \mathsf{Real}^{\uparrow}$$

Concretely, the consumer first reads the compact finite-net and finite-dimensional convex-cell rows K, V, then the continuous self-map row M, then the Sperner labelled-simplex handoff S, then the Brouwer mesh route L, then the metric residual row A, and only then the terminal Real seal R. No host fixed-point choice or ambient compactness theorem is exported by this route.

Proof. Start from an accepted carrier $F = (K, V, M, S, L, A, R, H, C, P, N)$. The rows K, V display the compact finite-net and finite-dimensional convex-cell surface on which the self-map is inspected.

The self-map information is then read through M. A consumer cannot interpret the mesh labels before this row is displayed, because the boundary labels and residual comparisons are induced by the carried continuous-map data.

The combinatorial handoff is supplied by S and L. The Sperner row exposes the fully labelled simplex, while the Brouwer row records the finite dyadic mesh route that turns this handoff into approximate fixed-simplex evidence.

The metric row A and Real seal R are downstream. They record residual bounds and real-name nonescape only after the compact, convex, map, Sperner, and Brouwer rows have already been displayed. Transport, replay, provenance, and local naming preserve the same route, so the packet exports no host fixed-point selection or unrestricted compactness principle. □

Falsifiable prediction: A $\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}$ consumer is refuted if it reaches a fixed-point-facing read without displaying compact finite-net data, finite-dimensional convex-cell rows, continuous-map modulus data, a Sperner labelled-simplex handoff, a Brouwer mesh route, metric residual bounds, Real sealing, transport, replay, provenance, and local NameCert evidence.

Independence witness: brouwer, sperner, metric, compact, convex, continuous, real: FiniteDimensionalBrouwerFi is not bijective to any listed sibling because it binds the finite-dimensional convex-cell route, finite mesh handoff, residual readback, and Real seal into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}$ packet is generated from compact finite-net rows, finite-dimensional convex-cell rows, continuous self-map rows, Sperner labelled-simplex handoff rows, Brouwer mesh-route rows, Brouwer fixed-point metric approximation rows, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8200.1, Definition 8200.2, and Definition 8200.3 seed the finite-dimensional Brouwer fixed-point mesh route through compact finite-net, convex-cell, continuous-map, Sperner, Brouwer, metric approximation, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalBrouwerFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an exact host fixed-point theorem, selected limits, open-cover compactness, quotient stream equality, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net routing, finite-dimensional convex-cell routing, continuous-map access, Sperner handoff exactness, Brouwer mesh routing, metric residual readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDimensionalBrouwerFixedPointUp.

Chapter 8201

A Concrete Naming Certificate for $\mathsf{DyadicConvergenceModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{DyadicConvergenceModulus}^{\uparrow}$ packet records the finite tolerance ledger by which dyadic convergence budgets are read before a terminal real-name seal is exposed. It sits over the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name chapter of chapter 38. The packet names a displayed convergence-control object for Real-facing consumers; it does not assert quotient equality of real names, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8201.1 (Dyadic convergence modulus carrier)**.** *A* $\mathsf{DyadicConvergenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M_{\mathrm{dy}} = (D, S, Q, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the dyadic tolerance row, storing the requested dyadic error bound, the comparison scale, and the finite arithmetic witnesses read from* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the observations used to compare the relevant prefixes of the candidate names.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, turning the observed windows into regular rational comparison data.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after D, S, Q have been displayed.*
5. *M is the convergence modulus ledger, recording the finite index budget that makes the D-tolerance stable for every later inspected window.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, stream-window, regular readback, Real seal, modulus ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a convergence request through D, S, Q, E, M, H.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicConvergenceModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, Q, E, M, H, C, P, N$. It has no coordinate for quotient Real equality, selected limits, countable choice, arbitrary Cauchy completeness, or a host convergence theorem detached from the displayed dyadic budget.

Theorem 8201.2 (Dyadic convergence modulus NameCert obligations)**.** *For every accepted* DyadicConvergenceMo *carrier*

$$M_{\mathrm{dy}} = (D, S, Q, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *expose the dyadic tolerance row D before any convergence budget is consumed;*
2. *route every inspected prefix through the finite stream windows S and the regular rational readback row Q;*
3. *display the modulus ledger M as the only source of later-index stability for the requested dyadic tolerance;*
4. *reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal E only after D, S, Q, M have been displayed;*
5. *preserve the route by componentwise* hsame *transport and displayed* Cont *replay through H, C;*
6. *source and name the same finite packet through* Pkg *provenance P and the local* NameCert *row N.*

No obligation row states quotient Real equality, selects a limiting Real name, supplies countable choice, proves ambient $\mathsf{Real}^{\uparrow}$ *completeness, or exports Lean verification.*

Proof. Project the carrier of Definition 8201.1. Its rows are exactly the dyadic tolerance data, finite stream windows, regular readback, terminal seal, modulus ledger, transport, replay, provenance, and local naming.

Read the numerical rows first. The dyadic tolerance row D fixes the precision request; the stream row S and the regular rational row Q provide the finite observations against which that request is checked.

The convergence control is then the ledger row M. It records the finite index budget that makes the displayed tolerance stable for later inspected windows, without invoking a selected limit or an ambient completeness principle.

Finally E, H, C, P, N seal, transport, replay, source, and name the same route. Since the carrier has no coordinates for quotient Real equality, countable choice, selected limits, ambient completeness, or Lean verification, the listed rows exhaust the local NameCert obligations. □

Theorem 8201.3 (Dyadic convergence modulus Real readback)**.** *Every Real-facing read of an accepted* $\mathsf{DyadicConvergenceModulus}^{\uparrow}$ *carrier factors through*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}.$$

The read exposes a finite dyadic convergence budget before the $\mathsf{Real}^{\uparrow}$ *seal is consumed. It supplies no quotient equality of real names, selected limit, countable-choice schedule, ambient Real completeness theorem, or Lean verification claim.*

Proof. Begin with the obligation theorem Definition 8201.2. It orders D, S, Q, M before the terminal seal E, so a Real-facing consumer cannot read the seal without first seeing the dyadic tolerance, finite windows, regular readback, and modulus ledger.

The displayed route is finite at each stage. The $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies arithmetic tolerance data, $\mathsf{StreamName}^{\uparrow}$ supplies inspected windows, and $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback before $\mathsf{Real}^{\uparrow}$ is reached.

The structural rows H, C, P, N preserve and name the same packet. They do not add quotient equality, selected limits, countable choice, ambient completeness, or Lean verification, so the Real readback remains the displayed finite dyadic convergence-control route. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicConvergenceModulus}^{\uparrow}$ packet is generated from dyadic tolerance data, finite StreamName windows, RegSeqRat readback, a terminal Real seal, a convergence modulus ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8201.1, Definition 8201.2, and Definition 8201.3 seed the finite dyadic convergence-control route over DyadicRatCore, StreamName, RegSeqRat, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicConvergenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Real equality, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, arbitrary convergence theorems, or Lean verification.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window routing, RegSeqRat readback, Real seal nonescape, modulus ledger stability, transport, replay, provenance, and local naming for BEDC.Derived.DyadicConvergenceModulusUp.

Chapter 8202

A Concrete Naming Certificate for $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria, the $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ packet records the finite route by which one displayed uniform Cauchy budget feeds the Real and Completion phase. It sits over the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the located comparison route of chapter 5848. The packet names a shared Cauchy budget as displayed BHist data; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8202.1 (Bishop uniform Cauchy principle carrier)**.** *A* $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row listing the finite stream windows whose tails are inspected by the same request.*
2. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *uniform-budget row, assigning one dyadic tolerance and one tail threshold to every displayed pair of retained windows.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained only from the window data in S and the dyadic comparisons in D.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the finite windows, dyadic budget, and regular rational readback have been displayed.*
5. *H stores componentwise* hsame *transport for stream windows, dyadic budget rows, regular readbacks, Real seals, replay, provenance, and local naming.*
6. *C stores displayed* Cont *replay from a uniform Cauchy request through S, D, R, E, H and back to the same finite request surface.*
7. *P is the* Pkg *provenance over* $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformCauchyCriterion}^{\uparrow}$, $\mathsf{LocatedUniformCauchyPrinciple}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient equality of streams, selected limits, countable-choice schedules, host real equality, or an ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Theorem 8202.2 (Bishop uniform Cauchy NameCert obligations)**.** *For every accepted* BishopUniformCauchyPrincip *carrier*

$$U = (S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}}$ *surface consists exactly of finite stream-window exposure, shared dyadic uniform-budget exposure, regular rational readback, terminal Real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any located or uniform Cauchy consumer named by* P *must read the same finite route before it may inspect the Real seal.*

Proof. Project the carrier $U = (S, D, R, E, H, C, P, N)$. The analytic rows are precisely the stream-window row S, the shared dyadic budget row D, the regular readback row R, and the terminal Real seal row E.

Induct over the finite list of BHist-visible windows in S. The base window has only the displayed dyadic request in D to read. In the step, adding one more retained window extends the same shared threshold row; it does not add a second limit object or a new equality principle.

The row R is downstream of this finite induction, and E is downstream of R. Thus every accepted consumer named by P reaches the Real-facing boundary through the same S, D, R, E route.

The structural rows H, C, P, N preserve, replay, source, and name only those rows. Since quotient stream equality, selected limits, countable choice, host real equality, and ambient $\mathsf{Real}^{\uparrow}$ completeness are not carrier coordinates, the listed rows exhaust the local NameCert obligations. □

Theorem 8202.3 (Bishop uniform Cauchy RegSeqRat handoff)**.** *Every accepted* $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ *carrier*

$$U = (S, D, R, E, H, C, P, N)$$

exports its $\mathsf{RegSeqRat}^{\uparrow}$ *readback only through the shared finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

Consequently a Real and Completion consumer cannot replace R *by quotient stream equality, a selected tail limit, a countable-choice schedule, or a host real-equality comparison.*

Proof. Start with the displayed stream windows. The row S lists the only finite observations that the carrier makes available to the request.

Next read the shared dyadic uniform budget D. For each visible pair of retained windows, D supplies the single tolerance and tail threshold used by the request, so the regular rational row R is a readback from the displayed window-budget surface rather than from an external stream quotient.

The transport row H then keeps the same windows and budgets stable under hsame, and the replay row C records the same dependency order. Since the carrier has no field for selected limits, countable choice, host real equality, or ambient completeness, the handoff to $\mathsf{RegSeqRat}^{\uparrow}$ is exactly the finite route shown above. □

Theorem 8202.4 (Bishop uniform Cauchy Real-seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read of an accepted* $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *rows attached to the same packet. The seal boundary exports no ambient Real completeness, no selected completed real, no quotient stream equality, no countable-choice family of moduli, and no host real equality.*

Proof. Read the packet in dependency order. The stream row S fixes the finite windows, the dyadic row D fixes the shared budget for those windows, and the regular row R is the only rational readback exposed by the carrier.

The Real seal row E is available only after S, D, R have been displayed. A finite-row induction over the retained windows shows that every additional window is absorbed by the same shared budget row before the seal is read.

Finally project H, C, P, N. These rows transport, replay, source, and name the same finite route, so the Real-facing consumer cannot escape to a quotient of streams, a selected limit, countable choice, host real equality, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$. □

Falsifiable prediction: Every $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ consumer reaches $\mathsf{Real}^{\uparrow}$ only after exposing finite $\mathsf{StreamName}^{\uparrow}$ windows, a shared $\mathsf{DyadicRatCore}^{\uparrow}$ uniform budget, a $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, real, uniformcauchycriterion, located-uniform-cauchy-principle: $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite stream windows, a shared dyadic uniform budget, regular rational readback, a Real seal boundary, transport, replay, provenance, and local naming in one certificate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}$ packet is generated from finite StreamName windows, one shared DyadicRatCore uniform budget, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8202.1, Definition 8202.2, Definition 8202.3, and Definition 8202.4 seed the finite uniform Cauchy route for the Real and Completion phase.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformCauchyPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, shared dyadic budget exactness, finite-window induction, RegSeqRat readback ordering, Real seal boundary routing, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformCauchyPrincipleUp.

Chapter 8203

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy criteria, the $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$ packet records the finite comparison of two displayed regular-Cauchy tail budgets before either budget is read as a Real or Completion handoff. It sits after the finite window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-budget service of chapter 906, the tail-diameter boundary of chapter 1746, and the terminal real-name seal of chapter 38. The packet gives later Cauchy-criterion arguments one local comparison object for budget alignment; it does not choose a limit, quotient streams, compare host real values, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8203.1 (Regular-Cauchy tail-budget comparison carrier)**.** *A* $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, B_0, B_1, E, H, C, P, N)$$

with the following displayed coordinates:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window service row whose finite tail window is shared by both budget reads;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row inspected through S;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the two budget reads;*
4. *B_0 and B_1 are the two displayed tail-budget rows over the same S, R, D window-and-tolerance surface;*
5. *E is the comparison endpoint row, recording whether the two budgets agree, one refines the other, or the packet exposes a finite obstruction to comparison;*
6. *H stores componentwise* hsame *transports for the stream, readback, dyadic, budget, endpoint, provenance, and local naming rows;*
7. *C stores displayed* Cont *replay routes for reading the shared window, reading both budgets, comparing their classifier rows, and exposing the endpoint;*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected limit, quotient stream equality, host real equality, unlisted tolerance, or ambient completion theorem.

Theorem 8203.2 (Regular-Cauchy tail-budget comparison NameCert obligations)**.** *For the carrier of Definition 8203.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *source and window binding: the two budget rows B_0, B_1 read the same* $\mathsf{StreamName}^{\uparrow}$ *window S, the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R, and the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D;*
2. *classifier comparison: the endpoint row E records exactly the displayed comparison between the two budget classifiers;*
3. *stability: componentwise* hsame *transport through H preserves the same source, window, dyadic, budget, comparison, and endpoint rows;*
4. *ledger non-escape: any downstream consumer of the comparison factors through $S, R, D, B_0, B_1, E, H, C, P, N$;*
5. *real-seal routing: a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer can read a terminal seal only after the shared window, regular readback, dyadic tolerance, two budget rows, comparison endpoint, transport, replay, provenance, and local naming rows have been exposed.*

Proof. Carrier admission is projection from the displayed tuple $T = (S, R, D, B_0, B_1, E, H, C, P, N)$. The two budget rows are not independent tail services; they are fields of one finite packet over the same stream window, regular readback, and dyadic tolerance rows.

The classifier comparison is read from E. Its alternatives are the displayed agreement, displayed refinement in one direction, displayed refinement in the other direction, or a finite obstruction row. No host real comparison or quotient-stream equality is available to refine that endpoint.

Stability and replay are supplied by H and C. Componentwise transport keeps the two budget rows over the same source data, while the continuation rows replay the window read, the two budget reads, the endpoint comparison, and the consumer handoff in the listed order.

The ledger and seal clauses then follow from absence of extra coordinates. A $\mathsf{Real}^{\uparrow}$ or completion-facing consumer sees only the displayed route through $S, R, D, B_0, B_1, E, H, C, P, N$, so the packet cannot export a selected limit, unlisted tolerance, host equality, or ambient completeness object. □

Theorem 8203.3 (Regular-Cauchy tail-budget comparison Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing read that uses an accepted* $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$ *packet factors first through the finite route*

$$S, R, D, B_0, B_1, E, H, C, P, N.$$

The route may certify that the two displayed tail budgets agree on the shared window, that one displayed budget refines the other, or that comparison stops at a finite obstruction row. It does not expose a selected real, a quotient of Cauchy streams, a host comparison of limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the source and window binding obligation from Definition 8203.2. It forces both budget reads through the same S, R, D surface before any endpoint row can be inspected.

Next read the classifier comparison obligation. The endpoint E records only the finite budget comparison over those displayed rows, so refinement or obstruction data remain tied to the two listed budget rows rather than to an external order on completed reals.

Finally use ledger non-escape and real-seal routing. The structural rows H, C, P, N transport, replay, source, and name the same finite route, and no coordinate exists for a selected limit, quotient stream, host comparison, countable choice, or ambient completeness theorem. Thus every Real or Completion consumer receives the comparison only through the displayed packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}$ packet is generated from a shared StreamName window, a RegSeqRat regular readback, a DyadicRatCore tolerance row, two displayed tail-budget rows, a comparison endpoint, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8203.1, Definition 8203.2, and Definition 8203.3 seed the finite L10 Real and Completion surface for comparing two displayed regular-Cauchy tail budgets.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailBudgetComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected limits, quotient stream equality, host real comparison, countable choice, ambient RealUp completeness, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window binding, classifier comparison, hsame stability, ledger non-escape, Real seal routing, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailBudgetCompar

Chapter 8204

A Concrete Naming Certificate for $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$

Following Bishop and Bridges on constructive completion and Mac Lane on Kan extensions, the $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ packet records the finite universal-mapping surface obtained when a Cauchy completion route is read as a displayed Kan-extension comparison. It sits between the completion spine of chapter 126, chapter 301, chapter 38, chapter 423, chapter 1456, and chapter 2319, and the categorical universal surface of chapter 3927. The packet names the source, dense embedding, completion seal, extension candidate, comparison natural transformation, uniqueness ledger, handoff, transport, replay, provenance, and local NameCert rows without importing quotient completions, selected limits, host completed spaces, or an external functor category.

Definition 8204.1 (Cauchy completion Kan-extension carrier)**.** *A* $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, D, Q, E, L, \eta, U, W, H, C, P, N)$$

with the following displayed rows:

1. *S is the Cauchy completion source row, recording the metric or finite-window source together with its* $\mathsf{StreamName}^{\uparrow}$ *observations.*
2. *D is the dense embedding row, admitting the source observations into the completion-facing boundary.*
3. *Q is the completion seal row, read through the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff rather than through quotient completion equality.*
4. *E is the extension candidate row, carrying the completion-facing map that extends a finite-window consumer.*
5. *L is the Kan-extension row, presenting the same extension candidate as a displayed* $\mathsf{KanExtension}^{\uparrow}$ *mediator.*
6. *η is the comparison natural-transformation row from the source-side consumer to the composite completion-facing route.*
7. *U is the uniqueness ledger, comparing two extension mediators only after their dense-source and comparison rows have been displayed.*

8. *W is the* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff row, exposing finite windows, regular rational readback, and terminal real-name sealing before any completion consumer inspects E or L.*
9. *H stores componentwise* hsame *transport for source, dense embedding, completion seal, extension candidate, Kan-extension mediator, comparison transformation, uniqueness, handoff, replay, provenance, and local naming rows.*
10. *C stores displayed* Cont *replay from a source request through $S, D, Q, E, L, \eta, U, W, H$ and back to the same finite universal-mapping surface.*
11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionAd}$ $\mathsf{CauchyCompletionUniversalProperty}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{KanExtension}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionKanExtension}^{\uparrow}}$ *row.*

The carrier contains no quotient of Cauchy names, selected representative, host completed metric space, countable-choice schedule, ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, or external functor-category object.*

Theorem 8204.2 (Cauchy completion Kan-extension NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ *carrier $K = (S, D, Q, E, L, \eta, U, W, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionK}}$ *surface consists exactly of carrier admission for the displayed tuple, source exposure through S, dense embedding through D, completion sealing through Q, extension-candidate exposure through E, Kan-extension mediator exposure through L, comparison natural-transformation exposure through η, uniqueness through U,* $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *handoff through W, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8204.1. The rows S, D, Q give the source, dense embedding, and completion seal; the rows E, L, η, U give the extension candidate, Kan-extension mediator, comparison transformation, and uniqueness ledger.

The handoff row W fixes the constructive completion route. It exposes the finite $\mathsf{StreamName}^{\uparrow}$ observations, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and terminal $\mathsf{Real}^{\uparrow}$ seal before either the extension row or the Kan-extension mediator may be read as a universal object.

Finally, H, C, P, N transport, replay, source, and name exactly the same packet. Since the carrier has no coordinate for quotient completion, selected representatives, host completed spaces, countable choice, ambient completeness, or an external functor category, the listed rows exhaust the local NameCert surface. □

Theorem 8204.3 (Cauchy completion Kan-extension universal route)**.** *Every public universal-mapping read of an accepted* $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchyCompletionFunctor}^{\uparrow} \longmapsto \mathsf{CauchyCompletionUniversalProperty}^{\uparrow} \mapsto$$

together with the dense embedding, comparison natural-transformation, uniqueness, transport, replay, provenance, and local naming rows of Definition 8204.1. The route exports no quotient completion, selected limit, host completed space, countable-choice family, ambient Real completeness, or external functor-category equality.

Proof. Begin with the finite completion handoff. The source row S exposes the finite windows, the dense row D admits them into the completion-facing boundary, and W forces the read through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ before the completion seal Q is available.

Next read the universal data. The extension candidate E is attached to the same completion seal, and the Kan-extension row L presents that extension as a displayed mediator. The comparison row η records the source-side natural transformation, while the uniqueness ledger U compares mediators only over the same dense-source comparison.

The structural rows preserve the route. The rows H and C transport and replay the displayed data, and P, N record its provenance and local name. No carrier row remains from which a quotient completion, selected limit, host completed space, choice schedule, ambient completeness theorem, or external functor-category equality could be read. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ universal read must expose the Cauchy source, dense embedding, completion seal, extension candidate, comparison natural-transformation row, uniqueness ledger, $\mathsf{StreamName}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ handoff, transport, replay, provenance, and local naming rows before a Kan-extension consumer may inspect the mediator.

Independence witness: cauchycompletionfunctor, cauchy-completion-adjunction, cauchy-completion-universal-property, completionuniversalproperty, kan-extension, streamname, regseqrat, real: CauchyCompletionKa is not bijective to any listed sibling because it jointly carries the constructive completion handoff and the Kan-extension comparison-and-uniqueness surface in one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionKanExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionKanExtension}^{\uparrow}$ packet is generated from a Cauchy completion source, dense embedding, completion seal, extension candidate, Kan-extension mediator, comparison natural-transformation row, uniqueness ledger, StreamName/RegSeqRat/Real handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKanExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8204.1, Definition 8204.2, and Definition 8204.3 seed the finite universal-mapping surface connecting constructive Cauchy completion to the Kan-extension mediator.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionKanExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion, selected limits, host completed spaces, countable choice, ambient Real completeness, external functor-category equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense embedding exactness, completion-seal handoff, comparison natural-transformation routing, uniqueness-ledger exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionKanExtensionUp.

Chapter 8205

A Concrete Naming Certificate for $\mathsf{UniformLimitDerivative}^{\uparrow}$

Following Bishop and Bridges, and the standard Rudin termwise-differentiation theorem, the $\mathsf{UniformLimitDerivative}^{\uparrow}$ packet records the finite BEDC route by which a sequence of differentiable real-valued names with uniformly convergent derivative rows and one convergent base-point row yields a derivative handoff for the displayed limit. It sits after the derivative certificate of chapter 122, the regular-Cauchy uniform-limit route of chapter 6460, the continuity boundary of chapter 1748, and the integral-side neighbor of chapter 8198. The packet names only the displayed termwise-differentiation route through finite histories; it does not import open-cover compactness, quotient function equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or full calculus.

Definition 8205.1 (Uniform limit derivative carrier)**.** *A* $\mathsf{UniformLimitDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, G, U, B, R, J, H, C, P, N)$$

with the following displayed rows:

1. *F is the sequence row listing differentiable* $\mathsf{Real}^{\uparrow}$ *maps together with their common interval window and their local* $\mathsf{Derivative}^{\uparrow}$ *certificates.*
2. *G is the derivative-sequence row, recording the displayed derivative names produced componentwise from F.*
3. *U is the uniform derivative-limit row through* $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$*, carrying the shared modulus and derivative-limit readback.*
4. *B is the base-point convergence row, read through* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, recording that one displayed point has a regular-Cauchy value limit for the original sequence.*
5. *R is the regular-Cauchy reconstruction row that combines U and B into the limit-function readback route.*
6. *J is the derivative handoff row, exposing the derivative of the limit only after the derivative-limit and base-point rows have been displayed.*
7. *H records componentwise* hsame *transport for F, G, U, B, R, J.*
8. *C records displayed* Cont *replay through the differentiability, uniform derivative-limit, base-point convergence, regular-Cauchy reconstruction, and derivative-handoff rows.*

9. *P is the* Pkg *provenance over* $\mathsf{UniformLimitDerivative}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RegularCauchyUniformLimit}^{\uparrow}$, $\mathsf{UniformLimitContinuous}^{\uparrow}$, $\mathsf{UniformLimitIntegral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformLimitDerivative}^{\uparrow}}$ *row.*

The carrier has no coordinate for an open-cover compactness principle, quotient equality of functions, selected host limits, ambient completeness of $\mathsf{Real}^{\uparrow}$*, unrestricted integration, Taylor expansion, inverse-function reasoning, or a full calculus library.*

Theorem 8205.2 (Uniform limit derivative NameCert obligations)**.** *For the carrier of Definition 8205.1, the local* $\mathsf{NameCert}_{\mathsf{UniformLimitDerivative}^{\uparrow}}$ *surface consists exactly of sequence admission through F, componentwise derivative exposure through G, uniform derivative-limit exposure through U, base-point regular-Cauchy convergence through B, limit readback through R, derivative handoff through J, componentwise transport through H, displayed continuation replay through C, package provenance through P, local naming through N, and non-escape for open-cover compactness, quotient function equality, selected limits, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, and full calculus.*

Proof. Project the carrier rows of Definition 8205.1. The differentiable sequence, derivative sequence, uniform derivative-limit, base-point convergence, limit readback, and derivative handoff are separate displayed coordinates before the local name is consumed.

The structural rows H, C, P, N preserve that same route under transport, replay, provenance, and local naming. Since the carrier has no coordinate for open-cover compactness, quotient function equality, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a full calculus interface, the listed rows exhaust the local NameCert surface. □

Theorem 8205.3 (Uniform limit derivative Cauchy route)**.** *Every accepted* $\mathsf{UniformLimitDerivative}^{\uparrow}$ *packet exposes the termwise-differentiation read only through the finite route*

$$F \longmapsto G \longmapsto U \longmapsto B \longmapsto R \longmapsto J \longmapsto H, C, P, N.$$

The derivative handoff J is downstream of both the uniformly convergent derivative sequence and the base-point $\mathsf{RegSeqRat}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *convergence row; it is not available from a quotient equality of functions, a selected limiting function, ambient completeness, open-cover compactness, or an unrestricted calculus principle.*

Proof. Use the NameCert obligations of Definition 8205.2. They expose F, G, U, B, R, J as ordered carrier rows and place the derivative handoff after the uniform derivative-limit row and the base-point convergence row.

Read the Cauchy data next. The row U supplies the shared derivative-limit modulus, while B supplies the single base-point regular-Cauchy convergence needed to reconstruct the displayed limit-function route R.

Finally replay through H, C, P, N. Transport and continuation keep the same finite route visible, and provenance records the derivative, uniform-limit, continuity, integral-neighbor, regular-Cauchy, and Real packets without adding host function equality, selected limits, ambient completeness, open-cover compactness, or a full calculus endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformLimitDerivative}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformLimitDerivative}^{\uparrow}$ packet is generated from differentiable RealUp map rows, their derivative rows, a uniform derivative-limit row, a base-point regular-Cauchy convergence row, limit readback, derivative handoff, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UniformLimitDerivative}^{\uparrow}}$, seed)

Scope closed: Definition 8205.1, Definition 8205.2, and Definition 8205.3 seed the finite termwise-differentiation route over Derivative$^{\uparrow}$, RegularCauchyUniformLimit$^{\uparrow}$, UniformLimitContinuous$^{\uparrow}$, UniformLimitIntegral$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\text{UniformLimitDerivative}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient function equality, selected limits, ambient Real$^{\uparrow}$ completeness, unrestricted integration, Taylor expansion, inverse-function reasoning, full calculus, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative-sequence exposure, uniform derivative-limit exposure, base-point regular-Cauchy convergence, derivative handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformLimitDerivativeUp.

Chapter 8206

A Concrete Naming Certificate for $\mathsf{LedgerModeClassifier}^{\uparrow}$

The $\mathsf{LedgerModeClassifier}^{\uparrow}$ packet realizes the evidence-mode taxonomy of section 9462.6 as finite NameCert data. It sits beside the hard-certificate layer of section 9462.5, the certified model-quality ledger of chapter 6625, the positive interpretability classifier of chapter 6202, and the tensor-source certificate surface of chapter 87. The carrier names evidence modes, mode completeness, hardening frontier, ledger-only residue, transport, replay, provenance, and local naming as one classifier packet rather than as a prose taxonomy.

Definition 8206.1 (Ledger-mode classifier carrier)**.** *A* $\mathsf{LedgerModeClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, C, F, R, G, H, T, P, N)$$

with the following displayed rows:

1. *E is the evidence-mode row, recording for each classifier-relevant NameCert field whether its support is empirical, paper, formal, hybrid, ledger-only, or open.*
2. *C is the mode-completeness row, asserting that every source, pattern, classifier, stability, and ledger field has a declared mode and that no accepted row remains open.*
3. *F is the hardening-frontier row, listing the hardenable rows that are not yet hardened and separating them from the non-hardenable residue.*
4. *R is the ledger-only residue row, recording the exact non-hardenable or not-yet-hardened residue that must remain visible to classifier-strength consumers.*
5. *G is the gap-refusal row, refusing any classifier-strength read when a required evidence-mode row, hardening-frontier row, or ledger-only residue row is absent.*
6. *H records componentwise* hsame *transport for evidence modes, mode completeness, hardening frontier, residue exactness, gap refusal, replay, provenance, and local naming.*
7. *T records displayed* Cont *replay from a classifier-strength request through E, C, F, R, G, H and back to the same ledger-mode surface.*
8. *P is the* Pkg *provenance over* $\mathsf{LedgerModeClassifier}^{\uparrow}$*, the hard-certificate layer, certified model quality, positive interpretability classifier novelty, Tensor NameCert,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{LedgerModeClassifier}^{\uparrow}}$ *row.*
The carrier has no coordinate for a hidden hardened proof, unledgered classifier strength, open-mode acceptance, certified model quality by itself, interpretability novelty by itself, or Tensor NameCert field by itself.

Theorem 8206.2 (Ledger-mode classifier NameCert obligations)**.** *For every accepted* $\mathsf{LedgerModeClassifier}^{\uparrow}$ *carrier* $M = (E, C, F, R, G, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LedgerModeClassifier}^{\uparrow}}$ *surface consists exactly of evidence-mode exposure through* E*, mode-completeness through* C*, hardening-frontier exposure through* F*, ledger-only residue exactness through* R*, gap refusal through* G*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* T*,* Pkg *provenance through* P*, and local naming through* N*. Any classifier-strength consumer must read those rows before it may inspect ledger-only status.*

Proof. Project the carrier in Definition 8206.1. The rows E, C, F, R, G are the analytic rows: they display evidence modes, certify mode completeness, expose the hardening frontier, record the ledger-only residue, and refuse gap-bearing reads.

The structural rows H and T preserve and replay the same surface. A transported or replayed classifier-strength request therefore still carries the evidence-mode ledger and hardening-frontier exposure before ledger-only status is inspected.

The provenance and local naming rows P, N attach the packet to its philosophy and model-quality siblings. Since the carrier has no hidden hardened proof, no unledgered strength row, and no open-mode acceptance coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8206.3 (Ledger-mode classifier consumer boundary)**.** *Every accepted* $\mathsf{LedgerModeClassifier}^{\uparrow}$ *read exposes its evidence-mode ledger* E*, mode-completeness row* C*, hardening-frontier row* F*, ledger-only residue row* R*, and gap-refusal row* G *before any certified model-quality, interpretability-novelty, Tensor NameCert, or classifier-strength consumer may inspect ledger-only status. A consumer that omits any of these rows is outside the accepted ledger-mode classifier surface.*

Proof. Read the NameCert obligations. They require E, C, F, R, G as the analytic rows of every accepted packet, with H, T, P, N preserving, replaying, sourcing, and naming the same data.

The certified model-quality, interpretability-novelty, Tensor NameCert, and classifier-strength consumers named by P receive only the exported packet. If such a consumer omits E, it cannot determine evidence mode; if it omits C, it cannot determine mode completeness; if it omits F or R, it cannot separate hardenable frontier from ledger-only residue; and if it omits G, it cannot refuse a mode gap.

Thus ledger-only status is not a free-standing predicate. It is inspected only after the displayed evidence-mode, completeness, frontier, residue, and refusal rows have been read. □

Theorem 8206.4 (Ledger-mode classifier TasteGate boundary)**.** *The future Lean* `TasteGate.lean` *development for* $\mathsf{LedgerModeClassifier}^{\uparrow}$ *must provide explicit* $\mathsf{Nontrivial}\ \mathsf{LedgerModeClassifier}^{\uparrow}$ *and* $\mathsf{FieldFaithful}\ \mathsf{LedgerModeClassifier}^{\uparrow}$ *instances for the carrier of Definition 8206.1. Nontriviality must separate an accepted mode-complete ledger from a gap-bearing candidate, and field faithfulness must preserve* $E, C, F, R, G, H, T, P, N$ *as distinct rows before a classifier-strength consumer can cite a checked carrier-alignment theorem.*

Proof. Nontriviality is forced by the gap-refusal row. A packet with declared evidence modes, mode completeness, hardening-frontier exposure, and ledger-only residue exactness is not the same carrier as one whose mode or frontier row is absent.

Field faithfulness is forced by the consumer boundary. Dropping E, C, F, R, or G changes which classifier-strength reads are legal, while dropping H, T, P, N changes transport, replay, provenance, or local naming.

Therefore a checked TasteGate surface must keep the accepted and refused sides distinct and must preserve all nine displayed rows. Otherwise ledger-only status could be inspected without the finite evidence-mode ledger that defines it. □

Falsifiable prediction: Every accepted $\mathsf{LedgerModeClassifier}^{\uparrow}$ read must display its evidence-mode ledger and hardening-frontier row before any classifier-strength consumer may inspect ledger-only status.

Independence witness: hard-certificate-layer, certified-model-quality, interpretability-classifier-novelty, tensor-namecert: $\mathsf{LedgerModeClassifier}^{\uparrow}$ is not bijective to these siblings because it jointly carries mode declarations, gap refusal, hardening-frontier exposure, and ledger-only residue exactness.

Closure status for $\mathsf{NameCert}_{\mathsf{LedgerModeClassifier}^{\uparrow}}$.

Constructive story: A $\mathsf{LedgerModeClassifier}^{\uparrow}$ packet is generated from evidence-mode rows, mode completeness, a hardening-frontier ledger, ledger-only residue exactness, gap refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LedgerModeClassifier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8206.1, Definition 8206.2, Definition 8206.3, and Definition 8206.4 seed the finite classifier surface for evidence modes, mode gaps, hardening frontier, and ledger-only residue.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LedgerModeClassifier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim checked TasteGate instances, certified model quality, interpretability classifier novelty, Tensor NameCert completeness, formal hardening of any row, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, evidence-mode exactness, mode-completeness refusal, hardening-frontier exposure, ledger-only residue exactness, nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.LedgerModeClassifierUp.

Chapter 8207

A Concrete Naming Certificate for $\mathsf{BisectionCauchy}^{\uparrow}$

Following Bishop and Bridges on constructive nested intervals and regular real names, the $\mathsf{BisectionCauchy}^{\uparrow}$ packet records the finite route by which located interval bisection data are read as a regular Cauchy rational name. It consumes the located bisection surface of chapter 1711, the closed bounded interval endpoint carrier of chapter 1591, the dyadic tolerance ledger of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the textbook interval-bisection-to-regular-Cauchy handoff as finite BEDC data; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, choose an infinite branch, quotient Cauchy streams, or select a host real.

Definition 8207.1 (Bisection Cauchy carrier)**.** *A* $\mathsf{BisectionCauchy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, L, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source interval row, including endpoint containment and the displayed starting width.*
2. *L is the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *ledger whose finite stages retain a located subinterval and record the side decision used at each bisection.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint, radius, and tolerance row used to measure the retained interval diameters.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the bisection stages inspected by the downstream Cauchy request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row formed from the retained dyadic centers and their displayed error budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the interval, bisection, dyadic, stream, and regular-rational rows have been exposed.*
7. *H records componentwise* hsame *transport for the interval, bisection, dyadic, stream, regular-rational, real-seal, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing request through I, L, D, W, R, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{BisectionCauchy}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BisectionCauchy}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, D, W, R, E, H, C, P, N$. It has no coordinate for a chosen infinite branch, quotient stream equality, host real equality, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8207.2 (Bisection Cauchy NameCert obligations)**.** *For every accepted* $\mathsf{BisectionCauchy}^{\uparrow}$ *carrier*

$$B = (I, L, D, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BisectionCauchy}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the closed bounded source interval, located bisection ledger, dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, transport, replay, provenance, and local naming rows;*
2. *source agreement, requiring I and L to name the same displayed interval before any midpoint or retained half is read;*
3. *dyadic diameter control, requiring each retained half in L to expose its midpoint and width through D;*
4. *finite-window extraction, requiring W to list only stages already present in the located bisection ledger;*
5. *regular-readback handoff, requiring R to read retained centers with the dyadic error budgets supplied by D before E is exposed;*
6. *non-escape, excluding chosen infinite branches, quotient stream equality, host real equality, countable choice, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the local certificate.*

No NameCert obligation is stored outside $I, L, D, W, R, E, H, C, P, N$.

Proof. Carrier admission is projection from Definition 8207.1. The displayed packet provides exactly the source interval, located bisection ledger, dyadic ledger, finite windows, regular readback, terminal seal, transport, replay, provenance, and local naming rows.

Source agreement is read through I and L. The bisection ledger has no independent interval source; every retained half is a row below the closed bounded interval named by I.

Dyadic diameter control is supplied by D. Each bisection stage replaces one retained interval by a displayed half and records the midpoint and width needed for the next finite tolerance request.

The stream window W only selects finitely many already displayed stages. The regular readback R then reads the retained centers together with their dyadic error budgets, and the terminal seal E is visible only after that readback.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no coordinate for chosen infinite branches, quotient stream equality, host real equality, countable choice, selected representatives, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8207.3 (Bisection Cauchy RegSeqRat handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BisectionCauchy}^{\uparrow}$ *packet must read the finite route*

$$I, L, D \longmapsto W, R, E \longmapsto H, C, P, N$$

before it can treat the bisection data as a $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy name or pass the result to the terminal* $\mathsf{Real}^{\uparrow}$ *seal. The consumer receives closed bounded interval data, located bisection stages, dyadic midpoint and diameter budgets, finite stream windows, regular rational readback, componentwise transport, continuation replay, provenance, and local naming. It receives no chosen infinite branch, quotient Cauchy stream, selected representative, countable-choice schedule, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the source interval and bisection ledger. The row I supplies the closed bounded interval, and L supplies the finite retained halves that a completion-facing request may inspect.

Apply the NameCert obligations of Definition 8207.2. They force the retained intervals to expose their midpoint and diameter budgets through D before any stream window is consumed.

The finite observation row W selects only displayed bisection stages. The row R reads those selected centers as a regular rational Cauchy name with the dyadic budgets supplied by D, and E is the terminal real-name seal available only after that readback.

The structural rows H, C, P, N preserve the same finite route for downstream completion consumers. Because no excluded coordinate is present in the carrier, the handoff is a regular-rational name route rather than a quotient stream, selected limit, countable-choice, host equality, or ambient-completeness assertion. □

Theorem 8207.4 (Bisection Cauchy closed-interval boundary)**.** *Every accepted* $\mathsf{BisectionCauchy}^{\uparrow}$ *packet keeps the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *source row visible until the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff has been exported. Thus a consumer that reads the terminal* $\mathsf{Real}^{\uparrow}$ *seal E also reads the original interval row I, the located bisection ledger L, and the dyadic diameter row D before any regular-rational or Real-facing output is available.*

Proof. Project the carrier of Definition 8207.1. The terminal seal E is downstream of the interval, bisection, dyadic, stream, and regular-rational rows.

Apply Definition 8207.3. The route to E factors through I, L, D, W, R before the structural rows package the output.

Therefore the closed bounded source interval remains part of every Real-facing read. The packet has no alternative Real output coordinate outside this route. □

Falsifiable prediction: An accepted $\mathsf{BisectionCauchy}^{\uparrow}$ consumer that reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without reading $I, L, D, W, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: located-interval-bisection, closedboundedinterval, dyadicratcore, streamname, regseqrat, real: no listed sibling supplies the joint packet containing the source interval, located bisection ledger, dyadic midpoint and diameter rows, finite windows, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BisectionCauchy}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BisectionCauchy}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp source, a LocatedIntervalBisectionUp ledger, DyadicRatCore midpoint and diameter budgets, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BisectionCauchy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8207.1, Definition 8207.2, and Definition 8207.3 seed the finite interval-bisection route from closed bounded interval and dyadic rows to regular Cauchy and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BisectionCauchy}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, chosen infinite branches, quotient Cauchy streams, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, dyadic diameter control, finite-window extraction, regular-readback handoff, and non-escape for BEDC.Derived.BisectionCauchyUp.

Chapter 8208

A Concrete Naming Certificate for $\mathsf{DyadicIntervalChain}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicIntervalChain}^{\uparrow}$ packet records a finite chain of dyadic interval cells whose inspected endpoints, nesting ledger, stream windows, regular rational readback, and terminal real-name seal are all displayed before any completion-facing consumer reads the route. It sits after the dyadic endpoint arithmetic of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the finite interval-cover ledger of chapter 5105. The packet is a finite interval-chain route; it is not a selected limit, quotient real equality, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8208.1 (Dyadic interval-chain carrier)**.** *A* $\mathsf{DyadicIntervalChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, N, W, Q, R, F, H, C, P, L)$$

with the following displayed rows:

1. *D is the finite list of dyadic interval-cell rows, each row naming lower and upper* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoints and its mesh scale.*
2. *N is the nesting ledger, recording adjacent containment, endpoint compatibility, and the inspected width budget for the chain.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the finite stage numbers and endpoint observations used by the packet.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed endpoint and width observations.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after D, N, W, Q have been replayed.*
6. *F is the finite interval-cover handoff row connecting the same cells to the finite cover surface of* $\mathsf{FiniteIntervalCover}^{\uparrow}$*.*
7. *H records componentwise* hsame *transport for dyadic cells, nesting rows, stream windows, regular readback, the Real seal, the finite-cover handoff, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from an interval-chain request through D, N, W, Q, R, F, H.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalChain}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FiniteIntervalCover}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. L is the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalChain}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, N, W, Q, R, F, H, C, P, L$. It has no coordinate for a selected nested-interval limit, quotient equality of real names, countable choice, arbitrary open covers, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8208.2 (Dyadic interval-chain NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalChain}^{\uparrow}$ *carrier*

$$I = (D, N, W, Q, R, F, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalChain}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic endpoint exposure, adjacent nesting exactness, finite window scheduling, regular rational readback, terminal Real sealing, finite interval-cover handoff, componentwise transport, displayed replay, provenance, and local naming. Every consumer must expose the dyadic rows D, the nesting ledger N, and the finite windows W before it may read Q, R, or F.*

Proof. Project the carrier of Definition 8208.1. The admitted object is exactly the ten-row packet $I = (D, N, W, Q, R, F, H, C, P, L)$, so the local name can range only over the displayed dyadic cells, nesting ledger, window row, readback row, Real seal, finite-cover handoff, transport, replay, provenance, and naming rows.

The endpoint and nesting obligations are read from D and N. The dyadic endpoint arithmetic is supplied by the $\mathsf{DyadicRatCore}^{\uparrow}$ rows, while the nesting ledger records only adjacent containment and inspected width data.

The downstream reads are ordered by the carrier. The finite windows W expose the observations used by the regular rational readback Q, the terminal seal R is reached after those rows, and the finite-cover handoff F uses the same displayed cells.

Since no other coordinate is present, the packet exports no selected limit, quotient real equality, countable choice, arbitrary open-cover compactness, or ambient completeness theorem. □

Theorem 8208.3 (Dyadic interval-chain nesting handoff)**.** *Every accepted* $\mathsf{DyadicIntervalChain}^{\uparrow}$ *packet hands a finite nested dyadic window to later* $\mathsf{Real}^{\uparrow}$ *and completion-facing consumers only through the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{FiniteIntervalCover}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff supplies displayed dyadic cells, adjacent containment, finite observation windows, regular rational readback, and a finite interval-cover row; it does not supply a selected limit point, quotient equality of real names, countable choice, arbitrary open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the accepted carrier $I = (D, N, W, Q, R, F, H, C, P, L)$. The cells D and nesting ledger N are the only source of interval-chain data, and both are dyadic rows.

The consumer then reads finite windows through W and regular rational observations through Q. The terminal seal R is downstream of those rows, while F records the finite interval-cover handoff for the same cells.

Transport and replay through H and C preserve this ordering, and P, L package and name the same packet. Therefore the handoff is the displayed finite route through the sibling rows and cannot be read as a selected limit, quotient equality, choice principle, open-cover compactness theorem, or ambient completeness theorem. □

Falsifiable prediction: Every $\mathsf{DyadicIntervalChain}^{\uparrow}$ Real-facing read exposes dyadic interval cells, adjacent nesting, finite StreamName windows, RegSeqRat readback, a finite interval-cover handoff, componentwise transport, displayed replay, provenance, and local naming before the terminal Real seal is visible.

Independence witness: dyadicratcore, streamname, regseqrat, real, finite-interval-cover: $\mathsf{DyadicIntervalChain}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite dyadic cells, adjacent nesting, finite windows, regular rational readback, a Real seal, finite interval-cover handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalChain}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalChain}^{\uparrow}$ packet is generated from finite dyadic interval-cell rows, an adjacent nesting ledger, finite StreamName windows, RegSeqRat readback, a RealUp seal, a finite interval-cover handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8208.1, Definition 8208.2, and Definition 8208.3 seed the finite dyadic interval-chain route from dyadic cells and nesting rows through finite windows, regular readback, finite-cover handoff, and a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected nested-interval limits, quotient real equality, countable choice, arbitrary open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, adjacent nesting exactness, finite window scheduling, regular rational readback, Real seal nonescape, finite interval-cover handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicIntervalChainUp.

Chapter 8209

A Concrete Naming Certificate for $\mathsf{RegularCauchyOscillationBound}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and explicit moduli of convergence, the $\mathsf{RegularCauchyOscillationBound}^{\uparrow}$ packet records the finite tail-oscillation bound by which a regular rational sequence can expose a Real-facing Cauchy control row before a terminal seal is read. It sits after the tail-diameter boundary of chapter 1746, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name chapter of chapter 38. The packet gives Real and Completion routes one local L10 source row for tail oscillation bounds; it does not choose a limit, quotient Cauchy streams, compare host real values, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8209.1 (Regular-Cauchy oscillation-bound carrier)**.** *A* $\mathsf{RegularCauchyOscillationBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (S, R, D, T, B, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window service row that selects the inspected tail windows;*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row whose values are compared on those windows;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row storing the requested oscillation radius and comparison scale;*
4. *T is the sibling* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *boundary row for the same S, R, D surface;*
5. *B is the oscillation-bound ledger, recording a finite index after which every inspected pair from S has D-bounded R-oscillation;*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, D, T, B have been displayed;*
7. *H stores componentwise* hsame *transports for the stream, regular readback, dyadic tolerance, tail-diameter, bound, seal, provenance, and local naming rows;*
8. *C stores displayed* Cont *replay routes for reading the tail windows, comparing the regular rational values, exposing the bound ledger, and handing the result to a Real-facing consumer;*
9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyOscillationBound}^{\uparrow}$, $\mathsf{CauchyTailDiameter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected limit, quotient stream equality, host real equality, unlisted tolerance, countable choice, or ambient completion theorem.

Theorem 8209.2 (Regular-Cauchy oscillation-bound NameCert obligations)**.** *For the carrier of Definition 8209.1, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationBound}^{\uparrow}}$ *surface consists of six finite obligations:*

1. *source binding: the bound ledger B reads the displayed* $\mathsf{StreamName}^{\uparrow}$ *window S,* $\mathsf{RegSeqRat}^{\uparrow}$ *source row R, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D;*
2. *tail-diameter anchoring: the sibling* $\mathsf{CauchyTailDiameter}^{\uparrow}$ *row T is read before any oscillation-bound consumer may inspect the terminal seal;*
3. *bound exactness: B records a finite tail index and a displayed pairwise comparison route witnessing D-bounded oscillation for the inspected tail windows;*
4. *stability: componentwise* hsame *transport through H preserves the same source, tolerance, tail-diameter, bound, seal, replay, provenance, and naming rows;*
5. *ledger non-escape: every downstream consumer of the oscillation bound factors through $S, R, D, T, B, E, H, C, P,$*
6. *real-seal routing: a* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer can read the terminal seal only after the stream window, regular readback, dyadic tolerance, tail-diameter boundary, oscillation-bound ledger, transport, replay, provenance, and local naming rows have been exposed.*

Proof. Carrier admission is projection from the displayed tuple $O = (S, R, D, T, B, E, H, C, P, N)$. The source binding clause reads the stream window, regular-rational values, and dyadic tolerance before any oscillation statement is available.

The tail-diameter and bound clauses are local. The row T supplies the sibling diameter boundary for the same displayed data, while B records the finite index and pairwise comparison route that make the requested oscillation bound visible on the inspected tail.

Stability and replay are supplied by H and C. Componentwise transport keeps every row over the same source data, and the continuation routes replay the window read, rational comparison, bound exposure, and Real-facing handoff in that order.

The non-escape and seal clauses follow from absence of extra coordinates. A $\mathsf{Real}^{\uparrow}$ or completion-facing consumer sees only the listed packet rows, so the certificate cannot export a selected limit, quotient stream equality, host comparison, countable choice, or ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationBound}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyOscillationBound}^{\uparrow}$ packet is generated from a finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, CauchyTailDiameter boundary, oscillation-bound ledger, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationBound}^{\uparrow}}$, seed)

Scope closed: Definition 8209.1 and Definition 8209.2 seed the finite L10 Real and Completion surface for regular-Cauchy tail oscillation bounds.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyOscillationBound}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, selected limits, quotient stream equality, host real comparison, countable choice, ambient RealUp completeness, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source binding, tail-diameter anchoring, bound exactness, hsame stability, ledger non-escape, Real seal routing, replay, provenance, and local naming for BEDC.Derived.RegularCauchyOscillati

Chapter 8210

A Concrete Naming Certificate for $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy real names, the $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ packet records the finite cofinal-modulus route by which a regular Cauchy name is read through a cofinal schedule without changing its modulus-controlled Real seal. The route sits over the dyadic tolerance carrier of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the reindexing handoff of chapter 1568.

Definition 8210.1 (RegularCauchyCofinalModulus carrier)**.** *A* $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, K, U, D, W, R, E, H, C, P, N)$$

with the following visible rows:

1. *S is the source regular Cauchy data row.*
2. *K is the cofinal schedule row, recording the finite monotone route along which the source is read.*
3. *U is the modulus row that assigns a displayed request bound to the cofinal schedule.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the modulus.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the cofinal schedule.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row on those windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached after the modulus, tolerance, window, and readback rows have been displayed.*
8. *H records componentwise* hsame *transport for S, K, U, D, W, R, E and the structural rows.*
9. *C records displayed* Cont *replay of the same cofinal-modulus route.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$*,* $\mathsf{CauchyReindexing}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, a selected representative, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.RegularCauchyCofinalModulusUp`

Theorem 8210.2 (RegularCauchyCofinalModulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ *carrier* $M = (S, K, U, D, W, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalMo}}$ *surface consists exactly of source regular Cauchy admission through* S*, cofinal schedule exposure through* K*, modulus-row exposure through* U*, dyadic tolerance exposure through* D*, StreamName windows through* W*, RegSeqRat readback through* R*, Real sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

No accepted read exports quotient stream equality, a selected representative, countable choice, host real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8210.1. Its analytic route is S, K, U, D, W, R, E, and its structural route is H, C, P, N.

The source row S is read only through the cofinal schedule K. The modulus row U then binds each displayed request to the same cofinal route, while the dyadic tolerance row D records the requested error surface.

The window and readback rows W and R expose the finite StreamName and RegSeqRat data before the terminal Real seal E is consumed. Transport, replay, provenance, and local naming preserve this same packet through H, C, P, N.

Since the carrier contains no row for quotient stream equality, representatives, choice, host equality, trichotomy, or ambient completeness, the listed rows exhaust the NameCert obligation surface. □

Theorem 8210.3 (RegularCauchyCofinalModulus Real handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{CauchyReindexing}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{StreamName}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

through the displayed rows K, D, W, R, E *before the* $\mathsf{Real}^{\uparrow}$ *seal is exported. The cofinal schedule preserves the modulus-controlled seal only as this finite packet route; it is not a quotient of regular Cauchy names, a selected host real, a countable-choice schedule, or an ambient completeness theorem.*

Proof. Start with the obligation surface of Definition 8210.2. It orders the source, cofinal schedule, modulus, dyadic tolerance, window, readback, and seal rows before any Real-facing consumer can inspect the packet.

Read the cofinal schedule row K as the handoff to chapter 1568. The row does not create a second stream; it only records the displayed cofinal route along which the source regular Cauchy data are inspected.

The dyadic, stream, and regular-readback rows D, W, R then route the same requests through chapter 291, chapter 126, and chapter 301. Only after those rows have been replayed may the consumer read the terminal $\mathsf{Real}^{\uparrow}$ seal E of chapter 38.

The structural rows H, C, P, N preserve the same finite route. Because no row supplies quotient equality, selected representatives, choice, host equality, or ambient completeness, the Real handoff is exactly the displayed cofinal-modulus route. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ Real-facing read exposes source regular Cauchy data, a cofinal schedule, a modulus row, DyadicRatCore tolerance, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local NameCert before the Real seal is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchyreindexing, regularcauchycofinalmodulus: $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the source regular Cauchy row, cofinal schedule, modulus row, tolerance, windows, readback, Real seal, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyCofinalModulus}^{\uparrow}$ packet is generated from source regular Cauchy data, a cofinal schedule, a modulus row, DyadicRatCore tolerance, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8210.1, Definition 8210.2, and Definition 8210.3 seed the finite cofinal-modulus route over the L10 Real path.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyCofinalModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient equality of regular Cauchy names, selected representatives, countable choice, trichotomy, host real equality, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal schedule exposure, modulus preservation, dyadic tolerance exactness, window readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCofinalModulusUp.

Chapter 8211

A Concrete Naming Certificate for NavierStokesFiniteEnergy$^{\uparrow}$

Following Leray and Temam, the NavierStokesFiniteEnergy$^{\uparrow}$ packet records the finite-energy weak-solution surface for the incompressible Navier-Stokes equations as BEDC carrier data. It sits over the PDE relation row of chapter 194, the finite-window comparison discipline of chapter 193, the Sobolev weak-velocity packet of chapter 440, the tagged energy-readback surface of chapter 1526, and the boundary-trace accounting of chapter 398. The packet names only the displayed finite-energy route; it does not assert global smoothness, uniqueness, Clay Millennium problem resolution, measure completion, classical weak compactness, or a host pressure quotient.

Definition 8211.1 (Navier-Stokes finite-energy carrier)**.** *A* NavierStokesFiniteEnergy$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (D, V, R, E, W, B, H, C, P, M)$$

with the following displayed rows:

1. *D is the* Pde$^{\uparrow}$ *source row naming the incompressible Navier-Stokes relation, including the displayed velocity, pressure, viscosity, forcing, divergence-free, and initial-data slots.*
2. *V is the* Sobolev$^{\uparrow}$ *weak velocity-field row, read as a finite Sobolev packet for the velocity and its weak-gradient observations.*
3. *R is the pressure and residual row, recording the displayed pressure term, divergence constraint residual, forcing residual, and weak-form defect ledger without quotienting pressure by a host constant.*
4. *E is the energy-inequality ledger, read through* RiemannIntegral$^{\uparrow}$ *rows for kinetic-energy and dissipation windows.*
5. *W is the finite time-window readback row. It names the time interval, endpoint observations, and ODE-facing comparison route used only as a finite evolution window.*
6. *B is the boundary row, recording no-slip, periodic, compact-support, or explicitly listed boundary data through bounded-variation and trace-facing ledgers.*
7. *H records componentwise* hsame *transport for the PDE source, weak velocity, pressure-residual, energy, time-window, boundary, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay through D, V, R, E, W, B before a consumer reads the finite-energy packet.*

9. *P is the* Pkg *provenance over* $\mathsf{NavierStokesFiniteEnergy}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Sobolev}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *M is the local* $\mathsf{NameCert}_{\mathsf{NavierStokesFiniteEnergy}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these rows. It has no coordinate for a smooth global solution, a uniqueness theorem, a measure-completed function space, a compactness extraction theorem, or a quotient pressure representative.

Theorem 8211.2 (Navier-Stokes finite-energy NameCert obligations)**.** *For every accepted* NavierStokesFiniteEnergy *carrier $N = (D, V, R, E, W, B, H, C, P, M)$, the local* $\mathsf{NameCert}_{\mathsf{NavierStokesFiniteEnergy}^{\uparrow}}$ *surface consists exactly of PDE-source admission, Sobolev weak-velocity exposure, pressure and residual ledger visibility, energy-inequality readback, finite time-window readback, boundary-row exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission projects the displayed packet of Definition 8211.1. The analytic source is the PDE row D, while the weak velocity is read through the Sobolev row V and the pressure-residual ledger R.

The energy and time-window obligations are separate rows. The energy inequality is read through E and its Riemann-integral provenance, while W records only the finite evolution window and endpoint observations.

The boundary and structural obligations are then visible through B, H, C, P, M. These rows transport, replay, source, and name the displayed carrier without adding smoothness, uniqueness, compactness extraction, measure completion, or pressure quotient data. □

Theorem 8211.3 (Navier-Stokes finite-energy nonescape)**.** *Every finite-energy read exported by an accepted* $\mathsf{NavierStokesFiniteEnergy}^{\uparrow}$ *carrier factors through*

$$D, V, R, E, W, B, H, C, P, M.$$

It may expose the PDE source, Sobolev weak velocity, pressure-residual ledger, energy inequality, finite time-window, boundary row, transport, replay, provenance, and local NameCert *evidence, but it cannot export global smoothness, uniqueness, Clay Millennium problem resolution, measure completion, classical weak compactness, or a host pressure quotient.*

Proof. Start with the route displayed in Definition 8211.1. Each consumer-facing read begins at the PDE row D and then consumes the weak velocity V, pressure-residual ledger R, energy ledger E, finite time-window W, and boundary row B.

The structural rows H, C, P, M preserve the same finite route under transport, replay, provenance, and local naming. They do not introduce a second analytic source or a hidden host object.

The excluded claims are absent by carrier inspection. No row names global smoothness, uniqueness, the Clay Millennium problem, measure completion, classical weak compactness, or a quotient pressure representative, so those claims cannot be recovered from an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{NavierStokesFiniteEnergy}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NavierStokesFiniteEnergy}^{\uparrow}}$, seed)

Scope closed: Definition 8211.1, Definition 8211.2, and Definition 8211.3 seed the finite-energy PDE carrier, NameCert obligation surface, and nonescape boundary.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NavierStokesFiniteEnergy}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, global smoothness, uniqueness, Clay Millennium problem resolution, measure completion, classical weak compactness, host pressure quotients, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, PDE-source exactness, Sobolev weak-velocity exposure, pressure-residual visibility, energy-window readback, boundary-row exposure, transport, replay, provenance, and local naming for BEDC.Derived.NavierStokesFiniteEnergyUp.

Constructive story: A NavierStokesFiniteEnergy$^{\uparrow}$ packet is generated from PDE source rows, Sobolev weak velocity rows, pressure and residual rows, energy inequality ledgers, finite time-window readbacks, boundary rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8212

A Concrete Naming Certificate for $\mathsf{PriestleySpace}^{\uparrow}$

Following Priestley and Davey–Priestley, the $\mathsf{PriestleySpace}^{\uparrow}$ packet records the ordered topological carrier used by Priestley duality as finite BEDC NameCert data. It sits after the meet–join order surface of chapter 55, the bounded endpoint rows of chapter 6501, the indexed-open carrier of chapter 88, the clopen ledger of chapter 261, and the duality-theorem packet of chapter 5166. The chapter separates the ordered topological carrier from the representation theorem: it names compact ordered clopen-upset observations, not selected prime filters, an ultrafilter construction, a powerset topology, quotient lattice equality, or a choice principle.

Definition 8212.1 (Priestley space carrier)**.** *A* $\mathsf{PriestleySpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, T, K, U, D, H, C, P, N)$$

with the following displayed rows:

1. *O is the bounded distributive-order row, read through* $\mathsf{Lattice}^{\uparrow}$ *meet–join observations and* $\mathsf{BoundedLattice}^{\uparrow}$ *endpoint rows.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open row, listing the finite open-neighbourhood observations available to the carrier.*
3. *K is the Stone-facing clopen ledger inherited from chapter 261, restricted to displayed clopen rows rather than host subsets.*
4. *U is the clopen-upset row, recording which displayed clopen rows are upward closed for the order observations in O.*
5. *D is the Priestley separation row: for displayed ordered observations whose order comparison is separated, D names a clopen upset that contains the upper observation and excludes the lower observation.*
6. *H records componentwise* hsame *transport for O, T, K, U, D, P, N.*
7. *C records displayed* Cont *replay from an order/topology query through the clopen-upset and separation rows.*
8. *P is the* Pkg *provenance over* $\mathsf{PriestleySpace}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{BoundedLattice}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{StoneDuality}^{\uparrow}$, $\mathsf{PriestleyDuality}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{PriestleySpace}^{\uparrow}}$ *row.*
The local classifier compares accepted packets only through $O, T, K, U, D, H, C, P, N$.

Theorem 8212.2 (Priestley space NameCert obligations)**.** *For every accepted* $\mathsf{PriestleySpace}^{\uparrow}$ *carrier $S = (O, T, K, U, D, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{PriestleySpace}^{\uparrow}}$ *surface consists exactly of bounded lattice order admission through O, topology admission through T, Stone clopen readback through K, clopen-upset classification through U, Priestley separation through D, componentwise transport through H, displayed continuation replay through C, provenance through P, and local naming through N. The certificate exports no ultrafilter construction, selected prime filters, powerset topology, quotient lattice equality, host spectral space, or choice principle.*

Proof. Project the carrier of Definition 8212.1. The rows O, T, K, U, D are the only order, topology, clopen, upset, and separation coordinates; H, C, P, N only transport, replay, source, and name those rows.

The order rows are read through the lattice and bounded-lattice siblings, while the topological rows are read through the topology sibling. The clopen ledger K is supplied by the Stone-duality interface as displayed clopen data, and U restricts those rows to the upward-closed observations visible from O.

The separation row D then records only the finite Priestley condition exposed by the packet. Componentwise transport and displayed continuation preserve the same finite route under H and C, and P, N package and name it.

Since no listed coordinate stores ultrafilters, selected prime filters, powerset opens, quotient lattice equality, host spectral points, or a choice principle, those objects are outside the local NameCert surface. □

Theorem 8212.3 (Priestley space Stone-order handoff)**.** *Every Stone-duality or Priestley-duality consumer of an accepted* $\mathsf{PriestleySpace}^{\uparrow}$ *carrier must read the ordered topological handoff through*

$$\mathsf{Lattice}^{\uparrow},\ \mathsf{BoundedLattice}^{\uparrow} \longrightarrow \mathsf{Topology}^{\uparrow},\ \mathsf{StoneDuality}^{\uparrow} \longrightarrow O, T, K, U, D, H, C, P, N.$$

The handoff exposes a bounded order row, indexed-open topology row, Stone clopen ledger, clopen-upset classifier, and finite separation row before any duality theorem packet may consume the carrier. It does not assert a host Priestley representation theorem, an ultrafilter construction, selected prime filters, a powerset topology, quotient lattice equality, or choice.

Proof. Begin with the order side. The rows O and D make the bounded distributive order and finite separation requests visible before a consumer can treat a clopen row as an order-sensitive observation.

Read the topological side next. The row T supplies indexed opens, K supplies the Stone-facing clopen ledger, and U records the clopen-upset restriction for the displayed order. These rows are the ordered topological carrier surface, not the full duality theorem.

Finally use the structural rows H, C, P, N. They transport, replay, source, and name the same handoff for Stone-duality and Priestley-duality consumers. Because the carrier contains no ultrafilter, selected prime-filter, powerset-topology, quotient-equality, host-representation, or choice coordinate, the downstream handoff remains finite BEDC data. □

Falsifiable prediction: A Priestley-duality consumer that reads a clopen-upset row without first exposing the bounded order row and topology row is not a $\mathsf{PriestleySpace}^{\uparrow}$ carrier read.

Independence witness: Nearest siblings: lattice, bounded-lattice, topology, stoneduality, priestleyduality. The carrier is not bijective to LatticeUp or BoundedLatticeUp because it adds indexed-open, clopen, and separation rows; not to TopologyUp because it requires bounded order and clopen-upset rows; not to StoneDualityUp because it records an order-sensitive separation row; not to PriestleyDualityUp because it supplies the ordered topological carrier rather than the representation theorem packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PriestleySpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PriestleySpace}^{\uparrow}$ packet is generated from bounded distributive-order rows, indexed topology observations, Stone clopen rows, clopen-upset classification, Priestley separation rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PriestleySpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8212.1, Definition 8212.2, Definition 8212.3, the falsifiable prediction, and the independence witness seed the ordered topological carrier surface for Priestley-duality consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PriestleySpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host Priestley representation, ultrafilter construction, selected prime filters, powerset topology, quotient lattice equality, Lean verification, choice, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded order admission, indexed-open topology admission, Stone clopen readback, clopen-upset classification, Priestley separation, and local NameCert exhaustion for BEDC.Derived.PriestleySpaceUp.

Chapter 8213

A Concrete Naming Certificate for $\mathsf{GroupCohomology}^{\uparrow}$

Following Brown and Cartan–Eilenberg on group cohomology, the $\mathsf{GroupCohomology}^{\uparrow}$ packet names the finite BEDC surface by which a group action on abelian or module coefficients is read as cocycle and boundary data before any cohomology group is inspected. It depends on the action carrier of chapter 41, the coefficient rows of chapter 42 and chapter 46, and the cocycle-boundary interface of chapter 99. The packet does not choose representatives in a quotient, import derived-functor machinery, assume projective resolutions, invoke countable choice, or claim an ambient exact-category theorem.

Definition 8213.1 (Group cohomology carrier)**.** *A* $\mathsf{GroupCohomology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, M, W, D, Z, B, T, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Group}^{\uparrow}$ *action row naming the finite group-operation surface and its action on coefficient reads.*
2. *M is the coefficient row, read either through an* $\mathsf{AbGroup}^{\uparrow}$ *additive surface or through a compatible* $\mathsf{Module}^{\uparrow}$ *row.*
3. *W is the finite cochain-window ledger listing the displayed cochain arities and argument windows being inspected.*
4. *D is the coboundary row, recording the finite alternating action-and-face route from one cochain window to the next.*
5. *Z is the cocycle row, asserting that the displayed coboundary route sends the inspected cochain window to the zero coefficient row.*
6. *B is the boundary row, recording the finite predecessor window whose coboundary route yields a displayed cocycle.*
7. *T stores componentwise* hsame *transport for the group action, coefficient, cochain window, coboundary, cocycle, boundary, replay, provenance, and naming rows.*
8. *C stores displayed* Cont *replay for reading the action, coefficient module, cochain window, coboundary row, cocycle row, and boundary row in that order.*

9. *P is the* Pkg *provenance over* $\mathsf{GroupCohomology}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{Cohomology}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{GroupCohomology}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient representatives, selected resolutions, derived functors, global exactness, countable choice, or an ambient category of modules.

Theorem 8213.2 (Group cohomology NameCert obligations)**.** *For the carrier of Definition 8213.1, the local* $\mathsf{NameCert}_{\mathsf{GroupCohomology}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *action exposure: the* $\mathsf{Group}^{\uparrow}$ *row A is read before any cochain, cocycle, or boundary row is available;*
2. *coefficient exposure: the* $\mathsf{AbGroup}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *coefficient row M is displayed before the coboundary route is inspected;*
3. *cochain-window exactness: the ledger W lists the finite argument windows and arities used by the cochain read;*
4. *coboundary routing: the row D displays the finite alternating action-and-face route between the relevant cochain windows;*
5. *cocycle admission: the row Z is admitted only after D has exposed a zero coboundary read in the coefficient surface;*
6. *boundary admission: the row B is admitted only through a displayed predecessor cochain window and its coboundary route;*
7. *stability and replay: T and C preserve the same action, coefficient, cochain-window, coboundary, cocycle, boundary, provenance, and naming rows under* hsame *transport and* Cont *replay;*
8. *non-escape: P and N expose the package provenance and local name without adding quotient representatives, selected resolutions, derived-functor objects, global exactness, countable choice, or ambient module-category data.*

Proof. Carrier admission is projection from the displayed tuple $G = (A, M, W, D, Z, B, T, C, P, N)$. The first three obligations expose the action, coefficient row, and finite cochain-window ledger before any cohomology read is possible.

The coboundary and cocycle obligations are local to the displayed windows. The row D supplies the alternating action-and-face route, and Z records zero coboundary only after that route has been read in the coefficient surface.

The boundary obligation is likewise finite. The row B names a predecessor window and its displayed coboundary route; it does not select a representative in a quotient or appeal to an external resolution.

Finally T, C, P, N preserve, replay, source, and name the same rows. Since the carrier has no coordinate for quotient representatives, selected resolutions, derived functors, global exactness, countable choice, or ambient module-category data, the listed obligations exhaust the local NameCert surface. □

Theorem 8213.3 (Group cohomology cocycle-boundary route)**.** *Every accepted consumer of a* $\mathsf{GroupCohomology}^{\uparrow}$ *packet must expose the group action row A, coefficient row M, cochain-window ledger W, cocycle row Z, and boundary row B before any cohomology read is available. In particular, no consumer can inspect a cohomology class by bypassing the displayed* $\mathsf{Group}^{\uparrow}$ *action,*

$\mathsf{AbGroup}^{\uparrow}$ *or* $\mathsf{Module}^{\uparrow}$ *coefficient surface, finite cochain windows, coboundary route, cocycle row, and boundary row.*

Proof. Project the carrier of Definition 8213.1. Its analytic rows appear as the action A, coefficient M, cochain window W, coboundary route D, cocycle row Z, and boundary row B before the transport, replay, provenance, and naming rows are read.

Apply the NameCert obligations of Definition 8213.2. Action exposure and coefficient exposure make A and M prerequisites for every downstream read, while cochain-window exactness and coboundary routing place W and D before either Z or B.

Cocycle admission and boundary admission then force the two cohomology-facing rows to be displayed. The replay and non-escape clauses keep the consumer inside $A, M, W, D, Z, B, T, C, P, N$, so there is no route through quotient representatives, selected resolutions, derived functors, global exactness, countable choice, or ambient module-category data. □

Closure status for $\mathsf{NameCert}_{\mathsf{GroupCohomology}^{\uparrow}}$.

Constructive story: A $\mathsf{GroupCohomology}^{\uparrow}$ packet is generated from a GroupUp action row, AbGroupUp or ModuleUp coefficient row, finite cochain-window ledger, coboundary route, cocycle row, boundary row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GroupCohomology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8213.1, Definition 8213.2, and Definition 8213.3 seed the finite NameCert surface for group cohomology reads over displayed action and coefficient rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GroupCohomology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient representatives, selected resolutions, derived functors, global exactness, countable choice, ambient module-category data, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, action exposure, coefficient exposure, cochain-window exactness, coboundary routing, cocycle admission, boundary admission, transport, replay, provenance, and local naming for BEDC.Derived.GroupCohomologyUp.

Chapter 8214

A Concrete Naming Certificate for $\mathsf{DavenportConstant}^{\uparrow}$

Following Davenport's zero-sum constant tradition in finite abelian groups, the $\mathsf{DavenportConstant}^{\uparrow}$ packet records the finite BEDC surface by which a displayed sequence over a finite abelian group is inspected for a nonempty zero-sum subsequence or for a bounded refusal ledger. It sits after the group operation rows of chapter 41, the commutative group source of chapter 42, the unary length and index budget of chapter 28, and the finite sequence spine of chapter 36. The packet names only the displayed finite additive-combinatorics data; it is not an ambient pigeonhole principle, a quotient group theorem, a choice principle over subsequences, or a host-side extremal existence oracle.

Definition 8214.1 (Davenport constant carrier)**.** *A* $\mathsf{DavenportConstant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (G, A, L, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *G is the finite* $\mathsf{AbGroup}^{\uparrow}$ *source, read through the* $\mathsf{Group}^{\uparrow}$ *operation, inverse, identity, associativity, commutativity, and equality rows.*
2. *A is the finite sequence row over the displayed group source. It is a* $\mathsf{List}^{\uparrow}$ *spine whose entries are group elements, not an unordered host multiset.*
3. *L is the* $\mathsf{Nat}^{\uparrow}$ *length row, recording the inspected sequence length, the bounded index set, and the threshold comparison used by the Davenport-constant request.*
4. *S is the partial-sum ledger. It records the finite prefix sums and the contiguous or subsequence index witnesses inspected by the packet.*
5. *W is the zero-sum witness or refusal row. In the witness case it names a nonempty displayed sublist and a proof that its transported group sum is the identity; in the refusal case it records the finite inspected obstruction rows available below the threshold.*
6. *R records componentwise* hsame *transport for the group source, sequence spine, length row, partial sums, witness or refusal row, replay, provenance, and local naming.*
7. *H records classifier comparison only through the visible group operation, list entries, length budget, partial-sum ledger, and zero-sum witness or refusal row.*
8. *C records displayed* Cont *replay from a zero-sum request through G, A, L, S, W, R, H.*

9. *P is the* Pkg *provenance over* $\mathsf{DavenportConstant}^{\uparrow}$, $\mathsf{AbGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{DavenportConstant}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, A, L, S, W, R, H, C, P, N$. It has no coordinate for an external enumeration of all subsequences, a quotient group equality, an unbounded choice of witnesses, or a host theorem asserting the optimal numerical value of the Davenport constant.

Lean4 ✓ `BEDC.Derived.DavenportConstantUp.DavenportConstantTasteGate single carrier alignment`

Theorem 8214.2 (Davenport constant NameCert obligations)**.** *For every accepted* $\mathsf{DavenportConstant}^{\uparrow}$ *carrier*

$$Z = (G, A, L, S, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DavenportConstant}^{\uparrow}}$ *surface consists exactly of finite abelian group source admission, displayed sequence membership, unary length budgeting, partial-sum ledger construction, zero-sum witness or refusal exposure, componentwise* hsame *transport, classifier comparison through displayed rows,* Cont *replay, provenance, and local naming.*

Proof. Project the accepted carrier of Definition 8214.1. Its coordinates are precisely the finite abelian group row, the list spine, the unary length budget, the partial-sum ledger, the witness-or-refusal row, transport, classifier, replay, provenance, and local naming.

The algebraic obligations are inherited in order. The $\mathsf{AbGroup}^{\uparrow}$ source supplies the commutative operation and identity rows through the underlying $\mathsf{Group}^{\uparrow}$ packet, while the $\mathsf{List}^{\uparrow}$ spine supplies only displayed finite entries. The $\mathsf{Nat}^{\uparrow}$ row bounds the inspected indices and fixes the length comparison before any zero-sum read is attempted.

The additive-combinatorics obligation is local to the ledger. The partial sums in S are finite sums over the displayed entries, and W either exposes a nonempty selected sublist with transported sum equal to the identity or records the finite refusal rows available below the displayed threshold.

Transport, classifier comparison, replay, provenance, and naming preserve the same rows. Since the carrier stores no external subsequence enumeration, quotient equality, choice functional, or host-side optimality theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 8214.3 (Davenport constant zero-sum handoff)**.** *Every downstream zero-sum consumer of an accepted* $\mathsf{DavenportConstant}^{\uparrow}$ *carrier reads the finite additive route*

$$\mathsf{AbGroup}^{\uparrow},\ \mathsf{Group}^{\uparrow},\ \mathsf{Nat}^{\uparrow},\ \mathsf{List}^{\uparrow} \longmapsto \mathsf{DavenportConstant}^{\uparrow}.$$

The handoff supplies a displayed finite abelian group source, a finite sequence spine, a unary length budget, a partial-sum ledger, and either a nonempty zero-sum sublist witness or a bounded refusal row. It does not supply quotient group equality, a global subsequence-choice functional, a host extremal theorem, or ambient completeness data.

Proof. Start from an accepted carrier $Z = (G, A, L, S, W, R, H, C, P, N)$. A consumer can read group addition only through G, sequence data only through A, and the inspected bound only through L.

The zero-sum decision surface is then read from S and W. The ledger S lists the finite partial sums and inspected index data, while W names the displayed witness or the bounded refusal rows. No later coordinate can introduce an unlisted subsequence or an unbounded selector.

Finally R, H, C, P, N transport, compare, replay, source, and name the same finite packet. Thus the handoff is exactly the displayed zero-sum route through the finite abelian group, length, list, and ledger rows, and not an ambient theorem outside the packet. □

Falsifiable prediction: Every accepted $\mathsf{DavenportConstant}^{\uparrow}$ consumer that exports a zero-sum conclusion while omitting one of the displayed finite abelian group source, sequence spine, unary length, partial-sum ledger, witness-or-refusal, transport, classifier, replay, provenance, or local naming rows refutes the packet.

Independence witness: abgroup, group, nat, list: $\mathsf{DavenportConstant}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite abelian group source, a sequence spine, a unary length budget, a partial-sum ledger, a zero-sum witness or refusal row, componentwise hsame transport, classifier comparison, Cont replay, Pkg provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{DavenportConstant}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DavenportConstant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8214.1, Definition 8214.2, and Definition 8214.3 seed the finite zero-sum route over abelian group rows, list spines, unary length budgets, partial-sum ledgers, witness-or-refusal rows, transport, classifier comparison, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DavenportConstant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient group equality, a host-side optimal Davenport constant theorem, global subsequence choice, ambient pigeonhole principles, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite abelian group source exposure, sequence spine well-formedness, unary length budgeting, partial-sum ledger exactness, zero-sum witness or refusal stability, transport, classifier comparison, replay, provenance, and local naming for BEDC.Derived.DavenportConstantUp.

Constructive story: A $\mathsf{DavenportConstant}^{\uparrow}$ packet is generated from finite abelian group rows, a displayed sequence spine, a unary length budget, a partial-sum ledger, a zero-sum witness or bounded refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8215

A Concrete Naming Certificate for $\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}$

Following Bishop and Bridges on regulated functions and regular Cauchy real names, the RegulatedCauchyStepApprc packet records the finite approximation schedule by which displayed step-function windows over a regulated source produce regular-rational names for Real-facing consumers. It sits after the regulated-function carrier of chapter 1906, the dyadic step-function surface of chapter 428, the uniform-limit route of chapter 463, the dyadic mesh gauge of chapter 7496, the regular rational readback of chapter 301, and the terminal real-name chapter of chapter 38. The packet gives Real and Completion routes one finite step-approximation bridge; it does not quotient functions, select a limit object, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8215.1 (Regulated Cauchy step approximation carrier)**.** *A* $\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, S, U, G, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegulatedFunction}^{\uparrow}$ *source row whose one-sided oscillation data are exposed on the displayed interval windows.*
2. *S is the* $\mathsf{StepFunction}^{\uparrow}$ *approximation ledger, listing finitely many step rows and their domains of constancy.*
3. *U is the* $\mathsf{UniformLimit}^{\uparrow}$ *handoff binding the step rows to the regulated source at the requested tolerance.*
4. *G is the* $\mathsf{DyadicMeshGauge}^{\uparrow}$ *mesh row that supplies the finite dyadic subdivision used by the step ledger.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row for the sampled approximation values and tail budgets.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R, S, U, G, Q have been displayed.*
7. *H stores componentwise* hsame *transport for the regulated source, step ledger, uniform-limit handoff, dyadic mesh, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from a regulated-function request through the finite mesh, step approximation ledger, regular readback, and Real-facing handoff.*

9. *P is the* Pkg *provenance over* $\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}$, $\mathsf{RegulatedFunction}^{\uparrow}$, $\mathsf{StepFunction}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{DyadicMeshGauge}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, S, U, G, Q, E, H, C, P, N$. No quotient function equality, selected limit, countable-choice schedule, or ambient completeness coordinate is part of the carrier.

Theorem 8215.2 (Regulated Cauchy step approximation NameCert obligations)**.** *For an accepted* $\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}$ *carrier $A = (R, S, U, G, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}}$ *surface consists exactly of carrier exposure for the regulated source, step-function ledger, uniform-limit handoff, dyadic mesh gauge, regular-rational readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows. Every accepted read first fixes the displayed regulated source R, then chooses only the finite mesh cells in G, then reads the step ledger S and uniform-limit handoff U, and finally exports the regular-rational and Real-facing rows Q, E, H, C, P, N.*

Proof. Project the carrier of Definition 8215.1. The rows $R, S, U, G, Q, E, H, C, P, N$ are the only displayed coordinates of the packet.

The source and mesh obligations read R and G before any step approximation is consumed. The step ledger S is therefore tied to the displayed dyadic cells rather than to an external partition choice.

The uniform-limit and regular-readback obligations use U and Q. They attach each tolerance request to the finite step ledger and regular rational tail data before the terminal Real seal E is available.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no row for quotient function equality, a selected limit object, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, none of those readings can enter the local certificate. □

Theorem 8215.3 (Regulated Cauchy step approximation RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reading an accepted* $\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}$ *packet factors through*

$$R \longmapsto G \longmapsto S \longmapsto U \longmapsto Q \longmapsto E \longmapsto H, C, P, N.$$

The consumer receives a regular-rational name assembled from finitely displayed step approximations and dyadic mesh gauges. It receives no quotient equality of regulated functions, selected uniform limit, countable-choice sequence, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 8215.2. They force a consumer to read the regulated source R, the dyadic mesh row G, the step ledger S, and the uniform-limit handoff U before Q can be inspected.

The row Q is the only regular-rational readback coordinate. Thus a $\mathsf{RegSeqRat}^{\uparrow}$ consumer receives the tail budget and sampled approximation values from the finite step schedule, not from an external limiting object.

The terminal seal E is downstream of Q, while H, C, P, N preserve the same route under transport, replay, provenance, and local naming. The route therefore cannot export quotient function equality, a selected limit, countable choice, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegulatedCauchyStepApproximation}^{\uparrow}}$.

Constructive story: A RegulatedCauchyStepApproximation$^{\uparrow}$ packet is generated from a RegulatedFunction source, StepFunction approximation ledger, UniformLimit handoff, DyadicMeshGauge mesh row, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate(NameCert$_{\text{RegulatedCauchyStepApproximation}\uparrow}$, seed)

Scope closed: Definition 8215.1, Definition 8215.2, and Definition 8215.3 seed the finite regulated step-approximation route from displayed regulated functions and step ledgers to regular-rational and Real-facing handoffs.

Formal verification: FormalStatus(NameCert$_{\text{RegulatedCauchyStepApproximation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient function equality, selected limits, countable choice, or ambient Real$^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, regulated-source binding, mesh exactness, step-ledger exposure, uniform-limit handoff, RegSeqRat readback, Real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.RegulatedCauchyStepApproximationUp.

Chapter 8216

A Concrete Naming Certificate for $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$

The $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ packet realizes the compact-uniform-continuity triangle-estimate branch as a finite replay surface: compact finite-net source cells, continuous-map local moduli, source and target metric triangle rows, rational tolerance splits, regular readback, and a terminal Real-facing seal are displayed before a uniform-modulus consumer reads the handoff. It is localized to the finite-net source and target triangle estimate route of chapter 9237; it does not claim broad compactness, select a global modulus outside the ledger, quotient metric points, choose centers externally, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8216.1 (Finite net triangle replay carrier)**.** *A* $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, U, M, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the displayed center bundle and coverage ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row read on the bundled source centers.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer-facing handoff row produced by the replay.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *source and target triangle ledger used for the two triangle estimates.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *tolerance-split row, including the finite third-radius and lower-bound comparisons.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row for rational comparison data that must be sealed for Real-facing consumers.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row.*
8. *H stores componentwise* hsame *transport for the compact source, continuous map, uniform-modulus handoff, metric triangle ledger, rational split, regular readback, Real seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a compact finite-net request through the source triangle, local modulus, target triangle, rational readback, and uniform-modulus handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{FiniteNetTriangleReplay}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $K, F, U, M, R, Q, E, H, C, P, N$. No external center selector, quotient point equality, global compactness theorem, selected uniform modulus, or ambient Real completeness coordinate is present.

The replay consumes the compact metric carrier of chapter 129, the continuous-map row of chapter 130, the uniform-modulus consumer boundary of chapter 369, the metric-space triangle ledger of chapter 4230, the rational tolerance row of chapter 37, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38 before exporting the uniform-modulus handoff.

Theorem 8216.2 (Finite net triangle replay NameCert obligations)**.** *For an accepted* $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ *carrier $T = (K, F, U, M, R, Q, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteNetTriangleReplay}^{\uparrow}}$ *surface consists exactly of carrier exposure for the compact finite-net source, continuous-map local rows, uniform-modulus consumer row, source and target metric triangle ledger, rational tolerance split, regular-rational readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows. A consumer must read the compact source row K, local map row F, triangle ledger M, and tolerance split R before it can inspect the uniform-modulus handoff U.*

Proof. Project the carrier of Definition 8216.1. The tuple displays the compact finite-net source, continuous-map row, uniform-modulus handoff, metric triangle ledger, rational split, regular readback, Real seal, transport, replay, provenance, and local name.

The source triangle estimate reads K, M, R first. These rows identify the bundled center, the source distance comparison, and the rational tolerance split that keeps the second source point inside the same local-modulus window.

The local modulus and target triangle estimates then read F, M, R, Q, E. The graph and metric rows produce the two target-side bounds, while the regular-rational and Real rows seal the displayed tolerance comparison.

Finally H, C, P, N preserve the same route. Since the carrier has no external center selector, quotient point equality, global compactness theorem, selected uniform modulus, or ambient Real completeness coordinate, the local NameCert surface is exhausted by the listed rows. □

Theorem 8216.3 (Finite net triangle replay uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer reading an accepted* $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ *packet factors through*

$$K, F, M, R \longmapsto Q, E \longmapsto U, H, C, P, N.$$

The handoff is the finite source-and-target triangle replay over compact-net centers, continuous-map local rows, metric-space triangle ledgers, rational tolerance splits, regular readback, and Real sealing. It exports no broad compactness theorem, external center choice, quotient point equality, selected modulus outside the packet, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 8216.2. They require the compact finite-net source K, continuous-map local rows F, triangle ledger M, and rational tolerance split R to be displayed before U is consumed.

The regular readback Q and Real seal E bind the rational estimates used by the source and target triangle calculations. A uniform-modulus consumer therefore reads concrete tolerance data rather than an unstated external modulus.

The transport, replay, provenance, and naming rows H, C, P, N keep the handoff on the same finite route. The intended Lean surface requires nontriviality and field faithfulness for this packet,

recorded as `Nontrivial FiniteNetTriangleReplayUp` and `FieldFaithful FiniteNetTriangleReplayUp` instances, so the replay cannot collapse into an empty or classifier-erasing carrier. □

Falsifiable prediction: Every accepted $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ uniform-modulus read factors through the compact finite-net source row, continuous-map local row, metric triangle ledger, rational tolerance split, regular readback, Real seal, componentwise transport, replay, provenance, and local $\mathsf{NameCert}$ before $\mathsf{UniformModulus}^{\uparrow}$ is consumed.

Independence witness: compactmetric, continuousmap, uniformmodulus, metricspace, real: $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact finite-net centers, continuous local rows, source and target triangle replay, rational tolerance splits, regular readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetTriangleReplay}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteNetTriangleReplay}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap local rows, UniformModulus consumer rows, MetricSpace triangle ledgers, RatUp tolerance splits, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteNetTriangleReplay}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8216.1, Definition 8216.2, and Definition 8216.3 seed the finite source-and-target triangle replay route for compact-uniform-continuity uniform-modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteNetTriangleReplay}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, broad compactness, external center choice, quotient point equality, selected uniform moduli, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net source binding, continuous local-row exposure, source and target triangle replay, rational tolerance split, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteNetTriangleReplayUp.

Chapter 8217

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$

Following Bishop and Bridges and Kelley on constructive dense completions, the $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$ packet records the finite non-quotient density route that sits between the dyadic source of chapter 291, the finite-window names of chapter 126, the regular rational readbacks of chapter 301, the terminal seal of chapter 38, and the dense-source face of chapter 3542. It gives Real-completion consumers a carrier-local approximation surface before any quotient completion, selected limit, countable-choice principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem is available.

Definition 8217.1 (RegularCauchyCompletionDensity carrier)**.** *A* $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (D, S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the dense dyadic source row, read through* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *and the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window service row used to expose source observations only at requested stages.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the regular rational representative and its displayed modulus discipline.*
4. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording precision requests, slack rows, and dyadic comparison evidence.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the dense source, stream window, regular-rational readback, and tolerance rows have been exposed.*
6. *H stores componentwise* hsame *transport for dense-source, stream-window, regular-rational, tolerance, seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from each approximation request through D, S, R, Q, E, H, P, N.*
8. *P is the* Pkg *provenance over the dense dyadic source,* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionDensity}^{\uparrow}}$ *row.*

The classifier reads accepted packets only through these rows and replay paths. It has no coordinate for quotient completions, selected representatives, selected limits, countable choice, host equality of completion classes, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyCompletionDensityUp`

Theorem 8217.2 (RegularCauchyCompletionDensity NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$ *carrier* $X = (D, S, R, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionDe}}$ *surface consists exactly of carrier admission for the dense dyadic source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed replay, provenance, and local naming. Any completion-facing consumer must read* D, S, R, Q *before it can consume the seal row* E*.*

Proof. Project the carrier of Definition 8217.1. The tuple displays dense-source, stream-window, regular-rational, dyadic-tolerance, Real-seal, transport, replay, provenance, and naming rows.

The dense-source row is source-facing and finite. The StreamName row exposes only requested windows, the RegSeqRat row supplies the regular rational readback, and the DyadicRatCore row supplies the tolerance ledger used before the Real seal is read.

The seal row E is downstream of those rows. Since the packet has no quotient-completion coordinate, selected-limit coordinate, countable-choice coordinate, or ambient-completeness coordinate, the local NameCert obligations are exhausted by the displayed finite route. □

Theorem 8217.3 (RegularCauchyCompletionDensity dyadic approximation)**.** *Every accepted* $\mathsf{RegularCauchyComp}$ *packet supplies a finite dyadic approximation route*

$$\mathsf{CauchyCompletionDensitySource}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For each requested approximation window, the consumer reads the dense source row D*, the stream window row* S*, the regular-rational readback row* R*, the dyadic tolerance row* Q*, transport* H*, replay* C*, provenance* P*, and local naming* N *before reading the* $\mathsf{Real}^{\uparrow}$ *seal row* E*.*

Proof. Begin with the NameCert obligations of Definition 8217.2. They force every completion-facing read to pass through the dense source, stream window, regular rational readback, and dyadic tolerance rows before the seal row can be consumed.

The sibling chapters determine the approximation route. The dense-source packet fixes the source boundary, $\mathsf{StreamName}^{\uparrow}$ restricts observation to finite windows, $\mathsf{RegSeqRat}^{\uparrow}$ gives the regular rational representative, and $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the tolerance ledger.

Transport and replay preserve that displayed route. Therefore the exported approximation is a finite dyadic source-to-seal packet, not a quotient completion, selected limit, countable-choice principle, host equality comparison, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal while omitting the dense source, stream window, RegSeqRat readback, DyadicRatCore tolerance, transport, replay, provenance, or local naming row refutes the packet.

Independence witness: cauchy-completion-density-source, dyadicratcore, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{RegularCauchyCompletionDensity}^{\uparrow}$ because the packet jointly carries dense-source evidence, finite observation windows, regular rational readback, dyadic tolerance accounting, Real-seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionDensity}^{\uparrow}}$ **·**

Constructive story: A RegularCauchyCompletionDensity$^{\uparrow}$ packet is generated from a dense dyadic source row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionDensity}^{\uparrow}}$, seed)

Scope closed: Definition 8217.1, Definition 8217.2, and Definition 8217.3 seed the dense dyadic approximation route consumed by constructive Cauchy completion readers.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionDensity}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.RegularCauchyCompletionDensityUp`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, selected limits, countable choice, trichotomy, host equality, ambient Real$^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dense-source exactness, StreamName window readback, RegSeqRat handoff, DyadicRatCore tolerance accounting, RealUp seal non-escape, transport replay, provenance, and TasteGate field faithfulness for BEDC.Derived.RegularCauchyCompletionDensityUp.

Chapter 8218

A Concrete Naming Certificate for $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$

Following Bishop and Bridges and Kelley on constructive dense completions, the $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ packet realizes the finite-window side of chapter 9238. It packages the dyadic approximation window before the $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ seal reads, using the dense source of chapter 3542, the dyadic tolerance rows of chapter 291, the observation windows of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet is a finite NameCert surface for Real-completeness consumers, not a claim of full ambient completeness.

Definition 8218.1 (RealCompletenessDensityWindow carrier)**.** *A* $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (V, D, S, R, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *V is the Real-completeness vision route row naming the finite density-window obligation that this packet realizes.*
2. *D is the* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ *dense-source row.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row through which approximation requests are observed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the window row.*
5. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, including precision request, slack, and dyadic comparison data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row read only after D, S, R, Q are exposed.*
7. *H stores componentwise* hsame *transport for the vision route, dense source, stream window, readback, tolerance, seal, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay from each Real-completeness density request through $V, D, S, R, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over chapter 9238,* $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessDensityWindow}^{\uparrow}}$ *row.*

The classifier admits only finite density-window packets. It does not identify real numbers with quotient representatives, choose completion limits, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RealCompletenessDensityWindowUp`

Theorem 8218.2 (RealCompletenessDensityWindow NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ *carrier* $W = (V, D, S, R, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealCompletenessDensity}}$ *surface consists exactly of the vision route row, dense-source row, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise transport, displayed replay, provenance, and local naming. A Real-completeness consumer must expose* D, S, R, Q *before it may read* E *as a seal.*

Proof. Project the carrier of Definition 8218.1. The packet displays the vision route, dense source, finite observation window, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming.

The finite density window is the only route from the vision row to the seal row. The dense-source and StreamName rows control source observation, the RegSeqRat row supplies readback, and the DyadicRatCore row records the requested tolerance before the seal is consumed.

Thus the NameCert obligations are carrier-local. Since no coordinate names quotient representatives, selected limits, countable choice, or ambient Real completeness, those objects cannot be part of the accepted window. □

Theorem 8218.3 (RealCompletenessDensityWindow seal handoff)**.** *Every accepted* $\mathsf{RealCompletenessDensityWindo}$ *packet realizes the Real-completeness density-window route*

$$\mathsf{CauchyCompletionDensitySource}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

as finite NameCert data. The handoff to a $\mathsf{Real}^{\uparrow}$ *consumer contains only the finite window, tolerance, readback, seal, transport, replay, provenance, and local naming rows displayed by* $W = (V, D, S, R, Q, E, H, C, P, N)$*.*

Proof. Start with the obligation surface of Definition 8218.2. It forces the Real-completeness consumer through the dense source, finite window, regular rational readback, and dyadic tolerance rows before the Real seal row is read.

The cited concrete-instance siblings provide the route. $\mathsf{CauchyCompletionDensitySource}^{\uparrow}$ fixes the dense source, $\mathsf{DyadicRatCore}^{\uparrow}$ fixes tolerance accounting, $\mathsf{StreamName}^{\uparrow}$ fixes finite observation, $\mathsf{RegSeqRat}^{\uparrow}$ fixes regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal row.

Transport and replay keep the handoff in the same finite packet. Therefore the chapter realizes a density-window NameCert packet for the vision, not quotient completion, selected limit extraction, countable choice, host equality of real representatives, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ consumer that reads a $\mathsf{Real}^{\uparrow}$ seal without the dense-source row, dyadic tolerance row, StreamName window, RegSeqRat readback, transport, replay, provenance, and local naming row refutes the packet.

Independence witness: real-completeness, cauchy-completion-density-source, dyadicratcore, streamname, regseqrat, real: no listed sibling is bijective with $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ because this packet jointly carries the vision route row, finite density window, tolerance ledger, readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletenessDensityWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletenessDensityWindow}^{\uparrow}$ packet is generated from a Real-completeness vision route row, a dense-source row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealCompletenessDensityWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8218.1, Definition 8218.2, and Definition 8218.3 seed the finite density-window route that the Real completeness vision can consume before seal reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealCompletenessDensityWindow}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RealCompletenessDensityWindowUp`

Bridge status: none

Not claimed: This chapter does not close full RealUp completeness, quotient completions, selected representatives, selected limits, countable choice, trichotomy, host equality, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, density-window exactness, DyadicRatCore tolerance accounting, StreamName window readback, RegSeqRat handoff, RealUp seal non-escape, transport replay, provenance, and TasteGate field faithfulness for BEDC.Derived.RealCompletenessDensityWindowUp.

Chapter 8219

A Concrete Naming Certificate for $\mathsf{FiniteStreamMerge}^{\uparrow}$

Following Bishop and Bridges, a finite merge of two lawlike source windows is a useful construction only when the two finite schedules, the merge order, and the downstream rational readback remain visible. The $\mathsf{FiniteStreamMerge}^{\uparrow}$ packet sits between the finite schedule surface of chapter 5916, the parity interleaving surface of chapter 7498, the stream-name readback of chapter 126, the regular rational route of chapter 301, the dyadic arithmetic core of chapter 291, and the terminal Real seal of chapter 38. It names a two-source finite merge certificate without replacing either source by host sequence equality or an unrecorded choice of positions.

Definition 8219.1 (Finite stream merge carrier)**.** *A* $\mathsf{FiniteStreamMerge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (F_0, F_1, M, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. F_0 *is the first* $\mathsf{FiniteStream}^{\uparrow}$ *source schedule, including its finite request row, list row, and window boundary.*
2. F_1 *is the second* $\mathsf{FiniteStream}^{\uparrow}$ *source schedule, with the same finite request/list/window discipline.*
3. M *is the finite merge-order row, recording which displayed output positions read from* F_0 *and which read from* F_1*.*
4. S *is the* $\mathsf{StreamName}^{\uparrow}$ *handoff row obtained after the two finite schedules and the merge-order row have been displayed.*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the source windows and the merged output window.*
6. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the rational reads at the requested finite precision.*
7. R *is the* $\mathsf{Real}^{\uparrow}$ *seal boundary, available only after* F_0, F_1, M, S, Q, D *have been displayed.*
8. H *records componentwise* hsame *transport for both finite sources, the merge order, stream-name handoff, regular rational readback, dyadic tolerance, Real seal, provenance, replay, and local naming.*
9. C *records displayed* Cont *replay from source-window inspection through merge-order selection, StreamName handoff, RegSeqRat readback, DyadicRatCore comparison, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteStreamMerge}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamInterleaving}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteStreamMerge}^{\uparrow}}$ *row.*

The carrier contains no coordinate for host sequence equality, countable choice over positions, an unbounded stream merge, a hidden subsequence selector, or a Real value that bypasses the displayed finite merge order.

Theorem 8219.2 (Finite stream merge NameCert obligations)**.** *For every accepted* $\mathsf{FiniteStreamMerge}^{\uparrow}$ *carrier*

$$G = (F_0, F_1, M, S, Q, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteStreamMerge}^{\uparrow}}$ *surface consists exactly of first finite-source schedule exposure, second finite-source schedule exposure, finite merge-order exposure, StreamName handoff, RegSeqRat readback, DyadicRatCore tolerance comparison, Real-seal boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation row may erase either finite source, reorder the merge outside M, replace the route by host sequence equality, or export a Real-facing read before the finite merge certificate is displayed.*

Proof. Project the carrier of Definition 8219.1. The first two rows are the source schedules F_0 and F_1, each read through the finite request/list/window discipline of $\mathsf{FiniteStream}^{\uparrow}$.

The merge-order row M is the only coordinate that combines the two sources. It records the finite output positions, so the packet cannot appeal to countable choice over later positions or to equality of host sequences.

The downstream rows S, Q, D, R expose StreamName handoff, regular rational readback, dyadic tolerance comparison, and Real sealing only after F_0, F_1, M have been displayed. Thus every analytic read remains attached to the finite merge route.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the excluded objects are absent from the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8219.3 (Finite stream merge StreamName handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *or* $\mathsf{StreamInterleaving}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteStreamMerge}^{\uparrow}$ *packet receives the handoff row S only through the two finite source schedules F_0, F_1 and the finite merge-order row M. The consumer may compare with the interleaving packet of chapter 7498, but it may not replace the displayed merge certificate by a private stream selector.*

Proof. Read F_0 and F_1 first as finite schedules. Each source exposes only a finite request, list, and window boundary, so no infinite host stream is available to the consumer.

Next read the merge-order row M. This row determines which source supplies each displayed output position before any $\mathsf{StreamName}^{\uparrow}$ handoff is issued.

The handoff row S is therefore downstream of the same finite merge certificate. The parity split route of Definition 7498.4 is a sibling consumer of this discipline: it may read the finite source windows, but it still receives the output through a displayed selection row rather than through hidden sequence equality. □

Theorem 8219.4 (Finite stream merge Real nonescape)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteStreamMerge}^{\uparrow}$ *packet factors through*

$$(F_0, F_1, M) \longmapsto S \longmapsto Q \longmapsto D \longmapsto R$$

with the same H, C, P, N rows attached. A Real-facing read cannot bypass the two finite source schedules, the merge-order row, the StreamName handoff, the regular rational readback, or the dyadic tolerance comparison.

Proof. Project the carrier. The Real seal row R is displayed after the finite sources F_0, F_1, the merge order M, the StreamName handoff S, the RegSeqRat readback Q, and the DyadicRatCore tolerance row D.

A regular rational consumer must therefore read Q as a readback of the displayed source and output windows, not as an independent rational sequence. The dyadic row D then checks the requested precision against that same finite data.

Finally the Real consumer reads R only after the route above has been replayed through C and transported through H. Provenance P and local naming N keep the same certificate attached, so a Real-facing value has no route around the finite merge packet. □

Falsifiable prediction: A $\mathsf{FiniteStreamMerge}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ without displaying $F_0, F_1, M, S, Q, D, H, C, P, N$ refutes the carrier of Definition 8219.1.

Independence witness: finite-stream, stream-interleaving, streamname, regseqrat, dyadicratcore, real: none is bijective because FiniteStreamMergeUp jointly carries two finite source schedules, one merge-order row, StreamName handoff, regular rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteStreamMerge}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteStreamMerge}^{\uparrow}$ packet is generated from two finite source schedules, a finite merge-order row, StreamName handoff, RegSeqRat readback, DyadicRatCore tolerance comparison, a Real seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteStreamMerge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8219.1, Definition 8219.2, Definition 8219.3, and Definition 8219.4 seed the finite two-source merge route between finite schedules, stream-name handoff, regular rational readback, dyadic tolerance, and Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteStreamMerge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host sequence equality, countable choice over positions, unbounded stream merging, quotient Cauchy equality, or a Real seal independent of the displayed finite merge route.

Upgrade path: Obligation closure requires checked carrier, merge-order, StreamName handoff, RegSeqRat readback, DyadicRatCore tolerance, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteStreamMergeUp.

Chapter 8220

A Concrete Naming Certificate for DyadicPiecewiseLinearInterpolation$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the DyadicPiecewiseLinearInterpolation$^{\uparrow}$ packet records the finite dyadic mesh route by which endpoint rational data is read as a piecewise-linear interpolation graph before any regular Cauchy or Real consumer sees a completion-facing handoff. It sits after the midpoint arithmetic of chapter 445, the dyadic rational core of chapter 291, the regular interpolation corridor of chapter 1740, the rational readback surface of chapter 301, and the terminal real-name boundary of chapter 38. The packet names only displayed finite mesh data; it is not a host function space, an ambient uniform-continuity theorem, a selected real limit, or a completeness principle for Real$^{\uparrow}$.

Definition 8220.1 (Dyadic piecewise-linear interpolation carrier)**.** *A* DyadicPiecewiseLinearInterpolation$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (M, E, S, G, R, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite dyadic mesh row. It lists ordered dyadic knots, endpoint inclusions, adjacent midpoint checks, and the local interval codes read through* DyadicMidpoint$^{\uparrow}$ *and* DyadicRatCore$^{\uparrow}$*.*
2. *E is the endpoint-value row. It assigns displayed dyadic rational values to the knots of M and records the equality checks needed at shared segment endpoints.*
3. *S is the segment-slope row. For every adjacent knot pair it records the displayed dyadic numerator, denominator, nonzero interval-width witness, and rational slope ledger.*
4. *G is the interpolation graph row. It records the affine value rule on each mesh segment, the endpoint agreement rows, and the segment-membership row used when a downstream reader asks for a graph value.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained by reading the graph on dyadic refinement windows rather than by invoking a host function.*
6. *L is the terminal* Real$^{\uparrow}$ *handoff row, available only after the mesh, endpoint, slope, graph, and regular rational readback rows have been displayed.*
7. *H records componentwise* hsame *transport for mesh knots, endpoint values, segment slopes, graph rows, regular rational readback, terminal handoff, replay, provenance, and local naming.*

8. *C records displayed* Cont *replay from an interpolation request through $M, E, S, G, R, L, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$, $\mathsf{DyadicMidpoint}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyInterpolation}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, S, G, R, L, H, C, P, N$. It has no coordinate for an external real-valued function, a host slope field, arbitrary real arithmetic, quotient stream equality, selected limits, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8220.2 (Dyadic piecewise-linear interpolation NameCert obligations)**.** *For every accepted* $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$ *carrier*

$$I = (M, E, S, G, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}}$ *surface consists exactly of finite dyadic mesh admission, endpoint-value admission, segment-slope ledger construction, interpolation graph exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier of Definition 8220.1. The rows M, E, S, G are the only mesh, endpoint, slope, and graph coordinates, while R, L, H, C, P, N only read back, seal, transport, replay, source, and name those rows.

The arithmetic obligations are local to the dyadic rows. The mesh row reads midpoint and dyadic rational evidence through $\mathsf{DyadicMidpoint}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$, the endpoint row records displayed values at mesh knots, and the slope row stores only the finite rational differences and interval-width witnesses for adjacent knots.

The graph obligation is then a finite segment ledger. The row G chooses a displayed segment by the membership row supplied by M, applies the affine rule recorded by S, and checks endpoint agreement against E.

Finally R reads the same graph through regular rational refinement windows, L exposes the Real-facing seal only after that readback, and H, C, P, N preserve the same route. Since no carrier coordinate stores a host function, arbitrary real arithmetic, quotient stream equality, selected limit, or ambient completeness principle, the listed rows exhaust the local certificate obligations. □

Theorem 8220.3 (Dyadic piecewise-linear interpolation RegSeqRat handoff)**.** *Every regular-rational or Real-and-Completion consumer of an accepted* $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$ *packet reads the interpolation route through*

$$\mathsf{DyadicMidpoint}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegularCauchyInterpolation}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

Concretely, the consumer must first expose the dyadic mesh row M, endpoint-value row E, segment-slope row S, and interpolation graph row G before it may read the $\mathsf{RegSeqRat}^{\uparrow}$ *handoff R or terminal seal L.*

Proof. Start from an accepted packet $I = (M, E, S, G, R, L, H, C, P, N)$. The only source of interval data is the finite mesh row M, and the only source of endpoint values is the row E tied to that mesh.

The segment-slope row S and graph row G turn this finite dyadic data into displayed affine segment reads. These rows are exactly the interpolation surface consumed by the regular interpolation corridor; no downstream consumer can bypass them to obtain a host function.

The $\mathsf{RegSeqRat}^{\uparrow}$ row R is downstream of the graph row and records rational refinement reads of the same finite interpolation ledger. The terminal $\mathsf{Real}^{\uparrow}$ row L is available only after R is displayed.

The transport, replay, provenance, and naming rows preserve this order. Therefore every regular-rational or completion-facing handoff factors through the displayed dyadic mesh, endpoint, slope, graph, and readback rows, and it exports no independent real function, selected limit, quotient stream equality, or ambient completeness principle. □

Falsifiable prediction: A completion-facing consumer that exports a $\mathsf{RegSeqRat}^{\uparrow}$ readback from $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$ while omitting one of the displayed mesh, endpoint, segment-slope, graph, transport, replay, provenance, or local naming rows is not reading this packet.

Independence witness: Nearest siblings: dyadicmidpoint, dyadicratcore, regular-cauchy-interpolation, regseqrat, real. The carrier is not bijective to DyadicMidpointUp or DyadicRatCoreUp because it adds finite mesh, endpoint, slope, and graph rows; not to RegularCauchyInterpolationUp because it fixes dyadic piecewise-linear data; not to RegSeqRatUp because it supplies the interpolation ledger before readback; and not to RealUp because it records the finite pre-seal route rather than a terminal real name alone.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8220.1, Definition 8220.2, and Definition 8220.3 seed the finite dyadic interpolation route from mesh rows and endpoint values to regular rational readback and a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, arbitrary real arithmetic, quotient stream equality, selected limits, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic mesh admission, endpoint-value stability, segment-slope ledger exactness, interpolation graph exposure, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.DyadicPiecewiseLinearInterpolationUp.

Constructive story: A $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$ packet is generated from finite dyadic mesh rows, endpoint-value rows, segment-slope rows, interpolation graph rows, RegSeqRat readback, a Real-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8221

A Concrete Naming Certificate for $\mathsf{RegularClosedSet}^{\uparrow}$

Following Engelking, the $\mathsf{RegularClosedSet}^{\uparrow}$ packet records the topology-facing closed sets that are recovered from the closure of their own interior. It sits beside the regular-open comparison route of chapter 6835, reads ambient open and closed observations through $\mathsf{Topology}^{\uparrow}$, and records membership provenance through $\mathsf{SetLike}^{\uparrow}$. The packet is a finite NameCert surface for closure-interior stability, not a host powerset equality, a Boolean algebra completion, a selected basis, or an imported compactness theorem.

Definition 8221.1 (Regular closed set carrier)**.** *A* $\mathsf{RegularClosedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, S, O, I, C, E, H, Q, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row naming the finite open and closed observations available to the packet.*
2. *S is the* $\mathsf{SetLike}^{\uparrow}$ *membership row for the underlying subset being inspected.*
3. *O is the interior row, recording the open part read from S through T.*
4. *I is the closure-of-interior row, recording the closed row reached from O inside the same topology.*
5. *C is the closedness row, asserting that the inspected subset is read as the closure row I.*
6. *E is the exactness row, recording the displayed equality of the subset row with the closure of its interior as a local certificate row.*
7. *H is componentwise* hsame *transport for T, S, O, I, C, E.*
8. *Q is displayed* Cont *replay for the route $S \to O \to I \to C \to E$.*
9. *P is* Pkg *provenance over* $\mathsf{RegularClosedSet}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{RegularOpenAlgebra}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularClosedSet}^{\uparrow}}$ *row.*

The carrier exports only the displayed topology, membership, interior, closure, closedness, exactness, transport, replay, provenance, and local naming rows.

Lean4 ✓ `BEDC.Derived.RegularClosedSetUp.RegularClosedSetTasteGate single carrier alignment`

Theorem 8221.2 (Regular closed set NameCert obligations)**.** *For the carrier of Definition 8221.1, the local* $\mathsf{NameCert}_{\mathsf{RegularClosedSet}^{\uparrow}}$ *surface consists exactly of carrier admission for* $R = (T, S, O, I, C, E, H, Q, P, N)$*, ambient topology exposure through* T*, set-membership exposure through* S*, interior exposure through* O*, closure-of-interior exposure through* I*, closedness exposure through* C*, exactness exposure through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* Q*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier. The tuple displays the ambient topology row, membership row, interior row, closure-of-interior row, closedness row, exactness row, and structural support rows.

Read the sibling anchors. $\mathsf{Topology}^{\uparrow}$ supplies the open and closed observation discipline, $\mathsf{SetLike}^{\uparrow}$ supplies membership provenance, and chapter 6835 supplies the neighbouring regular-open comparison route without replacing the closed-set carrier.

The remaining rows H, Q, P, N transport, replay, source, and name the same finite route. Since the carrier has no further coordinate, the NameCert obligations cannot export a host powerset equality, selected basis, Boolean algebra completion, compactness theorem, or ambient quotient of closed sets. □

Theorem 8221.3 (Regular closed set closure-interior stability)**.** *Let* $R = (T, S, O, I, C, E, H, Q, P, N)$ *be an accepted* $\mathsf{RegularClosedSet}^{\uparrow}$ *packet. Every accepted read of the underlying subset row* S *that passes through the displayed topology row* T *and interior row* O *returns to the same closed row* I *after closure, and the exactness row* E *keeps the carrier classified as a regular closed set. The stable route is*

$$S \to O \to I \to C \to E,$$

not a host powerset equality, selected basis, Boolean completion, compactness principle, or quotient equality of subsets.

Proof. Begin with the carrier of Definition 8221.1. The subset row is not read directly as a host set; it is read through the topology row, then through the displayed interior and closure-of-interior rows.

Apply the NameCert obligations of Definition 8221.2. They require the same T, S, O, I, C, E route before a local certificate can expose regular closedness.

The transport and replay rows preserve only those displayed coordinates. Thus a downstream topology or set-like consumer receives closure-interior stability for the finite carrier, while the excluded host powerset equality, selected basis, Boolean completion, compactness principle, and quotient subset equality remain outside the packet. □

Falsifiable prediction: A claimed $\mathsf{RegularClosedSet}^{\uparrow}$ packet whose subset row is not recovered from the closure of its displayed interior cannot satisfy the exactness row E.

Independence witness: topology, setlike, regularopenalgebra: $\mathsf{RegularClosedSet}^{\uparrow}$ is not bijective to any listed sibling because it binds ambient topology, set-membership provenance, interior, closure-of-interior, closedness, exactness, componentwise transport, replay, provenance, and local NameCert rows in one packet. TopologyUp supplies open and closed observations without the regular-closed exactness row, SetLikeUp supplies membership without closure-interior stability, and RegularOpenAlgebraUp supplies the neighbouring regular-open comparison route rather than the closed-set carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularClosedSet}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularClosedSet}^{\uparrow}$ packet is generated from ambient TopologyUp observations, SetLikeUp membership provenance, an interior row, a closure-of-interior row, a closedness row, an exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{RegularClosedSet}^{\uparrow}}$, seed)

Scope closed: Definition 8221.1, Definition 8221.2, and Definition 8221.3 seed the regular-closed carrier, obligation surface, and closure-interior stability route over Topology$^{\uparrow}$, SetLike$^{\uparrow}$, RegularOpenAlgebra$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\mathsf{RegularClosedSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host powerset equality, selected bases, Boolean algebra completion, compactness, quotient subset equality, or ambient topological completeness.

Upgrade path: Formal closure requires a Lean carrier and obligation package for the same topology, membership, interior, closure-of-interior, closedness, exactness, transport, replay, provenance, and local naming rows.

Chapter 8222

A Concrete Naming Certificate for $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$ packet records the finite-net search route for a continuous real-valued map on a displayed compact real interval. It sits after the dyadic endpoint core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the uniform-modulus surface of chapter 369, the graph rows of chapter 130, the finite epsilon-net carrier of chapter 1767, and the located bisection route of chapter 1711. The packet names a finite compact-interval search carrier; it does not invoke open-cover compactness, selected host extrema, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8222.1 (Compact real interval net-search carrier)**.** *A* $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, D, U, B, V, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact real interval endpoint row. Its lower and upper endpoints are read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, finite* $\mathsf{StreamName}^{\uparrow}$ *windows, and terminal* $\mathsf{Real}^{\uparrow}$ *names.*
2. *D is the dyadic finite-net cell row, listing the mesh cells, their dyadic endpoints, center probes, and coverage witnesses consumed from* $\mathsf{FiniteEpsilonNet}^{\uparrow}$*.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *row for the displayed* $\mathsf{ContinuousMap}^{\uparrow}$ *graph on the interval source named by I.*
4. *B is the located bisection row, recording the retained cell branch and the finite bisection depth read through* $\mathsf{LocatedIntervalBisection}^{\uparrow}$*.*
5. *V is the value-bracket row, storing lower and upper value comparisons for the inspected cells with the tolerance budget supplied by U.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic endpoints, cell centers, tolerance comparisons, bisection depth, and value brackets.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the interval endpoints, finite-net cells, bisection row, value bracket, and regular rational readback have been exposed.*

8. *H stores componentwise* hsame *transport for the interval endpoints, dyadic finite-net cells, uniform-modulus row, located bisection, value bracket, readback, Real seal, replay, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a compact-interval search request through $I, D, U, B, V, R, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSearch}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $I, D, U, B, V, R, E, H, C, P, N$. No host-selected extremum, open-cover compactness proof, quotient equality of real names, or ambient completeness coordinate is part of the packet.

Theorem 8222.2 (Compact real interval net-search obligations)**.** *For every accepted* CompactRealIntervalNetSearch *carrier $S = (I, D, U, B, V, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSearch}^{\uparrow}}$ *surface consists exactly of carrier admission for the interval endpoints, dyadic finite-net cells, uniform-modulus data, located bisection, value bracket, regular rational readback, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming rows. A consumer must read I, D, U, B, V before it may inspect the readback R or the Real seal E.*

Proof. Project the carrier of Definition 8222.1. The displayed analytic rows are the interval endpoint row I, the dyadic finite-net row D, the uniform-modulus row U, the located bisection row B, and the value bracket row V.

The readback rows are downstream. The regular rational row R repacks only the dyadic endpoints, mesh centers, bisection depth, and value comparisons already displayed by I, D, U, B, V, and the Real seal E is terminal after that readback.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no open-cover compactness proof, host-selected extremum, quotient equality coordinate, or ambient completeness row, the listed rows exhaust the local NameCert surface. □

Theorem 8222.3 (Compact real interval net-search dyadic-net soundness)**.** *Every accepted* CompactRealIntervalNe *search read factors through the dyadic finite-net route*

$$I, D, U \longmapsto B, V \longmapsto R, E, H, C, P, N.$$

The finite cells in D cover the displayed interval endpoints of I, the located bisection row B refines only those cells, and the value bracket V uses only $\mathsf{ContinuousMap}^{\uparrow}$ *values controlled by U. A Real-facing consumer receives no cell outside the finite net and no value comparison detached from the displayed modulus budget.*

Proof. Start from I and D. The interval endpoints and dyadic mesh cells are displayed before the search begins, so every cell inspected by the packet is a row of the finite net.

Use U and B next. The uniform-modulus row supplies the tolerance budget for graph reads, while the located bisection row refines a displayed cell from D rather than choosing a point externally.

The value bracket V is then attached to those cells and to that modulus budget. The readback and seal rows R, E can only package the resulting finite data, and H, C, P, N preserve the same route for downstream consumers. □

Theorem 8222.4 (Compact real interval net-search termination)**.** *For an accepted* $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$ *carrier* $S = (I, D, U, B, V, R, E, H, C, P, N)$*, the search terminates at the displayed finite depth of* B*. The terminal read returns a finite cell family and value bracket whose mesh cells are listed in* D*, whose tolerance budget is supplied by* U*, and whose Real-facing read passes through* R *and* E*.*

Proof. The bisection row B is finite carrier data. Its depth is a displayed row, not a function selected from an ambient compactness theorem.

Apply dyadic-net soundness from Definition 8222.3. Each bisection step refines a cell already listed by D and reads values with the tolerance budget supplied by U.

At the terminal depth, the packet returns only the cell rows and value brackets stored in V. The regular rational readback R and the Real seal E package those rows, so termination is a finite ledger fact of the carrier. □

Theorem 8222.5 (Compact real interval net-search NameCert export)**.** *The public* $\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSea}}$ *export is exactly the finite route*

$\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, Located

It exports a compact-interval finite-net search certificate for downstream real-completion, uniform-continuity, and extreme-value consumers, while excluding open-cover compactness, host-selected extrema, quotient real equality, and ambient Real completeness.

Proof. Combine the carrier obligations of Definition 8222.2 with dyadic-net soundness in Definition 8222.3. The source rows are exactly the dyadic endpoint core, finite stream windows, regular rational readback, Real seal, uniform modulus, continuous-map graph, finite epsilon-net cells, and located bisection route.

Apply termination from Definition 8222.4. The exported search result is a finite terminal cell family with value brackets, transported and replayed through H, C and named by P, N.

The excluded principles are absent from the carrier. Therefore no public consumer can obtain open-cover compactness, a host-selected extremum, quotient real equality, or ambient Real completeness from this NameCert export. □

Falsifiable prediction: Every accepted $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$ read must display interval endpoints, dyadic finite-net cells, a uniform-modulus row, located bisection, value brackets, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert before any compact-interval search result is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, uniformmodulus, continuousmap, finite-epsilon-net, located-interval-bisection: $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries interval endpoints, dyadic finite-net cells, uniform-modulus data, located bisection, value brackets, readback, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSearch}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSearch}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8222.1, Definition 8222.2, Definition 8222.3, Definition 8222.4, and Definition 8222.5 seed the constructive compact real interval finite-net search route over dyadic endpoints, finite cells, uniform-modulus data, located bisection, value brackets, readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactRealIntervalNetSearch}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, host-selected extrema, quotient real equality, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{CompactRealIntervalNetSearch}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, dyadic-net soundness, finite-depth termination, readback exactness, Real-seal nonescape, transport stability, and public NameCert export for BEDC.Derived.CompactRealIntervalNetSearchUp.

Constructive story: A CompactRealIntervalNetSearch$^{\uparrow}$ packet is generated from interval endpoints, dyadic finite-net cells, UniformModulusUp data, ContinuousMapUp graph rows, a LocatedIntervalBisectionUp finite branch, value brackets, RegSeqRatUp readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8223

A Concrete Naming Certificate for $\mathsf{HalesJewett}^{\uparrow}$

Following Hales and Jewett's finite-word theorem, the $\mathsf{HalesJewett}^{\uparrow}$ packet records the finite alphabet, word window, variable-word line, and coloring readback surface as displayed NameCert data. It sits beside the finite-coloring witness discipline of chapter 203 and reads words through the $\mathsf{List}^{\uparrow}$ spine of chapter 36. The packet names a finite combinatorial-line certificate; it is not an ambient infinite-choice principle, host language equality, unrestricted substitution schema, or external Hales–Jewett theorem oracle.

Definition 8223.1 (Hales-Jewett carrier)**.** *A* $\mathsf{HalesJewett}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (A, W, V, L, C, H, R, P, N)$$

with the following displayed rows:

1. *A is the finite alphabet row, including the displayed color endpoints and the finite symbol classifier used by all word reads.*
2. *W is the finite word-window row. Each word is read as a* $\mathsf{List}^{\uparrow}$ *spine over A, and the window records the inspected length and membership rows.*
3. *V is the variable-word row. It records a finite word spine over A together with at least one displayed variable position.*
4. *L is the combinatorial-line row obtained by substituting each displayed alphabet symbol into every variable position of V while leaving the constant positions fixed.*
5. *C is the finite coloring row on the word window, exposing colors only for the words listed by W and the line entries listed by L.*
6. *H records componentwise* hsame *transport for the alphabet, word window, variable word, line row, coloring row, replay, provenance, and local naming.*
7. *R records displayed* Cont *replay for alphabet membership, word-spine reads, variable substitution, line enumeration, coloring lookup, and monochromatic-line readback.*
8. *P is the* Pkg *provenance over* $\mathsf{HalesJewett}^{\uparrow}$*,* $\mathsf{Ramsey}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{Nat}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HalesJewett}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $A, W, V, L, C, H, R, P, N$. It contains no coordinate for host language equality, infinite choice of substitutions, an unrestricted coloring function, or an ambient combinatorial principle beyond the displayed finite packet.

Theorem 8223.2 (Hales-Jewett NameCert obligations)**.** *For every accepted* $\mathsf{HalesJewett}^{\uparrow}$ *carrier*

$$J = (A, W, V, L, C, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HalesJewett}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite alphabet row, word-window exposure, variable-word admission with a displayed variable position, substitution stability for the combinatorial-line row, finite coloring lookup, monochromatic-line readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every consumer reads the line through the displayed* $\mathsf{List}^{\uparrow}$ *word spines and may use the* $\mathsf{Ramsey}^{\uparrow}$ *sibling only as a finite-coloring neighbor; no consumer obtains infinite choice, host language equality, an unrestricted coloring oracle, or an ambient combinatorial theorem from the packet.*

Proof. Project the accepted carrier. The rows A, W, V, L, C name the finite alphabet, the finite word window, the variable word, the line generated by substitutions into the displayed variable positions, and the coloring values available on that finite window.

Word and line admission are finite. The word window W reads each word through a $\mathsf{List}^{\uparrow}$ spine over A, while V marks the variable positions and L lists exactly the words obtained by substituting displayed alphabet symbols into those positions.

Coloring and monochromatic readback are also local to the packet. The row C is consulted only on words exposed by W and line entries exposed by L, so a monochromatic-line consumer can compare only those listed color rows.

Finally H, R, P, N transport, replay, source, and name the same finite data. Since the carrier has no coordinate for infinite substitution choice, host language equality, an external coloring function, or an ambient Hales–Jewett theorem, the listed rows exhaust the NameCert obligations. □

Theorem 8223.3 (Hales-Jewett finite-line handoff)**.** *Every downstream finite-combinatorics consumer of an accepted* $\mathsf{HalesJewett}^{\uparrow}$ *packet reads the route*

$$\mathsf{List}^{\uparrow},\ \mathsf{Ramsey}^{\uparrow},\ \mathsf{Nat}^{\uparrow} \longmapsto \mathsf{HalesJewett}^{\uparrow}$$

only through the displayed alphabet row, word-window row, variable-word row, combinatorial-line row, coloring row, componentwise transport, replay, provenance, and local naming. The handoff supplies a finite variable-word line and its monochromatic readback, not a host word language, an infinite choice sequence, or an unrestricted combinatorial principle.

Proof. Read the packet rows in order. The $\mathsf{List}^{\uparrow}$ spine supplies finite word syntax, the $\mathsf{Nat}^{\uparrow}$ row supplies the inspected length and position budget, and the $\mathsf{Ramsey}^{\uparrow}$ sibling supplies only the neighboring finite-coloring discipline.

The line handoff is the row L together with the coloring row C. Substitution is performed only at the variable positions displayed by V, and every resulting word must already be exposed in the finite window W before its color can be compared.

The structural rows H, R, P, N preserve this same finite route. Therefore a downstream consumer receives the displayed variable-word line and monochromatic readback, while the excluded host and infinitary objects remain outside the accepted carrier. □

Falsifiable prediction: Every accepted $\mathsf{HalesJewett}^{\uparrow}$ line read factors through a displayed finite alphabet row, a $\mathsf{List}^{\uparrow}$ word-window row, a variable-word row with a visible variable position, a finite combinatorial-line row, a coloring row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: ramsey, list, nat: $\mathsf{HalesJewett}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite alphabet rows, word-window rows, variable-word substitution rows, combinatorial-line rows, coloring readback, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{HalesJewett}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HalesJewett}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8223.1, Definition 8223.2, and Definition 8223.3 seed the finite word-line route over alphabet rows, ListUp word spines, variable-word substitution, finite coloring rows, RamseyUp neighboring coloring discipline, NatUp budgets, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HalesJewett}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host language equality, infinite choice of substitutions, unrestricted coloring functions, ambient Hales–Jewett theorem use, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, word-window exposure, variable substitution stability, monochromatic-line readback, coloring-window exactness, transport, replay, provenance, and local naming for BEDC.Derived.HalesJewettUp.

Constructive story: A $\mathsf{HalesJewett}^{\uparrow}$ packet is generated from finite alphabet rows, ListUp word-window rows, a variable-word row, a finite combinatorial-line row, a coloring row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8224

A Concrete Naming Certificate for $\mathsf{ChineseRemainder}^{\uparrow}$

Following Gauss and the standard algebraic Chinese remainder theorem, the $\mathsf{ChineseRemainder}^{\uparrow}$ packet records finite congruence ledgers over displayed integer, ring, ideal, prime, coprime, and unary-index rows. It sits after the integer carrier of chapter 31, the operation rows of chapter 43, the modulus rows of chapter 81, the prime and coprime ledger rows of chapter 64, and the finite index discipline of chapter 28. The packet names only the displayed residue computation route; it is not a quotient-ring primitive, a selected representative oracle, an ambient ideal factorization theorem, or a host-side modular arithmetic black box.

Definition 8224.1 (Chinese remainder carrier)**.** *A* $\mathsf{ChineseRemainder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, A, M, C, U, L, V, T, H, Q, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Int}^{\uparrow}$ *source row for the displayed residue values and reconstructed integer candidate.*
2. *A is the* $\mathsf{Ring}^{\uparrow}$ *operation row used for addition, multiplication, subtraction, and unit reads during recombination.*
3. *M is the finite modulus row, read through* $\mathsf{Ideal}^{\uparrow}$*, listing the displayed ideals or integer-modulus rows against which congruences are checked.*
4. *C is the* $\mathsf{Prime}^{\uparrow}$ *and coprime ledger row, recording the pairwise coprimality witnesses required by the displayed moduli.*
5. *U is the* $\mathsf{Nat}^{\uparrow}$ *finite index row, naming the inspected modulus positions and the finite recursion order.*
6. *L is the congruence ledger, storing each residue row, its modulus row, and the local proof that the candidate agrees with the residue modulo that row.*
7. *V is the recombination row, displaying the finite Bezout or unit coefficients used to assemble the candidate from the listed residues.*
8. *T is the transport row, recording the componentwise* hsame *movement of residues, moduli, coefficients, congruence checks, and reconstructed candidate data.*
9. *H is the replay row, storing displayed* Cont *replay from the residue request through I, A, M, C, U, L, V, T.*

10. *Q is the classifier row, comparing accepted packets only by the displayed residue ledger, coprime ledger, recombination row, transport, and replay data.*
11. *P is the* Pkg *provenance over* $\mathsf{ChineseRemainder}^{\uparrow}$, $\mathsf{Int}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Ideal}^{\uparrow}$, $\mathsf{Prime}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ChineseRemainder}^{\uparrow}}$ *row.*

The classifier has no coordinate for quotient-ring equality, a hidden representative selector, an infinite family of moduli, a non-displayed ideal decomposition, or a detached host proof of the Chinese remainder theorem.

Theorem 8224.2 (Chinese remainder NameCert obligations)**.** *For every accepted* $\mathsf{ChineseRemainder}^{\uparrow}$ *carrier*

$$R = (I, A, M, C, U, L, V, T, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChineseRemainder}^{\uparrow}}$ *surface consists exactly of integer residue admission, ring-operation admission, finite modulus-row admission, coprime ledger admission, unary index budgeting, congruence ledger exposure, recombination coefficient exposure, componentwise* hsame *transport, displayed* Cont *replay, classifier comparison through displayed rows, provenance, and local naming.*

Proof. Project the carrier of Definition 8224.1. The rows I, A, M, C, U expose the arithmetic source, operation surface, modulus list, coprime witnesses, and finite index budget before any residue computation can be read.

Read the ledger and recombination rows next. The row L stores the finite congruence checks, and V stores the displayed coefficient data used to assemble the reconstructed candidate; neither row can be replaced by a quotient-ring equality or a selected representative.

Finally T, H, Q, P, N transport, replay, compare, source, and name the same finite packet. Since the carrier contains no other coordinate, these rows exhaust the local NameCert obligations. □

Theorem 8224.3 (Chinese remainder congruence ledger)**.** *Let $R = (I, A, M, C, U, L, V, T, H, Q, P, N)$ be an accepted* $\mathsf{ChineseRemainder}^{\uparrow}$ *carrier. For every modulus position displayed by U, the reconstructed candidate named by I and V agrees with the corresponding residue row of L modulo the corresponding modulus row of M, and the agreement is replayed through the same coprime ledger C and transport row T.*

Proof. Induct over the finite index row U. In the base case, the first displayed modulus row is read from M, its residue row is read from L, and the recombination row V supplies the coefficient data whose local congruence is checked by the ring operations in A.

For the induction step, assume the already-inspected prefix has been replayed through H and transported by T. The next index exposes its modulus row and coprime witnesses through M and C, and the next congruence row of L checks the reconstructed candidate against that modulus using only displayed operations.

Because the induction ranges only over the finite row list, it cannot introduce quotient-ring representatives, an infinite modulus family, or an external CRT oracle. The replay row H and provenance row P then package the same finite congruence ledger as the public local certificate. □

Falsifiable prediction: An accepted $\mathsf{ChineseRemainder}^{\uparrow}$ consumer is refuted by any reconstructed integer read that omits one of the displayed integer residue, ring operation, finite modulus, coprime ledger, unary index, congruence ledger, recombination, transport, replay, provenance, or local naming rows.

Independence witness: int, ring, ideal, prime, nat: $\mathsf{ChineseRemainder}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores residue rows, operation rows, finite modulus rows, pairwise coprime witnesses, index data, congruence ledgers, recombination coefficients, transport, replay, classifier comparison, provenance, and local NameCert data in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ChineseRemainder}^{\uparrow}}$.

Constructive story: A $\mathsf{ChineseRemainder}^{\uparrow}$ packet is generated from integer residue rows, ring operation rows, finite modulus rows, coprime ledger rows, unary index data, congruence ledgers, recombination coefficients, componentwise hsame transport, displayed Cont replay, classifier comparison, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChineseRemainder}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8224.1, Definition 8224.2, and Definition 8224.3 seed the finite congruence-ledger route over IntUp, RingUp, IdealUp, PrimeUp, coprime, NatUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChineseRemainder}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient-ring equality, selected representatives, ideal factorization, infinite modulus families, or an ambient Chinese remainder theorem.

Upgrade path: Obligation closure requires checked carrier admission, finite modulus exposure, coprime ledger exactness, congruence-row replay, recombination-row stability, transport, classifier comparison, provenance, and local naming for BEDC.Derived.ChineseRemainderUp.

Chapter 8225

A Concrete Naming Certificate for $\mathsf{RationalIntervalPartition}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalIntervalPartition}^{\uparrow}$ packet records a finite partition of a rational interval as displayed rational endpoints, dyadic refinement witnesses, stream-window access, regular-rational readback, and a terminal Real-facing boundary. It sits after the rational carrier of chapter 37, the dyadic rational core of chapter 291, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The packet names a finite partition certificate only; it is not an open-cover compactness theorem, a selected refinement principle, quotient stream equality, arbitrary real interval arithmetic, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8225.1 (Rational interval partition carrier)**.** *A* $\mathsf{RationalIntervalPartition}^{\uparrow}$ *carrier is a finite packet*

$$P = (I, E, O, L, D, S, Q, R, H, C, G, N)$$

with the following displayed rows:

1. *I is the closed rational interval row, recording the left endpoint, right endpoint, and rational endpoint comparison through* $\mathsf{Rat}^{\uparrow}$*;*
2. *E is the finite endpoint-list row, recording the ordered rational breakpoints from the left endpoint to the right endpoint;*
3. *O is the adjacent-order row, recording for each neighboring pair the displayed rational comparison that makes a subinterval;*
4. *L is the local-length row, recording rational length data for each adjacent subinterval without completing it to a real measure;*
5. *D is the dyadic-refinement row, recording the* $\mathsf{DyadicRatCore}^{\uparrow}$ *witnesses used when a downstream reader asks for dyadic tolerances on the partition;*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording finite observation windows for the ordered endpoint list and its adjacent pairs;*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording regular rational observations of endpoint windows and dyadic tolerance rows;*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *handoff row, available only after I, E, O, L, D, S, Q have been displayed;*

9. *H records componentwise* hsame *transport for interval endpoints, endpoint lists, adjacent-order rows, length rows, dyadic witnesses, stream windows, regular readback, real handoff, replay, provenance, and local naming;*
10. *C records displayed* Cont *replay through $I, E, O, L, D, S, Q, R, H, G, N$;*
11. *G is the* Pkg *provenance over* $\mathsf{RationalIntervalPartition}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an arbitrary cover, a host supremum or infimum, a selected compactness witness, quotient equality of real names, countable choice, or ambient completeness.

Theorem 8225.2 (Rational interval partition NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalPartition}^{\uparrow}$ *carrier*

$$P = (I, E, O, L, D, S, Q, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RationalIntervalPartition}^{\uparrow}}$ *surface consists exactly of rational interval admission, finite endpoint-list admission, adjacent-order checks, local rational length rows, dyadic refinement witnesses, stream-window exposure, regular rational readback, terminal Real-facing handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8225.1. The interval data are exactly the rational endpoint row I, finite endpoint list E, adjacent-order row O, and local length row L.

The refinement and observation obligations are the rows D, S, Q, R. Dyadic tolerance requests read D, finite endpoint observations read S, regular rational consumers read Q, and Real-facing consumers reach R only after the preceding rows are present.

The structural rows H, C, G, N preserve and name that same finite route. Since no carrier coordinate stores an arbitrary open cover, selected refinement, quotient real equality, countable-choice schedule, or ambient completeness principle, the listed rows exhaust the local NameCert obligations. □

Theorem 8225.3 (Rational interval partition completion handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalIntervalPartition}^{\uparrow}$ *packet reads the partition through the route*

$$\mathsf{Rat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

In particular, the consumer must expose the rational interval row I, finite endpoint-list row E, adjacent-order row O, local length row L, dyadic-refinement row D, and stream-window row S before it may read the regular-rational row Q or terminal Real-facing row R.

Proof. Start from an accepted carrier $P = (I, E, O, L, D, S, Q, R, H, C, G, N)$. The only interval source is the rational row I, and the only partition source is the finite endpoint list E together with the adjacent-order checks O.

The local length row L and dyadic-refinement row D keep each subinterval inside rational and dyadic data. The stream-window row S is therefore the only finite observation surface for downstream reads.

The regular-rational row Q is downstream of those windows, and the terminal Real-facing row R is downstream of Q. Transport, replay, provenance, and local naming preserve this order and do not add an open-cover compactness row or a selected limit. □

Falsifiable prediction: A completion-facing consumer that exports a $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ readback from $\mathsf{RationalIntervalPartition}^{\uparrow}$ while omitting one of the displayed rational interval, endpoint-list, adjacent-order, length, dyadic-refinement, stream-window, transport, replay, provenance, or local naming rows is not reading this packet.

Independence witness: Nearest siblings: rat, dyadicratcore, streamname, regseqrat, real. The carrier is not bijective to RatUp because it adds a finite ordered endpoint list and adjacent subinterval rows; not to DyadicRatCoreUp because dyadic data only refines displayed rational intervals; not to StreamNameUp because windows observe a fixed partition surface; not to RegSeqRatUp because readback is downstream of the partition ledger; and not to RealUp because the terminal seal is only a handoff row.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalPartition}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8225.1, Definition 8225.2, and Definition 8225.3 seed the finite rational interval partition route from rational endpoints to regular rational readback and a Real-facing seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected refinements, quotient real equality, countable choice, arbitrary real interval arithmetic, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational endpoint ordering, finite endpoint-list stability, adjacent subinterval exactness, dyadic refinement, stream-window readback, RegSeqRat handoff, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.RationalIntervalPartitionUp.

Constructive story: A $\mathsf{RationalIntervalPartition}^{\uparrow}$ packet is generated from rational interval endpoints, a finite endpoint list, adjacent-order rows, rational length rows, dyadic-refinement witnesses, stream-window rows, RegSeqRat readback, a Real-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8226

A Concrete Naming Certificate for $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$

Following Bishop and Bridges and Kelley on completion universal properties, the $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ packet records the located-completion unit and extension route as finite NameCert data. It sits beside the metric-completion carrier of chapter 1506, the located completion seal of chapter 1805, the located uniform-completion route of chapter 1692, the regular-Cauchy completion functor of chapter 3956, and the Cauchy completion adjunction of chapter 1456. The packet names the located unit, located extension, uniqueness ledger, and non-escape route without adding quotient completions, selected limits, countable choice, or ambient Real completeness.

Definition 8226.1 (Located completion adjunction carrier)**.** *A* $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, U, E, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *source row, including the displayed metric-completion route and its finite tolerance readback.*
2. *S is the* $\mathsf{LocatedCompletionSeal}^{\uparrow}$ *row that seals located Cauchy data before any completion-facing consumer reads the target.*
3. *U is the located unit row from source observations into the located completion packet.*
4. *E is the located extension row for maps whose source-side reads preserve the displayed locatedness data.*
5. *Q is the uniqueness ledger comparing two located extension rows only after their source, seal, and unit rows have been displayed.*
6. *A is the adjunction row, read through the sibling* $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ *and specialized to the located carrier surface.*
7. *H records componentwise* hsame *transport for metric-completion source, located seal, unit, extension, uniqueness, adjunction, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a located source request through M, S, U, E, Q, A, H.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{LocatedCompletionSeal}^{\uparrow}$, $\mathsf{LocatedUniformCompletion}^{\uparrow}$, $\mathsf{RegularCauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedCompletionAdjunction}^{\uparrow}}$ *row.*
The carrier contains no quotient completion class, selected representative, selected limit, countable-choice schedule, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Theorem 8226.2 (Located completion adjunction NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ *carrier*

$$L = (M, S, U, E, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompletionAdjunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed tuple, metric-completion source exposure through M, located seal exposure through S, located unit exposure through U, located extension exposure through E, uniqueness through Q, adjunction routing through A, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8226.1. The rows M, S, U, E, Q, A give the metric-completion source, located seal, unit, extension, uniqueness, and adjunction data, while H, C, P, N give transport, replay, provenance, and local naming.

The located route is read in order. A consumer first sees the metric-completion source row M, then the located seal row S, and only then the unit and extension rows U, E.

Uniqueness is local to the same packet. The row Q compares located extensions after the source and seal rows are displayed, and A records the adjunction route through the sibling completion adjunction rather than through an external completed object.

The structural rows H, C, P, N transport, replay, source, and name exactly this tuple. Since no carrier coordinate stores quotient completions, selected representatives, selected limits, countable choice, host equality, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8226.3 (Located completion adjunction unit-counit route)**.** *Every unit-side or counit-side read of an accepted* $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ *packet factors through the same displayed route*

$$\mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{LocatedCompletionSeal}^{\uparrow} \longmapsto \mathsf{LocatedUniformCompletion}^{\uparrow} \longmapsto \mathsf{RegularCauchyCompletionFunc}$$

together with the unit row U, extension row E, uniqueness ledger Q, adjunction row A, componentwise transport H, displayed replay C, provenance P, and local naming row N of Definition 8226.1. Thus the unit and counit are read as located finite routes, not as quotient-completion equality or host-level natural isomorphism.

Proof. Start with the NameCert obligations of Definition 8226.2. They identify the accepted packet with the displayed rows $M, S, U, E, Q, A, H, C, P, N$.

For a unit-side read, use M and S before U. The metric-completion source row fixes the completion-facing boundary, and the located seal keeps located Cauchy data visible before the source observation enters the completion packet.

For a counit-side read, use E, Q, A after the same source and seal rows. The extension row is compared only by the uniqueness ledger, and the adjunction row is routed through the sibling $\mathsf{CauchyCompletionAdjunction}^{\uparrow}$ surface specialized to located data.

The rows H, C, P, N preserve the same finite route for transport, replay, provenance, and local naming. Hence neither side of the unit-counit read can escape to quotient-completion equality, a host-level natural isomorphism, countable choice, or ambient completeness. □

Theorem 8226.4 (Located completion adjunction non-escape)**.** *Every consumer read of an accepted* $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ *packet remains inside the displayed rows* $M, S, U, E, Q, A, H, C, P, N$*. In particular, the packet may expose the metric-completion source, located completion seal, located unit, located extension, uniqueness ledger, adjunction route, transport, replay, provenance, and local naming rows, but it cannot expose quotient completions, selected limits, countable choice, host equality of completed objects, or ambient Real completeness.*

Proof. Project the carrier and apply the obligation theorem. The accepted packet has exactly the rows $M, S, U, E, Q, A, H, C, P, N$, and the local NameCert surface lists no additional completion object.

Apply the unit-counit route theorem. It forces both source-to-completion and completion-to-located-extension reads through the same metric source, located seal, located uniform-completion route, regular-Cauchy completion functor, and Cauchy completion adjunction surface.

Finally inspect the excluded endpoints. Quotient completions, selected limits, countable-choice schedules, host equality of completed objects, and ambient Real completeness are not rows of the carrier and are not introduced by H, C, P, N. Therefore no consumer read can extract them from the located adjunction packet. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ read must expose a MetricCompletionUp source row, a LocatedCompletionSealUp row, a located unit row, a located extension row, a uniqueness ledger, a CauchyCompletionAdjunctionUp route, componentwise transport, displayed replay, provenance, and local naming before any located-completion universal-property consumer may inspect the packet.

Independence witness: metriccompletion, located-completion-seal, located-uniform-completion, regular-cauchy-completion-functor, cauchy-completion-adjunction: $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly records located sealing, unit-extension comparison, uniqueness, and adjunction routing in one finite NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionAdjunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedCompletionAdjunction}^{\uparrow}$ packet is generated from a metric-completion source row, located completion seal, located unit, located extension, uniqueness ledger, adjunction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletionAdjunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8226.1, Definition 8226.2, Definition 8226.3, and Definition 8226.4 seed the located completion universal-property surface over the MetricCompletion, LocatedCompletionSeal, LocatedUniformCompletion, RegularCauchyCompletionFunctor, and CauchyCompletionAdjunction rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletionAdjunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected limits, countable choice, host equality of completed objects, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located unit routing, located extension routing, uniqueness-ledger exhaustion, adjunction-row compatibility, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompletionAdjunctionUp.

Chapter 8227

A Concrete Naming Certificate for $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ packet records the finite modulus data used by the diagonal-limit route of chapter 9238. It sits beside the finite $\mathsf{StreamName}^{\uparrow}$ window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the Cauchy-limit boundary of chapter 386. The packet names a finite modulus certificate for the Real-completeness diagonal theorem; it is not a selected host limit, quotient stream equality, countable-choice schedule, open-cover compactness argument, or ambient completeness principle for $\mathsf{Real}^{\uparrow}$.

Definition 8227.1 (Diagonal limit modulus certificate carrier)**.** *A* $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ *carrier is a finite packet*

$$M = (S, T, D, Q, L, R, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-sequence row, recording the displayed regular Cauchy input over* $\mathsf{RegSeqRat}^{\uparrow}$*;*
2. *T is the finite tail-threshold row, recording the modulus requests and selected threshold indices as displayed data rather than as a choice functional;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic bounds used to compare source terms with the diagonal representative;*
4. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording finite observations of the source sequence at the threshold indices;*
5. *L is the* $\mathsf{RegSeqRat}^{\uparrow}$ *diagonal readback row, recording the regular rational name assembled from those windows;*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row attached to the diagonal readback;*
7. *U is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row, recording that the same finite route is eligible for the limit-seal consumer;*
8. *H records componentwise* hsame *transport for the source sequence, threshold row, dyadic tolerance row, stream windows, diagonal readback, Real seal, Cauchy-limit seal, replay, provenance, and local naming;*

9. *C records displayed* Cont *replay through $S, T, D, Q, L, R, U, H, P, N$;*
10. *P is the* Pkg *provenance over* $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected infinite subsequence, a quotient of regular rational streams, a host real limit, countable choice, open-cover compactness, or ambient Real completeness.

Theorem 8227.2 (Diagonal limit modulus certificate NameCert obligations)**.** *For every accepted* $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ *carrier*

$$M = (S, T, D, Q, L, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}}$ *surface consists exactly of source-sequence admission, finite tail-threshold admission, dyadic tolerance exactness, finite stream-window exposure, regular rational diagonal readback, terminal Real-facing seal, Cauchy-limit seal compatibility, component-wise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8227.1. The source and modulus data are exactly S, T, D: the regular Cauchy input, finite threshold schedule, and dyadic tolerance ledger.

The diagonal readback route is then Q, L, R, U. Stream windows expose only finite observations at the displayed thresholds, the regular rational row assembles the diagonal readback from those observations, the Real row seals that readback, and the Cauchy-limit row records the same route as a limit-seal boundary.

The structural rows H, C, P, N transport, replay, source, and name this finite route. Since the carrier has no coordinate for a selected host limit, quotient stream equality, countable-choice schedule, open-cover compactness, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8227.3 (Diagonal limit modulus certificate seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *consumer of an accepted* $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ *packet reads the diagonal modulus route through*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{CauchyLimitSeal}^{\uparrow}.$$

Concretely, the consumer must expose the source-sequence row S, tail-threshold row T, dyadic tolerance row D, finite window row Q, and regular rational diagonal row L before it may read the Real seal R or the Cauchy-limit seal U.

Proof. Start from an accepted carrier $M = (S, T, D, Q, L, R, U, H, C, P, N)$. The only source sequence visible to the consumer is S, and the only modulus data are the finite threshold and dyadic tolerance rows T, D.

The stream-window row Q reads those displayed thresholds, and the regular rational row L is downstream of Q. Hence a Real-facing consumer reaches R only after the finite windows and regular rational diagonal readback have been exposed.

The Cauchy-limit seal row U consumes the same route and has no second source coordinate. Transport, replay, provenance, and local naming preserve the route, so no downstream reader obtains a selected host limit, quotient stream equality, countable-choice schedule, open-cover compactness argument, or ambient completeness theorem from this packet. □

Falsifiable prediction: A Real-completeness consumer that exports a $\mathsf{Real}^{\uparrow}$ or $\mathsf{CauchyLimitSeal}^{\uparrow}$ limit read from $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ while omitting one of the displayed source-sequence, threshold, dyadic tolerance, stream-window, regular readback, transport, replay, provenance, or local naming rows is not reading this packet.

Independence witness: Nearest siblings: streamname, regseqrat, dyadicratcore, real, cauchylimitseal. The carrier is not bijective to StreamNameUp because it adds threshold and dyadic modulus rows; not to RegSeqRatUp because regular readback is downstream of the diagonal schedule; not to DyadicRatCoreUp because dyadic data only supplies tolerance evidence; not to RealUp because the Real row is a terminal handoff; and not to CauchyLimitSealUp because the limit seal consumes the displayed diagonal modulus route rather than replacing it.

Closure status for $\mathsf{NameCert}_{\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8227.1, Definition 8227.2, and Definition 8227.3 seed the finite diagonal modulus route from regular rational source data to a Real-facing and Cauchy-limit seal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected host limits, quotient stream equality, countable choice, open-cover compactness, ambient Real completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-sequence stability, tail-threshold exactness, dyadic tolerance exactness, stream-window readback, RegSeqRat diagonal handoff, Real handoff, CauchyLimitSeal compatibility, transport, replay, provenance, and local naming for BEDC.Derived.DiagonalLimitModulusCertificateUp.

Constructive story: A $\mathsf{DiagonalLimitModulusCertificate}^{\uparrow}$ packet is generated from a regular rational source sequence, finite tail thresholds, dyadic tolerance rows, StreamName windows, RegSeqRat diagonal readback, a Real seal, a CauchyLimitSeal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8228

Fitting Lemma Name Certificate Construction

Following Fitting and Atiyah–Macdonald, the $\mathsf{FittingLemma}^{\uparrow}$ packet records the finite decomposition surface for an endomorphism of a Noetherian module. It sits over the module carrier of chapter 46, the Noetherian finiteness surface of chapter 3648, the linear-map rows of chapter 48, and the Fitting-ideal packet of chapter 6447; it does not import an ambient abelian-category splitting theorem, quotient equality, or choice of complements.

Definition 8228.1 (Fitting lemma carrier)**.** *A* $\mathsf{FittingLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, N, E, I, K, T, S, R, H, C, P, L)$$

with the following displayed rows:

1. *M is the underlying* $\mathsf{Module}^{\uparrow}$ *row, including the visible additive and scalar-operation classifier data.*
2. *N is the* $\mathsf{NoetherianModule}^{\uparrow}$ *row for the same module carrier, recording the finite ascending-chain and generator witnesses used by the packet.*
3. *E is the* $\mathsf{LinMap}^{\uparrow}$ *endomorphism row, with source and target both read from M.*
4. *I is the* $\mathsf{FittingIdeal}^{\uparrow}$ *row generated by the displayed determinantal data of E on the finite Noetherian presentation.*
5. *K is the finite kernel-stabilization ledger listing the inspected rows for $\ker(E^n)$ and $\ker(E^{n+1})$.*
6. *T is the finite image-stabilization ledger listing the inspected rows for $\mathrm{im}(E^n)$ and $\mathrm{im}(E^{n+1})$.*
7. *S is the decomposition row asserting that the stabilized kernel and image rows are disjoint on the displayed module coordinates and jointly cover the accepted carrier.*
8. *R records the replay routes from E, N, I, K, T to S, including the finite powers of the endomorphism actually inspected.*
9. *H stores componentwise* hsame *transport for the module, Noetherian, linear-map, Fitting-ideal, stabilization, decomposition, replay, provenance, and local-name rows.*
10. *C stores displayed* Cont *replay for kernel reads, image reads, Fitting-ideal reads, stabilized decomposition reads, and consumer handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{FittingLemma}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{NoetherianModule}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{FittingIdeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *L is the local* $\mathsf{NameCert}_{\mathsf{FittingLemma}^{\uparrow}}$ *row.*

The classifier accepts exactly these finite rows. It has no coordinate for an external complement selector, quotient-space equality, classical primary decomposition, or a host theorem proving the Fitting lemma outside the displayed packet.

Theorem 8228.2 (Fitting lemma NameCert obligations)**.** *For every accepted* $\mathsf{FittingLemma}^{\uparrow}$ *carrier* $Q = (M, N, E, I, K, T, S, R, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{FittingLemma}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, module-row exposure through M, Noetherian-row exposure through N, endomorphism exposure through E, Fitting-ideal exposure through I, kernel and image stabilization through K and T, decomposition replay through S and R, componentwise transport through H, continuation replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier and read the structural rows. The module row, Noetherian row, linear endomorphism row, and Fitting-ideal row are the only algebraic coordinates available to the classifier.

Inspect the stabilization ledgers next. The kernel ledger K and image ledger T list the finite powers of E whose stabilized rows are used by the decomposition surface.

Finally replay the decomposition row. The route R witnesses that S is consumed only after the displayed stabilization rows and their transports have been read, while C, P, L replay, source, and name the same packet. No other NameCert obligation is exported. □

Theorem 8228.3 (Fitting lemma kernel-image splitting route)**.** *Every accepted* $\mathsf{FittingLemma}^{\uparrow}$ *carrier exposes a finite route from the* $\mathsf{Module}^{\uparrow}$, $\mathsf{NoetherianModule}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, *and* $\mathsf{FittingIdeal}^{\uparrow}$ *rows to the stabilized kernel-image decomposition. A consumer of the decomposition row must first read*

$$M, N, E, I \longmapsto K, T \longmapsto S$$

together with the replay, transport, provenance, and local-name rows R, H, C, P, L.

Proof. Read the algebraic base rows M, N, E, I. These rows identify the module, its Noetherian finiteness witness, the displayed endomorphism, and the Fitting-ideal data attached to that endomorphism.

The stabilization rows are downstream from this base. The packet records only the finite kernel rows in K and finite image rows in T that are reached by replaying powers of E through the Noetherian and Fitting-ideal ledgers.

The splitting row S is then consumed through R, H, C, P, L. Since no complement selector or host quotient equality is a coordinate of Q, the consumer obtains only the displayed kernel-image route and no stronger ambient decomposition principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{FittingLemma}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FittingLemma}^{\uparrow}$ packet is generated from module, Noetherian, endomorphism, Fitting-ideal, kernel-stabilization, image-stabilization, decomposition, replay, transport, continuation, provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FittingLemma}^{\uparrow}}$, seed)

Scope closed: Definition 8228.1, Definition 8228.2, and Definition 8228.3 bind the finite module-endomorphism decomposition packet and its kernel-image replay route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FittingLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Lean verification, bridge checking, classical complement choice, quotient equality, primary decomposition, or an ambient abelian-category splitting theorem.

Upgrade path: Obligation closure requires checked carrier admission, stabilization-row exposure, kernel-image replay, transport, provenance, naming, and non-escape for the same finite packet.

Chapter 8229

A Concrete Naming Certificate for $\mathsf{SpecializationTopology}^{\uparrow}$

Following Kolmogorov's T_0 separation reading and Alexandroff's order-theoretic presentation of finite topologies, the $\mathsf{SpecializationTopology}^{\uparrow}$ packet records the classical route from displayed opens to the specialization preorder as finite BEDC NameCert data. It sits after the indexed-open carrier of chapter 88, the preorder carrier of chapter 52, and the observable-open classifier of chapter 1860. The packet names only the finite topology/preorder/Sierpinski bridge; it does not import host opens, quotient point equality, excluded middle over opens, selected representatives, open-cover compactness, or ambient point-set topology.

Definition 8229.1 (Specialization topology carrier)**.** *A* $\mathsf{SpecializationTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, S, R, H, C, P, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *indexed-open row, carrying the open indices, finite membership reads, finite-intersection rows, union rows, and boundary rows supplied by chapter 88.*
2. *S is the* $\mathsf{SierpinskiSpace}^{\uparrow}$ *observable-truth row, reading each displayed open-membership request as a two-observation classifier rather than as a host proposition.*
3. *R is the* $\mathsf{Preorder}^{\uparrow}$ *specialization row, where $x \preceq y$ is recorded only by the displayed implication route saying that every observable open true at x is also true at y.*
4. *H stores componentwise* hsame *transport for the topology row, Sierpinski row, specialization-preorder row, replay, provenance, and local name.*
5. *C stores displayed* Cont *replay from a topology membership request through S into the specialization row R.*
6. *P is the* Pkg *provenance over* $\mathsf{SpecializationTopology}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SierpinskiSpace}^{\uparrow}$, $\mathsf{Preorder}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
7. *N is the local* $\mathsf{NameCert}_{\mathsf{SpecializationTopology}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through T, S, R, H, C, P, N. There is no coordinate for a host lattice of opens, quotient point equality, proof irrelevance for open membership, excluded middle, selected representatives, or open-cover compactness.

Lean4 (definition) `BEDC.Derived.SpecializationTopologyUp.SpecializationTopologyUp`

Theorem 8229.2 (Specialization topology NameCert obligations)**.** *For every accepted* $\mathsf{SpecializationTopology}^{\uparrow}$ *carrier* $K = (T, S, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SpecializationTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the topology, Sierpinski truth, specialization preorder, transport, replay, provenance, and local naming rows; topology exactness through* T*; observable-open exactness through* S*; specialization-preorder exactness through* R*; and provenance exhaustion through* P, N*. No obligation is discharged by host opens, quotient point equality, proof irrelevance, excluded middle over open membership, selected representatives, or open-cover compactness.*

Proof. Project the carrier of Definition 8229.1. The only visible rows are T, S, R, H, C, P, N, so each local obligation must be read from the indexed topology row, the observable-truth row, the specialization-preorder row, or the structural rows.

Topology exactness is supplied by T. The packet can inspect only the named open indices and their displayed closure witnesses, so it has no access to a host lattice of all opens.

Observable-open exactness is supplied by S. Each membership request becomes Sierpinski classifier data before it is used by the preorder row, and therefore remains displayed truth data rather than an ambient proposition.

Specialization exactness is supplied by R. Reflexivity and transitivity are read as preorder data over the observable implication route. The remaining rows H, C, P, N transport, replay, source, and name that finite route, while the refused host objects are absent from the carrier. □

Theorem 8229.3 (Specialization topology Sierpinski-preorder route)**.** *Every consumer that reads a specialization comparison from an accepted* $\mathsf{SpecializationTopology}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{Topology}^{\uparrow} \longmapsto \mathsf{SierpinskiSpace}^{\uparrow} \longmapsto \mathsf{Preorder}^{\uparrow}.$$

The topology row supplies open indices, the Sierpinski row supplies observable truth values for those indices, and the preorder row records only the resulting specialization implication. The route exports no host-open lattice, quotient point equality, selected representative function, excluded middle over opens, proof irrelevance, or open-cover compactness principle.

Proof. Start with T. A specialization read can ask only for open indices and membership requests already displayed by the $\mathsf{Topology}^{\uparrow}$ row.

Replay the request through S. The $\mathsf{SierpinskiSpace}^{\uparrow}$ row turns each open-membership read into observable truth data, so the consumer never receives an ambient truth predicate over all host opens.

Feed those truth rows into R. The $\mathsf{Preorder}^{\uparrow}$ row records the implication route for specialization comparisons and supplies the preorder surface available to downstream order consumers.

Since the carrier contains no quotient point coordinate, selected representative row, excluded-middle row, proof-irrelevance row, or open-cover compactness row, none of those objects can be exported by the route. □

Falsifiable prediction: Every accepted $\mathsf{SpecializationTopology}^{\uparrow}$ read must display a Topology indexed-open row, a SierpinskiSpace observable-truth row, a Preorder specialization row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert before any specialization comparison is consumed.

Independence witness: topology, preorder, sierpinski-space: $\mathsf{SpecializationTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries indexed-open rows, observable Sierpinski truth rows, specialization-preorder rows, transport, replay, provenance, and local naming in one finite bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SpecializationTopology}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpecializationTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8229.1, Definition 8229.2, and Definition 8229.3 seed the finite topology, Sierpinski-truth, and specialization-preorder bridge surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpecializationTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host opens, quotient point equality, proof irrelevance, excluded middle over opens, selected representatives, open-cover compactness, Lean NameCert verification, or bridge checking for $\mathsf{SpecializationTopology}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, topology exactness, Sierpinski observable-truth exactness, specialization-preorder exactness, transport, replay, provenance, and local naming for BEDC.Derived.SpecializationTopologyUp.

Constructive story: A $\mathsf{SpecializationTopology}^{\uparrow}$ packet is generated from a Topology indexed-open row, a SierpinskiSpace observable-truth row, a Preorder specialization row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8230

A Concrete Naming Certificate for CuspNeighborhood$^{\uparrow}$

Following Beardon and Ratcliffe on hyperbolic manifolds, the CuspNeighborhood$^{\uparrow}$ packet records a finite horoball-based cusp-neighborhood certificate at a displayed parabolic boundary end. It sits beside the horoball surface of chapter 7843, the upper-half-plane model of chapter 7806, the discrete action rows of chapter 7282, the metric readback of chapter 3474, and the terminal scalar seal of chapter 38. The packet names only displayed cusp data; it is not a quotient hyperbolic surface, a selected fundamental domain, a completed ideal boundary object, or an ambient finite-volume theorem.

Definition 8230.1 (Cusp-neighborhood carrier)**.** *A* CuspNeighborhood$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, H, S, M, R, E, T, C, P, N)$$

with the following displayed rows:

1. *B is the parabolic boundary-point row, read in the same upper-half-plane boundary surface used by* PoincareHalfPlane$^{\uparrow}$*.*
2. *H is the* HyperbolicHoroball$^{\uparrow}$ *row, recording the horoball attached to B together with its displayed height or Busemann-threshold data.*
3. *S is the boundary-stabilizer row, recording the finite* FuchsianGroupAction$^{\uparrow}$ *word data that preserves the same boundary point and horoball side.*
4. *M is the* HyperbolicMetric$^{\uparrow}$ *metric-threshold readback row used to compare points with the horoball boundary.*
5. *R is the terminal* Real$^{\uparrow}$ *seal for the threshold and metric comparison values.*
6. *E records the local cusp-neighborhood export row, namely the finite region accepted after the boundary point, horoball threshold, stabilizer word, metric readback, and Real seal have all been displayed.*
7. *T records componentwise* hsame *transport for B, H, S, M, R, E and the local certificate row.*
8. *C records displayed* Cont *replay from the upper-half-plane boundary point through the horoball, stabilizer, metric threshold, Real seal, export, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* CuspNeighborhood$^{\uparrow}$*,* HyperbolicHoroball$^{\uparrow}$*,* PoincareHalfPlane$^{\uparrow}$*,* FuchsianGroupAction HyperbolicMetric$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CuspNeighborhood}^{\uparrow}}$ *row.*
The carrier has no coordinate for a quotient cusp surface, a selected fundamental domain, global discreteness of the ambient group, finite-volume completion, or a host ideal-boundary object.

Theorem 8230.2 (Cusp-neighborhood NameCert obligations)**.** *For every accepted* $\mathsf{CuspNeighborhood}^{\uparrow}$ *carrier*

$$K = (B, H, S, M, R, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CuspNeighborhood}^{\uparrow}}$ *surface consists exactly of boundary-point admission through B, horoball and cusp-threshold exposure through H, boundary-stabilizer exposure through S, hyperbolic metric-threshold readback through M, Real sealing through R, local cusp-neighborhood export through E, componentwise* hsame *transport through T, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The first five rows expose the parabolic boundary point, the horoball threshold, the stabilizer word data, the metric readback, and the terminal Real seal.

Read the local export row E only after those rows have been displayed. The export is therefore a cusp-neighborhood row over a named boundary end and horoball threshold, not an ambient quotient surface.

Finally read T, C, P, N. These structural rows transport, replay, source, and name the same finite data. Since the carrier has no coordinate for quotienting by the full group, selecting a fundamental domain, completing the ideal boundary, or proving finite volume, the listed rows exhaust the NameCert obligations. □

Theorem 8230.3 (Cusp-neighborhood horoball handoff)**.** *Every downstream consumer of an accepted* $\mathsf{CuspNeighborhood}^{\uparrow}$ *packet receives the horoball route*

$$\mathsf{PoincareHalfPlane}^{\uparrow},\ \mathsf{HyperbolicHoroball}^{\uparrow},\ \mathsf{FuchsianGroupAction}^{\uparrow},\ \mathsf{HyperbolicMetric}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

only through the displayed boundary point B, horoball row H, boundary-stabilizer row S, metric-threshold row M, Real seal R, export row E, transport row T, replay row C, provenance row P, and local naming row N. The handoff supplies a finite cusp-neighborhood certificate, not a quotient manifold cusp, a selected fundamental region, a global parabolic subgroup theorem, or an ambient finite-volume claim.

Proof. Start from the boundary row B and the horoball row H. They are read through the upper-half-plane and horoball sibling certificates before any cusp-neighborhood export is available.

Next read the stabilizer and metric rows. The row S records only displayed action-word data preserving the same boundary side, and M, R record the threshold comparison and its Real seal.

The handoff row E is therefore downstream of B, H, S, M, R. The structural rows T, C, P, N preserve the same finite route, so a consumer receives only the listed rows and none of the excluded quotient, selection, global-group, or finite-volume objects. □

Falsifiable prediction: Any accepted $\mathsf{CuspNeighborhood}^{\uparrow}$ consumer that reaches a cusp-neighborhood export without first displaying $B, H, S, M, R, T, C, P, N$ fails to read the accepted carrier.

Independence witness: hyperbolic-horoball, poincare-half-plane, fuchsian-group-action, hyperbolic-metric, real: no listed sibling is bijective to $\mathsf{CuspNeighborhood}^{\uparrow}$ because only this packet binds a boundary point, horoball threshold, boundary stabilizer, hyperbolic metric readback, Real seal, cusp export, transport, replay, provenance, and local NameCert row in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CuspNeighborhood}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CuspNeighborhood}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8230.1, Definition 8230.2, and Definition 8230.3 seed the horoball cusp-neighborhood route over boundary-point, horoball-threshold, boundary-stabilizer, metric-threshold, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CuspNeighborhood}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, quotient cusp surfaces, selected fundamental domains, global parabolic subgroup theorems, completed ideal-boundary objects, ambient finite-volume claims, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-point exactness, horoball-threshold exactness, boundary-stabilizer exactness, metric-threshold readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CuspNeighborhoodUp.

Constructive story: A $\mathsf{CuspNeighborhood}^{\uparrow}$ packet is generated from a parabolic boundary-point row, horoball threshold row, boundary-stabilizer row, HyperbolicMetric readback row, Real seal row, local cusp-neighborhood export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8231

A Concrete Naming Certificate for $\mathsf{RemezExchange}^{\uparrow}$

Following Cheney, Approximation Theory, the $\mathsf{RemezExchange}^{\uparrow}$ packet records the finite exchange step used by constructive minimax approximation on a displayed real interval. It consumes the density route of chapter 1634, the alternation surface of chapter 6013, the denominator-bounded comparison boundary of **??**, the compact interval source of chapter 7620, the finite interval-uniform-continuity readback of chapter 6163, and the coefficient carrier of chapter 50. The packet names one displayed exchange move; it is not a host optimizer, an ambient supremum operator, a selected dense enumeration, or a completed quotient function space.

Definition 8231.1 (Remez exchange carrier)**.** *A* $\mathsf{RemezExchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, S, P, E, \Sigma, A, B, G, H, C, Q, N)$$

with the following displayed rows:

1. *I is the compact interval sample row, read through* $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$ *with endpoint containment and interval seals already displayed.*
2. *S is the ordered sample table, listing the finitely many inspected points and the local mesh cells through which each point is read.*
3. *P is the* $\mathsf{Poly}^{\uparrow}$ *approximant row, including the coefficient window and degree budget used by the exchange step.*
4. *E is the residual-value row for the inspected target-minus-approximant values on S.*
5. *Σ is the residual-sign row, recording the alternating sign pattern carried by the current sample.*
6. *A is the alternation-window row, imported from the* $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ *surface when the displayed signs and magnitudes form a minimax window.*
7. *B is the dyadic sup-norm budget row, giving the finite upper and comparison tolerances used to judge the exchange.*
8. *G is the exchange-step row, replacing one displayed sample cell by a stronger residual cell while preserving the ordered interval route.*
9. *H records componentwise* hsame *transport for the interval, sample, polynomial, residual, sign, alternation, budget, exchange, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a minimax request through $I, S, P, E, \Sigma, A, B, G, H, Q, N$.*
11. *Q is the* Pkg *provenance over* $\mathsf{RemezExchange}^{\uparrow}$, $\mathsf{WeierstrassApproximation}^{\uparrow}$, $\mathsf{ChebyshevEquioscillation}^{\uparrow}$, $\mathsf{RationalBestApproximation}^{\uparrow}$, $\mathsf{ConstructiveRealClosedInterval}^{\uparrow}$, $\mathsf{RealIntervalUniformContinuity}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RemezExchange}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host supremum, a selected global optimizer, an unbounded sample search, quotient real-function equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8231.2 (Remez exchange NameCert obligations)**.** *For every accepted* $\mathsf{RemezExchange}^{\uparrow}$ *carrier*

$$X = (I, S, P, E, \Sigma, A, B, G, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{RemezExchange}^{\uparrow}}$ *surface consists exactly of compact interval sample admission, polynomial approximant admission, residual-value readback, residual-sign admission, alternation-window compatibility, dyadic sup-norm budget exposure, exchange-step exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8231.1. The displayed tuple exposes the interval, sample, polynomial, residual, sign, alternation, budget, exchange, transport, replay, provenance, and local naming rows.

The approximation rows then share one finite source route. The interval row I supplies the only endpoint and containment data, the sample row S lists the inspected cells, and the polynomial row P supplies the only approximant admitted by the packet.

The residual and alternation obligations are finite. The rows E and Σ attach residual magnitudes and signs to the inspected sample cells, while A reads the equioscillation window through the sibling alternation certificate. The dyadic budget B is the only sup-norm-facing tolerance available to the exchange.

Finally the exchange row G records the displayed replacement cell. The structural rows H, C, Q, N transport, replay, source, and name the same route, so no host optimizer, ambient supremum, unbounded search, quotient equality, choice principle, or completeness coordinate can enter the local certificate. □

Theorem 8231.3 (Remez exchange equioscillation window)**.** *Every alternation read of an accepted* $\mathsf{RemezExchange}^{\uparrow}$ *carrier factors through the finite route*

$$I, S, P, E, \Sigma, B \longmapsto A \longmapsto G, H, C, Q, N.$$

Thus the equioscillation window consumed by the exchange is witnessed by the displayed sample order, residual signs, dyadic sup-norm budget, and sibling $\mathsf{ChebyshevEquioscillation}^{\uparrow}$ *row, not by an ambient compactness theorem or an uninspected function-space norm.*

Proof. Begin with the carrier inventory. The only data available before the alternation row are the interval row I, the ordered sample table S, the approximant row P, the residual row E, the sign row Σ, and the dyadic budget B.

Apply Definition 8231.2. It forces the alternation-window row A to read the same interval, sample, polynomial, residual, sign, and dyadic-budget rows that were admitted by the carrier.

Consequently an exchange consumer can inspect the equioscillation surface only after those rows are fixed. The exchange, transport, replay, provenance, and local name rows then package the same finite route, with no additional compactness or host norm coordinate available. □

Theorem 8231.4 (Remez exchange finite improvement)**.** *Every finite improvement claim exported by an accepted* $\mathsf{RemezExchange}^{\uparrow}$ *packet is read from the displayed exchange row G together with the dyadic budget B and the alternation-window row A. The handoff may state that the displayed replacement cell improves the inspected residual budget on the named sample route, but it exports no global minimax optimizer, no selected limiting subsequence, no quotient function-space equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Use Definition 8231.3. It places the interval, sample, polynomial, residual, sign, and dyadic-budget rows before the alternation window is available.

The exchange row G can therefore compare only the displayed replacement cell against that same finite window. Its improvement content is a budget comparison over B and A, not a statement about all possible sample sets or a completed function space.

The provenance row records the relationship with the Weierstrass, rational-best, interval-uniform-continuity, and polynomial chapters. Those siblings supply density, comparison, interval readback, and coefficient data, but none of them adds a carrier coordinate for a host optimizer or selected limiting process inside $\mathsf{RemezExchange}^{\uparrow}$. □

Falsifiable prediction: Every accepted $\mathsf{RemezExchange}^{\uparrow}$ read that claims an exchange improvement must display the compact interval sample row, ordered sample table, polynomial approximant row, residual-value row, residual-sign row, alternation-window row, dyadic sup-norm budget, exchange-step row, hsame transport, Cont replay, Pkg provenance, and local NameCert before the improvement conclusion is inspected.

Independence witness: weierstrass-approximation, chebyshev-equioscillation, rational-best-approximation, constructive-real-closed-interval, real-interval-uniform-continuity, polynomial: $\mathsf{RemezExchange}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite exchange-step row, a residual-sign row, an alternation-window row, and a dyadic sup-norm budget over one displayed compact interval sample.

Closure status for $\mathsf{NameCert}_{\mathsf{RemezExchange}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RemezExchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8231.1, Definition 8231.2, Definition 8231.3, and Definition 8231.4 seed the finite Remez exchange carrier, local obligation surface, alternation-window route, and inspected improvement handoff for constructive minimax approximation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RemezExchange}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global minimax existence, host suprema, selected optimizers, limiting exchange convergence, quotient function spaces, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sample-window compatibility, polynomial approximant admission, residual readback, alternation-window compatibility, dyadic budget soundness, exchange-step exactness, transport, replay, provenance, and local naming for BEDC.Derived.RemezExchangeUp.

Constructive story: A $\mathsf{RemezExchange}^{\uparrow}$ packet is generated from compact interval sample rows, an ordered sample table, a displayed polynomial approximant row, residual values, residual signs, an alternation-window row, a dyadic sup-norm budget, one exchange-step row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8232

A Concrete Naming Certificate for $\mathsf{SequentialCompletionMorphism}^{\uparrow}$

Following Bishop and Bridges' constructive completion language, the $\mathsf{SequentialCompletionMorphism}^{\uparrow}$ packet records the finite map-level route between displayed sequential completion packets. It sits between the source and target surfaces of chapter 1683, the extension surface of chapter 1632, the regular rational readback of chapter 301, the finite observation schedule of chapter 126, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only the displayed completion morphism route; it does not import quotient streams, selected representatives, host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8232.1 (Sequential completion morphism carrier)**.** *A* $\mathsf{SequentialCompletionMorphism}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, T, F, W, D, U, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{SequentialCompletion}^{\uparrow}$ *packet whose finite stream, regular rational, dyadic tolerance, criterion, and* $\mathsf{Real}^{\uparrow}$ *seal rows are being mapped.*
2. *T is the target* $\mathsf{SequentialCompletion}^{\uparrow}$ *packet receiving the mapped completion data.*
3. *F is the* $\mathsf{RegSeqRat}^{\uparrow}$*-compatible map row, displaying how regular rational source windows are sent to target regular rational windows.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to inspect the source and target names before any completed seal is read.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the displayed map estimates.*
6. *U is the* $\mathsf{CauchyContinuousExtension}^{\uparrow}$ *row that exposes the extension handoff associated to F.*
7. *H stores componentwise* hsame *transport for the source, target, map, window, dyadic, extension, replay, provenance, and naming rows.*
8. *C stores displayed* Cont *replay from a morphism request through $S, T, F, W, D, U, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SequentialCompletionMorphism}^{\uparrow}$, $\mathsf{SequentialCompletion}^{\uparrow}$, $\mathsf{CauchyContinuousExtensio}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialCompletionMorphism}^{\uparrow}}$ *row.*

The classifier compares accepted morphism packets only through $S, T, F, W, D, U, H, C, P, N$. No quotient stream representative, host function equality, selected limit, countable-choice selector, ambient $\mathsf{Real}^{\uparrow}$ *completeness witness, or bridge checker is part of the carrier.*

Theorem 8232.2 (Sequential completion morphism stability)**.** *For an accepted* $\mathsf{SequentialCompletionMorphism}^{\uparrow}$ *carrier $M = (S, T, F, W, D, U, H, C, P, N)$, the map row F is stable componentwise under the transport row H and the replay row C. Any source-window read displayed by W and measured by D is transported to the same target* $\mathsf{SequentialCompletion}^{\uparrow}$ *row T before the extension row U or any* $\mathsf{Real}^{\uparrow}$ *seal is consumed.*

Proof. Project the carrier of Definition 8232.1. The source and target completion packets are S and T, while F, W, D, U display the regular-rational map, finite windows, tolerance ledger, and extension handoff.

Read H componentwise. It transports the source packet, target packet, map row, window schedule, dyadic ledger, and extension row together, so the map row cannot move independently of the completion packets it relates.

Now apply the replay row C. The replay has no coordinate except the route through $S, T, F, W, D, U, H, P, N$, and therefore every transported map read is replayed through the same finite completion-morphism packet before the local name N is exported. □

Theorem 8232.3 (Sequential completion morphism extension route)**.** *Every extension consumer of an accepted* $\mathsf{SequentialCompletionMorphism}^{\uparrow}$ *carrier must pass through*

$$S, T, F, W, D, U$$

before reading any $\mathsf{Real}^{\uparrow}$ *seal. The consumer receives a displayed map-level handoff from the source sequential completion packet to the target sequential completion packet, together with its regular-rational compatibility, finite stream windows, dyadic tolerance ledger, and Cauchy-continuous extension row. It receives no quotient stream, host function equality, selected limit, countable choice, ambient* $\mathsf{Real}^{\uparrow}$ *completeness assertion, or bridge-checking certificate.*

Proof. Start with the carrier projection. The only extension-facing rows are the source completion packet S, target completion packet T, map row F, window schedule W, tolerance ledger D, and Cauchy-continuous extension row U.

Apply the stability theorem, Definition 8232.2. It keeps F attached to the same source and target completion rows through H and C, so a consumer cannot bypass the displayed map route by reading a completed Real seal first.

Finally use the local provenance and naming rows P, N. They package only the finite route S, T, F, W, D, U, H, C and contain no coordinate for quotient streams, host function equality, selected limits, countable choice, ambient completeness, or bridge checking. □

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialCompletionMorphism}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialCompletionMorphism}^{\uparrow}$ packet is generated from source and target SequentialCompletionUp rows, a RegSeqRatUp-compatible map row, StreamName window schedules, DyadicRatCore tolerance ledgers, a CauchyContinuousExtensionUp row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialCompletionMorphism}^{\uparrow}}$, seed)

Scope closed: Definition 8232.1, Definition 8232.2, and Definition 8232.3 seed the finite map-level route between displayed SequentialCompletionUp packets through RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, CauchyContinuousExtensionUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SequentialCompletionMorphism}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient streams, host function equality, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, map-row stability, extension-consumer routing, transport exactness, replay exactness, provenance, and local naming for BEDC.Derived.SequentialCompletionMorphismUp.

Chapter 8233

A Concrete Naming Certificate for $\mathsf{ChoiceSequenceSpread}^{\uparrow}$

Following Brouwer on choice sequences and spreads, and Bishop–Bridges on lawlike finite approximations to constructive sequences, the $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ packet names the finite prefix surface through which a choice sequence is admitted by a spread law before any infinite branch, choice function, or completed real object is exposed. It sits after the $\mathsf{SpreadLaw}^{\uparrow}$ admission row of chapter 1532, the finite observation schedule of chapter 126, the list spine of chapter 36, and the Boolean endpoint discipline of chapter 32. The packet is a finite BEDC carrier for prefix inspection; it is not countable choice, not a selected infinite branch, and not an ambient fan theorem.

Definition 8233.1 (Choice-sequence spread carrier)**.** *A* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, L, A, S, W, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{Bool}^{\uparrow}$ *endpoint row used by each displayed binary choice.*
2. *L is the* $\mathsf{List}^{\uparrow}$ *finite-prefix row, listing the inspected Boolean prefixes and their parent-prefix inclusions.*
3. *A is the* $\mathsf{SpreadLaw}^{\uparrow}$ *admission row, recording that every displayed prefix in L is accepted by the same spread law and that accepted extensions remain in the displayed prefix tree.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row naming the finite moments at which the choice sequence is observed.*
5. *W is the prefix-window ledger aligning the StreamName observations with the finite List prefixes admitted by A.*
6. *R is the finite readback row, saying which Boolean endpoint in B is read at each displayed position of the schedule.*
7. *H records componentwise* hsame *transport for $B, L, A, S, W, R, C, P, N$.*
8. *C records displayed* Cont *replay of the finite route*

$$B \longmapsto L \longmapsto A \longmapsto S \longmapsto W \longmapsto R.$$

9. *P is the* Pkg *provenance over* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$*,* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{SpreadLaw}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{ChoiceSequenceSpread}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $B, L, A, S, W, R, H, C, P, N$. It has no coordinate for a selected infinite branch, countable choice, quotient equality of streams, fan compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8233.2 (Choice-sequence spread NameCert obligations)**.** *For every accepted* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ *carrier*

$$Q = (B, L, A, S, W, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ChoiceSequenceSpread}^{\uparrow}}$ *surface consists exactly of carrier admission for the Boolean endpoint row, List prefix row, SpreadLaw admission row, StreamName schedule row, prefix-window ledger, finite readback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every public read of the packet factors through those displayed rows.*

Proof. Project the carrier of Definition 8233.1. The accepted tuple exposes exactly $B, L, A, S, W, R, H, C, P, N$, so the local certificate has no hidden row from which to read a branch selector or a host-level sequence.

The prefix data are finite. The $\mathsf{Bool}^{\uparrow}$ row supplies the endpoints, the $\mathsf{List}^{\uparrow}$ row lists the inspected prefixes, and the $\mathsf{SpreadLaw}^{\uparrow}$ row admits only those displayed prefixes and their displayed extensions.

The schedule data are finite as well. The $\mathsf{StreamName}^{\uparrow}$ row names the observed positions, while W and R align those positions with the displayed prefix tree and endpoint reads.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for countable choice, quotient stream equality, fan compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8233.3 (Choice-sequence spread prefix closure)**.** *Every accepted* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ *carrier is closed under displayed prefix restriction: if a consumer reads a prefix from the ledger L through the window W, then each earlier prefix on the same displayed branch is read through the same* $\mathsf{Bool}^{\uparrow}$*,* $\mathsf{List}^{\uparrow}$*,* $\mathsf{SpreadLaw}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* hsame*,* Cont*,* Pkg*, and local* $\mathsf{NameCert}$ *rows.*

Proof. Read the displayed prefix from the L coordinate. The List row stores the parent-prefix inclusions for the finite prefixes currently under inspection.

Apply the admission row A. Because A is the same $\mathsf{SpreadLaw}^{\uparrow}$ row for the whole packet, restricting to an earlier displayed prefix keeps the read inside the same spread-law admission surface.

The window and schedule rows do not introduce a second branch. They only align the earlier prefix with already displayed $\mathsf{StreamName}^{\uparrow}$ observations and Boolean endpoint reads.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite packet. Thus prefix restriction remains inside the accepted $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ carrier and exports no infinite selector. □

Theorem 8233.4 (Choice-sequence spread StreamName handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ *packet must first expose the finite route*

$$\mathsf{Bool}^{\uparrow} \longmapsto \mathsf{List}^{\uparrow} \longmapsto \mathsf{SpreadLaw}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto W \longmapsto R.$$

The schedule is therefore a finite observation handoff from spread-admitted prefixes to StreamName reads, not a selected branch or countable family of choices.

Proof. Start from Definition 8233.2. A StreamName-facing read can cite the packet only after the Boolean endpoint row, List prefix row, and SpreadLaw admission row have been displayed.

The schedule row S is downstream of that admission data. The window ledger W records which displayed prefixes are observed, and the readback row R records the Boolean endpoints read at the displayed positions.

The structural rows H, C, P, N preserve this same route. They do not add a selector for a full infinite branch, a countable-choice function, or quotient equality of streams. □

Theorem 8233.5 (Choice-sequence spread nonescape)**.** *No consumer of an accepted* $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ *carrier can extract anything beyond the displayed finite packet*

$$B, L, A, S, W, R, H, C, P, N.$$

In particular the packet does not export a chosen infinite branch, countable choice, quotient equality of streams, fan compactness, bar induction, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8233.1 to enumerate the carrier coordinates. The only analytic surface available to consumers is the finite prefix route through B, L, A, S, W, R.

Use Definition 8233.3 to keep every prefix restriction inside that same displayed route. No restricted read creates a new coordinate outside the packet.

Use Definition 8233.4 for StreamName-facing consumers. They receive only the finite observation handoff from spread-admitted prefixes to Boolean endpoint readback.

The remaining rows H, C, P, N are structural. They transport, replay, source, and name the finite packet, but they do not contain a branch selector, a countable-choice schedule, quotient stream equality, fan compactness, bar induction, or a completeness witness for $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{ChoiceSequenceSpread}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ChoiceSequenceSpread}^{\uparrow}$ packet is generated from Boolean endpoint rows, List prefix rows, a SpreadLaw admission row, a StreamName schedule row, a prefix-window ledger, finite readback, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceSpread}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8233.1, Definition 8233.2, Definition 8233.3, Definition 8233.4, and Definition 8233.5 seed the finite spread-admitted choice-sequence prefix route and its StreamName handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ChoiceSequenceSpread}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected infinite branches, countable choice, quotient stream equality, fan compactness, bar induction, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, SpreadLaw prefix admission, StreamName schedule alignment, finite readback, prefix closure, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ChoiceSequenceSpreadUp.

Chapter 8234

A Concrete Naming Certificate for $\mathsf{RegulaFalsi}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegulaFalsi}^{\uparrow}$ packet records the false-position root-bracketing route as finite NameCert data. It sits after the constructive intermediate-value route of chapter 6410, beside the bisection surface of chapter 2108 and the secant surface of chapter 3776, and before the dyadic, stream, regular-rational, and real-name handoff through chapter 291, chapter 126, chapter 301, and chapter 38. The packet names the finite bracketing rows consumed by root-finding consumers; it does not assert classical completeness, trichotomy, a selected zero, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ equality.

Definition 8234.1 (RegulaFalsi carrier)**.** *A* $\mathsf{RegulaFalsi}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, S, Q, D, W, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the sign-changing interval row supplied through* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$*;*
2. *S is the false-position secant row, recording the endpoint values and the chord intersection requested at the current bracket;*
3. *Q is the bracket-retention row, selecting the retained side only through displayed sign data rather than through a host trichotomy;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic ledger for endpoint values, chord denominators, and tolerance budgets;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording which endpoint and function-value reads are inspected;*
6. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row handed to the terminal* $\mathsf{Real}^{\uparrow}$ *seal;*
7. *H records componentwise* hsame *transport for the interval, secant, bracket, dyadic, window, readback, and seal rows;*
8. *C records the displayed* Cont *routes from intermediate-value bracketing through bisection-compatible retention and secant interpolation;*
9. *P is the* Pkg *provenance over* $\mathsf{RegulaFalsi}^{\uparrow}$*,* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$*,* $\mathsf{BisectionMethod}^{\uparrow}$*,* $\mathsf{SecantMethod}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{RegulaFalsi}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected root, a global convergence theorem, an ambient real equality test, countable choice, or a classical completeness principle.

Theorem 8234.2 (RegulaFalsi NameCert obligations)**.** *For every accepted* $\mathsf{RegulaFalsi}^{\uparrow}$ *carrier* $R = (I, S, Q, D, W, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegulaFalsi}^{\uparrow}}$ *surface consists exactly of carrier admission, constructive intermediate-value bracket exposure through* I*, false-position secant exposure through* S*, retained-bracket exposure through* Q*, dyadic arithmetic exactness through* D*, finite-window replay through* W*, regular-rational readback and real-seal handoff through* E*, componentwise* hsame *transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8234.1. Its rows list precisely the sign-changing bracket, false-position chord, retained side, dyadic ledger, finite observation window, regular-rational readback, transport, continuation, provenance, and local naming coordinates.

Read the neighbouring certificates in their displayed roles. The constructive intermediate-value packet supplies the sign-changing bracket, the bisection packet supplies the retained-bracket discipline, and the secant packet supplies the chord-intersection row.

The remaining rows control arithmetic and replay. The dyadic ledger, stream window, RegSeqRat readback, and Real seal expose only finite inspected data, so the NameCert obligations are exhausted by the rows of R and cannot add a selected root or host completeness claim. □

Theorem 8234.3 (RegulaFalsi bracket-secant handoff)**.** *Every accepted* $\mathsf{RegulaFalsi}^{\uparrow}$ *consumer that reads the false-position secant row* S *must retain the same sign-changing interval row* I*, bracket-retention row* Q*, dyadic arithmetic row* D*, finite-window row* W*, regular-rational readback row* E*, and structural rows* H, C, P, N*. The handoff from bracketing to secant interpolation therefore exports a finite root-bracketing route, not a selected zero or an unrestricted secant iteration.*

Proof. Start with an accepted packet $R = (I, S, Q, D, W, E, H, C, P, N)$. The carrier makes S visible only as one row of the same finite bracketing packet.

Apply the NameCert obligations of Definition 8234.2. They require the consumer to replay the constructive bracket, retained side, dyadic arithmetic, finite windows, readback, transport, continuation, provenance, and local naming rows whenever the secant row is cited.

Thus a consumer cannot detach the chord intersection from the bracket that licenses it. A detached secant iteration, selected root, or convergence claim would require an additional coordinate not present in Definition 8234.1. □

Theorem 8234.4 (RegulaFalsi Real seal non-escape)**.** *The terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by an accepted* $\mathsf{RegulaFalsi}^{\uparrow}$ *packet is exposed only after the route through* $\mathsf{ConstructiveIntermediateValue}^{\uparrow}$*,* $\mathsf{BisectionMethod}^{\uparrow}$*,* $\mathsf{SecantMethod}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *has been replayed. It exports no host real equality, selected completed root, ambient completeness theorem, or countable-choice schedule.*

Proof. Follow the carrier route from I through S, Q, D, W, E. The intermediate-value row starts the bracket, the bisection-compatible row records retention, the secant row records the false-position chord, and the dyadic and stream rows determine the finite inspections.

The RegSeqRat row E is the only route to the terminal Real seal. By Definition 8234.2 and Definition 8234.3, that route remains attached to the same bracket, chord, arithmetic, and replay rows.

Since the carrier has no selected-root coordinate, no quotient-real equality coordinate, no countable-choice schedule, and no ambient completeness row, the Real seal cannot export any of those objects. □

Falsifiable prediction: A claimed $\mathsf{RegulaFalsi}^{\uparrow}$ consumer that reads a Real seal without replaying the displayed bracket, secant, dyadic, StreamName, and RegSeqRat rows refutes the packet.

Independence witness: Nearest siblings: constructive-intermediate-value, bisection-method, secant-method, dyadicratcore, streamname, regseqrat, real. The packet is not bijective to any sibling because it simultaneously stores the bracket, false-position chord, retained side, arithmetic ledger, finite windows, regular-rational readback, and terminal seal rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegulaFalsi}^{\uparrow}}$.

Constructive story: A $\mathsf{RegulaFalsi}^{\uparrow}$ packet is generated from a constructive sign-changing bracket, a false-position secant row, a retained-bracket row, dyadic arithmetic, finite observation windows, regular-rational readback, a terminal Real seal, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegulaFalsi}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8234.1, Definition 8234.2, Definition 8234.3, and Definition 8234.4 seed the false-position root-bracketing route over constructive IVT, bisection, secant, dyadic, stream, regular-rational, Real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegulaFalsi}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Lean verification, bridge checking, selected roots, host real equality, classical completeness, trichotomy, countable choice, or ambient RealUp equality.

Upgrade path: Obligation closure requires checked carrier admission, bracket retention, secant handoff, dyadic arithmetic exactness, finite-window replay, RegSeqRat-to-Real non-escape, and TasteGate nontriviality with field faithfulness.

Chapter 8235

A Concrete Naming Certificate for $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$

The $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ packet realizes the Leibniz equality branch of chapter 9382 as finite NameCert data. It consumes the typed example gallery of chapter 756, the typed-example reduction trace of chapter 2330, the Church eliminator regression matrix of chapter 924, and the decidable-boundary route of chapter 749. The packet names the equality type, reflexivity proof, eliminator motive, transport target, checker row, closedness row, reduction row, replay route, provenance row, and local NameCert row for selected typed examples; it does not claim global subject reduction, global confluence, erased host equality, or unrestricted proof irrelevance.

Definition 8235.1 (MetaCIC typed equality eliminator carrier)**.** *A* $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, Q, R, M, L, K, D, X, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite typed-example row selecting the Leibniz equality examples from the typed example gallery;*
2. *Q is the Leibniz equality type row, including the displayed source type, endpoints, and equality proposition;*
3. *R is the reflexivity proof row for the selected endpoint examples;*
4. *M is the motive row used by the typed eliminator;*
5. *L is the transport target row reached by eliminating the reflexivity proof against M;*
6. *K is the checker row recording the typed-example checker result for Q, R, M, L;*
7. *D is the closedness and reduction row, tying the selected equality proof to the typed-example reduction trace;*
8. *X is the Church eliminator regression row that compares the equality eliminator against neighbouring bool, nat, list, and sum eliminator examples;*
9. *H records componentwise* hsame *transport for the typed example, equality, reflexivity, motive, transport, checker, reduction, and regression rows;*

10. *C records displayed* Cont *replay from an equality-eliminator request through checker, closedness, reduction, transport, regression, provenance, and naming rows;*
11. *P records* Pkg *provenance over* $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$, $\mathsf{TypedExampleGallery}^{\uparrow}$, TypedExampleReduction ChurchEliminatorRegressionMatrix$^{\uparrow}$, $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, Q, R, M, L, K, D, X, H, C, P, N$. It has no coordinate for host equality, unrestricted subject reduction, global confluence, proof irrelevance, quotient syntax equality, or an erased equality-eliminator theorem.

Theorem 8235.2 (MetaCIC typed equality eliminator NameCert obligations)**.** *For every accepted* $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ *carrier $E = (T, Q, R, M, L, K, D, X, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}}$ *surface consists exactly of typed-example exposure, Leibniz equality type exposure, reflexivity proof exposure, motive exposure, transport-target exposure, checker exposure, closedness and reduction exposure, Church-eliminator regression exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8235.1. The rows T, Q, R, M, L are the finite equality-eliminator data: a selected typed example, its Leibniz equality type, a reflexivity proof, a motive, and the transported target.

Rows K, D, X bind the same data to the checker, closedness, reduction, and regression surfaces. The checker row keeps the packet in the typed-example gallery, the reduction row ties it to the typed-example reduction trace, and the regression row compares it with the neighbouring Church eliminators without collapsing them into one theorem.

Rows H, C, P, N transport, replay, source, and name the finite surface. Since no row stores host equality, unrestricted subject reduction, global confluence, proof irrelevance, quotient syntax equality, or an erased eliminator theorem, the listed rows exhaust the NameCert obligations. □

Theorem 8235.3 (MetaCIC typed equality eliminator reduction boundary)**.** *Every accepted* $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ *reduction read must retain the same typed-example row T, Leibniz equality row Q, reflexivity row R, motive row M, transport target L, checker row K, reduction row D, regression row X, and structural rows H, C, P, N. The packet therefore realizes selected Leibniz equality examples as finite checker, closedness, reduction, transport, replay, provenance, and NameCert rows, not as a global subject-reduction, confluence, or host-equality result.*

Proof. Begin with the accepted carrier $E = (T, Q, R, M, L, K, D, X, H, C, P, N)$. The reduction row D is not free-standing: it records the closedness and reduction trace for the selected equality data named by T, Q, R, M, L.

Apply the NameCert obligations of Definition 8235.2. They require every equality-eliminator read to replay the checker, closedness, reduction, regression, transport, continuation, provenance, and local naming rows.

Thus a consumer cannot turn the selected Leibniz equality examples into a theorem about all typed reductions. Such a theorem would require additional subject-reduction and confluence rows beyond the carrier of Definition 8235.1. □

Falsifiable prediction: A claimed $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ read that accepts a Leibniz equality eliminator without the typedexamplegallery, typed-example-reduction-trace, church-eliminator-regression-matrix, and metacicdecidableboundary rows refutes the packet.

Independence witness: typedexamplegallery, typed-example-reduction-trace, church-eliminator-regression-matrix, metacicdecidableboundary: the gallery supplies selected typed terms, the trace supplies reduction rows, the regression matrix supplies neighbouring eliminator comparisons, and the decidable boundary supplies checker limits, but none alone carries the equality type, reflexivity proof, motive, transport target, checker, closedness, reduction, regression, replay, provenance, and local NameCert rows.

The Lean follow-up in `lean4/BEDC/Derived/MetacicTypedEqualityEliminatorUp/TasteGate.lean` must provide explicit Nontrivial $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ and FieldFaithful $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ instances preserving $T, Q, R, M, L, K, D, X, H, C, P, N$ before any positive gate may treat this packet as field-faithful.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}$ packet is generated from selected typed-example rows, Leibniz equality types, reflexivity proofs, motives, transport targets, checker rows, closedness and reduction traces, Church-eliminator regression rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8235.1, Definition 8235.2, and Definition 8235.3 seed the finite typed equality eliminator route over selected Leibniz equality examples, checker rows, closedness, reduction, transport, regression, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicTypedEqualityEliminator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim global subject reduction, global confluence, host equality, proof irrelevance, quotient syntax equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Leibniz equality type exposure, reflexivity proof exposure, motive and transport exposure, checker stability, reduction-boundary stability, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.MetacicTypedEqualityEliminatorUp.

Chapter 8236

A Concrete Naming Certificate for $\mathsf{FinitePositiveMinimum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{FinitePositiveMinimum}^{\uparrow}$ packet records the finite lower-bound fold by which finitely many positive rational radius rows produce one tolerance-only positive row for compact-uniform-modulus consumers. It sits after the rational source of chapter 37, the compact finite-net surface of chapter 129, and the selector route of chapter 914; it is consumed by the uniform-modulus and compact-uniform-continuity surfaces of chapter 369, chapter 2299, and chapter 388. The packet is a displayed finite fold over positive $\mathsf{Rat}^{\uparrow}$ rows, not a host minimum operator, selected subcover, open-cover compactness theorem, or ambient completeness principle.

Definition 8236.1 (FinitePositiveMinimum carrier)**.** *A* $\mathsf{FinitePositiveMinimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, R, L, K, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite* $\mathsf{ProbeBundle}$ *index row naming the compact-net probes whose local radius rows are inspected.*
2. *R is the family of positive* $\mathsf{Rat}^{\uparrow}$ *radius rows indexed by B.*
3. *L is the positive lower-bound row produced by primitive finite folding over the rows in R.*
4. *K is the comparison ledger proving that L is a positive rational row and lies below every displayed radius row in R.*
5. *H records componentwise* hsame *transport for the probe bundle, radius family, lower-bound row, comparison ledger, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from compact-net selection through the positive radius family and comparison ledger to the lower-bound handoff.*
7. *P is the* Pkg *provenance over* $\mathsf{FinitePositiveMinimum}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactNetModulusSelector}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{CompactUniformModulus}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePositiveMinimum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through B, R, L, K, H, C, P, N. It has no coordinate for a host finite-set minimum, open-cover compactness, a selected subcover, quotient equality of compact points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8236.2 (FinitePositiveMinimum NameCert obligations)**.** *For every accepted* $\mathsf{FinitePositiveMinimum}^{\uparrow}$ *carrier*

$$F = (B, R, L, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitePositiveMinimum}^{\uparrow}}$ *surface consists exactly of finite probe-bundle admission, positive* $\mathsf{Rat}^{\uparrow}$ *radius-family admission, lower-bound fold exposure, comparison-ledger exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8236.1. The mathematical rows are the probe bundle B, the positive rational radius family R, the lower-bound fold row L, and the comparison ledger K.

Read the finite fold before any consumer handoff. Since B is finite and R is displayed only over the probes in B, the row L is produced by primitive finite recursion over named positive rational rows rather than by a host minimum operation.

The comparison ledger K records positivity of L and its lower-bound relation to every radius row in R. Transport and replay through H and C preserve the same componentwise route, while P and N source and name the packet. No further NameCert clause is available from compactness, choice, subcover selection, quotient equality, or completeness. □

Theorem 8236.3 (FinitePositiveMinimum compact-uniform-modulus handoff)**.** *Every compact-uniform-modulus consumer of an accepted* $\mathsf{FinitePositiveMinimum}^{\uparrow}$ *carrier receives the positive lower-bound row only through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{CompactNetModulusSelector}^{\uparrow},\ \mathsf{Rat}^{\uparrow},\ \mathsf{ProbeBundle},\ L, K, H, C, P, N \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

Thus the handoff supports the finite positive rational lower-bound step used by Definition 9237.5 without exporting a host finite-set minimum, selected subcover, open-cover compactness theorem, quotient point equality, countable-choice functional, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the compact-net side. The $\mathsf{CompactMetric}^{\uparrow}$ and $\mathsf{CompactNetModulusSelector}^{\uparrow}$ consumers expose the finite probe bundle B and the positive rational radius rows R before any tolerance-only output can be read.

Apply the NameCert obligations of Definition 8236.2. They force the read through the lower-bound row L and comparison ledger K, with componentwise transport and displayed replay supplied by H and C.

Finally hand the resulting positive row to the $\mathsf{UniformModulus}^{\uparrow}$ and $\mathsf{CompactUniformModulus}^{\uparrow}$ surfaces. The provenance P and local name N keep the handoff attached to the same finite packet, so the downstream $\mathsf{CompactUniformContinuity}^{\uparrow}$ route receives a BEDC lower-bound ledger and not an external minimum, compactness theorem, selected subcover, quotient equality, choice principle, or ambient completeness row. □

Falsifiable prediction: An accepted $\mathsf{FinitePositiveMinimum}^{\uparrow}$ read is refuted if a compact-uniform-modulus consumer receives a tolerance-only lower-bound row without displaying the finite probe bundle, positive rational radius family, comparison ledger, componentwise transport, continuation replay, provenance, and local naming rows.

Independence witness: rat, compactmetric, compactnetmodulusselector, uniformmodulus, compact-uniform-modulus, compactuniformcontinuity: no listed sibling is bijective with $\mathsf{FinitePositiveMinimum}^{\uparrow}$

because this packet jointly carries the finite probe index, positive rational radius family, folded lower-bound row, comparison ledger, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePositiveMinimum}\uparrow}$.

Constructive story: A $\mathsf{FinitePositiveMinimum}^{\uparrow}$ packet is generated from a finite ProbeBundle index row, positive RatUp radius rows, a folded positive lower-bound row, a comparison ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitePositiveMinimum}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8236.1, Definition 8236.2, and Definition 8236.3 seed the finite positive rational lower-bound fold consumed by compact-uniform-modulus routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitePositiveMinimum}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host finite-set minima, selected subcovers, open-cover compactness, quotient equality of compact points, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive rational family exposure, lower-bound fold exactness, comparison-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.FinitePositiveMinimumUp.

Chapter 8237

A Concrete Naming Certificate for $\mathsf{CauchyModulusLimiter}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{CauchyModulusLimiter}^{\uparrow}$ packet records the finite limiter row by which a regular-Cauchy tail modulus is read before a Real-facing consumer receives a bounded tail window. It sits after the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the shared threshold discipline of chapter 1299. The packet names the limiter as displayed finite NameCert data; it does not choose a host limit, compare quotient streams, use countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8237.1 (Cauchy modulus limiter carrier)**.** *A* $\mathsf{CauchyModulusLimiter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (M, L, T, W, R, D, H, C, P, N)$$

with the following displayed rows:

1. *M is the source Cauchy modulus row attached to a regular-Cauchy rational presentation.*
2. *L is the limiter row, naming the finite bound through which the source modulus is allowed to serve a downstream tail request.*
3. *T is the normalized tail-threshold row read through* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$*.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *readback window opened at the limited tail threshold.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite window.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the limiter row with the requested precision.*
7. *H records componentwise* hsame *transport for the modulus, limiter, threshold, readback, dyadic, replay, provenance, and local name rows.*
8. *C records displayed* Cont *replay from a Real-facing tail request through $M, L, T, W, R, D, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyModulusLimiter}^{\uparrow}$, $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusLimiter}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected limit, quotient stream equality, countable-choice schedule, host real equality, or an ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyModulusLimiterUp.CauchyModulusLimiterTasteGate single carrier alignment`

Theorem 8237.2 (Cauchy modulus limiter NameCert obligations)**.** *For every accepted* $\mathsf{CauchyModulusLimiter}^{\uparrow}$ *carrier* $Q = (M, L, T, W, R, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyModulusLimiter}^{\uparrow}}$ *surface consists exactly of source modulus admission, limiter-row exposure, normalized tail-threshold exposure, StreamName readback, RegSeqRat readback, dyadic tolerance comparison, componentwise transport, displayed replay, package provenance, local naming, and non-escape from selected limits, quotient streams, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8237.1. The analytic rows are M, L, T, W, R, D, and the structural rows are H, C, P, N.

The limiter obligation is the ordered read from the source modulus M to the limiter row L and then to the normalized threshold T. This records the finite bound before any downstream tail window can be opened.

The readback obligations are downstream of the threshold. The rows W and R expose the finite StreamName and RegSeqRat data, while D supplies the dyadic comparison needed by a precision request.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier omits selected limits, quotient streams, countable choice, host equality, and ambient completeness, the displayed rows exhaust the local NameCert surface. □

Theorem 8237.3 (Cauchy modulus limiter tail-bound induction)**.** *Every accepted* $\mathsf{CauchyModulusLimiter}^{\uparrow}$ *carrier* $Q = (M, L, T, W, R, D, H, C, P, N)$ *supports finite induction over the limiter row: the base tail request reads* M, L, T*, and each later bounded request preserves the same* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, transport, replay, provenance, and local naming route. Thus a* $\mathsf{Real}^{\uparrow}$ *consumer sees a bounded tail-modulus certificate rather than a private modulus parameter or an ambient completeness claim.*

Proof. The base step is the first accepted tail request. It reads the source modulus M, the limiter row L, and the normalized threshold T before any window or real-facing seal is available.

For the successor step, assume the current bounded request has already been routed through $M, L, T, W, R, D, H, C, P, N$. A later request reuses the same limiter row and advances only inside the displayed finite tail discipline; the StreamName window W, RegSeqRat readback R, and dyadic comparison ledger D remain downstream of that row.

The structural rows H, C, P, N preserve the route across the induction step. Therefore every bounded tail read factors through the same finite limiter packet, and no excluded limit, quotient, choice, host equality, or completeness coordinate can be extracted. □

Falsifiable prediction: Every accepted $\mathsf{CauchyModulusLimiter}^{\uparrow}$ read must display the source modulus, limiter row, normalized threshold, StreamName window, RegSeqRat readback, DyadicRatCore comparison, hsame transport, Cont replay, Pkg provenance, and local NameCert row before a Real-facing bounded tail request is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchytailthresholdnormalizer: $\mathsf{CauchyModulusLimiter}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source modulus, limiter row, normalized tail threshold, finite stream window, regular rational readback, dyadic tolerance comparison, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyModulusLimiter}^{\uparrow}}$**.**

Constructive story: A CauchyModulusLimiter$^{\uparrow}$ packet is generated from a regular-Cauchy source modulus, a finite limiter row, a normalized tail threshold, StreamName and RegSeqRat readbacks, a DyadicRatCore tolerance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{CauchyModulusLimiter}\uparrow}$, seed)

Scope closed: Definition 8237.1, Definition 8237.2, and Definition 8237.3 seed the finite limiter route for regular-Cauchy tail moduli read by Real-facing consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{CauchyModulusLimiter}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient streams, countable choice, host real equality, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, limiter-row exactness, threshold normalization, StreamName and RegSeqRat readback, dyadic tolerance comparison, transport, replay, provenance, and nonescape for BEDC.Derived.CauchyModulusLimiterUp.

Chapter 8238

A Concrete Naming Certificate for $\mathsf{ProjectiveLimitMetric}^{\uparrow}$

Following Bourbaki and Kelley on projective limits of metric spaces, the $\mathsf{ProjectiveLimitMetric}^{\uparrow}$ packet records a finite projection-window presentation of a compatible metric family. It sits beside $\mathsf{InverseLimitMetric}^{\uparrow}$ in chapter 2168: the sibling names finite inverse-limit metric observations, while this chapter names the projective-limit metric carrier that later completion chapters can consume through displayed windows, distance rows, and completion handoff data.

Definition 8238.1 (ProjectiveLimitMetric carrier)**.** *A* $\mathsf{ProjectiveLimitMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, W, \Pi, B, \Delta, K, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the finite diagram ledger naming the metric-space indices visible to the packet;*
2. *W is the finite projection-window row, including the* $\mathsf{StreamName}^{\uparrow}$ *windows used to read nodes and projection paths;*
3. *Π is the bonding-map compatibility row for every displayed composable projection path inside W;*
4. *B records the* $\mathsf{Met}^{\uparrow}$ *distance rows carried by the displayed nodes;*
5. *Δ records the projective-limit distance read as the finite compatible family of nodewise distance rows;*
6. *K records the* $\mathsf{CompleteMetric}^{\uparrow}$ *and* $\mathsf{CauchyFilterCompletion}^{\uparrow}$ *completion handoff accepted by downstream completion consumers;*
7. *Q records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows used by the finite distance comparisons;*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal for the displayed distance values after the regular rational readbacks have been checked;*
9. *E records the sibling dependency on* $\mathsf{InverseLimitMetric}^{\uparrow}$ *and keeps the inverse-limit metric packet as a named dependency rather than as a hidden host object;*
10. *H records componentwise* hsame *transport for the diagram, projection-window, bonding, distance, completion, readback, and seal rows;*

11. *C records displayed* Cont *replay from projection windows to distance reads and from distance reads to the completion handoff;*
12. *P records* Pkg *provenance over* ProjectiveLimitMetric$^\uparrow$, InverseLimitMetric$^\uparrow$, Met$^\uparrow$, CompleteMetric$^\uparrow$, CauchyFilterCompletion$^\uparrow$, StreamName$^\uparrow$, RegSeqRat$^\uparrow$, Real$^\uparrow$, BHist, hsame, Cont, *and* NameCert *rows;*
13. *N is the local* NameCert$_{\text{ProjectiveLimitMetric}^\uparrow}$ *row.*

The carrier has no coordinate for a quotient completion, selected representative family, ambient projective-limit object, hidden bonding-map chooser, or global completeness oracle.

Theorem 8238.2 (ProjectiveLimitMetric NameCert obligations)**.** *For every accepted* ProjectiveLimitMetric$^\uparrow$ *carrier $M = (D, W, \Pi, B, \Delta, K, Q, R, E, H, C, P, N)$, the local* NameCert$_{\text{ProjectiveLimitMetric}^\uparrow}$ *surface consists of exactly these obligation rows: carrier admission for the finite diagram and projection windows, bonding-map compatibility,* Met$^\uparrow$ *distance-row visibility, projective-limit distance readback,* CompleteMetric$^\uparrow$ *and* CauchyFilterCompletion$^\uparrow$ *completion handoff,* InverseLimitMetric$^\uparrow$ *sibling dependency,* StreamName$^\uparrow$ *window routing,* RegSeqRat$^\uparrow$ *readback,* Real$^\uparrow$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8238.1. The rows D, W, Π expose the finite diagram, projection windows, and bonding-map checks before any distance or completion row is read.

Next read the metric rows. The rows B, Δ, Q, R keep every distance comparison inside the displayed Met$^\uparrow$, RegSeqRat$^\uparrow$, and Real$^\uparrow$ data, while E records the sibling dependency on chapter 2168.

Finally use K, H, C, P, N. The completion handoff is a displayed row, transport is componentwise, replay is routed through C, and provenance and naming are local. No omitted quotient, representative family, ambient projective limit, chooser, or completeness oracle can enter the NameCert surface. □

Theorem 8238.3 (ProjectiveLimitMetric completion handoff)**.** *Every completion consumer of* ProjectiveLimitMetric$^\uparrow$ *must read the finite projection-window route*

$$D, W, \Pi, B, \Delta, K, Q, R, E, H, C, P, N$$

before using the projective-limit metric as a completion input. The exported handoff is the displayed K row over CompleteMetric$^\uparrow$ *and* CauchyFilterCompletion$^\uparrow$*, with distance values sealed through* RegSeqRat$^\uparrow$ *and* Real$^\uparrow$ *and with the* InverseLimitMetric$^\uparrow$ *sibling dependency still visible.*

Proof. Start with the NameCert obligations of Definition 8238.2. They force the consumer to enter through the finite diagram, projection-window, bonding, distance, readback, real-seal, and sibling-dependency rows.

Then project the completion row K. Since K is listed after the finite distance read and before transport, replay, provenance, and naming, a consumer cannot treat completion as a quotient completion equality or as a selected family of representatives.

The structural rows H, C, P, N finish the route. They preserve the displayed packet under componentwise transport, replay only the visible route, record provenance, and name the local certificate. Hence the completion handoff remains a finite projection-window consumer of the projective-limit metric packet. □

Closure status for NameCert$_{\text{ProjectiveLimitMetric}^\uparrow}$.

Constructive story: A ProjectiveLimitMetric$^\uparrow$ packet is generated from finite diagram rows, projection-window rows, bonding-map compatibility, MetricSpace distance rows, completion handoff data, StreamName windows, RegSeqRat readbacks, Real seals, sibling dependency, transport, replay, provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{ProjectiveLimitMetric}\uparrow}$, seed)

Scope closed: Definition 8238.1, Definition 8238.2, and Definition 8238.3 seed the finite projection-window metric packet and its completion-facing handoff surface.

Formal verification: FormalStatus(NameCert$_{\mathsf{ProjectiveLimitMetric}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public-object export, quotient completion equality, selected representatives, or ambient projective-limit existence.

Upgrade path: Obligation closure requires checked carrier admission, bonding compatibility, distance-row visibility, completion handoff, StreamName routing, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.ProjectiveLimitMetricUp.

Chapter 8239

A Concrete Naming Certificate for $\mathsf{CompactCompleteFixedPoint}^{\uparrow}$

Following Bishop and Bridges on compact metric spaces and Banach's fixed-point theorem, the $\mathsf{CompactCompleteFixedPoint}^{\uparrow}$ packet records the finite certificate route by which a contraction on a compact complete metric source exports a fixed-point orbit and a completion-facing endpoint. The packet sits after the complete metric surface of chapter 128, the compact metric surface of chapter 129, the continuous-map graph row of chapter 130, the contraction packet of chapter 3529, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It is a NameCert reconstruction of the classical compact-complete fixed-point handoff, not a selected global choice function or a host-space equality principle.

Definition 8239.1 (Compact complete fixed-point carrier)**.** *A* $\mathsf{CompactCompleteFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, T, B, O, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row naming the source by finite covers, displayed metric data, and compactness witnesses.*
2. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row naming the same source as a completion-facing metric packet.*
3. *T is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the self-map being iterated.*
4. *B is the* $\mathsf{BanachContraction}^{\uparrow}$ *row recording the contraction modulus and the Picard-step boundary.*
5. *O is the finite orbit ledger, exposing the inspected Picard iterates and their contraction-budget comparisons.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the Cauchy orbit estimates.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the regular readback and completion boundary are displayed.*
8. *H records componentwise* hsame *transport for $K, M, T, B, O, Q, E, C, P, N$.*
9. *C records the displayed* Cont *replay of compactness, completeness, continuity, contraction, orbit, readback, and endpoint handoff rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactCompleteFixedPoint}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactCompleteFixedPoint}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, T, B, O, Q, E, H, C, P, N$. It has no coordinate for selected fixed points, quotient orbit equality, host metric completion equality, countable choice, or ambient compactness beyond the displayed $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{CompleteMetric}^{\uparrow}$ *rows.*

Lean4 (statement) `BEDC.Derived.CompactCompleteFixedPointUp`

Theorem 8239.2 (Compact complete fixed-point NameCert obligations)**.** *For the carrier of Definition 8239.1, the local* $\mathsf{NameCert}_{\mathsf{CompactCompleteFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for $F = (K, M, T, B, O, Q, E, H, C, P, N)$, compact metric source exposure through K, complete metric boundary exposure through M, continuous self-map replay through T, contraction data through B, finite orbit ledger exposure through O, regular rational readback through Q, terminal real seal through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted packet to the eleven displayed rows. The rows K, M, T, B, O, Q, E are the only mathematical content rows, while H, C, P, N provide transport, replay, provenance, and local naming.

Read the source rows first. The row K supplies compact metric data by chapter 129, and M supplies the completion-facing metric boundary by chapter 128. These rows provide finite compact and complete surfaces without adding a separate host-space equality row.

Read the map and orbit rows next. The row T is a $\mathsf{ContinuousMap}^{\uparrow}$ self-map row, B is the contraction row supplied by chapter 3529, and O is the finite Picard-orbit ledger. Thus every endpoint request must pass through a displayed contraction-budget comparison before it reaches the readback row.

Finally read Q and E. The row Q turns the orbit estimates into a $\mathsf{RegSeqRat}^{\uparrow}$ regular readback, and E seals the endpoint at the $\mathsf{Real}^{\uparrow}$ boundary. Since the carrier has no further endpoint coordinate, the listed rows exhaust the NameCert obligation surface. □

Theorem 8239.3 (Compact complete fixed-point Cauchy orbit route)**.** *Every accepted* CompactCompleteFixedPoint *consumer that exports a fixed-point endpoint must first expose the route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{BanachContraction}^{\uparrow},\ O,\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The route presents the endpoint as a compact-complete contraction orbit with a regular Cauchy readback and a terminal real seal. It exports no selected global fixed-point function, quotient equality of orbits, host completion equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with carrier admission from Definition 8239.1. The public packet displays exactly the rows $K, M, T, B, O, Q, E, H, C, P, N$.

Apply the NameCert obligations of Definition 8239.2. They force any endpoint read to pass through compactness, completeness, continuous self-map replay, contraction data, and the finite orbit ledger before the regular readback can be consumed.

The readback and endpoint boundary are then fixed by Q and E. Because selected fixed points, quotient orbit equality, host completion equality, countable choice, and ambient real completeness are not coordinates of the carrier, they cannot be repacked by the handoff rows H, C, P, N. □

Falsifiable prediction: Any accepted CompactCompleteFixedPointUp consumer that exports a fixed-point endpoint while bypassing compact metric exposure, complete metric exposure, continuous self-map replay, contraction data, the finite orbit ledger, regular rational readback, or the terminal RealUp seal fails the carrier classifier.

Independence witness: compactmetric, completemetric, continuousmap, banachcontraction, regseqrat, real: none carries compact metric exposure, complete metric exposure, continuous self-map replay, contraction data, a finite Picard-orbit ledger, regular rational readback, terminal Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and one local NameCert row in a single fixed-point packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCompleteFixedPoint}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactCompleteFixedPoint}^{\uparrow}$ packet is generated from CompactMetricUp source data, CompleteMetricUp boundary data, ContinuousMapUp self-map replay, BanachContractionUp contraction data, a finite Picard-orbit ledger, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactCompleteFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8239.1, Definition 8239.2, and Definition 8239.3 seed the compact-complete fixed-point route over CompactMetricUp, CompleteMetricUp, ContinuousMapUp, BanachContractionUp, RegSeqRatUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactCompleteFixedPoint}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected fixed-point functions, quotient orbit equality, host completion equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-complete source exposure, continuous-map replay, contraction-budget exactness, finite orbit readback, endpoint sealing, transport, replay, provenance, and local naming for BEDC.Derived.CompactCompleteFixedPointUp.

Chapter 8240

A Concrete Naming Certificate for $\mathsf{HautusTest}^{\uparrow}$

Following Hautus and standard finite-dimensional control theory, the $\mathsf{HautusTest}^{\uparrow}$ packet records the finite rank-test surface for controllability and observability of a displayed linear plant. It sits after the controllability certificate of chapter 297, the observability certificate of chapter 294, the matrix carrier of chapter 49, the linear-map carrier of chapter 48, and the vector-space carrier of chapter 47. The packet names only finite matrix-pencil rows, eigenvalue probes, rank windows, transport, replay, provenance, and local naming data; it does not import a spectral decomposition theorem, analytic transfer-function equality, a host quotient state space, or an infinite-dimensional control result.

Definition 8240.1 (HautusTest carrier)**.** *A* $\mathsf{HautusTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (X, U, Y, A, B, C, \Lambda, \Pi, Q, O, M, V, T, R, P, N)$$

with the following displayed rows:

1. *X is the finite state row, U is the input row, and Y is the output row, each read through displayed* $\mathsf{VecSpace}^{\uparrow}$ *coordinates.*
2. *$A : X \to X$, $B : U \to X$, and $C : X \to Y$ are the finite plant, input, and output rows, read through* $\mathsf{LinMap}^{\uparrow}$ *and* $\mathsf{Mat}^{\uparrow}$ *presentations.*
3. *Λ is the finite eigenvalue-probe ledger for the displayed plant row A; it records only the probes used by the packet.*
4. *Π is the matrix-pencil ledger containing the displayed rows for $sI - A$, the controllability pencil $(sI - A, B)$, and the observability pencil $(sI - A, C)$ at every probe s named by Λ.*
5. *Q is the controllability rank-window row consumed by* $\mathsf{ControlControllability}^{\uparrow}$*.*
6. *O is the observability rank-window row consumed by* $\mathsf{ControlObservability}^{\uparrow}$*.*
7. *M records the finite matrix-entry and rank-readback rows used by Π, Q, O.*
8. *V records the vector-space basis and dimension rows against which the rank windows are measured.*
9. *T records componentwise* hsame *transport for $X, U, Y, A, B, C, \Lambda, \Pi, Q, O, M, V$ and the local certificate row.*

10. *R records displayed* Cont *replay from the plant rows through the probe ledger, matrix-pencil rows, controllability window, and observability window.*
11. *P is the* Pkg *provenance over* $\mathsf{HautusTest}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HautusTest}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host spectral decomposition, quotient state-space semantics, selected canonical bases, transfer-function equality, stochastic covariance, or infinite-dimensional observability and controllability theorems.

Lean4 ✓ `BEDC.Derived.HautusTestUp.HautusTestTasteGate single carrier alignment`

Theorem 8240.2 (HautusTest NameCert obligations)**.** *For every accepted* $\mathsf{HautusTest}^{\uparrow}$ *carrier*

$$H = (X, U, Y, A, B, C, \Lambda, \Pi, Q, O, M, V, T, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HautusTest}^{\uparrow}}$ *surface consists exactly of finite state, input, and output admission through X, U, Y, plant admission through A, B, C, eigenvalue-probe admission through Λ, matrix-pencil admission through Π, controllability rank-window admission through Q, observability rank-window admission through O, matrix readback through M, vector-space and dimension readback through V, componentwise* hsame *transport through T, displayed* Cont *replay through R, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8240.1. The rows X, U, Y, A, B, C display the finite control-system data before any rank test is visible.

The probe ledger Λ and matrix-pencil ledger Π then expose the finite rows for $sI-A$, $(sI-A, B)$, and $(sI - A, C)$. The row Q is the controllability read of those rows, while O is the observability read of the same plant and probe surface.

Finally M, V, T, R, P, N record matrix readback, vector-space dimension readback, transport, replay, provenance, and local naming. Since the carrier contains no coordinate for host spectral decomposition, quotient state spaces, selected canonical bases, transfer functions, stochastic covariance, or infinite-dimensional semantics, these displayed rows exhaust the local certificate surface. □

Theorem 8240.3 (HautusTest controllability-observability handoff)**.** *Every downstream finite-control consumer of an accepted* $\mathsf{HautusTest}^{\uparrow}$ *packet that asks for a rank-test certificate must read the same displayed route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{VecSpace}^{\uparrow} \longmapsto \Lambda, \Pi, Q, O, M, V, T, R, P, N.$$

The controllability side reaches $\mathsf{ControlControllability}^{\uparrow}$ *only through Q, and the observability side reaches* $\mathsf{ControlObservability}^{\uparrow}$ *only through O. Both rows are tied to the same plant rows A, B, C, the same matrix-pencil ledger Π, and the same vector-space dimension row V.*

Proof. Start with Definition 8240.2. It forces the finite plant rows, probe ledger, matrix-pencil ledger, controllability rank window, and observability rank window to be displayed before a consumer can read the certificate.

The controllability handoff is the row Q over $(sI - A, B)$, and the observability handoff is the row O over $(sI - A, C)$. Both are measured against the same matrix row M and vector-space row V, so neither handoff can replace the shared packet by a separate ambient rank theorem.

The structural rows T, R, P, N then transport, replay, source, and name exactly that finite route. A consumer that bypasses Q or O, or that reads an unlogged spectral decomposition, quotient state space, transfer function, stochastic covariance, or infinite-dimensional theorem, has left the accepted $\mathsf{HautusTest}^{\uparrow}$ packet. □

Falsifiable prediction: An accepted $\mathsf{HautusTest}^{\uparrow}$ packet is refuted by any finite-control consumer that reads a controllability or observability rank result while bypassing the displayed probe ledger Λ, the matrix-pencil ledger Π, or either rank-window row Q, O.

Independence witness: controlcontrollability, controlobservability, matrix, linearmap, vecspace: none is bijective to $\mathsf{HautusTest}^{\uparrow}$ because the Hautus-test packet jointly carries plant rows, eigenvalue probes, two matrix-pencil rank windows, shared matrix readback, vector-space dimension readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{HautusTest}^{\uparrow}}$.

Constructive story: A $\mathsf{HautusTest}^{\uparrow}$ packet is generated from finite state, input, output, plant, eigenvalue-probe, matrix-pencil, controllability rank-window, observability rank-window, matrix readback, vector-space dimension, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HautusTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8240.1, Definition 8240.2, Definition 8240.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite Hautus rank-test NameCert surface over controllability, observability, matrix, linear-map, and vector-space rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HautusTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host spectral decomposition, quotient state-space semantics, selected canonical bases, transfer-function equality, stochastic covariance, or infinite-dimensional control theory.

Upgrade path: Obligation closure requires checked carrier admission, probe-ledger admission, matrix-pencil exactness, controllability and observability rank-window admission, transport, replay, provenance, and local naming for BEDC.Derived.HautusTestUp.

Chapter 8241

A Concrete Naming Certificate for $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$

Following Coddington–Levinson and Bishop–Bridges, the $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$ packet records the finite local flow-box surface by which an ordinary differential equation is read near a displayed nonstationary point through rational time-state windows, Picard local handoff rows, and Gronwall stability budgets. It sits after the ODE source of chapter 193, the initial-value carrier of chapter 3979, the Picard–Lindelof handoff of chapter 1888, the Gronwall comparison surface of chapter 2034, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a local coordinate and flow-window certificate; it does not select a host solution curve, assert global existence, quotient paths by equality, or invoke ambient real completeness.

Definition 8241.1 (Constructive ODE flow-box carrier)**.** *A* $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (O, I, L, P, G, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *source row, carrying the local time-state window and vector-field read.*
2. *I is the* $\mathsf{InitialValueProblem}^{\uparrow}$ *row naming the base point and initial-time boundary.*
3. *L is the local nonstationary and coordinate-window row, storing the rational box, transverse coordinate, and time strip on which the flow-box read is admitted.*
4. *P is the* $\mathsf{PicardLindelof}^{\uparrow}$ *local handoff row for the displayed initial-value data and box.*
5. *G is the* $\mathsf{GronwallInequality}^{\uparrow}$ *stability row used to compare nearby Picard windows inside the same strip.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the local coordinate and flow-window approximants, and E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after R is displayed.*
7. *H records componentwise* hsame *transport for the ODE source, initial-value row, local coordinate window, Picard handoff, Gronwall stability row, regular readback, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay through*

$$O, I, L, P, G, R, E \longmapsto H, Q, N.$$

9. *Q is the* Pkg *provenance over* $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{InitialValueProblem}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveOdeFlowBox}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, I, L, P, G, R, E, H, C, Q, N$. It has no coordinate for a selected host solution, maximal continuation interval, quotient path equality, trichotomy on real values, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8241.2 (Constructive ODE flow-box obligations)**.** *For every accepted* $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$ *carrier $F = (O, I, L, P, G, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveOdeFlowBox}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed ODE source, initial-value row, local coordinate window, Picard–Lindelof handoff, Gronwall stability row, regular rational readback, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8241.1. The ODE source and initial-value boundary are the rows O and I, so every local flow-box read is tied to a displayed time-state window and base point.

Read the local coordinate row L. It stores the finite box, transverse coordinate, and time strip on which the nonstationary hypothesis is visible to the packet, rather than as an external differentiable-chart theorem.

The analytic handoff rows are P, G, R, E. The Picard row supplies the local solution-window handoff, the Gronwall row supplies stability inside the strip, the regular rational row records the finite approximants, and the Real seal is downstream of that readback.

Finally H, C, Q, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores a selected host solution, maximal interval, quotient path equality, trichotomy, countable-choice schedule, or ambient completeness witness, those objects cannot enter the local NameCert surface. □

Theorem 8241.3 (Constructive ODE flow-box Picard local handoff)**.** *Every accepted* $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$ *packet hands its local flow-box read to downstream ODE consumers only through*

$$\mathsf{Ode}^{\uparrow}, \quad \mathsf{InitialValueProblem}^{\uparrow}, \quad \mathsf{PicardLindelof}^{\uparrow}, \quad \mathsf{GronwallInequality}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}.$$

The local coordinate row L must be displayed before the Picard handoff P is consumed, and the Gronwall row G must be displayed before any Real-facing seal E is read. The route exports no selected solution curve, host flow map, quotient path equality, global existence theorem, countable choice, or ambient real completeness.

Proof. Start with the source rows O, I, L. They fix the ODE request, initial-value boundary, and local coordinate box before any solution-window handoff is available.

Apply the Picard–Lindelof row P only after that local box is displayed. The handoff therefore reads finite Picard windows over the same time-state strip, not a host solution curve or global flow.

Next read the Gronwall row G. It compares neighboring Picard windows inside the displayed strip and supplies the stability budget needed before the regular rational readback R can be consumed.

The terminal Real seal E is downstream of R, while H, C, Q, N preserve and name the same route. Coordinate exhaustion excludes selected solution curves, host flow maps, quotient path equality, global existence, countable choice, and ambient completeness from the exported handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveOdeFlowBox}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveOdeFlowBox}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8241.1, Definition 8241.2, and Definition 8241.3 seed the finite local ODE flow-box packet from displayed ODE, initial-value, Picard, Gronwall, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveOdeFlowBox}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected host solution curves, global existence, maximal continuation, quotient path equality, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local coordinate-window exactness, Picard local handoff, Gronwall stability, RegSeqRat readback, Real seal discipline, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveOdeFlowBoxUp.

Constructive story: A $\mathsf{ConstructiveOdeFlowBox}^{\uparrow}$ packet is generated from Ode, InitialValueProblem, local coordinate-window, PicardLindelof, GronwallInequality, RegSeqRat, Real, componentwise hsame, displayed Cont, Pkg provenance, and local NameCert rows.

Chapter 8242

A Concrete Naming Certificate for $\mathsf{CompactUniformTriangleChain}^{\uparrow}$

Following Heine–Cantor and Bishop–Bridges compact-uniform reasoning, the $\mathsf{CompactUniformTriangleChain}^{\uparrow}$ packet records the finite source-and-target triangle chain by which compact metric coverage, pointwise continuity, rational tolerance folds, and target metric estimates are read before a $\mathsf{UniformModulus}^{\uparrow}$ consumer receives a tolerance-only handoff. It sits after the compact metric source of chapter 129, the continuous-map graph of chapter 130, the metric law surface of chapter 57, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It shares the final estimate boundary with chapter 7260 and chapter 8118, but this packet names the whole chain from source coverage to target estimate as one finite NameCert carrier.

Definition 8242.1 (Compact-uniform triangle-chain carrier)**.** *A* $\mathsf{CompactUniformTriangleChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, U, M_X, M_Y, D, S, A, R, E, H, C, P, N)$$

with the following visible rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-source row, listing the selected compact-net center, source ball, and inspected source point pair.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row whose pointwise-modulus reads are attached to the center named by K.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row produced only after the triangle chain is complete.*
4. *M_X and M_Y are the source and target* $\mathsf{Met}^{\uparrow}$ *law rows, including the triangle witnesses used on each side of F.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance fold row, splitting the requested tolerance among source-radius, pointwise, and target-triangle contributions.*
6. *S is the source-triangle row, showing that both source points remain in the displayed local ball around the selected center.*
7. *A is the target-triangle row, joining the two pointwise target estimates through the center image.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational tolerance and metric-window data, and E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*

9. *H records componentwise* hsame *transport for compact-net, continuous-map, uniform-modulus, source metric, target metric, dyadic fold, source triangle, target triangle, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay through*

$$K, F, M_X, M_Y, D, S, A, R, E \longmapsto U, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformTriangleChain}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleChain}^{\uparrow}}$ *row.*

The classifier compares accepted triangle-chain packets only through $K, F, U, M_X, M_Y, D, S, A, R, E, H, C, P, N$. It has no coordinate for a host compactness theorem, an external modulus selector, hidden center choice, quotient function equality, selected limits, or ambient real completeness.

Theorem 8242.2 (Compact-uniform triangle-chain obligations)**.** *For every accepted* CompactUniformTriangleChain *carrier*

$$T = (K, F, U, M_X, M_Y, D, S, A, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleChain}^{\uparrow}}$ *surface consists exactly of compact-source admission, continuous-map pointwise admission, source metric triangle admission, target metric triangle admission, dyadic tolerance-fold exactness, source-triangle compatibility, target-triangle compatibility, regular rational readback, Real seal routing, UniformModulus handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8242.1. The compact-source and continuous-map data are K and F, so the chain begins with a displayed center and a pointwise graph read at that center.

Read the metric and tolerance rows M_X, M_Y, D. The source and target metric rows provide the two triangle laws, while the dyadic fold row records the finite rational split of the requested tolerance.

The triangle rows are S and A. The source triangle keeps both source points inside the selected local ball, and the target triangle composes the two pointwise target estimates through the center image.

Finally R, E, U, H, C, P, N read back, seal, export, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host compactness, external modulus selection, hidden center choice, quotient function equality, selected limits, or ambient completeness, the listed rows exhaust the NameCert surface. □

Theorem 8242.3 (Compact-uniform triangle-chain UniformModulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$*-facing read of an accepted* $\mathsf{CompactUniformTriangleChain}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{ContinuousMap}^{\uparrow}, \quad \mathsf{Met}^{\uparrow}, \quad \mathsf{DyadicRatCore}^{\uparrow}, \quad \mathsf{RegSeqRat}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

before the handoff row U is available. In carrier notation, the consumer must read $K, F, M_X, M_Y, D, S, A, R, E$ before U, H, C, P, N can export the tolerance-only modulus route, and it receives no host compactness theorem, hidden center choice, quotient equality, selected limit, or ambient real completeness principle.

Proof. Start with the source packet K and graph packet F. These rows display the compact-net center, the source point pair, and the pointwise continuity read consumed by the triangle chain.

Apply the metric rows M_X, M_Y and the dyadic fold row D. The tolerance split is finite, and both triangle estimates are read as metric-law rows rather than as an ambient continuity theorem.

Use the source and target triangle rows S, A. They turn the compact-source coverage and pointwise center estimate into the target-distance estimate, after which R and E read the regular rational and Real-facing windows.

Only then can the handoff row U be exported. The structural rows H, C, P, N preserve and name this route, so a downstream consumer obtains a finite UniformModulus handoff and none of the refused host-level objects. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformTriangleChain}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformTriangleChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8242.1, Definition 8242.2, and Definition 8242.3 seed the finite source-and-target triangle chain from CompactMetric, ContinuousMap, Metric, DyadicRatCore, RegSeqRat, Real, and UniformModulus rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformTriangleChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host compactness, external modulus selection, hidden center choice, quotient function equality, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked compact-source admission, pointwise-continuity admission, source and target metric triangle exactness, dyadic tolerance-fold exactness, RegSeqRat readback, Real seal routing, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformTriangleChainUp.

Constructive story: A $\mathsf{CompactUniformTriangleChain}^{\uparrow}$ packet is generated from CompactMetric finite-source rows, ContinuousMap pointwise rows, UniformModulus handoff rows, Metric source and target triangle laws, DyadicRatCore tolerance folds, RegSeqRat readbacks, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8243

A Concrete Naming Certificate for $\mathsf{ClosedSubspaceComplete}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{ClosedSubspaceComplete}^{\uparrow}$ packet records the constructive theorem that a closed subspace of a complete metric carrier is complete as finite BEDC NameCert data. It sits after the complete-metric service of chapter 3687, the closed-subset boundary of chapter 4229, the metric carrier of chapter 57, the finite stream interface of chapter 126, and the regular rational readback of chapter 301. The packet names limit retention inside the displayed closed subspace; it does not assert a quotient completion, choose a host representative, invoke countable choice, add ambient compactness, or identify completed reals by host equality.

Definition 8243.1 (Closed subspace complete carrier)**.** *A* $\mathsf{ClosedSubspaceComplete}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, F, D, W, R, C, L, H, Q, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row whose distance requests are visible to the subspace consumer.*
2. *F is the* $\mathsf{ClosedSet}^{\uparrow}$ *boundary row naming the subspace as closed inside the ambient metric carrier.*
3. *D is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row for the ambient carrier.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the accepted Cauchy name inside the subspace.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the rational tolerance schedule of that Cauchy name.*
6. *C is the Cauchy-admission row recording that the displayed stream stays inside the closed subspace.*
7. *L is the limit-retention row: the ambient complete-metric limit read supplied by D is retained by the closed-set boundary F.*
8. *H records componentwise* hsame *transport for M, F, D, W, R, C, L and the local certificate row.*
9. *Q records displayed* Cont *replay from a subspace Cauchy request through $M, F, D, W, R, C, L, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{ClosedSubspaceComplete}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedSubspaceComplete}^{\uparrow}}$ *row.*

The carrier exports only the displayed ambient metric, closed-subspace boundary, ambient completeness service, finite Cauchy readback, limit-retention row, and structural transport, replay, provenance, and naming rows.

Lean4 (statement) `BEDC.Derived.ClosedSubspaceCompleteUp`

Theorem 8243.2 (Closed subspace complete NameCert obligations)**.** *For the carrier of Definition 8243.1, the local* $\mathsf{NameCert}_{\mathsf{ClosedSubspaceComplete}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (M, F, D, W, R, C, L, H, Q, P, N),$$

ambient metric exposure through M, closed-set boundary exposure through F, ambient complete-metric service through D, finite-window Cauchy exposure through W, regular-rational tolerance readback through R, subspace Cauchy admission through C, limit retention through L, componentwise transport through H, displayed replay through Q, package provenance through P, and local naming through N.

Proof. Project the carrier coordinates. The ambient rows M, F, D provide the metric source, closed-subspace boundary, and complete-metric service, while W, R, C provide the finite Cauchy name and its regular rational tolerance readback.

Read the retention row L. It is available only after the ambient limit service D and closed boundary F have been displayed for the same Cauchy name, so the limit remains inside the subspace carrier rather than leaving to a host completion.

Finally read H, Q, P, N. These rows transport, replay, source, and name the same displayed route, and there is no coordinate for quotient completion, selected representatives, host real equality, countable choice, or ambient compactness. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 8243.3 (Closed subspace complete Cauchy-limit retention)**.** *Every completion-facing consumer of an accepted* $\mathsf{ClosedSubspaceComplete}^{\uparrow}$ *carrier must route a subspace Cauchy name through*

$$W, R, C \longmapsto D \longmapsto F \longmapsto L$$

before it can read a retained limit. The retained limit is therefore a displayed closed-subspace endpoint supplied by the ambient $\mathsf{CompleteMetric}^{\uparrow}$ *service and the* $\mathsf{ClosedSet}^{\uparrow}$ *boundary, not a quotient completion class, not a selected host representative, and not an ambient completeness theorem for unrelated subspaces.*

Proof. Start with the finite-window and rational readback rows W and R. They expose the accepted Cauchy observations that the subspace consumer is allowed to inspect.

Use the Cauchy-admission row C to keep those observations inside the displayed closed subspace. The ambient complete-metric service D may then be read for that same Cauchy name, but only along the route already tied to M, F, W, R, C.

Apply the closed-set boundary row F and the retention row L. These rows record that the ambient limit returned by D is retained inside the closed subspace, while H, Q, P, N preserve the same route under transport, replay, provenance, and local naming.

Since the carrier has no coordinate for quotient completion, selected host representatives, countable choice, host real equality, or ambient compactness, no completion-facing read can export those surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedSubspaceComplete}^{\uparrow}}$.

Constructive story: A $\mathsf{ClosedSubspaceComplete}^{\uparrow}$ packet is generated from an ambient Metric row, a ClosedSet boundary row, an ambient CompleteMetric service row, finite StreamName windows, RegSeqRat tolerance readback, subspace Cauchy admission, limit retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedSubspaceComplete}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8243.1, Definition 8243.2, and Definition 8243.3 seed the finite retention route for closed subspaces of complete metric carriers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedSubspaceComplete}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.ClosedSubspaceCompleteUp`

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected host representatives, countable choice, host real equality, ambient compactness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-boundary retention, ambient complete-metric handoff, finite-window readback, transport, replay, provenance, and local naming for the same packet.

Chapter 8244

A Concrete Naming Certificate for $\mathsf{GrussInequality}^{\uparrow}$

Following Gruss and Bishop–Bridges constructive analysis, the $\mathsf{GrussInequality}^{\uparrow}$ packet records the finite BEDC route by which a bounded pair of integrable real-valued maps on a displayed compact metric source yields a covariance-bound certificate. It sits after the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream-name window of chapter 126, the continuous-map graph rows of chapter 130, the integral carrier of chapter 123, and the compact metric source rows of chapter 129. The packet names a finite covariance-bound route; it does not assert host equality of functions, measure completion, selected extrema, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8244.1 (Gruss inequality covariance-bound carrier)**.** *A* $\mathsf{GrussInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, F, L, B, I, Q, W, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, naming the compact metric domain together with the finite observation covers consumed by the bound request.*
2. *F is the paired* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row for the two real-valued maps whose covariance is being bounded.*
3. *L is the value-window row, recording displayed lower and upper Real bounds for each map.*
4. *B is the bounded-oscillation budget row, exposing the four endpoint differences used by the Gruss constant.*
5. *I is the* $\mathsf{Integral}^{\uparrow}$ *row for the four integral reads: the two single-map reads, the product read, and the normalization read of the compact source.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint differences, integral values, product-integral comparison, and tolerance budget.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the endpoint, graph, and integral reads are observed.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the displayed covariance-bound value.*

9. *H records componentwise* hsame *transport for the compact source, paired maps, bounds, oscillation budget, integral rows, readback, stream window, Real seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay through $K, F, L, B, I, Q, W, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{GrussInequality}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GrussInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, L, B, I, Q, W, E, H, C, P, N$. There is no coordinate for host function equality, selected extrema, a measure-completion object, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8244.2 (Gruss inequality NameCert obligations)**.** *For every accepted* $\mathsf{GrussInequality}^{\uparrow}$ *carrier $G = (K, F, L, B, I, Q, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GrussInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact metric source, paired continuous-map graphs, displayed lower and upper value bounds, bounded-oscillation budget, integral readback, regular rational comparison, finite stream observation, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming rows.*

Proof. Project the carrier of Definition 8244.1. The analytic rows are the compact source K, the paired graph row F, the bound row L, the oscillation budget B, and the integral row I.

Readback and observation are downstream. The row Q repacks only the displayed endpoint differences and integral comparisons, while W fixes the finite observation window and E seals the resulting Real-bound value.

The structural rows H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no host function-equality, selected-extremum, measure-completion, countable-choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8244.3 (Gruss inequality integral covariance bound)**.** *Every accepted* $\mathsf{GrussInequality}^{\uparrow}$ *packet presents the covariance read through the finite route*

$$K, F, L, B, I \longmapsto Q, W, E, H, C, P, N.$$

The bound compares the displayed integral covariance only with the Real-sealed budget

$$\frac{1}{4}(L_f^+ - L_f^-)(L_g^+ - L_g^-),$$

where the four endpoint values are the rows stored in L and the comparison is read through Q, W, E. A consumer receives no covariance estimate unless the compact metric source, the two continuous-map rows, the bounded windows, and the integral rows have all been exposed.

Proof. Start from K, F, L, B, I. The compact metric source and paired continuous graphs are displayed before any integral read is consumed, and the bound row records the lower and upper windows used by the Gruss constant.

Use the integral row I to expose the two single-map integral reads, the product read, and the normalization read. The row B supplies only the four endpoint differences already present in L.

The regular rational row Q compares these integral reads with the displayed quarter-product budget, the stream row W records the finite observation window, and E seals the comparison as a Real-facing value. Transport, replay, provenance, and naming through H, C, P, N preserve the same route for downstream consumers. □

Theorem 8244.4 (Gruss inequality L10 nonescape)**.** *Every L10 consumer of an accepted* $\mathsf{GrussInequality}^{\uparrow}$ *packet must factor through*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Integral}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto K, F, L, B, I, Q, W, E, H, C, P,$$

Thus the packet exports a finite covariance-bound certificate, while excluding host function equality, selected extrema, detached measure completion, countable choice, quotient equality of real names, and ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the obligation theorem Definition 8244.2. It forces any consumer to read the compact metric source, paired continuous-map graphs, bound rows, integral rows, regular rational comparisons, stream observation, Real sealing, transport, replay, provenance, and local name.

Apply the covariance-bound theorem Definition 8244.3. The only Real-facing estimate is the displayed quarter-product route; no independent equality or selection row appears in the carrier.

The excluded principles are absent from the carrier coordinates. Therefore an L10 consumer can replay the finite covariance-bound certificate but cannot extract host function equality, selected extrema, a detached measure-completion object, countable choice, quotient equality of real names, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{GrussInequality}^{\uparrow}$ read must display a CompactMetric source, paired ContinuousMap graphs, lower and upper value windows, an oscillation budget, Integral rows, RegSeqRat comparison, StreamName observation, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert before any covariance-bound value is consumed.

Independence witness: real, regseqrat, streamname, continuousmap, integral, compactmetric: $\mathsf{GrussInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact-source rows, paired graph rows, bound windows, covariance integral reads, rational comparison, stream observation, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{GrussInequality}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GrussInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8244.1, Definition 8244.2, Definition 8244.3, and Definition 8244.4 seed the constructive covariance-bound route over compact metric source rows, paired continuous-map graphs, displayed bounds, integral reads, rational comparison, stream observation, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GrussInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host equality of functions, selected extrema, detached measure completion, countable choice, quotient equality of real names, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{GrussInequality}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, bound-window exactness, integral covariance readback, rational comparison, Real-seal nonescape, transport stability, and local NameCert export for BEDC.Derived.GrussInequalityUp.

Constructive story: A $\mathsf{GrussInequality}^{\uparrow}$ packet is generated from a compact metric source, paired continuous-map graphs, lower and upper value windows, a bounded-oscillation budget, integral rows, regular rational readback, stream observation, Real sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8245

A Concrete Naming Certificate for $\mathsf{ReedyCategory}^{\uparrow}$

Following Reedy and Quillen, the $\mathsf{ReedyCategory}^{\uparrow}$ packet records the degree-directed category surface used by latching and matching constructions as finite NameCert data. It sits after the categorical carrier of chapter 61, the functorial transport surface of chapter 62, the simplicial-set row family of chapter 157, and the model-category lifting and factorisation surface of chapter 158. Those sibling chapters expose categories, functors, simplicial degrees, and model-category classes separately; this carrier binds degree, direct maps, inverse maps, unique direct-inverse factorisation, latching boundary, matching boundary, transport, replay, provenance, and local naming into one finite packet.

Definition 8245.1 (Reedy category carrier)**.** *A* $\mathsf{ReedyCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (C, D, A^{+}, A^{-}, F, L, M, H, T, P, N)$$

with the following displayed rows:

1. *C is the consumed* $\mathsf{Cat}^{\uparrow}$ *row, recording objects, morphisms, identities, composition, and the categorical classifier boundary.*
2. *D is the degree row, assigning a displayed natural degree to every object visible in the packet.*
3. *A^{+} is the direct-map row, recording morphisms that strictly raise degree unless they are identities.*
4. *A^{-} is the inverse-map row, recording morphisms that strictly lower degree unless they are identities.*
5. *F is the factorisation row, recording the unique decomposition of every displayed morphism as an inverse map followed by a direct map.*
6. *L is the latching-boundary row, recording the finite direct-source boundary used by diagram consumers.*
7. *M is the matching-boundary row, recording the finite inverse-target boundary used by diagram consumers.*
8. *H stores componentwise* hsame *transport for the category, degree, direct, inverse, factorisation, latching, matching, replay, provenance, and local naming rows.*

9. *T stores displayed* Cont *replay from a Reedy request through degree comparison, direct-inverse factorisation, latching boundary, matching boundary, and sibling category-theory consumers.*
10. *P is the* Pkg *provenance over* $\mathsf{ReedyCategory}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{ModelCat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ReedyCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, D, A^+, A^-, F, L, M, H, T, P, N$. It has no coordinate for a host indexing category, a hidden well-foundedness proof, a selected factorisation outside F, an ambient latching colimit, an ambient matching limit, or a model-category theorem.

Theorem 8245.2 (Reedy category NameCert obligations)**.** *For every accepted* $\mathsf{ReedyCategory}^{\uparrow}$ *carrier $R = (C, D, A^+, A^-, F, L, M, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ReedyCategory}^{\uparrow}}$ *surface consists exactly of carrier admission, degree exposure, direct-map exposure, inverse-map exposure, direct-inverse factorisation, latching-boundary exposure, matching-boundary exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8245.1. The category row C supplies the displayed object and morphism boundary, while the degree row D gives the measure used to separate direct and inverse maps.

Rows A^+ and A^- expose the two Reedy morphism classes. The factorisation row F binds them by recording the unique inverse-then-direct decomposition of every displayed morphism; this is the row that prevents a consumer from choosing a hidden decomposition.

The latching row L and matching row M are then read as finite boundary ledgers over the same degree and morphism rows. They prepare the sibling routes to $\mathsf{Functor}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, and $\mathsf{ModelCat}^{\uparrow}$ without importing a host latching colimit or matching limit.

Finally H, T, P, N transport, replay, source, and name the same rows. Since the carrier has no further coordinate, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{ReedyCategory}^{\uparrow}}$ obligations. □

Theorem 8245.3 (Reedy category degree-factorization ledger)**.** *Every displayed morphism read from an accepted* $\mathsf{ReedyCategory}^{\uparrow}$ *carrier factors through the degree ledger*

$$C, D, A^-, A^+, F$$

before it can be consumed by a latching row, matching row, functor row, simplicial-set row, or model-category row. The factorisation is recorded in F and is transported only through H, T, P, N.

Proof. Start with a morphism in the category row C. The degree row D determines whether a non-identity component may be read as direct or inverse, and the rows A^+ and A^- record the two permitted directions.

Apply the factorisation row F. It supplies the unique inverse-then-direct decomposition attached to the displayed morphism, so the latching boundary L and matching boundary M consume the same finite ledger rather than an ambient choice of decomposition.

The sibling consumers do not add a second factorisation route. $\mathsf{Functor}^{\uparrow}$ reads the displayed functorial transport, $\mathsf{SimplicialSet}^{\uparrow}$ reads degree-indexed simplex rows, and $\mathsf{ModelCat}^{\uparrow}$ reads lifting and factorisation classes, all through the same packet route H, T, P, N.

Thus every downstream read of a Reedy morphism factors through the displayed degree-factorisation ledger. □

Closure status for $\mathsf{NameCert}_{\mathsf{ReedyCategory}^{\uparrow}}$**.**

Constructive story: A ReedyCategory$^{\uparrow}$ packet is generated from a category row, degree row, direct-map row, inverse-map row, factorisation row, latching-boundary row, matching-boundary row, componentwise transport, continuation replay, provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{ReedyCategory}\uparrow}$, obligation)

Scope closed: Definition 8245.1, Definition 8245.2, and Definition 8245.3 close the finite carrier and obligation surface for degree-directed Reedy category reads.

Formal verification: FormalStatus(NameCert$_{\text{ReedyCategory}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, ambient latching colimits, ambient matching limits, full Reedy model structures, or host category equivalence.

Upgrade path: Lean closure requires checked carrier admission, degree exposure, direct and inverse map exposure, factorisation uniqueness, latching and matching boundary exposure, transport, replay, provenance, and local naming for BEDC.Derived.ReedyCategoryUp.

Chapter 8246

A Concrete Naming Certificate for $\mathsf{ReedyModelStructure}^{\uparrow}$

Following Reedy and Quillen, the $\mathsf{ReedyModelStructure}^{\uparrow}$ packet records the finite diagram-index model-category surface used to put model structures on Reedy diagrams. It sits after the degree-factorisation carrier of chapter 8245, the lifting and factorisation rows of chapter 158, the simplicial indexing rows of chapter 157, the displayed replacement witness of chapter 308, and the localization packet of chapter 325. Those siblings expose Reedy categories, ambient model classes, simplicial rows, finite cofibrant witnesses, and selected localizing rows separately; this carrier binds the diagram-index model structure as one NameCert surface.

Definition 8246.1 (Reedy model structure carrier)**.** *A* $\mathsf{ReedyModelStructure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, D, A, L, K, C, W, F, T, H, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{ReedyCategory}^{\uparrow}$ *row, recording the finite degree data, direct maps, inverse maps, and unique direct-inverse factorisation ledger.*
2. *D is the diagram row, recording the displayed finite family of objects and arrows indexed by the Reedy category.*
3. *A is the direct/inverse factorisation row, repacking the direct and inverse sides of R as the dependency route for diagram maps.*
4. *L is the latching-object row, recording the finite direct-source boundary visible to cofibration reads.*
5. *K is the matching-object row, recording the finite inverse-target boundary visible to fibration reads.*
6. *C is the model-class row, recording Reedy cofibration, Reedy fibration, and objectwise weak-equivalence reads through* $\mathsf{ModelCat}^{\uparrow}$*.*
7. *W is the weak-equivalence and replacement row, exposing the objectwise weak-equivalence ledger together with any displayed* $\mathsf{CofibrantReplacement}^{\uparrow}$ *witness.*
8. *F is the selected localization row, present only when a downstream consumer reads a displayed* $\mathsf{BousfieldLocalization}^{\uparrow}$ *packet.*

9. *T stores componentwise* hsame *transport for Reedy data, diagram rows, latching rows, matching rows, model-class rows, replacement rows, localization rows, replay, provenance, and local naming.*
10. *H stores displayed* Cont *replay from a diagram-model request through Reedy degree comparison, latching and matching inspection, model-class reads, replacement reads, and optional localization reads.*
11. *P is the* Pkg *provenance over* $\mathsf{ReedyModelStructure}^{\uparrow}$, $\mathsf{ReedyCategory}^{\uparrow}$, $\mathsf{ModelCat}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{CofibrantReplacement}^{\uparrow}$, $\mathsf{BousfieldLocalization}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ReedyModelStructure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, D, A, L, K, C, W, F, T, H, P, N$. It has no coordinate for an ambient functor category, a hidden latching colimit, a hidden matching limit, an unlisted factorisation, a global cofibrant replacement choice, a localization existence theorem, or a homotopy-limit theorem.

Theorem 8246.2 (Reedy model structure NameCert obligations)**.** *For every accepted* $\mathsf{ReedyModelStructure}^{\uparrow}$ *carrier*

$$M = (R, D, A, L, K, C, W, F, T, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ReedyModelStructure}^{\uparrow}}$ *surface consists exactly of carrier admission, Reedy degree exposure, direct and inverse factorisation exposure, diagram-row exposure, latching-object exposure, matching-object exposure, model-class exposure, replacement-row exposure, optional localization-row exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8246.1. The Reedy row R supplies the degree, direct-map, inverse-map, and factorisation data, while the diagram row D supplies the finite indexed objects and arrows consumed by the model-structure read.

The latching and matching rows are then read from the same Reedy ledger. The latching row L exposes direct-source boundary data for cofibration reads, and the matching row K exposes inverse-target boundary data for fibration reads. Neither row imports an ambient limit or colimit outside the carrier.

The model-class rows C, W, F are downstream. They read cofibration, fibration, objectwise weak-equivalence, displayed replacement, and displayed localization data through $\mathsf{ModelCat}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{CofibrantReplacement}^{\uparrow}$, and $\mathsf{BousfieldLocalization}^{\uparrow}$ without adding global replacement choice or localization existence.

Finally T, H, P, N transport, replay, source, and name the same rows. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8246.3 (Reedy model structure finite diagram route)**.** *Every* $\mathsf{ReedyModelStructure}^{\uparrow}$ *consumer that reads a diagram-model cofibration, fibration, weak equivalence, replacement, or localization row must first expose the finite route*

$$R, D, A \longmapsto L, K \longmapsto C, W, F \longmapsto T, H, P, N.$$

In particular, Reedy degree data and direct/inverse factorisation precede latching and matching inspection, latching and matching inspection precede model-class reads, and model-class reads precede replacement or localization consumers.

Proof. Start with a consumer read of the accepted carrier M. The only index-facing rows are R, D, A, so the read first exposes the Reedy category data, the displayed diagram, and the direct/inverse factorisation route.

Next the latching and matching rows become available. The cofibration side reads the finite latching boundary L, while the fibration side reads the finite matching boundary K. Both rows are attached to the same degree and factorisation ledger.

The model-class stage reads C, W, F. The $\mathsf{ModelCat}^{\uparrow}$ row supplies cofibration, fibration, and weak-equivalence classes, the $\mathsf{CofibrantReplacement}^{\uparrow}$ dependency supplies only displayed replacement witnesses, and the $\mathsf{BousfieldLocalization}^{\uparrow}$ dependency supplies only displayed selected-map and local-object rows when present.

Transport and replay through T, H, P, N preserve this ordering. Thus no accepted consumer can replace the finite diagram route by an ambient functor category, hidden latching or matching construction, global replacement choice, localization existence theorem, homotopy-limit theorem, or homotopy-category quotient. □

Closure status for $\mathsf{NameCert}_{\mathsf{ReedyModelStructure}^{\uparrow}}$.

Constructive story: A $\mathsf{ReedyModelStructure}^{\uparrow}$ packet is generated from Reedy category rows, finite diagram rows, direct and inverse factorisation rows, latching and matching rows, model-class rows, replacement rows, optional localization rows, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ReedyModelStructure}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 8246.1, Definition 8246.2, and Definition 8246.3 close the finite carrier and obligation surface for Reedy diagram model-structure reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ReedyModelStructure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, ambient functor categories, hidden latching colimits, hidden matching limits, global cofibrant replacement choice, localization existence, homotopy limits, or homotopy-category quotients.

Upgrade path: Lean closure requires checked carrier admission, Reedy degree exposure, direct and inverse factorisation exposure, latching and matching row exposure, model-class exposure, replacement and localization row exposure, transport, replay, provenance, and local naming for BEDC.Derived.ReedyModelStructureUp.

Chapter 8247

A Concrete Naming Certificate for $\mathsf{NestedIntervalSqueeze}^{\uparrow}$

Following Bishop and Bridges on nested intervals and constructive real approximation, the $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ packet records a finite squeeze corridor from nested dyadic interval rows to a regular rational readout before any $\mathsf{Real}^{\uparrow}$ consumer sees the terminal seal. It sits beside the dyadic rational core of chapter 291, the finite window service of chapter 126, the regular rational readback surface of chapter 301, the terminal real-name boundary of chapter 38, and the dyadic interval net of chapter 5966. The packet names only finite rows: nested dyadic interval refinements, windowed endpoint reads, regular rational readouts, a Real-facing seal, transport, replay, provenance, and local naming.

Definition 8247.1 (NestedIntervalSqueeze carrier)**.** *A* $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Z = (I, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested dyadic interval row, listing the retained interval cells, endpoint rows, containment witnesses, and diameter-refinement checks through* $\mathsf{DyadicRatCore}^{\uparrow}$ *and* $\mathsf{DyadicIntervalNet}^{\uparrow}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which endpoint, containment, and dyadic-radius observations are inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readout row obtained from the midpoint or endpoint witnesses of the same finite windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after I, S, R have been displayed.*
5. *H records componentwise* hsame *transport for interval rows, window rows, readout rows, Real sealing, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay from a Real or Completion-facing squeeze request through I, S, R, E, H.*
7. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalSqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalSqueeze}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through I, S, R, E, H, C, P, N. It has no coordinate for Real completeness, Heine-Borel compactness, open-cover compactness, countable choice, trichotomy, host equality, quotient reals, or a selected intersection point.

Theorem 8247.2 (NestedIntervalSqueeze NameCert obligations)**.** *For every accepted* $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ *carrier* $Z = (I, S, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalSqueeze}^{\uparrow}}$ *surface is exhausted by carrier admission, nested dyadic refinement admission, finite* $\mathsf{StreamName}^{\uparrow}$ *window coverage,* $\mathsf{RegSeqRat}^{\uparrow}$ *readout admission,* $\mathsf{Real}^{\uparrow}$ *seal nonescape, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every obligation is read through the finite route*

$$I, S, R \longrightarrow E \longrightarrow H, C, P, N.$$

Proof. Project the carrier of Definition 8247.1. The nested interval source is I, and it already contains the dyadic endpoint, containment, and diameter-refinement rows.

The observation route is finite. The row S displays the endpoint and radius windows that are inspected, and the row R reads the same windows as a regular rational sequence surface.

The Real-facing seal E is downstream of I, S, R. Hence a Real or Completion consumer receives only the displayed squeeze corridor before the terminal seal is read.

Finally H, C, P, N transport, replay, source, and locally name the same finite packet. Since the carrier has no coordinate for completeness, compactness, choice, trichotomy, host equality, quotient reals, or a selected intersection point, the listed rows exhaust the local NameCert obligations. □

Theorem 8247.3 (NestedIntervalSqueeze dyadic-refinement stability)**.** *Let* $Z = (I, S, R, E, H, C, P, N)$ *and* $Z' = (I', S', R', E', H', C', P', N')$ *be accepted* $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ *carriers whose nested dyadic interval rows agree by componentwise* hsame *on endpoint rows, containment witnesses, and diameter-refinement checks. If their finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspect the same dyadic refinement rows, then the induced* $\mathsf{RegSeqRat}^{\uparrow}$ *readout rows expose the same public squeeze route through* I, S, R, E, H, C, P, N *and* $I', S', R', E', H', C', P', N'$*.*

Proof. Induct over the finite list of nested dyadic interval rows in I and I'. The initial row is transported by the displayed endpoint and containment hsame witnesses.

For the refinement step, the dyadic diameter and containment checks are rows of the same $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{DyadicIntervalNet}^{\uparrow}$ corridor. The shared finite windows S and S' inspect exactly those rows, so the next readout entry is transported to the corresponding entry of R'.

After the finite induction, the regular rational readout rows agree on the displayed squeeze route. The structural rows H, C, P, N and H', C', P', N' only transport, replay, package, and name that route, so no host equality, quotient real, choice, compactness, or completeness endpoint is introduced. □

Theorem 8247.4 (NestedIntervalSqueeze RegSeqRat readout)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ *carrier factors through the nested dyadic interval row* I*, the finite* $\mathsf{StreamName}^{\uparrow}$ *window row* S*, and the readout row* R *before reaching the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*. The readout is therefore a finite regular-rational route through dyadic interval refinement data, not an appeal to interval intersection, quotient reals, host equality, Heine-Borel compactness, open-cover compactness, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted carrier $Z = (I, S, R, E, H, C, P, N)$. The only interval source is I, and the only observation route is the finite window row S.

The $\mathsf{RegSeqRat}^{\uparrow}$ readout row R is built from the endpoint and radius witnesses inspected by S. Thus any regular-rational consumer must read I and S before it can inspect R.

The terminal seal E is available only after that finite readout has been displayed. The remaining rows H, C, P, N preserve the same route by transport, replay, provenance, and local naming.

Since none of the carrier coordinates stores a completed intersection point, quotient real, host equality, compactness theorem, choice schedule, trichotomy witness, or ambient completeness principle, the RegSeqRat readout cannot export any such endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalSqueeze}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalSqueeze}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8247.1, Definition 8247.2, Definition 8247.3, and Definition 8247.4 seed the finite route from nested dyadic interval rows through StreamName windows, RegSeqRat readout, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalSqueeze}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Real completeness, Heine-Borel compactness, open-cover compactness, choice, trichotomy, host equality, quotient reals, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic refinement stability, StreamName window coverage, RegSeqRat readout, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NestedIntervalSqueezeU

Constructive story: A $\mathsf{NestedIntervalSqueeze}^{\uparrow}$ packet is generated from nested dyadic interval rows, StreamName windows, RegSeqRat readout rows, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8248

A Concrete Naming Certificate for $\mathsf{CoreCompactSpace}^{\uparrow}$

Following Kelley and Johnstone on compact neighbourhoods and core-compact topology, the $\mathsf{CoreCompactSpace}^{\uparrow}$ packet records a traditional topological-space carrier whose open-neighbourhood requests are mediated by compact containment and way-below data. It sits beside the indexed topology surface of chapter 88, the compact carrier of chapter 60, the neighbourhood-filter route of chapter 4133, the Scott-open handoff of chapter 5950, and the sober-space point reconstruction boundary of chapter 6495. The packet gives compact-neighbourhood, Scott-topology, and sober-space consumers a finite NameCert surface for the way-below neighbourhood step, without asserting host powersets of opens, selected compact neighbourhoods, quotient open equality, choice-indexed bases, or ambient local compactness.

Definition 8248.1 (CoreCompactSpace carrier)**.** *A* $\mathsf{CoreCompactSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (T, O, C, W, Nb, H, R, P, L)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the point classifier, indexed open rows, finite-meet ledger, arbitrary-union ledger, and visible open-membership stability.*
2. *O is the displayed open-neighbourhood request. It names the open being inspected and the point or finite neighbourhood observation through which a consumer asks for compact containment.*
3. *C is the compact-containment witness row, recording that the requested neighbourhood admits a compact support row from the* $\mathsf{Compact}^{\uparrow}$ *surface before any consumer may read compactness.*
4. *W is the way-below and compact-neighbourhood handoff row. It records the finite route from C to the way-below neighbourhood relation consumed by Scott-topology and sober-space reads.*
5. *Nb is the* $\mathsf{NeighborhoodFilter}^{\uparrow}$ *row, retaining the local filter discipline around the same displayed request rather than a host collection of all neighbourhoods.*
6. *H records componentwise* hsame *transport for topology source, open-neighbourhood request, compact containment, way-below handoff, neighbourhood filter, replay, provenance, and local naming.*
7. *R records displayed* Cont *replay from an open-neighbourhood request through T, O, C, W, Nb, H.*

8. *P is the* Pkg *provenance over* $\mathsf{CoreCompactSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{NeighborhoodFilter}^{\uparrow}$, $\mathsf{ScottTopology}^{\uparrow}$, $\mathsf{SoberSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *L is the local* $\mathsf{NameCert}_{\mathsf{CoreCompactSpace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, O, C, W, Nb, H, R, P, L$. It has no coordinate for host powersets of opens, selected compact neighbourhoods, quotient-open equality, a choice-indexed basis, ambient local compactness, or global spatiality.

Theorem 8248.2 (CoreCompactSpace NameCert obligations)**.** *For every accepted* $\mathsf{CoreCompactSpace}^{\uparrow}$ *carrier $K = (T, O, C, W, Nb, H, R, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{CoreCompactSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission, displayed open-neighbourhood request admission, compact-containment witness exposure, way-below compact-neighbourhood handoff, neighbourhood-filter retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every compact-neighbourhood consumer must read the route*

$$T, O, C, W, Nb, H, R, P, L$$

before treating the request as a public core-compact-space handoff.

Proof. Carrier admission is projection from Definition 8248.1. The packet exposes one topology row, one displayed open-neighbourhood request, one compact-containment witness, one way-below handoff, and one neighbourhood-filter row.

The compact-containment step is held by C. A consumer may not replace it by a selected compact neighbourhood or an open-cover compactness theorem, because the carrier stores only the displayed compact support row.

The way-below handoff is held by W and remains attached to the same request O. The neighbourhood-filter row Nb records local filter discipline for that request, not a host set of all neighbourhoods.

Finally H, R, P, L transport, replay, source, and name the same finite route. Since the excluded host powersets, selected compact neighbourhoods, quotient-open equalities, choice-indexed bases, ambient local compactness, and global spatiality data are absent from the carrier, no local NameCert obligation can export them. □

Theorem 8248.3 (CoreCompactSpace way-below neighbourhood handoff)**.** *Let $K = (T, O, C, W, Nb, H, R, P, L)$ be an accepted* $\mathsf{CoreCompactSpace}^{\uparrow}$ *carrier. Any Scott-topology, sober-space, or compact-neighbourhood read that reaches the way-below row must first expose the* $\mathsf{Topology}^{\uparrow}$ *source row T, the displayed request O, and the compact-containment row C. Only then may it read W as the compact-neighbourhood handoff and Nb as the matching* $\mathsf{NeighborhoodFilter}^{\uparrow}$ *route. The handoff exports no selected basis, no host compact-neighbourhood object, no quotient-open equality, no choice-indexed local compactness, and no global spatiality claim.*

Proof. Start with an accepted carrier and project T, O, C. These rows identify the topology source, the concrete open-neighbourhood request, and the compact support attached to that request.

Apply Definition 8248.2. It requires the way-below handoff W and the neighbourhood-filter row Nb to be read in the same route as T, O, C, then preserves the route through H, R, P, L.

A $\mathsf{ScottTopology}^{\uparrow}$ consumer may use W as the compact-neighbourhood way-below input, and a $\mathsf{SoberSpace}^{\uparrow}$ consumer may use the same visible neighbourhood route when point-reconstruction prose needs compact local support. In both cases the read remains the finite route named by the packet, so it cannot detach into selected bases, host compact neighbourhoods, quotient opens, choice-indexed local compactness, or global spatiality. □

Closure status for $\mathsf{NameCert}_{\mathsf{CoreCompactSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{CoreCompactSpace}^{\uparrow}$ packet is generated from a TopologyUp source row, displayed open-neighbourhood request, compact-containment witness row, way-below compact-neighbourhood handoff row, NeighborhoodFilterUp row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoreCompactSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8248.1, Definition 8248.2, and Definition 8248.3 seed the finite core-compact-space interface over topology, compact containment, way-below neighbourhoods, neighbourhood filters, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CoreCompactSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host powersets of opens, selected compact neighbourhoods, quotient-open equality, choice-indexed bases, ambient local compactness, global spatiality, or bridge checking.

Upgrade path: Obligation closure requires checked topology-source admission, displayed open-neighbourhood request admission, compact-containment exposure, way-below handoff, neighbourhood-filter retention, transport, replay, provenance, and local naming for BEDC.Derived.CoreCompactSpaceUp.

Chapter 8249

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealComparator}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ packet records a constructive located comparison witness for displayed $\mathsf{Real}^{\uparrow}$ names as finite NameCert data. It sits beside the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the located-real row of **??**, and the order-and-apartness surface of chapter 5562. The packet names the finite route by which two real names expose enough located window data for a comparison-facing consumer; it is not host trichotomy, quotient real equality, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8249.1 (Bishop located real comparator carrier)**.** *A* $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, W_X, W_Y, D_X, D_Y, R_X, R_Y, L, A, J, H, C, P, N)$$

with the following displayed rows:

1. *X and Y are the two source* $\mathsf{Real}^{\uparrow}$ *name rows.*
2. *W_X and W_Y are finite* $\mathsf{StreamName}^{\uparrow}$ *windows inspected for the two names.*
3. *D_X and D_Y are the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-and-tolerance rows read from those windows.*
4. *R_X and R_Y are the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows that expose the regular rational names behind the two* $\mathsf{Real}^{\uparrow}$ *seals.*
5. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *locatedness row, displaying the positive-radius or separation window used by the comparison request.*
6. *A is the* $\mathsf{ApartnessReal}^{\uparrow}$ *or real-apartness-field row recording the apartness-facing handoff when the displayed windows separate.*
7. *J is the finite comparator witness row. Its alternatives are window-left, window-right, and overlap-pending, each tied to the displayed dyadic and regular rows rather than to a host order on completed reals.*
8. *H records componentwise* hsame *transport for the two real rows, windows, dyadic ledgers, readbacks, locatedness row, apartness handoff, comparator witness, replay, provenance, and local name.*

9. *C records displayed* Cont *replay from a comparison request through* $X, Y, W_X, W_Y, D_X, D_Y, R_X, R_Y, L, A, J$ *and onward to provenance and naming.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealComparator}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealComparator}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for host trichotomy, quotient real equality, selected representatives, countable choice, or an ambient completeness theorem.

Theorem 8249.2 (Bishop located real comparator NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ *carrier* $K = (X, Y, W_X, W_Y, D_X, D_Y, R_X, R_Y, L, A, J, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealComparator}^{\uparrow}}$ *surface consists exactly of two* $\mathsf{Real}^{\uparrow}$ *source admissions, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, a* $\mathsf{LocatedReal}^{\uparrow}$ *locatedness row, an* $\mathsf{ApartnessReal}^{\uparrow}$ *handoff row, the finite comparator witness* J*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The analytic rows are precisely the two source real names, their finite observation windows, their dyadic tolerance ledgers, their regular rational readbacks, the locatedness row, the apartness handoff, and the comparator witness.

Read the comparator witness only after those rows are displayed. In a window-left branch, J records that the inspected X window is separated below the inspected Y window by the dyadic and regular rows. In a window-right branch, the same finite evidence is read with the two sources exchanged. In an overlap-pending branch, J records that the displayed data do not license a strict comparison at this tolerance.

The structural rows H, C, P, N transport, replay, source, and name exactly that finite surface. Since no carrier coordinate names host trichotomy, quotient equality, selected representatives, countable choice, or completeness, none of those objects can be exported by the local NameCert row. □

Theorem 8249.3 (Bishop located real comparator stability)**.** *Let* $K = (X, Y, W_X, W_Y, D_X, D_Y, R_X, R_Y, L, A, J, H$ *be an accepted* $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ *carrier. Any componentwise* hsame *transport recorded in* H *preserves the same comparator alternative in* J *together with the same* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{ApartnessReal}^{\uparrow}$, Pkg, *and* NameCert *rows.*

Proof. Inspect the transport row H. It is componentwise over the displayed source, window, dyadic, readback, locatedness, apartness, comparator, replay, provenance, and naming rows.

Case-split on J. In the window-left branch, transport preserves the two windows and their dyadic separation witness before the left comparison is read. In the window-right branch, the same argument preserves the exchanged separation witness. In the overlap-pending branch, transport preserves the absence of a licensed strict comparison at the displayed tolerance.

The continuation row C replays the transported rows in the same order, and P, N only record provenance and local naming. Thus stability is local to the carrier and does not introduce a host order, quotient equality, or completeness principle. □

Theorem 8249.4 (Bishop located real comparator non-escape)**.** *Every* $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ *consumer read factors through the finite route*

$$X, Y, W_X, W_Y, D_X, D_Y, R_X, R_Y, L, A, J, H, C, P, N.$$

The packet exports no host trichotomy for $\mathsf{Real}^{\uparrow}$*, no quotient real equality test, no selected representative, no countable-choice schedule, and no ambient completeness witness.*

Proof. Start from the carrier inventory. Its only comparison row is J, and J is downstream of the displayed real names, finite stream windows, dyadic tolerance rows, regular rational readbacks, locatedness row, and apartness handoff.

Any consumer route must then pass through H and C to transport and replay the same displayed rows. The provenance and local naming rows record where the finite packet came from, but they do not add comparison data.

Therefore the listed route is exhaustive. The refused host objects are absent from the carrier and cannot be projected from an accepted packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealComparator}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealComparator}^{\uparrow}$ packet is generated from two RealUp source rows, finite StreamName windows, DyadicRatCore tolerance ledgers, RegSeqRat readbacks, a LocatedReal row, an ApartnessReal handoff, a finite comparator witness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealComparator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8249.1, Definition 8249.2, Definition 8249.3, and Definition 8249.4 seed the finite located comparison witness for displayed RealUp names.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealComparator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient real equality, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopLocatedRealComparator}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-window comparison exactness, locatedness and apartness handoff, transport stability, provenance, local naming, and non-escape for BEDC.Derived.BishopLocatedRealComparatorUp.

Chapter 8250

A Concrete Naming Certificate for $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$

The $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ packet realizes the classifier-membership reading of chapter 9367 as finite context, rule, membership, refusal, replay, and NameCert rows. It sits beside the MetaCIC typed audit surfaces chapter 775, chapter 2330, chapter 3616, chapter 8235, and chapter 4238. Those siblings expose typed examples, reduction traces, decidable typing frontiers, equality eliminator checks, and diamond-frontier checks; this packet binds a type-checking run to its classifier-membership and refusal trace without exporting a host type theory.

Definition 8250.1 (Typechecking classifier trace carrier)**.** *A* $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (\Gamma, t, \tau, R, E, J, S, U, H, C, P, N)$$

with the following displayed rows:

1. Γ *is the context row, recording the displayed typing context and its closed variable boundary.*
2. t *is the term row read as a finite* BHist *object rather than as host syntax.*
3. τ *is the candidate type row.*
4. R *is the rule-ledger row, recording the finite typing rules inspected by the checker.*
5. E *is the* Ext*-membership row, recording accepted classifier membership when the typing run succeeds.*
6. J *is the judgment-trace row, recording the derivation route from* Γ, t, τ, R *to the membership decision.*
7. S *is the subject-reduction handoff row, recording the typed* Cont *route exposed to reduction consumers.*
8. U *is the refusal row, recording the first visible classifier-membership failure when the term is not accepted.*
9. H *stores componentwise* hsame *transport for context, term, type, rule, membership, judgment, subject-reduction, refusal, replay, provenance, and local naming rows.*
10. C *stores displayed* Cont *replay from a type-checking request through rule inspection, classifier membership, refusal, and reduction handoff.*

11. *P is the* Pkg *provenance over* $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$*, MetaCIC typed example rows,* Ext*,* Cont*,* SigRel*,* BHist*,* hsame*,* Pkg*, and* NameCert*.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}$ *row.*

The classifier compares accepted traces only through $\Gamma, t, \tau, R, E, J, S, U, H, C, P, N$. It has no coordinate for erased host conversion, unrestricted subject reduction, global confluence, proof irrelevance, proof-term erasure as equality, or an oracle deciding all type systems.

Theorem 8250.2 (Typechecking classifier trace NameCert obligations)**.** *For every accepted* TypecheckingClassifierT *carrier $Q = (\Gamma, t, \tau, R, E, J, S, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}$ *surface consists exactly of context exposure, term exposure, candidate-type exposure, rule-ledger exposure,* Ext*-membership exposure, judgment-trace exposure, subject-reduction handoff, refusal exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8250.1. The rows Γ, t, τ, R display the finite data inspected by the checker before any classifier decision is made.

Rows E and J record the positive membership route: E stores the Ext-membership read and J stores the derivation trace that connects the context, term, type, and rule ledger to that read. The subject-reduction handoff S is a separate continuation-facing row, not a theorem about all reductions.

The refusal row U records the negative route when membership fails. It keeps the failed rule, context boundary, term row, and type row visible instead of allowing the checker to disappear into host computation.

Finally H, C, P, N transport, replay, source, and name the same rows. Since the carrier has no further coordinate, these rows exhaust the local $\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}$ obligations. □

Theorem 8250.3 (Typechecking classifier trace membership refusal)**.** *Every* $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ *read chooses exactly one visible classifier route: either it exposes an* Ext*-membership row through E, J, S, H, C, P, N, or it exposes a refusal row through U, H, C, P, N. In neither case may the trace replace classifier membership by erased host conversion, proof irrelevance, global confluence, or an unrestricted subject-reduction theorem.*

Proof. Read the rule ledger R against the context, term, and candidate type rows Γ, t, τ. The carrier has one positive membership coordinate E and one refusal coordinate U.

In the accepted case, the judgment trace J binds the inspected rules to the Ext-membership row E, and the subject-reduction handoff S exports only the typed continuation route displayed by the packet. The structural rows H, C, P, N keep this positive route named and replayable.

In the refused case, the row U records the visible classifier-membership failure. The same structural rows carry the failed route without turning it into a host conversion judgment.

Thus a consumer receives either a displayed membership trace or a displayed refusal trace. The forbidden readings named in the theorem have no carrier coordinate and cannot be imported through the local NameCert. □

Falsifiable prediction: If a $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ packet accepts a term while omitting either the Ext-membership row or the visible rule ledger, the packet is refuted.

Independence witness: metacictypedexamplesgallery, typed-example-reduction-trace, metacic-decidable-typing-frontier, metacic-typed-equality-eliminator, metacic-parallel-diamond-frontier: the siblings expose typed examples, reduction rows, decidable checker frontiers, equality-eliminator

rows, and diamond-frontier rows, but none alone binds context, term, type, rule ledger, membership, refusal, subject-reduction handoff, replay, provenance, and local NameCert rows into the same classifier trace.

The Lean TasteGate route for $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ must provide explicit Nontrivial TypecheckingClassifier and FieldFaithful $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ instances in `lean4/BEDC/Derived/TypecheckingClassifierTraceU` The nontriviality witness must expose at least one accepted or refused classifier trace, and the field-faithfulness witness must preserve $\Gamma, t, \tau, R, E, J, S, U, H, C, P, N$ as distinct rows before any checked marker may cite `BEDC.Derived.TypecheckingClassifierTraceUp`.

Closure status for $\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{TypecheckingClassifierTrace}^{\uparrow}$ packet is generated from context, term, candidate type, rule ledger, Ext-membership, judgment trace, subject-reduction handoff, refusal, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}, \mathsf{obligation})$

Scope closed: Definition 8250.1, Definition 8250.2, and Definition 8250.3 close the finite classifier-trace carrier and its membership-or-refusal obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TypecheckingClassifierTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close Lean verification, bridge checking, global subject reduction, global confluence, proof irrelevance, erased host conversion, or a general oracle for all type systems.

Upgrade path: Lean closure requires checked carrier admission, rule-ledger exposure, Ext-membership exposure, refusal exposure, subject-reduction handoff, Nontrivial evidence, and FieldFaithful evidence for BEDC.Derived.TypecheckingClassifierTraceUp.

Chapter 8251

A Concrete Naming Certificate for $\mathsf{CombSpace}^{\uparrow}$

Following Steen and Seebach and Engelking, the $\mathsf{CombSpace}^{\uparrow}$ packet records the topologist's comb as finite BEDC topology and metric boundary data. It sits after the indexed-open surface of chapter 88, the distance-law carrier of chapter 57, the terminal real-name seal of chapter 38, and the finite observation windows of chapter 126. The packet names real-axis base windows, vertical tooth rows, an accumulation-spine row, topology classifier rows, and metric handoff rows without importing a host subspace, quotient point equality, selected infinite teeth, or ambient compactness.

Definition 8251.1 (CombSpace carrier)**.** *A* $\mathsf{CombSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, V, S, T, M, H, C, P, N)$$

with the following displayed rows:

1. *A is the real-axis base-window row. It lists the inspected rational intervals on the base segment and records the* $\mathsf{Real}^{\uparrow}$ *endpoint seals used by those windows.*
2. *V is the vertical-tooth row. It stores finitely many tooth indices, their rational height windows, and the displayed attachment point on the base axis.*
3. *S is the accumulation-spine row. It records the finite evidence that teeth with displayed indices approach the spine boundary through the visible* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *T is the topology classifier row. It names the basic-neighbourhood tests for base-axis points, tooth points, and spine-near observations through the* $\mathsf{Topology}^{\uparrow}$ *carrier.*
5. *M is the metric handoff row. It records only the finite* $\mathsf{Met}^{\uparrow}$ *distance windows that compare displayed base, tooth, and spine observations after their* $\mathsf{Real}^{\uparrow}$ *readbacks are present.*
6. *H records componentwise* hsame *transport for the base-window, tooth, spine, topology, metric, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay through*

$$A, V, S, T, M \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{CombSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{CombSpace}^\uparrow}$ *row.*
The classifier compares accepted packets only through $A, V, S, T, M, H, C, P, N$. It has no coordinate for a host subset of the plane, quotient point equality, an infinite selected family of teeth, open-cover compactness, sequential compactness, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Theorem 8251.2 (CombSpace NameCert obligations)**.** *For every accepted* $\mathsf{CombSpace}^\uparrow$ *carrier*

$$K = (A, V, S, T, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CombSpace}^\uparrow}$ *surface consists exactly of carrier admission for the real-axis base windows, vertical tooth rows, accumulation-spine rows, topology classifier rows, metric handoff rows, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8251.1. The rows A, V, S display the base axis, the inspected teeth, and the accumulation-spine evidence before any topology or metric consumer can read the packet.

Next read T and M. The topology classifier is finite because it only inspects the displayed neighbourhood tests, and the metric handoff is finite because every distance row is tied to the shown real-name and stream-window data.

Finally use H, C, P, N. Transport is componentwise, replay follows the displayed rows, provenance names the source packets, and the local NameCert row closes the finite carrier surface. Since no carrier coordinate stores a host plane subset, quotient equality, selected infinite teeth, compactness theorem, or ambient completeness witness, those objects cannot enter the NameCert obligations. □

Theorem 8251.3 (CombSpace topology-metric boundary)**.** *Every topology-facing or metric-facing read of an accepted* $\mathsf{CombSpace}^\uparrow$ *packet factors through*

$$\mathsf{Topology}^\uparrow, \quad \mathsf{Met}^\uparrow, \quad \mathsf{Real}^\uparrow, \quad \mathsf{StreamName}^\uparrow$$

as displayed by A, V, S, T, M. The topology consumer receives only basic-neighbourhood classifier rows, and the metric consumer receives only finite distance-window handoffs. Neither consumer receives host point-set equality, a selected infinite tooth family, compactness, sequential compactness, or ambient $\mathsf{Real}^\uparrow$ *completeness.*

Proof. Start with the base and tooth rows A, V. They expose the finite real-axis windows and the inspected vertical teeth, so both topology and metric reads are tied to displayed observations.

Use the spine row S before reading either classifier. The accumulation behaviour is visible only through the finite stream windows recorded in the packet.

The topology row T then supplies neighbourhood tests, while the metric row M supplies distance-window handoffs. Both rows depend on the same displayed base, tooth, spine, real-name, and stream data.

The structural rows H, C, P, N preserve and name this route. Because the carrier has no coordinate for host point-set equality, a selected infinite tooth family, compactness, sequential compactness, or ambient completeness, the topology-metric boundary remains exactly the finite one stated above. □

Closure status for $\mathsf{NameCert}_{\mathsf{CombSpace}^\uparrow}$.
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CombSpace}^\uparrow}, \mathsf{seed})$

Scope closed: Definition 8251.1, Definition 8251.2, and Definition 8251.3 seed the finite comb-space packet from real-axis base windows, vertical tooth rows, accumulation-spine rows, topology classifier rows, metric handoff rows, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CombSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, public-object export, host point-set equality, selected infinite teeth, compactness, sequential compactness, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, topology classifier exactness, metric handoff exactness, accumulation-spine routing, transport, replay, provenance, and local naming for BEDC.Derived.CombSpaceUp.

Constructive story: A $\mathsf{CombSpace}^{\uparrow}$ packet is generated from displayed real-axis base windows, vertical tooth rows, accumulation-spine rows, topology classifier rows, metric handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8252

A Concrete Naming Certificate for $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$

Following Brouwer and Troelstra–van Dalen on finite-prefix continuity for choice sequences, the $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$ packet records the handoff that turns Brouwer-continuity evidence into a finite modulus ledger consumable by StreamName, RegSeqRat, and Real-name data. It sits between the continuity surface of chapter 3465, the choice-sequence observations of chapter 1482, the finite-window schedule of chapter 126, the rational readback of chapter 301, the endpoint seal of chapter 38, and the effective finite-prefix route of chapter 1743. The chapter packages the bridge as NameCert data; it does not import host functional continuity, countable choice, quotient stream equality, selected real representatives, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8252.1 (Brouwer continuity modulus bridge carrier)**.** *A* $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, Q, S, R, E, M, H, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ *row, naming the finite-prefix continuity principle whose output read is being bridged.*
2. *Q is the* $\mathsf{ChoiceSequence}^{\uparrow}$ *finite-prefix row, recording only the observed choice-sequence cells admitted by the bridge.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the requested output window and the finite schedule used to answer it.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled stream window.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the choice prefix, stream window, rational readback, and modulus ledger have been displayed.*
6. *M is the finite modulus ledger, assigning each scheduled output window exactly the input-prefix budget used for replay.*
7. *H records componentwise* hsame *transport for $C, Q, S, R, E, M, K, P, N$.*
8. *K records displayed* Cont *replay from Brouwer continuity evidence to choice-sequence observations, from observations to StreamName windows, from windows to RegSeqRat readback, from the modulus ledger to the Real seal, and from the whole route to the local naming row.*

9. *P is the* Pkg *provenance over* $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$, $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$, $\mathsf{ChoiceSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}}$ *row.*

The classifier compares accepted bridge packets only through $C, Q, S, R, E, M, H, K, P, N$. It has no coordinate for a completed host functional, a choice-selected modulus, quotient stream equality, a selected real limit, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8252.2 (Brouwer continuity modulus bridge NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$ *carrier $B = (C, Q, S, R, E, M, H, K, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BrouwerContinuityModul}}$ *surface consists exactly of carrier admission for the Brouwer-continuity row, choice-sequence finite-prefix row, StreamName window row, RegSeqRat readback row, Real seal row, finite modulus ledger, componentwise transport, displayed replay, provenance, and local naming rows. Each accepted output-window request must pass through the displayed finite-prefix route*

$$C, Q \longmapsto M \longmapsto S, R \longmapsto E \longmapsto H, K, P, N.$$

No local obligation is stored outside these displayed rows.

Proof. Project the accepted carrier. The rows C, Q, S, R, E, M are the only computational rows, and the rows H, K, P, N are the only structural rows.

The Brouwer-continuity row C supplies the finite-prefix dependence surface, while Q records the choice-sequence cells actually inspected by the route. The StreamName row S cannot answer a window request until the modulus ledger M displays the corresponding input-prefix budget.

Once the window is scheduled, R gives the regular rational readback and E records the endpoint seal. The transport, replay, provenance, and naming rows preserve that order and add no hidden selector or completion theorem.

Thus the local NameCert obligations are exactly the displayed bridge rows. A consumer seeking countable choice, quotient stream equality, a completed host functional, or ambient Real completeness must obtain it outside this packet. □

Theorem 8252.3 (Brouwer continuity modulus bridge StreamName handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$ *consumer of an accepted* $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$ *carrier must first read the* $\mathsf{BrouwerContinuityPrinciple}^{\uparrow}$ *row C, the* $\mathsf{ChoiceSequence}^{\uparrow}$ *finite-prefix row Q, and the finite modulus ledger M. The consumer may then inspect the scheduled StreamName window S, the RegSeqRat readback R, and the Real seal E. The handoff exports finite-prefix real-name evidence only; it exports no host functional continuity theorem, countable-choice selector, quotient stream equality, selected real representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a StreamName request. The request is represented by S, but the carrier permits S to be read only as part of the bridge route from C and Q through the ledger M.

Open the ledger row. Each entry of M names the input-prefix budget attached to one displayed output-window request, so the consumer receives a finite prefix rather than a total host function or a choice-selected modulus.

The readback rows then follow deterministically inside the packet. Row R records the regular rational data for the scheduled window, and row E seals the Real-name endpoint after that readback has been displayed.

The structural rows H, K, P, N replay and name the same route. Since none of the refused principles is a carrier coordinate, the StreamName handoff remains a finite-prefix real-name bridge. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}$ packet is generated from Brouwer-continuity evidence, choice-sequence finite-prefix observations, StreamName windows, RegSeqRat readback, a Real seal, a finite modulus ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8252.1, Definition 8252.2, and Definition 8252.3 seed the finite-prefix bridge from Brouwer-continuity and choice-sequence data to StreamName, RegSeqRat, and Real-name consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerContinuityModulusBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host functional continuity, countable choice, quotient stream equality, selected real representatives, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix exactness, StreamName window exactness, RegSeqRat readback, Real-seal handoff, modulus-ledger exactness, and nonescape for BEDC.Derived.BrouwerContinuityModulusBridg

Chapter 8253

A Concrete Naming Certificate for $\mathsf{BanachContractionSequence}^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the $\mathsf{BanachContractionSequence}^{\uparrow}$ packet records the finite Picard-orbit Cauchy handoff that sits between the contraction iteration surface and any completed fixed-point endpoint. It reads the $\mathsf{PicardIteration}^{\uparrow}$ orbit of chapter 2359, the $\mathsf{ContractionMapping}^{\uparrow}$ source of chapter 1418, the $\mathsf{CompleteMetric}^{\uparrow}$ endpoint-admission boundary of chapter 128, the $\mathsf{CauchyModulus}^{\uparrow}$ route of chapter 292, the $\mathsf{RegSeqRat}^{\uparrow}$ handoff of chapter 301, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names the orbit-as-Cauchy carrier only; it does not assert a completed fixed point, host equality, a selected limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8253.1 (Banach contraction sequence carrier)**.** *A* $\mathsf{BanachContractionSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, I, M, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{ContractionMapping}^{\uparrow}$ *row, carrying the self-map graph, contraction bound, and one-step comparison surface used by the orbit.*
2. *I is the* $\mathsf{PicardIteration}^{\uparrow}$ *row, exposing the finite orbit ledger and adjacent residual-distance rows.*
3. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row extracted from the displayed Picard residuals.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row generated from the orbit and modulus rows.*
5. *R is the* $\mathsf{CompleteMetric}^{\uparrow}$ *read of the same Cauchy data as endpoint-admissible input, not as a selected endpoint.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after the regular rational handoff has been displayed.*
7. *H records componentwise* hsame *transport for K, I, M, Q, R, E and the local certificate rows.*
8. *C records displayed* Cont *replay from contraction admission through Picard iteration, modulus extraction, regular rational handoff, complete-metric admission, and real sealing.*
9. *P is the* Pkg *provenance row over* $\mathsf{BanachContractionSequence}^{\uparrow}$, $\mathsf{ContractionMapping}^{\uparrow}$, $\mathsf{PicardIteration}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachContractionSequence}^{\uparrow}}$ *row.*

The carrier exports a finite Cauchy handoff for the Picard orbit. It contains no coordinate for a fixed point, host function extensionality, quotient completion equality, a selected representative, countable choice, or ambient completeness.

Theorem 8253.2 (Banach contraction sequence NameCert obligations)**.** *For an accepted* $\mathsf{BanachContractionSequen}$ *carrier* $S = (K, I, M, Q, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BanachContractionSequence}^{\uparrow}}$ *surface consists exactly of contraction-map visibility, Picard-orbit ledger visibility, residual-modulus exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff visibility,* $\mathsf{CompleteMetric}^{\uparrow}$ *endpoint-admission visibility, terminal* $\mathsf{Real}^{\uparrow}$ *seal visibility, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 8253.1.*

Proof. Project the carrier. The mathematical rows are K, I, M, Q, R, E, and the support rows are H, C, P, N.

Read K and I first. The contraction row supplies the self-map and contraction bound, while the Picard row supplies the finite orbit ledger and residual-distance comparisons.

Read M, Q, R, E next. The modulus row is extracted from the displayed residuals, the regular rational row is generated from that modulus, the complete-metric row admits the same Cauchy data as endpoint-facing input, and the real seal is downstream of the regular handoff.

The transport, replay, provenance, and naming rows preserve only this displayed route. Since no excluded endpoint or choice object appears in the carrier, the local NameCert cannot export one. □

Theorem 8253.3 (Banach contraction sequence Picard-Cauchy handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{BanachContractionSequence}^{\uparrow}$ *packet must pass through the finite route*

$$\mathsf{ContractionMapping}^{\uparrow} \longmapsto \mathsf{PicardIteration}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route turns the finite Picard orbit into named Cauchy handoff data before any endpoint-facing read is allowed. It does not supply a completed fixed point, selected limit, quotient stream equality, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the contraction and Picard rows. They display the self-map graph, the initial orbit data, the finite iterate ledger, and the residual-distance comparisons.

Apply the obligation theorem above. It places the $\mathsf{CauchyModulus}^{\uparrow}$ row downstream of those residuals and places the $\mathsf{RegSeqRat}^{\uparrow}$ handoff downstream of the modulus.

The complete-metric and real-seal rows are then read as boundaries for later consumers. They receive the named regular Cauchy handoff; they do not create an endpoint selector or a host fixed-point equality.

Thus the packet is precisely the finite Picard-orbit Cauchy handoff. Any consumer asking for a fixed point must add its own endpoint and uniqueness obligations after this route. □

Falsifiable prediction: Every accepted $\mathsf{BanachContractionSequence}^{\uparrow}$ read factors through one ContractionMapping row, one PicardIteration orbit row, one CauchyModulus row, one RegSeqRat handoff, one CompleteMetric endpoint-admission row, one RealUp seal, hsame transport, Cont replay, Pkg provenance, and NameCert row before any fixed-point endpoint is consumed.

Independence witness: picard-iteration, contractionmapping, completemetric, cauchymodulus, regseqrat, real: none is bijective with $\mathsf{BanachContractionSequence}^{\uparrow}$ because the packet jointly stores the contraction source, finite Picard orbit, residual modulus, regular rational handoff, complete-metric admission boundary, real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContractionSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachContractionSequence}^{\uparrow}$ packet is generated from a ContractionMapping row, a PicardIteration orbit row, a CauchyModulus row, a RegSeqRat handoff, a CompleteMetric endpoint-admission row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachContractionSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8253.1, Definition 8253.2, and Definition 8253.3 seed the finite Picard-orbit Cauchy handoff route without asserting a completed fixed point.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachContractionSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a completed fixed point, selected limit, quotient stream equality, host equality, host function extensionality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked contraction-map visibility, Picard-orbit visibility, residual-modulus extraction, RegSeqRat handoff exactness, CompleteMetric endpoint-admission nonescape, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 8254

A Concrete Naming Certificate for MetacicConfluenceResidualFrontier$^{\uparrow}$

The MetacicConfluenceResidualFrontier$^{\uparrow}$ packet realizes the MetaCIC confluence audit map of chapter 9378 as finite retained-premise, candidate-join, obstruction, and closed-fragment NameCert data. It sits after the typed-window and redex-frontier packets of chapter 6433 and chapter 1008, the local-join ledgers of chapter 4126, the residual checker and envelope of chapter 3827 and chapter 3921, and the closed-normal confluence seal of chapter 741. The packet keeps the substitution-compatibility boundary visible; it does not claim full Church–Rosser, arbitrary closed-term confluence, or discharge of residual substitution.

Definition 8254.1 (MetaCIC confluence residual frontier carrier)**.** *A* MetacicConfluenceResidualFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (T, R, J, O, D, S, A, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed MetaCIC source-window row naming the closed or open term shape under inspection.*
2. *R is the residual frontier row, recording the beta redex positions and residual-substitution sites that remain visible to the audit map.*
3. *J is the finite candidate-join row for the inspected local peak.*
4. *O is the obstruction-retention row naming the residual-substitution compatibility input when the candidate join cannot be closed.*
5. *D is the closed-fragment discharge row for normal, atom, or other shape-limited cases already available in the confluence substrate.*
6. *S is the substitution-boundary handoff row, kept as a premise boundary rather than erased into a global theorem.*
7. *A is the audit-map readback row tying T, R, J, O, D, S to the confluence audit map.*
8. *H records componentwise* hsame *transport for all displayed frontier rows and the local certificate row.*
9. *C records displayed* Cont *replay from typed window through residual frontier, candidate join, obstruction retention, closed-fragment discharge, substitution boundary, and audit readback.*

10. *P is the* Pkg *provenance row over* $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$*, MetaCIC reduction rows,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}}$ *row.*

The carrier exports a finite confluence-frontier packet. It contains no coordinate for full parallel diamond discharge, arbitrary closed-star confluence, global Church–Rosser, or residual-substitution compatibility as a theorem.

Theorem 8254.2 (MetaCIC confluence residual frontier NameCert obligations)**.** *For an accepted* $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ *carrier* $F = (T, R, J, O, D, S, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}}$ *surface consists exactly of typed-window visibility, residual-frontier visibility, candidate-join visibility, obstruction-retention visibility, closed-fragment discharge visibility, substitution-boundary handoff, audit-map readback, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 8254.1.*

Proof. Project the carrier. The confluence-facing rows are T, R, J, O, D, S, A, and the structural rows are H, C, P, N.

Read the typed source and residual frontier first. These rows identify the local peak and the residual-substitution sites that the audit map refuses to hide.

Read the candidate join and obstruction rows next. A closed fragment may discharge through D, while any remaining substitution compatibility demand stays named in O and S.

Finally read the audit-map and structural rows. They preserve the finite frontier under transport, replay, provenance, and local naming, but they do not add a theorem proving full confluence or residual substitution compatibility. □

Theorem 8254.3 (MetaCIC confluence residual frontier vision handoff)**.** *Every manuscript citation of* $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ *must read the confluence audit map through the displayed finite route*

$$T,\ R,\ J,\ O,\ D,\ S,\ A,\ H,\ C,\ P,\ N.$$

Closed normal and atom fragments may be consumed through D, and conditional parallel-diamond or closed-star confluence handoffs may be recorded through S. The route does not turn the residual-substitution boundary into a discharged theorem, and it does not assert full Church–Rosser or arbitrary closed-term confluence for BetaStarStep*.*

Proof. Start from the carrier inventory. The only rows that speak about confluence are the typed window, residual frontier, candidate join, obstruction, closed-fragment discharge, substitution-boundary handoff, and audit readback rows.

Apply the NameCert obligations. They require the obstruction and substitution-boundary rows to remain displayed whenever the candidate join is not a shape-limited closed fragment.

The closed-fragment row may be consumed for the normal and atom cases isolated by the audit map. It does not rewrite the retained substitution boundary into a global parallel diamond.

Thus the packet is a finite handoff from the vision audit map to concrete NameCert data. Any future full confluence theorem must supply separate residual-substitution discharge before this frontier can be read as a closed Church–Rosser proof. □

The future TasteGate surface for $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ must provide explicit Nontrivial MetacicCon and FieldFaithful $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ instances. Nontriviality must separate a packet with retained residual-substitution obstruction from a packet claiming discharge, and field faithfulness must preserve $T, R, J, O, D, S, A, H, C, P, N$ as distinct rows.

Falsifiable prediction: Every accepted $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ read keeps a typed source window, residual frontier, candidate join, obstruction-retention row, closed-fragment row, substitution-boundary handoff, audit readback, hsame transport, Cont replay, Pkg provenance, and NameCert row visible before any confluence consumer cites it.

Independence witness: metacic-confluence-audit-map, metacic-residual-checker, metacic-confluence-residual-envelope, closednormalconfluenceseal, metacic-local-join-ledger: none is bijective with $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ because the packet jointly stores retained premises, candidate joins, obstruction rows, closed-fragment discharge, substitution-boundary handoff, audit readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}$ packet is generated from a typed source window, residual frontier, candidate join, obstruction-retention row, closed-fragment discharge row, substitution-boundary handoff, audit-map readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8254.1, Definition 8254.2, Definition 8254.3, the falsifiable prediction, and the independence witness seed the finite residual-frontier packet for the MetaCIC confluence audit boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicConfluenceResidualFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full parallel diamond discharge, arbitrary closed-star confluence, global Church–Rosser, residual-substitution compatibility as a theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked typed-window visibility, residual-frontier visibility, candidate-join visibility, obstruction retention, closed-fragment discharge, substitution-boundary handoff, audit-map readback, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming.

Chapter 8255

A Concrete Naming Certificate for $\mathsf{TheoremOfAscoli}^{\uparrow}$

Following Arzela, Ascoli, Kelley, and Bishop–Bridges, the $\mathsf{TheoremOfAscoli}^{\uparrow}$ packet records the compact-open theorem surface as finite BEDC data. It sits after the compact-open topology route of chapter 4138, the Arzela–Ascoli family surface of chapter 412, the compact metric source of chapter 129, and the real-name readback of chapter 38. The packet names the theorem-facing handoff from compact metric data, compact-open topology, equicontinuity, bounded-family control, finite stream windows, regular rational readback, and a terminal real seal; it does not add a host function space or a subsequence selector.

Definition 8255.1 (TheoremOfAscoli carrier)**.** *A* $\mathsf{TheoremOfAscoli}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, O, E, B, A, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact metric observations consumed by the theorem surface.*
2. *O is the* $\mathsf{CompactOpenTopology}^{\uparrow}$ *row, naming the compact-open neighbourhood and finite subbasic-window route read by consumers.*
3. *E is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row, carrying the shared equicontinuity ledger for the displayed family.*
4. *B is the* $\mathsf{BoundedFunctionFamily}^{\uparrow}$ *row, carrying the pointwise and sup-norm bound ledger visible to the compact-open consumer.*
5. *A is the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *row, recording the finite extraction and compactness-facing dependency already present in the Arzela–Ascoli packet.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite observation schedule for compact-open convergence reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying regular rational comparison data for the displayed windows.*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal, recording only terminal real values already read through R.*
9. *H records componentwise* hsame *transport for all displayed theorem rows.*

10. *C records displayed* Cont *replay through*

$$K, O, E, B, A, W, R, S \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{TheoremOfAscoli}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompactOpenTopology}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{BoundedFunctionFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{TheoremOfAscoli}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, O, E, B, A, W, R, S, H, C, P, N$. It has no coordinate for host function-space compactness, a selected subsequence, quotient function equality, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8255.2 (TheoremOfAscoli NameCert obligations)**.** *For every accepted* $\mathsf{TheoremOfAscoli}^{\uparrow}$ *carrier $T = (K, O, E, B, A, W, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TheoremOfAscoli}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the compact metric source and compact-open topology rows K, O;*
2. *family-control admission for the equicontinuity, bounded-family, and Arzela–Ascoli rows E, B, A;*
3. *value-window admission for the stream-window, regular-rational, and real-seal rows W, R, S;*
4. *componentwise transport and replay through H, C;*
5. *provenance and terminal local naming through P, N.*

No accepted packet can export host function-space compactness, selected subsequences, quotient function equality, open-cover compactness, ambient real completeness, Lean verification, or bridge checking as part of this local surface.

Theorem 8255.3 (TheoremOfAscoli compact-open handoff)**.** *Every compact-open Ascoli consumer of an accepted* $\mathsf{TheoremOfAscoli}^{\uparrow}$ *carrier must first pass through*

$$\mathsf{CompactMetric}^{\uparrow}, \quad \mathsf{CompactOpenTopology}^{\uparrow}, \quad \mathsf{EquicontinuityFamily}^{\uparrow}, \quad \mathsf{BoundedFunctionFamily}^{\uparrow}, \quad \mathsf{ArzelaAscoli}^{\uparrow},$$

before exporting a compact-open convergence read. The exported read is therefore a finite route through $K, O, E, B, A, W, R, S, H, C, P, N$, not a function-space compactness theorem, subsequence choice, quotient function equality, open-cover compactness principle, or ambient completeness assertion.

Closure status for $\mathsf{NameCert}_{\mathsf{TheoremOfAscoli}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TheoremOfAscoli}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8255.1, Definition 8255.2, and Definition 8255.3 seed the finite compact-open Ascoli packet from compact metric, compact-open topology, family-control, value-window, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TheoremOfAscoli}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function-space compactness, selected subsequences, quotient function equality, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-open topology routing, family-control routing, value-window exactness, transport, replay, provenance, and local naming for BEDC.Derived.TheoremOfAscoliUp.

Constructive story: A $\mathsf{TheoremOfAscoli}^{\uparrow}$ packet is generated from CompactMetricUp, CompactOpenTopologyUp, EquicontinuityFamilyUp, BoundedFunctionFamilyUp, ArzelaAscoliUp, StreamNameUp, RegSeqRatUp, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8256

A Concrete Naming Certificate for $\mathsf{HyperbolicCannonThurstonBoundary}^{\uparrow}$

Following Cannon and Thurston, the $\mathsf{HyperbolicCannonThurstonBoundary}^{\uparrow}$ packet records a finite BEDC boundary-extension handoff for hyperbolic visual-boundary reads. It realizes the observer-expansion route of chapter 9463 after the boundary-shadow packet of chapter 3813, the visual-boundary route of chapter 4181, the hyperbolic metric packet of chapter 3474, the Poincare disk metric of chapter 6209, the Gromov boundary route of chapter 6470, and the terminal real-name seal of chapter 38. The packet names only displayed shadow, visual-boundary, metric, disk, Gromov-boundary, value-readback, transport, replay, provenance, and local naming rows; it does not assert a host group action, completed quotient boundary, selected geodesic ray, or ambient compactification theorem.

Definition 8256.1 (HyperbolicCannonThurstonBoundary carrier)**.** *A* $\mathsf{HyperbolicCannonThurstonBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, V, M, D, G, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, recording the visible boundary-shadow window inspected by the boundary-extension read.*
2. *V is the* $\mathsf{HyperbolicVisualBoundary}^{\uparrow}$ *row, exposing the visual-boundary face used by the extension handoff.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row, carrying finite metric comparisons attached to the same boundary and disk observations.*
4. *D is the* $\mathsf{PoincareDiskMetric}^{\uparrow}$ *row, recording the disk-metric readback for finite Poincare windows.*
5. *G is the* $\mathsf{GromovBoundary}^{\uparrow}$ *row, carrying the ray-boundary token through which the extension is read.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing finite observation schedules for boundary and disk reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, carrying regular rational comparison data for those windows.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal, recording terminal real values only after W and R are visible.*

9. *H records componentwise* hsame *transport for every displayed row of Q.*

10. *C records displayed* Cont *replay through*

$$S, V, M, D, G, W, R, E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* HyperbolicCannonThurstonBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, GromovBoundary$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* NameCert$_{\text{HyperbolicCannonThurstonBoundary}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, V, M, D, G, W, R, E, H, C, P, N$. It has no coordinate for a host Cannon–Thurston map, completed ideal-boundary quotient, selected ray representative, global hyperbolic group action, or ambient compactification theorem.

Theorem 8256.2 (HyperbolicCannonThurstonBoundary NameCert obligations)**.** *For every accepted* HyperbolicCannonThurstonBoundary$^{\uparrow}$ *carrier $Q = (S, V, M, D, G, W, R, E, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicCannonThurstonBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the boundary-shadow and visual-boundary rows, metric and Poincare disk readback, Gromov-boundary routing, finite stream and regular-rational readback, terminal real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Theorem 8256.3 (HyperbolicCannonThurstonBoundary shadow handoff)**.** *Every observer-expansion consumer of an accepted* HyperbolicCannonThurstonBoundary$^{\uparrow}$ *carrier must first read*

HyperbolicBoundaryShadow$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, GromovB

before it exports a boundary-extension read. The exported read is a finite route through $S, V, M, D, G, W, R, E, H, C,$ and exports no host group action, quotient ideal boundary, selected geodesic ray, completed visual compactification, or ambient real-completeness witness.

Closure status for NameCert$_{\text{HyperbolicCannonThurstonBoundary}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicCannonThurstonBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 8256.1, Definition 8256.2, and Definition 8256.3 seed the finite boundary-extension packet from boundary-shadow, visual-boundary, metric, disk, Gromov-boundary, stream, rational, real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicCannonThurstonBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host Cannon–Thurston map, global hyperbolic group action, completed quotient boundary, selected geodesic rays, ambient compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow routing, visual-boundary routing, metric and disk readback, Gromov-boundary routing, value-readback exactness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicCannonThurstonBoundaryUp.

Constructive story: A HyperbolicCannonThurstonBoundary$^{\uparrow}$ packet is generated from HyperbolicBoundaryShadowUp, HyperbolicVisualBoundaryUp, HyperbolicMetricUp, PoincareDiskMetricUp, GromovBoundaryUp, StreamNameUp, RegSeqRatUp, RealUp, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8257

A Concrete Naming Certificate for $\mathsf{EntourageFilter}^{\uparrow}$

Following Bourbaki and Kelley on uniform structures and filters, the $\mathsf{EntourageFilter}^{\uparrow}$ packet names the finite route by which displayed entourages generate a filter-base surface before any Cauchy-filter or completion-facing consumer can read it. It sits between the uniform-space carrier of chapter 339, the filter-base route of chapter 1601, the Cauchy-filter surface of chapter 333, the real-uniform route of chapter 1624, and the dyadic tolerance ledger of chapter 291. The packet is a finite entourage-to-filter interface; it is not a quotient filter, a selected limit, countable choice, host equality, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8257.1 (Entourage-filter carrier)**.** *An* $\mathsf{EntourageFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, B, G, F, D, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage-data row, exposing only the displayed diagonal, symmetry, refinement, and composition requests.*
2. *B is the* $\mathsf{FilterBase}^{\uparrow}$ *generation row, recording the finite basis entries generated from the displayed entourage requests.*
3. *G is the* $\mathsf{CauchyFilter}^{\uparrow}$ *handoff row, naming the Cauchy-facing consumer only after the generated filter-base row has been displayed.*
4. *F is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *completion-facing route row, used only as a reader of the displayed uniform entourage and filter-base data.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and radius row, recording precision requests when an L10 completion route compares entourage requests with dyadic bounds.*
6. *H records componentwise* hsame *transport for the uniform entourage, filter-base generation, Cauchy handoff, real-uniform route, dyadic tolerance, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an entourage request through U, B, G, F, D, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{EntourageFilter}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{FilterBase}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{EntourageFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, B, G, F, D, H, C, P, N$. It has no coordinate for quotient filters, selected limits, countable-choice schedules, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8257.2 (Entourage-filter NameCert obligations)**.** *For every accepted* $\mathsf{EntourageFilter}^{\uparrow}$ *carrier*

$$E = (U, B, G, F, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{EntourageFilter}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform entourage row U, filter-base generation through B, Cauchy-filter handoff through G, completion nonescape through the real-uniform route F and dyadic tolerance row D, and provenance locality through H, C, P, N.*

Proof. Project the carrier of Definition 8257.1. The accepted packet exposes exactly the uniform entourage, filter-base, Cauchy handoff, real-uniform route, dyadic tolerance, transport, replay, provenance, and local naming rows.

The entourage-to-filter generation is the passage from U to B. The row U supplies displayed uniform-space requests, and B records the finite basis entries generated from those requests before any Cauchy-facing row is public.

The Cauchy and completion-facing reads are downstream. The row G names the $\mathsf{CauchyFilter}^{\uparrow}$ handoff only after B has been displayed, while F and D record the real-uniform and dyadic tolerance route used by completion consumers.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded quotient, selected limit, countable-choice, host-equality, or ambient-completeness coordinate occurs in the carrier, the listed rows exhaust the local obligations. □

Theorem 8257.3 (Entourage-filter Cauchy handoff)**.** *Every completion-facing consumer of an accepted* $\mathsf{EntourageFilter}^{\uparrow}$ *carrier $E = (U, B, G, F, D, H, C, P, N)$ reads through*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{FilterBase}^{\uparrow} \longmapsto \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{RealUniformStructure}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{BHist}, \mathsf{hsame},$$

before any completion use is available. The route exports no quotient filter, selected limit, countable-choice schedule, host equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with Definition 8257.2. It places every accepted completion-facing read on the displayed uniform entourage row, generated filter-base row, Cauchy-filter handoff row, real-uniform route row, and dyadic tolerance row.

Read U and B first. This makes the entourage request and its generated filter-base entries visible before a consumer can ask for Cauchy readiness through G.

Next read G, F, D. The Cauchy handoff remains a finite consumer row, while the real-uniform and dyadic rows record only the tolerance and radius data needed by the L10 completion route.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Therefore any completion use is downstream of the displayed packet, and the excluded quotient, choice, host-equality, selected-limit, and ambient-completeness endpoints are unavailable. □

Falsifiable prediction: An accepted $\mathsf{EntourageFilter}^{\uparrow}$ completion read is refuted if it reaches a Cauchy-filter or real-uniform completion consumer without displaying the UniformSpace entourage

row, FilterBase generation row, CauchyFilter handoff row, DyadicRatCore tolerance row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Independence witness: uniformspace, filterbase, cauchyfilter, real-uniform-structure, dyadicratcore: no listed sibling supplies the whole $\mathsf{EntourageFilter}^{\uparrow}$ packet because the packet jointly binds displayed uniform entourages, finite filter-base generation, Cauchy handoff, completion-facing tolerance data, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{EntourageFilter}^{\uparrow}}$.

Constructive story: An $\mathsf{EntourageFilter}^{\uparrow}$ packet is generated from UniformSpace entourage data, FilterBase generation rows, a CauchyFilter handoff row, RealUniformStructure completion-facing route data, DyadicRatCore tolerance and radius rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EntourageFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8257.1, Definition 8257.2, and Definition 8257.3 seed the finite route by which displayed uniform entourages generate a filter-base surface for Cauchy-filter and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EntourageFilter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient filters, selected limits, countable choice, host equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage-to-filter generation, Cauchy handoff, completion nonescape, transport, replay, provenance, and local naming for BEDC.Derived.EntourageFilterUp.

Chapter 8258

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$ packet records the finite route by which located real comparison data is read before a Bishop completion-pair consumer reaches the terminal Real seal. It sits over the located real comparison source of chapter 1933, the Bishop completion-pair route of chapter 6298, the dyadic tolerance core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite located completion-pair NameCert surface; it is not a quotient completion, selected representative, host limit, countable-choice schedule, located-trichotomy oracle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8258.1 (Bishop located completion-pair carrier)**.** *A* $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (L, M, D, W, R, T, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row, exposing finite located-real windows and comparison evidence before any completion-facing read proceeds.*
2. *M is the metric-source row for the pre-completion space.*
3. *D is the dense-route row tying source points to the Bishop completion-pair route.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by completion and Real consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row over the windows in W.*
6. *T is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling located comparison, regular readback, and seal requests.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal handoff, available only after L, M, D, W, R, T have been displayed.*
8. *H records componentwise* hsame *transport for the located, metric-source, dense-route, window, readback, tolerance, Real seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from each located completion-pair request through $L, M, D, W, R, T, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionPair}^{\uparrow}}$ *row.*

The carrier stores no quotient class, selected representative, host real equality, countable-choice schedule, hidden completed point, located-trichotomy row, or ambient completeness witness.

Theorem 8258.2 (Bishop located completion-pair NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$ *carrier* $K = (L, M, D, W, R, T, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletio}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the located-real row L, metric-source row M, dense-route row D,* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger T, and* $\mathsf{Real}^{\uparrow}$ *seal handoff E;*
2. *located-source routing, requiring every completion-facing read to display L before the dense completion-pair route is consumed;*
3. *dense-completion routing, requiring M and D to be read before any window, readback, tolerance, or seal row is public;*
4. *regular-Cauchy exactness, requiring W, R, T to be read as one finite window-and-tolerance packet before E is exported;*
5. *Real-seal non-escape, requiring every Real-facing read to pass through L, M, D, W, R, T before it reaches E;*
6. *transport and replay through H and C, preserving the same rows componentwise;*
7. *ledger refusal through P and N, excluding quotient completion, selected representatives, host real equality, countable choice, located trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8258.1. Its analytic rows are exactly L, M, D, W, R, T, E, and its structural rows are exactly H, C, P, N.

The located-source route begins at L. A completion-facing consumer may use located comparison data only after the finite located-real row is displayed, so the consumer does not obtain a host trichotomy or quotient-real comparison.

The completion-pair route then reads M and D, followed by the finite windows W, regular readback R, and dyadic tolerance ledger T. The Real seal row E is downstream of that ordered route.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for the refused host objects, the seven listed rows exhaust the local NameCert surface. □

Theorem 8258.3 (Bishop located completion-pair finite means)**.** *Every completion-facing consumer of an accepted* $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$ *carrier reaches the* $\mathsf{Real}^{\uparrow}$ *seal only after the located row, dense row, finite windows, regular readback, and dyadic tolerance ledger are displayed:*

$$L \longmapsto M \longmapsto D \longmapsto W \longmapsto R \longmapsto T \longmapsto E.$$

Thus the completion-pair read is finite means data over $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{BishopCauchyCompletionPair}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$*, and* $\mathsf{Real}^{\uparrow}$*, not a quotient class, selected representative, countable-choice schedule, host comparison oracle, or ambient completeness proof.*

Proof. Use the NameCert obligations of Definition 8258.2. Located-source routing exposes L before any completion row is consumed, and dense-completion routing then exposes M and D before the naming rows are interpreted.

Regular-Cauchy exactness ties the windows, readback, and tolerance ledger into the single finite packet W, R, T. The seal row E is admitted only after that packet is displayed, so a consumer has no route to E that bypasses located evidence, dense routing, finite windows, regular readback, or dyadic tolerances.

The transport, replay, provenance, and local naming rows preserve this order componentwise. Hence every completion-facing read reaches the Real seal by finite means alone. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionPair}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$ packet is generated from located-real comparison data, source metric data, a dense completion-pair route, StreamName finite windows, RegSeqRat regular-Cauchy readback, DyadicRatCore tolerance ledgers, a Real seal handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionPair}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8258.1, Definition 8258.2, and Definition 8258.3 seed the finite located Bishop completion-pair route from located comparison data through dense completion, finite windows, regular readback, dyadic tolerance, and Real seal handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedCompletionPair}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected representatives, countable choice, host real equality, located trichotomy, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{BishopLocatedCompletionPair}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, located-source routing, dense-completion routing, regular-Cauchy exactness, Real-seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedComplet

Chapter 8259

A Concrete Naming Certificate for $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ packet records the finite witness grid by which a regular Cauchy construction answers a displayed family of precision requests without appealing to quotient sequence equality, countable choice, selected limits, or ambient completeness. It sits on the Real and Completion route after the finite observation interface of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback surface of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the finite threshold-selection surface of chapter 7210. The packet names a displayed matrix of witness rows; it does not name a completed real, a quotient class, or an unbounded selector.

Definition 8259.1 (Finite Cauchy witness matrix carrier)**.** *A* $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (A, T, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the finite precision-request axis, listing the requests whose Cauchy witnesses are being recorded.*
2. *T is the finite threshold axis, giving the admitted threshold row for each request in A.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window matrix, recording the finite stream windows inspected at those thresholds.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance matrix, recording dyadic radii, denominator budgets, slack comparisons, and rowwise inequalities.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback matrix, obtained from the same windows and dyadic rows.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after A, T, S, D, R have been displayed.*
7. *H records componentwise* hsame *transport for requests, thresholds, windows, dyadic tolerances, readbacks, seal, provenance, and local naming.*
8. *C records displayed* Cont *replay from each precision request through its threshold, window, tolerance, readback, and seal rows.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$, $\mathsf{BishopCompletionModulusSelection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}}$ *row.*
The classifier compares accepted matrices only through these rows. It has no coordinate for quotient stream equality, a selected completed limit, countable choice over precision requests, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8259.2 (Finite Cauchy witness matrix NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ *carrier* $W = (A, T, S, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite precision requests, finite thresholds,* $\mathsf{StreamName}^{\uparrow}$ *window matrix,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance matrix,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback matrix, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer that reads a Cauchy witness row must display the same* $A, T, S, D, R, E, H, C, P, N$ *packet before exporting its conclusion.*

Proof. Project the carrier of Definition 8259.1. The analytic rows are the request axis, threshold axis, stream-window matrix, dyadic tolerance matrix, readback matrix, and Real seal.

The threshold row is finite and displayed. The Bishop completion modulus selection route of chapter 7210 supplies the sibling discipline for reading a threshold before a window or tolerance row is consumed.

The window, tolerance, and readback rows are then forced to remain aligned. The sibling routes chapter 126, chapter 291, and chapter 301 provide the finite observation, dyadic, and regular-rational surfaces used by S, D, R.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite matrix. Since the carrier contains no quotient, selected limit, choice schedule, host equality, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8259.3 (Finite Cauchy witness matrix Real handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ *packet reaches the* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$A, T \longmapsto S, D \longmapsto R \longmapsto E \longmapsto H, C, P, N.$$

Thus the handoff exposes finite precision requests, finite thresholds, $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming before any Real-facing conclusion is exported.*

Proof. Start from the NameCert obligations. They require every witness read to display $A, T, S, D, R, E, H, C, P, N$ as one finite packet.

Read the threshold axis before the analytic rows. The selection sibling chapter 7210 keeps T as a displayed finite threshold row rather than a hidden choice function.

Next read S, D, R through the StreamName, DyadicRatCore, and RegSeqRat siblings. The same finite windows and tolerance entries feed the readback matrix, so the consumer cannot replace the matrix by quotient stream equality or by a selected limit.

The terminal handoff is the seal row E of chapter 38, transported and replayed by H and C and sourced by P, N. Hence a Real or Completion consumer receives only the displayed finite witness matrix and not countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without displaying the finite request axis, threshold axis, StreamName windows, DyadicRatCore tolerances, and RegSeqRat readbacks refutes the carrier surface.

Independence witness: streamname, dyadicratcore, regseqrat, real, bishop-completion-modulus-selection: no listed sibling is bijective to $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ because this packet jointly

carries finite precision requests, finite thresholds, windows, tolerances, readbacks, a Real seal, transport, replay, provenance, and local NameCert rows as one witness matrix.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}$ packet is generated from finite precision requests, finite threshold rows, StreamName windows, DyadicRatCore tolerance rows, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8259.1, Definition 8259.2, Definition 8259.3, the falsifiable prediction, and the independence witness seed the finite witness-grid route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyWitnessMatrix}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient stream equality, selected completed limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, threshold-row exposure, StreamName window readback, DyadicRatCore tolerance routing, RegSeqRat handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCauchyWitnessMatrixUp.

Chapter 8260

Finite Uniform Discrepancy NameCert Construction

Following Weyl and Kuipers–Niederreiter, the $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ packet records finite uniform-discrepancy ledgers over dyadic real windows as BEDC inspection data. It reads low-discrepancy sequence windows from chapter 5173, dyadic rational budgets from chapter 291, finite cell coverage from chapter 1767, terminal real-name sealing from chapter 38, and finite observation schedules from chapter 126. The packet names a finite discrepancy ledger for displayed windows; it is not an asymptotic equidistribution theorem, a selected limiting density, a host measure equality, or an ambient completeness principle.

Definition 8260.1 (Finite uniform discrepancy carrier)**.** *A* $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (L, W, Q, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. L *is the* $\mathsf{LowDiscrepancySequence}^{\uparrow}$ *source row supplying the finite sampled sequence segment;*
2. W *is a finite ledger of dyadic test windows, each with displayed endpoints and a requested scale;*
3. Q *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and arithmetic ledger used to compare observed counts with dyadic volume rows;*
4. E *is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *cell ledger whose boxes refine the displayed windows at the active scale;*
5. R *is the* $\mathsf{Real}^{\uparrow}$ *readback and seal row for the dyadic volumes and discrepancy bounds named by* W, Q, E*;*
6. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule used to inspect the sampled points and endpoint names;*
7. H *records componentwise* hsame *transport for sequence windows, dyadic tolerances, net cells, count ledgers, Real seal rows, and stream schedules;*
8. C *records displayed* Cont *replay from the sampled sequence through window counting, dyadic comparison, finite-net coverage, StreamName inspection, and Real sealing;*
9. P *is the* Pkg *provenance over* $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$, $\mathsf{LowDiscrepancySequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteUniformDiscrepancy}^{\uparrow}}$ *row.*

The carrier exports only finite sampled windows, dyadic count comparisons, finite-net cells, Real seal readback, transport, replay, provenance, and local naming. It contains no row for an infinite limiting distribution, selected subsequence, host measure space, or asymptotic discrepancy principle.

Theorem 8260.2 (Finite uniform discrepancy NameCert obligations)**.** *For every accepted* FiniteUniformDiscrepancy *carrier $D = (L, W, Q, E, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteUniformDiscrepancy}^{\uparrow}}$ *obligations are exactly carrier admission, finite-window exposure, dyadic count comparison, finite-net coverage, StreamName observation, Real seal descent, componentwise transport, displayed replay, provenance, and local naming.*

Every discrepancy read factors through $L, W, Q, E, R, S, H, C, P, N$. The packet exports no asymptotic equidistribution theorem, selected limiting density, quotient stream equality, host measure equality, countable-choice sampling schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the accepted carrier. The sampled sequence segment is visible only through L, and the tested boxes are the displayed dyadic windows in W.

The discrepancy comparison is finite. Counts are compared with dyadic volumes through Q, and the window coverage is refined through the finite cell ledger E before any Real-facing read reaches R.

The observation and structural rows S, H, C, P, N keep this route attached to the same finite packet. Since no carrier coordinate names an infinite limiting distribution, host measure equality, selected subsequence, or ambient completeness principle, the local certificate surface is exhausted by the listed rows. □

Theorem 8260.3 (Finite uniform discrepancy L10 route)**.** *Every L10 consumer of an accepted* $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{LowDiscrepancySequence}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Nar}$$

before consuming a discrepancy bound. The route first exposes the sampled low-discrepancy segment, then the dyadic window and tolerance ledger, then the finite epsilon-net cells, then the stream inspection schedule, and only then the terminal Real seal for the displayed discrepancy bound.

Thus the packet is a finite quantitative-analysis object over dyadic real windows, not a statement about asymptotic uniform distribution or a completed measure-theoretic limit.

Proof. Start with the sampled sequence row supplied by $\mathsf{LowDiscrepancySequence}^{\uparrow}$. A consumer receives only the finite segment named in the carrier, so every later count is tied to displayed sampled points.

Next consume the dyadic and finite-net rows. $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the arithmetic budgets for window volume and count comparison, while $\mathsf{FiniteEpsilonNet}^{\uparrow}$ supplies the finite cells used to refine the inspected boxes.

Finally read the finite observation schedule and Real seal. $\mathsf{StreamName}^{\uparrow}$ displays the inspected windows, and $\mathsf{Real}^{\uparrow}$ seals only the discrepancy bounds already produced from L, W, Q, E. The structural rows $\mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}$ preserve this route and exclude any bypass through asymptotic sequence principles or ambient measure completeness. □

Falsifiable prediction: Every accepted $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ read exposes the sampled low-discrepancy segment, dyadic tolerance ledger, finite epsilon-net cells, StreamName windows, Real seal, componentwise hsame, Cont replay, Pkg provenance, and local NameCert rows before a discrepancy bound is consumed.

Independence witness: low-discrepancy-sequence, dyadicratcore, finite-epsilon-net, real, streamname: no listed sibling is bijective with $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ because this packet alone binds a finite sampled segment, dyadic window ledger, finite coverage cells, count comparison, Real seal, transport, replay, provenance, and local naming into one discrepancy surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteUniformDiscrepancy}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteUniformDiscrepancy}^{\uparrow}$ packet is generated from a LowDiscrepancySequenceUp finite segment, dyadic window and tolerance rows, finite epsilon-net cells, StreamName observation windows, a RealUp discrepancy-bound seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteUniformDiscrepancy}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8260.1, Definition 8260.2, and Definition 8260.3 bind the seed finite-discrepancy carrier and its L10 route through low-discrepancy, dyadic, finite-net, stream, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteUniformDiscrepancy}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.FiniteUniformDiscrepancyUp`

Bridge status: none

Not claimed: This chapter does not claim asymptotic equidistribution, host measure equality, selected limiting density, quotient stream equality, countable choice, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, dyadic count comparison, finite-net coverage, StreamName observation, Real seal descent, transport, replay, provenance, and local naming for BEDC.Derived.FiniteUniformDiscrepancyUp.

Chapter 8261

A Concrete Naming Certificate for $\mathsf{SobczykTheorem}^{\uparrow}$

Following Sobczyk and the constructive Banach-space reading of separable extension theory, the $\mathsf{SobczykTheorem}^{\uparrow}$ packet records only the finite projection data visible when a displayed separable Banach row is read through a named c_0 subspace boundary. It sits over the Banach carrier of chapter 90, the norm and linear-map rows of chapter 89 and chapter 48, the finite observation discipline of chapter 126, and the Hahn–Banach boundary of chapter 3922. The packet names a finite-modulus projection corridor; it does not assert full Hahn–Banach, unrestricted choice of extensions, arbitrary complementability, or a host-level projection operator on every Banach space.

Definition 8261.1 (Sobczyk theorem carrier)**.** *A* $\mathsf{SobczykTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, C, E, M, P_0, B, H, R, Q, N)$$

with the following displayed rows:

1. *X is the separable* $\mathsf{Banach}^{\uparrow}$ *source row whose dense finite inspection schedule is read through* $\mathsf{StreamName}^{\uparrow}$*.*
2. *C is the named c_0 subspace row, equipped with its inherited* $\mathsf{Norm}^{\uparrow}$ *and inclusion as a displayed* $\mathsf{LinMap}^{\uparrow}$ *row.*
3. *E is the finite extension-window row recording the bounded coordinate functionals inspected at the current schedule depth.*
4. *M is the projection-modulus row, giving a rational bound for the finite coordinate projection read from E.*
5. *P_0 is the displayed partial projection row from the inspected window of X back to the c_0 row.*
6. *B is the boundedness ledger comparing the norm of P_0 against M inside the same finite window.*
7. *H records componentwise* hsame *transport for the source, subspace, window, modulus, projection, and bound rows.*
8. *R records displayed* Cont *replay from separable Banach source through the finite extension window to the projection row.*
9. *Q is the* Pkg *provenance row over* $\mathsf{SobczykTheorem}^{\uparrow}$*,* $\mathsf{Banach}^{\uparrow}$*,* $\mathsf{Norm}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SobczykTheorem}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global Hahn–Banach oracle, a choice-selected extension family, a quotient Banach-space equality, an unbounded projection, or a complementability assertion outside the displayed separable c_0 corridor.

Theorem 8261.2 (Sobczyk theorem NameCert obligations)**.** *For an accepted* $\mathsf{SobczykTheorem}^{\uparrow}$ *carrier $S = (X, C, E, M, P_0, B, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{SobczykTheorem}^{\uparrow}}$ *surface consists exactly of separable Banach-source visibility, c_0 subspace visibility, finite extension-window visibility, projection-modulus visibility, displayed partial-projection visibility, boundedness ledgering, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 8261.1.*

In particular, every public Sobczyk read is a constructive finite-modulus projection read: it presents a bounded projection witness over the inspected window and its replay ledger before any consumer may cite complementability. It refuses full Hahn–Banach, unrestricted extension choice, ambient quotient equality, or an unbounded host projection as part of the certificate.

Proof. Project the carrier. The analytic rows are X, C, E, M, P_0, B, and the support rows are H, R, Q, N.

Read X and C first. The source row supplies the separable Banach inspection schedule, while the c_0 row supplies the named subspace together with its norm and inclusion rows.

Read E, M, P_0, B next. The extension-window row lists the finitely inspected coordinate data, the modulus row bounds the projection read on that window, the partial projection row displays the map back to c_0, and the boundedness ledger checks the same modulus against the displayed norm rows.

Finally use transport, replay, provenance, and local naming. These rows preserve the finite projection corridor under NameCert reading, but they do not add a global Hahn–Banach principle, a choice-selected extension family, quotient equality, or an unrestricted complementability theorem. □

Falsifiable prediction: Any accepted $\mathsf{SobczykTheorem}^{\uparrow}$ read that cites complementability without exposing a separable Banach source row, a named c_0 subspace row, a finite extension window, a projection modulus, a displayed partial projection, boundedness, transport, replay, provenance, and local naming refutes the packet.

Independence witness: banach, norm, linearmap, streamname, hahn-banach: none is bijective with $\mathsf{SobczykTheorem}^{\uparrow}$ because the packet jointly stores the separable source, c_0 subspace boundary, finite extension window, bounded projection modulus, partial projection row, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{SobczykTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SobczykTheorem}^{\uparrow}$ packet is generated from a separable Banach source row, a named c0 subspace row, finite extension-window data, a projection modulus, a partial projection row, boundedness ledgering, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobczykTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8261.1 and Definition 8261.2 seed the finite-modulus Sobczyk projection corridor without asserting full Hahn–Banach or unrestricted choice.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobczykTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Hahn–Banach, unrestricted extension choice, arbitrary complementability, quotient Banach-space equality, a selected global projection, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked separable-source visibility, c0 subspace visibility, extension-window visibility, projection-modulus exactness, boundedness, transport, replay, provenance, and local naming.

Chapter 8262

A Concrete Naming Certificate for $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$

The $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$ packet realizes the parallel-diamond and substitution-compatibility fork of chapter 9378 as finite source, branch, candidate-join, residual-boundary, and NameCert rows. It sits beside the typed parallel-diamond boundary of chapter 6433, the confluence residual checker of chapter 3827, the residual envelope of chapter 3921, the local-join ledger of chapter 4126, and the residual frontier of chapter 8254. The packet names the finite fork certificate only; it does not discharge full parallel diamond, residual substitution compatibility, arbitrary closed-star confluence, or Church–Rosser for every closed source.

Definition 8262.1 (MetaCIC confluence fork certificate carrier)**.** *A* $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (S, L, R, J, B, D, A, H, C, P, N)$$

with the following displayed rows:

1. *S is the typed MetaCIC source row whose local peak is inspected by the audit map.*
2. *L and R are the left and right branch rows of the fork, recording the two visible* BetaParallel *or* BetaStarStep *directions under inspection.*
3. *J is the candidate-join row proposed for the two branches.*
4. *B is the residual-boundary row naming the substitution-compatibility premise still required when the candidate join is not closed by a shape-limited fragment.*
5. *D is the closed-fragment discharge row for normal, atom, and other already checked shapes.*
6. *A is the audit-map readback row tying S, L, R, J, B, D to the confluence fork named in chapter 9378.*
7. *H records componentwise* hsame *transport for source, branch, candidate-join, residual-boundary, discharge, audit, and local certificate rows.*
8. *C records displayed* Cont *replay from source through the two branches, candidate join, residual boundary, closed-fragment discharge, and audit readback.*
9. *P is the* Pkg *provenance row over* $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$*, the MetaCIC confluence audit map,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}}$ *row.*
The carrier has no coordinate for erasing the substitution boundary, promoting a conditional bridge to an unconditional theorem, or turning closed-fragment discharge into global Church–Rosser.

Theorem 8262.2 (MetaCIC confluence fork certificate NameCert obligations)**.** *For an accepted* $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$ *carrier* $F = (S, L, R, J, B, D, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetacicConfluenceFork}}$ *surface consists exactly of typed-source visibility, left-branch visibility, right-branch visibility, candidate-join visibility, residual-boundary visibility, closed-fragment discharge visibility, audit-map readback, componentwise transport, displayed replay, package provenance, and local naming for the finite packet of Definition 8262.1.*

The certificate instructs future $\mathsf{Nontrivial\ MetacicConfluenceForkCertificate}^{\uparrow}$ *instances to separate a fork retaining B from a fork claiming full discharge. It instructs future* $\mathsf{FieldFaithful\ MetacicConfluenceForkCertifica}$ *instances to preserve $S, L, R, J, B, D, A, H, C, P, N$ as distinct rows, especially separating the candidate join J from the residual-boundary row B and the closed-fragment row D.*

Proof. Project the carrier. The confluence-facing rows are S, L, R, J, B, D, A, and the support rows are H, C, P, N.

Read the source and branch rows first. They display the local peak under inspection and keep the two fork branches visible before any join is cited.

Read the candidate join, residual boundary, and closed-fragment discharge next. The candidate row proposes the join, the residual-boundary row retains the substitution-compatibility premise when needed, and the discharge row records only shape-limited closed cases already available to the audit map.

Finally use the audit readback, transport, replay, provenance, and naming rows. They keep the fork certificate finite and source-traceable, but they do not erase B, promote a conditional bridge to an unconditional theorem, or convert D into arbitrary closed-source confluence. □

Falsifiable prediction: Any accepted MetaCIC confluence fork read that cites a candidate join without exposing the typed source, both branches, residual-boundary row, closed-fragment row, audit readback, transport, replay, provenance, and local naming refutes $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$.

Independence witness: metacic-confluence-audit-map, metacic-typed-parallel-diamond-boundary, metacic-confluence-residual-checker, metacic-confluence-residual-envelope, metacic-local-join-ledger: none is bijective with $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$ because the packet jointly stores source, two branches, candidate join, residual boundary, closed-fragment discharge, audit readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}$ packet is generated from a typed MetaCIC source row, two branch rows, a candidate-join row, a residual-substitution boundary row, a closed-fragment discharge row, audit-map readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8262.1, Definition 8262.2, the falsifiable prediction, and the independence witness seed the finite confluence-fork certificate for the MetaCIC audit-map boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicConfluenceForkCertificate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full parallel diamond discharge, residual-substitution compatibility as a theorem, arbitrary closed-star confluence, global Church–Rosser, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked source visibility, branch visibility, candidate-join visibility, residual-boundary retention, closed-fragment discharge, audit readback, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming.

Chapter 8263

A Concrete Naming Certificate for $\mathsf{CompactModulusLedger}^{\uparrow}$

Following Bishop and Bridges on constructive compactness and uniform continuity, the $\mathsf{CompactModulusLedger}^{\uparrow}$ packet records the finite ledger by which compact finite-net data, pointwise continuity rows, and rational lower-bound folds hand one public modulus boundary to $\mathsf{UniformModulus}^{\uparrow}$. It sits over the compact metric source of chapter 129, the continuous-map row of chapter 130, the finite lower-bound fold of chapter 4096, the finite stream naming surface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the compact-uniform-continuity ledger as displayed BEDC data; it does not import open-cover compactness, semantic continuity, countable choice, a selected infinite cover, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8263.1 (CompactModulusLedger carrier)**.** *A* $\mathsf{CompactModulusLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, F, C, W, R, E, B, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row naming the compact source by finite centers, radii, and coverage checks.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-continuity row for the displayed map on the compact source.*
3. *C is the compact-net comparison row that attaches every inspected source point to a displayed finite-net center.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule through which the finite centers, source points, and target values are read.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row for the pointwise target values and the candidate tolerance bounds.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row used only after the regular rational readbacks have been displayed.*
7. *B is the* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *row folding the finitely many local positive radii into one public lower-bound ledger.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row that receives the folded lower bound together with the finite-net and continuity rows.*

9. *H records componentwise* hsame *transport for compact-net rows, pointwise continuity rows, stream windows, rational readbacks, real seals, finite folds, uniform-modulus handoffs, replay, provenance, and local naming.*
10. *T records displayed* Cont *replay for the same compact-modulus ledger.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactModulusLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, FiniteLowerBoundFold UniformModulus$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactModulusLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their inherited transports. It has no coordinate for open-cover compactness, semantic continuity, selected infinite subcovers, choice, quotient equality of functions, or ambient real completeness.

Theorem 8263.2 (CompactModulusLedger NameCert obligations)**.** *For every accepted* $\mathsf{CompactModulusLedger}^{\uparrow}$ *carrier*

$$L = (K, F, C, W, R, E, B, U, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactModulusLedger}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure, pointwise continuous-map exposure, finite center comparison, stream-window access, regular rational readback, real-seal boundary, finite lower-bound folding,* UniformModulus$^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read the public compact-uniform-modulus boundary only after K, F, C, W, R, E, B, U have all been displayed.*

Proof. Project the carrier $L = (K, F, C, W, R, E, B, U, H, T, P, N)$. The analytic rows are exactly the compact finite-net row, the pointwise continuous-map row, the center comparison row, the stream window, the rational readback, the real seal, the finite fold, and the uniform-modulus consumer row.

The finite fold B can be read only after the finite family of local radii has been exposed through K, F, C, W, R, E. It supplies one public lower-bound ledger, not an open-cover argument or a choice-selected subcover.

The structural rows H, T, P, N transport, replay, source, and locally name the same finite packet. Since the carrier has no coordinate for semantic continuity, selected infinite covers, function quotient equality, countable choice, or ambient real completeness, no local NameCert obligation can export those endpoints. □

Theorem 8263.3 (CompactModulusLedger uniform handoff)**.** *Every public* UniformModulus$^{\uparrow}$ *read of an accepted* $\mathsf{CompactModulusLedger}^{\uparrow}$ *carrier factors through the compact finite-net row K, the pointwise* $\mathsf{ContinuousMap}^{\uparrow}$ *row F, the center comparison row C, the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the terminal* $\mathsf{Real}^{\uparrow}$ *seal E, and the* $\mathsf{FiniteLowerBoundFold}^{\uparrow}$ *row B. The handoff exports the finite compact-uniform-continuity ledger U and no open-cover compactness, countable-choice schedule, host semantic-continuity theorem, selected infinite subcover, or ambient completeness principle.*

Proof. Start with the compact row K and the pointwise row F. They expose only finite centers, displayed source requests, and pointwise target estimates, so the route begins with compact finite-net data rather than an open cover.

Next use C, W, R, E to compare an inspected source point with a finite center and to read the target estimates through regular rational data before the terminal real seal is consumed. These rows are the only scalar-facing access to the continuity estimates.

Finally apply the finite lower-bound fold B and repack the result as the uniform-modulus row U. The transport, replay, provenance, and local-name rows preserve the same displayed ledger, so the handoff reaches $\mathsf{UniformModulus}^{\uparrow}$ without adding choice, semantic continuity, selected infinite covers, quotient function equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactModulusLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactModulusLedger}^{\uparrow}$ packet is generated from compact finite-net data, pointwise continuous-map rows, center comparisons, finite stream windows, regular rational readbacks, real seals, a finite lower-bound fold, a uniform-modulus consumer row, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactModulusLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8263.1, Definition 8263.2, and Definition 8263.3 seed the finite compact-uniform-continuity ledger for downstream $\mathsf{UniformModulus}^{\uparrow}$ consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactModulusLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, semantic continuity, selected infinite subcovers, countable choice, quotient equality of functions, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, pointwise-continuity exposure, finite-fold exactness, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactModulusL

Chapter 8264

A Concrete Naming Certificate for $\mathsf{JordanVariation}^{\uparrow}$

Following Bishop and Bridges on functions of bounded variation and the classical Jordan treatment of positive and negative variation, the $\mathsf{JordanVariation}^{\uparrow}$ packet records signed variation as finite NameCert data over displayed partition ledgers. It sits after the bounded-variation surface of chapter 398, the cumulative total-variation route of chapter 2257, the variation-measure ledger of chapter 3593, the uniform partition row of chapter 2033, and the terminal real-name seal of chapter 38. The chapter names only finite positive and negative variation rows attached to displayed partitions; it does not import a signed measure, a quotient of functions, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8264.1 (Jordan variation carrier)**.** *A* $\mathsf{JordanVariation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (F, V^+, V^-, T, L, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the bounded-variation source row, read through* $\mathsf{BoundedVariation}^{\uparrow}$ *and the displayed real-valued endpoint names.*
2. *V^+ is the positive-variation row, listing finite positive edge contributions on the displayed partition ledger.*
3. *V^- is the negative-variation row, listing finite negative edge contributions on the same partition ledger.*
4. *T is the total-variation readback row, recording the equality of the displayed total ledger with the finite sum of V^+ and V^- rows.*
5. *L is the partition ledger, recording the uniform-partition source, refinement tags, endpoint order, and finite edge names used by all three variation rows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for endpoint values, edge readback, and total-variation comparison.*
7. *H records componentwise* hsame *transport for the source, positive row, negative row, total-variation row, partition ledger, real seal, provenance, and local naming.*
8. *C records displayed* Cont *replay from carrier admission through positive variation, negative variation, total readback, partition transport, real-seal readback, provenance, and local naming.*

9. *P is the* Pkg *provenance over* BoundedVariation$^{\uparrow}$, TotalVariationFunction$^{\uparrow}$, VariationMeasure$^{\uparrow}$, UniformPartition$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{JordanVariation}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host signed measure, a quotient equality class of functions, selected representatives of real values, an unlisted partition family, or an ambient completeness principle.

Theorem 8264.2 (Jordan variation NameCert obligations)**.** *For the carrier of Definition 8264.1, the local* NameCert$_{\text{JordanVariation}^{\uparrow}}$ *surface consists exactly of carrier admission for J, bounded-variation source admission through F, positive and negative variation admission through V^+ and V^-, total-variation readback through T, partition-ledger exposure through L, real-seal readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Every accepted consumer reads signed variation from this finite surface before it may pass the packet to regulated, Riemann–Stieltjes, or variation-measure routes.

Proof. Carrier admission is projection from the finite packet $J = (F, V^+, V^-, T, L, R, H, C, P, N)$. The bounded-variation source row F and the partition ledger L are present before either signed row is inspected.

The split exactness is then read from V^+, V^-, and T. The positive and negative rows record finite edge contributions on the same displayed ledger, while T records their total-variation readback through the TotalVariationFunction$^{\uparrow}$ and Real$^{\uparrow}$ routes.

The partition ledger cannot escape the packet. Refinements, endpoint order, edge names, and uniform-partition source are recorded in L and transported only through H and C; no consumer receives an unlisted partition family or a host supremum.

Finally read P and N. Provenance ties the carrier to the bounded-variation, total-variation, variation-measure, uniform-partition, and real-name siblings, and the local NameCert row names exactly that finite surface. Since no coordinate stores a signed measure, quotient equality, selected representative, or ambient completeness principle, each such read is refused at the carrier boundary. □

Falsifiable prediction: If a JordanVariationUp packet exports a positive or negative variation row without the common partition ledger L and real seal R, the carrier is refuted.

Independence witness: boundedvariation, total-variation-function, variation-measure, uniform-partition, and real: none is bijective to JordanVariation$^{\uparrow}$ because this packet stores the signed positive row, signed negative row, total-variation readback, partition ledger, Real seal, transport, replay, provenance, and local NameCert rows together as one finite surface.

Closure status for NameCert$_{\text{JordanVariation}^{\uparrow}}$.

Constructive story: A JordanVariation$^{\uparrow}$ packet is generated by displaying a bounded-variation source, positive variation row, negative variation row, total-variation readback, partition ledger, Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert row in one finite BHist carrier.

Theory closure: TheoryGate(NameCert$_{\text{JordanVariation}^{\uparrow}}$, seed)

Scope closed: Definition 8264.1 and Definition 8264.2 seed the finite signed-variation surface over BoundedVariation$^{\uparrow}$, TotalVariationFunction$^{\uparrow}$, VariationMeasure$^{\uparrow}$, UniformPartition$^{\uparrow}$, and Real$^{\uparrow}$.

Formal verification: FormalStatus(NameCert$_{\text{JordanVariation}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close host signed measures, quotient equality of functions, selected representatives, unlisted partition families, countable choice, bridge checking, Lean verification, or ambient completeness of Real$^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, split exactness, total-variation readback, partition-ledger nonescape, transport, replay, provenance, and refusal rows for the displayed packet.

Chapter 8265

A Concrete Naming Certificate for $\mathsf{AscoliRealCompletion}^{\uparrow}$

Following Arzela, Ascoli, Bishop, and Bridges, the $\mathsf{AscoliRealCompletion}^{\uparrow}$ packet records the finite compact-continuity data that an Arzela–Ascoli style family hands to the L10 Real-and-Completion route. It sits after the finite family and compact-source surface of chapter 412, the compact-uniform-continuity packet of chapter 388, the regular rational readback of chapter 301, the finite stream-window source of chapter 126, and the terminal real-name seal of chapter 38. The packet names only displayed finite-net, equicontinuity, stream, regular-rational, Real, transport, replay, provenance, and local naming rows; it does not assert open-cover compactness, selected subsequences, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8265.1 (Ascoli real-completion carrier)**.** *An* $\mathsf{AscoliRealCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (F, K, U, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *family row, exposing the finite family, source compactness, and pointwise readback data consumed by the Ascoli route.*
2. *K is the* $\mathsf{CompactUniformContinuity}^{\uparrow}$ *row, recording the finite-net and modulus handoff for the same compact source.*
3. *U is the compact-continuity ledger that ties family windows, finite-net witnesses, and tolerance requests to one inspected source surface.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened by the compact family and modulus data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to those finite windows.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after W and R are visible.*
7. *H records componentwise* hsame *transport for the family, compact-uniform, ledger, stream, regular, Real, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from compact family inspection through finite-net continuity, stream windows, regular readback, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{AscoliRealCompletion}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{CompactUniformContinuity}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{AscoliRealCompletion}^{\uparrow}}$ *row.*
The classifier accepts only packets whose completion-facing read uses the displayed rows $F, K, U, W, R, E, H, C, P, N$ It has no coordinate for selected subsequences, open-cover compactness, quotient equality of functions, host completeness, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8265.2 (Ascoli real-completion NameCert obligations)**.** *For every accepted* $\mathsf{AscoliRealCompletion}^{\uparrow}$ *carrier $A = (F, K, U, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AscoliRealCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, Arzela–Ascoli family exposure through F, compact-uniform-continuity exposure through K, compact-continuity ledger visibility through U, stream windows through W, regular rational readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8265.1. The tuple lists the family row, compact-uniform row, ledger row, stream windows, regular readback, Real seal, and structural rows as the whole accepted surface.

Read the analytic source through F, K, U. The family row supplies the Ascoli data, the compact-uniform row supplies the finite-net modulus route, and the ledger row keeps those rows tied to the same inspected compact source before any completion-facing read is available.

Finally route completion-facing output through W, R, E, H, C, P, N. The stream and regular rows expose finite windows and rational readback, the Real row seals the terminal value, and the structural rows transport, replay, source, and name the same packet. Since no selected subsequence, open-cover compactness, quotient equality, choice, host completeness, or ambient completeness coordinate appears in the carrier, the listed rows exhaust the NameCert surface. □

Theorem 8265.3 (Ascoli real-completion modulus handoff)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{AscoliRealCompletion}^{\uparrow}$ *packet receives its completion-facing data through the finite route*

$$\mathsf{ArzelaAscoli}^{\uparrow} \longmapsto \mathsf{CompactUniformContinuity}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exposes only the displayed family, compact-continuity, finite-window, regular-readback, Real-seal, transport, replay, provenance, and local naming rows. It exports no open-cover compactness theorem, no selected subsequence, no quotient equality of functions, no host completeness principle, no countable-choice schedule, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier surface. The rows F, K, U force the consumer to read the Ascoli family, compact-uniform-continuity packet, and compact-continuity ledger before it reaches any Real-facing object.

Next consume the completion-facing rows W, R, E. The finite stream windows expose only inspected name fragments, the regular rational row supplies the displayed readback, and the Real row seals the terminal value after those rows are visible.

The structural rows H, C, P, N then preserve the same route under transport, replay, provenance, and local naming. Because the packet contains no selected subsequence, open-cover compactness, quotient function equality, host completeness, choice schedule, or ambient Real-completeness coordinate, no such endpoint can be read from the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{AscoliRealCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{AscoliRealCompletion}^{\uparrow}$ packet is generated from ArzelaAscoliUp family data, CompactUniformContinuityUp finite-net data, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{AscoliRealCompletion}\uparrow}$, seed)

Scope closed: Definition 8265.1, Definition 8265.2, and Definition 8265.3 seed the finite Ascoli-to-Real completion route through family, compact-uniform, stream, regular-rational, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{AscoliRealCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subsequences, quotient function equality, countable choice, host completeness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Ascoli family exposure, compact-uniform-continuity routing, stream-window exposure, regular-rational readback, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.AscoliRealCompletionUp.

Chapter 8266

A Concrete Naming Certificate for $\mathsf{LocatedMonotoneSequence}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ packet records the finite L10 route by which a bounded monotone sequence is read through a located-supremum handoff rather than through ambient completeness. It sits after the monotone convergence packet of chapter 3928, the bounded monotone packet of chapter 7987, the located-supremum packet of chapter 1427, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the displayed route from monotone source data to located supremum data; it does not assert arbitrary $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient stream equality, or countable choice.

Definition 8266.1 (Located monotone sequence carrier)**.** *A* $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, B, S, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the accepted* $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$ *source row, exposing the monotone sequence schedule and its convergence-facing finite route.*
2. *B is the accepted* $\mathsf{BoundedMonotoneSequence}^{\uparrow}$ *row, exposing the same sequence through displayed upper-bound and lower-bound evidence.*
3. *S is the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row, carrying upper-bound and lower-approximation data for the source sequence.*
4. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *precision-window row through which sequence observations and located-supremum requests are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the windowed observations and the located-supremum approximation ledger.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic precision requests, comparison radii, and tail thresholds.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after M, B, S, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the source, boundedness, located-supremum, window, readback, tolerance, real-seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a located monotone sequence request through $M, B, S, W, R, D, E, H, P, N$.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedMonotoneSequence}^{\uparrow}$, $\mathsf{MonotoneConvergenceSequence}^{\uparrow}$, BoundedMonotoneSe LocatedSupremum$^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedMonotoneSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through

$$M, B, S, W, R, D, E, H, C, P, N.$$

It has no coordinate for ambient real completeness, a selected limit, quotient stream equality, trichotomy, countable choice, or a host-level monotone convergence theorem.

Theorem 8266.2 (Located monotone sequence NameCert obligations)**.** *For every accepted* LocatedMonotoneSeque *carrier*

$$L = (M, B, S, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedMonotoneSequence}^{\uparrow}}$ *surface consists exactly of carrier admission, monotone convergence source exposure, bounded monotone source exposure, located-supremum handoff, shared finite-window exposure, regular rational readback, dyadic tolerance replay, terminal Real-seal ordering, componentwise transport, displayed replay, provenance, and local naming for the same finite packet.*

Proof. Project the carrier of Definition 8266.1. Carrier admission exposes exactly $M, B, S, W, R, D, E, H, C, P, N$, so the only source-facing rows are the monotone convergence source M and the bounded monotone source B.

Read the order and approximation rows next. The located-supremum handoff S is the only row that can expose upper-bound and lower-approximation data, while W, R, D provide the shared finite windows, regular rational readback, and dyadic tolerance accounting.

The Real-facing seal is downstream of these rows. The structural rows H, C, P, N can only transport, replay, source, and name the same displayed packet, so the local NameCert surface has no coordinate for a selected limit, quotient equality, countable choice, or ambient completeness. □

Theorem 8266.3 (Located monotone sequence located-supremum handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ *carrier factors through the bounded monotone source rows M, B, then through the* $\mathsf{LocatedSupremum}^{\uparrow}$ *handoff row S, the shared* $\mathsf{StreamName}^{\uparrow}$ *window W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal E. Thus the L10 monotone-sequence-to-located-supremum route is a displayed finite handoff, not an appeal to arbitrary* $\mathsf{Real}^{\uparrow}$ *completeness or a choice-selected limit.*

Proof. Start with an accepted packet $L = (M, B, S, W, R, D, E, H, C, P, N)$. By Definition 8266.1, the terminal real row is E, and it appears only after the source, boundedness, located-supremum, window, readback, and tolerance rows have been displayed.

Apply Definition 8266.2. It forces the NameCert surface to expose the monotone convergence source M and bounded monotone source B before the located-supremum handoff S can feed the readback rows W, R, D.

The rows H, C, P, N preserve this route under transport, replay, provenance, and naming. Since the carrier contains no ambient completeness, selected-limit, quotient-equality, or countable-choice coordinate, every Real-facing read remains a finite located-supremum handoff. □

Falsifiable prediction: Every accepted $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ Real-facing read displays a monotone convergence source, a bounded monotone source, a located-supremum handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before any consumer may inspect it.

Independence witness: monotone-convergence-sequence, bounded-monotone-sequence, located-supremum, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a bounded monotone source and a located-supremum handoff before the Real-facing seal is exposed.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedMonotoneSequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8266.1, Definition 8266.2, and Definition 8266.3 seed the finite route from bounded monotone sequence data to a located-supremum Real-facing read.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedMonotoneSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim arbitrary $\mathsf{Real}^{\uparrow}$ completeness, trichotomy, quotient stream equality, countable choice, a selected ambient limit, Lean verification, or bridge checking.

Upgrade path: Formal verification can encode carrier admission, source exposure, bounded monotone exposure, located-supremum handoff, RegSeqRat readback, dyadic tolerance replay, and Real-seal non-escape for BEDC.Derived.LocatedMonotoneSeque

Constructive story: A $\mathsf{LocatedMonotoneSequence}^{\uparrow}$ packet is generated from a MonotoneConvergenceSequence source, a BoundedMonotoneSequence source, a LocatedSupremum handoff, a StreamName precision window, a RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8267

A Concrete Naming Certificate for $\mathsf{PreuniformBase}^{\uparrow}$

Following Bourbaki and Willard, the $\mathsf{PreuniformBase}^{\uparrow}$ packet names the finite entourage-base data that can feed uniformity and completion consumers before a full uniformity object has been closed. It sits below the filter route of chapter 8257, the regular-Cauchy uniformity route of chapter 1628, and the Real-specific entourage basis of chapter 2060. The packet is a displayed preuniform basis surface; it is not a quotient uniformity, not a selected completion, not host equality, and not an ambient Real completeness principle.

Definition 8267.1 (Preuniform-base carrier)**.** *A* $\mathsf{PreuniformBase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (E, D, S, M, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the entourage-base row whose entries name only displayed binary-neighborhood requests.*
2. *D is the diagonal witness row, recording that each admitted base entourage contains the displayed diagonal request.*
3. *S is the symmetry witness row, sending each admitted base request to a displayed symmetric refinement.*
4. *M is the finite-meet and refinement witness row, displaying a common smaller base request for each accepted finite pair.*
5. *R is the consumer route to* $\mathsf{EntourageFilter}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, *and* $\mathsf{RealUniformEntourageBase}^{\uparrow}$.
6. *H records componentwise* hsame *transport for the base row, diagonal row, symmetry row, finite-meet row, consumer route, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a downstream entourage request through E, D, S, M, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{PreuniformBase}^{\uparrow}$, $\mathsf{EntourageFilter}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, $\mathsf{RealUniformEntourageBase}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{PreuniformBase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, D, S, M, R, H, C, P, N$. It has no coordinate for a completed uniformity, quotient filter, selected limit, host equality, countable-choice selector, or ambient Real completeness.

Theorem 8267.2 (Preuniform-base NameCert obligations)**.** *For every accepted* $\mathsf{PreuniformBase}^{\uparrow}$ *carrier*

$$B = (E, D, S, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PreuniformBase}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed entourage-base row* E*, diagonal exposure through* D*, symmetry exposure through* S*, finite-meet and refinement exposure through* M*, downstream consumer routing through* R*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, local naming through* N*, and non-escape for completed uniformities, quotient filters, selected limits, host equality, countable-choice selectors, and ambient Real completeness.*

Proof. Project the carrier of Definition 8267.1. The accepted packet exposes exactly one entourage-base row, one diagonal row, one symmetry row, one finite-meet refinement row, one consumer route, and four structural rows.

The basis obligations are local to E, D, S, M. The diagonal row supplies the displayed diagonal containment, the symmetry row supplies a displayed symmetric refinement, and the meet row supplies a displayed common refinement for each finite pair before any downstream filter or uniformity consumer is opened.

The consumer route is downstream. The row R permits $\mathsf{EntourageFilter}^{\uparrow}$, $\mathsf{RegularCauchyUniformity}^{\uparrow}$, and $\mathsf{RealUniformEntourageBase}^{\uparrow}$ readers to consume the same basis data, while H, C, P, N transport, replay, source, and name that data without adding a completed uniformity or a quotient filter.

Since the carrier has no coordinate for selected limits, host equality, countable choice, or ambient Real completeness, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8267.3 (Preuniform-base downstream handoff)**.** *Every* $\mathsf{EntourageFilter}^{\uparrow}$*,* $\mathsf{RegularCauchyUniformity}^{\uparrow}$*, or* $\mathsf{RealUniformEntourageBase}^{\uparrow}$ *consumer of an accepted* $\mathsf{PreuniformBase}^{\uparrow}$ *carrier must first read the displayed route*

$$E \longmapsto D, S, M \longmapsto R \longmapsto H, C, P, N.$$

The handoff exports a preuniform basis only as finite entourage-base data, not as a completed uniformity, quotient filter, selected limit, host equality, countable-choice selector, or ambient Real completeness theorem.

Proof. Start with Definition 8267.2. It places every accepted consumer read on the displayed base row E and then on the diagonal, symmetry, and finite-meet rows D, S, M.

Only after those rows are visible may the route R be read. The route records the three downstream consumers named in the statement, and each of them receives the same finite basis surface rather than a private completion object.

The remaining rows H, C, P, N preserve the same route under transport, continuation replay, provenance, and local naming. Because the carrier lacks completed-uniformity, quotient-filter, selected-limit, host-equality, choice, and Real-completeness coordinates, the downstream handoff cannot export any of those endpoints. □

Falsifiable prediction: A downstream uniformity or completion consumer is refuted if it reads a PreuniformBase route without displaying the entourage-base row, diagonal row, symmetry row, finite-meet refinement row, consumer route, componentwise transport, continuation replay, package provenance, and local NameCert row.

Independence witness: entourage-filter, regular-cauchy-uniformity, real-uniform-entourage-base: no listed sibling supplies the whole $\mathsf{PreuniformBase}^{\uparrow}$ packet because those chapters consume or

specialize basis data, while this packet keeps the preuniform diagonal, symmetry, finite-meet, and downstream route rows as one carrier-local certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{PreuniformBase}^{\uparrow}}$.

Constructive story: A $\mathsf{PreuniformBase}^{\uparrow}$ packet is generated from displayed entourage-base rows, diagonal witnesses, symmetry witnesses, finite-meet refinement witnesses, a consumer route to EntourageFilter, RegularCauchyUniformity, and RealUniformEntourageBase rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PreuniformBase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8267.1, Definition 8267.2, and Definition 8267.3 seed the finite preuniform basis surface below the existing uniformity and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PreuniformBase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full uniformities, quotient filters, selected limits, host equality, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal exposure, symmetry exposure, finite-meet refinement, consumer routing, transport, replay, provenance, and local naming for BEDC.Derived.PreuniformBaseUp.

Chapter 8268

A Concrete Naming Certificate for $\mathsf{BanachContractionModulus}^{\uparrow}$

Following Banach's fixed-point theorem and Bishop–Bridges constructive metric analysis, the $\mathsf{BanachContractionModulus}^{\uparrow}$ packet isolates the finite contraction-budget ledger before any endpoint or fixed-point equality is read. It sits after the contraction-map surface of chapter 3529, the constructive contraction modulus of chapter 7631, the Cauchy orbit seal of chapter 7047, the complete-metric endpoint boundary of chapter 128, the Cauchy-modulus route of chapter 292, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the downstream fixed-point corridor of chapter 8031. The packet names the modulus surface only; it is not a completed fixed point, uniqueness theorem, selected limit, quotient Cauchy equality, host map equality, countable-choice schedule, or ambient completeness claim.

Definition 8268.1 (Banach contraction modulus carrier)**.** *A* $\mathsf{BanachContractionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, K, O, C, Q, R, E, H, T, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BanachContraction}^{\uparrow}$ *source row, exposing the self-map, contraction constant, and one-step distance comparison.*
2. *K is the* $\mathsf{ConstructiveContractionModulus}^{\uparrow}$ *row, storing the finite budget that turns a target tolerance into an iteration-depth request.*
3. *O is the* $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$ *row that reads the Picard-orbit residuals without selecting a completed endpoint.*
4. *C is the* $\mathsf{CauchyModulus}^{\uparrow}$ *row generated from the contraction budget and orbit residuals.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the resulting regular Cauchy schedule.*
6. *R is the* $\mathsf{CompleteMetric}^{\uparrow}$ *admission row that permits completion-facing consumers to inspect the same Cauchy data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available after the regular rational readback has been displayed.*
8. *H records componentwise* hsame *transport for the contraction, budget, orbit, Cauchy, completion, Real, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay along the same route.*

10. *P is the* Pkg *provenance row over* $\mathsf{BanachContractionModulus}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{ConstructiveContractionMod}$ $\mathsf{CauchyFixedPointOrbitSeal}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BanachContractionModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and inherited transports. It has no coordinate for a fixed point, endpoint equality, representative selection, quotient completion equality, host map equality, or ambient completeness.

Theorem 8268.2 (Banach contraction modulus NameCert obligations)**.** *For every accepted* $\mathsf{BanachContractionMod}$ *carrier*

$$M = (B, K, O, C, Q, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BanachContractionModulus}^{\uparrow}}$ *surface consists exactly of contraction-source visibility, finite contraction-budget visibility, Picard-orbit residual visibility, Cauchy-modulus extraction,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{CompleteMetric}^{\uparrow}$ *admission, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The analytic rows are B, K, O, C, Q, R, E, and the structural rows are H, T, P, N.

Read B, K, O first. The contraction source supplies the self-map and contraction bound, the modulus row turns tolerances into finite iteration requests, and the orbit seal records the displayed residuals without selecting an endpoint.

Read C, Q, R, E next. The Cauchy modulus is extracted from the contraction budget, the regular rational readback packages the schedule, the complete-metric row admits that schedule as endpoint-facing input, and the Real seal is downstream of the regular readback.

The transport, replay, provenance, and naming rows preserve only this displayed route. Since no excluded endpoint or choice coordinate appears in the carrier, the local NameCert cannot export one. □

Theorem 8268.3 (Banach contraction modulus complete-metric handoff)**.** *Every complete-metric or fixed-point consumer of an accepted* $\mathsf{BanachContractionModulus}^{\uparrow}$ *packet must first pass through the finite route*

$$\mathsf{BanachContraction}^{\uparrow} \longmapsto \mathsf{ConstructiveContractionModulus}^{\uparrow} \longmapsto \mathsf{CauchyFixedPointOrbitSeal}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow} \longmapsto$$

The route exports the contraction budget and Cauchy handoff needed by chapter 8031; it does not export a fixed point, selected limit, quotient stream equality, host equality of maps, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the contraction and budget rows. They determine only finite iteration-depth requests and residual comparisons, so the consumer receives a displayed modulus rather than an endpoint.

Apply the obligation theorem. It places the orbit seal, Cauchy-modulus row, regular rational readback, complete-metric admission, and Real seal in one route before any fixed-point corridor may inspect the data.

The $\mathsf{LipschitzFixedPoint}^{\uparrow}$ consumer may therefore read a named contraction-budget handoff. It must supply any endpoint existence, uniqueness, or equality claim in its own packet, because none of those rows occurs in the modulus carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{BanachContractionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BanachContractionModulus}^{\uparrow}$ packet is generated from a BanachContraction source row, a ConstructiveContractionModulus budget row, a CauchyFixedPointOrbitSeal row, a CauchyModulus row, a RegSeqRat readback, a CompleteMetric admission boundary, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BanachContractionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8268.1, Definition 8268.2, and Definition 8268.3 seed the finite contraction-modulus route before fixed-point endpoint reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BanachContractionModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a fixed point, uniqueness, selected limit, quotient Cauchy equality, host map equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-source visibility, finite budget extraction, orbit-seal visibility, Cauchy-modulus readback, CompleteMetric handoff, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BanachContractionModulusUp.

Chapter 8269

A Concrete Naming Certificate for $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$

Following the Bishop–Bridges finite-net proof of Heine–Cantor in chapter 9237, the FiniteEpsilonNetUniformModulus packet records the finite ε-net ledger that turns pointwise continuity rows on a compact metric source into a tolerance-only uniform-modulus handoff. It sits over the compact-metric carrier of chapter 129, the finite-net carrier of chapter 1767, the pointwise graph route of chapter 130, the uniform-modulus consumer of chapter 369, the metric comparison source of chapter 57, the rational tolerance rows of chapter 37, and the terminal real-name seal of chapter 38. The packet names the finite net-to-modulus handoff; it is not open-cover compactness, a semantic continuity theorem, a selected infinite subcover, quotient function equality, countable choice, or ambient real completeness.

Definition 8269.1 (Finite epsilon-net uniform-modulus carrier)**.** *A* $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, G, L, Q, R, E, V, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the compact metric carrier by finite coverage data.*
2. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *row, storing the bundled centers, radius rows, and coverage witnesses.*
3. *G is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph and pointwise-modulus row for the displayed map.*
4. *L is the local radius ledger that attaches each bundled center to a positive* $\mathsf{Rat}^{\uparrow}$ *tolerance row.*
5. *Q is the folded lower-bound row over the finite center bundle.*
6. *R is the* $\mathsf{Met}^{\uparrow}$ *comparison row used to move from a source point to a nearby center and then to a second source point.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for target-distance readback after rational comparisons have been displayed.*
8. *V is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row receiving the folded tolerance-only precision ledger.*
9. *H records componentwise* hsame *transport for compact, net, continuous-map, rational, metric, Real, uniform-modulus, replay, provenance, and local naming rows.*

10. *T records displayed* Cont *replay for the same finite-net uniform-modulus route.*
11. *P is the* Pkg *provenance row over* $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and inherited transports. It has no coordinate for an open cover, semantic continuity, an infinite subcover selector, quotient function equality, countable choice, or ambient completeness.

Theorem 8269.2 (Finite epsilon-net uniform-modulus NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$ *carrier*

$$U = (K, F, G, L, Q, R, E, V, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}}$ *surface consists exactly of compact-metric source visibility, finite epsilon-net visibility, continuous-map pointwise-modulus visibility, rational local-radius exposure, finite lower-bound folding, metric comparison, Real seal readback,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier. The mathematical rows are K, F, G, L, Q, R, E, V, and the structural rows are H, T, P, N.

Read K, F, G, L first. These rows expose a compact metric source, a finite bundle of centers, the pointwise continuity data at those centers, and the rational local-radius ledger.

Read Q, R, E, V next. The finite fold gives one tolerance-only precision row, the metric comparison row moves through the chosen center, the Real seal reads target-distance estimates, and the uniform-modulus row receives the folded ledger.

The structural rows preserve only this displayed route. Since no open-cover object, semantic function equality, infinite selector, choice schedule, or ambient completeness witness occurs in the carrier, the local NameCert cannot export such an endpoint. □

Theorem 8269.3 (Finite epsilon-net uniform-modulus compact handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$ *carrier factors through*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{FiniteEpsilonNet}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Rat}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The handoff exports a finite tolerance-only uniform-modulus ledger. It does not export open-cover compactness, semantic continuity, selected infinite subcovers, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the compact-metric and finite-net rows. They provide a finite bundle of centers and coverage witnesses, so the route begins with displayed finite data rather than an arbitrary open cover.

Apply the continuous-map and rational-radius rows at each center. The finite lower-bound fold then produces one precision ledger that is below all local radii in the bundle.

Finally use the metric comparison and Real seal rows to replay the usual two-triangle estimate through the chosen center before the uniform-modulus row is consumed. The packet therefore realizes the compact-uniform-continuity handoff as finite BEDC data and leaves all excluded global endpoints outside the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}$ packet is generated from compact-metric data, finite epsilon-net centers and coverage witnesses, continuous-map pointwise rows, rational local-radius rows, a finite lower-bound fold, metric comparison, Real sealing, a UniformModulus consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8269.1, Definition 8269.2, and Definition 8269.3 seed the finite epsilon-net route from compact pointwise continuity to a tolerance-only uniform-modulus ledger.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetUniformModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, semantic continuity, selected infinite subcovers, quotient function equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric visibility, finite-net coverage, continuous-map pointwise rows, rational fold exactness, metric comparison, Real seal nonescape, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteEpsilonNetUniformModulusUp.

Chapter 8270

A Concrete Naming Certificate for $\mathsf{FanTheoremModulus}^{\uparrow}$

Following Brouwer's fan theorem and Bishop–Bridges constructive uniform-continuity analysis, the $\mathsf{FanTheoremModulus}^{\uparrow}$ packet reads a displayed $\mathsf{FanTheorem}^{\uparrow}$ finite bound as a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff. It sits after the finite fan certificate of chapter 400, the Bishop fan-modulus route of chapter 1707, the bar-modulus route of chapter 6151, the compact-uniform fan packet of chapter 7954, the downstream uniform-modulus surface of chapter 369, the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal real-name seal of chapter 38. The packet records the theorem-level handoff from already displayed fan-bound data to a uniform modulus; it does not reprove the bar theorem, select an infinite branch, invoke open-cover compactness, choose a host modulus, quotient stream names, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8270.1 (Fan theorem modulus carrier)**.** *A* $\mathsf{FanTheoremModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, B, T, U, S, Q, D, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FanTheorem}^{\uparrow}$ *finite-bound row, exposing a barred binary-spread depth already admitted by the fan-theorem packet.*
2. *B is the* $\mathsf{BishopFanModulus}^{\uparrow}$ *schedule row, turning the displayed fan depth into finite observation windows for Real and Completion consumers.*
3. *T is the* $\mathsf{FanTheoremBarModulus}^{\uparrow}$ *row, recording the bar-coverage-to-tolerance extraction already available at the bar-modulus surface.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row, read only after F, B, T have displayed the finite bound and its tolerance interpretation.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for the inspected prefixes and tolerance requests.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the displayed windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare requested precision with the fan-bound schedule.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the stream, regular, and dyadic rows have been exposed.*

9. *H records componentwise* hsame *transport for F, B, T, U, S, Q, D, R and their structural support.*
10. *C records displayed* Cont *replay from the fan-bound row through the Bishop schedule, bar-modulus row, tolerance ledger, and uniform-modulus handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FanTheoremModulus}^{\uparrow}$, $\mathsf{FanTheorem}^{\uparrow}$, $\mathsf{BishopFanModulus}^{\uparrow}$, $\mathsf{FanTheoremBarModulus}^{\uparrow}$, $\mathsf{CompactUniformFanModulus}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FanTheoremModulus}^{\uparrow}}$ *row.*

The classifier accepts only packets whose uniform-modulus read is routed through the displayed rows $F, B, T, U, S, Q, D, R, H, C, P, N$. It has no coordinate for a selected infinite branch, open-cover compactness theorem, host modulus function, quotient stream equality, countable-choice schedule, or ambient real completeness.

Theorem 8270.2 (Fan theorem modulus NameCert obligations)**.** *For every accepted* $\mathsf{FanTheoremModulus}^{\uparrow}$ *carrier $M = (F, B, T, U, S, Q, D, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FanTheoremModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the twelve displayed rows; fan-bound exposure through F; Bishop fan-modulus scheduling through B; bar-modulus extraction through T; tolerance-only uniform-modulus handoff through U; finite-window, regular-rational, dyadic-tolerance, and Real-seal readback through S, Q, D, R; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8270.1. Its fan and modulus rows are exactly F, B, T, U, its readback rows are exactly S, Q, D, R, and its structural rows are exactly H, C, P, N.

Read F as the already displayed fan-theorem finite bound. The Bishop fan-modulus row B turns that bound into finite observation windows, and the bar-modulus row T records the tolerance extraction that is available before a uniform-modulus consumer reads U.

The rows S, Q, D, R supply only finite windows, regular rational readback, dyadic tolerance comparison, and terminal Real sealing. The structural rows then transport, replay, source, and name the same packet. Since no additional coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations and block branch selection, open-cover compactness, host modulus selection, quotient stream equality, countable choice, and ambient Real completeness. □

Theorem 8270.3 (Fan theorem modulus compact-uniform handoff)**.** *Every compact-uniform or Real-and-Completion consumer of an accepted* $\mathsf{FanTheoremModulus}^{\uparrow}$ *packet receives its uniform-modulus data through the finite route*

$$\mathsf{FanTheorem}^{\uparrow} \longmapsto \mathsf{BishopFanModulus}^{\uparrow} \longmapsto \mathsf{FanTheoremBarModulus}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{R}$$

When the consumer is the compact-uniform fan route, the same handoff may be cited beside $\mathsf{CompactUniformFanModulus}^{\uparrow}$*, but only as the displayed fan-bound-to-uniform-modulus package F, B, T, U, S, Q, D, R. It exports no open-cover compactness theorem, selected branch, selected cover center, external modulus oracle, quotient stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8270.2. They force every accepted read to expose the fan-bound row, Bishop schedule row, bar-modulus row, uniform-modulus handoff, readback rows, and structural rows in the displayed carrier.

The compact-uniform fan surface may consume this packet only after the fan-bound-to-uniform-modulus route has already been displayed. Thus $\mathsf{CompactUniformFanModulus}^{\uparrow}$ is a sibling consumer of the same finite handoff, not a source of an additional branch selector or host compactness object.

Finally inspect the excluded coordinates of Definition 8270.1. The carrier has no slot for branch selection, open-cover compactness, selected centers, external moduli, quotient stream equality, countable choice, or ambient Real completeness, so none of those objects can be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FanTheoremModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{FanTheoremModulus}^{\uparrow}$ packet is generated from a FanTheoremUp finite-bound row, BishopFanModulusUp schedule row, FanTheoremBarModulusUp extraction row, UniformModulusUp handoff, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparison, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FanTheoremModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8270.1, Definition 8270.2, and Definition 8270.3 seed the finite fan-bound-to-uniform-modulus handoff through fan, Bishop schedule, bar-modulus, uniform-modulus, stream, regular-rational, dyadic, Real, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FanTheoremModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, open-cover compactness, branch selection, selected cover centers, external modulus oracles, quotient stream equality, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, fan-bound exposure, Bishop schedule routing, bar-modulus extraction, UniformModulus handoff, finite-window readback, regular-rational readback, dyadic tolerance comparison, RealUp sealing, transport, replay, provenance, and local naming for BEDC.Derived.FanTheoremModulusUp.

Chapter 8271

A Concrete Naming Certificate for LebesgueCriterionRiemannIntegrability$^{\uparrow}$

Following Riemann, Lebesgue, and Bishop–Bridges constructive analysis, the LebesgueCriterionRiemannIntegrability$^{\uparrow}$ packet records the finite discontinuity-ledger route by which a bounded real function on a displayed compact interval is admitted to the Riemann integrability boundary. It sits beside the finite discontinuity packet of chapter 7684, the Darboux oscillation criterion of chapter 7252, the Darboux finite-sum surface of chapter 1880, and the Riemann integral readback of chapter 1526. The packet names only the finite BEDC rows needed to route discontinuity evidence into Darboux gap control; it does not import a measure-zero theorem, a countable exceptional set, quotient function equality, selected partitions, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8271.1 (Lebesgue criterion for Riemann integrability carrier)**.** *A* LebesgueCriterionRiemannIntegrability$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, F, O, D, J, U, V, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the* Real$^{\uparrow}$ *compact-interval row naming the endpoints and orientation on which the bounded-function read is made.*
2. *F is the bounded-function observation row, exposing only the finite windows requested by the criterion.*
3. *O is the local oscillation row that records the displayed oscillation tests used to detect discontinuity candidates.*
4. *D is the finite discontinuity ledger row, listing the displayed discontinuity names and their interval windows.*
5. *J is the Darboux cell-routing row, separating the cells assigned to D from the continuity cells read through O.*
6. *U and V are the upper and lower* DarbouxSum$^{\uparrow}$ *rows over the displayed cell route.*
7. *G is the finite Darboux gap row comparing U and V against a dyadic tolerance.*
8. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the displayed gap comparison.*
9. *E is the* RiemannIntegral$^{\uparrow}$ *handoff row, visible only after $I, F, O, D, J, U, V, G, R$ have been displayed.*

10. *H records componentwise* hsame *transport for the interval, function, oscillation, ledger, Darboux, gap, readback, handoff, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay from the interval and bounded-function request through the discontinuity ledger, Darboux comparison, regular readback, and Riemann handoff.*

12. *P is the* Pkg *provenance over* $\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}$, $\mathsf{RiemannIntegrabilityDiscontinuity}^{\uparrow}$, $\mathsf{DarbouxSum}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RiemannIntegral}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}$ *row.*

The carrier has no coordinate for measure completion, null-set equality, countable exceptional families, selected refinement sequences, quotient functions, host integration, or ambient real completeness.

Theorem 8271.2 (Lebesgue criterion NameCert obligations)**.** *For every accepted* LebesgueCriterionRiemannIntegral *carrier*

$$L = (I, F, O, D, J, U, V, G, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval, bounded-function observation, oscillation test, discontinuity ledger, Darboux routing, Darboux sums, gap, regular readback, Riemann handoff, transport, replay, provenance, and local naming rows;*

2. *discontinuity-ledger exposure, requiring every discontinuity candidate consumed by the criterion to appear in the finite ledger D with a displayed interval window;*

3. *off-ledger continuity routing, requiring J to send every non-ledger cell through the oscillation row O before any Darboux comparison is read;*

4. *Darboux gap control, requiring U, V, G to compare upper and lower finite sums only over the cells exposed by D, J;*

5. *Riemann handoff nonescape, requiring E to be read only after the finite discontinuity, Darboux, and regular readback rows are visible.*

Thus the packet supplies a finite BEDC surface for the Lebesgue-style discontinuity criterion without exporting measure-zero data or an ambient completeness principle.

Proof. Project the carrier of Definition 8271.1. The analytic rows are exactly $I, F, O, D, J, U, V, G, R, E$; the remaining rows H, C, P, N transport, replay, source, and name that same packet.

The discontinuity side is read first. The ledger D lists only displayed discontinuity windows, while J records how the remaining cells are routed through the oscillation row O. No countable exceptional family or measure object is present in this route.

The Darboux side then reads the same cell route. The upper and lower rows U, V compute finite sums over the displayed cells, and the gap row G compares them before the regular readback R is consumed.

Finally the Riemann handoff E is downstream of those rows. Since the carrier omits measure completion, null-set equality, selected refinement limits, quotient function equality, countable choice, host integration, and ambient completeness, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}$ surface. □

Theorem 8271.3 (Lebesgue criterion Darboux discontinuity route)**.** *Every* $\mathsf{RiemannIntegral}^{\uparrow}$ *or* $\mathsf{DarbouxSum}^{\uparrow}$ *consumer of an accepted* $\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}$ *carrier must read the finite route*

$$I, F, O, D, J \longmapsto U, V \longmapsto G \longmapsto R \longmapsto E.$$

Consequently the criterion exposes Riemann integrability only through displayed discontinuity ledgers, Darboux finite sums, and regular readback; it does not expose a measure-zero certificate, a countable discontinuity set, quotient function equality, selected partitions, countable choice, host integration, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8271.2. They force any criterion consumer to display the discontinuity ledger D, the off-ledger oscillation route O, and the cell-routing row J before a Darboux comparison is available.

The Darboux rows are then fixed by the displayed route. Rows U and V compute upper and lower finite sums on the same cells, while G records the finite upper-minus-lower gap.

The regular readback row R exposes the gap before the Riemann handoff E is consumed. The structural rows H, C, P, N preserve the same packet and add no measure, quotient, choice, host-integration, or completeness endpoint. □

Falsifiable prediction: A purported $\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}$ read that reaches a $\mathsf{RiemannIntegral}^{\uparrow}$ handoff without displaying the interval, bounded-function observation, oscillation, finite discontinuity ledger, Darboux cell route, upper and lower Darboux rows, finite gap, $\mathsf{RegSeqRat}^{\uparrow}$ readback, componentwise hsame, displayed Cont, Pkg, and local NameCert rows refutes the carrier of Definition 8271.1.

Independence witness: riemann-integrability-discontinuity, darboux-oscillation-criterion, darboux-sum, riemannintegral: $\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}$ is not bijective with any listed sibling because it joins oscillation-ledger exposure, finite discontinuity routing, Darboux gap control, regular readback, Riemann handoff, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}$.

Constructive story: A $\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}$ packet is generated from a Real interval-domain row, bounded-function observations, oscillation tests, a finite discontinuity ledger, Darboux cell routing, upper and lower Darboux rows, a finite gap row, RegSeqRat readback, RiemannIntegral handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8271.1, Definition 8271.2, and Definition 8271.3 seed the finite discontinuity-ledger route from Lebesgue-style criterion data to Darboux gap control and Riemann handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LebesgueCriterionRiemannIntegrability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close measure-zero equivalence, countable exceptional families, null-set equality, quotient function equality, selected refinement sequences, host integration, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, discontinuity-ledger exposure, off-ledger continuity routing, Darboux gap control, Riemann handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueCriterionRiemannIntegrabilityUp.

Chapter 8272

A Concrete Naming Certificate for $\mathsf{UniformContinuityFanModulus}^{\uparrow}$

Following Brouwer and Bishop fan-theorem constructive analysis, the $\mathsf{UniformContinuityFanModulus}^{\uparrow}$ packet records the finite bar route by which pointwise continuity on a compact metric source yields one displayed uniform-modulus row. It sits over the compact finite-net data of chapter 129, the continuous-map pointwise rows of chapter 130, the rational arithmetic of chapter 37, the terminal real-name seal of chapter 38, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet names finite fan-bar inspection data only; it does not import open-cover compactness, a selected infinite branch, semantic continuity, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8272.1 (Uniform-continuity fan-modulus carrier)**.** *A* $\mathsf{UniformContinuityFanModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, M, A, B, R, E, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, exposing the inspected centers and cover radii.*
2. *M is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-continuity row for the map on that compact source.*
3. *A is the finite fan-bar row whose nodes record the inspected source windows and their local continuity radii.*
4. *B is the finite* ProbeBundle *induction ledger that certifies every accepted source request meets a bar node.*
5. *R is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row over the finitely many positive local radii.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row used only after the rational fold and target-value readbacks are displayed.*
7. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row that receives the folded radius as the tolerance-only modulus boundary.*
8. *H records componentwise* hsame *transport for compact-net, continuous-map, fan-bar, bundle, rational-fold, Real-seal, uniform-modulus, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay from compact finite-net inspection through fan-bar induction and rational lower-bound folding to the uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{UniformContinuityFanModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformContinuityFanModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an infinite branch selector, open-cover compactness, host equality of real functions, countable choice, quotient real equality, semantic continuity, or ambient completeness.

Theorem 8272.2 (Uniform-continuity fan-modulus NameCert obligations)**.** *For every accepted* $\mathsf{UniformContinuityFanModulus}^{\uparrow}$ *carrier* $F = (K, M, A, B, R, E, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UniformContinuityFanMo}}$ *surface consists exactly of compact finite-net exposure, continuous-map pointwise exposure, finite fan-bar admission,* ProbeBundle *induction, rational lower-bound folding, Real-seal readback,* $\mathsf{UniformModulus}^{\uparrow}$ *consumer handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read the uniform modulus only after* K, M, A, B, R, E *have all been displayed.*

Proof. Project the carrier of Definition 8272.1. The tuple lists the compact metric source, pointwise continuous-map row, fan-bar row, bundle-induction ledger, rational fold, Real seal, uniform-modulus output, and structural support rows as the whole accepted surface.

The finite fan-bar stage is A, B. The bar row lists the inspected nodes and local radii, while the ProbeBundle induction ledger proves that every accepted source request reaches one of those nodes. This is a finite induction over displayed bundle entries, not a selected infinite branch.

The modulus stage is R, E, U. The rational row folds the displayed positive radii to one lower-bound row, the Real row seals the scalar readback only after that fold is visible, and the uniform-modulus row receives exactly that finite boundary. The rows H, C, P, N transport, replay, source, and name the same packet, so the local ledger cannot export open-cover compactness, semantic continuity, choice, quotient equality, or ambient completeness. □

Theorem 8272.3 (Uniform-continuity fan-modulus fan-bar route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{UniformContinuityFanModulus}^{\uparrow}$ *packet factors through the finite fan-bar route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow} \longmapsto A, B \longmapsto \mathsf{Rat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

Thus the consumer reads compact finite-net coverage, pointwise continuity rows, finite fan-bar nodes, ProbeBundle *induction, rational lower-bound folds, the terminal Real seal, componentwise transport, replay, provenance, and the local NameCert ledger before exporting any modulus data.*

Proof. Start with K and M. The compact metric row supplies the finite source inspection surface, and the continuous-map row supplies only pointwise local estimates attached to that same source.

Next read A and B. The fan-bar row stores the finite bar nodes, and the bundle induction ledger certifies coverage of the inspected source requests. Transport by H and replay by C keep these rows componentwise stable under the accepted classifier.

Finally fold through R, seal through E, and hand the result to U. The provenance row P and local name row N record that the exported modulus is the displayed finite route. Since no coordinate stores an infinite branch, open-cover compactness, selected representative, countable choice, host real equality, or ambient completeness, none of those objects can be read by the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformContinuityFanModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{UniformContinuityFanModulus}^{\uparrow}$ packet is generated from CompactMetricUp finite-net data, ContinuousMapUp pointwise rows, a finite fan-bar row, a ProbeBundle induction ledger, RatUp lower-bound folds, a

RealUp seal, a UniformModulusUp consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{UniformContinuityFanModulus}\uparrow}$, seed)

Scope closed: Definition 8272.1, Definition 8272.2, and Definition 8272.3 seed the finite fan-bar route from compact finite-net and pointwise-continuity rows to a UniformModulus consumer boundary.

Formal verification: FormalStatus(NameCert$_{\text{UniformContinuityFanModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, infinite branch selection, semantic continuity, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, continuous-map pointwise exposure, fan-bar coverage, ProbeBundle induction, rational lower-bound fold exactness, RealUp sealing, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.UniformContinuityFanModulusUp.

Chapter 8273

A Concrete Naming Certificate for $\mathsf{UniformCover}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces and uniform covers, the $\mathsf{UniformCover}^{\uparrow}$ packet records the finite cover surface that an L10 uniform-space consumer may read before passing to star refinements or completion. It sits after the uniform-space surface of chapter 339 and the entourage-base surface of chapter 1819, before the star-refinement surface of chapter 2167 and the uniform-completion boundary of chapter 1473. The packet names only displayed cover, entourage, membership, refinement, transport, replay, provenance, and local naming rows; it does not assert open-cover compactness, selected subcovers, paracompact refinement, ambient completeness, or a host powerset cover principle.

Definition 8273.1 (UniformCover carrier)**.** *A* $\mathsf{UniformCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, E, C, M, R, H, T, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row naming the underlying uniform-space interface.*
2. *E is the* $\mathsf{EntourageBase}^{\uparrow}$ *row from which the cover is generated.*
3. *C is the finite cover row, listing the displayed members that a consumer may inspect.*
4. *M is the membership-window row, recording which named points or finite probes are admitted to each cover member.*
5. *R is the refinement-read row, exposing how an entourage-basis request may refine the cover row.*
6. *H records componentwise* hsame *transport for the source, entourage base, cover, membership, refinement, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay of the route*

$$S, E \longmapsto C, M, R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{UniformCover}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* $\mathsf{EntourageBase}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCover}^{\uparrow}}$ *row.*

The carrier predicate admits exactly these rows. Its classifier compares accepted packets only through $S, E, C, M, R, H, T, P, N$ and has no coordinate for compactness of all open covers, choice-selected subcovers, paracompactness, a star-refinement witness, or completion.

Theorem 8273.2 (UniformCover NameCert obligations)**.** *For an accepted* $\mathsf{UniformCover}^{\uparrow}$ *carrier*

$$U = (S, E, C, M, R, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCover}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the uniform-space source, entourage-base, cover, membership, refinement, transport, replay, provenance, and local naming rows;*
2. *cover generation, requiring C to be read from the displayed uniform-space and entourage-base rows S, E;*
3. *membership exposure, requiring every cover-member read to pass through the finite window row M;*
4. *refinement exposure, requiring every refinement-facing consumer to pass through R before citing an entourage-base refinement;*
5. *classifier transport, requiring H and T to preserve the same rows componentwise under* hsame *and displayed continuation;*
6. *non-escape, excluding open-cover compactness, selected subcovers, paracompact refinements, star-refinement witnesses, and completion claims.*

No NameCert obligation is stored outside $S, E, C, M, R, H, T, P, N$.

Proof. Project the carrier of Definition 8273.1. The accepted packet exposes exactly the uniform-space, entourage-base, cover, membership, refinement, transport, replay, provenance, and local naming rows.

The cover generation and membership clauses are row reads. The cover row C is downstream of S, E, while each member inspection is mediated by the finite membership-window row M.

The refinement clause is separate. A consumer may request an entourage-base refinement only through R, so the cover packet does not silently become a star-refinement or completion theorem.

Finally H, T, P, N preserve the same finite route by componentwise transport, replay, provenance, and local naming. Since the excluded host principles are not coordinates of the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8273.3 (UniformCover entourage refinement route)**.** *Let*

$$U = (S, E, C, M, R, H, T, P, N)$$

be an accepted $\mathsf{UniformCover}^{\uparrow}$ *carrier. Every consumer that treats the cover as generated by a uniform entourage factors through the finite route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto \mathsf{EntourageBase}^{\uparrow} \longmapsto C, M, R \longmapsto H, T, P, N.$$

The route may feed the star-refinement surface of chapter 2167 and the completion boundary of chapter 1473, but it exports no selected refinement, no compactness principle, and no ambient completion object.

Proof. Start with the accepted carrier. The source and entourage-base rows S, E are the only entries from which the cover row can be generated.

Apply Definition 8273.2. Its membership and refinement obligations force every cover read through C, M, R before any downstream refinement or completion consumer can cite the cover.

The star-refinement and completion consumers therefore receive only the displayed cover route. Transport, replay, provenance, and local naming preserve that route through H, T, P, N, and the absent compactness, selection, and completion coordinates cannot be projected from the packet. □

Falsifiable prediction: A uniform-space consumer that cites a cover without displaying the $\mathsf{UniformSpace}^{\uparrow}$ source row, the $\mathsf{EntourageBase}^{\uparrow}$ generator row, and the finite membership window is not reading a UniformCoverUp carrier.

Independence witness: uniformspace, entouragebase, starrefinementuniformcover, uniformcompletion: none is bijective because $\mathsf{UniformCover}^{\uparrow}$ stores the cover and membership route between the uniform-space source and later refinement or completion consumers. UniformSpaceUp supplies the uniformity but not the finite cover row; EntourageBaseUp supplies basis refinement but not cover membership; StarRefinementUniformCoverUp consumes a cover with an extra star-containment row; UniformCompletionUp consumes Cauchy and completion data rather than a bare uniform-cover carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCover}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCover}^{\uparrow}$ packet is generated from a UniformSpaceUp source row, an EntourageBaseUp row, finite cover and membership rows, an entourage-refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8273.1, Definition 8273.2, and Definition 8273.3 seed the finite uniform-cover surface consumed by star-refinement and completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, compactness, selected subcovers, paracompactness, star-refinement containment, or ambient completion.

Upgrade path: Obligation closure requires checked carrier admission, cover generation, membership exposure, entourage refinement, classifier transport, and non-escape for BEDC.Derived.UniformCoverUp.

Chapter 8274

A Concrete Naming Certificate for $\mathsf{RadoSelectionLemma}^{\uparrow}$

Following Rado's selection lemma and the finite matroid/transversal tradition, the $\mathsf{RadoSelectionLemma}^{\uparrow}$ packet records the certificate surface by which a finite family of local choices is assembled into a global independent selection. It reads the finite-index rows of chapter 36 and chapter 28, the independence carrier of chapter 202, and the edge-selection boundary of chapter 234. The chapter names only the displayed finite selection packet and its NameCert obligations; it does not assert an infinite choice principle, a host transversal selector, quotient equality of selections, or an ambient maximality theorem.

Definition 8274.1 (Rado selection lemma carrier)**.** *A* $\mathsf{RadoSelectionLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (I, A, M, G, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index surface, presented by* $\mathsf{List}^{\uparrow}$ *rows and bounded by* $\mathsf{Nat}^{\uparrow}$ *row counters.*
2. *A assigns to each displayed index row a finite admissible choice list, with every choice row kept inside the same* BHist *carrier.*
3. *M is the* $\mathsf{Matroid}^{\uparrow}$ *independence row on the displayed ground, including the hereditary and exchange fields used by local selections.*
4. *G is the* $\mathsf{Matching}^{\uparrow}$ *incidence row recording the finite bipartite choice graph between index rows and admissible choice rows.*
5. *S is the selected transversal row, displaying one carried choice for each index row and recording that the selected choices are independent in M.*
6. *H records componentwise* hsame *transport for I, A, M, G, S.*
7. *C records displayed* Cont *replay of the finite route from the index rows and admissible choices through matroid independence and matching incidence to the selected transversal row.*
8. *P is the* Pkg *provenance over* $\mathsf{RadoSelectionLemma}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RadoSelectionLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed finite rows and their componentwise transport, replay, provenance, and local naming data.

Theorem 8274.2 (Rado selection lemma NameCert obligations)**.** *For every accepted* $\mathsf{RadoSelectionLemma}^{\uparrow}$ *carrier*

$$R = (I, A, M, G, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RadoSelectionLemma}^{\uparrow}}$ *surface consists exactly of the finite-index admission rows, admissible-choice rows, matroid independence rows, matching incidence rows, selected-transversal row, componentwise transport, displayed replay, provenance, and local naming row. No obligation row is stored outside the displayed packet.*

Proof. Project the carrier of Definition 8274.1. Its finite data are the index surface I, admissible choice rows A, matroid row M, matching row G, and selected transversal row S.

The NameCert admission clauses are rowwise. The finite-index part is read through $\mathsf{List}^{\uparrow}$ and $\mathsf{Nat}^{\uparrow}$, the independence requirements are read through $\mathsf{Matroid}^{\uparrow}$, and the incidence constraints are read through $\mathsf{Matching}^{\uparrow}$ before the selected row S is available.

Transport and replay preserve the same surface. The H row moves each displayed component by hsame, the C row replays the same finite route, and P, N source and name the resulting packet. Since none of these rows contains an infinite choice principle, a host transversal selector, quotient equality of selections, or an ambient maximality theorem, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RadoSelectionLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{RadoSelectionLemma}^{\uparrow}$ packet is generated from finite index rows, admissible choice lists, a matroid independence row, a matching incidence row, a selected transversal row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RadoSelectionLemma}^{\uparrow}}$, seed)

Scope closed: Definition 8274.1 and Definition 8274.2 seed the finite Rado selection NameCert surface over $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Matroid}^{\uparrow}$, and $\mathsf{Matching}^{\uparrow}$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RadoSelectionLemma}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close infinite choice, host transversal selection, quotient equality of selections, ambient maximality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-index stability, matroid independence transport, matching incidence transport, selected-transversal exactness, and a Lean obligation surface for BEDC.Derived.RadoSelectionLemmaU

Chapter 8275

A Concrete Naming Certificate for $\mathsf{ProofTraceConfluence}^{\uparrow}$

The $\mathsf{ProofTraceConfluence}^{\uparrow}$ packet realizes the conditional MetaCIC confluence boundary of chapter 9378 as finite NameCert data. It sits beside the critical-path surface of chapter 765, the normalization frontier of chapter 892, the confluence audit packet of chapter 735, the candidate-normalization handoff of chapter 5547, and the subject-reduction discharge boundary of chapter 718. The packet names proof-trace confluence only as a displayed route through reduction traces, residual-substitution rows, closed-normal fragments, and conditional diamond inputs; it does not turn any retained premise into full closed confluence.

Definition 8275.1 (ProofTraceConfluence carrier)**.** *A* $\mathsf{ProofTraceConfluence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (T, R, N, D, C, B, F, H, E, P, L)$$

with the following displayed rows:

1. *T is the MetaCIC proof-trace row naming the two reduction traces or local peak being compared.*
2. *R is the residual-substitution row, retaining the substitution-compatibility input when a beta-residual branch requires it.*
3. *N is the closed-normal fragment row, recording the closed normal, sort, or impossible closed-variable cases that are already unconditional.*
4. *D is the conditional-diamond input row, naming either the substitution-compatibility input for a parallel diamond or the closed parallel-diamond input for closed star confluence.*
5. *C is the confluence-audit consumer row, read against the audit map and confluence audit packet.*
6. *B is the blocked-premise row, recording which residual-substitution, closed-diamond, subject-reduction, or normal-form consistency input remains visible.*
7. *F is the frontier route through* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *and* $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$.
8. *H records componentwise* hsame *transport for trace, residual, closed-normal, diamond, audit, blocked-premise, frontier, replay, provenance, and local naming rows.*
9. *E records displayed* Cont *replay of the route*

$$T, R, N, D, C, B, F \longmapsto H, P, L.$$

10. *P is the* Pkg *provenance over* ProofTraceConfluence$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, MetaCICConfluenceAuditPacket$^{\uparrow}$, SubjectReductionDischarge$^{\uparrow}$, NormalFormConsistencySeal$^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
11. *L is the local* NameCert$_{\mathsf{ProofTraceConfluence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, N, D, C, B, F, H, E, P, L$. It has no coordinate for unconditional arbitrary closed Church–Rosser, unrestricted residual substitution, a hidden subject-reduction theorem, quotient syntax equality, evaluator soundness, or normal-form consistency detached from its seal.

Theorem 8275.2 (ProofTraceConfluence NameCert obligations)**.** *For an accepted* ProofTraceConfluence$^{\uparrow}$ *carrier*

$$Q = (T, R, N, D, C, B, F, H, E, P, L),$$

the local NameCert$_{\mathsf{ProofTraceConfluence}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for proof traces, residual-substitution input, closed-normal fragments, conditional diamond input, audit consumer, blocked-premise, frontier, transport, replay, provenance, and local naming rows;*
2. *residual visibility, requiring every full parallel-diamond read to display the residual-substitution row R or record its absence in B;*
3. *closed-diamond visibility, requiring every closed star-confluence read to display the closed-diamond row D or record its absence in B;*
4. *closed-normal fragment separation, requiring N to remain a shape-limited unconditional fragment rather than a full confluence theorem;*
5. *frontier and audit handoff, requiring F and C to route every consumer through the critical-path, normalization-frontier, and confluence-audit packets;*
6. *non-escape, excluding unconditional closed confluence, unrestricted subject reduction, quotient syntax equality, evaluator soundness, and unsealed normal-form consistency.*

No obligation is stored outside $T, R, N, D, C, B, F, H, E, P, L$.

Proof. Project the carrier of Definition 8275.1. The accepted packet exposes proof traces, residual-substitution data, closed-normal fragments, conditional-diamond inputs, audit rows, blocked premises, frontier rows, and structural rows.

The residual and closed-diamond clauses are premise-retention clauses. A full parallel-diamond route must display R, and a closed star-confluence route must display D; when either input is absent, the blocked-premise row B remains visible.

The closed-normal row N is shape-limited. It records the available normal, sort, and impossible closed-variable cases without adding a coordinate for arbitrary closed confluence.

Finally F, C, H, E, P, L preserve and name the same route through the critical-path and audit surfaces. Since the excluded global endpoints are not carrier coordinates, the displayed rows exhaust the local NameCert obligations. □

Theorem 8275.3 (ProofTraceConfluence conditional handoff)**.** *Every confluence-facing consumer of an accepted* ProofTraceConfluence$^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{MetaCICNormalizationFrontier}^{\uparrow} \longmapsto T, R, N, D, C, B \longmapsto H, E, P, L.$$

If the consumer claims full parallel diamond, it must display the substitution-compatibility input in R. If it claims full closed star confluence, it must display the closed-diamond input in D. Otherwise the blocked-premise row B remains part of the exported handoff.

Proof. Start from the frontier row F. It places the proof-trace read after the critical-path and normalization-frontier surfaces, so a confluence-facing consumer receives a displayed route rather than a detached theorem.

Apply Definition 8275.2. The residual visibility and closed-diamond visibility obligations force R or D to be present for the corresponding full confluence claim, while B records any retained premise.

The closed-normal fragment row N may discharge only its shape-limited cases. Transport, replay, provenance, and local naming then preserve the same finite handoff through H, E, P, L, and no absent global endpoint can be cited as if it were a packet field. □

Falsifiable prediction: Any proof-trace confluence route that claims full closed confluence while omitting both the substitution-compatibility input and the closed-diamond input is rejected by the ProofTraceConfluenceUp classifier.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, subjectreductiondischarge, normalformconsistencyseal: none is bijective because $\mathsf{ProofTraceConfluence}^{\uparrow}$ stores proof traces, residual-substitution premises, closed-normal fragments, conditional-diamond inputs, audit consumers, blocked premises, frontier rows, transport, replay, provenance, and local NameCert rows in one carrier. MetaCICCriticalPathUp records the critical route but not the confluence proof trace; MetaCICNormalizationFrontierUp records candidate and endpoint boundaries without the residual-substitution handoff; SubjectReductionDischargeUp addresses typing preservation rather than confluence joins; NormalFormConsistencySealUp seals endpoint consistency without displaying the conditional confluence inputs.

The Lean follow-up must provide `Nontrivial ProofTraceConfluenceUp` and `FieldFaithful ProofTraceConfluenceUp` instances that preserve $T, R, N, D, C, B, F, H, E, P, L$ without discharging the retained confluence premises by definition.

Closure status for $\mathsf{NameCert}_{\mathsf{ProofTraceConfluence}^{\uparrow}}$.

Constructive story: A $\mathsf{ProofTraceConfluence}^{\uparrow}$ packet is generated from proof-trace rows, residual-substitution premises, closed-normal fragments, conditional-diamond inputs, confluence-audit consumers, blocked-premise rows, MetaCIC frontier rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ProofTraceConfluence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8275.1, Definition 8275.2, and Definition 8275.3 seed the proof-trace confluence route while retaining substitution and closed-diamond premises.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ProofTraceConfluence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, full arbitrary closed confluence, unrestricted residual substitution, subject reduction, quotient syntax equality, evaluator soundness, or unsealed normal-form consistency.

Upgrade path: Obligation closure requires checked carrier admission, residual visibility, closed-diamond visibility, closed-normal fragment separation, frontier handoff, audit handoff, and non-escape for BEDC.Derived.ProofTraceConfluenceUp.

Chapter 8276

A Concrete Naming Certificate for $\mathsf{CousinIProblem}^{\uparrow}$

Following Cousin and Cartan, the $\mathsf{CousinIProblem}^{\uparrow}$ packet records the first Cousin problem as finite local principal divisor data over an analytic cover. It sits beside the holomorphic source of chapter 68, the complex analytic boundary of chapter 76, the sheaf gluing surface of chapter 151, the sheafification packet of chapter 7336, and the analytic-set certificate of chapter 8008. The packet names local meromorphic-principal rows, overlap cocycle rows, obstruction rows, and local readback rows without importing a host Stein theorem, global divisor selector, quotient sheaf cohomology class, or ambient choice principle.

Definition 8276.1 (Cousin I problem carrier)**.** *A* $\mathsf{CousinIProblem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, U, F, O, Z, Q, G, H, R, P, N)$$

with the following visible rows:

1. *X is the complex analytic source row, read through the* $\mathsf{CplxAnalytic}^{\uparrow}$ *and* $\mathsf{Holomorphic}^{\uparrow}$ *neighbourhood surfaces;*
2. *U is the finite cover row listing the inspected analytic opens and their overlap windows;*
3. *F is the local meromorphic-principal family row, recording one displayed principal datum on each member of U;*
4. *O is the overlap-difference row, recording the holomorphic comparison on each inspected pairwise overlap;*
5. *Z is the obstruction row, separating vanishing local coboundary data from a still-visible nonzero cocycle boundary;*
6. *Q is the sheaf and sheafification route row through which local sections and overlap comparisons are read;*
7. *G is the local principal readback row, available only for windows whose obstruction coordinate in Z is displayed as vanishing;*
8. *H records componentwise* hsame *transport for X, U, F, O, Z, Q, G and the local structural rows;*
9. *R records displayed* Cont *replay for cover restriction, overlap comparison, sheaf routing, and local readback;*

10. *P is the* Pkg *provenance over* $\mathsf{CousinIProblem}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{CplxAnalytic}^{\uparrow}$, $\mathsf{Sheaf}^{\uparrow}$, $\mathsf{Sheafification}^{\uparrow}$, $\mathsf{AnalyticSet}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CousinIProblem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, U, F, O, Z, Q, G, H, R, P, N$. It has no coordinate for a selected global meromorphic function, host sheaf cohomology quotient, Stein vanishing theorem, unrestricted refinement choice, or ambient analytic continuation oracle.

Theorem 8276.2 (Cousin I problem NameCert obligations)**.** *For every accepted* $\mathsf{CousinIProblem}^{\uparrow}$ *carrier $K = (X, U, F, O, Z, Q, G, H, R, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CousinIProblem}^{\uparrow}}$ *surface consists exactly of carrier admission for the analytic source, finite cover, local principal family, overlap-difference, obstruction, sheaf-route, and local readback rows; overlap compatibility for O over the cover row U; obstruction persistence for Z; componentwise* hsame *transport through H; displayed* Cont *replay through R; provenance through P; and local naming through N.*

Consequently a consumer cannot replace the visible obstruction row by a host Cartan theorem, a hidden Stein-space hypothesis, a selected global divisor, quotient equality of cohomology classes, or countable-choice refinement data.

Proof. Project the carrier of Definition 8276.1. The rows $X, U, F, O, Z, Q, G, H, R, P, N$ are the complete local certificate surface, so admission and classifier comparison are componentwise reads from the finite packet.

Read the analytic and sheaf routes next. The holomorphic, complex analytic, sheaf, sheafification, and analytic-set sibling chapters supply the named source and local-section surfaces, while U, F, O, Q record only the inspected cover, local principal data, overlap comparisons, and sheaf route.

Finally inspect Z, G, H, R, P, N. The obstruction row is stored before any local principal readback is exported, and G is available only through that displayed boundary. Transport, replay, provenance, and naming preserve these rows rather than creating a global meromorphic selector or a host cohomology quotient. □

Theorem 8276.3 (Cousin I problem local principal readback)**.** *Every accepted* $\mathsf{CousinIProblem}^{\uparrow}$ *consumer that reads a local principal solution on an inspected analytic window must first display the route*

$$\mathsf{Holomorphic}^{\uparrow}, \quad \mathsf{CplxAnalytic}^{\uparrow}, \quad U, \quad F, \quad O, \quad Z, \quad Q$$

inside the carrier of Definition 8276.1. The readback row G may be consumed only after the obstruction coordinate in Z is displayed for that window, and it exports a local principal read rather than a global solution of the first Cousin problem.

Proof. Start with the NameCert obligations of Definition 8276.2. They force the consumer to expose the analytic source, cover row, local principal family, overlap-difference row, obstruction row, and sheaf route before local naming.

Use the sibling routes for the source data. Holomorphic and complex analytic rows provide the local analytic windows; the sheaf and sheafification rows provide the local-section and restriction discipline; and the analytic-set row records the divisor-facing support boundary.

The local readback row G is therefore downstream of Z and Q. Since the carrier contains no global selector, quotient cohomology class, Stein vanishing theorem, or refinement-choice coordinate, a consumer can read only the displayed local principal row and cannot infer a detached global Cousin solution. □

Falsifiable prediction: Every accepted $\mathsf{CousinIProblem}^{\uparrow}$ read exposes a complex analytic source, finite analytic cover, local meromorphic-principal family, holomorphic overlap-difference row, obstruction row, sheaf route, local principal readback row when available, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: holomorphic, complex-analytic, sheaf, sheafification, analytic-set: none is bijective to $\mathsf{CousinIProblem}^{\uparrow}$ because this packet jointly binds the analytic cover, local principal family, overlap-difference cocycle, obstruction row, sheaf route, conditional local readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CousinIProblem}^{\uparrow}}$.

Constructive story: A $\mathsf{CousinIProblem}^{\uparrow}$ packet is generated from complex analytic source rows, a finite analytic cover, local meromorphic-principal rows, holomorphic overlap-difference rows, an obstruction row, a sheaf route, local principal readback rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CousinIProblem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8276.1, Definition 8276.2, and Definition 8276.3 seed the finite Cousin I problem route over holomorphic, complex analytic, sheaf, sheafification, analytic-set, obstruction, local readback, hsame, Cont, Pkg, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CousinIProblem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Stein vanishing, global meromorphic solution selection, host sheaf cohomology quotients, unrestricted analytic continuation, countable choice, Lean verification, or bridge checking for $\mathsf{CousinIProblem}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, cover compatibility, overlap-difference exactness, obstruction persistence, local principal readback, sheaf-route provenance, transport, replay, and local naming for BEDC.Derived.CousinIProblemUp.

Chapter 8277

A Concrete Naming Certificate for $\mathsf{LocatedRealCauchyBoundary}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{LocatedRealCauchyBoundary}^{\uparrow}$ packet records the finite boundary at which a located Cauchy presentation can be inspected before a $\mathsf{Real}^{\uparrow}$ readback is sealed. It sits beside the stream-name source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the located completion embedding of chapter 7471, and the finite-prefix stream certificate of chapter 7253. The packet names a boundary object for displayed finite means; it is not quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8277.1 (LocatedRealCauchyBoundary carrier)**.** *A* $\mathsf{LocatedRealCauchyBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (\rho, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *ρ is the located-radius row, naming the dyadic tolerance radius and the finite comparison window used for the boundary read;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the finite stream window that supplies the observed approximants;*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row carrying the regular rational readback of the displayed stream window;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row that records the dyadic arithmetic, radius comparison, and tolerance ledger;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, R, and D have been displayed;*
6. *H records componentwise* hsame *transport for the located-radius, stream, regular rational, dyadic, real-seal, package, and local naming rows;*
7. *C records the displayed* Cont *routes for finite-prefix inspection, located-radius tightening, regular-rational readback, dyadic comparison, and Real-facing seal handoff;*
8. *P is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *chapter 7471, chapter 7253,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyBoundary}^{\uparrow}}$ *row.*

Theorem 8277.2 (LocatedRealCauchyBoundary NameCert obligations)**.** *For every accepted* LocatedRealCauchyBo *carrier* $B = (\rho, S, R, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyBoundary}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located-radius exposure through* ρ*, finite StreamName inspection through* S*, regular rational readback through* R*, dyadic tolerance accounting through* D*, Real seal readback through* E*, componentwise transport through* H*, displayed route replay through* C*, package provenance through* P*, and local naming through* N*. It exports no quotient stream, selected limit, countable choice, host real equality, or ambient completeness principle.*

Proof. Project the carrier of Definition 8277.1. The only rows available to a consumer are $\rho, S, R, D, E, H, C, P, N$, so carrier admission is finite packet admission rather than admission to a completed ambient real line.

Read the Cauchy-facing evidence next. The stream source is named by S, regular rational readback by R, and dyadic tolerance comparison by D. The located-radius row ρ binds the finite comparison window before the $\mathsf{Real}^{\uparrow}$ seal row E can be inspected.

Finally use the structural rows. The transport row H preserves the same displayed coordinates, the continuation row C replays finite-prefix and seal handoff routes, and P, N package and name the packet. Since no row stores quotient stream equality, selected limits, countable choice, host equality, or ambient completeness, the local NameCert surface is exactly the listed finite boundary. □

Theorem 8277.3 (LocatedRealCauchyBoundary Real handoff)**.** *Every Real-facing read of an accepted* $\mathsf{LocatedRealCauchyBoundary}^{\uparrow}$ *carrier must pass through the located-radius row* ρ*, the* $\mathsf{StreamName}^{\uparrow}$ *row* S*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row* D*, the* $\mathsf{Real}^{\uparrow}$ *seal row* E*, and the displayed structural rows* H, C, P, N*. The handoff may cite the located completion embedding and finite-prefix stream certificate, but it cannot replace the boundary by a quotient stream, a selected limit, a hidden representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the finite-prefix side. The row S is the only stream-name coordinate, and the finite-prefix stream certificate supplies the discipline that a consumer reads displayed windows rather than an infinite stream quotient.

Next pass through the regular and dyadic rows. The row R carries the regular rational readback, while D records the dyadic tolerance comparison against the located-radius row ρ. The Bishop located completion embedding can therefore be cited only through those displayed rows.

The Real-facing seal is last. The row E is reached through the continuation row C after the preceding finite evidence has been exposed, and H, P, N preserve, package, and name the same packet. Thus the handoff exports a finite Real-readback boundary, not a selected completed point or an ambient completeness theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealCauchyBoundary}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealCauchyBoundary}^{\uparrow}$ packet is generated from a located-radius row, finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance accounting, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transports, displayed Cont routes, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealCauchyBoundary}^{\uparrow}}$, seed)

Scope closed: Definition 8277.1, Definition 8277.2, and Definition 8277.3 seed the finite located Cauchy boundary and its Real-facing handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealCauchyBoundary}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient Cauchy streams, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-radius exposure, finite-prefix inspection, regular rational readback, dyadic tolerance accounting, Real seal handoff, and non-escape for the displayed packet.

Chapter 8278

A Concrete Naming Certificate for $\mathsf{SequentialArchimedeanReal}^{\uparrow}$

Following Bishop and Bridges on real-number names and explicit Archimedean bounds, the SequentialArchimedeanR packet records the finite sequential request that turns a displayed $\mathsf{Real}^{\uparrow}$ name into a witnessed rational or dyadic bound for a requested observation index. It sits over the natural-number request surface of chapter 28, the rational and dyadic witness surfaces of chapter 37 and chapter 291, the finite stream-window discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a sequential Archimedean handoff; it is not trichotomy, a Dedekind cut, quotient representative selection, countable choice, or a completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 8278.1 (Sequential Archimedean real carrier)**.** *A* $\mathsf{SequentialArchimedeanReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, i, Q, D, W, G, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *name whose sequential Archimedean bound is being requested.*
2. *i is the unary* $\mathsf{Nat}^{\uparrow}$ *index row naming the requested observation and bound scale.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *witness row exporting the rational bound visible at that request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *witness row presenting the same bound in the dyadic scale consumed by finite windows.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window opened at the displayed index and bound request.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after i, Q, D, W, G have been displayed.*
8. *H records componentwise* hsame *transport for the real name, index request, rational witness, dyadic witness, finite window, regular readback, Real seal, continuation, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the unary request through the StreamName window, RegSeqRat readback, rational and dyadic witnesses, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{SequentialArchimedeanReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanReal}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $R, i, Q, D, W, G, E, H, C, P, N$. It has no coordinate for trichotomy, Dedekind cuts, quotient representatives, countable-choice schedules, selected completed streams, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialArchimedeanRealUp.SequentialArchimedeanRealTasteGate single carrier alignment`

Theorem 8278.2 (Sequential Archimedean real NameCert obligations)**.** *For every accepted* SequentialArchimedean *carrier*

$$S = (R, i, Q, D, W, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanReal}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real name, unary index request, rational witness, dyadic witness, finite window, regular readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows; request compatibility binding i to the same window W that produces G; rational-dyadic witness coherence binding Q and D to the same sequential bound; Real-seal ordering requiring E to be read only after i, Q, D, W, G; and non-escape excluding trichotomy, Dedekind cuts, quotient representatives, countable choice, selected completed streams, and ambient Real completeness.*

Proof. Project the carrier of Definition 8278.1. The rows $R, i, Q, D, W, G, E, H, C, P, N$ are the complete packet inventory, so carrier admission has no hidden coordinate.

The request compatibility clause follows from the order of the rows. The unary $\mathsf{Nat}^{\uparrow}$ request i opens the $\mathsf{StreamName}^{\uparrow}$ window W, and the $\mathsf{RegSeqRat}^{\uparrow}$ readback G is extracted from that same finite window before any Real-facing seal is available.

The rational and dyadic witnesses are read together. The $\mathsf{Rat}^{\uparrow}$ row Q and $\mathsf{DyadicRatCore}^{\uparrow}$ row D describe one displayed sequential bound for R at the request i, transported componentwise through H and replayed through C.

Finally the Real seal and non-escape clauses use the absence of further coordinates. Since E is the only terminal $\mathsf{Real}^{\uparrow}$ seal and the packet contains no trichotomy branch, Dedekind cut, quotient representative, countable-choice schedule, selected completed stream, or completeness object, every accepted consumer remains inside the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{SequentialArchimedeanReal}^{\uparrow}$ Real-facing read exposes a RealUp name, a NatUp unary request, RatUp and DyadicRatCoreUp bound witnesses, a StreamNameUp finite window, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before using the sequential Archimedean handoff.

Independence witness: real, nat, rat, dyadicratcore, streamname, regseqrat: $\mathsf{SequentialArchimedeanReal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a unary sequential request, rational and dyadic bound witnesses, finite stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming while refusing trichotomy, Dedekind cuts, quotient representatives, countable choice, selected completed streams, and Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanReal}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialArchimedeanReal}^{\uparrow}$ packet is generated from a RealUp name, a NatUp unary request, RatUp and DyadicRatCoreUp witness rows, a StreamNameUp finite window, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SequentialArchimedeanReal}^{\uparrow}}$, seed)

Scope closed: Definition 8278.1 and Definition 8278.2 seed the finite sequential Archimedean bound route over explicit index requests, rational and dyadic witnesses, finite windows, regular readbacks, and RealUp seals.

Formal verification: FormalStatus(NameCert$_{\mathsf{SequentialArchimedeanReal}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close trichotomy, Dedekind cuts, quotient representatives, countable choice, selected completed streams, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request compatibility, rational-dyadic witness coherence, Real-seal ordering, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.SequentialArchimedeanRealUp.

Chapter 8279

A Concrete Naming Certificate for $\mathsf{RealOrderWindow}^{\uparrow}$

Following Bishop and Bridges constructive analysis, $\mathsf{RealOrderWindow}^{\uparrow}$ records a finite comparison-window certificate over chapter 38, chapter 126, chapter 301, chapter 291, and chapter 7489. It is a local order-read packet for a displayed $\mathsf{Real}^{\uparrow}$ name, not a trichotomy principle, quotient stream equality test, selected supremum, host real equality, or ambient completeness theorem.

Definition 8279.1 (Real order window carrier)**.** *A* $\mathsf{RealOrderWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, S, Q, D, L, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the sealed* $\mathsf{Real}^{\uparrow}$ *row whose order-facing read is being inspected.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row attached to the inspected comparison request.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same visible window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the dyadic comparison radius and endpoint arithmetic.*
5. *L is the lower comparison row exposed through D, S, Q.*
6. *U is the upper comparison row exposed through the same D, S, Q route.*
7. *H records componentwise* hsame *transport for $X, S, Q, D, L, U, C, P, N$.*
8. *C records displayed* Cont *replay from the finite comparison request through the readback, tolerance, lower, upper, seal, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{RealOrderWindow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RealArchimedeanWindow}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RealOrderWindow}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, S, Q, D, L, U, H, C, P, N$. It has no coordinate for trichotomy, host real equality, quotient stream equality, selected suprema, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8279.2 (Real order window NameCert obligations)**.** *For every accepted* $\mathsf{RealOrderWindow}^{\uparrow}$ *carrier* $R = (X, S, Q, D, L, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RealOrderWindow}^{\uparrow}}$ *surface consists exactly of carrier admission, sealed* $\mathsf{Real}^{\uparrow}$ *exposure through* X*, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exactness through* D*, lower and upper comparison exposure through* L, U*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8279.1. The accepted packet exposes the real seal X, finite observation window S, regular readback Q, dyadic tolerance ledger D, and the two comparison rows L, U before any structural row is consumed.

The lower and upper rows are not independent order primitives. They are read only after D, S, Q have fixed the dyadic tolerance, inspected window, and regular rational readback for the same sealed real row.

The support rows H, C, P, N transport, replay, source, and name exactly that displayed route. Since the carrier contains no coordinate for trichotomy, host real equality, quotient stream equality, selected suprema, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8279.3 (Real order window Archimedean handoff)**.** *Every order-facing* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealOrderWindow}^{\uparrow}$ *packet must pass through the* $\mathsf{RealArchimedeanWindow}^{\uparrow}$ *surface of chapter 7489 before it uses the lower and upper comparison rows* L, U*. The exported order read is therefore the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RealArchimedeanWindow}^{\uparrow} \longmapsto \mathsf{RealOrderWindow}^{\uparrow},$$

and it exports no trichotomy, host real equality, quotient stream equality, selected supremum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier rows $X, S, Q, D, L, U, H, C, P, N$. The rows L, U are downstream from the same dyadic tolerance ledger, finite stream window, and regular rational readback that expose the sealed real row X.

Now read the Archimedean window cited in P. Its bracketing surface supplies the finite lower-and-upper window through $\mathsf{RealArchimedeanWindow}^{\uparrow}$ before a consumer may interpret L, U as order-facing comparison rows.

The remaining rows H, C, P, N preserve the same handoff. Because neither the carrier nor the Archimedean handoff contains a coordinate for trichotomy, quotient stream equality, selected suprema, host real equality, or ambient completeness, the order consumer receives only the finite comparison-window certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RealOrderWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealOrderWindow}^{\uparrow}$ packet is generated from a sealed Real row, a finite StreamName window, RegSeqRat readback, a DyadicRatCore tolerance ledger, lower and upper comparison rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealOrderWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8279.1, Definition 8279.2, and Definition 8279.3 seed the finite comparison-window surface for order-facing Real reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealOrderWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, host real equality, quotient stream equality, selected suprema, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, dyadic tolerance exactness, Real seal non-escape, Archimedean handoff, transport, replay, provenance, and local naming for BEDC.Derived.RealOrderWindowUp.

Chapter 8280

A Concrete Naming Certificate for $\mathsf{ClarksonInequality}^{\uparrow}$

Following Clarkson's inequalities for Lp spaces and the Bishop–Bridges finite-norm reading, the $\mathsf{ClarksonInequality}^{\uparrow}$ packet records the displayed convexity inequality surface by which an L^p norm comparison produces a uniform-convexity route. It sits between the $\mathsf{LpSpace}^{\uparrow}$ carrier of chapter 8060, the modulus route of chapter 6689, the uniformly convex consumer of chapter 5831, and the terminal scalar comparisons of chapter 38. The packet names only finite norm-window rows, conjugate-exponent comparison rows, midpoint-drop rows, Real tolerance seals, transport, replay, provenance, and local naming data; it does not import host Banach-space equality, selected extremizers, measure-theoretic quotient equality, or a completed ambient Clarkson theorem.

Definition 8280.1 (Clarkson inequality carrier)**.** *A* $\mathsf{ClarksonInequality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (L, N, E, M, D, R, T, Q, P, A)$$

with the following displayed rows:

1. *L is the inspected* $\mathsf{LpSpace}^{\uparrow}$ *row, including the finite norm windows for the two displayed vectors.*
2. *N is the norm-comparison row that reads $\|x+y\|$, $\|x-y\|$, $\|x\|$, and $\|y\|$ only through the local L^p windows.*
3. *E is the exponent ledger separating the $1 < p \leq 2$ and $2 \leq p < \infty$ Clarkson regimes as finite case data.*
4. *M is the midpoint-drop row that packages the inequality output as a modulus-facing convexity witness.*
5. *D is the* $\mathsf{ModulusOfConvexity}^{\uparrow}$ *handoff row that records the extracted tolerance budget.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the scalar comparisons and tolerance inequalities.*
7. *T records componentwise* hsame *transport for L, N, E, M, D, R.*
8. *Q records displayed* Cont *replay for the norm-window, exponent, midpoint, modulus, and Real-seal reads.*
9. *P is the* Pkg *provenance over* $\mathsf{ClarksonInequality}^{\uparrow}$, $\mathsf{LpSpace}^{\uparrow}$, $\mathsf{ModulusOfConvexity}^{\uparrow}$, $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
10. *A is the local* $\mathsf{NameCert}_{\mathsf{ClarksonInequality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and has no coordinate for host norm equality, selected extremizers, quotient classes of functions, or an ambient Banach-space completion theorem.

Lean4 (statement) `BEDC.Derived.ClarksonInequalityUp`

Theorem 8280.2 (Clarkson inequality NameCert obligations)**.** *For every accepted* $\mathsf{ClarksonInequality}^{\uparrow}$ *carrier*

$$C = (L, N, E, M, D, R, T, Q, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{ClarksonInequality}^{\uparrow}}$ *surface consists exactly of carrier admission for the* L^p *row, norm-window comparison, exponent-regime ledger, midpoint-drop witness, modulus handoff, Real tolerance seal, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming. No obligation row is stored outside the displayed packet.*

Proof. Project the carrier of Definition 8280.1. The rows $L, N, E, M, D, R, T, Q, P, A$ are the complete inspection surface, so admission and classifier comparison are componentwise reads from the finite packet.

Read the analytic content through the sibling rows. The $\mathsf{LpSpace}^{\uparrow}$ row supplies the inspected norm windows, E selects the finite Clarkson regime, N records the displayed norm comparisons, and M packages the resulting midpoint drop.

The modulus and scalar routes are downstream. Row D hands the drop to $\mathsf{ModulusOfConvexity}^{\uparrow}$, row R seals the scalar tolerance through $\mathsf{Real}^{\uparrow}$, and T, Q, P, A only transport, replay, source, and name this displayed route. Since none of the rows contains a host equality of functions, a selected extremizer, a quotient norm class, or an ambient completion theorem, the listed clauses exhaust the local obligations. □

Theorem 8280.3 (Clarkson inequality uniform-convexity route)**.** *Every* $\mathsf{ClarksonInequality}^{\uparrow}$ *packet that exports a uniform-convexity read must first expose the route*

$$\mathsf{LpSpace}^{\uparrow}, \quad \mathsf{ClarksonInequality}^{\uparrow}, \quad \mathsf{ModulusOfConvexity}^{\uparrow}, \quad \mathsf{UniformlyConvexSpace}^{\uparrow}, \quad \mathsf{Real}^{\uparrow}$$

inside the finite carrier of Definition 8280.1. The exported object is a modulus-facing convexity witness for the inspected L^p *windows, not a host-level proof of Banach-space uniform convexity.*

Proof. Start from the NameCert obligations of Definition 8280.2. They force the consumer to expose the L^p norm windows, exponent-regime row, midpoint-drop row, modulus handoff, and Real tolerance seal before local naming.

The uniformly convex read is therefore downstream of the displayed Clarkson packet. The $\mathsf{ModulusOfConvexity}^{\uparrow}$ row receives the finite drop witness, and the $\mathsf{UniformlyConvexSpace}^{\uparrow}$ row consumes that witness only after the Real tolerance comparisons have been sealed.

Nothing in the carrier provides host norm equality, selected extremizers, quotient function equality, or an ambient completed Banach theorem. The route exports exactly the finite modulus-facing witness displayed by the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClarksonInequality}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ClarksonInequality}^{\uparrow}$ packet is generated from an Lp-space row, norm-window comparison row, exponent-regime ledger, midpoint-drop witness, modulus handoff, Real tolerance seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClarksonInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8280.1, Definition 8280.2, and Definition 8280.3 seed the finite Clarkson inequality route over $\mathsf{LpSpace}^{\uparrow}$, $\mathsf{ModulusOfConvexity}^{\uparrow}$, $\mathsf{UniformlyConvexSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ClarksonInequality}^{\uparrow}}$, formalTarget)
Lean target: `BEDC.Derived.ClarksonInequalityUp`
Bridge status: none
Not claimed: This chapter does not close host Banach-space equality, selected extremizers, quotient equality of functions, measure-theoretic completion, theorem checking, axiom-clean audit, or bridge checking for ClarksonInequality$^{\uparrow}$.
Upgrade path: Obligation closure requires checked carrier admission, norm-window exactness, exponent-regime stability, midpoint-drop extraction, modulus handoff, Real tolerance sealing, transport, replay, provenance, and local naming for BEDC.Derived.ClarksonInequalityUp.

Chapter 8281

A Concrete Naming Certificate for $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy construction may glue local modulus schedules only after their overlap requests, dyadic tolerance rows, and regular-rational readbacks are visible. The $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ packet records that finite semilocal modulus surface for L10 Real-and-Completion consumers. It sits between the minimum-modulus route of chapter 5544 and the gluing route of chapter 5899, while still reading the finite $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and terminal $\mathsf{Real}^{\uparrow}$ seal before any glued Cauchy route is exported. The packet names a displayed semilocal modulus ledger, not quotient stream equality, selected representatives, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8281.1 (Semilocal regular Cauchy modulus carrier)**.** *A* $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, V, O, M, G, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *U and V are the two local regular-Cauchy modulus schedules whose overlap is being compared.*
2. *O is the semilocal overlap ledger, naming the finite region on which the two schedules are jointly visible.*
3. *M is the* $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ *row that displays the common request budget used on the overlap.*
4. *G is the* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *source row waiting to consume the semilocal modulus budget.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened by the common request budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same displayed windows.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger comparing the local schedules, overlap row, and common request budget.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after U, V, O, M, G, W, R, D have been displayed.*
9. *H records componentwise* hsame *transport for the local schedules, overlap, common budget, gluing source, windows, readback, dyadic ledger, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from a Real-and-Completion request through* $U, V, O, M, G, W, R, D, E, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyMinModulus}^{\uparrow}$, $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, a selected common representative, countable choice over local neighborhoods, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8281.2 (Semilocal regular Cauchy modulus NameCert obligations)**.** *For every accepted* $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ *carrier*

$$S = (U, V, O, M, G, W, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the two local modulus schedules, semilocal overlap ledger, minimum-modulus request budget, gluing source row, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise transport, displayed replay, package provenance, local naming, and non-escape from quotient stream equality, selected representatives, countable choice, host equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8281.1. The local schedules are U, V, and the semilocal overlap row is O.

The common request budget is read through M. By the sibling minimum-modulus chapter chapter 5544, that row is a displayed finite schedule rather than a selected representative or choice functional.

The gluing-facing obligation is then G, W, R, D, E. The gluing row waits until the finite windows, regular readback, dyadic tolerance ledger, and terminal Real seal are visible, matching the L10 dependency route of chapter 5899.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier omits quotient stream equality, selected representatives, countable choice, host equality, and ambient completeness, the displayed rows exhaust the local NameCert surface. □

Theorem 8281.3 (Semilocal regular Cauchy modulus gluing scope)**.** *Every gluing consumer of an accepted* $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ *packet must read the finite route*

$$U, V, O \longmapsto M, D \longmapsto G, W, R \longmapsto E \longmapsto H, C, P, N.$$

Thus the semilocal modulus data may feed $\mathsf{RegularCauchyGluing}^{\uparrow}$ *only through the displayed overlap, minimum-modulus, dyadic tolerance, finite-window, regular-readback, and Real-seal rows. It does not export quotient stream equality, selected common representatives, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $S = (U, V, O, M, G, W, R, D, E, H, C, P, N)$. The two local schedules and the semilocal overlap row are the only local inputs visible to a consumer.

Apply the obligation theorem above. It forces the common request budget to pass through M and the dyadic comparisons to pass through D before any gluing row is consumed.

The gluing read is then G, W, R, E, with the finite windows and regular-rational readback exposed before the terminal Real seal. The structural rows H, C, P, N keep this route attached to the same packet, so none of the excluded quotient, choice, host-equality, or completeness coordinates can be projected from the carrier. □

Falsifiable prediction: A Real-and-Completion consumer that cites a semilocal regular-Cauchy modulus for gluing without displaying $U, V, O, M, G, W, R, D, E, H, C, P, N$ is not reading a SemilocalRegularCauchy packet.

Independence witness: regularcauchyminmodulus, regularcauchygluing, streamname, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ because this packet jointly carries two local modulus schedules, a semilocal overlap ledger, a common request budget, a gluing source row, finite windows, regular readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}$ packet is generated from two local regular-Cauchy modulus schedules, a semilocal overlap ledger, a RegularCauchyMinModulus common request row, a RegularCauchyGluing source row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8281.1, Definition 8281.2, and Definition 8281.3 seed the finite semilocal modulus route consumed by regular-Cauchy gluing and Real-facing completion readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SemilocalRegularCauchyModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, quotient stream equality, selected representatives, countable choice, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, semilocal overlap exactness, minimum-modulus compatibility, gluing-source routing, StreamName and RegSeqRat readback, dyadic tolerance comparison, Real sealing, transport, replay, provenance, and nonescape for BEDC.Derived.SemilocalRegularCauchyModulusUp.

Chapter 8282

A Concrete Naming Certificate for $\mathsf{CauchyBoundSelector}^{\uparrow}$

Following Bishop and Bridges constructive analysis, $\mathsf{CauchyBoundSelector}^{\uparrow}$ records the finite tail-bound selection surface needed by L10 completion routes without invoking countable choice or a host-side least-bound oracle. It sits over the stream, regular-rational, dyadic, real, and signed-interval packets of chapter 126, chapter 301, chapter 291, chapter 38, and chapter 8197. The packet exports an explicit bounded-tail window for later diagonal-limit and completeness arguments; it does not claim located suprema, quotient stream equality, a choice principle for all Cauchy predicates, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8282.1 (Cauchy bound selector carrier)**.** *A* $\mathsf{CauchyBoundSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, Q, D, R, I, W, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row whose finite tail windows are inspected.*
2. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same stream window.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger naming the dyadic radius, comparison budget, and endpoint arithmetic used by the tail request.*
4. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *row reached by the regular-rational readback when the tail window is accepted.*
5. *I is the* $\mathsf{SignedDyadicInterval}^{\uparrow}$ *bound row recording the displayed lower and upper dyadic endpoints for the inspected tail.*
6. *W is the selected tail-window row, consisting of a finite threshold name and the finite set of inspected windows that justify the displayed bound.*
7. *E is the exactness row asserting that the same S, Q, D, R, I data support the selected window W.*
8. *H records componentwise* hsame *transport for $S, Q, D, R, I, W, E, C, P, N$.*
9. *C records displayed* Cont *replay from the tail-bound request through S, Q, D, R, I, W, E and then to the support rows.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyBoundSelector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SignedDyadicInterval}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBoundSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, D, R, I, W, E, H, C, P, N$. It has no coordinate for a hidden choice function, least-index search over all predicates, quotient stream equality, located supremum, or ambient completeness theorem.

Lean4 ✓ `BEDC.Derived.CauchyBoundSelectorUp.CauchyBoundSelectorTasteGate single carrier alignment`

Theorem 8282.2 (Cauchy bound selector NameCert obligations)**.** *For every accepted* $\mathsf{CauchyBoundSelector}^{\uparrow}$ *carrier $B = (S, Q, D, R, I, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyBoundSelector}^{\uparrow}}$ *surface consists exactly of the following five public rows, each with structural transport, replay, provenance, and local naming attached:*

1. $\mathsf{StreamName}^{\uparrow}$ *window exposure through S;*
2. $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback through Q;*
3. $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and endpoint arithmetic through D;*
4. $\mathsf{Real}^{\uparrow}$ *seal exposure through R;*
5. $\mathsf{SignedDyadicInterval}^{\uparrow}$ *bounded-tail enclosure through I, together with selected window W and exactness row E.*

The packet therefore names an explicit bounded-tail selector for a displayed finite Cauchy route, not a global countable-choice principle or a host-side least-bound operator.

Lean4 ✓ `BEDC.Derived.CauchyBoundSelectorUp.CauchyBoundSelectorNamecertObligations`

Proof. Project the carrier of Definition 8282.1. The first five mathematical rows expose the stream name, regular rational readback, dyadic tolerance ledger, real seal, and signed dyadic interval before any selected window can be consumed.

The selected window W is not an independent oracle. It is accepted only together with the exactness row E, which binds the same S, Q, D, R, I data to the displayed finite threshold and inspected windows.

The support rows H, C, P, N transport, replay, source, and name exactly that route. Since no carrier coordinate stores a hidden choice function, a least-index search over all predicates, quotient stream equality, a located supremum, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8282.3 (Cauchy bound selector window stability)**.** *Let $B = (S, Q, D, R, I, W, E, H, C, P, N)$ and $B' = (S', Q', D', R', I', W', E', H', C', P', N')$ be accepted* $\mathsf{CauchyBoundSelector}^{\uparrow}$ *carriers. If the rows S, Q, D, R, I are componentwise* hsame *to S', Q', D', R', I' and both exactness rows read the same dyadic tolerance ledger, then the selected windows W and W' name the same bounded-tail enclosure up to componentwise* hsame*. Consequently a completion-facing consumer may transport the bounded-tail certificate across equal finite windows without acquiring a new choice principle.*

Proof. Read the two carriers through the NameCert obligations of Definition 8282.2. Both accepted packets expose the same stream, regular readback, dyadic tolerance ledger, real seal, and signed dyadic interval up to componentwise hsame before either selected window is available.

Use the exactness rows E and E'. Because they read the same dyadic tolerance ledger and the same displayed source rows, each selected threshold is justified by the same finite tail-bound request and the same signed dyadic enclosure.

The transport rows H, H' then carry this agreement to the selected-window coordinates, while C, C', P, P', N, N' replay and source only the displayed route. Thus the bounded-tail enclosure is stable under the stated finite-window transport, and the consumer receives no additional global selection principle. □

Lean4 ✓ `BEDC.Derived.CauchyBoundSelectorUp.CauchyBoundSelectorCarrier window stability`

Falsifiable prediction: Every accepted $\mathsf{CauchyBoundSelector}^{\uparrow}$ consumer that exports a bounded Cauchy tail must display the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{SignedDyadicInterval}^{\uparrow}$, selected-window, exactness, transport, replay, provenance, and local NameCert rows.

Independence witness: streamname, regseqrat, dyadicratcore, real, signed-dyadic-interval: no listed sibling is bijective to $\mathsf{CauchyBoundSelector}^{\uparrow}$ because this packet jointly binds a stream window, regular readback, dyadic tolerance, real seal, signed interval bound, selected finite threshold, exactness row, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBoundSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyBoundSelector}^{\uparrow}$ packet is generated from a StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, SignedDyadicInterval enclosure, selected finite threshold, exactness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBoundSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8282.1, Definition 8282.2, and Definition 8282.3 seed the explicit bounded-tail selection surface for L10 completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBoundSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, least-index search, quotient stream equality, located suprema, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName exposure, RegSeqRat readback, DyadicRatCore tolerance exactness, Real seal non-escape, SignedDyadicInterval bound exposure, selected-window stability, transport, replay, provenance, and local naming for BEDC.Derived.CauchyBoundSelectorUp.

Chapter 8283

A Concrete Naming Certificate for MetaCICConfluenceBudgetMatrix$^{\uparrow}$

The MetaCICConfluenceBudgetMatrix$^{\uparrow}$ packet realizes the budget-matrix frontier in section 9386.3 as finite NameCert data. It sits beside the residual-substitution boundary of chapter 2181, the confluence diamond ledger of chapter 6547, the residual local-diamond witness of chapter 8046, the residual-join budget of chapter 7378, and the parallel-diamond selector of chapter 7989. The packet records bounded residual-substitution, closed parallel-diamond, and arbitrary closed-star confluence frontiers in one matrix; it does not supply unconditional substitution compatibility, arbitrary closed-term Church–Rosser, global subject reduction, or kernel consistency.

Definition 8283.1 (MetaCIC confluence budget-matrix carrier)**.** *A* MetaCICConfluenceBudgetMatrix$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (T, R, D, S, J, B, O, L, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed closed-window row naming the inspected MetaCIC source, context boundary, and closedness budget.*
2. *R is the residual-substitution frontier row recording the substitution compatibility data that remain visible.*
3. *D is the closed parallel-diamond frontier row recording the bounded diamond premise or retained diamond obstruction.*
4. *S is the closed star-confluence frontier row recording the finite multi-step budget attached to the same source window.*
5. *J is the local-join scope row listing the candidate joins that are admitted inside the displayed matrix.*
6. *B is the budget matrix row aligning residual-substitution, parallel-diamond, and closed-star budgets by finite row and column names.*
7. *O is the obstruction row retaining the boundary names not discharged by R, D, S, J, B.*
8. *L is the Lean TasteGate obligation row, naming the later need for* Nontrivial MetaCICConfluenceBudgetMatrix$^{\uparrow}$ *and* FieldFaithful MetaCICConfluenceBudgetMatrix$^{\uparrow}$ *instances before a checked TasteGate theorem can read the matrix as a single carrier.*

9. *H records componentwise* hsame *transport for $T, R, D, S, J, B, O, L, C, P, N$.*
10. *C records displayed* Cont *replay from a confluence-frontier request through T, R, D, S, J, B, O, L and then to the structural rows.*
11. *P is the* Pkg *provenance over* MetaCICConfluenceBudgetMatrix$^{\uparrow}$, MetaCICResidualSubstitutionBoundary$^{\uparrow}$, MetaCICConfluenceDiamondLedger$^{\uparrow}$, MetaCICParallelDiamondSelector$^{\uparrow}$, MetacicResidualDiamondReadback$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{MetaCICConfluenceBudgetMatrix}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, R, D, S, J, B, O, L, H, C, P, N$. It has no coordinate for unconditional substitution compatibility, arbitrary closed-term Church–Rosser, a hidden confluence oracle, unbounded checker search, or kernel consistency.

Theorem 8283.2 (MetaCIC confluence budget-matrix NameCert obligations)**.** *For every accepted* MetaCICConfluenceBudgetMatrix$^{\uparrow}$ *carrier $M = (T, R, D, S, J, B, O, L, H, C, P, N)$, the local* NameCert$_{\text{MetaCICConfluenceBudgetMatrix}^{\uparrow}}$ *surface consists exactly of typed closed-window exposure through T, residual-substitution frontier exposure through R, closed parallel-diamond frontier exposure through D, closed star-confluence frontier exposure through S, local-join scope through J, finite budget-matrix alignment through B, obstruction retention through O, Lean TasteGate obligation naming through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8283.1. The source row T fixes the typed closed window before any confluence-facing frontier row can be read.

The rows R, D, S expose the three open confluence frontiers as visible data: residual-substitution compatibility, closed parallel diamond, and arbitrary closed-star confluence. The local-join row J and matrix row B align only finite candidate joins and finite row-column budgets for that same closed window.

The obstruction row O remains visible, so the matrix cannot erase a missing substitution-compatibility input or promote a bounded local join into arbitrary closed-term Church–Rosser. The TasteGate row L records that later Lean work must provide Nontrivial and FieldFaithful instances for this carrier before a checked gate can certify single-carrier alignment.

Finally, H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores an unconditional confluence theorem, hidden oracle, unbounded checker, or kernel-consistency endpoint, the listed rows exhaust the local NameCert obligations. □

Theorem 8283.3 (MetaCIC confluence budget-matrix local join scope)**.** *Every accepted* MetaCICConfluenceBudget *carrier that exports a local join from J must keep the typed closed-window row T, residual-substitution frontier R, closed parallel-diamond frontier D, closed star-confluence frontier S, budget matrix B, and obstruction row O visible on the same route. Thus a local join admitted by the matrix is scoped to the displayed finite budget and cannot be read as unconditional substitution compatibility, arbitrary closed-term Church–Rosser, or global subject reduction.*

Proof. Start with the carrier rows of Definition 8283.1. The local-join row J is displayed only together with the frontier rows R, D, S and the budget matrix B for the same typed closed window T.

Apply the NameCert obligations of Definition 8283.2. They force any confluence-facing read to expose the residual-substitution frontier, closed parallel-diamond frontier, closed star-confluence frontier, local-join scope, finite budget alignment, and obstruction retention before the structural rows can be consumed.

The obstruction row O prevents the matrix from hiding the conditional boundary around substitution compatibility. Transport through H, replay through C, provenance through P, and naming through N preserve only the displayed matrix route, so the exported local join remains scoped to the finite budget rather than becoming an unconditional confluence endpoint. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}$ consumer that exports a confluence-facing local join must display typed closed-window, residual-substitution frontier, closed parallel-diamond frontier, closed star-confluence frontier, finite budget-matrix, obstruction, TasteGate-obligation, transport, replay, provenance, and local NameCert rows.

Independence witness: metacic-residual-substitution-boundary, metacic-confluence-diamond-ledger, metacic-residual-local-diamond-witness, metacic-residual-join-budget, metacic-parallel-diamond-selector: no listed sibling is bijective to $\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}$ because this packet jointly carries the residual-substitution, closed parallel-diamond, closed star-confluence, local-join, finite matrix, obstruction-retention, TasteGate-obligation, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}$ packet is generated from a typed closed-window row, residual-substitution frontier, closed parallel-diamond frontier, closed star-confluence frontier, local-join scope, finite budget matrix, obstruction row, Lean TasteGate obligation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8283.1, Definition 8283.2, and Definition 8283.3 seed the finite budget-matrix frontier for MetaCIC confluence work.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICConfluenceBudgetMatrix}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unconditional substitution compatibility, arbitrary closed-term Church–Rosser, global subject reduction, unbounded checker search, Lean verification, bridge checking, or kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-substitution frontier exposure, closed parallel-diamond frontier exposure, closed star-confluence frontier exposure, local-join scope, budget-matrix alignment, obstruction retention, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICConfluenceBudgetMatrixUp.

Chapter 8284

A Concrete Naming Certificate for MetaCICCandidatePruningBudget$^{\uparrow}$

The MetaCICCandidatePruningBudget$^{\uparrow}$ packet realizes the audit-synthesis frontier of section 9385.6 as finite candidate-pruning data. It sits beside the residual-choice budget of chapter 8191, the candidate-normalization confluence handoff of chapter 5547, the residual diamond frontier of chapter 8111, and the normal-form consistency seal of chapter 740. The packet records bounded proof-search pruning as a displayed candidate ledger and checker budget; it does not assert global confluence, normalization, subject reduction, kernel consistency, or an unbounded proof-search oracle.

Definition 8284.1 (MetaCIC candidate-pruning budget carrier)**.** *A* MetaCICCandidatePruningBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, K, Q, R, C, O, H, J, P, N)$$

with the following displayed rows:

1. *T is the typed closed-window row naming the MetaCIC source fragment, context boundary, and closedness budget under inspection.*
2. *K is the candidate row listing the finite candidate proofs, terms, residual joins, or normal endpoints admitted for pruning.*
3. *Q is the pruning-budget row recording the finite fuel, rank, residual-depth, and branch-count limits used by the candidate search.*
4. *R is the residual-frontier row naming the remaining unpruned residual choices and the frontier routes shared with chapter 8191 and chapter 8111.*
5. *C is the bounded-checker row. It records the local checker that may inspect T, K, Q, R and reject a pruning read when the candidate row or checker budget is absent.*
6. *O is the obstruction row retaining the confluence, normalization, and subject-reduction boundaries not discharged by the bounded checker.*
7. *H records componentwise* hsame *transport for typed windows, candidates, pruning budget, residual frontier, bounded checker, obstruction, replay, provenance, and local naming rows.*
8. *J records displayed* Cont *replay from an audit-synthesis request through $T, K, Q, R, C, O, H, P, N$.*

9. *P is the* Pkg *provenance over* MetaCICCandidatePruningBudget$^{\uparrow}$, MetaCICResidualChoiceBudget$^{\uparrow}$, MetaCICParallelDiamondFrontier$^{\uparrow}$, MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$, NormalFormConsistencySe BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{MetaCICCandidatePruningBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, K, Q, R, C, O, H, J, P, N$. It has no coordinate for candidate-free pruning, unbounded checker search, global confluence, global normalization, subject reduction, or kernel consistency.

Theorem 8284.2 (MetaCIC candidate-pruning budget obligations)**.** *For every accepted* MetaCICCandidatePruning *carrier*

$$B = (T, K, Q, R, C, O, H, J, P, N),$$

the local NameCert$_{\text{MetaCICCandidatePruningBudget}^{\uparrow}}$ *surface consists exactly of typed closed-window exposure, candidate row exposure, pruning-budget exposure, residual-frontier exposure, bounded-checker exposure, obstruction retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from candidate-free pruning, unbounded checker search, global confluence, global normalization, subject reduction, and kernel consistency.*

Proof. Project the carrier of Definition 8284.1. The typed window T fixes the inspected closed fragment before any proof-search pruning read can be accepted.

The pruning data are K, Q, R, C. The candidate row K lists the finite objects being pruned, the budget row Q bounds the search, the residual-frontier row R retains the unpruned boundary, and the bounded checker C is the only local checker allowed to inspect that display.

The obstruction row O remains visible. It prevents a bounded pruning result from becoming global confluence, normalization, subject reduction, or kernel consistency.

Finally H, J, P, N transport, replay, source, and name the same finite route. Since no excluded endpoint is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8284.3 (MetaCIC candidate-pruning bounded checker rejection)**.** *Every accepted* MetaCICCandidatePru *pruning read must expose both the candidate row K and the bounded-checker row C on the same route as T, Q, R, O, H, J, P, N. A read that supplies a pruning budget without the candidate row and bounded checker is outside the classifier.*

Proof. Start from an accepted carrier $B = (T, K, Q, R, C, O, H, J, P, N)$. The classifier of Definition 8284.1 compares accepted packets only through the full displayed inventory, including K and C.

Apply the obligation theorem above. It makes candidate exposure and bounded-checker exposure separate mandatory NameCert clauses before the residual-frontier and pruning-budget rows can be consumed.

Therefore a read with Q but without K and C is not an accepted packet. Transport through H, replay through J, provenance through P, and naming through N preserve the same displayed route and do not add a hidden candidate or checker. □

The Lean boundary for this carrier must provide explicit Nontrivial MetaCICCandidatePruningBudget$^{\uparrow}$ and FieldFaithful MetaCICCandidatePruningBudget$^{\uparrow}$ instances before a checked TasteGate theorem may read the displayed rows $T, K, Q, R, C, O, H, J, P, N$ as one carrier.

Falsifiable prediction: A MetaCIC pruning read that lacks either the candidate row K or the bounded-checker row C is rejected by the MetaCICCandidatePruningBudget$^{\uparrow}$ classifier even when it names a pruning budget row.

Independence witness: metacic-proof-search-frontier, metacic-residual-choice-budget, metacic-parallel-diamond-frontier, metacic-candidate-normalization-confluence-handoff, normalformconsistencyseal: none is bijective to $\mathsf{MetaCICCandidatePruningBudget}^{\uparrow}$ because this packet jointly carries typed windows, candidates, pruning budgets, residual frontiers, bounded checker, obstruction retention, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCandidatePruningBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCandidatePruningBudget}^{\uparrow}$ packet is generated from a typed closed-window row, candidate row, pruning-budget row, residual-frontier row, bounded-checker row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCandidatePruningBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8284.1, Definition 8284.2, and Definition 8284.3 seed the finite candidate-pruning budget route for the MetaCIC audit-synthesis frontier.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCandidatePruningBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global confluence, normalization, subject reduction, kernel consistency, unbounded proof-search pruning, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, candidate exposure, pruning-budget exactness, residual-frontier exposure, bounded-checker rejection, obstruction retention, transport, replay, provenance, local naming, and TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICCandidatePruningBudgetUp.

Chapter 8285

A Concrete Naming Certificate for $\mathsf{FredholmOperator}^{\uparrow}$

Following Fredholm and Riesz operator theory, the $\mathsf{FredholmOperator}^{\uparrow}$ packet records the finite BEDC carrier by which a displayed bounded linear operator is read together with finite kernel, cokernel-facing obstruction, and index ledger rows. It sits after the bounded-operator surface of chapter 1644, the compact-operator route of chapter 1952, the Banach and Hilbert endpoint carriers of chapter 90 and chapter 91, and the alternative-facing consumer of chapter 3425. The packet supplies the operator/index dependency read by downstream index arguments such as chapter 273; it does not import a host quotient cokernel, selected complement, ambient index equality, spectral decomposition, Lean verification, or bridge checking.

Definition 8285.1 (Fredholm operator carrier)**.** *A* $\mathsf{FredholmOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Y, B, K, E, C, I, A, H, R, P, N)$$

with the following displayed rows:

1. *X is the source endpoint row, read through a displayed* $\mathsf{Banach}^{\uparrow}$ *carrier and, when orthogonal data are present, a compatible* $\mathsf{Hilbert}^{\uparrow}$ *carrier.*
2. *Y is the target endpoint row, read through the same Banach or Hilbert endpoint discipline.*
3. *B is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row naming the displayed linear action and norm-bound ledger from X to Y.*
4. *K is the kernel row, recording the finite kernel witness, finite-dimensional-kernel ledger, or explicit kernel-refusal boundary for B.*
5. *E is the cokernel-facing obstruction row, recording finite codimension evidence, range-defect data, or a displayed refusal to pass to a host quotient.*
6. *C is the* $\mathsf{CompactOperator}^{\uparrow}$ *compatibility row, available when the Fredholm read is consumed through a compact perturbation or compact remainder route.*
7. *I is the index ledger row, recording only the displayed difference between the kernel side K and the cokernel-facing side E as BEDC data.*
8. *A is the* $\mathsf{FredholmAlternative}^{\uparrow}$ *handoff row, exposing the same kernel-or-obstruction boundary when an alternative-facing consumer reads the operator.*

9. *H records componentwise* hsame *transport for endpoint, bounded-action, kernel, cokernel-facing, compactness, index, and handoff rows.*
10. *R records displayed* Cont *replay from endpoint admission through bounded action, kernel/cokernel-facing exposure, index readback, and handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{FredholmOperator}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{FredholmAlternative}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FredholmOperator}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host quotient cokernel, selected complement of the range, selected kernel basis, ambient Fredholm index equality, spectral decomposition, parametrix theorem, Lean proof, or standard bridge.

Theorem 8285.2 (Fredholm operator NameCert obligations)**.** *For every accepted* $\mathsf{FredholmOperator}^{\uparrow}$ *carrier*

$$F = (X, Y, B, K, E, C, I, A, H, R, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FredholmOperator}^{\uparrow}}$ *surface consists exactly of endpoint admission through X, Y, bounded-action exposure through B, kernel exposure through K, cokernel-facing obstruction exposure through E, compact-operator compatibility through C, index-ledger readback through I, alternative-facing handoff through A, componentwise transport through H, displayed replay through R, package provenance through P, and local naming through N.*

Proof. Project the carrier tuple. The endpoint rows X, Y are the only Banach or Hilbert sources, and the bounded-action row B is the only operator action available to the packet.

The finite Fredholm data are read next. The kernel side is K, the cokernel-facing obstruction side is E, and the index ledger I records only the displayed comparison between those two rows. Thus the index read cannot be replaced by a host quotient or an ambient dimension theorem.

The compactness and alternative rows are dependency handoffs. The compact row C lets compact-operator consumers recognize the same bounded action, while A exposes the same kernel-or-obstruction boundary to the $\mathsf{FredholmAlternative}^{\uparrow}$ surface.

Finally H, R, P, N preserve and name the route. Since the carrier contains no quotient cokernel, selected complement, selected basis, spectral decomposition, Lean target, or bridge coordinate, the listed rows exhaust the local certificate obligations. □

Theorem 8285.3 (Fredholm operator index kernel–cokernel handoff)**.** *Every index-facing consumer of an accepted* $\mathsf{FredholmOperator}^{\uparrow}$ *packet must read the bounded operator row B over the endpoint rows X, Y, then read the kernel row K and the cokernel-facing obstruction row E, before consuming the index ledger I or the* $\mathsf{FredholmAlternative}^{\uparrow}$ *handoff row A. The exported index surface is the finite route*

$$X, Y, B \longmapsto K, E \longmapsto I, A$$

together with H, R, P, N; it does not export a host quotient cokernel, selected range complement, ambient Fredholm index equality, spectral decomposition, Lean verification, or bridge checking.

Proof. Begin with the NameCert obligations of Definition 8285.2. They place endpoint admission and bounded-action exposure before the kernel, cokernel-facing, index, and handoff rows.

The rows K and E are paired but not identified with host objects. The kernel side records finite kernel evidence, and the cokernel-facing side records obstruction or finite-codimension evidence without passing to an ambient quotient carrier.

The index ledger I is downstream of that pair. It can be consumed only as the displayed BEDC comparison between K and E, and the alternative handoff A carries the same boundary into chapter 3425.

Componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert naming preserve this same route. Therefore downstream index packets, including the analytic-index side of chapter 273, receive a finite operator/index dependency rather than an external Fredholm operator notion. □

Falsifiable prediction: Every accepted $\mathsf{FredholmOperator}^{\uparrow}$ index read displays bounded action, kernel, cokernel-facing obstruction, index ledger, transport, replay, provenance, and local NameCert rows before any index-facing consumer may use the packet.

Independence witness: boundedlinearoperator, compactoperator, banach, hilbert, fredholm-alternative: $\mathsf{FredholmOperator}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds endpoint admission, bounded action, kernel evidence, cokernel-facing obstruction, compact compatibility, index readback, and alternative handoff as one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FredholmOperator}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FredholmOperator}^{\uparrow}$ packet is generated from Banach or Hilbert endpoint rows, a bounded-linear-operator row, finite kernel evidence, cokernel-facing obstruction data, compact-operator compatibility, an index ledger, a Fredholm-alternative handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FredholmOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8285.1, Definition 8285.2, and Definition 8285.3 seed the finite Fredholm operator carrier over endpoint, bounded-action, kernel, cokernel-facing, compactness, index, handoff, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FredholmOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host quotient cokernels, selected complements, selected kernel bases, ambient Fredholm index equality, spectral decompositions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, bounded-action exposure, kernel exposure, cokernel-facing obstruction exposure, compact compatibility, index-ledger readback, alternative handoff, transport, replay, provenance, and local naming for BEDC.Derived.FredholmOperatorUp.

Chapter 8286

A Concrete Naming Certificate for $\mathsf{HenstockGaugePartition}^{\uparrow}$

Following Henstock's gauge integration and Cousin-style fine partitions, the $\mathsf{HenstockGaugePartition}^{\uparrow}$ packet names the finite tagged partition object that sits between the existence route of chapter 1861, the fine-partition ledger of chapter 6467, the control route of chapter 7413, and the integration consumer of chapter 1999. It records only displayed tagged intervals, pointwise gauge-radius rows, endpoint readback through located intervals and $\mathsf{Real}^{\uparrow}$, finite fineness and coverage ledgers, replay, provenance, and a local certificate.

Definition 8286.1 (Henstock gauge partition carrier)**.** *A* $\mathsf{HenstockGaugePartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (I, G, T, E, F, C, D, R, Q, N)$$

whose rows expose:

1. *I, the interval source row read through* $\mathsf{LocatedInterval}^{\uparrow}$ *and sealed against the endpoint order available in* $\mathsf{Real}^{\uparrow}$*;*
2. *G, the gauge-radius row assigning a positive local radius to every admitted tag over the displayed interval;*
3. *T, the finite tagged-interval ledger listing tags, left and right endpoints, cell order, and cell membership;*
4. *E, the endpoint readback row carrying the* $\mathsf{LocatedInterval}^{\uparrow}$ *boundary data and the terminal* $\mathsf{Real}^{\uparrow}$ *endpoint seal for each tagged cell;*
5. *F, the fineness ledger stating that every tagged interval of T lies inside the radius supplied by G at its tag;*
6. *C, the coverage ledger stating that the finite tagged intervals cover the displayed interval without leaving a named gap;*
7. *D, the disjointness ledger stating that distinct interiors in the tagged-interval list do not overlap;*
8. *R, the displayed* Cont *replay row preserving the route from interval and gauge data to the same finite partition packet;*
9. *Q, the* Pkg *provenance over* $\mathsf{HenstockGaugePartition}^{\uparrow}$, $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, $\mathsf{HenstockLemma}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, Cont, *and* $\mathsf{NameCert}$*;*

10. N, the local $\mathsf{NameCert}_{\mathsf{HenstockGaugePartition}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $I, G, T, E, F, C, D, R, Q, N$. It has no coordinate for a choice-selected partition family, open-cover compactness, quotient equality of functions, an external integral theorem, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.HenstockGaugePartitionUp`

Theorem 8286.2 (Henstock gauge partition NameCert obligations)**.** *For every accepted* $\mathsf{HenstockGaugePartition}^{\uparrow}$ *carrier $P = (I, G, T, E, F, C, D, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{HenstockGaugePartition}^{\uparrow}}$ *surface is exhausted by interval-source admission, gauge-radius admission, finite tagged-interval admission, endpoint readback through* $\mathsf{LocatedInterval}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, fineness, coverage, disjointness, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{FinePartitionGauge}^{\uparrow}$*,* $\mathsf{HenstockLemma}^{\uparrow}$*, or* $\mathsf{GaugeIntegral}^{\uparrow}$ *consumer must read these rows before using the partition as a gauge-fine object.*

Proof. Project the carrier of Definition 8286.1. The analytic rows are I, G, T, E, F, C, D, and the structural rows are R, Q, N.

The endpoint and fineness obligations are read before any integral-facing consumer can use the packet. The endpoint row E binds each tagged interval to located endpoint data and to the terminal $\mathsf{Real}^{\uparrow}$ seal, while F checks the cell against the radius supplied by G at the displayed tag.

Coverage and disjointness are finite ledger rows on the same tagged-interval list. The replay and provenance rows preserve that finite route, and the local certificate has no coordinate for host choice, open-cover compactness, quotient equality, external integration, or ambient completeness. Hence the listed rows exhaust the local NameCert surface. □

Theorem 8286.3 (Henstock gauge partition fineness ledger)**.** *Every accepted* $\mathsf{HenstockGaugePartition}^{\uparrow}$ *carrier exposes a single finite route*

$$I, G, T, E \longmapsto F \longmapsto C, D$$

from located endpoint data and positive gauge radii to the coverage and disjointness ledgers. The row F is the only fineness witness visible to $\mathsf{FinePartitionGauge}^{\uparrow}$ *and* $\mathsf{HenstockLemma}^{\uparrow}$ *consumers, and it is read from the same tags and endpoints displayed by T and E.*

Proof. Start with I, G, T, E. These rows name the displayed interval, the positive radius assigned to each admitted tag, the finite tagged-interval list, and the located endpoint readback.

The fineness row F consumes exactly those rows. It cannot change the tag list or endpoints because it is a ledger row over the tagged intervals already listed in T and read back in E.

The coverage and disjointness rows C, D are downstream finite checks on the same list. Thus any fine-partition or Henstock-lemma consumer that reads the packet receives the displayed fineness ledger before it receives coverage or disjointness as usable partition data. □

Theorem 8286.4 (Henstock gauge partition integral consumer handoff)**.** *Every* $\mathsf{GaugeIntegral}^{\uparrow}$ *consumer of an accepted* $\mathsf{HenstockGaugePartition}^{\uparrow}$ *carrier factors through the partition route*

$$I, G, T, E, F, C, D \longmapsto R, Q, N.$$

The consumer receives located endpoint readback, $\mathsf{Real}^{\uparrow}$ *endpoint sealing, gauge fineness, coverage, disjointness, replay, provenance, and local naming; it receives no selected family of partitions, no open-cover compactness theorem, no quotient equality of functions, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Read the finite partition rows first. The interval row I, gauge row G, tagged-interval row T, and endpoint row E bind the consumer to one displayed partition packet.

Next consume the ledger rows F, C, D. They certify gauge fineness, coverage, and interior disjointness over the same finite list, so the gauge-integral consumer does not import a separate existence theorem at the point of use.

Finally read the replay, provenance, and local naming rows. These rows preserve the route into $\mathsf{GaugeIntegral}^{\uparrow}$, $\mathsf{FinePartitionGauge}^{\uparrow}$, $\mathsf{CousinLemma}^{\uparrow}$, and $\mathsf{HenstockLemma}^{\uparrow}$ without adding any host choice, compactness, quotient, external integral, or ambient completeness coordinate. □

Falsifiable prediction: Every accepted $\mathsf{HenstockGaugePartition}^{\uparrow}$ packet must expose interval source, gauge-radius, finite tagged-interval, located endpoint, Real seal, fineness, coverage, disjointness, replay, provenance, and local NameCert rows before a gauge-integral consumer reads it.

Independence witness: gaugeintegral, finepartitiongauge, cousinlemma, henstocklemma, locatedinterval, real: $\mathsf{HenstockGaugePartition}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite tagged intervals, pointwise gauge-radius data, located endpoint readback, fineness, coverage, disjointness, replay, provenance, and local naming before the integral consumer handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{HenstockGaugePartition}^{\uparrow}}$.

Constructive story: A $\mathsf{HenstockGaugePartition}^{\uparrow}$ packet is generated from interval source data, gauge-radius data, finite tagged intervals, located endpoint readback, Real endpoint sealing, fineness, coverage, disjointness, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HenstockGaugePartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8286.1, Definition 8286.2, Definition 8286.3, and Definition 8286.4 seed the finite Henstock gauge-partition object between fine-partition, Henstock-lemma, and gauge-integral consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HenstockGaugePartition}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close selected partition families, open-cover compactness, quotient equality of functions, external integral theorems, ambient Real completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked interval admission, gauge-radius admission, finite tagged-interval admission, endpoint readback, fineness, coverage, disjointness, replay, provenance, and local naming for BEDC.Derived.HenstockGaugePartitio

Chapter 8287

A Concrete Naming Certificate for $\mathsf{RealUniformPartition}^{\uparrow}$

Following Bishop and Bridges constructive real analysis, the $\mathsf{RealUniformPartition}^{\uparrow}$ packet records the finite uniform partitions used to inspect a closed real interval by dyadic mesh scale. It sits after the dyadic tolerance arithmetic of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the located interval-cover route of chapter 1885. The packet names endpoints, mesh cells, finite windows, readback rows, and local certificate data only; it does not assert open-cover compactness, a finite subcover principle, quotient real equality, or completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8287.1 (RealUniformPartition carrier)**.** *A* $\mathsf{RealUniformPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (A, B, M, I, E, S, R, Z, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the lower and upper* $\mathsf{Real}^{\uparrow}$ *endpoint names, read only through their displayed real-seal rows.*
2. *M is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-scale row, recording a positive dyadic step, its refinement budget, and the comparison cells used by the finite partition.*
3. *I is the ordered finite window of partition indices, stored as constructor-generated finite data rather than as a host interval or hidden enumeration.*
4. *E is the endpoint ledger assigning to each displayed index in I the corresponding dyadic endpoint history between A and B.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row used to inspect endpoint names, mesh rows, and the finite index window.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint and mesh observations displayed by S.*
7. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the dyadic mesh, ordered finite window, endpoint ledger, finite observations, and regular rational readback have been displayed.*
8. *H records componentwise* hsame *transport for endpoints, mesh scale, finite index window, endpoint ledger, StreamName observations, RegSeqRat readback, Real seal, replay, provenance, and local certificate.*

9. *C records displayed* Cont *replay of the route from endpoint names and dyadic mesh through finite windows, readback, and Real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{RealUniformPartition}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedIntervalCover}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealUniformPartition}^{\uparrow}}$ *row.*

The carrier predicate requires the finite endpoint ledger E to be ordered by the displayed dyadic mesh row M, to cover exactly the finite window I, and to be readable through S, R, Z, H, C, P, N. It has no coordinate for an arbitrary open cover, a selected subcover, quotient real equality, host interval equality, countable choice, or ambient completeness.

Theorem 8287.2 (RealUniformPartition NameCert obligations)**.** *For every accepted* $\mathsf{RealUniformPartition}^{\uparrow}$ *carrier $U = (A, B, M, I, E, S, R, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealUniformPartition}^{\uparrow}}$ *surface consists exactly of carrier admission for the two* $\mathsf{Real}^{\uparrow}$ *endpoint names, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-scale row, the ordered finite partition window, the endpoint ledger,* $\mathsf{StreamName}^{\uparrow}$ *finite observations,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every partition consumer must expose M, I, E, S, R before reading the Real seal Z.*

Proof. Project the accepted carrier. The rows before the Real seal are precisely the endpoint names A, B, the dyadic mesh M, the finite index window I, the endpoint ledger E, the finite observation row S, and the regular rational readback R.

The ordered partition obligation is finite. The mesh row supplies the dyadic step and comparison cells, while the finite window lists the partition indices and the endpoint ledger attaches each index to its displayed endpoint history.

Readback and sealing are downstream. The StreamName row records exactly the finite observations used by the RegSeqRat row, and the Real seal is then read from that regular rational boundary through Z.

Finally transport, replay, provenance, and local naming are supplied by H, C, P, N. Since the carrier contains no row for open-cover compactness, subcover choice, quotient real equality, host interval equality, countable choice, or completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8287.3 (RealUniformPartition RegSeqRat scope)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RealUniformPartition}^{\uparrow}$ *carrier must factor through the finite route*

$$A, B, M, I, E, S, R, Z, H, C, P, N.$$

In particular, the regular rational readback R is scoped by the common dyadic mesh row M and the displayed finite window I before the Real seal Z is available. The route exports no infinite stream, quotient real equality, selected limit, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the carrier rows. The only window available to a StreamName-facing consumer is S, and S is displayed after the endpoint names, mesh scale, finite index window, and endpoint ledger have already been projected.

The RegSeqRat readback R therefore cannot be read independently of the finite partition. Its observations are exactly those exposed by S, with the mesh comparisons supplied by M and the endpoint rows supplied by E.

The Real seal Z is terminal in the same finite route. Transport by H and replay by C preserve the mesh, window, readback, provenance, and local name together, so a downstream Real-facing consumer remains attached to $A, B, M, I, E, S, R, Z, H, C, P, N$.

No excluded coordinate appears in the carrier inventory. Hence the scoped route cannot export an infinite stream, quotient real equality, selected limit, open-cover compactness, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{RealUniformPartition}^{\uparrow}$ read is refuted if a consumer reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without displaying the endpoint names, dyadic mesh scale, ordered finite window, endpoint ledger, finite StreamName observations, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence.

Independence witness: dyadicratcore, streamname, regseqrat, real, located-interval-cover: $\mathsf{RealUniformPartition}^{\uparrow}$ is not bijective to any listed sibling because it binds endpoint names, a dyadic mesh scale, ordered finite partition indices, endpoint ledgers, finite observations, regular rational readback, Real sealing, transport, replay, provenance, and local naming in one partition packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealUniformPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{RealUniformPartition}^{\uparrow}$ packet is generated from RealUp endpoint names, a DyadicRatCoreUp mesh scale, an ordered finite partition window, endpoint ledger rows, StreamName finite observations, RegSeqRat readback, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealUniformPartition}^{\uparrow}}$, seed)

Scope closed: Definition 8287.1, Definition 8287.2, and Definition 8287.3 seed the finite uniform partition route from dyadic mesh data to StreamName, RegSeqRat, and RealUp consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealUniformPartition}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected finite subcovers, quotient real equality, host interval equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite mesh ordering, endpoint-ledger coverage, StreamName observation scope, RegSeqRat readback scope, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RealUniformPartitionUp.

Chapter 8288

A Concrete Naming Certificate for RegularCauchyProductModulus$^{\uparrow}$

Following Bishop and Bridges, the RegularCauchyProductModulus$^{\uparrow}$ packet records the finite product-modulus boundary needed to read multiplication of displayed regular rational Cauchy names through bounded windows. It sits over the RegSeqRat$^{\uparrow}$ source rows of chapter 301, the synchronized window discipline of chapter 126, the DyadicRatCore$^{\uparrow}$ arithmetic rows of chapter 291, the terminal real-name seal of chapter 38, and the product carrier of chapter 1702. The packet is a finite modulus certificate for the product window; it is not quotient real multiplication, a selected limit, trichotomy, an ambient completeness theorem, or a host real norm.

Definition 8288.1 (RegularCauchyProductModulus carrier)**.** *A* RegularCauchyProductModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, W, D, R, P, E, H, C, Q, N)$$

with the following displayed rows:

1. *X and Y are the two* RegSeqRat$^{\uparrow}$ *source rows for regular rational Cauchy real names.*
2. *W is the* StreamName$^{\uparrow}$ *product-window ledger that lists the finite source observations inspected for each requested output precision.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *error-budget row containing the displayed source tolerances, product tolerance, and slack allocation used by the window computation.*
4. *R is the regular readback row that turns the windowed dyadic product data into a* RegSeqRat$^{\uparrow}$ *product-name prefix.*
5. *P is the product-modulus row. For each requested output precision it stores the finite source-window depth and dyadic slack sufficient for the product readback.*
6. *E is the* Real$^{\uparrow}$ *seal row reached only after X, Y, W, D, R, P have supplied the regular product-modulus boundary.*
7. *H records componentwise* hsame *transport for the source rows, product windows, dyadic error budget, regular readback, product modulus, real seal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from any product-modulus precision request through $X, Y, W, D, R, P, E, H, Q, N$.*
9. *Q is the* Pkg *provenance over* RegularCauchyProductModulus$^{\uparrow}$, RegSeqRat$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyMultiplication$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyProductModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Y, W, D, R, P, E, H, C, Q, N$. The carrier has no coordinate for quotient real multiplication, selected limits, trichotomy, global completeness, host real norms, Lean verification, or bridge checking.

Theorem 8288.2 (Regular Cauchy product window bound)**.** *For every accepted* $\mathsf{RegularCauchyProductModulus}^{\uparrow}$ *carrier*

$$M = (X, Y, W, D, R, P, E, H, C, Q, N),$$

each product read requested at a displayed output precision factors through a finite window bound recorded in P before the regular readback row R or the $\mathsf{Real}^{\uparrow}$ *seal row E may be consumed.*

Proof. Start with the precision request handled by the accepted carrier. The only row that assigns a product-facing source-window depth is P, and P is keyed to the synchronized observations listed by W and to the dyadic slack listed by D.

Once P has named that finite bound, the readback row R may use only the displayed source prefixes from X and Y, the window ledger W, and the error-budget row D. Thus the product readback is determined before any terminal real-name seal is exposed.

The $\mathsf{Real}^{\uparrow}$ seal row E is downstream from X, Y, W, D, R, P. Since the carrier contains no host norm, quotient Cauchy class, selected limit, or ambient completeness coordinate, every accepted product read reaches E only through the finite window bound already recorded in P. □

Theorem 8288.3 (Regular Cauchy product-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyProductModulus}^{\uparrow}$ *carrier*

$$M = (X, Y, W, D, R, P, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyProductModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *source rows, synchronized* $\mathsf{StreamName}^{\uparrow}$ *product windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *error-budget row, regular readback, product-modulus row,* $\mathsf{Real}^{\uparrow}$ *seal, and structural rows;*
2. *source-window exposure, requiring each product-modulus request to inspect only the finite source prefixes named by W;*
3. *dyadic error-budget exposure, requiring D to carry the displayed source tolerances, product tolerance, and slack allocation used by the product bound;*
4. *product-modulus determinacy, requiring P to name the finite bound before the readback row R or the seal row E is available;*
5. *regular readback compatibility, requiring R to be the* $\mathsf{RegSeqRat}^{\uparrow}$ *prefix obtained from the rows X, Y, W, D, P;*
6. *Real seal nonescape, requiring every* $\mathsf{Real}^{\uparrow}$ *consumer to read through X, Y, W, D, R, P before E is exposed;*
7. *componentwise transport, replay, provenance, and local naming, requiring H, C, Q, N to preserve and name exactly the same finite product-modulus packet;*
8. *refusal of quotient real multiplication, selected limits, trichotomy, global completeness, host real norms, Lean verification, and bridge checking as local NameCert data.*

No product-modulus obligation is stored outside these finite rows.

Falsifiable prediction: An accepted $\mathsf{RegularCauchyProductModulus}^{\uparrow}$ read is refuted if a product-facing precision request reaches R or E without a finite source-window bound in P, a synchronized $\mathsf{StreamName}^{\uparrow}$ window in W, and a $\mathsf{DyadicRatCore}^{\uparrow}$ error-budget row in D.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-multiplication: $\mathsf{RegularCauchyProductModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two regular Cauchy source rows, product windows, dyadic error budgets, a regular readback row, a product-modulus row, a real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyProductModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyProductModulus}^{\uparrow}$ packet is generated from two RegSeqRat source rows, a finite StreamName product-window ledger, a DyadicRatCore error-budget row, a regular readback row, a product-modulus row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8288.1, Definition 8288.2, and Definition 8288.3 seed the finite product-modulus boundary consumed by regular Cauchy multiplication and Real-facing completion readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyProductModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient real multiplication, selected limits, trichotomy, host real norms, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exposure, dyadic error-budget exposure, product-modulus determinacy, regular readback compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyProductModulusUp.

Chapter 8289

A Concrete Naming Certificate for $\mathsf{MartingaleFiltration}^{\uparrow}$

Following Doob on filtrations and martingales, the $\mathsf{MartingaleFiltration}^{\uparrow}$ packet records the finite observation schedule that a martingale or stopped martingale may consume before it reads conditional-expectation data. It sits between the probability source of chapter 184, the random-variable endpoint rows used by chapter 190, the finite stopping decisions of chapter 344, and the conditional-expectation faces of chapter 188. The packet gives martingale and stopping-time consumers an explicit filtration carrier; it is not a completed sigma-algebra tower, a selected optional process, an almost-sure quotient, or a measure-completion theorem.

Definition 8289.1 (Martingale filtration carrier)**.** *A* $\mathsf{MartingaleFiltration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (\Omega, W, A, C, S, B, T, R, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *row naming the probability source and its event classifier.*
2. W *is a finite filtration-window ledger whose entries name the inspected times and the event rows available at each time.*
3. A *is the adaptedness row tying each displayed* $\mathsf{RandomVar}^{\uparrow}$ *endpoint read to the corresponding entry of* W*.*
4. C *is the family of* $\mathsf{CondExp}^{\uparrow}$ *faces that compare successor endpoint rows against the previous filtration entry.*
5. S *is the bounded stopping-window row recording which entries of* W *may be stopped and read by* $\mathsf{StoppingTime}^{\uparrow}$ *or* $\mathsf{BoundedStoppingTime}^{\uparrow}$ *consumers.*
6. B *is the optional-stopping handoff row for bounded windows, read only after* W, A, C, S *have been displayed.*
7. T *records componentwise* hsame *transport for the probability source, filtration window, adaptedness, conditional-expectation faces, stopping rows, handoff, provenance, and local naming.*
8. R *records displayed* Cont *replay of the same finite route.*
9. P *is the* Pkg *provenance over* $\mathsf{MartingaleFiltration}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{CondExp}^{\uparrow}$, $\mathsf{Martingale}^{\uparrow}$, $\mathsf{StoppingTime}^{\uparrow}$, $\mathsf{BoundedStoppingTime}^{\uparrow}$, $\mathsf{OptionalStopping}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{MartingaleFiltration}^{\uparrow}}$ *row.*

The carrier has no coordinate for completed filtrations, countable joins of sigma-algebras, optional projections, unbounded stopping choices, almost-sure quotient equality, or ambient measure completion.

Lean4 ✓ `BEDC.Derived.MartingaleFiltrationUp.TasteGate.MartingaleFiltrationTasteGate single carrier alignment`

Theorem 8289.2 (Martingale filtration NameCert obligations)**.** *For every accepted* $\mathsf{MartingaleFiltration}^{\uparrow}$ *carrier* $F = (\Omega, W, A, C, S, B, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MartingaleFiltration}^{\uparrow}}$ *surface consists exactly of carrier admission, finite filtration-window exposure, adaptedness of endpoint rows through* A*, conditional-expectation exposure through* C*, bounded stopping-window exposure through* S*, optional-stopping handoff through* B*, componentwise transport through* T*, displayed replay through* R*, provenance through* P*, and local naming through* N*. Every public martingale or stopping-time read of the packet must preserve those rows before it reaches a* $\mathsf{Martingale}^{\uparrow}$*,* $\mathsf{StoppingTime}^{\uparrow}$*,* $\mathsf{BoundedStoppingTime}^{\uparrow}$*, or* $\mathsf{OptionalStopping}^{\uparrow}$ *consumer.*

Proof. Project the carrier of Definition 8289.1. The only analytic coordinates are the probability source, the finite filtration window, adaptedness rows, conditional-expectation faces, bounded stopping rows, and optional-stopping handoff.

The martingale-facing route first reads W and A. Thus each endpoint row is attached to a visible filtration entry before the $\mathsf{Martingale}^{\uparrow}$ consumer reads conditional-expectation information.

The stopping-facing route then reads S and B. The stopping row records the bounded decision window, while the handoff row records the optional-stopping surface only after the same W, A, C rows have already been exposed.

Finally T, R, P, N transport, replay, source, and name only that displayed packet. Since the carrier omits completed filtrations, countable joins, optional projections, unbounded stopping choices, almost-sure quotient equality, and measure completion, no local obligation can export those endpoints. □

Theorem 8289.3 (Martingale filtration stopping-window handoff)**.** *Every accepted* $\mathsf{MartingaleFiltration}^{\uparrow}$ *public read that is consumed by a* $\mathsf{StoppingTime}^{\uparrow}$*,* $\mathsf{BoundedStoppingTime}^{\uparrow}$*, or* $\mathsf{OptionalStopping}^{\uparrow}$ *row first factors through the common finite window* W*, the adaptedness row* A*, the conditional-expectation faces* C*, and the bounded stopping-window row* S*. Hence a stopped martingale read receives the same finite filtration rows that the* $\mathsf{Martingale}^{\uparrow}$ *conditional-expectation read uses, rather than an ambient filtration or an unbounded stopping selector.*

Proof. Start from an accepted carrier $F = (\Omega, W, A, C, S, B, T, R, P, N)$. The window W is the only filtration coordinate, so every time-indexed event read begins there.

Apply the NameCert obligations of Definition 8289.2. They force martingale endpoint rows through A and conditional-expectation faces through C before any public martingale consumer can read the packet.

For stopping consumers, the same obligation surface forces bounded stopping reads through S before the optional-stopping handoff B is available. The structural rows T, R, P, N preserve the same finite route, so the stopped read cannot replace the displayed window by a completed filtration, an unbounded stopping rule, or an almost-sure quotient. □

Closure status for $\mathsf{NameCert}_{\mathsf{MartingaleFiltration}^{\uparrow}}$**.**

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartingaleFiltration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8289.1, Definition 8289.2, and Definition 8289.3 seed the finite filtration-window packet consumed by martingale and bounded-stopping rows.

Formal verification: FormalStatus(NameCert$_{\text{MartingaleFiltration}\uparrow}$, theoremChecked)

Lean target: `BEDC.Derived.MartingaleFiltrationUp.TasteGate.MartingaleFiltrationTasteGate\_single\_carrier\_alignm`

Bridge status: none

Not claimed: This chapter does not close completed filtrations, countable joins of sigma-algebras, optional projections, unbounded stopping choices, almost-sure quotient equality, measure completion, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, adaptedness routing, conditional-expectation face exposure, bounded stopping-window handoff, transport, replay, provenance, and local naming for BEDC.Derived.MartingaleFiltrationUp.

Constructive story: A MartingaleFiltration$^{\uparrow}$ packet is generated from a probability-space row, a finite filtration-window ledger, adapted random-variable endpoint rows, conditional-expectation faces, bounded stopping-window rows, an optional-stopping handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8290

A Concrete Naming Certificate for $\mathsf{DyadicUniformCover}^{\uparrow}$

Following Bishop and Bridges on compact intervals and finite covers, the $\mathsf{DyadicUniformCover}^{\uparrow}$ packet records the dyadic finite-cover side of the L10 compactness route described in chapter 9237. It sits over the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular-rational readback of chapter 301, the terminal real-name seal of chapter 38, and the compact interval source of chapter 3986. The packet names finite cover rows only; it is not an open-cover compactness theorem, a selected infinite subcover, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8290.1 (Dyadic uniform cover carrier)**.** *A* $\mathsf{DyadicUniformCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, D, W, Q, R, C, H, K, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *source interval row.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger naming dyadic endpoints, radii, overlaps, and tolerance comparisons.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *inspection window used to read interval endpoints and cover cells.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for dyadic cell centers and endpoint approximations.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after W, Q, D have been displayed.*
6. *C is the finite cover row listing the displayed dyadic cells, their membership checks, and the local coverage certificate for the interval row I.*
7. *H records componentwise* hsame *transport for the interval, dyadic, stream, regular-rational, real-seal, cover, replay, provenance, and local naming rows.*
8. *K records displayed* Cont *replay of the same finite cover route.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicUniformCover}^{\uparrow}$, $\mathsf{BishopCompactInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicUniformCover}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary open covers, infinite subcover selection, quotient stream equality, host real equality, trichotomy, countable choice, selected limits, or ambient compactness.

Theorem 8290.2 (Dyadic uniform cover NameCert obligations)**.** *For every accepted* $\mathsf{DyadicUniformCover}^{\uparrow}$ *carrier* $U = (I, D, W, Q, R, C, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DyadicUniformCover}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact interval source, dyadic ledger, finite StreamName window, regular-rational readback, Real seal, finite cover row, componentwise transport, displayed replay, provenance, and local naming. Every compactness or completion consumer of the packet must read the cover row* C *through* D, W, Q, R *before it consumes the interval row* I *as a finite-cover source.*

Proof. Project the carrier of Definition 8290.1. Its analytic rows are exactly I, D, W, Q, R, C, with H, K, P, N providing structural transport, replay, provenance, and local naming.

The dyadic ledger D names the cell endpoints and tolerance comparisons. The stream window W and regular-rational row Q expose only finitely many endpoint and center reads before the terminal real seal R is visible.

The cover row C is therefore consumed as a finite dyadic cover over the interval row I. Since arbitrary open covers, infinite subcover selection, quotient equality, host real equality, trichotomy, countable choice, selected limits, and ambient compactness are absent from the carrier, no obligation can export them. □

Theorem 8290.3 (Dyadic uniform cover L10 handoff)**.** *Every L10 compactness or completion consumer of an accepted* $\mathsf{DyadicUniformCover}^{\uparrow}$ *packet factors through the dyadic ledger* D*, the finite StreamName window* W*, the regular-rational readback* Q*, the Real seal* R*, and the finite cover row* C *before it consumes the* $\mathsf{BishopCompactInterval}^{\uparrow}$ *source* I*. Thus the finite-cover direction is a displayed dyadic NameCert route, not an open-cover compactness principle or a choice-selected subcover.*

Proof. Begin with the accepted carrier $U = (I, D, W, Q, R, C, H, K, P, N)$. The interval source I is not read in isolation; the carrier pairs it with the dyadic ledger and finite observation rows.

Apply Definition 8290.2. It requires every public compactness or completion read to expose D, W, Q, R, C before treating I as a finite-cover source.

Finally read the structural rows H, K, P, N. They transport, replay, source, and name only the displayed dyadic cover route, so the handoff cannot be recast as arbitrary open-cover compactness, infinite subcover choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicUniformCover}^{\uparrow}}$**.**

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicUniformCover}^{\uparrow}}$, seed)

Scope closed: Definition 8290.1, Definition 8290.2, and Definition 8290.3 seed the finite dyadic cover route for compact interval and completion consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicUniformCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, infinite subcover selection, quotient stream equality, host real equality, trichotomy, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exactness, finite-window readback, regular-rational handoff, Real-seal exposure, finite-cover coverage, transport, replay, provenance, and local naming for BEDC.Derived.DyadicUniformCoverUp.

Constructive story: A $\mathsf{DyadicUniformCover}^{\uparrow}$ packet is generated from a Bishop compact interval row, dyadic endpoint and tolerance data, a finite StreamName window, RegSeqRat readback, a Real seal, finite cover cells, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8291

A Concrete Naming Certificate for $\mathsf{RationalBallDomain}^{\uparrow}$

Following Edalat–Heckmann formal-ball domains and Bishop–Bridges constructive completion, the $\mathsf{RationalBallDomain}^{\uparrow}$ packet records the finite rational-ball domain surface used by L10 completion routes before any completed point can be consumed. It sits after the rational-ball carrier of chapter 355, the rational-ball basis of chapter 7051, the formal-ball domain route of chapter 5723, the dyadic tolerance core of chapter 291, the finite stream-name windows of chapter 126, and the regular rational readback of chapter 301. The packet gives downstream Real and Completion chapters a non-quotient rational-ball-domain handoff; it does not choose Cauchy representatives, quotient filters, invoke host point equality, or assume ambient completeness.

Definition 8291.1 (RationalBallDomain carrier)**.** *A* $\mathsf{RationalBallDomain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, K, F, O, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{RationalBall}^{\uparrow}$ *observation row, carrying finite rational center-radius packets.*
2. *K is the* $\mathsf{RationalBallBasis}^{\uparrow}$ *row, recording the inspected basis windows and their finite refinement comparisons.*
3. *F is the* $\mathsf{FormalBallDomain}^{\uparrow}$ *row, supplying the rounded-domain order discipline into which rational balls are embedded.*
4. *O is the overlap and directedness ledger for finite families of rational balls.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule used by completion-facing consumers.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed rational-ball windows.*
7. *E is the endpoint handoff row, read by* $\mathsf{Completion}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *consumers only after B, K, F, O, S, R have been displayed.*
8. *H records componentwise* hsame *transport for rational balls, basis windows, formal-domain rows, overlap ledgers, stream schedules, regular readbacks, endpoints, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from rational-ball-domain requests through $B, K, F, O, S, R, E, H, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{RationalBallDomain}^{\uparrow}$, $\mathsf{RationalBall}^{\uparrow}$, $\mathsf{RationalBallBasis}^{\uparrow}$, $\mathsf{FormalBallDomain}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalBallDomain}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, K, F, O, S, R, E, H, C, P, N$. It has no coordinate for quotient completion, selected representatives, host metric equality, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RationalBallDomainUp.RationalBallDomainTasteGate single carrier alignment`

Theorem 8291.2 (RationalBallDomain NameCert obligations)**.** *For every accepted* $\mathsf{RationalBallDomain}^{\uparrow}$ *carrier $D = (B, K, F, O, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalBallDomain}^{\uparrow}}$ *surface consists exactly of carrier admission for the rational-ball row, rational-ball-basis row, formal-ball-domain row, overlap ledger, stream schedule, regular rational readback, endpoint handoff, componentwise transport, displayed replay, provenance, and local naming. In particular, rational-ball containment must be read through B, K, F, O, completion-facing observation through S, R, E, and structural stability through H, C, P, N.*

Proof. Project the carrier. The rational-ball source is visible only as B, the basis route only as K, and the rounded-domain discipline only as F.

The overlap row O records the finite directed family of rational balls before any stream or regular-rational consumer can read it. The schedule and readback rows S and R therefore remain downstream of the displayed rational-ball-domain surface, and the endpoint row E is terminal for that route.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores quotient completion, selected representatives, host metric equality, countable choice, or ambient completeness, the listed rows exhaust the local certificate surface. □

Theorem 8291.3 (RationalBallDomain completion handoff)**.** *Every* $\mathsf{Completion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RationalBallDomain}^{\uparrow}$ *carrier must first expose the finite route*

$$\mathsf{RationalBall}^{\uparrow} \longmapsto \mathsf{RationalBallBasis}^{\uparrow} \longmapsto \mathsf{FormalBallDomain}^{\uparrow} \longmapsto O \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports rational-ball-domain coverage, finite stream observation, regular rational readback, endpoint sealing, hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming. It exports no quotient sequence equality, selected limit, host metric equality, countable-choice selector, or ambient completion theorem.*

Proof. Start with the accepted carrier $D = (B, K, F, O, S, R, E, H, C, P, N)$. A completion-facing request first reads the rational-ball row B and the basis row K, then checks that those windows live inside the rounded formal-domain row F.

The overlap ledger O is the finite directedness witness for the rational-ball family. Only after that row is displayed can the consumer read the finite schedule S and the regular rational readback R.

The endpoint row E is therefore downstream of B, K, F, O, S, R. Transport through H and replay through C keep the same route, while P and N source and name it. The excluded quotient, selected-limit, host-equality, choice, and ambient-completeness data have no row from which a consumer could read them. □

Falsifiable prediction: Every accepted $\mathsf{RationalBallDomain}^{\uparrow}$ completion-facing read displays RationalBallUp, RationalBallBasisUp, FormalBallDomainUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, endpoint handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before a Real or Completion consumer can use the endpoint.

Independence witness: rationalball, rational-ball-basis, formal-ball-domain, dyadicratcore, streamname, regseqrat: $\mathsf{RationalBallDomain}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds rational-ball coverage, basis refinement, rounded formal-domain discipline, dyadic tolerance, finite stream observation, regular rational readback, endpoint handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalBallDomain}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalBallDomain}^{\uparrow}$ packet is generated from RationalBallUp rows, RationalBallBasisUp rows, FormalBallDomainUp rows, finite overlap ledgers, StreamNameUp schedules, RegSeqRatUp readback rows, CompletionUp and RealUp endpoint handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalBallDomain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8291.1, Definition 8291.2, and Definition 8291.3 seed the finite rational-ball-domain route from rational coverage to completion-facing endpoint consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalBallDomain}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.RationalBallDomainUp.RationalBallDomainTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, host metric equality, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rational-ball coverage, basis refinement, formal-domain embedding, overlap directedness, stream scheduling, regular readback, endpoint handoff, transport, replay, provenance, and local naming for BEDC.Derived.RationalBallDomainUp.

Chapter 8292

A Concrete Naming Certificate for $\mathsf{PositiveRealSquareRoot}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ packet records the finite square-root service available for a displayed positive real source before any total real square-root operator is claimed. It sits after the regular Cauchy square-root service of chapter 1756, the Heron recurrence route of chapter 3818, the dyadic tolerance ledger of chapter 291, the finite stream window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a bounded constructive service for one positive input; it is not a host square-root function, a trichotomy principle, quotient real equality, selected limit construction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8292.1 (Positive real square-root carrier)**.** *A* $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, A, G, R, H, D, S, V, E, T, C, P, N)$$

with the following visible rows:

1. *X is the positive* $\mathsf{Real}^{\uparrow}$ *source row whose displayed witness keeps the input in the positive real interface;*
2. *A is the apartness and nonnegative guard row, recording the local refusal of the zero or negative branch without invoking real trichotomy;*
3. *G is the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *readback row for the regular Cauchy square-root service;*
4. *R is the* $\mathsf{HeronSquareRoot}^{\uparrow}$ *recurrence route that supplies the finite iterative square-root approximants;*
5. *H is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the displayed Heron and regular Cauchy estimates;*
6. *D is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposing only finitely many source and approximation observations;*
7. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational square-root name;*
8. *V is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the source, guard, recurrence, tolerance, window, and readback rows are displayed;*
9. *E stores componentwise* hsame *transport for the source, guard, recurrence, tolerance, window, readback, and seal rows;*

10. *T records the displayed* Cont *replay by which a consumer reads the same finite square-root service;*
11. *P records* Pkg *provenance over* $\mathsf{PositiveRealSquareRoot}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{HeronSquareRoot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{PositiveRealSquareRoot}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a total host square-root function, a trichotomy case split on arbitrary reals, quotient real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8292.2 (Positive real square-root NameCert obligations)**.** *For the carrier of Definition 8292.1, the local* $\mathsf{NameCert}_{\mathsf{PositiveRealSquareRoot}^{\uparrow}}$ *surface consists exactly of five finite obligations: carrier admission for $Q = (X, A, G, R, H, D, S, V, E, T, C, P, N)$, positivity and apartness guarding through X, A, regular Cauchy square-root readback through G, S, V, Heron recurrence and dyadic tolerance accounting through R, H, D, and componentwise transport, replay, provenance, and local naming through E, T, C, P, N.*

Proof. Project the carrier rows. The source and guard rows X, A are displayed before any square-root service is read, so the certificate speaks only about a positive input with an explicit apartness and nonnegative guard.

Next compose the sibling routes. The regular Cauchy square-root service is read through G, while the Heron recurrence row R supplies the constructive approximants and the dyadic tolerance row H records the finite numerical budget exposed through the stream windows D.

Finally pass through the readback, seal, transport, replay, provenance, and naming rows S, V, E, T, C, P, N. These rows preserve only the displayed finite service, and none of them adds a host square-root operator, trichotomy, quotient real equality, selected limit, or ambient completeness principle. □

Theorem 8292.3 (Positive real square-root regular Cauchy service)**.** *Every accepted* $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ *consumer that asks for a square-root value must first read the positive* $\mathsf{Real}^{\uparrow}$ *source row, the apartness and nonnegative guard, the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *readback row, the* $\mathsf{HeronSquareRoot}^{\uparrow}$ *recurrence route, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, the* $\mathsf{StreamName}^{\uparrow}$ *windows, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, the terminal* $\mathsf{Real}^{\uparrow}$ *seal, transport, replay, provenance, and local naming. The service therefore exports only the bounded regular Cauchy square-root route for the displayed positive input.*

Proof. Begin with the NameCert obligations of Definition 8292.2. They require $X, A, G, R, H, D, S, V, E, T, C, P, N$ before a consumer can read the local square-root name.

Use chapter 1756 for the regular Cauchy readback and chapter 3818 for the Heron recurrence route. The dyadic ledger and stream windows keep the requested tolerance budget finite before the readback row S reaches the real seal V.

The structural rows E, T, C, P, N then transport, replay, source, and name the same bounded route. Since the carrier has no coordinate for a host square-root function, real trichotomy, quotient real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no consumer can read those objects from the service. □

Falsifiable prediction: Any accepted PositiveRealSquareRootUp service that bypasses the positive source guard, Heron recurrence route, dyadic tolerance ledger, stream windows, regular rational readback, or terminal Real seal refutes the carrier.

Independence witness: regular-cauchy-square-root, heron-square-root, dyadicratcore, streamname, regseqrat, real: $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a positive source guard, recurrence route, tolerance ledger, finite windows, readback, terminal seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{PositiveRealSquareRoot}^{\uparrow}}$.

Constructive story: A $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ packet is generated from a positive RealUp source row, an apartness and nonnegative guard, regular Cauchy square-root readback, Heron recurrence, dyadic tolerance accounting, stream windows, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PositiveRealSquareRoot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8292.1, Definition 8292.2, and Definition 8292.3 seed the bounded positive-input square-root service over the displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PositiveRealSquareRoot}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a host square-root function, real trichotomy, quotient real equality, selected limits, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, positive-source guarding, Heron recurrence accounting, dyadic tolerance accounting, regular Cauchy readback, stream-window replay, Real sealing, transport, provenance, and local naming for BEDC.Derived.PositiveRealSquareRootUp.

Chapter 8293

A Concrete Naming Certificate for $\mathsf{RegularCauchySieve}^{\uparrow}$

Following Bishop and Bridges, a regular Cauchy object is read through explicit moduli and finite tails before any completion seal is consumed. The $\mathsf{RegularCauchySieve}^{\uparrow}$ packet records that reading as a finite directed-tail sieve for the L10 Real and Completion route, sitting between the dyadic core of chapter 291, the finite request windows of chapter 126, the regular rational sequence readback of chapter 301, and the Real seal of chapter 38.

Definition 8293.1 (Regular Cauchy sieve carrier)**.** *A* $\mathsf{RegularCauchySieve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, Q, L, T, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row naming the finite dyadic scale at which the tail is inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row listing the requests whose indices lie beyond the displayed tail bound.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence readback row reached from the same dyadic tolerance and stream window.*
4. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row, readable only after D, W, Q have been displayed.*
5. *T is the directed finite-tail sieve row: every accepted refinement replaces D, W, Q, L by a later finite window over the same route and records the inclusion of the older window into the later one.*
6. *H records componentwise* hsame *transport for the dyadic tolerance, window, regular-sequence readback, Real seal, sieve refinement, and local naming rows.*
7. *C records displayed* Cont *replay from dyadic tolerance through StreamName window, RegSeqRat readback, directed-tail refinement, Real seal, transport, provenance, and local naming.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchySieve}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for a selected infinite subsequence, quotient-stream equality, host limit, ambient completeness principle, or hidden modulus choice outside the directed finite-tail sieve.

Theorem 8293.2 (Regular Cauchy sieve NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchySieve}^{\uparrow}$ *carrier*

$$S = (D, W, Q, L, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchySieve}^{\uparrow}}$ *surface consists exactly of dyadic tolerance exposure through* D*, finite StreamName window exposure through* W*, RegSeqRat readback through* Q*, RealUp seal exposure through* L*, directed finite-tail refinement through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8293.1. The rows D, W, Q, L expose the L10 route in dependency order: dyadic tolerance, finite request window, regular rational readback, and Real seal.

Read the sieve row T next. It is directed because any two displayed finite tails may be refined by a later finite window over the same dyadic, StreamName, RegSeqRat, and RealUp route; the packet records that later window as another finite row rather than selecting an infinite subsequence.

The transport, replay, provenance, and naming rows preserve only this displayed route. Since no coordinate stores a host limit, quotient stream, ambient completeness rule, or hidden modulus, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchySieve}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchySieve}^{\uparrow}$ packet is generated from dyadic tolerance data, finite StreamName request windows, RegSeqRat readback, a RealUp seal, a directed finite-tail refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchySieve}^{\uparrow}}$, seed)

Scope closed: Definition 8293.1 and Definition 8293.2 seed the finite directed-tail sieve used by the L10 Real and Completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchySieve}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Real completeness, quotient-stream equality, selected limits, infinite subsequence choice, hidden modulus extraction, or Lean verification for $\mathsf{RegularCauchySieve}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, directed finite-tail refinement, transport stability, replay, provenance, and local naming for the same finite L10 route.

Chapter 8294

A Concrete Naming Certificate for $\mathsf{RegularCauchyRateTransform}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ packet records the finite transformation from arbitrary displayed Cauchy modulus data to the regular-Cauchy rate discipline consumed by $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$. It sits after the regular rational readback surface of chapter 301, the finite window discipline of chapter 126, the dyadic tolerance rows of chapter 291, the terminal real-name seal of chapter 38, and the modulus comparison route of chapter 7213. The packet names the L10 regularization route for Cauchy modulus rows without selecting limits, quotienting streams, or asserting ambient completeness.

Definition 8294.1 (Regular Cauchy rate transform carrier)**.** *A* $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (M, W, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the source Cauchy modulus table. It records the finite threshold rows available from the input Cauchy data before any regular rate is read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the source thresholds are inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic requests, target regular tolerances, and comparison budget used by the rate transformation.*
4. *R is the rate-normalization replay row. For every displayed target tolerance it names the finite source threshold and window read used to produce a regular-Cauchy rate request.*
5. *H stores componentwise* hsame *transport for M, W, D, R and for the structural rows below.*
6. *C stores displayed* Cont *replay from a regular-rate request through the source modulus, finite window, dyadic ledger, and normalized rate row.*
7. *P records* Pkg *provenance over* $\mathsf{RegularCauchyRateTransform}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyModulusComparison}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *data.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransform}^{\uparrow}}$ *row.*

Accepted packets are compared only through M, W, D, R, H, C, P, N. The carrier has no coordinate for quotient stream equality, a selected limit, countable choice, ambient completeness, host real equality, or a terminal $\mathsf{Real}^{\uparrow}$ *equality test.*

Theorem 8294.2 (Regular Cauchy rate transform NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ *carrier* $T = (M, W, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransform}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the source Cauchy modulus rows, finite window, dyadic tolerance ledger, rate-normalization replay, transport, replay, provenance, and local naming;*
2. *source-modulus exposure, requiring every regular-rate request to cite a displayed threshold row in* M*;*
3. *finite-window exposure, requiring the cited threshold to be read through the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*;*
4. *dyadic tolerance compatibility, requiring* D *to contain the target regular tolerance and the comparison budget used for the request;*
5. *rate-normalization replay, requiring* R *to store the finite route from the target regular rate back to the source modulus row;*
6. *componentwise transport, continuation replay, package provenance, and local naming through* H, C, P, N*.*

No NameCert obligation is stored outside these rows, and none of the rows supplies quotient stream equality, selected limits, countable choice, ambient completeness, or host real equality.

Proof. Project the accepted carrier of Definition 8294.1. The tuple exposes exactly the source modulus table, finite window, dyadic tolerance ledger, normalized rate row, transport, replay, provenance, and local name.

The source-modulus and finite-window obligations are immediate from M and W. A regular-rate request can cite only displayed source thresholds, and those thresholds are inspected only through the finite window row.

The dyadic obligation is the row D. It records the target regular tolerance together with the comparison budget that lets the source threshold be read as a regular-Cauchy rate request.

Finally R records the replay from the target rate to the source row, while H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier omits quotient stream equality, selected limits, countable choice, ambient completeness, and host real equality, none of those principles can be exported by the local certificate. □

Theorem 8294.3 (Regular Cauchy rate transform window induction)**.** *Let* $T = (M, W, D, R, H, C, P, N)$ *be an accepted* $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ *carrier. Every normalized regular-rate request whose source observations lie in* W *is consumed by finite induction over the displayed window rows: the base row reads the first source threshold from* M *under the dyadic tolerance ledger* D*, and the step appends the next displayed source observation while replaying the same normalization row* R *and structural rows* H, C, P, N*. The induction exports only the rows of* T*.*

Proof. For the base case, read the first displayed observation in W. The associated source threshold is a row of M, the target tolerance and comparison budget are rows of D, and the normalized regular-rate route is recorded by R.

For the induction step, append one further observation from the finite window W. The same carrier rows remain available: M supplies the cited source threshold, D supplies the tolerance budget, and R records the normalization replay.

The structural rows H, C, P, N preserve the packet under componentwise transport, continuation replay, provenance, and local naming. Thus the finite-window induction never leaves

M, W, D, R, H, C, P, N and cannot produce quotient stream equality, a selected limit, countable choice, ambient completeness, or host real equality. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ read is refuted if a target regular-rate request reaches $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ without displaying a source Cauchy modulus row in M, a finite $\mathsf{StreamName}^{\uparrow}$ window in W, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger in D, and the rate-normalization replay row R.

Independence witness: regseqrat, streamname, dyadicratcore, real, regular-cauchy-modulus-comparison: $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries source Cauchy modulus rows, finite windows, dyadic tolerance data, rate-normalization replay, transport, continuation replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransform}^{\uparrow}}$ ·

Constructive story: A $\mathsf{RegularCauchyRateTransform}^{\uparrow}$ packet is generated from displayed source Cauchy modulus rows, one StreamName finite window, DyadicRatCore tolerance rows, a rate-normalization replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransform}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8294.1, Definition 8294.2, and Definition 8294.3 seed the finite rate-transformation route from arbitrary Cauchy modulus rows to the regular-Cauchy rate discipline consumed by RegSeqRat and Real readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRateTransform}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, ambient completeness, host real equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-modulus exposure, finite-window exposure, dyadic tolerance compatibility, rate-normalization replay, transport, provenance, and local naming for BEDC.Derived.RegularCauchyRateT

Chapter 8295

A Concrete Naming Certificate for $\mathsf{CauchyRealEmbedding}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{CauchyRealEmbedding}^{\uparrow}$ packet records the general seal route from an accepted regular Cauchy source to the terminal $\mathsf{Real}^{\uparrow}$ interface. It sits after the regular Cauchy carrier of chapter 371, the finite stream windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the stationary rational subcase of chapter 364, and the terminal real-name seal of chapter 38. The packet names a general regular-Cauchy-to-Real handoff; it is not a quotient Cauchy class, a selected host limit, a stream equality theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8295.1 (CauchyRealEmbedding carrier)**.** *A* $\mathsf{CauchyRealEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (G, W, R, D, S, H, C, P, N)$$

with the following visible rows:

1. *G is the accepted* $\mathsf{RegularCauchyName}^{\uparrow}$ *source packet whose finite windows, dyadic-radius rows, regular rational readbacks, and real seal are visible to the consumer.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window handoff selected for the requested precision reads.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback boundary read through the displayed window.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the regularity and comparison rows.*
5. *S is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after G, W, R, D have been displayed.*
6. *H records componentwise* hsame *transport for the regular Cauchy source, stream window, regular rational readback, dyadic tolerance ledger, seal row, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay of the same regular-Cauchy-to-Real route.*
8. *P records* Pkg *provenance over* $\mathsf{CauchyRealEmbedding}^{\uparrow}$, $\mathsf{RegularCauchyName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StationaryRationalCauchy}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyRealEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $G, W, R, D, S, H, C, P, N$. It has no coordinate for quotient Cauchy classes, host sequence equality, selected limits, countable choice, or ambient real completeness.

Theorem 8295.2 (CauchyRealEmbedding NameCert obligations)**.** *For every accepted* $\mathsf{CauchyRealEmbedding}^{\uparrow}$ *carrier* $E = (G, W, R, D, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CauchyRealEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the regular Cauchy source, finite StreamName window, regular rational readback, dyadic tolerance ledger, terminal Real seal, componentwise transport, displayed replay, provenance, and local naming. The stationary rational route of Definition 364.8 is the constant-source subcase; the general route consumes the same kind of rows without restricting* G *to a stationary rational window.*

Proof. Project the carrier rows. The source row G supplies the accepted $\mathsf{RegularCauchyName}^{\uparrow}$ packet, while W, R, D expose the stream window, regular rational readback, and dyadic tolerance information required before the seal row can be read.

Use the regular Cauchy seal boundary and factorization in chapter 371. They place every $\mathsf{Real}^{\uparrow}$ read downstream of the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows of the source packet.

The stationary rational theorem is then a visible subcase: when the regular Cauchy source is constant, Definition 364.8 identifies the same seal route through the hidden rational seed, constant stream windows, stationary regular rational member, and dyadic ledger. The carrier here keeps the general source row G, so no quotient class, selected host limit, or ambient completeness datum is added. □

Theorem 8295.3 (CauchyRealEmbedding Real seal scope)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CauchyRealEmbedding}^{\uparrow}$ *packet must read the displayed route*

$$\mathsf{RegularCauchyName}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through $G, W, R, D, S, H, C, P, N$ *before the terminal seal is consumed. The route separates the general regular Cauchy embedding from the stationary rational subcase and exports no quotient stream equality, selected limit, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with Definition 8295.1. The only source-facing row is G, and the only readback rows before the terminal seal are W, R, D.

Apply Definition 8295.2. It requires the regular Cauchy source, finite window, regular rational readback, dyadic tolerance ledger, seal row, transport, replay, provenance, and local naming to be visible in the same packet.

Finally compare the constant-source branch with Definition 364.8. That theorem supplies the stationary rational exactness row, while the present carrier records the general route from any accepted regular Cauchy source. Since no carrier coordinate names quotient stream equality, selected limits, countable choice, or ambient completeness, the seal scope is exactly the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyRealEmbedding}^{\uparrow}$ read is refuted if it consumes a terminal $\mathsf{Real}^{\uparrow}$ seal before displaying the $\mathsf{RegularCauchyName}^{\uparrow}$ source, $\mathsf{StreamName}^{\uparrow}$ window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, transport, replay, provenance, and local $\mathsf{NameCert}$ rows.

Independence witness: regular-cauchy-name, streamname, regseqrat, dyadicratcore, stationary-rational-cauchy, real: $\mathsf{CauchyRealEmbedding}^{\uparrow}$ is not bijective to any listed sibling because it jointly records the general regular Cauchy source, finite window, regular rational readback, dyadic tolerance ledger, terminal seal, transport, replay, provenance, and local naming route.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyRealEmbedding}^{\uparrow}}$**.**

Constructive story: A CauchyRealEmbedding$^{\uparrow}$ packet is generated from a RegularCauchyNameUp source, StreamNameUp finite window, RegSeqRatUp readback boundary, DyadicRatCoreUp tolerance ledger, RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyRealEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 8295.1, Definition 8295.2, and Definition 8295.3 seed the general regular-Cauchy-to-Real seal route.

Formal verification: FormalStatus(NameCert$_{\text{CauchyRealEmbedding}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient Cauchy classes, host sequence equality, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular Cauchy source exposure, StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyRealEmbeddingUp.

Chapter 8296

A Concrete Naming Certificate for $\mathsf{MartinBoundary}^{\uparrow}$

Following Martin and Doob on positive harmonic functions and boundary kernels, the $\mathsf{MartinBoundary}^{\uparrow}$ packet records the finite transition-kernel boundary route used by hyperbolic observer-expansion consumers before any host compactification or quotient boundary equality is asserted. It sits beside the hyperbolic metric rows of chapter 3474, the Gromov boundary of chapter 6470, the boundary-shadow packet of chapter 3813, the Poisson-kernel route of chapter 3925, and the terminal real-name seal of chapter 38. The packet names only finite kernel, positive-harmonic, shadow, metric, Real-seal, transport, replay, provenance, and naming rows.

Definition 8296.1 (Martin boundary carrier)**.** *A* $\mathsf{MartinBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, K, H, B, S, P_o, V, R, T, C, G, N)$$

with the following visible rows:

1. *X is the displayed state or basepoint window consumed by the transition-kernel reads.*
2. *K is the finite transition-kernel ledger whose positive entries are inspected by the boundary packet.*
3. *H is the positive-harmonic row read through the kernel ledger.*
4. *B is the* $\mathsf{GromovBoundary}^{\uparrow}$ *handoff row available to hyperbolic consumers.*
5. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *shadow row attached to the same boundary-facing read.*
6. *P_o is the* $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$ *row that turns the boundary and kernel data into finite Real-valued weights.*
7. *V is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric route used by the shadow and kernel comparisons.*
8. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for finite kernel weights and normalized comparisons.*
9. *T records componentwise* hsame *transport for the state, kernel, harmonic, boundary, shadow, Poisson-kernel, metric, Real-seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same finite Martin-boundary read.*
11. *G records* Pkg *provenance over* $\mathsf{MartinBoundary}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{GromovBoundary}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShad}$ $\mathsf{HyperbolicPoissonKernel}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

12. N is the local $\mathsf{NameCert}_{\mathsf{MartinBoundary}^\uparrow}$ *row.*
The classifier compares accepted packets only through $X, K, H, B, S, P_o, V, R, T, C, G, N$. It has no coordinate for a host compactification, quotient boundary equality, selected minimal harmonic function, countable choice, or ambient real completeness.

Theorem 8296.2 (Martin boundary NameCert obligations)**.** *For every accepted* $\mathsf{MartinBoundary}^\uparrow$ *carrier $M = (X, K, H, B, S, P_o, V, R, T, C, G, N)$, the local* $\mathsf{NameCert}_{\mathsf{MartinBoundary}^\uparrow}$ *surface consists exactly of carrier admission for the displayed state window, transition-kernel ledger, positive-harmonic row, Gromov-boundary handoff, boundary-shadow row, Poisson-kernel row, hyperbolic-metric route, Real seal, componentwise transport, displayed replay, provenance, and local naming. Each boundary-facing read must expose the kernel and positive-harmonic rows before it reaches the shadow, Poisson-kernel, metric, or Real-seal rows.*

Proof. Project the carrier. The state window X, transition-kernel ledger K, and positive-harmonic row H are the source rows for the Martin-boundary read.

The hyperbolic boundary surface is downstream. The rows B, S, V expose the Gromov boundary, boundary shadow, and hyperbolic metric route, while P_o reads the Poisson-kernel weight only after those boundary-facing rows are visible.

The terminal Real seal R and the structural rows T, C, G, N preserve the same finite route. Since the carrier contains no host compactification, quotient boundary equality, selected minimal harmonic function, choice schedule, or ambient completeness row, the listed obligations exhaust the local certificate. □

Theorem 8296.3 (Martin boundary shadow handoff)**.** *Every hyperbolic observer-expansion consumer of an accepted* $\mathsf{MartinBoundary}^\uparrow$ *packet must read the finite route*

$$K, H \longmapsto \mathsf{GromovBoundary}^\uparrow, \mathsf{HyperbolicBoundaryShadow}^\uparrow, \mathsf{HyperbolicPoissonKernel}^\uparrow, \mathsf{HyperbolicMetric}^\uparrow, \mathsf{Real}^\uparrow$$

through $X, K, H, B, S, P_o, V, R, T, C, G, N$. The handoff unifies kernel, positive-harmonic, shadow, Poisson-kernel, metric, and Real-seal rows without asserting a host compactification or equality with any quotient boundary.

Proof. Start from Definition 8296.1. The only boundary-producing source rows are the transition-kernel ledger K and the positive-harmonic row H, attached to the displayed state window X.

Apply Definition 8296.2. It forces the Gromov-boundary handoff B, boundary-shadow row S, Poisson-kernel row P_o, hyperbolic-metric row V, and terminal Real seal R to be read as downstream rows of the same finite packet.

The transport, replay, provenance, and local naming rows T, C, G, N keep the route componentwise. Therefore the observer-expansion consumer receives a finite Martin-boundary handoff, not a compactification theorem, quotient boundary equality, selected minimal harmonic function, countable-choice schedule, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{MartinBoundary}^\uparrow$ read is refuted if it reaches a boundary shadow, Poisson-kernel weight, hyperbolic metric comparison, or terminal Real seal without displaying the transition-kernel ledger, positive-harmonic row, Gromov-boundary handoff, transport, replay, provenance, and local NameCert rows.

Independence witness: hyperbolic-metric, gromov-boundary, hyperbolic-boundary-shadow, hyperbolic-poisson-kernel, real: $\mathsf{MartinBoundary}^\uparrow$ is not bijective to any listed sibling because it jointly carries

transition-kernel, positive-harmonic, boundary, shadow, Poisson-kernel, metric, Real-seal, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MartinBoundary}\uparrow}$.

Constructive story: A $\mathsf{MartinBoundary}^{\uparrow}$ packet is generated from a state window, transition-kernel ledger, positive-harmonic row, GromovBoundaryUp handoff, HyperbolicBoundaryShadowUp shadow row, HyperbolicPoissonKernelUp row, HyperbolicMetricUp metric route, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MartinBoundary}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8296.1, Definition 8296.2, and Definition 8296.3 seed the finite Martin-boundary route for hyperbolic observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MartinBoundary}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host compactification, quotient boundary equality, selected minimal harmonic functions, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, transition-kernel exposure, positive-harmonic routing, Gromov-boundary handoff, shadow handoff, Poisson-kernel weighting, hyperbolic-metric routing, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.MartinBoundaryUp.

Chapter 8297

A Concrete Naming Certificate for $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$ packet records the finite square-root service available when the positive input is read from a displayed compact interval source rather than from an isolated positive real row. It sits after the one-input positive square-root packet of chapter 8292, the compact finite-cover route of chapter 8290, the dyadic tolerance ledger of chapter 291, the finite stream window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names a uniform compact-source bracket service; it is not a host square-root function on an interval, an open-cover compactness theorem, a trichotomy principle, quotient real equality, a selected limit construction, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8297.1 (Compact positive real square-root carrier)**.** *A* $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, X, B, D, W, R, H, G, S, V, E, T, C, P, N)$$

with the following visible rows:

1. *I is the compact interval source row whose endpoints and finite subcover route are read through the compact-source interface;*
2. *X is the positive* $\mathsf{Real}^{\uparrow}$ *source row exposed inside the compact interval source;*
3. *B is the dyadic bracket ledger that records a positive lower bracket and an upper bracket for the square-root request on the displayed interval;*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the bracket endpoints, interval mesh, and requested precision;*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing only the source observations and bracket windows needed by the request;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational source and square-root approximants;*
7. *H is the* $\mathsf{HeronSquareRoot}^{\uparrow}$ *recurrence row for the bracketed Heron approximants;*
8. *G is the* $\mathsf{RegularCauchySquareRoot}^{\uparrow}$ *regular-Cauchy square-root row reached after the bracket and recurrence rows are displayed;*

9. *S is the* $\mathsf{PositiveRealSquareRoot}^{\uparrow}$ *service row that reads the positive source, bracket, recurrence, and regular-Cauchy data as one local positive-input service;*
10. *V is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached after the compact source, dyadic bracket, finite windows, regular rational readback, Heron route, regular-Cauchy route, and positive service row are displayed;*
11. *E stores componentwise* hsame *transport for the compact interval, positive source, bracket, tolerance, window, readback, recurrence, regular-Cauchy, positive-service, and seal rows;*
12. *T records the displayed* Cont *replay by which a consumer reads the same finite compact-source square-root service;*
13. *C is the classifier row comparing accepted packets only through the listed compact-source, bracket, readback, service, transport, and replay coordinates;*
14. *P records* Pkg *provenance over* $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$, $\mathsf{PositiveRealSquareRoot}^{\uparrow}$, $\mathsf{CompactInterval}^{\uparrow}$, $\mathsf{PositiveReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchySquareRoot}^{\uparrow}$, $\mathsf{HeronSquareRoot}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*
15. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}}$ *row.*

The classifier has no coordinate for a total host square-root operator on a compact interval, an open-cover compactness theorem, a trichotomy split on reals, quotient real equality, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8297.2 (Compact positive real square-root NameCert obligations)**.** *For the carrier of Definition 8297.1, the local* $\mathsf{NameCert}_{\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}}$ *surface consists exactly of six finite obligations: carrier admission for $Q = (I, X, B, D, W, R, H, G, S, V, E, T, C, P, N)$, compact interval and positive source admission through I, X, dyadic bracket and tolerance accounting through B, D, finite window and regular rational readback through W, R, Heron and regular-Cauchy square-root service rows through H, G, S, V, and componentwise transport, replay, classifier comparison, provenance, and local naming through E, T, C, P, N.*

Proof. Project the carrier rows. The compact source I and positive source X must be displayed before the bracket service is read, so the certificate starts from a compact interval input and a positive real row rather than from an ambient square-root operator.

Next read the numerical rows. The dyadic bracket B and tolerance ledger D expose the finite lower and upper bracket data; the stream windows W and regular rational readback R keep the request finite.

Finally attach the square-root service rows. The Heron row H, regular-Cauchy row G, positive square-root row S, and Real seal V give the bounded service, while E, T, C, P, N transport, replay, compare, source, and name the same service. None of these rows adds open-cover compactness, trichotomy, quotient real equality, selected limits, or ambient completeness. □

Theorem 8297.3 (Compact positive real square-root uniform bracket service)**.** *Every accepted* $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$ *consumer that asks for a square-root value over the displayed compact interval must first read the compact interval source, positive real source, dyadic bracket ledger, dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, Heron recurrence row, regular-Cauchy square-root row, positive square-root service row, terminal Real seal, componentwise transport, displayed replay, classifier comparison, provenance, and local naming. The service therefore exports only the finite uniform bracket route over the compact positive source.*

Proof. Begin with the obligations of Definition 8297.2. They force $I, X, B, D, W, R, H, G, S, V, E, T, C, P, N$ to be visible before a consumer can read the compact-source square-root name.

Use the compact-cover source of chapter 8290 together with the dyadic ledger of chapter 291. These rows keep the interval mesh, bracket endpoints, and requested precision finite.

Read the finite observations through chapter 126 and the regular rational readback through chapter 301. The Heron and regular-Cauchy rows then feed the positive square-root service of chapter 8292, and the endpoint is sealed only through chapter 38.

The structural rows E, T, C, P, N preserve that route. Since the carrier contains no coordinate for a host square-root function on an interval, open-cover compactness, trichotomy, quotient real equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness, no consumer can read those objects from the service. □

Falsifiable prediction: Any accepted CompactPositiveRealSquareRootUp service that bypasses the compact interval source, positive Real source, dyadic bracket ledger, StreamName finite windows, RegSeqRat readback, Heron row, regular-Cauchy square-root row, PositiveRealSquareRoot service row, or terminal Real seal refutes the carrier.

Independence witness: positive-real-square-root, dyadic-uniform-cover, dyadicratcore, streamname, regseqrat, real: $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact interval source data, positive source data, dyadic bracket rows, finite windows, readback, Heron and regular-Cauchy service rows, Real sealing, transport, replay, classifier comparison, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}$ packet is generated from a compact interval source, positive Real source, dyadic bracket ledger, tolerance accounting, finite StreamName windows, RegSeqRat readback, Heron recurrence, regular-Cauchy square-root readback, positive square-root service, terminal Real sealing, componentwise transport, displayed replay, classifier comparison, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8297.1, Definition 8297.2, and Definition 8297.3 seed the compact-source uniform bracket service over the displayed finite rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactPositiveRealSquareRoot}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close a host square-root operator on compact intervals, open-cover compactness, real trichotomy, quotient real equality, selected limits, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-source admission, positive-source guarding, dyadic bracket accounting, finite-window replay, regular rational readback, Heron recurrence accounting, regular-Cauchy square-root readback, Real sealing, transport, provenance, and local naming for BEDC.Derived.CompactPositiveRealSquareRootUp.

Chapter 8298

A Concrete Naming Certificate for $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$

The $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$ packet realizes the observer-phase locality route of chapter 9463 as finite MetaCIC residual-window data. It sits beside the critical-path packet of chapter 765, the normalization frontier of chapter 892, the confluence residual envelope of chapter 3921, the decidability boundary of chapter 749, and the observer phase route of chapter 6920. The packet names a local observer-phase read over residual windows; it does not assert global confluence, subject reduction, beta-conversion decidability, quotient syntax equality, a selected normal form, or kernel consistency.

Definition 8298.1 (MetaCIC observer-phase locality carrier)**.** *A* $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (O, R, J, B, K, D, A, E, H, T, C, P, N)$$

with the following visible rows:

1. *O is the observer-phase row whose read is local to a displayed MetaCIC audit route;*
2. *R is the finite residual-window row retaining the redex and residual observations that feed the local read;*
3. *J is the local-join row, recording the candidate join available inside the displayed residual window;*
4. *B is the candidate-boundary row separating local candidate evidence from any global normalization or confluence assertion;*
5. *K is the bounded checker row consumed through the decidability boundary;*
6. *D is the obstruction-retention row that keeps failed subject-reduction, confluence, or conversion reads visible rather than erased;*
7. *A is the adjacent critical-path row through which candidate-mediated rows, residual budget, bounded checker rows, and L10 faces remain auditable;*
8. *E stores componentwise* hsame *transport for the observer-phase, residual-window, local-join, candidate-boundary, checker, obstruction, and critical-path rows;*
9. *H records the displayed* Cont *replay by which a consumer reads the same local observer-phase route;*

10. *T is the taste-facing instance slot reserved for later Nontrivial and FieldFaithful evidence;*
11. *C is the classifier row comparing accepted packets only through the listed local rows;*
12. *P records* Pkg *provenance over* $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, $\mathsf{MetaCICNormalizationFron}$ $\mathsf{MetaCICConfluenceResidualEnvelope}^{\uparrow}$, $\mathsf{MetaCICDecidableBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows;*
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MetacicObserverPhaseLocality}^{\uparrow}}$ *row.*

The classifier has no coordinate for global confluence, subject reduction, beta-conversion decidability, quotient term equality, selected normal forms, or kernel consistency.

Theorem 8298.2 (MetaCIC observer-phase locality NameCert obligations)**.** *For the carrier of Definition 8298.1, the local* $\mathsf{NameCert}_{\mathsf{MetacicObserverPhaseLocality}^{\uparrow}}$ *surface consists exactly of six finite obligations: carrier admission for $L = (O, R, J, B, K, D, A, E, H, T, C, P, N)$, observer-phase and residual-window admission through O, R, local-join and candidate-boundary separation through J, B, bounded checker and obstruction-retention accounting through K, D, critical-path transport and replay through A, E, H, and taste-facing instance, classifier, provenance, and local naming through T, C, P, N.*

Proof. Project the carrier rows. The observer-phase row O is local because it can be read only with the residual window R, not as an unscoped phase surface.

Next attach the MetaCIC rows. The local join J, candidate boundary B, bounded checker K, and obstruction-retention row D keep the route inside the residual-window envelope while the critical-path row A exposes the candidate-mediated and L10-facing dependencies already present in the surrounding MetaCIC surface.

Finally read E, H, T, C, P, N. Transport and replay preserve the same finite route, the taste-facing slot records that later Lean TasteGate work must provide Nontrivial and FieldFaithful instances, and the classifier, provenance, and local NameCert rows add no global confluence, subject reduction, conversion decider, quotient syntax equality, selected normal form, or kernel-consistency theorem. □

Falsifiable prediction: Any accepted MetacicObserverPhaseLocalityUp packet that exports observer-phase locality without the residual window, local join, candidate boundary, obstruction-retention row, bounded checker, critical-path dependency, transport, replay, provenance, and local NameCert rows refutes the carrier.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacic-confluence-residual-envelope, metacicdecidableboundary: $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries observer-phase locality, residual windows, local joins, candidate-boundary separation, obstruction retention, bounded checker rows, critical-path dependency, taste-facing instance slots, transport, replay, classifier comparison, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicObserverPhaseLocality}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicObserverPhaseLocality}^{\uparrow}$ packet is generated from observer-phase, residual-window, local-join, candidate-boundary, bounded-checker, obstruction-retention, critical-path, taste-facing instance, transport, replay, classifier, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicObserverPhaseLocality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8298.1 and Definition 8298.2 seed the observer-phase locality packet over displayed MetaCIC residual windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicObserverPhaseLocality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not close global confluence, subject reduction, beta-conversion decidability, quotient syntax equality, selected normal forms, Lean verification, bridge checking, or kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, residual-window locality, local-join accounting, candidate-boundary separation, bounded checker routing, obstruction retention, critical-path dependency, Nontrivial and FieldFaithful TasteGate instances, transport, provenance, and local naming for BEDC.Derived.MetacicObserverPhaseLocalityUp.

Chapter 8299

A Concrete Naming Certificate for UniformlyCauchyRealSequence$^{\uparrow}$

Following Bishop and Bridges constructive analysis and Kelley's sequential viewpoint, the UniformlyCauchyRealSequ packet records a real-valued uniformly Cauchy sequence as finite NameCert data. It refines the generic schedule of chapter 3696 by requiring each inspected window to be read through the StreamName$^{\uparrow}$ surface of chapter 126, the regular rational readback of chapter 301, and the Real$^{\uparrow}$ seal of chapter 38. The packet supplies an L10 Real and Completion consumer edge; it does not assert quotient streams, selected representatives, selected limits, countable choice, or ambient real completeness.

Definition 8299.1 (Uniformly Cauchy real sequence carrier)**.** *A* UniformlyCauchyRealSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, W, R, D, M, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the real sequence source row, naming the displayed real-valued stream whose finite observations are admitted by the packet.*
2. *W is the* StreamName$^{\uparrow}$ *window row, exposing the finite indices and comparison windows used by a uniform Cauchy request.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational data visible in those windows.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, storing the precision budget used to compare late real-name windows.*
5. *M is the* CauchyConvergenceModulus$^{\uparrow}$ *row, recording one displayed tail threshold for each requested dyadic tolerance.*
6. *L is the* Real$^{\uparrow}$ *seal row, available only after S, W, R, D, M have been displayed.*
7. *H records componentwise* hsame *transport for the source, window, readback, tolerance, modulus, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a real-sequence request through $S, W, R, D, M, L, H, P, N$.*
9. *P is the* Pkg *provenance over* UniformlyCauchyRealSequence$^{\uparrow}$, UniformlyCauchySequence$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyConvergenceModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformlyCauchyRealSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S, W, R, D, M, L, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, hidden cofinal subsequences, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8299.2 (Uniformly Cauchy real sequence NameCert obligations)**.** *For every accepted* $\mathsf{UniformlyCauchyRealSequence}^{\uparrow}$ *carrier*

$$U = (S, W, R, D, M, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformlyCauchyRealSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the real sequence source S,* $\mathsf{StreamName}^{\uparrow}$ *windows W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger D,* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *schedule M,* $\mathsf{Real}^{\uparrow}$ *seal L, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 8299.1. The analytic rows are the real sequence source S, finite windows W, regular rational readback R, dyadic tolerance ledger D, convergence modulus M, and Real seal L.

The uniformity obligation is read from W, D, M. For a requested tolerance, M supplies one displayed tail threshold, W supplies the finite windows at and beyond that threshold, and D supplies the dyadic comparison budget used by those windows.

The real-valued readback is downstream of the same finite route. The row R records regular rational data for the displayed windows, while L seals the corresponding real-name boundary only after the source, windows, readback, tolerance, and modulus rows are visible.

Finally H, C, P, N transport, replay, source, and name the same route. Since no excluded quotient, choice, selected-representative, selected-limit, host-equality, or ambient-completeness coordinate occurs in U, the listed rows exhaust the local NameCert obligations. □

Theorem 8299.3 (Uniformly Cauchy real sequence RegSeqRat route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer exported by an accepted* $\mathsf{UniformlyCauchyRealSequence}^{\uparrow}$ *packet factors through*

$$S \longmapsto W \longmapsto R, D, M \longmapsto L \longmapsto H, C, P, N.$$

Consequently RealSequentialCompleteness and EffectiveCauchyCompletion consumers may use the displayed source row, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CauchyConvergenceModulus}^{\uparrow}$ *tail schedule, terminal* $\mathsf{Real}^{\uparrow}$ *seal, and local structural rows, but they receive no quotient stream, selected representative, selected limit, hidden cofinal tail, countable choice, host equality, or ambient real completeness.*

Proof. Start with the source and window rows. The row S names the real-valued stream, and W gives only finite observations of that stream for the requested late-window comparison.

Next read R, D, M. The regular rational readback row R supplies the rational data visible in the selected windows, D supplies the dyadic tolerance ledger, and M supplies the single tail threshold required by the uniform Cauchy request.

Only after those rows have been displayed does the packet expose L as a $\mathsf{Real}^{\uparrow}$ seal. Thus a real-name or completion consumer reaches the seal through the same finite schedule rather than through a quotient stream or a selected limit.

The structural rows H, C, P, N preserve the route under componentwise transport, displayed replay, package provenance, and local naming. Since the carrier has no coordinate for the excluded objects, no downstream consumer can bypass the StreamName, RegSeqRat, DyadicRatCore, modulus, and Real-seal boundary. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformlyCauchyRealSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformlyCauchyRealSequence}^{\uparrow}$ packet is generated from a real sequence source row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a CauchyConvergenceModulus tail schedule, a RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformlyCauchyRealSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8299.1, Definition 8299.2, and Definition 8299.3 seed the finite real-valued uniformly Cauchy sequence surface for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformlyCauchyRealSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected representatives, selected limits, hidden cofinal tails, countable choice, host equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coverage, regular rational readback, dyadic tolerance confinement, convergence-modulus exactness, Real seal nonescape, transport stability, continuation replay, and provenance exhaustion for BEDC.Derived.UniformlyCauchyRealSequenceUp.

Chapter 8300

A Concrete Naming Certificate for $\mathsf{NestedClosedSets}^{\uparrow}$

Following Bishop and Bridges on constructive complete metric spaces and nested closed-set principles, the $\mathsf{NestedClosedSets}^{\uparrow}$ packet records the finite BEDC surface for a decreasing inhabited located closed-set chain with an explicit diameter modulus. It sits beside the complete-metric carrier of chapter 128, the nested closed-ball route of chapter 3526, the dyadic tolerance core of chapter 291, the finite observation windows of chapter 126, the regular-rational readback surface of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing route of chapter 1506. The packet names a displayed nested closed-set certificate only; it does not choose points from the sets, quotient equal real names, invoke countable choice, import open-cover compactness, or appeal to ambient $\mathsf{Real}^{\uparrow}$ or metric completeness.

Definition 8300.1 (Nested closed sets carrier)**.** *A* $\mathsf{NestedClosedSets}^{\uparrow}$ *carrier over a displayed complete-metric source is a finite* BHist *packet*

$$Z = (M, F, I, D, B, W, Q, A, H, C, P, N)$$

with the following rows:

1. *M is the consumed* $\mathsf{CompleteMetric}^{\uparrow}$ *source row, exposed only as the metric context in which the closed-set ledgers are read.*
2. *F is the decreasing located closed-set ledger; each displayed level is inhabited, located, and closed by local rows.*
3. *I records the monotone inclusion comparisons $F_{n+1} \subseteq F_n$ as finite classifier data.*
4. *D is the diameter ledger and B is the modulus row forcing the displayed diameters below each requested dyadic tolerance.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window used to read the requested levels of the chain.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic diameter and tolerance observations.*
7. *A is the* $\mathsf{Real}^{\uparrow}$ *seal exposed to downstream real-name consumers after the finite windows and regular-rational rows have been displayed.*
8. *H records componentwise* hsame *transport for M, F, I, D, B, W, Q, A and the local naming rows.*
9. *C records displayed* Cont *replay from the metric source through closed-set inclusion, diameter control, readback, and real sealing.*

10. *P is the* Pkg *provenance over* $\mathsf{NestedClosedSets}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{NestedClosedBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedClosedSets}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, F, I, D, B, W, Q, A, H, C, P, N$. It has no coordinate for countable choice, selected points in the closed sets, quotient equality of reals or streams, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or a host complete-metric theorem.*

Theorem 8300.2 (Nested closed sets NameCert obligations)**.** *For every accepted* $\mathsf{NestedClosedSets}^{\uparrow}$ *carrier*

$$Z = (M, F, I, D, B, W, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedClosedSets}^{\uparrow}}$ *surface consists exactly of complete-metric source exposure through M, decreasing inhabited located closed-set rows through F, inclusion comparisons through I, diameter and modulus rows through D, B, finite observation through W, regular-rational readback through Q, Real sealing through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8300.1. The source side is the displayed complete-metric row M together with the finite closed-set, inclusion, diameter, and modulus ledgers F, I, D, B.

The readback side is reached only through W, Q, A. The observation window W displays the finite levels under inspection, Q reads the dyadic diameter and tolerance data as regular-rational rows, and A seals the downstream real-name observation after those rows are present.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since no selected point, quotient equality, countable choice principle, open-cover compactness row, or ambient completeness theorem is a carrier coordinate, the listed rows exhaust the local certificate surface. □

Theorem 8300.3 (Nested closed sets diameter handoff)**.** *Every completion-facing or real-name consumer of an accepted* $\mathsf{NestedClosedSets}^{\uparrow}$ *packet must read the diameter handoff through*

$$\mathsf{CompleteMetric}^{\uparrow}, \mathsf{NestedClosedBall}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{MetricCompletion}^{\uparrow}$$

before it consumes the terminal row A. The handoff preserves the decreasing located closed-set rows F, inclusion ledger I, diameter ledger D, modulus row B, and structural rows H, C, P, N; it exports no selected point, quotient equality, countable choice, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or ambient metric completeness.*

Proof. Start with the carrier projection. The only diameter data are D and B, and both are indexed by the displayed closed-set chain F and inclusion comparisons I over the complete-metric source M.

The nested closed-ball sibling supplies the local ball-style reading of the same shrinking surface, while $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ provide the tolerance, window, and readback rows. The Real seal A is therefore downstream of a finite observation route rather than an ambient completeness assertion.

Finally use H, C, P, N. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row keep the handoff inside the packet and record the $\mathsf{MetricCompletion}^{\uparrow}$ consumer route. No row remains from which a point selector, quotient equality, countable choice, open-cover compactness, or ambient completeness principle can be read. □

Falsifiable prediction: A consumer requesting a nested closed-set completion witness from $\mathsf{NestedClosedSets}^{\uparrow}$ must display decreasing inhabited located closed-set rows, inclusion rows, diameter and modulus rows, finite StreamName windows, RegSeqRat readback, a Real seal, transport, replay, provenance, and local NameCert rows before any terminal handoff is accepted.

Independence witness: completemetric, nestedclosedball, dyadicratcore, streamname, regseqrat, real, metriccompletion: $\mathsf{NestedClosedSets}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a decreasing located closed-set chain, inhabitedness, inclusion, diameter decay, finite readback, Real sealing, completion-facing handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedClosedSets}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedClosedSets}^{\uparrow}$ packet is generated from a CompleteMetricUp source, decreasing inhabited located closed-set rows, finite inclusion rows, diameter and modulus rows, StreamName windows, RegSeqRat readback, a Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedClosedSets}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8300.1, Definition 8300.2, and Definition 8300.3 seed the finite nested closed-set route from decreasing located closed sets to completion-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedClosedSets}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected intersection points, quotient equality of real names or streams, countable choice, open-cover compactness, ambient Real completeness, ambient metric completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier exposure, decreasing-set inclusion, inhabited locatedness, diameter-modulus handoff, readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.NestedClosedSetsUp.

Chapter 8301

A Concrete Naming Certificate for LindenbaumAlgebra$^{\uparrow}$

Following the Lindenbaum-Tarski algebra for first-order logic, the LindenbaumAlgebra$^{\uparrow}$ packet records formula syntax modulo displayed provable-equivalence evidence as finite NameCert data. It sits beside the syntax-and-deduction surface of chapter 197, the satisfaction-facing carrier of chapter 198, the term-and-substitution surface of chapter 200, and the MetaCIC route boundary of chapter 765. The packet gives MetaCIC a finite algebraic consumer route for formula rows without importing host quotient carriers, Boolean prime ideals, maximal theories, completeness, or choice principles.

Definition 8301.1 (Lindenbaum algebra carrier)**.** *A* LindenbaumAlgebra$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, D, E, B, S, K, H, C, P, N)$$

with the following displayed rows:

1. *F is the* FirstOrder$^{\uparrow}$ *formula-source row, naming the finite formulas admitted by the packet.*
2. *D is the deduction row, recording the finite proof traces whose conclusions are visible to the packet.*
3. *E is the provable-equivalence ledger, containing pairs of formula rows together with displayed derivations in both directions.*
4. *B is the finite Boolean-operation row for negation, conjunction, disjunction, implication, top, and bottom on admitted formulas.*
5. *S is the substitution row, read through the* LambdaCalc$^{\uparrow}$ *term-and-substitution boundary when term substitution is required.*
6. *K is the MetaCIC consumer-route row, recording when the syntax algebra may be passed to* MetaCICCriticalPath$^{\uparrow}$ *as finite formula data.*
7. *H records componentwise* hsame *transport for the formula, deduction, equivalence, operation, substitution, consumer-route, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a syntax-algebra request through $F, D, E, B, S, K, H, P, N$.*
9. *P is the* Pkg *provenance over* LindenbaumAlgebra$^{\uparrow}$*,* FirstOrder$^{\uparrow}$*,* ModelTheory$^{\uparrow}$*,* LambdaCalc$^{\uparrow}$*,* MetaCICCriticalPath$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LindenbaumAlgebra}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, D, E, B, S, K, H, C, P, N$. It has no coordinate for a host quotient set of formulas, a selected representative of an equivalence class, a Boolean prime ideal, a maximal consistent theory, a completeness theorem, semantic truth in all structures, or Classical choice.

Theorem 8301.2 (Lindenbaum algebra NameCert obligations)**.** *For every accepted* $\mathsf{LindenbaumAlgebra}^{\uparrow}$ *carrier*

$$L = (F, D, E, B, S, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LindenbaumAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{FirstOrder}^{\uparrow}$ *formula row F, deduction exposure through D, provable-equivalence exposure through E, finite Boolean-operation exposure through B, substitution exposure through S, MetaCIC consumer routing through K, componentwise transport H, displayed replay C, package provenance P, and local naming row N.*

Proof. Project the carrier of Definition 8301.1. The formula, deduction, provable-equivalence, Boolean-operation, substitution, and consumer-route data are precisely the rows F, D, E, B, S, K.

The NameCert read cannot replace these rows by a host algebra. The equivalence ledger E stores displayed derivations in both directions for named formula pairs, while B stores only finite operation rows on admitted formulas.

Substitution and MetaCIC consumption are likewise explicit rows. The row S keeps term substitution inside the displayed $\mathsf{LambdaCalc}^{\uparrow}$ boundary, and K records the route by which a MetaCIC consumer receives formula data.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded quotient carrier, representative selection, prime ideal, maximal theory, completeness witness, semantic-totality row, or choice principle occurs in L, the listed rows exhaust the local NameCert obligations. □

Theorem 8301.3 (Lindenbaum algebra substitution stability)**.** *In an accepted* $\mathsf{LindenbaumAlgebra}^{\uparrow}$ *packet, every substitution read factors through the displayed route*

$$F, D, E \longmapsto S \longmapsto H, C, P, N.$$

If two formula rows are related by the provable-equivalence ledger E, then any admitted substitution instance may be compared only after the same equivalence evidence has been transported through the substitution row S and the componentwise hsame *row H.*

Proof. Begin with the equivalence ledger. A comparison of formula rows is visible only when E contains the two displayed derivations connecting the formulas.

The substitution row S is downstream of that ledger. It may form a substituted formula row only from the admitted formula source F and the displayed substitution boundary, so it cannot silently quotient formulas or choose a representative.

Transport is then componentwise. The row H moves the formula, equivalence, and substitution rows together, while C, P, N replay, source, and name that same route. Thus substitution stability is a property of the finite displayed ledger, not of an ambient equality of host formula classes. □

Theorem 8301.4 (Lindenbaum algebra finite Boolean operations)**.** *Every Boolean operation exported by an accepted* $\mathsf{LindenbaumAlgebra}^{\uparrow}$ *packet is read from the finite operation row B together with the visible formula and provable-equivalence rows F, D, E. In particular, a consumer may use*

negation, conjunction, disjunction, implication, top, and bottom only as displayed operations on admitted formula rows, and no consumer receives a completed Boolean algebra of host equivalence classes.

Proof. Inspect the operation row B. Its entries name the operation kind and the admitted input and output formula rows, all of which are read through F.

Compatibility with provable equivalence is checked only through D and E. The deduction row gives the finite proof traces, and the equivalence ledger records the bidirectional derivations needed to compare operation outputs.

The structural rows then preserve this operation surface under transport and replay. Because the carrier contains no quotient set, ideal, ultrafilter, maximal theory, or semantic completion row, finite Boolean operations remain displayed syntax operations rather than a host Boolean algebra. □

Theorem 8301.5 (Lindenbaum algebra MetaCIC consumer route)**.** *Every* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *consumer of an accepted* $\mathsf{LindenbaumAlgebra}^{\uparrow}$ *packet factors through*

$$\mathsf{FirstOrder}^{\uparrow},\ \mathsf{ModelTheory}^{\uparrow},\ \mathsf{LambdaCalc}^{\uparrow},\ F, D, E, B, S, K, H, C, P, N.$$

The consumer receives finite formula rows, deduction traces, provable-equivalence evidence, Boolean-operation rows, substitution rows, and local NameCert provenance; it does not receive a host quotient carrier, semantic completeness theorem, Boolean prime ideal, maximal theory, or Classical-choice selection function.

Proof. The route begins with the first-order syntax row F and the deduction row D. These rows supply the formula endpoints and proof traces consumed by the syntax algebra.

The algebraic information is displayed next. The equivalence ledger E records bidirectional provability evidence, and the operation row B records finite Boolean syntax operations on admitted formulas.

Substitution and MetaCIC routing are separate downstream rows. The row S keeps substitution inside the displayed lambda-calculus or term boundary, while K is the only row that exports the packet to $\mathsf{MetaCICCriticalPath}^{\uparrow}$.

The remaining rows H, C, P, N preserve the same packet under transport, replay, provenance, and local naming. Therefore the MetaCIC consumer sees exactly the finite syntax-algebra surface and cannot infer quotient-class, maximality, completeness, or choice data from the route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LindenbaumAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{LindenbaumAlgebra}^{\uparrow}$ packet is generated from FirstOrder formula rows, finite deduction traces, provable-equivalence ledger rows, finite Boolean-operation rows, substitution rows, a MetaCIC consumer-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LindenbaumAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8301.1, Definition 8301.2, Definition 8301.3, Definition 8301.4, and Definition 8301.5 seed the finite provable-equivalence syntax-algebra surface for MetaCIC consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LindenbaumAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host quotient carriers, selected representatives, Boolean prime ideals, maximal theories, semantic completeness, Classical choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, deduction exposure, provable-equivalence exactness, finite Boolean-operation confinement, substitution stability, MetaCIC route nonescape, transport stability, continuation replay, and provenance exhaustion for BEDC.Derived.LindenbaumAlgebraUp.

Chapter 8302

A Concrete Naming Certificate for $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$ packet records the finite source-level equality-modulus route by which two regular Cauchy rational names are compared before a $\mathsf{RealClassifier}^{\uparrow}$ consumer reads an equality boundary. It sits between the classifier surface of chapter 1620, the regular rational schedules of chapter 301, the finite windows of chapter 126, the tolerance ledgers of chapter 291, the regular-Cauchy equivalence boundary of chapter 1404, the terminal real seal of chapter 38, and the Real-facing equality-modulus route of chapter 7601. The chapter names the source equality-modulus row before any quotient stream equality or ambient completeness principle could be mistaken for classifier data.

Definition 8302.1 (Regular Cauchy equality-modulus carrier)**.** *A* $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, Y, S_X, S_Y, W, D, E, C, H, K, P, N)$$

with the following displayed rows:

1. *X and Y are the two source regular Cauchy names whose equality-modulus route is being exposed.*
2. *S_X and S_Y are the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules attached to X and Y.*
3. *W is the common* $\mathsf{StreamName}^{\uparrow}$ *finite window through which both schedules are inspected.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data, recording the displayed radii, split budgets, and comparison cells for the equality request.*
5. *E is the* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row that records the source-level regular-Cauchy equivalence handoff visible before terminal real classification.*
6. *C is the* $\mathsf{RealClassifier}^{\uparrow}$ *readback row that consumes the displayed source route without replacing it by host equality.*
7. *H stores componentwise* hsame *transport for the two names, schedules, common window, dyadic ledger, equivalence row, classifier row, replay, provenance, and local name.*
8. *K stores displayed* Cont *replay of the route*

$$X, Y \longmapsto S_X, S_Y \longmapsto W \longmapsto D \longmapsto E \longmapsto C.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$, $\mathsf{RealClassifier}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyEquivalence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityModulus}^{\uparrow}}$ *row.*

The packet compares accepted carriers only through $X, Y, S_X, S_Y, W, D, E, C, H, K, P, N$. It has no coordinate for host real equality, quotient stream equality, trichotomy, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8302.2 (Regular Cauchy equality-modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$ *carrier*

$$M = (X, Y, S_X, S_Y, W, D, E, C, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityModulus}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the paired source names, paired* $\mathsf{RegSeqRat}^{\uparrow}$ *schedules, common* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance data,* $\mathsf{RegularCauchyEquivalence}^{\uparrow}$ *row,* $\mathsf{RealClassifier}^{\uparrow}$ *readback, transport, replay, provenance, and local naming;*
2. *common-window stability, requiring both schedules to be read through the same finite window W before any equality-modulus answer is consumed;*
3. *dyadic tolerance exactness, requiring the ledger D to display the radii, split budgets, and comparison cells used by the equality request;*
4. *regular-equivalence handoff, requiring the source route to pass through E before a Real-facing classifier row is read;*
5. *RealClassifier nonescape, requiring the classifier row C to consume only the displayed source route and not a host equality or quotient stream equality;*
6. *ledger exhaustion, requiring H, K, P, N to transport, replay, source, and name only the displayed finite packet.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8302.1. The accepted packet displays exactly the two source names, two schedules, common window, dyadic ledger, equivalence row, classifier row, and structural rows.

The common-window and dyadic clauses are read from W and D. Since both schedules are inspected through W and the equality request uses the displayed radii and split budgets of D, the equality-modulus route has no independent hidden window or tolerance source.

The regular-equivalence handoff is the row E, and the classifier readback is the row C. Thus a Real-facing consumer reaches the classifier only after the source regular-Cauchy equivalence boundary has been displayed.

Finally the structural rows H, K, P, N transport, replay, source, and locally name the same packet. Because the carrier omits host real equality, quotient stream equality, trichotomy, countable choice, selected limits, and ambient completeness, none of those principles can be exported by the local NameCert surface. □

Theorem 8302.3 (Regular Cauchy equality-modulus classifier route)**.** *Every* $\mathsf{RealClassifier}^{\uparrow}$*-facing equality read exported by an accepted* $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyEquivalence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{hsame} \longmapsto \mathsf{Cont} \mapsto$$

In carrier notation, the read consumes S_X, S_Y, then W, then D, then E, then the Real-facing classifier boundary over X, Y, and finally the structural rows H, K, P, N. It exports a source-level equality-modulus certificate, not host real equality, quotient stream equality, trichotomy, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted carrier $M = (X, Y, S_X, S_Y, W, D, E, C, H, K, P, N)$. Projection exposes the two $\mathsf{RegSeqRat}^{\uparrow}$ schedules S_X, S_Y before any classifier-facing equality read is available.

Next read the common $\mathsf{StreamName}^{\uparrow}$ window W and the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger D. These rows fix the finite requests and the dyadic tolerance data for the equality-modulus route.

The source equivalence boundary is then the row E. The classifier row C is downstream of E, so a $\mathsf{RealClassifier}^{\uparrow}$ consumer cannot replace the source route by a direct equality test on terminal real data.

Finally consume H, K, P, N. They provide componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming for exactly the same finite packet, and the carrier has no coordinate for the excluded equality, choice, order, selection, or completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEqualityModulus}^{\uparrow}$ packet is generated from two source regular Cauchy names, paired RegSeqRat schedules, one common StreamName window, DyadicRatCore tolerance data, a RegularCauchyEquivalence row, a RealClassifier readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8302.1, Definition 8302.2, and Definition 8302.3 seed the source-level equality-modulus route from paired regular rational schedules to the RealClassifier boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEqualityModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host real equality, quotient stream equality, trichotomy, countable choice, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-window stability, dyadic tolerance exactness, regular-equivalence handoff, RealClassifier nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyEqualityModulusUp.

Chapter 8303

A Concrete Naming Certificate for $\mathsf{FiniteContractionOrbitError}^{\uparrow}$

Following Banach fixed-point theory and Bishop–Bridges constructive analysis, a $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ packet records the finite Picard-orbit error budget used before a contraction route is sealed for Real-facing consumers. It sits beside the contraction data of chapter 3529, the Cauchy orbit route of chapter 2350, and the iterator packet of chapter 6020. The packet gives downstream fixed-point and Picard chapters a finite non-choice error certificate rather than an ambient completeness or selected-limit assertion.

Definition 8303.1 (Finite contraction orbit error carrier)**.** *A* $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, X, F, W, D, Q, E_0, H, C, P, N)$$

with the following displayed rows:

1. *K is the contraction-modulus and contractive-map row read from* $\mathsf{BanachContraction}^{\uparrow}$ *data.*
2. *X is the metric carrier and starting-point row for the finite orbit window.*
3. *F is the self-map replay row for the displayed finite Picard iterates.*
4. *W is the finite iterate window that records the source iterate, terminal iterate, and observed step bound.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row carrying the dyadic tolerance and finite arithmetic ledger.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{CauchyContractionOrbit}^{\uparrow}$ *route that turns the finite orbit window into a regular Cauchy readback.*
7. *E_0 is the* $\mathsf{Real}^{\uparrow}$ *seal row reached from the displayed dyadic and regular-sequence route.*
8. *H records componentwise* hsame *transports for the contraction, orbit, budget, readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from contraction data through the finite window, dyadic budget, Cauchy route, and Real seal.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteContractionOrbitError}^{\uparrow}$, $\mathsf{BanachContraction}^{\uparrow}$, $\mathsf{CauchyContractionOrbit}^{\uparrow}$, $\mathsf{ContractiveCauchyIterator}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteContractionOrbitError}^{\uparrow}}$ *row.*
The carrier has no coordinate for a selected fixed point, quotient orbit equality, host completeness proof, trichotomy comparison, or hidden Real error estimate.

Lean4 (statement) `BEDC.Derived.FiniteContractionOrbitErrorUp`

Theorem 8303.2 (Finite contraction orbit error NameCert obligations)**.** *For every accepted* $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ *carrier*

$$E = (K, X, F, W, D, Q, E_0, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteContractionOrbitError}^{\uparrow}}$ *surface consists of exactly five finite rows of obligation:*

1. *carrier admission for the displayed packet $E = (K, X, F, W, D, Q, E_0, H, C, P, N)$;*
2. *contraction and finite-orbit exposure through K, X, F, W;*
3. *dyadic error-budget exactness through D;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{CauchyContractionOrbit}^{\uparrow}$ *readback through Q followed by the* $\mathsf{Real}^{\uparrow}$ *seal row E_0;*
5. *componentwise transport, replay, provenance, local naming, and non-escape through H, C, P, N.*

Proof. Project the carrier of Definition 8303.1. The rows K, X, F, W are the only contraction and finite-orbit rows, D is the only dyadic budget row, Q is the only Cauchy and regular-sequence readback row, and E_0 is the only Real-facing seal.

The structural rows H, C, P, N preserve, replay, source, and name those displayed rows. Since the carrier contains no selected fixed point, quotient orbit equality, host completeness proof, trichotomy comparison, or hidden Real error estimate, the five listed duties exhaust the local NameCert surface. □

Theorem 8303.3 (Finite contraction orbit error Cauchy route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ *packet reaches the error budget only through the displayed route*

$$\mathsf{BanachContraction}^{\uparrow},\ \mathsf{CauchyContractionOrbit}^{\uparrow},\ \mathsf{ContractiveCauchyIterator}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

In carrier coordinates this route is $K, X, F, W, D, Q, E_0, H, C, P, N$, and no consumer can substitute ambient completeness, a selected limit, quotient orbit equality, or an unrecorded Real comparison for that route.

Proof. Start with an accepted carrier $E = (K, X, F, W, D, Q, E_0, H, C, P, N)$. The contraction data are read through K, X, F, W, so the finite orbit window is visible before any error budget is exported.

Read the budget row next. The only error-budget coordinate is D, and it is a $\mathsf{DyadicRatCore}^{\uparrow}$ ledger tied to the same finite iterate window.

Read the Cauchy and Real-facing rows. The row Q carries the $\mathsf{CauchyContractionOrbit}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ handoff, and E_0 seals the displayed read through $\mathsf{Real}^{\uparrow}$.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same packet; they do not add selected limits, quotient equality, ambient completeness, or hidden comparison data. Therefore the error budget reaches Real-facing consumers only through the displayed Cauchy, regular-sequence, dyadic, and Real route. □

Falsifiable prediction: A candidate packet that omits either the finite iterate window W, the dyadic budget row D, or the Cauchy readback row Q cannot export the same $\mathsf{Real}^{\uparrow}$ seal row E_0 as an accepted $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ packet.

Independence witness: banach-contraction, cauchy-contraction-orbit, contractive-cauchy-iterator, dyadicratcore, regseqrat, real: none is bijective to $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ because this packet jointly carries contraction data, a finite iterate window, dyadic error budget, regular Cauchy readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteContractionOrbitError}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteContractionOrbitError}^{\uparrow}$ packet is generated from contraction data, a metric starting row, self-map replay, a finite iterate window, a dyadic error budget, RegSeqRat and Cauchy contraction-orbit readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteContractionOrbitError}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8303.1, Definition 8303.2, and Definition 8303.3 seed the finite contraction-orbit error packet and its Cauchy, dyadic, regular-sequence, and Real-facing route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteContractionOrbitError}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Banach fixed-point existence, selected limits, ambient completeness, quotient orbit equality, trichotomy comparison, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, contraction-window exposure, dyadic budget exactness, Cauchy and RegSeqRat handoff, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteContractionOrbitErrorUp.

Chapter 8304

A Concrete Naming Certificate for $\mathsf{LocatedSignApartness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedSignApartness}^{\uparrow}$ packet records guarded located sign reads for displayed real names at the L10 Real boundary. It sits beside the located-apartness real bridge of chapter 3564, the dyadic arithmetic core of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite guarded sign-read certificate: it is not trichotomy, not total sign on $\mathsf{Real}^{\uparrow}$, not quotient real equality, and not $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8304.1 (Located sign apartness carrier)**.** *A* $\mathsf{LocatedSignApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, A, D, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the sealed* $\mathsf{Real}^{\uparrow}$ *endpoint row whose sign is being read only under a displayed guard.*
2. *A is the located-apartness real bridge row that supplies the positive separation guard from the zero row or from a named comparison endpoint.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold ledger carrying the positive dyadic radius, tolerance arithmetic, and sign-side comparison data.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window on which the sign read is inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the same finite window.*
6. *E is the real-seal boundary row reached after A, D, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the real row, apartness guard, dyadic ledger, window, readback, seal boundary, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the guarded request through threshold inspection, finite-window readback, regular-rational readback, real-seal handoff, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedSignApartness}^{\uparrow}$*, the located-apartness real bridge,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed guard, threshold, finite-window, readback, seal, transport, replay, provenance, and local naming rows. It contains no coordinate for deciding the sign of an arbitrary $\mathsf{Real}^{\uparrow}$ *name.*

Theorem 8304.2 (Located sign apartness NameCert obligations)**.** *For every accepted* $\mathsf{LocatedSignApartness}^{\uparrow}$ *carrier* $S = (R, A, D, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located-apartness guard exposure through* A*, dyadic threshold exactness through* D*, finite window exposure through* W*, regular rational readback through* Q*, Real seal boundary exposure through* E*, componentwise transport through* H*, displayed replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8304.1. The accepted packet exposes exactly the rows $R, A, D, W, Q, E, H, C, P, N$, so the local certificate begins as finite packet admission rather than a global order principle on constructive reals.

Read the guard and threshold rows next. The located-apartness bridge row A supplies the positive guard, while the dyadic row D supplies the displayed radius and sign-side comparison ledger. The finite window W and regular rational readback Q are the only observations from which the guarded sign read is formed.

Finally use the structural rows. The seal row E is reached only after the guard, threshold, window, and readback rows have been displayed, and H, C, P, N preserve, replay, source, and name exactly that route. Since no row stores trichotomy, total sign, quotient real equality, or completeness, those principles are not local NameCert obligations. □

Theorem 8304.3 (Located sign apartness threshold window)**.** *Every permitted guarded sign read of an accepted* $\mathsf{LocatedSignApartness}^{\uparrow}$ *packet factors through a single displayed threshold-window route*

located-apartness guard A, $\mathsf{DyadicRatCore}^{\uparrow}$ *threshold* D, $\mathsf{StreamName}^{\uparrow}$ *window* W, $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q.

The route authorizes a positive or negative sign read only relative to the displayed guard and threshold. It does not decide zero versus nonzero for arbitrary $\mathsf{Real}^{\uparrow}$ *names.*

Proof. Start from the guard row A. A sign read is admitted only when the located-apartness bridge has already supplied the positive separation data needed to ask for a side of zero or of the named comparison endpoint.

Next inspect the threshold and window rows. The dyadic ledger D fixes the positive radius and comparison arithmetic, while W fixes the finite stream observations and Q fixes their regular rational readback.

The exported sign is therefore scoped by those four rows. Without A there is no apartness guard, without D there is no positive threshold, and without W, Q there is no finite readback. The packet consequently refuses an unguarded total sign function on $\mathsf{Real}^{\uparrow}$. □

Theorem 8304.4 (Located sign apartness Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedSignApartness}^{\uparrow}$ *packet must read the real-seal boundary* E *only after the located-apartness guard* A*, dyadic threshold ledger* D*, finite stream window* W*, regular rational readback* Q*, transport row* H*, replay row* C*, provenance row* P*, and local* $\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}$ *row* N *have been displayed. The boundary exports a guarded sign-read certificate, not quotient real equality, trichotomy, total sign on* $\mathsf{Real}^{\uparrow}$*, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8304.2 to expose the local certificate rows. The Real-facing seal is one row of the same packet, not a detached host-real endpoint.

Apply Definition 8304.3. The sign read reaches the seal only through the located-apartness guard, dyadic threshold, finite window, and regular rational readback rows.

The remaining structural rows keep the boundary stable. Componentwise transport, replay, provenance, and local naming preserve the same displayed packet through H, C, P, N. Because the carrier has no field for quotient equality, trichotomy, total sign, or completeness, none of those objects can be exported at the Real seal boundary. □

Falsifiable prediction: A consumer refutes a $\mathsf{LocatedSignApartness}^{\uparrow}$ packet if it exports a sign read without displaying the located-apartness guard, dyadic threshold ledger, finite stream window, regular rational readback, real-seal boundary, transport, replay, provenance, and local NameCert rows.

Independence witness: located-apartness-real-bridge, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{LocatedSignApartness}^{\uparrow}$ because only this packet binds the located-apartness guard, dyadic threshold ledger, finite observation window, regular rational readback, Real seal boundary, transport, replay, provenance, and local naming into one guarded sign-read carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedSignApartness}^{\uparrow}$ packet is generated from a sealed Real row, a located-apartness guard, a DyadicRatCore threshold ledger, a finite StreamName window, a RegSeqRat readback row, a Real seal boundary, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8304.1, Definition 8304.2, Definition 8304.3, and Definition 8304.4 seed the guarded located sign-read surface at the L10 Real boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedSignApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, total sign on $\mathsf{Real}^{\uparrow}$, quotient real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-apartness guard exposure, dyadic threshold exactness, finite-window readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedSignApartnessUp.

Chapter 8305

A Concrete Naming Certificate for $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$

Following Borel, Cantelli, and standard probability texts, the $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$ packet records the independence-side converse deliberately absent from the first-lemma and finite-window packets of chapter 2357 and chapter 7718. It sits over the normalized probability source of chapter 184, the finite independence ledger of chapter 187, and the terminal scalar readback of chapter 38. The packet names only the finite event-sequence, divergent partial-sum, and independence witness rows needed to expose the converse route as BEDC data; it is not a completed almost-sure quotient, a countable-choice selector, a host product-measure theorem, or an ambient probability-limit principle.

Definition 8305.1 (Borel–Cantelli second-lemma carrier)**.** *A* $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (\Omega, E, W, I, A, D, R, L, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the probability carrier from which all event reads are taken.*
2. E *is the event-sequence row, recording the displayed event names, membership readbacks, and measurable-event witnesses.*
3. W *is the finite repeated-hit window row, exposing the inspected prefix and tail windows before any limiting conclusion is visible.*
4. I *is the* $\mathsf{Independence}^{\uparrow}$ *row for the same displayed event family.*
5. A *is the pairwise or finite-family independence audit row consumed by the converse route.*
6. D *is the divergent partial-probability-sum row for the inspected event probabilities.*
7. R *is the repeated-hit request row, recording that the consumer asks for infinitely many displayed hits only through finite windows.*
8. L *is the converse ledger row, recording the route from independence and divergent partial sums to the repeated-hit surface.*
9. H *records componentwise* hsame *transport for* $\Omega, E, W, I, A, D, R, L, C, P, N$.

10. *C records displayed* Cont *replay from Ω through E, W, I, A, D, R, L before the local name is exposed.*
11. *P is the* Pkg *provenance over* $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$, $\mathsf{BorelCantelli}^{\uparrow}$, $\mathsf{FiniteBorelCantelli}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Independence}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BorelCantelliSecondLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $\Omega, E, W, I, A, D, R, L, H, C, P, N$. It has no coordinate for a completed sigma algebra, quotient almost-sure equality, selected infinite subsequence, host product measure, or ambient real convergence theorem.

Theorem 8305.2 (Borel–Cantelli second-lemma NameCert obligations)**.** *For every accepted* BorelCantelliSecondLe *carrier $S = (\Omega, E, W, I, A, D, R, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BorelCantelliSecondLemma}^{\uparrow}}$ *surface consists exactly of probability-source admission through Ω, event-sequence exposure through E, repeated-hit window exposure through W, independence exposure through I, A, divergent partial-sum exposure through D, repeated-hit request exposure through R, converse ledgering through L, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8305.1. The displayed tuple exposes the probability source, event sequence, finite windows, independence rows, divergent partial-sum row, repeated-hit request, converse ledger, transport, replay, provenance, and local naming.

The event route must pass through Ω, E, W before any converse ledger is read. The independence rows I, A and the divergent partial-sum row D are therefore attached to the same displayed event family and finite windows, rather than to an ambient host sequence.

Finally R, L, H, C, P, N record the repeated-hit request, the converse route, structural transport, replay, source, and local name. Since the packet has no coordinate for a completed sigma algebra, quotient almost-sure equality, selected infinite subsequence, host product measure, or ambient convergence theorem, the listed rows exhaust the NameCert obligations. □

Theorem 8305.3 (Borel–Cantelli second-lemma independence route)**.** *Every accepted* $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$ *converse read factors through*

$$\mathsf{BorelCantelli}^{\uparrow},\ \mathsf{FiniteBorelCantelli}^{\uparrow},\ \mathsf{Independence}^{\uparrow},\ \mathsf{ProbSpace}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The probability source and event-sequence rows are exposed before the finite repeated-hit windows; the independence audit and divergent partial-sum row are then read over that same displayed event family; only after those rows are visible may the converse ledger expose the repeated-hit request. The route exports no first-lemma summability conclusion, no finite-window-only bound, no countable-choice tail selector, no quotient almost-sure equality, and no host product-measure completion.

Proof. Start from the sibling first-lemma and finite-window packets. They provide the event-sequence and bounded-window boundaries named in chapter 2357 and chapter 7718, while leaving the independence converse off their public surfaces.

Next read Ω, E, W, I, A, D in order. The probability source of chapter 184 supplies event probabilities, the independence packet of chapter 187 supplies the displayed independence audit, and the $\mathsf{Real}^{\uparrow}$ surface of chapter 38 supplies the scalar partial-sum readback. These rows share the same event family.

The repeated-hit request R and ledger L are therefore local consumers of the displayed independence and divergence evidence. Componentwise transport, replay, provenance, and local naming through H, C, P, N preserve that route and do not add a quotient almost-sure object, selected infinite subsequence, host product measure, or ambient convergence principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BorelCantelliSecondLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{BorelCantelliSecondLemma}^{\uparrow}$ packet is generated from a probability source row, event-sequence row, finite repeated-hit windows, displayed independence rows, divergent partial-probability sums, a repeated-hit request, a converse ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelCantelliSecondLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8305.1, Definition 8305.2, and Definition 8305.3 seed the independence-side Borel–Cantelli converse route as a finite NameCert surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelCantelliSecondLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed sigma algebras, quotient almost-sure equality, countable-choice tail selection, host product-measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, event-window exactness, independence audit exposure, divergent partial-sum routing, repeated-hit request non-escape, converse ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.BorelCantelliSecondLemmaUp.

Chapter 8306

A Concrete Naming Certificate for $\mathsf{FiniteRadonTightness}^{\uparrow}$

Following Billingsley and Prokhorov, the packet records finite compact-window tightness evidence. It sits beside the probability source of chapter 184, the measure surface of chapter 92, the compact metric test interface of chapter 129, the real comparison boundary of chapter 38, the finite stream windows of chapter 126, and the regular rational readback of chapter 301. It supplies a tightness row for the Prokhorov and Portmanteau consumers of chapter 4008 and chapter 4193 without importing host measures, countable choice, or selected compact sets.

Definition 8306.1 (Finite Radon tightness carrier)**.** *A* $\mathsf{FiniteRadonTightness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (P, M, K, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row whose probability context is visible before any outside-mass read.*
2. *M is the* $\mathsf{Measure}^{\uparrow}$ *event-surface row attached to the same probability context.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-window row used as the finite test window.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row listing the inspected compact windows and tolerance requests.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational tolerance and outside-mass comparisons.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *comparison seal for the displayed mass bounds.*
7. *H records componentwise* hsame *transport for the probability, measure, compact-window, stream, readback, real, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay of the same finite tightness route.*
9. *Q is the* Pkg *provenance over* $\mathsf{FiniteRadonTightness}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRadonTightness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host Radon measure, a chosen compact exhaustion, weak compactness, selected subsequences, quotient event equality, countable choice, or ambient real completeness.

Theorem 8306.2 (Finite Radon tightness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteRadonTightness}^{\uparrow}$ *carrier*

$$T = (P, M, K, S, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteRadonTightness}^{\uparrow}}$ *surface consists exactly of carrier admission for the probability source, measure event surface, compact metric window, finite stream schedule, regular rational tolerance readback, real comparison seal, componentwise transport, displayed replay, package provenance, and local naming. Every Prokhorov- or Portmanteau-facing tightness read therefore factors through* $P, M, K, S, R, E, H, C, Q, N$ *before a weak-convergence consumer can inspect it.*

The packet supplies no host measure object, no selected compact set, no compact exhaustion, no weak compactness theorem, no countable-choice schedule, and no quotient equality of events.

Proof. Project the displayed carrier. The rows P, M, K, S, R, E are the only probability, measure, compact-window, finite-schedule, rational-readback, and real-comparison coordinates available to a tightness consumer.

The route is finite. The stream row S lists the inspected compact windows, the readback row R carries the tolerance comparisons, and the real seal E records the visible outside-mass bounds. This is the data later consumed by $\mathsf{ProkhorovTightProbability}^{\uparrow}$ and $\mathsf{Portmanteau}^{\uparrow}$.

The structural rows H, C, Q, N transport, replay, source, and name exactly that route. Since the carrier contains no coordinate for host measures, selected compact sets, compact exhaustions, weak compactness, countable choice, or quotient event equality, no accepted read can export those objects. □

Falsifiable prediction: Every accepted FiniteRadonTightnessUp consumer that reads a compact-window tightness bound without first displaying the probability, measure, compact-window, stream, readback, and real rows violates the NameCert obligations.

Independence witness: Nearest siblings: ProbSpaceUp, MeasureUp, CompactMetricUp, ProkhorovTightProbabilityUp, and PortmanteauUp. None is bijective to FiniteRadonTightnessUp because each sibling omits at least one row among finite compact-window scheduling, rational outside-mass readback, and the local tightness NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRadonTightness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRadonTightness}^{\uparrow}$ packet is generated from probability source rows, measure event-surface rows, compact metric window rows, finite stream schedules, regular rational tolerance readbacks, real comparison seals, componentwise transport, displayed replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRadonTightness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8306.1, Definition 8306.2, the falsifiable prediction, and the independence witness bind the finite compact-window tightness carrier and its immediate consumer route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRadonTightness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host Radon measures, selected compact exhaustions, weak compactness, countable choice, quotient event equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-window exposure, outside-mass exactness, Prokhorov and Portmanteau consumer nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRadonTightne

Chapter 8307

A Concrete Naming Certificate for $\mathsf{LocatedWeakKonig}^{\uparrow}$

Following Troelstra and van Dalen on choice sequences, bars, and constructive weak Konig readings, the $\mathsf{LocatedWeakKonig}^{\uparrow}$ packet records the finite located-branch surface used when completion and real-name consumers inspect binary trees through explicit prefix windows. It sits after the boundary refusal row of chapter 3482, the finite-prefix route of chapter 2092, the finite stream windows of chapter 126, the Cantor prefix surface of chapter 1475, and the regular-rational readback of chapter 301. The packet names located finite branch evidence; it does not export countable choice, an open-cover compactness theorem, quotient stream equality, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8307.1 (Located weak Konig carrier)**.** *A* $\mathsf{LocatedWeakKonig}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (T, B, W, E, H, C, P, N)$$

with the following displayed rows:

1. *T is the finite binary tree row, carrying decidable node membership, prefix closure, and finite successor checks through the* $\mathsf{KonigLemma}^{\uparrow}$ *and* $\mathsf{CantorSpace}^{\uparrow}$ *sibling routes.*
2. *B is the decidable located bar row, recording for the current request which finite prefixes are already blocked, which remain open inside the displayed window, and which comparison rows are still unresolved.*
3. *W is the finite prefix window row, read through* $\mathsf{StreamName}^{\uparrow}$ *observations and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback before any completion-facing consumer sees branch data.*
4. *E is the branch witness row, storing a finite compatible prefix or a finite obstruction for the displayed window, not a completed infinite branch and not a choice-selected path.*
5. *H records componentwise* hsame *transport for the tree, located bar, prefix window, branch witness, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from a located branch request through T, B, W, E, H, P, N.*
7. *P is the* Pkg *provenance over* $\mathsf{LocatedWeakKonig}^{\uparrow}$, $\mathsf{WeakKonigBoundary}^{\uparrow}$, $\mathsf{KonigLemma}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedWeakKonig}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite located-branch packet. It has no coordinate for countable choice, open-cover compactness, quotient stream equality, selected infinite branches, host path equality, or ambient Real completeness.

Lean4 (statement) `BEDC.Derived.LocatedWeakKonigUp`

Theorem 8307.2 (Located weak Konig NameCert obligations)**.** *For every accepted* $\mathsf{LocatedWeakKonig}^{\uparrow}$ *carrier*

$$L = (T, B, W, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedWeakKonig}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the finite binary tree, decidable located bar, finite prefix window, branch witness, transport, replay, provenance, and local naming rows;*
2. *tree-window exactness, requiring every branch-facing read to expose* T *and* W *before the witness row* E *is consumed;*
3. *located-bar decidability, requiring the bar row* B *to display the current finite blocked/open alternatives inside the same prefix window;*
4. *branch-witness locality, requiring* E *to be a finite compatible prefix or finite obstruction read through* T, B, W*;*
5. *transport and replay preservation through* H *and* C*, with provenance and local naming through* P *and* N*;*
6. *non-escape, excluding countable choice, open-cover compactness, quotient stream equality, selected infinite branches, host path equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No located weak Konig obligation is stored outside T, B, W, E, H, C, P, N*.*

Proof. Project the carrier of Definition 8307.1. The accepted packet displays exactly the finite tree, located bar, finite prefix window, finite witness, and structural rows.

Tree-window exactness reads the $\mathsf{KonigLemma}^{\uparrow}$ and $\mathsf{WeakKonigBoundary}^{\uparrow}$ sibling routes first. Those routes permit finite tree and prefix inspection while refusing branch selection and choice schedules.

The located bar row B and prefix window row W make the branch request finite. A consumer sees only the current blocked/open alternatives and the stream-window readback supplied by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{CantorSpace}^{\uparrow}$, and $\mathsf{RegSeqRat}^{\uparrow}$ before reaching E.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since none of the carrier rows stores a selected infinite path, quotient stream equality, open-cover compactness object, choice schedule, or ambient Real-completeness witness, the listed rows exhaust the local certificate surface. □

Lean4 ✓ `BEDC.Derived.LocatedWeakKonigUp.LocatedWeakKonig namecert obligations`

Theorem 8307.3 (Located weak Konig finite branch route)**.** *Every Real, completion, or Cantor-facing consumer of an accepted* $\mathsf{LocatedWeakKonig}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{WeakKonigBoundary}^{\uparrow},\ \mathsf{KonigLemma}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{CantorSpace}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ T, B, W, E, H, C, P, N.$$

The consumer may inspect located finite branch evidence and finite obstructions inside the displayed prefix window. It receives no countable-choice schedule, no open-cover compactness theorem, no quotient stream equality, no selected infinite branch, and no ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with a consumer read of $L = (T, B, W, E, H, C, P, N)$. Carrier admission exposes a finite binary tree, a decidable located bar, a prefix window, and a finite branch witness or obstruction.

Use the $\mathsf{WeakKonigBoundary}^{\uparrow}$ refusal surface and the $\mathsf{KonigLemma}^{\uparrow}$ finite-prefix route. Together they force tree and branch reasoning to remain in finite prefix data before any path-like consumer can read a witness row.

Next read the stream and Cantor siblings. The finite prefix window W is observed through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{CantorSpace}^{\uparrow}$, and the completion-facing readback goes through $\mathsf{RegSeqRat}^{\uparrow}$ before any Real or completion consumer uses the branch evidence.

The branch witness row E is therefore located inside the displayed finite window. Transport, replay, provenance, and local naming through H, C, P, N preserve that route and add none of the excluded global principles. □

Falsifiable prediction: A $\mathsf{LocatedWeakKonig}^{\uparrow}$ consumer that obtains a selected infinite branch, countable-choice schedule, quotient stream equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness witness without first displaying T, B, W, E, H, C, P, N refutes the carrier surface.

Independence witness: weak-konig-boundary, konig-lemma, streamname, cantorspace, regseqrat: $\mathsf{LocatedWeakKonig}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite binary tree, a decidable located bar, a prefix window, a finite branch witness or obstruction, transport, replay, provenance, and local NameCert row in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedWeakKonig}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedWeakKonig}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8307.1, Definition 8307.2, and Definition 8307.3 seed the finite located-branch NameCert surface over binary trees, located bars, and prefix windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedWeakKonig}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.LocatedWeakKonigUp`

Bridge status: none

Not claimed: This chapter does not close weak Konig's lemma as a global rule, countable choice, selected infinite branches, quotient stream equality, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tree-window exactness, located-bar decidability, finite branch witness locality, transport, replay, and non-escape for BEDC.Derived.LocatedWeakKonigUp.

Constructive story: A $\mathsf{LocatedWeakKonig}^{\uparrow}$ packet is generated from a finite binary tree row, decidable located bar, finite prefix window, finite branch witness or obstruction, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8308

A Concrete Naming Certificate for $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$

Following Bishop and Bridges on finite approximations to real data, the $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ packet records the finite read surface by which a $\mathsf{StreamName}^{\uparrow}$ schedule is observed before a regular rational or real-facing consumer uses it. It sits after the countable-name gate of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names only finite prefix indices, finite observation rows, handoff rows, transport, replay, provenance, and local naming; it is not a countable choice principle and not a host equality test for streams or completed reals.

Definition 8308.1 (Finite-prefix observation interface carrier)**.** *A* $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (I, F, S, R, D, H, K, P, N)$$

with the following displayed rows:

1. *I is the finite prefix index row naming the inspected initial segment of a* $\mathsf{StreamName}^{\uparrow}$ *schedule.*
2. *F is the finite observation row storing exactly the reads made at the indices named by I.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *handoff row whose public requests are restricted to the displayed prefix.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same finite stream observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the precision, radius, and comparison budget attached to the prefix read.*
6. *H records componentwise* hsame *transport for the prefix index, observation row, stream handoff, regular readback, dyadic ledger, provenance, and local naming rows.*
7. *K records displayed* Cont *replay from the finite prefix index through F, S, R, D to the consumer-facing boundary.*
8. *P records* Pkg *provenance over* $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitePrefixObservationInterface}^{\uparrow}}$ *row.*

The carrier has no coordinate for a countable-choice schedule, infinite stream equality, selected limit, host real equality, trichotomy, or ambient completeness principle.

Theorem 8308.2 (Finite-prefix observation NameCert obligations)**.** *For every accepted* FinitePrefixObservationInte *carrier*

$$O = (I, F, S, R, D, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitePrefixObservationInterface}^{\uparrow}}$ *surface consists exactly of finite prefix admission through* I*, finite observation exposure through* F*,* $\mathsf{StreamName}^{\uparrow}$ *handoff through* S*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* R*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance accounting through* D*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* K*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8308.1. The prefix index I determines the only inspected positions, and the observation row F stores only the finite reads at those positions.

The stream handoff S is consumed through that prefix before the regular rational readback R is available. The dyadic ledger D records the tolerance data attached to the same finite observation row, so a consumer cannot replace the readback by a selected infinite stream, host real value, or unbounded choice schedule.

The structural rows H, K, P, N keep the route local. Componentwise hsame transport preserves the displayed prefix rows, Cont replay reuses the same finite route, Pkg provenance records the sibling packets, and the local NameCert names no data beyond the carrier. □

Theorem 8308.3 (Finite-prefix observation handoff boundary)**.** *Every downstream read of an accepted* $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ *packet factors through the finite route*

$$I \longmapsto F \longmapsto S \longmapsto R \longmapsto D$$

with structural transport, replay, provenance, and local naming through H, K, P, N*. The read may be handed to* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*, or* $\mathsf{Real}^{\uparrow}$ *consumers only as this displayed finite prefix boundary, not as countable choice, infinite stream equality, selected limit, host real equality, or completeness data.*

Proof. Start with an accepted packet $O = (I, F, S, R, D, H, K, P, N)$. The carrier definition gives a single route from the prefix index to the observation row and then to the stream, regular rational, and dyadic tolerance rows.

The NameCert obligations of Definition 8308.2 account for every accepted public read. Since those obligations list only $I, F, S, R, D, H, K, P, N$, a consumer has no separate coordinate from which to extract an infinite schedule, a host equality decision, or a completion principle.

Finally use the structural rows. Transport by H and replay by K preserve the same finite prefix route, while P and N record provenance and local naming without adding analytic content. □

Falsifiable prediction: Every accepted $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ read displays a finite prefix index, finite observation row, StreamName handoff, RegSeqRat readback, DyadicRatCore tolerance ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert before any downstream real-facing consumer can use the observation boundary.

Independence witness: stream name, regular rational sequence, dyadic rational core, real: $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ is not bijective to any listed sibling because it binds finite prefix observation rows between a StreamName schedule and RegSeqRat or Real-facing readback.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitePrefixObservationInterface}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FinitePrefixObservationInterface}^{\uparrow}$ packet is generated from a finite prefix index, a finite observation row, a StreamName handoff, a RegSeqRat readback, DyadicRatCore tolerance data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{FinitePrefixObservationInterface}\uparrow}$, seed)

Scope closed: Definition 8308.1 and Definition 8308.2 seed the finite observation route from StreamName schedules to regular rational and real-facing readback data.

Formal verification: FormalStatus(NameCert$_{\mathsf{FinitePrefixObservationInterface}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close countable choice, infinite stream equality, selected limits, host real equality, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked prefix admission, finite observation exposure, StreamName handoff, RegSeqRat readback, DyadicRatCore tolerance accounting, transport, replay, provenance, and local naming for BEDC.Derived.FinitePrefixObservationInterfaceUp.

Chapter 8309

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$ packet records the located regular-Cauchy real interface as finite BEDC NameCert data. It sits over the dyadic tolerance ledger of chapter 291, the finite-window naming surface of chapter 126, the regular rational readback of chapter 301, the terminal real seal of chapter 38, and the located-interval packet of chapter 394. The packet names a constructive locator for a regular Cauchy real name; it is not a selected real representative, quotient stream, trichotomy principle, ambient completeness theorem, or host interval object.

Definition 8309.1 (Bishop regular Cauchy locator carrier)**.** *A* $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, I, E, H, C, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule inspected by the locator request;*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to that schedule;*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the dyadic radius, midpoint, and comparison budget used by the request;*
4. I *is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row naming the displayed interval against which the regular Cauchy name is located;*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after* S, R, D, I *have been displayed;*
6. H *records componentwise* hsame *transport for the schedule, readback, dyadic tolerance, located interval, Real seal, replay, provenance, and local name;*
7. C *records displayed* Cont *replay of the route*

$$S \longmapsto R \longmapsto D \longmapsto I \longmapsto E;$$

8. P *is the* Pkg *provenance over* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLocator}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, D, I, E, H, C, P, N$. It has no coordinate for a selected host real, quotient equality of streams, undecidable trichotomy, hidden interval endpoint, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8309.2 (Bishop regular Cauchy locator NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$ *carrier*

$$L = (S, R, D, I, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLocator}^{\uparrow}}$ *surface consists exactly of the following five obligations:*

1. *carrier admission for the StreamName window, RegSeqRat readback, dyadic tolerance row, located interval, RealUp seal, transport, replay, provenance, and local name;*
2. *locator-window compatibility, requiring S and R to expose the same finite regular-Cauchy request before the located interval row is read;*
3. *dyadic-interval exactness, requiring D and I to display the midpoint, radius, and interval-side data used by the locator;*
4. *Real-seal nonescape, requiring E to consume only the displayed StreamName, RegSeqRat, DyadicRatCore, and LocatedInterval route;*
5. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the displayed packet.*

No locator obligation is stored in a host representative, quotient stream, trichotomy oracle, selected interval endpoint, choice schedule, or ambient completeness row.

Proof. Project the carrier of Definition 8309.1. Its analytic rows are exactly the finite window S, regular rational readback R, dyadic tolerance row D, located interval I, and Real seal E.

Read the locator route in order. The StreamName and RegSeqRat rows expose the inspected regular-Cauchy request; the dyadic row supplies the tolerance data; and the LocatedInterval row records the interval side against which the request is located.

Finally inspect the structural rows. The hsame transport, Cont replay, Pkg provenance, and local $\mathsf{NameCert}$ row preserve the same finite route, while the carrier excludes host representatives, quotient streams, trichotomy, selected endpoints, choice schedules, and ambient completeness. □

Theorem 8309.3 (Bishop regular Cauchy locator Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing locator read exported by an accepted* $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{LocatedInterval}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff exports a finite located regular-Cauchy route, not a completed host real, quotient-stream equality, hidden interval endpoint, countable-choice selector, or ambient completeness claim.

Proof. Start with $L = (S, R, D, I, E, H, C, P, N)$. Projection exposes S, R, D, I before the terminal Real-facing row E is available.

The route through S and R fixes the inspected regular-Cauchy window. The dyadic row D fixes the tolerance budget, and the located interval I fixes the interval evidence for that same request.

The Real seal E is therefore downstream of the displayed finite locator route. Transport, replay, provenance, and local naming do not add another route, so the packet supplies only the constructive located handoff named in the statement. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLocator}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCauchyLocator}^{\uparrow}$ packet is generated from a StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, LocatedInterval row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLocator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8309.1, Definition 8309.2, and Definition 8309.3 seed the finite located regular-Cauchy locator route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCauchyLocator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient stream equality, selected host representatives, selected interval endpoints, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locator-window compatibility, dyadic-interval exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegularCauchyLocatorUp.

Chapter 8310

A Concrete Naming Certificate for $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$ packet records the finite modulus data used by the Real-completeness diagonal representative of Definition 9238.3. It consumes the regular rational readback of chapter 301, the finite-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal Real seal of chapter 38, and the Cauchy-limit boundary of chapter 386. The packet names the diagonal-limit modulus as displayed finite data; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient-stream equality, a selected limit, countable choice, or proof-extensional host equality.

Definition 8310.1 (Regular Cauchy diagonal-limit modulus carrier)**.** *A* $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, S, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *family row from which the diagonal representative is read;*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule selecting the visible diagonal requests;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the precision split used by the diagonal modulus;*
4. *Q is the* $\mathsf{CauchyLimitSeal}^{\uparrow}$ *row certifying that the displayed diagonal route is the one consumed by the limit handoff;*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after R, S, D, Q have been displayed;*
6. *H records componentwise* hsame *transport for the family, windows, dyadic tolerance, Cauchy-limit seal, Real seal, replay, provenance, and local name;*
7. *C records displayed* Cont *replay of the diagonal-limit route*

$$R \longmapsto S \longmapsto D \longmapsto Q \longmapsto E;$$

8. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyLimitSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $R, S, D, Q, E, H, C, P, N$ and has no coordinate for a host-selected diagonal limit, quotient stream, ambient completion principle, countable choice, or proof-extensional equality.

Theorem 8310.2 (Regular Cauchy diagonal-limit modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$ *carrier*

$$M = (R, S, D, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}}$ *surface consists exactly of the following rows:*

1. *carrier admission for the RegSeqRat family row, StreamName selected windows, DyadicRatCore tolerance ledger, CauchyLimitSeal row, RealUp seal, transport, replay, provenance, and local name;*
2. *diagonal-window compatibility, requiring the selected windows in S to be read against the same regular rational family R;*
3. *modulus-budget exactness, requiring D to expose the precision split and dyadic tolerance data used by the diagonal-limit modulus;*
4. *limit-seal handoff, requiring Q and E to consume the displayed R, S, D route before any Real-facing limit read is exported;*
5. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the displayed finite packet.*

No local obligation is stored in a host limit, quotient stream, hidden modulus selector, countable-choice schedule, proof-extensional equality, or ambient completeness row.

Proof. Project the carrier of Definition 8310.1. The analytic rows are the regular rational family R, selected finite windows S, dyadic modulus ledger D, Cauchy-limit seal Q, and Real seal E.

Read the diagonal route in dependency order. The family row and selected windows determine the visible diagonal requests; the dyadic ledger supplies the precision split for those requests; and the Cauchy-limit seal records that the same route is consumed by the Real-facing handoff.

Finally inspect the structural rows. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local $\mathsf{NameCert}$ row preserve the same finite packet, while the carrier omits host limits, quotient streams, countable choice, proof extensionality, hidden modulus selectors, and ambient completeness. □

Theorem 8310.3 (Regular Cauchy diagonal-limit modulus Real route)**.** *Every diagonal-limit modulus read exported by an accepted* $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$ *packet factors through*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyLimitSeal}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route exports the finite modulus and seal data needed by the diagonal representative, not a host-selected limit, quotient stream, hidden choice schedule, proof-extensional equality, or ambient Real-completeness theorem.

Proof. Start from $M = (R, S, D, Q, E, H, C, P, N)$. Projection exposes the RegSeqRat family, selected StreamName windows, dyadic tolerance ledger, and Cauchy-limit seal before the terminal Real row can be read.

The dyadic ledger D fixes the explicit modulus budget for the selected diagonal windows. The seal row Q forces the Real-facing route to consume that same budget rather than a detached host limit.

Transport, replay, provenance, and local naming preserve only the displayed finite packet. Therefore every exported diagonal-limit modulus read remains on the stated RegSeqRat-to-Real route. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}$ packet is generated from a RegSeqRat family row, selected StreamName windows, DyadicRatCore tolerance ledger, CauchyLimitSeal row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8310.1, Definition 8310.2, and Definition 8310.3 seed the finite diagonal-limit modulus route for Real-completeness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyDiagonalLimitModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected diagonal limits, countable choice, proof-extensional equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-window compatibility, modulus-budget exactness, limit-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyDiagonalLimitModulusUp.

Chapter 8311

A Concrete Naming Certificate for $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completions, the $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ packet records the finite reflector surface that turns a named Cauchy stream into regular-rational readback and then into a terminal real-name seal. It sits beside the finite stream interface of chapter 126, the dyadic tolerance core of chapter 291, the regular-rational readback route of chapter 301, the real-name boundary of chapter 38, and the completion reflector of chapter 1585. The packet names a non-quotient handoff surface; it does not select a representative stream, assert host equality of completion points, invoke countable choice, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8311.1 (Regular Cauchy stream reflector carrier)**.** *A* $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ *carrier is a finite packet*

$$R = (S, D, Q, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected stream prefixes and tail requests.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the requested radius, comparison budget, and endpoint arithmetic for the same windows.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S and D.*
4. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream, dyadic, and regular-rational rows have been replayed.*
5. *H records componentwise* hsame *transport for S, D, Q, L, C, P, N.*
6. *C records displayed* Cont *replay of the handoff*

$$S, D \longmapsto Q \longmapsto L.$$

7. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionReflector}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyStreamReflector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through S, D, Q, L, H, C, P, N. It has no coordinate for quotient stream equality, selected representatives, hidden cofinal tails, host completion equality, countable choice, or ambient completeness.

Lean4 (statement) `BEDC.Derived.RegularCauchyStreamReflectorUp`

Theorem 8311.2 (Regular Cauchy stream reflector NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ *carrier* $R = (S, D, Q, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyStreamReflector}^{\uparrow}}$ *surface consists exactly of StreamName finite-window exposure through* S*, DyadicRatCore tolerance exposure through* D*, RegSeqRat readback through* Q*, RealUp seal exposure through* L*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. The reflector may be consumed by a* $\mathsf{CauchyCompletionReflector}^{\uparrow}$ *route only through the displayed chain*

$$\mathsf{StreamName}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

It is not a quotient completion, a selected representative, a hidden choice schedule, or an ambient real-completeness theorem.

Proof. Project the carrier of Definition 8311.1. The only stream-facing rows are S and D, so every read of the packet starts with finite windows and a dyadic tolerance ledger.

The regular-rational row Q is downstream of those two rows, and the terminal real-name row L is downstream of Q. Thus the visible handoff is exactly the displayed StreamName-to-RegSeqRat-to-RealUp route, with the dyadic ledger still attached.

The structural rows H, C, P, N transport, replay, source, and name that same finite route. Since the carrier has no coordinate for quotient stream equality, selected representatives, hidden cofinal tails, host completion equality, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ consumer that exports a real-name handoff must display the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: streamname, dyadicratcore, regseqrat, real, cauchycompletionreflector: no listed sibling is bijective to $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ because this packet jointly binds finite stream windows, dyadic tolerance, regular-rational readback, a real-name seal, reflector provenance, transport, replay, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyStreamReflector}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyStreamReflector}^{\uparrow}$ packet is generated from StreamName finite windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyStreamReflector}^{\uparrow}}$, seed)

Scope closed: Definition 8311.1 and Definition 8311.2 seed the non-quotient StreamName-to-RegSeqRat-to-RealUp reflector route for the L10 Real and Completion phase.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyStreamReflector}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.RegularCauchyStreamReflectorUp`

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, hidden cofinal tails, host completion equality, countable choice, ambient RealUp completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, StreamName finite-window exposure, DyadicRatCore tolerance exactness, RegSeqRat readback, RealUp seal nonescape, componentwise transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyStreamReflectorUp.

Chapter 8312

A Concrete Naming Certificate for $\mathsf{KolmogorovConsistency}^{\uparrow}$

Following Kolmogorov, the $\mathsf{KolmogorovConsistency}^{\uparrow}$ packet records finite index-family probability rows together with their marginal restriction ledgers. It sits between the finite-window surface of chapter 6120, the conditional-law interface of chapter 6929, the located tightness route of chapter 3795, and the tight-probability handoff of chapter 4008. The packet names finite consistency data only; it does not assert an infinite extension, choose a projective limit, or identify host measure-space quotients.

Definition 8312.1 (KolmogorovConsistency carrier)**.** *A* $\mathsf{KolmogorovConsistency}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, F, M, \rho, L, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite index-family row;*
2. *F is the finite family of probability rows over the displayed index windows;*
3. *M records the marginal maps from a larger displayed window to a smaller displayed window;*
4. *ρ is the restriction ledger comparing each larger-window probability row with the smaller-window row named by F;*
5. *L is the finite consistency ledger collecting all displayed restriction checks;*
6. *H records componentwise* hsame *transport for $I, F, M, \rho, L, C, P, N$;*
7. *C records the displayed* Cont *replay of finite-window restriction reads;*
8. *P is the* Pkg *provenance over* $\mathsf{KolmogorovConsistency}^{\uparrow}$, $\mathsf{KolmogorovExtensionFiniteWindow}^{\uparrow}$, $\mathsf{RegularConditionalDi}$ $\mathsf{RealTightness}^{\uparrow}$, $\mathsf{ProkhorovTightProbability}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{KolmogorovConsistency}^{\uparrow}}$ *row.*

The carrier contains no coordinate for an infinite product measure, a selected projective-limit object, quotient event equality, or a host measure-space completion.

Theorem 8312.2 (KolmogorovConsistency obligation surface)**.** *For the carrier of Definition 8312.1, the local* $\mathsf{NameCert}_{\mathsf{KolmogorovConsistency}^{\uparrow}}$ *surface consists exactly of carrier admission for $K = (I, F, M, \rho, L, H, C, P, N$ finite probability-row exposure through F, marginal-map exposure through M, restriction-ledger*

exposure through ρ, consistency-ledger exposure through L, componentwise transport through H, replay through C, package provenance through P, and local naming through N.

Proof. Project the carrier rows. The finite probability family is visible only as the indexed row F, and every comparison between windows is visible only through M, ρ, L.

The structural rows then bind the same packet. The row H transports the finite family and all restriction ledgers componentwise, while C replays only the displayed finite-window restriction reads. The package and naming rows P, N expose the packet as a Kolmogorov consistency surface without adding any host product-measure object. □

Theorem 8312.3 (KolmogorovConsistency marginal ledger)**.** *Every accepted* $\mathsf{KolmogorovConsistency}^{\uparrow}$ *marginal read from a displayed larger window to a displayed smaller window factors through the same rows*

$$I, F, M, \rho, L, H, C, P, N.$$

The read first exposes the two finite windows in I, then the probability rows in F, then the marginal map in M, and then the restriction comparison in ρ as recorded by L.

Proof. Start with the index-family row I and the probability-family row F. A marginal read has no accepted source until both finite windows and their probability rows have been displayed.

Apply the marginal-map and ledger rows. The row M names the finite restriction map, ρ names the comparison with the smaller-window row, and L records that this comparison belongs to the displayed consistency ledger.

Finally use H, C, P, N to transport, replay, package, and name the same finite route. None of these structural rows introduces an infinite extension, quotient event equality, or selected projective-limit witness. □

Theorem 8312.4 (KolmogorovConsistency public certificate)**.** *The public* $\mathsf{KolmogorovConsistency}^{\uparrow}$ *certificate is exactly the finite route through the index-family row, probability-family rows, marginal-map rows, restriction ledger, consistency ledger, componentwise transport, displayed continuation replay, package provenance, and local NameCert. Downstream probability consumers receive this finite certificate before any request for the stronger surfaces named by chapter 6120, chapter 6929, chapter 3795, or chapter 4008.*

Proof. Use the obligation surface to identify the complete public row set. It exposes only $I, F, M, \rho, L, H, C, P, N$ and therefore supplies a finite consistency certificate rather than an ambient measure-space construction.

Use the marginal-ledger theorem for every smaller-window read. It forces each consumer to pass through the displayed finite windows, probability rows, marginal map, and restriction comparison before any downstream probability surface can inspect the packet.

The sibling references are then read as consumers, not as extra coordinates of the certificate. They may consume the finite consistency route, but the packet itself does not claim full infinite extension, choice of projective limits, or host measure-space quotient equality. □

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovConsistency}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovConsistency}^{\uparrow}$ packet is generated from finite index-family rows, probability-family rows, marginal maps, restriction ledgers, consistency ledgers, componentwise transport, displayed replay, provenance, and local NameCert evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovConsistency}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8312.1, Definition 8312.2, Definition 8312.3, and Definition 8312.4 display the finite consistency carrier, marginal restriction ledger, public certificate, and sibling probability routes.

Formal verification: FormalStatus(NameCert$_{\mathsf{KolmogorovConsistency}^{\uparrow}}$, unformalized)
Bridge status: none
Origin: human
Not claimed: This chapter does not close full infinite extension, selected projective limits, host measure-space quotient equality, Lean theorem checking, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, marginal-map exactness, restriction-ledger stability, transport, replay, provenance, and local naming for the finite consistency packet.

Chapter 8313

A Concrete Naming Certificate for $\mathsf{ModulusTailSelection}^{\uparrow}$

Bishop and Bridges present Cauchy convergence through explicit moduli, finite tail estimates, and regular rational readback before a completed real object is consumed. The $\mathsf{ModulusTailSelection}^{\uparrow}$ packet records the local selector that turns a displayed modulus request into the finite tail threshold read by Real and Completion consumers. It sits after the tail-selection criterion of chapter 1618, the convergence-modulus schedule of chapter 1438, the modulus certificate of chapter 7756, and the Cauchy estimate ledger of chapter 1825. The packet exports a finite handoff from modulus data to regular readback and Real sealing; it does not assert quotient stream equality, a selected limit, countable choice, host sequence convergence, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8313.1 (Modulus tail selection carrier)**.** *A* $\mathsf{ModulusTailSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, T, S, R, D, E, H, C, P, N)$$

with the following visible rows:

1. *M is the modulus request row, naming the requested dyadic tolerance and the accepted convergence-modulus surface to be queried.*
2. *T is the displayed tail threshold selected for the request in M.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row opened at and beyond the threshold T.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed tail windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the modulus request, the tail threshold, and the Cauchy estimate comparison.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after M, T, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the modulus request, tail threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a modulus request through $M, T, S, R, D, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{ModulusTailSelection}^{\uparrow}$, $\mathsf{CauchyTailSelectionCriterion}^{\uparrow}$, $\mathsf{CauchyConvergenceModulus}^{\uparrow}$, $\mathsf{CauchyModulusCertificate}^{\uparrow}$, $\mathsf{CauchyEstimate}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{ModulusTailSelection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $M, T, S, R, D, E, H, C, P, N$. It has no coordinate for quotient Cauchy classes, selected representatives, selected limits, countable choice, host real equality, hidden unbounded search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8313.2 (Modulus tail selection NameCert obligations)**.** *For every accepted* $\mathsf{ModulusTailSelection}^{\uparrow}$ *carrier $K = (M, T, S, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusTailSelection}^{\uparrow}}$ *surface consists exactly of carrier admission for the modulus request, displayed tail threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, componentwise transport, displayed replay, package provenance, and local naming. The carrier consumes the sibling surfaces of chapter 1618, chapter 1438, chapter 7756, and chapter 1825 before exporting any tail-read row.*

Proof. Project the carrier of Definition 8313.1. The analytic rows are precisely the modulus request M, selected threshold T, finite windows S, regular rational readback R, dyadic tolerance row D, and terminal seal E.

The request and threshold rows are read first. The request M is the displayed query into the convergence-modulus and certificate surfaces, while T is the finite threshold returned to the tail-selection route.

The readback rows are downstream of that threshold. The row S exposes only StreamName windows at and beyond T, the row R gives the matching RegSeqRat readback, and the row D supplies the dyadic tolerance arithmetic used by the estimate ledger.

Finally E, H, C, P, N seal, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for quotient names, selected limits, countable choice, host equality, hidden unbounded search, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8313.3 (Modulus tail selection Cauchy handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{ModulusTailSelection}^{\uparrow}$ *packet must read the route*

$$\mathsf{CauchyConvergenceModulus}^{\uparrow},\ \mathsf{CauchyModulusCertificate}^{\uparrow} \longmapsto M, T \longmapsto \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}$$

through $M, T, S, R, D, E, H, C, P, N$. Thus the packet supplies a finite tail-selection certificate between convergence moduli and RegSeqRat/RealUp reads without claiming ambient Real completeness.

Proof. Begin with the sibling modulus surfaces. The convergence-modulus schedule supplies the admissible request row, and the modulus certificate makes the displayed threshold eligible for downstream tail reads.

Apply the tail-selection criterion. The request row M and threshold row T bind the requested dyadic tolerance to one displayed tail threshold, rather than to a hidden search over all later indices.

Read the finite windows and estimates next. The StreamName row S opens the selected tail windows, the RegSeqRat row R supplies their rational readback, the DyadicRatCore row D supplies the tolerance arithmetic, and the Cauchy estimate surface records the comparison consumed before the Real seal.

The Real row E is therefore reached only after the finite modulus, threshold, window, readback, tolerance, and estimate route has been displayed. The structural rows H, C, P, N preserve that route under transport, replay, provenance, and local naming, so no ambient completeness or choice principle is exported. □

Falsifiable prediction: A $\mathsf{ModulusTailSelection}^{\uparrow}$ read is refuted whenever a Real or Completion consumer uses a selected tail threshold without displaying the modulus request, tail threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: cauchy-tail-selection-criterion, cauchy-convergence-modulus, cauchy-modulus-certificate, cauchy-estimate, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{ModulusTailSelection}^{\uparrow}$ because the selector jointly records the request, threshold, window, readback, tolerance, seal, transport, replay, provenance, and local naming route.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusTailSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusTailSelection}^{\uparrow}$ packet is generated from a modulus request, displayed tail threshold, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance row, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusTailSelection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8313.1, Definition 8313.2, and Definition 8313.3 seed the finite selector route from convergence-modulus data to RegSeqRat readback and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusTailSelection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient Cauchy classes, selected representatives, selected limits, countable choice, host real equality, hidden unbounded search, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request exposure, threshold selection, StreamName window coverage, RegSeqRat readback, DyadicRatCore tolerance accounting, Cauchy estimate handoff, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.ModulusTailSelectionUp.

Chapter 8314

A Concrete Naming Certificate for $\mathsf{NoetherianInduction}^{\uparrow}$

Following Emmy Noether's finite-chain viewpoint and the algebraic use in Atiyah–Macdonald, the $\mathsf{NoetherianInduction}^{\uparrow}$ packet records descent arguments as finite BEDC rows rather than as host well-founded induction. It sits beside the ideal-chain surface of chapter 3637, the module-chain surface of chapter 3648, the finite rank discipline of chapter 7374, and the chain-cover carrier of chapter 7370. The packet gives algebra chapters a reusable finite descent certificate while leaving ambient Noetherian induction, selected counterexample chains, classical minimal elements, and quotient carrier equality outside the public surface.

Definition 8314.1 (Noetherian induction carrier)**.** *A* $\mathsf{NoetherianInduction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, D, O, E, T, R, P, N, L)$$

with the following displayed rows:

1. *S is the source row, naming the* $\mathsf{NoetherianRing}^{\uparrow}$ *or* $\mathsf{NoetherianModule}^{\uparrow}$ *surface from which the descent request is read.*
2. *D is the descending-chain row, listing the inspected obstruction chain and the finite predecessor relation used by the request.*
3. *O is the obstruction row, recording the currently unclosed counterexample or subobject boundary.*
4. *E is the descent-step row, recording the finite step that replaces a visible obstruction by a strictly earlier row in D.*
5. *T is the stabilization row, exposing the finite stage at which the displayed chain cannot continue to produce fresh obstructions.*
6. *R is the transport row for the source, chain, obstruction, descent-step, stabilization, replay, provenance, and local naming rows.*
7. *P is the displayed replay row, specifying how a consumer replays the same finite descent route before using the stabilized conclusion.*
8. *N is the* Pkg *provenance over* $\mathsf{NoetherianInduction}^{\uparrow}$, $\mathsf{NoetherianRing}^{\uparrow}$, $\mathsf{NoetherianModule}^{\uparrow}$, $\mathsf{WellFoundedTreeRank}^{\uparrow}$ $\mathsf{FiniteChainDecomposition}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *L is the local* $\mathsf{NameCert}_{\mathsf{NoetherianInduction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for host well-founded induction, a globally selected minimal counterexample, an infinite descending chain, quotient subobject equality, classical choice, or an ambient Noetherian principle.

Theorem 8314.2 (Noetherian induction NameCert obligations)**.** *For every accepted* $\mathsf{NoetherianInduction}^{\uparrow}$ *carrier*

$$I = (S, D, O, E, T, R, P, N, L),$$

the local $\mathsf{NameCert}_{\mathsf{NoetherianInduction}^{\uparrow}}$ *surface consists exactly of source admission through* S*, descending-chain exposure through* D*, obstruction visibility through* O*, descent-step exposure through* E*, stabilization exposure through* T*, componentwise transport through* R*, displayed replay through* P*, provenance through* N*, and local naming through* L*. A consumer may use the induction packet only after the finite chain, the current obstruction, and the step-to-earlier-row witness are displayed.*

Proof. Project the carrier of Definition 8314.1. The source row S fixes the Noetherian ring or module surface before a descent request is read, and the row D names the finite chain on which the request is evaluated.

The obstruction row O and the descent-step row E are paired. A consumer cannot cite a smaller obstruction unless E displays the finite predecessor relation inside the same chain row D.

The stabilization row T closes the displayed descent by giving a finite stage where no fresh obstruction row remains available. Transport and replay through R and P preserve the same source, chain, obstruction, step, and stabilization rows, while N and L source and name the packet.

Since host well-founded induction, selected minimal counterexamples, infinite descending chains, quotient subobject equality, choice, and ambient Noetherian principles have no coordinate in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8314.3 (Noetherian induction chain descent)**.** *Every accepted* $\mathsf{NoetherianInduction}^{\uparrow}$ *descent read factors through the finite route*

$$\mathsf{NoetherianRing}^{\uparrow},\ \mathsf{NoetherianModule}^{\uparrow},\ \mathsf{WellFoundedTreeRank}^{\uparrow},\ \mathsf{FiniteChainDecomposition}^{\uparrow}.$$

The chain row supplies the inspected predecessor spine, the rank row or chain decomposition bounds the visible descent, the obstruction row is consumed by the displayed descent step, and the stabilization row records the endpoint where no new obstruction can be produced. The read exports no host well-founded induction theorem, no selected minimal counterexample, no infinite descending chain, and no classical choice principle.

Proof. Start from the source row. If the descent request is algebraic, the relevant $\mathsf{NoetherianRing}^{\uparrow}$ or $\mathsf{NoetherianModule}^{\uparrow}$ packet supplies the finite chain-stabilization surface; if the request is purely order-theoretic, the $\mathsf{WellFoundedTreeRank}^{\uparrow}$ and $\mathsf{FiniteChainDecomposition}^{\uparrow}$ siblings supply the finite rank or chain-spine rows.

Next read D, O, E. The chain row exposes the inspected predecessor sequence, the obstruction row names the current failed subclaim, and the descent-step row replaces it by an earlier displayed row. This is finite chain descent, not an appeal to a host induction principle.

Finally consume T, R, P, N, L. Stabilization prevents an endless supply of fresh obstruction rows, while transport, replay, provenance, and local naming keep the argument on the same finite packet. The excluded host induction, selector, infinite-chain, quotient, and choice objects therefore cannot be exported by an accepted read. □

Falsifiable prediction: An accepted $\mathsf{NoetherianInduction}^{\uparrow}$ consumer is refuted if it reaches a stabilized conclusion without first displaying the source row, finite descending-chain row, obstruction row, descent-step row, stabilization row, transport, replay, provenance, and local naming rows.

Independence witness: Nearest siblings: noetherian-ring, noetherian-module, well-founded-tree-rank, and finite-chain-decomposition. None is bijective to $\mathsf{NoetherianInduction}^{\uparrow}$ because this packet jointly carries a descent request, obstruction row, finite descent step, stabilization row, replay, provenance, and local naming for a single induction-facing read.

Closure status for $\mathsf{NameCert}_{\mathsf{NoetherianInduction}^{\uparrow}}$.

Constructive story: A $\mathsf{NoetherianInduction}^{\uparrow}$ packet is generated from a Noetherian ring or module source row, finite descending-chain row, obstruction row, descent-step row, stabilization row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NoetherianInduction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8314.1, Definition 8314.2, and Definition 8314.3 seed the finite descent packet over source, chain, obstruction, step, stabilization, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NoetherianInduction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host well-founded induction, selected minimal counterexamples, infinite descending chains, quotient subobject equality, classical choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, descending-chain exposure, obstruction visibility, descent-step exactness, stabilization exposure, transport, replay, provenance, and local naming for BEDC.Derived.NoetherianInductionUp.

Chapter 8315

A Concrete Naming Certificate for $\mathsf{LocatedCompletionCore}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{LocatedCompletionCore}^{\uparrow}$ packet records the finite located Cauchy-completion core that a Real-facing construction may consume before any quotient completion or selected limit is named. It sits beside the metric completion route of chapter 1506, the complete metric service of chapter 128, the Cauchy filter surface of chapter 333, the finite StreamName interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, and the terminal Real seal of chapter 38. The carrier is a finite L10 completion spine; it is not a quotient completion object, a chosen limit, a countable-choice schedule, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8315.1 (LocatedCompletionCore carrier)**.** *A* $\mathsf{LocatedCompletionCore}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, S, F, W, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the completion source row, naming the metric or completion-facing input before any completed point is exposed.*
2. *S is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, recording only the displayed service interface used by the completion read.*
3. *F is the* $\mathsf{LocatedCauchyFilter}^{\uparrow}$ *row, carrying the finite located Cauchy filter evidence read by the core.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window through which Cauchy requests and located tests are inspected.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed window and filter data.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the precision, radius, and comparison budget visible to the read.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after M, S, F, W, R, D have been displayed.*
8. *H records componentwise* hsame *transport for the source, service, located Cauchy filter, window, readback, tolerance ledger, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from any limit-facing request through $M, S, F, W, R, D, E, H, P, N$.*

10. *P records* Pkg *provenance over* $\mathsf{LocatedCompletionCore}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{LocatedCauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionCore}^{\uparrow}}$ *row.*

The packet has no coordinate for quotient completion equality, selected completed points, hidden representatives, countable choice, trichotomy, or ambient Real completeness.

Theorem 8315.2 (LocatedCompletionCore NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompletionCore}^{\uparrow}$ *carrier $L = (M, S, F, W, R, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LocatedCompletionCore}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the completion source, complete service, located Cauchy filter, finite window, regular rational readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local name;*
2. *located Cauchy exposure, requiring every completion-facing read to display F before any readback or seal is consumed;*
3. *finite-window exactness, requiring W and D to carry the visible requests, tolerances, and comparison budget used by R;*
4. *Real seal non-escape, requiring E to be consumed only as the terminal seal downstream of M, S, F, W, R, D;*
5. *structural exhaustion, requiring H, C, P, N to transport, replay, source, and name only the displayed finite packet.*

No local NameCert obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 8315.1. The accepted packet exposes exactly the completion source, complete service row, located Cauchy filter, finite window, regular rational readback, dyadic tolerance ledger, terminal Real seal, and structural rows.

Located Cauchy exposure is the row F. Since F is upstream of W, R, D, E, a completion-facing consumer cannot treat the terminal seal as a selected completed point before the located filter evidence is visible.

Finite-window exactness uses W, D, R. The window stores the inspected requests, the dyadic ledger stores the tolerance data, and the readback row records only the regular rational data available through those finite rows.

The remaining rows transport, replay, source, and locally name the same packet. Because the carrier omits quotient completion equality, selected completed points, hidden representatives, countable choice, trichotomy, and ambient Real completeness, no NameCert obligation can export them. □

Theorem 8315.3 (LocatedCompletionCore choice-free limit route)**.** *Every limit-facing read of an accepted* $\mathsf{LocatedCompletionCore}^{\uparrow}$ *carrier factors through the displayed finite rows*

$$M, S, F, W, R, D, E, H, C, P, N.$$

In particular, a consumer receives the completion source, complete service, located Cauchy filter, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row, and receives no quotient completion, selected limit, countable choice, trichotomy, or ambient Real completeness.*

Proof. Start with the carrier of Definition 8315.1. The completion-facing input is M, the only complete-service coordinate is S, and the located Cauchy evidence is the displayed filter row F.

The finite analytic read is then forced through W, R, D. The StreamName window supplies the inspected requests, the RegSeqRat row supplies regular rational readback, and the dyadic ledger supplies the tolerance budget attached to that read.

Apply the NameCert obligations of Definition 8315.2. They place the terminal Real seal E downstream of M, S, F, W, R, D and exhaust every structural read through H, C, P, N.

Since the carrier has no coordinate for quotient completions, selected limits, countable choice, trichotomy, or ambient Real completeness, a limit-facing consumer cannot cite any of those principles as $\mathsf{LocatedCompletionCore}^{\uparrow}$ evidence. □

Falsifiable prediction: Every accepted $\mathsf{LocatedCompletionCore}^{\uparrow}$ read is refuted if it reaches a Real-facing seal without displaying the completion source, complete service row, located Cauchy filter, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, transport, replay, provenance, and local NameCert rows.

Independence witness: metriccompletion, completemetric, cauchyfilter, streamname, regseqrat, dyadicratcore, real: $\mathsf{LocatedCompletionCore}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a completion source, complete service, located Cauchy filter, finite window, regular readback, dyadic tolerance ledger, terminal Real seal, transport, replay, provenance, and local naming as one finite core.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompletionCore}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompletionCore}^{\uparrow}$ packet is generated from a completion source, complete service row, located Cauchy filter, finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompletionCore}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8315.1, Definition 8315.2, and Definition 8315.3 seed the finite located completion core consumed by Real-facing completion routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompletionCore}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected completed points, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located Cauchy exposure, finite-window exactness, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompletionCoreUp.

Chapter 8316

A Concrete Naming Certificate for MetacicResidualCriticalPairSieve$^{\uparrow}$

The MetacicResidualCriticalPairSieve$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as a finite residual sieve surface. It sits beside the critical-path carrier of chapter 765, the confluence audit packet of chapter 735, the candidate-normalization handoff of chapter 5547, and the decidable boundary of chapter 749. The sieve records bounded residual candidates and blocked edges before any confluence-facing read is public; it does not assert full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency.

Definition 8316.1 (Metacic residual critical-pair sieve carrier)**.** *A* MetacicResidualCriticalPairSieve$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, Q, C, H, D, R, B, T, K, P, N)$$

with the following displayed rows:

1. *A is the MetaCIC audit anchor read through* MetaCICCriticalPath$^{\uparrow}$*.*
2. *Q is the finite residual critical-pair candidate list, naming the inspected source, left residual edge, right residual edge, and local overlap code for each candidate.*
3. *C is the* MetaCICConfluenceAuditPacket$^{\uparrow}$ *row that records how the candidate list is read by the confluence audit surface.*
4. *H is the* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *row, retaining candidate-normalization evidence before any bounded endpoint is cited.*
5. *D is the* MetaCICDecidableBoundary$^{\uparrow}$ *row used only as a bounded checker and not as global conversion decidability.*
6. *R is the residual-window row, recording the finite reduction neighborhood in which each critical pair is inspected.*
7. *B is the blocked-edge ledger, recording candidates whose local join is not discharged by the displayed window and checker rows.*
8. *T records componentwise* hsame *transport for the anchor, candidate list, audit packet, handoff, decidable boundary, residual window, blocked-edge ledger, replay, provenance, and local naming rows.*

9. *K records displayed* Cont *replay from a sieve request through* $A, Q, C, H, D, R, B, T, P, N$.
10. *P records* Pkg *provenance over* MetacicResidualCriticalPairSieve$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICConfluenceAudit MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$, MetaCICDecidableBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* NameCert$_{\text{MetacicResidualCriticalPairSieve}^{\uparrow}}$ *row.*

The packet has no coordinate for a global confluence theorem, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency.

Theorem 8316.2 (Metacic residual critical-pair sieve NameCert obligations)**.** *For every accepted* MetacicResidualCriticalPairSieve$^{\uparrow}$ *carrier* $S = (A, Q, C, H, D, R, B, T, K, P, N)$*, the local* NameCert$_{\text{MetacicResidualCritical}}$ *surface consists exactly of carrier admission, residual-candidate exposure, audit-packet routing, candidate-normalization handoff retention, decidable-boundary boundedness, blocked-edge retention, componentwise transport, displayed replay, package provenance, and local naming. Every public read factors through*

$$A, Q, C, H, D, R, B, T, K, P, N$$

before it may be cited as sieve evidence.

Proof. Carrier admission is projection from Definition 8316.1. The accepted packet exposes the audit anchor, finite residual candidate list, confluence audit row, candidate-normalization handoff, decidable boundary, residual window, blocked-edge ledger, and structural rows.

Residual-candidate exposure is the row Q together with the residual window R. These rows name the inspected critical pairs and the bounded neighborhood in which their residual edges are compared.

Audit routing and handoff retention use C, H, D, B. The confluence audit packet reads the candidate list, the candidate-normalization handoff retains its premise surface, the decidable boundary supplies only bounded checking, and the blocked-edge row keeps non-discharged candidates visible.

The structural rows T, K, P, N transport, replay, source, and locally name the same finite packet. Since the carrier omits global confluence, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, and consistency, no local NameCert obligation can export those endpoints. □

Theorem 8316.3 (Metacic residual critical-pair sieve boundary)**.** *Every confluence-facing read of an accepted* MetacicResidualCriticalPairSieve$^{\uparrow}$ *packet must first display the* MetaCICCriticalPath$^{\uparrow}$ *anchor, the finite residual critical-pair candidate list, the* MetaCICConfluenceAuditPacket$^{\uparrow}$ *row, the* MetacicCandidateNormalizationConfluenceHandoff$^{\uparrow}$ *row, the* MetaCICDecidableBoundary$^{\uparrow}$ *bounded checker row, residual-window data, blocked-edge retention, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* NameCert *row. The read is a finite sieve over residual critical pairs, not full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, or consistency.*

Proof. Start with the carrier of Definition 8316.1. The anchor A fixes the critical-path surface, while Q and R name the finite residual critical-pair window being inspected.

The confluence audit row C and the candidate-normalization handoff H keep the read attached to the audit and candidate premise surfaces. The decidable boundary row D is only a bounded checker for the displayed window, and the blocked-edge row B records candidates not discharged by that bounded check.

Apply the NameCert obligations of Definition 8316.2. They exhaust transport, replay, provenance, and local naming through T, K, P, N.

Because none of the carrier coordinates is a global Church–Rosser proof, unrestricted subject-reduction proof, global conversion decider, quotient syntax equality, host evaluator soundness principle, or consistency theorem, no public read of the sieve may cite such an endpoint. □

Falsifiable prediction: Every accepted $\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}$ read is refuted if it exports a confluence-facing candidate while omitting the critical-path anchor, finite residual candidate list, confluence audit packet, candidate-normalization handoff, decidable-boundary checker, residual window, blocked-edge ledger, transport, replay, provenance, or local NameCert rows.

Independence witness: metaciccriticalpath, metacicconfluenceauditpacket, metacic-candidate-normalization-confluence-handoff, metacicdecidableboundary, metacic-residual-critical-pair: none is bijective to $\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}$ because the sieve jointly carries residual critical-pair candidates, residual windows, bounded checker status, blocked-edge retention, audit routing, candidate-normalization handoff, transport, replay, provenance, and local naming in one finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}}$.

Constructive story: A $\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}$ packet is generated from a MetaCICCriticalPath anchor, finite residual critical-pair candidates, a MetaCICConfluenceAuditPacket row, a MetacicCandidateNormalizationConfluence-Handoff row, a MetaCICDecidableBoundary bounded checker, residual windows, blocked-edge retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8316.1, Definition 8316.2, and Definition 8316.3 seed the finite residual critical-pair sieve route for the MetaCIC confluence audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetacicResidualCriticalPairSieve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Church–Rosser, unrestricted subject reduction, global conversion decidability, quotient syntax equality, host evaluator soundness, consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-candidate exposure, audit routing, candidate-normalization handoff retention, decidable-boundary boundedness, blocked-edge retention, transport, replay, provenance, and local naming for BEDC.Derived.MetacicResidualCriticalPairSieveUp.

Chapter 8317

A Concrete Naming Certificate for MetaCICCriticalPairResidualScheduler$^{\uparrow}$

The MetaCICCriticalPairResidualScheduler$^{\uparrow}$ packet realizes the confluence audit map of chapter 9378 as a finite scheduler for critical-pair residual reads. It sits beside the critical-path route of chapter 765, the normalization frontier of chapter 892, the confluence audit packet of chapter 735, and the parallel-diamond residual boundary of chapter 5126. The packet is a bounded residual and local-diamond scheduler; it is not full Church–Rosser, subject reduction, evaluator equality, quotient syntax equality, or MetaCIC kernel consistency.

Definition 8317.1 (MetaCIC critical-pair residual scheduler carrier)**.** *A* MetaCICCriticalPairResidualScheduler$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, A, R, J, B, O, H, C, P, N)$$

with the following displayed rows:

1. *K is the critical-pair row, naming the finite local peak and the inspected binder window.*
2. *F is the normalization-frontier row, recording the candidate-normalization boundary available for the same peak.*
3. *A is the confluence-audit row, retaining the checked fragment and the named blocked premises from the audit map.*
4. *R is the residual-schedule row, ordering residual reads before any local diamond handoff is exposed.*
5. *J is the candidate local-join row produced by the schedule when the bounded residual rows agree.*
6. *B is the bounded residual-checker row, recording the finite budget and the local tests performed by the scheduler.*
7. *O is the obstruction row, retaining residual-substitution, subject-reduction, evaluator-equality, quotient-equality, and kernel-consistency boundaries when the schedule does not expose a local join.*
8. *H records componentwise* hsame *transport for the critical-pair, frontier, audit, schedule, local-join, checker, obstruction, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay through the same residual-scheduler route.*

10. *P is the* Pkg *provenance over* $\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}$, $\mathsf{MetaCICCriticalPath}^{\uparrow}$, MetaCICNormalizatic $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, $\mathsf{ParallelDiamondResidual}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, unbounded residual search, or MetaCIC kernel consistency.

Theorem 8317.2 (MetaCIC critical-pair residual scheduler obligations)**.** *For every accepted* MetaCICCriticalPairRe *carrier*

$$S = (K, F, A, R, J, B, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}}$ *surface consists exactly of critical-pair exposure through K, normalization-frontier exposure through F, confluence-audit exposure through A, residual-schedule exposure through R, candidate local-join exposure through J, bounded-checker exposure through B, obstruction visibility through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N. A confluence-facing consumer may inspect a local diamond handoff only after the residual schedule and bounded checker rows are displayed.*

Proof. Project the carrier of Definition 8317.1. The row K fixes the critical pair, F fixes the normalization boundary, and A fixes the confluence audit context before any residual read is scheduled.

The residual-schedule row R is read before the candidate join row J. The bounded checker row B records the finite tests that justify exposing J; otherwise the obstruction row O remains visible.

Transport and replay through H and C preserve the same schedule, checker, local-join, and obstruction rows. Provenance and local naming through P, N close only that finite packet.

Since full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, unbounded residual search, and kernel consistency have no carrier coordinate, the listed rows exhaust the NameCert surface. □

Theorem 8317.3 (MetaCIC critical-pair residual scheduler diamond boundary)**.** *Every local-diamond read exported by an accepted* $\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}$ *packet is bounded by*

$$\mathsf{MetaCICCriticalPath}^{\uparrow},\ \mathsf{MetaCICNormalizationFrontier}^{\uparrow},\ \mathsf{MetaCICConfluenceAuditPacket}^{\uparrow},\ \mathsf{ParallelDiamondResidual}^{\uparrow}.$$

The residual schedule must read the critical pair, candidate normalization frontier, confluence audit packet, bounded residual checker, and obstruction row before it can expose a candidate local join. The boundary exports no full Church–Rosser theorem, no subject-reduction theorem, no evaluator equality, no quotient syntax equality, and no kernel-consistency theorem.

Proof. Start with the critical-pair and frontier rows K, F. They locate the local peak and the candidate normalization boundary before any residual-diamond consumer can ask for a join.

Next consume A, R, B, O. The audit row identifies the conditional confluence map, the scheduler row orders residual reads, the bounded checker row records the finite tests, and the obstruction row remains visible when those tests do not certify the candidate join.

Only after those rows are displayed may J be exported as a local-diamond handoff. Transport, replay, provenance, and local naming through H, C, P, N keep the handoff on the same finite packet, while the excluded global theorems remain outside the carrier. □

Falsifiable prediction: If a residual read skips the scheduler row R and reaches a candidate local join directly, it is not an accepted $\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}$ carrier read.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacic-confluence-audit-packet, parallel-diamond-residual: none is bijective to $\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}$ because this packet jointly carries residual scheduling, bounded checker, candidate local join, obstruction retention, transport, replay, provenance, and local naming rows.

The Lean TasteGate route is expected to provide `Nontrivial MetaCICCriticalPairResidualSchedulerUp` with an explicit witness pair and `FieldFaithful MetaCICCriticalPairResidualSchedulerUp` with `.mk`-derived fields and a match/injection proof.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}$ packet is generated from a critical-pair row, normalization-frontier row, confluence-audit row, residual-schedule row, candidate local-join row, bounded residual-checker row, obstruction row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8317.1, Definition 8317.2, and Definition 8317.3 seed the bounded residual scheduler over critical pairs, candidate frontiers, audit rows, local joins, obstruction rows, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCriticalPairResidualScheduler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full Church–Rosser, unrestricted subject reduction, evaluator equality, quotient syntax equality, unbounded residual search, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, critical-pair exposure, frontier exposure, audit exposure, residual-schedule exactness, bounded-checker exactness, candidate-join exposure, obstruction retention, transport, replay, provenance, local naming, and TasteGate nontriviality and field-faithfulness for BEDC.Derived.MetaCICCriticalPairResidualSchedu

Chapter 8318

A Concrete Naming Certificate for UniformCauchyCompletionBridge$^{\uparrow}$

Following Bishop and Bridges on uniform spaces and constructive completion, the UniformCauchyCompletionBridge$^{\uparrow}$ packet records the finite route by which a uniform Cauchy presentation enters the completion handoff and reaches the terminal Real seal. It sits beside the uniform Cauchy criterion of chapter 435, the uniform completion functor of chapter 1892, the metric completion packet of chapter 1506, the finite stream-name windows of chapter 126, the regular rational readback of chapter 301, and the real-name seal of chapter 38. The bridge names a displayed finite completion route; it is not a quotient completion, selected limit, countable-choice schedule, host equality of completed points, or ambient Real$^{\uparrow}$ completeness theorem.

Definition 8318.1 (Uniform Cauchy completion bridge carrier)**.** *A* UniformCauchyCompletionBridge$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, F, M, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the* UniformCauchyCriterion$^{\uparrow}$ *row naming the shared uniform Cauchy threshold surface consumed by the bridge.*
2. *F is the* UniformCompletionFunctor$^{\uparrow}$ *row that exposes the functorial completion handoff without selecting a quotient representative.*
3. *M is the* MetricCompletion$^{\uparrow}$ *row used by completion-facing consumers after the uniform route has been displayed.*
4. *S is the* StreamName$^{\uparrow}$ *finite-window row through which the uniform Cauchy data are inspected.*
5. *R is the* RegSeqRat$^{\uparrow}$ *regular rational readback row attached to the same finite windows.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after U, F, M, S, R have been exposed.*
7. *H records componentwise* hsame *transport for the uniform criterion, uniform completion functor, metric completion handoff, finite windows, regular readback, real seal, and local certificate rows.*
8. *C records displayed* Cont *replay from a uniform Cauchy request through U, F, M, S, R, E.*
9. *P is the* Pkg *provenance over* UniformCauchyCompletionBridge$^{\uparrow}$*,* UniformCauchyCriterion$^{\uparrow}$*,* UniformCompletionFun MetricCompletion$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionBridge}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $U, F, M, S, R, E, H, C, P, N$. It has no coordinate for quotient completions, selected limits, countable choice, host equality of completion points, ambient real completeness, Lean verification, or bridge checking.

Theorem 8318.2 (Uniform Cauchy completion bridge NameCert obligations)**.** *For every accepted* $\mathsf{UniformCauchyCompletionBridge}^{\uparrow}$ *carrier*

$$B = (U, F, M, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionBridge}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform Cauchy criterion row, uniform completion functor row, metric completion handoff row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every completion-facing read is therefore routed through $U, F, M, S, R, E, H, C, P, N$ before the Real seal is consumed.*

Proof. Project the carrier of Definition 8318.1. The rows U, F, M, S, R, E are the only coordinates through which a consumer can read uniform Cauchy data, completion handoff data, finite windows, regular rational readback, and the terminal real seal.

The uniform side is read through U and F. The criterion row supplies the shared threshold surface, while the functor row exposes the completion handoff as displayed data rather than as a selected representative or quotient construction.

The Real-facing side is read through S, R, E. Finite stream windows expose the inspected names, regular rational readback carries the same finite observations, and the seal row is available only after those rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no quotient, selector, choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8318.3 (Uniform Cauchy completion bridge finite route)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or completion-facing consumer of an accepted* $\mathsf{UniformCauchyCompletionBridge}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{UniformCauchyCriterion}^{\uparrow},\ \mathsf{UniformCompletionFunctor}^{\uparrow},\ \mathsf{MetricCompletion}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow},\ \mathsf{BHis}$$

through $U, F, M, S, R, E, H, C, P, N$. The route packages uniform Cauchy data into the completion and Real seal corridor without invoking quotient completion, selected limits, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8318.2. They identify every accepted public read with the displayed rows $U, F, M, S, R, E, H, C, P, N$.

The completion side is forced through U, F, M. A consumer first reads the uniform Cauchy criterion, then the uniform completion functor handoff, and only then the metric completion row that downstream completion chapters may use.

The Real-facing side is forced through S, R, E. The stream windows and regular rational readback expose finite observations before the terminal seal is available.

Transport and replay by H and C preserve the same route, while P and N provide provenance and local naming. No remaining row can supply quotient completion, selected limits, countable choice, host equality, or ambient real completeness. □

Falsifiable prediction: Every accepted $\mathsf{UniformCauchyCompletionBridge}^{\uparrow}$ consumer that reaches a completion or Real-facing seal first displays the uniform criterion row, uniform completion functor handoff, metric completion row, finite stream windows, regular rational readback, real seal, transport, replay, provenance, and local NameCert rows.

Independence witness: uniformcauchycriterion, uniformcompletionfunctor, metriccompletion, streamname, regseqrat, real: $\mathsf{UniformCauchyCompletionBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the uniform criterion, completion functor, metric completion handoff, finite windows, regular readback, Real seal, transport, replay, provenance, and local naming in one bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCauchyCompletionBridge}^{\uparrow}$ packet is generated from a uniform Cauchy criterion row, a uniform completion functor handoff, a metric completion row, finite StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8318.1, Definition 8318.2, and Definition 8318.3 seed the finite uniform Cauchy route into completion and Real-facing readback data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCauchyCompletionBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform criterion exposure, completion handoff, finite windows, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.UniformCauchyCompletionBri

Chapter 8319

A Concrete Naming Certificate for $\mathsf{RegularLagrangian}^{\uparrow}$

Following Weinstein's symplectic geometry convention for Lagrangian submanifolds, the $\mathsf{RegularLagrangian}^{\uparrow}$ packet records a displayed finite Lagrangian carrier whose tangent, restriction, and regularity rows are visible before any symplectic consumer may cite it. It sits beside the symplectic source of chapter 138, the manifold carrier of chapter 96, the differential-form surface of chapter 136, the Lagrangian-mechanics packet of chapter 337, and the bundle-local surface of chapter 97. The chapter names a finite regular Lagrangian interface; it is not a host submanifold primitive, a selected Weinstein neighbourhood, a Hamiltonian-isotopy theorem, a Floer complex, or an ambient transversality principle.

Definition 8319.1 (Regular Lagrangian carrier)**.** *A* $\mathsf{RegularLagrangian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, M, F, A, T, R, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Symplectic}^{\uparrow}$ *source row naming the ambient closed nondegenerate 2-form.*
2. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart row for the carried domain on which the Lagrangian surface is inspected.*
3. *F is the* $\mathsf{DiffForm}^{\uparrow}$ *restriction row that records the pulled-back symplectic form on the displayed domain.*
4. *A is the finite atlas-and-admission row for the carried Lagrangian locus inside the ambient symplectic packet.*
5. *T is the tangent-rank row recording that the displayed tangent data are half-dimensional and isotropic against the form row F.*
6. *R is the regularity row: finite chart windows, transition readbacks, and rank witnesses are stable under the local carrier relation.*
7. *B is the* $\mathsf{Bundle}^{\uparrow}$ *normal or tangent-bundle bookkeeping row used by later neighbourhood, Hamiltonian-isotopy, or Floer-style consumers.*
8. *H records componentwise* hsame *transport for the symplectic source, manifold charts, differential-form restriction, atlas admission, tangent-rank row, regularity row, bundle bookkeeping, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a regular Lagrangian request through S, M, F, A, T, R, B.*
10. *P is the* Pkg *provenance over* $\mathsf{RegularLagrangian}^{\uparrow}$, $\mathsf{Symplectic}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{DiffForm}^{\uparrow}$, $\mathsf{LagrangianMechanics}^{\uparrow}$, $\mathsf{Bundle}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host submanifold object, selected Darboux chart, Weinstein neighbourhood, Hamiltonian isotopy, Floer differential, ambient compactness, Lean verification, or bridge checking.

Theorem 8319.2 (Regular Lagrangian NameCert obligations)**.** *For every accepted* $\mathsf{RegularLagrangian}^{\uparrow}$ *carrier*

$$L = (S, M, F, A, T, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}$ *surface consists exactly of carrier admission for the symplectic source, manifold chart row, differential-form restriction, finite atlas admission, tangent-rank row, regularity row, bundle bookkeeping, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every regular Lagrangian read is therefore routed through $S, M, F, A, T, R, B, H, C, P, N$.*

Proof. Project the carrier of Definition 8319.1. The rows S, M, F, A, T, R, B are the only coordinates through which a consumer can read the ambient symplectic form, charted locus, restricted form, finite admission data, tangent-rank evidence, regularity witnesses, and bundle bookkeeping.

The Lagrangian condition is read through F and T. The differential-form row supplies the restricted symplectic form, while the tangent-rank row records half-dimensional isotropic data against that same restriction.

The regularity surface is read through A, R, B. Finite atlas admission names the carried locus, the regularity row keeps chart windows and rank witnesses stable, and the bundle row exposes only the bookkeeping needed by later local-neighbourhood or dynamics consumers.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no host submanifold, selected Darboux chart, Weinstein neighbourhood, Hamiltonian-isotopy theorem, Floer differential, or ambient-compactness coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8319.3 (Regular Lagrangian symplectic handoff)**.** *Every* $\mathsf{Symplectic}^{\uparrow}$*-,* $\mathsf{LagrangianMechanics}^{\uparrow}$*-, or bundle-facing consumer of an accepted* $\mathsf{RegularLagrangian}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Symplectic}^{\uparrow},\ \mathsf{Manifold}^{\uparrow},\ \mathsf{DiffForm}^{\uparrow},\ \mathsf{Bundle}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}$$

through $S, M, F, A, T, R, B, H, C, P, N$ before using a regular Lagrangian boundary. The handoff supplies displayed tangent-rank, restricted-form, chart-regularity, and bundle-bookkeeping rows, but no host submanifold primitive, selected Weinstein neighbourhood, Hamiltonian isotopy, Floer complex, global transversality theorem, or ambient compactness principle.

Proof. Start with the NameCert obligations of Definition 8319.2. They identify every accepted public read with the displayed rows $S, M, F, A, T, R, B, H, C, P, N$.

The symplectic side is forced through S, F, T. A consumer first reads the ambient symplectic source, then the restricted differential-form row, and only then the tangent-rank evidence that certifies the Lagrangian boundary visible to the packet.

The carried regular surface is forced through M, A, R, B. The manifold row supplies chart windows, the atlas-admission row names the finite locus, the regularity row stabilizes the rank

witnesses, and the bundle row supplies the local bookkeeping consumed by later mechanics and neighbourhood packets.

Transport and replay by H and C preserve the same route, while P and N provide provenance and local naming. Therefore the handoff reaches symplectic, Lagrangian-mechanics, and bundle-facing consumers without exporting a separate host submanifold primitive or any of the excluded ambient structures. □

Falsifiable prediction: Every accepted $\mathsf{RegularLagrangian}^{\uparrow}$ consumer that reaches a symplectic, mechanics, or bundle-facing boundary first displays the symplectic source, manifold chart, differential-form restriction, finite atlas admission, tangent-rank, regularity, bundle bookkeeping, transport, replay, provenance, and local NameCert rows.

Independence witness: symplectic, manifold, diffform, lagrangianmechanics, bundle: $\mathsf{RegularLagrangian}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds restricted symplectic form data, half-dimensional tangent-rank evidence, finite regularity witnesses, and bundle-local bookkeeping in one certificate packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularLagrangian}^{\uparrow}$ packet is generated from a symplectic source row, manifold chart row, differential-form restriction, finite atlas admission, tangent-rank row, regularity row, bundle bookkeeping, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8319.1, Definition 8319.2, and Definition 8319.3 seed the finite regular Lagrangian route into symplectic, mechanics, and bundle-facing readback data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularLagrangian}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host submanifold primitives, selected Weinstein neighbourhoods, Hamiltonian isotopies, Floer complexes, global transversality, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, restricted-form exposure, tangent-rank evidence, regularity stability, bundle bookkeeping, transport, replay, provenance, and local naming for BEDC.Derived.RegularLagrangianUp.

Chapter 8320

A Concrete Naming Certificate for $\mathsf{CauchyCondensationModulus}^{\uparrow}$

Following Cauchy's condensation test and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationModulus}^{\uparrow}$ packet records the finite modulus handoff by which a displayed condensation schedule becomes a Cauchy/RegSeqRat/Real-facing tail budget. It sits after the condensation packet of chapter 1464, the modulus surface of chapter 292, the minimum-modulus route of chapter 5544, the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names a finite Cauchy-condensation modulus route; it is not a quotient of series tails, a selected infinite subsequence, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8320.1 (Cauchy condensation modulus carrier)**.** *A* $\mathsf{CauchyCondensationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, M, B, W, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the accepted* $\mathsf{CauchyCondensation}^{\uparrow}$ *source row, including the monotone tail, dyadic block schedule, block-sum ledger, and tail-bound data.*
2. *M is the* $\mathsf{CauchyModulus}^{\uparrow}$ *request row extracted from the condensation tail budget.*
3. *B is the finite condensation-block modulus row, recording which dyadic block bound answers the current tolerance request.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger opened by the block modulus.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those same windows.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing the dyadic radius, block comparison, denominator budget, and slack rows used by M and B.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, reachable only after K, M, B, W, Q, D have been displayed.*
8. *H records componentwise* hsame *transport for the condensation source, modulus request, block modulus, windows, readback, dyadic ledger, real seal, replay, provenance, and local name.*
9. *C records displayed* Cont *replay from a tolerance request through K, M, B, W, Q, D, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{CauchyCondensationModulus}^{\uparrow}$, $\mathsf{CauchyCondensation}^{\uparrow}$, $\mathsf{CauchyModulus}^{\uparrow}$, $\mathsf{RegularCauchyMinModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCondensationModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, B, W, Q, D, E, H, C, P, N$. It has no coordinate for quotient series equality, selected subsequences, selected sums, countable choice, trichotomy on arbitrary tails, host real equality, or ambient completion.

Theorem 8320.2 (Cauchy condensation modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCondensationModulus}^{\uparrow}$ *carrier*

$$G = (K, M, B, W, Q, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCondensationModulus}^{\uparrow}}$ *surface consists exactly of carrier admission for the condensation source row, Cauchy-modulus request row, finite block-modulus row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise transport, displayed replay, package provenance, and local naming. The modulus row must be read after the* $\mathsf{CauchyCondensation}^{\uparrow}$ *source and before any* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer reaches Q or E.*

Proof. Project the carrier of Definition 8320.1. The analytic rows are precisely the condensation source K, the modulus request M, the finite block modulus B, the windows W, the readback Q, the dyadic ledger D, and the seal E.

The condensation source is read first. It supplies the dyadic block schedule and tail-bound ledger consumed by the modulus request, while the $\mathsf{CauchyModulus}^{\uparrow}$ row records the finite tolerance request to be answered.

The block-modulus row B and dyadic ledger D then determine the finite windows W and the regular-rational readback Q. The terminal seal E is downstream of those rows, and H, C, P, N transport, replay, source, and name the same route.

Since no carrier coordinate stores quotient tails, selected sums, selected subsequences, countable choice, host real equality, or ambient completion, the listed rows exhaust the local certificate surface. □

Theorem 8320.3 (Cauchy condensation modulus handoff)**.** *Every Cauchy, RegSeqRat, or Real-facing consumer of an accepted* $\mathsf{CauchyCondensationModulus}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{CauchyCondensation}^{\uparrow} \longmapsto \mathsf{CauchyModulus}^{\uparrow}, \mathsf{RegularCauchyMinModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatC}$$

The handoff exposes $K, M, B, W, Q, D, E, H, C, P, N$ and exports no quotient series equality, selected subsequence, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Begin with the accepted carrier. The condensation source row K is the only row carrying the dyadic block schedule and tail-bound comparison data, so any consumer that wants a modulus handoff must first read K.

Next read the modulus side. The row M presents the Cauchy tolerance request, the row B answers it with a finite condensation-block budget, and the sibling $\mathsf{RegularCauchyMinModulus}^{\uparrow}$ route supplies the displayed minimum-budget discipline when two local Cauchy windows share one request.

The window and readback rows are downstream of that modulus answer. The StreamName row W, RegSeqRat row Q, and DyadicRatCore ledger D expose the finite windows and tolerance comparisons before the Real seal E is consumed.

Finally H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Thus every consumer factors through the displayed handoff and receives no host quotient, selected infinite object, choice schedule, or ambient completeness coordinate. □

Falsifiable prediction: An accepted $\mathsf{CauchyCondensationModulus}^{\uparrow}$ read is refuted whenever a Cauchy, RegSeqRat, or Real-facing consumer reaches a window, readback, or seal without displaying $K, M, B, W, Q, D, E, H, C, P, N$.

Independence witness: cauchycondensation, cauchymodulus, regular-cauchy-min-modulus, streamname, regseqrat, dyadicratcore, real: none alone is bijective with $\mathsf{CauchyCondensationModulus}^{\uparrow}$ because the packet jointly records condensation source rows, a modulus request, a finite block-modulus answer, windows, readback, dyadic tolerance, real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCondensationModulus}^{\uparrow}$ packet is generated from a CauchyCondensation source row, CauchyModulus request row, finite condensation-block modulus row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8320.1, Definition 8320.2, and Definition 8320.3 seed the finite handoff from condensation schedules to Cauchy, RegSeqRat, and Real-facing modulus consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationModulus}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.CauchyCondensationModulusUp.CauchyCondensationModulusUp`

Bridge status: none

Not claimed: This chapter does not close quotient series equality, selected subsequences, selected sums, countable choice, trichotomy on arbitrary tails, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, condensation-source exposure, block-modulus exactness, window coverage, RegSeqRat readback, DyadicRatCore tolerance accounting, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationModulusUp.

Chapter 8321

A Concrete Naming Certificate for $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$ packet records equality of real names as a finite epsilon–delta request and response surface. It sits on the L10 corridor through the dyadic tolerance core of chapter 291, the finite stream windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the RealEquality classifier boundary of chapter 1636. The packet names the displayed equality route only; it does not turn equality into quotient real equality or into host equality of selected representatives.

Definition 8321.1 (Bishop epsilon-delta real equality carrier)**.** *A* $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, \Delta, D, S, R, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the epsilon-request row, recording the finite positive tolerance requested by the equality consumer;*
2. *Δ is the delta-response row, giving the finite modulus answer used to compare the two real-name windows at tolerance Q;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that carries the dyadic comparison budget used by the response;*
4. *S is the pair of* $\mathsf{StreamName}^{\uparrow}$ *finite windows inspected for the two real names at the requested tolerance;*
5. *R is the pair of* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows obtained from the displayed stream windows;*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row for the two terminal real-name boundaries, reached only after Q, Δ, D, S, R have been displayed;*
7. *H records the componentwise* hsame *transports for epsilon requests, delta responses, dyadic tolerances, stream windows, regular readbacks, real seals, and the local packet shape;*
8. *C records the displayed* Cont *replay from epsilon request through delta response, dyadic tolerance, finite windows, regular readbacks, Real seal, and local naming;*

9. *P is the* Pkg *provenance over* $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RealEquality}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through these rows. It has no coordinate for quotient real equality, selected representatives, trichotomy, countable choice, ambient Real completeness, or host equality of completed real objects.

Theorem 8321.2 (Bishop epsilon-delta real equality NameCert obligations)**.** *For every accepted* $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$ *carrier*

$$E = (Q, \Delta, D, S, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}}$ *surface consists exactly of carrier admission for the epsilon request Q, delta response Δ, dyadic tolerance row D, finite* $\mathsf{StreamName}^{\uparrow}$ *windows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks R, terminal* $\mathsf{Real}^{\uparrow}$ *seal L, componentwise* hsame *transport H, displayed* Cont *replay C, package provenance P, and local naming row N. Every equality-facing consumer must expose those rows before it can read the RealEquality boundary.*

Proof. Project the carrier of Definition 8321.1. Its equality data are the epsilon request, delta response, dyadic tolerance ledger, two finite stream windows, two regular rational readbacks, and the terminal Real seal row.

Read the route in dependency order. The request Q determines which tolerance must be answered, Δ supplies the displayed response budget, D records the dyadic tolerance used by that response, and S records the finite windows inspected under that budget.

The readback row R is then obtained from the displayed windows, and the seal row L is reached only after the readbacks have been exposed. The structural rows H, C, P, N transport, replay, source, and name the same finite packet, so the listed rows exhaust the local NameCert obligations. □

Theorem 8321.3 (Bishop epsilon-delta real equality Real seal nonescape)**.** *Every Real-facing equality read of an accepted* $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$ *packet factors through the finite route*

$$Q, \Delta, D, S, R, L, H, C, P, N.$$

The terminal $\mathsf{Real}^{\uparrow}$ *seal row L may be inspected only after the epsilon request, delta response, dyadic tolerance, StreamName windows, and RegSeqRat readbacks have been displayed. The packet exports no quotient real equality, selected representative, trichotomy, countable-choice schedule, ambient Real completeness, host equality, Lean verification claim, or bridge check.*

Proof. Start with the NameCert obligations of Definition 8321.2. They force every equality-facing consumer to expose the epsilon request, delta response, dyadic tolerance, finite windows, and regular readbacks before the Real seal row is available.

Now apply the sibling route through chapter 1636. That boundary accepts equality only through displayed finite windows, regular readbacks, and dyadic tolerance data, not through a quotient of completed streams or a host equality predicate.

Finally inspect the carrier coordinates. Since no coordinate names a selected representative, trichotomy principle, countable-choice schedule, ambient completeness theorem, Lean target, or standard bridge, none of those objects can be exported by the local Real seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}$ packet is generated from a finite epsilon request, delta response, dyadic tolerance row, finite StreamName windows, RegSeqRat readbacks, terminal Real seal, componentwise transport, continuation replay, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter binds the finite epsilon–delta Real-equality carrier, its local NameCert obligations, and the Real-seal nonescape boundary along the L10 Real and Completion corridor.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopEpsilonDeltaRealEquality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: It does not close quotient real equality, selected representatives, trichotomy, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Reaching obligation closure requires a Lean carrier and checked proof that every accepted equality consumer exposes the same epsilon request, delta response, dyadic tolerance, finite-window, readback, and Real-seal route.

Chapter 8322

A Concrete Naming Certificate for $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$

Bishop-style constructive compactness treats an ϵ-net as displayed finite data rather than as a choice made from an ambient compactness theorem. The $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ packet records that finite selector surface for a $\mathsf{CompactMetric}^{\uparrow}$ object: it reads the $\mathsf{Met}^{\uparrow}$ carrier, a $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ positive-radius ledger, finite $\mathsf{StreamName}^{\uparrow}$ observation windows, $\mathsf{RegSeqRat}^{\uparrow}$ rational readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal before exporting any selected net row. The selector is consumed only after the compact source of chapter 129, the metric readback of chapter 57, and the radius ledger of chapter 452 have exposed the windows later read through StreamName, RegSeqRat, and Real rows. It is a selector carrier for compact Real-and-Completion work, not a quotient cover, a hidden subcover choice, or a host compactness principle.

Definition 8322.1 (Finite epsilon-net choice carrier)**.** *A* $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, M, \Lambda, W, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row whose compact presentation supplies finite observation data.*
2. *M is the underlying* $\mathsf{Met}^{\uparrow}$ *row, keeping the metric carrier and distance readback visible.*
3. *Λ is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *row that provides the positive radius ledger used by the net request.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family naming the candidate centers inspected by the selector.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row used to compare displayed radii and metric distances.*
7. *S is the selected finite epsilon-net row, recorded only after K, M, Λ, W, Q, R have been displayed.*
8. *H records componentwise* hsame *transport for the compact source, metric row, Lebesgue-number ledger, windows, rational readback, Real seal, selected-net row, replay, provenance, and local name.*
9. *C stores displayed* Cont *replay from a finite radius request through $K, M, \Lambda, W, Q, R, S, H$.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{FiniteLebesgueNumber}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for an arbitrary open cover, a choice-selected subcover, quotient metric equality, host compactness, countable choice, or a selected completion object.

Theorem 8322.2 (Finite epsilon-net choice NameCert obligations)**.** *For every accepted* $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ *carrier*

$$E = (K, M, \Lambda, W, Q, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, compact source exposure through K, metric readback through M, finite positive-radius exposure through Λ, finite window exposure through W, rational readback through Q, Real comparison through R, selected-net export through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8322.1. The analytic rows are $K, M, \Lambda, W, Q, R, S$, and the structural rows are H, C, P, N.

The compact source and metric rows are read first. The selector therefore receives a displayed compact metric presentation rather than an arbitrary cover or host compactness assertion.

Next the finite Lebesgue-number row Λ fixes the positive-radius ledger. The windows W, rational readback Q, and Real seal R are downstream of that ledger, so the selector row S can record only centers inspected through the displayed finite data.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate stores open-cover choice, quotient metric equality, host compactness, countable choice, or a selected completion object, the listed rows exhaust the certificate surface. □

Theorem 8322.3 (Finite epsilon-net compact handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ *packet must expose the finite route*

$$K, M, \Lambda, W, Q, R, S, H, C, P, N$$

before using the selected epsilon-net row. In particular, the handoff from compactness to a finite net passes through the $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *positive-radius ledger,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal before any downstream Real-and-Completion consumer may inspect S.*

Proof. Start with the NameCert obligations. They make $K, M, \Lambda, W, Q, R, S, H, C, P, N$ the complete public surface of the accepted selector packet.

The positive-radius step is forced through Λ. A consumer cannot read S until the compact source, metric row, and finite Lebesgue-number ledger have already determined the displayed radius budget.

The window and readback rows then determine which finite centers are visible. The $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows provide the finite observations, and the $\mathsf{Real}^{\uparrow}$ seal records the displayed metric comparison.

Thus the selected-net row is a finite handoff from compact metric data to Real-facing consumers. Because the carrier lacks open-cover choice, quotient metric equality, host compactness, countable choice, and selected completion coordinates, no stronger compactness principle is exported. □

Falsifiable prediction: An accepted $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ consumer that reaches a selected epsilon-net row without reading $K, M, \Lambda, W, Q, R, S, H, C, P, N$ refutes the selector carrier.

Independence witness: compactmetric, metricspace, finitelebesguenumber, streamname, regseqrat, real: none of these siblings alone carries the joint finite selector packet containing compact source, metric readback, positive-radius ledger, observation windows, regular-rational readback, Real comparison, selected net, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteEpsilonNetSelector}^{\uparrow}$ packet is generated from a CompactMetric source row, MetricSpace readback, FiniteLebesgueNumber positive-radius ledger, StreamName finite windows, RegSeqRat rational readback, Real seal, selected epsilon-net row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8322.1, Definition 8322.2, and Definition 8322.3 seed the finite selector route from constructive compactness to Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteEpsilonNetSelector}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, arbitrary open-cover subchoice, quotient metric equality, host compactness, countable choice, or selected completion objects.

Upgrade path: Obligation closure requires checked carrier admission, radius-ledger compatibility, finite-window readback, Real-seal comparison, and selector nonescape for BEDC.Derived.FiniteEpsilonNetSelectorUp.

Chapter 8323

A Concrete Naming Certificate for $\mathsf{HyperbolicBigonThinness}^{\uparrow}$

The $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ packet realizes the bigon-thinness branch of chapter 9463 as finite endpoint, side, metric, boundary-shadow, and Real-seal NameCert data. It sits beside the metric route of chapter 3474, the boundary route of chapter 3491, the visual comparison route of chapter 3866, and the ambient finite metric discipline of chapter 4230. The packet records a displayed two-sided geodesic boundary comparison; it does not assert global curvature, arbitrary geodesic uniqueness, host properness, or a selected geodesic representative outside the finite rows.

Definition 8323.1 (Hyperbolic bigon thinness carrier)**.** *A* $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row carrying the hyperbolic metric read.*
2. *G is the* $\mathsf{Met}^{\uparrow}$ *row that keeps the underlying finite metric carrier visible.*
3. *∂ is the* $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$ *row naming the boundary endpoints used by the bigon.*
4. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row used to compare the boundary shadows.*
5. *E_0 and E_1 are the two displayed endpoint rows of the bigon.*
6. *L_0 and L_1 are the two geodesic-side rows whose fellow-traveller comparison is being read.*
7. *D is the finite distance ledger comparing side points through the hyperbolic metric.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed thinness tolerance.*
9. *Σ is the boundary-shadow ledger recording that the visual-metric read and the geodesic-boundary read refer to the same endpoints.*
10. *H records componentwise* hsame *transport for metric, boundary, visual, endpoint, side, distance, Real-seal, shadow, replay, provenance, and local naming rows.*
11. *C stores displayed* Cont *replay from an endpoint-pair request through $M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{HyperbolicBigonThinness}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

13. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicBigonThinness}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for global CAT curvature, arbitrary geodesic uniqueness, host properness, selected geodesic representatives, quotient boundary equality, or an unbounded visual compactification.

Theorem 8323.2 (Hyperbolic bigon thinness NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ *carrier*

$$B = (M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicBigonThinness}^{\uparrow}}$ *surface consists exactly of hyperbolic-metric exposure through M, ambient metric exposure through G, geodesic-boundary exposure through ∂, visual-metric exposure through V, endpoint exposure through E_0, E_1, geodesic-side exposure through L_0, L_1, distance-ledger exposure through D, Real thinness tolerance through R, boundary-shadow compatibility through Σ, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8323.1. The geometric rows are $M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma$, and the structural rows are H, C, P, N.

The metric and boundary rows are read before the sides. Thus the two geodesic-side rows are tied to the displayed hyperbolic metric, the underlying metric carrier, and the same geodesic-boundary endpoints.

The visual-metric and shadow rows then compare the endpoint data. The distance ledger D and Real seal R record only the finite thinness tolerance visible through those rows.

Finally the transport, replay, provenance, and local naming rows keep the same packet intact. Since no carrier coordinate stores global curvature, arbitrary geodesic uniqueness, host properness, selected geodesic representatives, quotient boundary equality, or visual compactification, the listed rows exhaust the local obligations. □

Theorem 8323.3 (Hyperbolic bigon thinness boundary route)**.** *Every boundary-facing consumer of an accepted* $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ *packet must expose*

$$M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma, H, C, P, N$$

before using a bigon-thinness conclusion. The read reaches the conclusion only after the $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HyperbolicGeodesicBoundary}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *rows have been displayed in that route.*

Proof. Begin with the NameCert obligation theorem. It makes the metric, boundary, visual, endpoint, geodesic-side, distance, Real-seal, shadow, transport, replay, provenance, and local naming rows the complete public surface.

The endpoint rows E_0, E_1 are read through ∂ and V. Thus a consumer cannot detach the boundary-shadow comparison from the displayed geodesic boundary or visual metric.

The side rows L_0, L_1 are then compared only through M, G, D, R. The hyperbolic metric, ambient metric carrier, finite distance ledger, and Real seal provide the thinness tolerance as a displayed row, not as a host global geometry fact.

Therefore the bigon-thinness conclusion remains a finite boundary route. It cannot be retyped as global curvature, arbitrary geodesic uniqueness, host properness, selected geodesic representation, quotient boundary equality, or an unbounded visual compactification. □

Falsifiable prediction: An accepted $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ boundary consumer that reads bigon thinness without exposing $M, G, \partial, V, E_0, E_1, L_0, L_1, D, R, \Sigma, H, C, P, N$ refutes the carrier surface.

Independence witness: hyperbolic-metric, hyperbolic-geodesic-boundary, hyperbolic-visual-metric, metricspace, real: none of these siblings alone carries the joint endpoint, two-side, distance-ledger, boundary-shadow, Real-seal, transport, replay, provenance, and local NameCert packet required by $\mathsf{HyperbolicBigonThinness}^{\uparrow}$.

Future Lean verification for this packet must supply nontriviality and field-faithfulness taste gates for the same carrier surface before any bridge can advertise a schema-level hyperbolic-thinness export.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBigonThinness}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicBigonThinness}^{\uparrow}$ packet is generated from HyperbolicMetric, MetricSpace, HyperbolicGeodesicBoundary, HyperbolicVisualMetric, endpoint, geodesic-side, distance-ledger, Real-seal, boundary-shadow, componentwise hsame, displayed Cont, Pkg, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicBigonThinness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8323.1, Definition 8323.2, and Definition 8323.3 seed the finite boundary route for hyperbolic bigon thinness.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicBigonThinness}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, global curvature, arbitrary geodesic uniqueness, host properness, selected geodesic representatives, quotient boundary equality, or visual compactification.

Upgrade path: Obligation closure requires checked metric exposure, endpoint and side visibility, boundary-shadow compatibility, Real thinness tolerance, and taste-gate nonescape for BEDC.Derived.HyperbolicBigonThinnessUp.

Chapter 8324

A Concrete Naming Certificate for $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$

Following Bishop–Bridges completion theory and Mac Lane's unit laws, the $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ packet records the finite BEDC surface saying that applying the completion unit to an already displayed completion endpoint leaves the same named endpoint route. It sits after the completion carrier of chapter 1506, the unit packet of chapter 7904, the separated-metric reflection of chapter 1790, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the eta law as finite NameCert data; it is not a quotient-completion equality, a selected representative theorem, or an ambient completeness principle.

Definition 8324.1 (Metric completion eta-law carrier)**.** *A* $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (X, T, U, S, R, Q, Z, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Met}^{\uparrow}$ *row.*
2. *T is the displayed* $\mathsf{MetricCompletion}^{\uparrow}$ *endpoint row already accepted by the completion carrier.*
3. *U is the* $\mathsf{MetricCompletionUnit}^{\uparrow}$ *row applied to the same displayed endpoint route.*
4. *S is the* $\mathsf{SeparatedMetricReflection}^{\uparrow}$ *row ensuring that comparison of the two endpoint reads is separated before any equality-like claim is consumed.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row witnessing that both endpoint routes expose the same finite regular-rational windows.*
6. *Q is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, U, S, R have been displayed.*
7. *Z is the eta-law exactness row binding the direct endpoint route and the unit-applied endpoint route to the same displayed completion name.*
8. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionEtaLaw}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, T, U, S, R, Q, Z, H, C, P, N$. It has no coordinate for quotient classes of Cauchy names, selected representatives, host completion equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8324.2 (Metric completion eta-law NameCert obligations)**.** *For every accepted* $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ *carrier* $E = (X, T, U, S, R, Q, Z, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetricCompletionEtaLaw}^{\uparrow}}$ *surface consists exactly of source metric exposure, displayed completion endpoint exposure, unit-row exposure, separated comparison, regular readback, real-seal exposure, eta-law exactness, transport, replay, provenance, and local naming. Every consumer of the eta law must read those rows before it treats the direct completion endpoint and the unit-applied endpoint as the same named route.*

Proof. Project the carrier of Definition 8324.1. The rows X, T, U name the metric source, the displayed completed endpoint, and the unit-applied endpoint route.

Next read the comparison and endpoint rows S, R, Q. Separation is supplied by S, finite regular-rational agreement by R, and terminal real-name exposure by Q; none of these rows contains quotient equality or a selected representative.

Finally use the eta-law exactness row Z and the support rows H, C, P, N. They bind the direct route and the unit-applied route to the same displayed completion name under transport, replay, provenance, and local naming, so the listed rows exhaust the NameCert surface. □

Theorem 8324.3 (Metric completion eta-law unit handoff)**.** *Let* $E = (X, T, U, S, R, Q, Z, H, C, P, N)$ *be an accepted* $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ *carrier. Any completion-facing consumer that enters through the unit row* U *must pass through the already displayed completion endpoint* T*, the separated comparison row* S*, the regular-rational readback* R*, and the eta-law exactness row* Z *before reading the terminal seal* Q*. The handoff therefore exposes the unit law as a finite route over the existing completion name, not as a quotient-completion identification or a host-side equality of completed points.*

Proof. Begin with the unit row U. By the carrier definition it is not an independent completion endpoint; it is attached to the same source metric row X and the displayed completion endpoint row T.

Read the separated comparison row S and regular-rational row R. These rows keep the direct endpoint and the unit-applied endpoint inside the same finite comparison surface before the seal Q can be consumed.

The exactness row Z supplies the eta-law handoff, and H, C, P, N only preserve that displayed route. Thus a consumer receives a named unit law for the existing completion endpoint without acquiring quotient completion equality, selected representatives, countable choice, host equality, or ambient real completeness. □

Independence witness: metriccompletion, metric-completion-unit, separatedmetricreflection, regseqrat, real: no listed sibling is bijective to $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ because this packet jointly binds a displayed completion endpoint, its unit-applied route, separated comparison, regular readback, real seal, eta-law exactness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricCompletionEtaLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricCompletionEtaLaw}^{\uparrow}$ packet is generated from a MetricSpace source row, a MetricCompletion endpoint row, a MetricCompletionUnit row, a SeparatedMetricReflection comparison row, RegSeqRat readback, a RealUp seal, eta-law exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{MetricCompletionEtaLaw}^{\uparrow}}$, seed)

Scope closed: Definition 8324.1, Definition 8324.2, and Definition 8324.3 seed the finite completion-unit eta-law surface over the existing L10 completion route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{MetricCompletionEtaLaw}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient-completion equality, selected Cauchy representatives, host equality of completed points, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-row exposure, separated comparison, regular readback agreement, eta-law exactness, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionEtaLawUp.

Chapter 8325

A Concrete Naming Certificate for $\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}$

Following Aronszajn and Smith on invariant subspaces for compact operators, the $\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}$ packet records the finite BEDC surface by which a compact operator on a Banach-facing scalar space exposes an invariant-subspace witness before any functional-analysis consumer reads the result. It sits over the compact-operator carrier of chapter 1952, the bounded-linear-operator route of chapter 1644, the functional-analysis ledger of chapter 94, the Banach carrier of chapter 90, the real scalar seal of chapter 38, and the complex scalar row of chapter 39. The chapter names the invariant-subspace certificate as finite NameCert data; it does not assert a full spectral theorem, choose an eigenvector, quotient a function space, import Hilbert-space orthogonality, use countable choice, or claim an ambient completeness principle.

Definition 8325.1 (Aronszajn–Smith invariant-subspace carrier)**.** *An* $\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (K, T, F, B, R, Z, W, L, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactOperator}^{\uparrow}$ *row recording compactness of the operator route.*
2. *T is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *row recording bounded linear action on the same displayed source.*
3. *F is the* $\mathsf{FunctionalAnalysis}^{\uparrow}$ *ledger row that admits operator and subspace reads only through the finite packet.*
4. *B is the* $\mathsf{Banach}^{\uparrow}$ *carrier row for the domain in which the invariant-subspace witness is read.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar-seal row used by norm and radius comparisons.*
6. *Z is the* $\mathsf{Complex}^{\uparrow}$ *scalar row, stored as finite BEDC scalar data rather than as an ambient algebraic closure claim.*
7. *W is the invariant-subspace witness row, recording a displayed nonzero proper subspace candidate.*
8. *L is the invariance ledger row saying that the bounded compact operator route sends the displayed witness row back through itself.*

9. *H records componentwise* hsame *transport for K, T, F, B, R, Z, W, L and for the package and local naming rows.*
10. *C records displayed* Cont *replay from compact-operator admission through bounded linearity, Banach scalar sealing, witness exposure, and invariance readback.*
11. *P is the* Pkg *provenance over* AronszajnSmithInvariantSubspace$^{\uparrow}$, CompactOperator$^{\uparrow}$, BoundedLinearOperator$^{\uparrow}$, FunctionalAnalysis$^{\uparrow}$, Banach$^{\uparrow}$, Real$^{\uparrow}$, Complex$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{AronszajnSmithInvariantSubspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a full spectral theorem, selected eigenvectors, quotient function spaces, host Hilbert orthogonality, countable choice, or ambient completeness.

Theorem 8325.2 (Aronszajn–Smith invariant-subspace NameCert obligations)**.** *For every accepted* AronszajnSmithInvariantSubspace$^{\uparrow}$ *carrier*

$$A = (K, T, F, B, R, Z, W, L, H, C, P, N),$$

the local NameCert$_{\text{AronszajnSmithInvariantSubspace}^{\uparrow}}$ *surface consists exactly of compact-operator admission, bounded-linear-operator exposure, functional-analysis ledger exposure, Banach carrier exposure, real and complex-facing scalar sealing, invariant-subspace witness exposure, invariance-ledger readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation is stored outside $K, T, F, B, R, Z, W, L, H, C, P, N$.*

Proof. Project the carrier of Definition 8325.1. The analytic rows are K, T, F, B, R, Z, W, L, and the structural rows are H, C, P, N.

The compact and bounded-linear rows are read first. They force any operator-facing consumer to enter through chapter 1952 and chapter 1644 before the witness row is visible.

Next the functional-analysis, Banach, and scalar rows expose the source discipline. The rows F, B, R, Z keep the normed carrier and scalar comparisons finite, with no coordinate for spectral decomposition or host-side algebraic closure.

Finally W and L provide the displayed witness and its invariance readback, while H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no row for selected eigenvectors, quotient spaces, Hilbert orthogonality, countable choice, or ambient completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8325.3 (Aronszajn–Smith compact-operator route)**.** *Every functional-analysis or Banach-facing consumer of an accepted* AronszajnSmithInvariantSubspace$^{\uparrow}$ *packet must expose the compact-operator row K, the bounded-linear row T, the functional-analysis ledger F, the Banach row B, the scalar rows R, Z, the invariant-subspace witness W, the invariance ledger L, and the support rows H, C, P, N before reading the invariant-subspace certificate. The route reaches the sibling surfaces of chapter 1952, chapter 1644, chapter 94, chapter 90, and chapter 38 only through those displayed rows.*

Proof. Start with the NameCert obligations of Definition 8325.2. They identify $K, T, F, B, R, Z, W, L, H, C, P, N$ as the complete public surface of the accepted packet.

The operator handoff passes through K and T. Compactness is therefore consumed as a displayed compact-operator row, while bounded linearity is consumed as a displayed bounded-linear-operator row over the same packet.

The source and scalar handoff passes through F, B, R, Z. These rows expose the functional-analysis ledger, Banach carrier, and scalar comparison data before the witness row can be read.

The witness handoff is W, L under H, C, P, N. Thus any consumer that reads the invariant-subspace certificate remains inside the finite packet and cannot replace it by a spectral theorem, eigenvector choice, quotient function space, Hilbert orthogonality, countable choice, or ambient completeness argument. □

Falsifiable prediction: An accepted $\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}$ consumer that reads the invariant-subspace witness without first exposing $K, T, F, B, R, Z, W, L, H, C, P, N$ refutes the carrier.

Independence witness: compactoperator, boundedlinearoperator, functionalanalysis, banach, real: none of these siblings alone carries the joint packet containing compact-operator admission, bounded-linear action, functional-analysis ledger, Banach source, real and complex-facing scalar rows, invariant-subspace witness, invariance readback, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}}$.

Constructive story: An $\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}$ packet is generated from a CompactOperator row, BoundedLinearOperator row, FunctionalAnalysis ledger, Banach source, Real scalar seal, Complex scalar row, invariant-subspace witness row, invariance ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8325.1, Definition 8325.2, and Definition 8325.3 seed the finite compact-operator route from Aronszajn–Smith invariant-subspace data to functional-analysis and Banach-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AronszajnSmithInvariantSubspace}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, a full spectral theorem, selected eigenvectors, quotient function spaces, Hilbert orthogonality, countable choice, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-operator exposure, bounded-linear exposure, scalar sealing, invariant-subspace witness exposure, invariance readback, transport, replay, provenance, and local naming for BEDC.Derived.AronszajnSmithInvariantSubspaceUp.

Chapter 8326

A Concrete Naming Certificate for $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$

Following Kantorovich and Rubinstein, the $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$ packet records the finite dual-test surface that compares a Wasserstein transport-cost row with a Lipschitz test-function row. It consumes the transport-plan carrier of chapter 5197, the finite-support linear-programming surface of chapter 326, the probability rows of chapter 184, the metric source of chapter 57, the test-function carrier of chapter 3762, and the terminal scalar seal of chapter 38. The chapter names only the displayed duality handoff; it does not assert measure completion, arbitrary Polish-space duality, selected optimal plans, selected extremal functions, quotient function-space equality, or an ambient real-valued supremum.

Definition 8326.1 (Kantorovich–Rubinstein duality carrier)**.** *A* $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (W, T, \mu, \nu, M, L, R, B, H, C, P, N)$$

with the following visible rows:

1. *W is a* $\mathsf{Wasserstein}^{\uparrow}$ *transport-plan row whose cost ledger is already displayed.*
2. *T is an* $\mathsf{OptimalTransport}^{\uparrow}$ *finite-support certificate row exposing the primal finite linear-programming surface.*
3. *μ and ν are* $\mathsf{ProbSpace}^{\uparrow}$ *source and target probability rows read by both the primal and dual ledgers.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *source row used by the transport cost and the Lipschitz constraint.*
5. *L is a* $\mathsf{LipschitzFunction}^{\uparrow}$ *test-function row whose displayed constant is bounded by* 1 *against M.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar row comparing the transport-cost ledger with the displayed test-function difference.*
7. *B is the dual-bound ledger: every accepted read of R factors through the* 1*-Lipschitz test row L, the probability rows μ, ν, and the primal transport row W.*
8. *H records componentwise* hsame *transport for $W, T, \mu, \nu, M, L, R, B, C, P, N$.*
9. *C stores displayed* Cont *replay from the transport and test-function rows to the scalar bound row.*

10. *P is the* Pkg *provenance over* $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$, $\mathsf{Wasserstein}^{\uparrow}$, $\mathsf{OptimalTransport}^{\uparrow}$, $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LipschitzFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{KantorovichRubinsteinDuality}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for completed measures, arbitrary bounded continuous functions, an unlisted supremum, a selected optimal coupling, a selected extremal Lipschitz function, quotient function-space equality, or host real equality.

Theorem 8326.2 (Kantorovich–Rubinstein NameCert obligations)**.** *For every accepted* KantorovichRubinsteinDuali *carrier*

$$D = (W, T, \mu, \nu, M, L, R, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KantorovichRubinsteinDuality}^{\uparrow}}$ *surface consists exactly of carrier admission, Wasserstein transport-cost exposure through W, finite primal certificate exposure through T, probability marginal exposure through μ, ν, metric readback through M,* 1*-Lipschitz test exposure through L, scalar comparison through R, dual-bound accounting through B, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8326.1. Its analytic rows are $W, T, \mu, \nu, M, L, R, B$, and its structural rows are H, C, P, N.

The primal side is forced by W and T. The Wasserstein row supplies the displayed transport-cost ledger, while the optimal-transport row supplies the finite linear-programming certificate that bounds the same finite support surface.

The dual side is forced by L, μ, ν, M, R, B. The Lipschitz row is read against the metric row M, the probability rows provide the two displayed integrals or finite sums, and B records only the resulting scalar comparison in R.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row stores completed measures, arbitrary bounded continuous functions, an unlisted supremum, selected optimizers, quotient function-space equality, or host real equality, the listed rows exhaust the local certificate surface. □

Theorem 8326.3 (Kantorovich–Rubinstein Lipschitz-test handoff)**.** *Every consumer that reads a scalar dual bound from an accepted* $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$ *carrier must first expose the finite route*

$$W, T, \mu, \nu, M, L, R, B, H, C, P, N.$$

In particular, the Lipschitz-test handoff cannot reach the $\mathsf{Real}^{\uparrow}$ *comparison row R without reading the* $\mathsf{Wasserstein}^{\uparrow}$ *transport ledger, the* $\mathsf{OptimalTransport}^{\uparrow}$ *finite primal certificate, the two* $\mathsf{ProbSpace}^{\uparrow}$ *marginals, the* $\mathsf{Met}^{\uparrow}$ *source, and the* $\mathsf{LipschitzFunction}^{\uparrow}$ *test row.*

Proof. Start from the NameCert obligations. They make the displayed carrier route the complete public surface of the accepted packet.

The transport side must be read before the scalar comparison. The rows W and T expose the primal cost and finite-support certificate, while μ, ν and M supply the probability and metric data shared with the dual test.

The Lipschitz side then supplies the only dual-test row. The row L carries the 1-Lipschitz constraint against M, and B records the comparison that reaches R.

Thus any consumer of R has already traversed the listed finite route. Because the carrier has no coordinate for completed measures, unlisted test functions, selected optimizers, quotient

function-space equality, or host real equality, no stronger Kantorovich–Rubinstein duality theorem is exported. □

Falsifiable prediction: An accepted $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$ consumer that reaches the scalar dual-bound row without reading $W, T, \mu, \nu, M, L, R, B, H, C, P, N$ refutes the duality carrier.

Independence witness: wasserstein, optimaltransport, probspace, metric, lipschitz-function, real: none of these siblings alone carries the joint packet containing transport cost, finite primal certificate, two probability marginals, metric source, Lipschitz test row, scalar comparison, dual-bound ledger, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{KantorovichRubinsteinDuality}^{\uparrow}}$.

Constructive story: A $\mathsf{KantorovichRubinsteinDuality}^{\uparrow}$ packet is generated from a Wasserstein transport-cost row, an OptimalTransport finite primal certificate, two ProbSpace marginal rows, a Metric source row, a LipschitzFunction test row, a Real scalar comparison row, a dual-bound ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KantorovichRubinsteinDuality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8326.1, Definition 8326.2, and Definition 8326.3 seed the displayed finite duality route from transport cost to Lipschitz-test scalar comparison.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KantorovichRubinsteinDuality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, measure completion, arbitrary Polish-space duality, selected optimal plans, selected extremal functions, quotient function-space equality, or ambient $\mathsf{Real}^{\uparrow}$ supremum claims.

Upgrade path: Obligation closure requires checked carrier admission, transport-cost exposure, finite primal certificate exposure, marginal readback, metric compatibility, Lipschitz-test compatibility, scalar comparison nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KantorovichRubinsteinDualityUp.

Chapter 8327

A Concrete Naming Certificate for $\mathsf{FiniteContinuedFraction}^{\uparrow}$

Following Hardy–Wright on finite continued fractions and rational convergents, the $\mathsf{FiniteContinuedFraction}^{\uparrow}$ packet records the finite-prefix object that sits between rational tree navigation and L10 rational readback. It is a bounded partial-quotient carrier whose endpoint can be consumed as a displayed $\mathsf{Rat}^{\uparrow}$ row before any infinite continued-fraction tail, quotient real equality, or choice-selected limit is present. The packet is positioned beside the rational arithmetic carrier of chapter 37, the Stern–Brocot tree of chapter 1704, the Farey-neighbor route of chapter 1759, the finite-prefix continued-fraction surface of chapter 342, the convergent ledger of chapter 1777, the dyadic tolerance core of chapter 291, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38.

Definition 8327.1 (FiniteContinuedFraction carrier)**.** *A* $\mathsf{FiniteContinuedFraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (A, N, D, Q, S, B, R, E, H, C, P, L)$$

with the following displayed rows:

1. *A is the finite partial-quotient spine, including its length row and the displayed prefix order.*
2. *N and D are the* $\mathsf{Rat}^{\uparrow}$ *numerator and denominator recurrence rows for the last displayed convergent.*
3. *Q is the normalized* $\mathsf{Rat}^{\uparrow}$ *endpoint read from N and D.*
4. *S is the sibling route row tying the prefix to* $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, *and* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$.
5. *B is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget row used when the endpoint is exposed to a regular rational consumer.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational-readback row built from the finite endpoint and dyadic budget.*
7. *E is the optional* $\mathsf{Real}^{\uparrow}$ *seal row reached only after R has been displayed.*
8. *H records componentwise* hsame *transport for partial quotients, rational endpoints, sibling routes, dyadic budgets, readback rows, the seal row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a finite-prefix request through $A, N, D, Q, S, B, R, E, H, P, L$.*

10. *P is the* Pkg *provenance row over* $\mathsf{FiniteContinuedFraction}^{\uparrow}$ *and all listed sibling carriers, and L is the local* $\mathsf{NameCert}_{\mathsf{FiniteContinuedFraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for an infinite tail, quotient equality of real names, a selected limit, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8327.2 (FiniteContinuedFraction NameCert obligations)**.** *For every accepted* $\mathsf{FiniteContinuedFraction}^{\uparrow}$ *carrier $F = (A, N, D, Q, S, B, R, E, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteContinuedFraction}^{\uparrow}}$ *surface consists exactly of the following ten obligation rows:*

1. *carrier admission for the displayed finite partial-quotient spine and its length row;*
2. *recurrence admission for the numerator and denominator rows N, D;*
3. *rational endpoint normalization through the* $\mathsf{Rat}^{\uparrow}$ *row Q;*
4. *sibling compatibility with* $\mathsf{SternBrocot}^{\uparrow}$, $\mathsf{FareySequence}^{\uparrow}$, $\mathsf{ContinuedFraction}^{\uparrow}$, *and* $\mathsf{ContinuedFractionConvergents}^{\uparrow}$ *through S;*
5. *dyadic budget exposure through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row B;*
6. *rational-readback exposure through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
7. *terminal real-seal discipline for the optional* $\mathsf{Real}^{\uparrow}$ *row E;*
8. *componentwise transport through H;*
9. *displayed replay and package provenance through C and P;*
10. *local naming through L, with no extra obligation outside the displayed packet.*

Proof. Carrier and recurrence admission are projections from Definition 8327.1. The prefix row A fixes the finite list being inspected, while N and D record the last convergent by displayed recurrence data.

The rational endpoint is read through Q. Since Q is a $\mathsf{Rat}^{\uparrow}$ row attached to the displayed numerator and denominator rows, rational readback is available before any infinite continued-fraction object is mentioned.

Sibling compatibility is carried by S. The Stern–Brocot and Farey rows supply finite rational navigation, while the continued-fraction and convergent rows supply the prefix and recurrence interpretation of the same endpoint.

The L10 readback route is then forced through B, R, E. The dyadic budget row precedes the regular rational row, and the optional real seal is terminal, so the certificate exports no quotient real equality, selected limit, or choice principle.

Finally, H, C, P, L transport, replay, package, and name the same finite packet. No additional coordinate remains from which another local obligation could be read. □

Theorem 8327.3 (FiniteContinuedFraction rational readback)**.** *Every accepted* $\mathsf{FiniteContinuedFraction}^{\uparrow}$ *packet exposes its rational endpoint through the finite route*

$$A, N, D \longmapsto Q \longmapsto B \longmapsto R \longmapsto E.$$

Thus an L10 consumer may read the endpoint as $\mathsf{Rat}^{\uparrow}$ *data and, when requested, as a* $\mathsf{RegSeqRat}^{\uparrow}$ *row with a terminal* $\mathsf{Real}^{\uparrow}$ *seal. The consumer receives no infinite continued fraction, no quotient real equality, no countable-choice selector, and no ambient completeness theorem.*

Proof. Start with the carrier projection. The only rational endpoint coordinate is Q, and it is downstream of the finite prefix and recurrence rows A, N, D.

The dyadic and regular rows are ordered after the endpoint. The row B supplies the finite tolerance budget, and R is the regular rational readback that consumes that budget together with Q.

The real-facing row E is terminal. Because the carrier has no coordinate for an infinite tail or a completed quotient real, every downstream read remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteContinuedFraction}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteContinuedFraction}^{\uparrow}$ packet is generated from a finite partial-quotient spine, rational recurrence rows, a normalized rational endpoint, sibling navigation rows, dyadic budget, regular rational readback, optional real seal, transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteContinuedFraction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8327.1, Definition 8327.2, and Definition 8327.3 seed the finite-prefix rational-readback corridor between continued fractions and L10 rational data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteContinuedFraction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite continued fractions, quotient real equality, selected limits, countable choice, ambient real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, recurrence exactness, rational endpoint normalization, sibling compatibility, dyadic budget exposure, regular rational readback, transport, replay, provenance, and local naming for BEDC.Derived.FiniteContinuedFractionUp.

Chapter 8328

A Concrete Naming Certificate for $\mathsf{SphericalCompletion}^{\uparrow}$

Following Kaplansky and Bourbaki on spherically complete ultrametric spaces, the $\mathsf{SphericalCompletion}^{\uparrow}$ packet records only the constructive finite nested-ball-chain completion boundary. It sits beside the constructive ultrametric completion route of chapter 5204, the metric completion surface of chapter 1506, the StreamName windows of chapter 126, the RegSeqRat readback of chapter 301, and the terminal real seal of chapter 38. The packet does not assert maximal spherical completeness, a Zorn-style extension, selected representatives of a host completion, or quotient equality of Cauchy names.

Definition 8328.1 (Spherical completion carrier)**.** *A* $\mathsf{SphericalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (U, B, R, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the ultrametric source row whose balls and strong-triangle comparisons are read before any completion-facing request.*
2. *B is the finite nested ball-chain row, listing the displayed ball centers and inclusions visible to the packet.*
3. *R is the radius ledger, recording the finite descent requests attached to the nested chain.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row used to expose finite observations of candidate names.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational radius and distance data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal that records the terminal real-distance comparison available to completion consumers.*
7. *H records componentwise* hsame *transport for the ultrametric source, ball chain, radius ledger, stream window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each completion-facing request through $U, B, R, S, Q, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SphericalCompletion}^{\uparrow}$, $\mathsf{ConstructiveUltrametricCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SphericalCompletion}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite nested-ball-chain completion boundary. It has no coordinate for maximal spherical completeness, Zorn extension, quotient completion classes, selected representatives, host ball intersections, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8328.2 (Spherical completion NameCert obligations)**.** *Every accepted* $\mathsf{SphericalCompletion}^{\uparrow}$ *carrier of Definition 8328.1 exposes the following finite obligation rows:*

1. *carrier admission for the displayed ultrametric source* U*, nested ball chain* B*, radius ledger* R*, StreamName window* S*, RegSeqRat readback* Q*, Real seal* E*, transport* H*, replay* C*, provenance* P*, and local NameCert row* N*;*
2. *nested-chain monotonicity, requiring every later displayed ball in* B *to be read as contained in the earlier finite rows of the same chain;*
3. *radius-descent visibility, requiring each radius comparison used by a completion-facing consumer to pass through* R *and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* Q*;*
4. *readback and seal handoff, requiring every real-distance conclusion to pass from* S *through* Q *into the terminal* $\mathsf{Real}^{\uparrow}$ *seal* E*;*
5. *nonescape from Zorn arguments, maximal-choice extensions, host intersections, quotient completion classes, selected representatives, countable choice, and ambient completeness.*

Proof. Project the carrier tuple. The ten displayed rows are the whole admitted surface, so carrier admission cannot introduce a separate completion object or a hidden ball-intersection row.

Read nested-chain monotonicity before any radius request. Since the only chain coordinate is B, each inclusion or later-ball request is compared against the earlier displayed rows of B and transported componentwise by H.

Next use the radius ledger, readback, and seal rows. A completion-facing request reaches the radius data through R, exposes the finite StreamName window S, reads the rational comparison through Q, and only then consumes the terminal Real seal E.

Finally inspect the replay, provenance, and local naming rows. The displayed Cont route C, Pkg provenance P, and local $\mathsf{NameCert}$ row N name exactly that finite route and contain no coordinate for Zorn, maximal choice, host quotients, selected representatives, or ambient completeness. □

Theorem 8328.3 (Spherical completion ball-chain nonescape)**.** *Every completion-facing read of an accepted* $\mathsf{SphericalCompletion}^{\uparrow}$ *packet factors through the displayed finite ball-chain rows*

$$U, B, R, S, Q, E, H, C, P, N.$$

In particular, a consumer may not replace the chain row B *by a maximal nest, the radius ledger* R *by a hidden convergence modulus, the readback rows* S, Q, E *by a quotient completion class, or the local certificate* N *by a host spherical-completeness theorem.*

Proof. Begin with the carrier admission row of Definition 8328.2. It identifies $U, B, R, S, Q, E, H, C, P, N$ as the complete packet inventory.

Use the nested-chain and radius-visibility rows next. They force every ball-chain read through B and every radius descent through R before the StreamName and RegSeqRat rows are available.

Then apply the readback and seal handoff. The only completion-facing Real read passes through S, Q, E, so quotient classes, selected representatives, and host limits have no carrier coordinate from which to enter.

The nonescape row excludes the remaining classical routes. Since H, C, P, N only transport, replay, record provenance, and name the displayed finite route, every completion-facing read factors through the stated rows. □

Falsifiable prediction: Every accepted $\mathsf{SphericalCompletion}^{\uparrow}$ completion-facing read displays ultrametric source, finite nested ball chain, radius ledger, StreamName window, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any consumer can use the boundary.

Independence witness: constructive-ultrametric-completion, metriccompletion, streamname, regseqrat, real: $\mathsf{SphericalCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a finite nested ball-chain ledger, radius descent, stream windows, rational readback, Real sealing, transport, replay, provenance, and local naming while refusing maximal spherical completeness and quotient completion.

Closure status for $\mathsf{NameCert}_{\mathsf{SphericalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{SphericalCompletion}^{\uparrow}$ packet is generated from an ultrametric source row, a finite nested ball-chain row, a radius ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SphericalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8328.1, Definition 8328.2, and Definition 8328.3 seed the finite nested-ball-chain completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SphericalCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close maximal spherical completeness, Zorn-style nest extension, quotient completion equality, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.SphericalCompletionUp and checked carrier, nested-chain, radius-visibility, readback, seal, transport, replay, provenance, and local naming obligations.

Chapter 8329

A Concrete Naming Certificate for $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$

Following Bishop–Bridges finite-net arguments and the classical overlap multiplicity of finite covers, the $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$ packet records the overlap-depth ledger used by the compact-uniform-continuity route of chapter 9237. It sits beside the compact cover nerve of chapter 6263, the finite cover nerve of chapter 7597, the compact metric source of chapter 129, the rational lower-bound fold of chapter 4096, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ consumer of chapter 369. The packet names finite overlap depth and rational-fold rows; it does not assert open-cover compactness, selected subcovers, host set equality, countable choice, or an ambient Lebesgue-number theorem.

Definition 8329.1 (FiniteCoverMultiplicity carrier)**.** *A* $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, V, O, D, W, R, F, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-cover source row, including the displayed* $\mathsf{ProbeBundle}$ *of centers and radius histories.*
2. *V is the cover-member row, recording which displayed cover members contain each inspected source point.*
3. *O is the finite overlap-incidence row inherited from the cover-nerve route.*
4. *D is the multiplicity-depth row, recording the displayed finite bound on how many cover members can be simultaneously active at an inspected point or face.*
5. *W is the rational-fold weight row assigning each active member its* $\mathsf{Rat}^{\uparrow}$ *radius or tolerance contribution.*
6. *R is the rational lower-bound and rational-fold readback row consumed by compact-uniform modulus arguments.*
7. *F is the* $\mathsf{FiniteCoverNerve}^{\uparrow}/\mathsf{CompactCoverNerve}^{\uparrow}$ *sibling handoff row.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *consumer row reached only after the finite depth and rational-fold rows are displayed.*
9. *H records componentwise* hsame *transport for finite cover source, member, overlap, depth, weight, fold, handoff, and structural rows.*

10. *C records displayed* Cont *replay through cover membership, overlap incidence, multiplicity depth, rational folding, sibling handoff, and uniform-modulus consumption.*
11. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{CompactCoverNerve}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverMultiplicity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, V, O, D, W, R, F, U, H, C, P, N$. It has no coordinate for arbitrary open covers, selected subcovers, quotient equality of cover members, host point equality, countable choice, or ambient compactness.

Theorem 8329.2 (FiniteCoverMultiplicity NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$ *carrier*

$$M = (K, V, O, D, W, R, F, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverMultiplicity}^{\uparrow}}$ *surface consists exactly of carrier admission; compact finite-cover source visibility through K; cover-member exposure through V; overlap-incidence readback through O; multiplicity-depth exactness through D; rational-fold weight exposure through W, R; cover-nerve sibling compatibility through F; uniform-modulus handoff through U; componentwise transport and replay through H, C; and provenance and local naming through P, N.*

Proof. Carrier admission is projection from Definition 8329.1. The accepted packet exposes exactly the compact source, cover-member, overlap, depth, rational weight, fold, sibling handoff, uniform-modulus, transport, replay, provenance, and local naming rows.

The cover and overlap obligations are read through K, V, O. Each membership and incidence row is tied to the same displayed finite ProbeBundle, so the certificate cannot widen to an arbitrary open-cover statement.

The multiplicity obligation is the row D. It counts only simultaneously active displayed members or faces already visible through V, O, and therefore records overlap depth as finite packet data rather than as host set cardinality.

The rational and uniform obligations are the route W, R, F, U. The weights and fold rows expose the rational accounting, the sibling handoff ties that accounting to the finite cover nerves, and the uniform-modulus row is terminal.

Finally, H, C, P, N transport, replay, source, and name the same finite inventory. Since no excluded object is a coordinate of the carrier, the listed rows exhaust the local certificate. □

Theorem 8329.3 (FiniteCoverMultiplicity overlap-depth handoff)**.** *Every compact-uniform-continuity consumer of an accepted* $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$ *packet reads overlap-depth and rational-fold data through the finite route*

$$K, V, O \longmapsto D, W, R \longmapsto F, U \longmapsto H, C, P, N.$$

The route supplies finite cover membership, finite overlap incidence, displayed multiplicity depth, rational-fold weights, cover-nerve compatibility, and a $\mathsf{UniformModulus}^{\uparrow}$ *handoff. It exports no selected subcover, no host nerve complex, no quotient equality of covers, no countable choice, and no ambient compactness theorem.*

Proof. Project the accepted carrier. The source-side route is K, V, O: compact metric cover rows expose the finite probe spine, cover membership records active members, and overlap incidence records the finite face data.

The accounting route is D, W, R. Multiplicity depth is computed only over the displayed active members, while the rational weight and fold rows record the finite radius accounting used by the uniform-modulus construction.

The consumer route is F, U, H, C, P, N. The cover-nerve handoff keeps the packet aligned with the sibling finite-nerve chapters, and the uniform-modulus row is consumed only after the depth and fold rows are visible.

Because the carrier has no coordinate for selected subcovers, host complexes, quotient cover equality, choice, or ambient compactness, every compact-uniform consumer remains inside the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverMultiplicity}\uparrow}$.

Constructive story: A $\mathsf{FiniteCoverMultiplicity}^{\uparrow}$ packet is generated from compact finite-cover rows, cover membership, overlap incidence, finite multiplicity depth, rational-fold weights, cover-nerve handoff, uniform-modulus consumption, transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCoverMultiplicity}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8329.1, Definition 8329.2, and Definition 8329.3 seed the overlap-depth and rational-fold route used by compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCoverMultiplicity}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host nerve complexes, quotient cover equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cover-member exactness, overlap-incidence exactness, multiplicity-depth exactness, rational-fold stability, cover-nerve compatibility, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCoverMultiplicityUp.

Chapter 8330

A Concrete Naming Certificate for $\mathsf{BishopRegSeqRealEta}^{\uparrow}$

Following Bishop–Bridges constructive completion, the $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ packet records the finite eta route by which a displayed regular rational sequence name is sealed as a $\mathsf{Real}^{\uparrow}$ name and then read back through the same finite windows. It sits over the regular-rational source of chapter 301, the terminal real-name seal of chapter 38, the finite window service of chapter 126, the dyadic tolerance ledger of chapter 291, and the completion handoff of chapter 423. The packet names the eta surface from a $\mathsf{RegSeqRat}^{\uparrow}$ display to a $\mathsf{Real}^{\uparrow}$ seal and back to the same displayed route; it does not identify quotient representatives, select a limit stream, invoke countable choice, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8330.1 (Bishop RegSeqRat-to-Real eta carrier)**.** *A* $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (Q, W, D, R, A, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, recording the regular rational sequence name and its displayed Cauchy modulus data.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, naming the finite observations through which the source sequence is inspected.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, denominator budgets, and slack comparisons used by the windows.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after Q, W, D have been displayed.*
5. *A is the eta readback row, requiring any read from the sealed real name back toward regular rational data to expose the same Q, W, D, R route.*
6. *H records componentwise* hsame *transport for the source row, windows, dyadic ledger, Real seal, eta readback, provenance, and local name.*
7. *C records displayed* Cont *replay from a finite precision request through Q, W, D, R, A, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopRegSeqRealEta}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRegSeqRealEta}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, W, D, R, A, H, C, P, N$. It has no coordinate for quotient equality of real names, selected representatives, countable-choice schedules, hidden completion objects, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8330.2 (Bishop RegSeqRat-to-Real eta NameCert obligations)**.** *For every accepted* $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ *carrier*

$$E = (Q, W, D, R, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopRegSeqRealEta}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Real}^{\uparrow}$ *seal, eta readback row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row; seal ordering requiring R to be read only after Q, W, D; eta readback requiring A to expose the same Q, W, D, R route; and non-escape excluding quotient representatives, selected limits, countable choice, hidden completion objects, and ambient Real completeness.*

Proof. Project the carrier of Definition 8330.1. The accepted packet displays $Q, W, D, R, A, H, C, P, N$, so carrier admission and local naming are finite row projections.

Read the seal ordering next. The $\mathsf{RegSeqRat}^{\uparrow}$ source row Q supplies the regular rational name, W supplies the finite $\mathsf{StreamName}^{\uparrow}$ observations, and D supplies the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger before the terminal $\mathsf{Real}^{\uparrow}$ seal R can be consumed.

Read the eta row A. It is not a second representative of the real name; it is the displayed return route that exposes the same source, window, tolerance, and seal rows when a consumer reads back from R toward regular rational data.

Finally inspect H, C, P, N. These rows transport, replay, source, and name the same finite route. Since no carrier coordinate stores quotient equality, a selected limit, a choice schedule, a hidden completion object, or Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8330.3 (Bishop RegSeqRat-to-Real eta readback nonescape)**.** *Every consumer that reads the eta row of an accepted* $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ *packet must carry the same* $\mathsf{RegSeqRat}^{\uparrow}$ *source,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and* $\mathsf{Real}^{\uparrow}$ *seal through H, C, P, N. A readback that omits any one of Q, W, D, R leaves the accepted carrier and cannot cite the packet as a RegSeqRat-to-Real eta certificate.*

Proof. Start with the NameCert obligations of Definition 8330.2. They require the eta row A to expose the same Q, W, D, R route that produced the Real seal.

Transport and replay do not add another route. The row H preserves the displayed components under hsame, while C replays the finite precision request through those components. The provenance row P and local name N only record the same package boundary.

Therefore a consumer that omits Q, W, D, or R is no longer reading the accepted eta packet. It may describe a partial source, partial window, partial tolerance ledger, or sealed real name, but it is not the $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ readback route. □

Falsifiable prediction: An accepted $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ readback exposes a RegSeqRatUp source row, StreamNameUp finite windows, DyadicRatCoreUp tolerance ledger, RealUp seal, eta row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before any consumer treats the sealed real name as returning to regular rational data.

Independence witness: regseqrat, real, streamname, dyadicratcore, cauchycompletionfunctor: none is bijective to $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ because the packet jointly carries the source regular

sequence, finite windows, dyadic tolerance ledger, Real seal, eta readback, transport, replay, provenance, and local NameCert rows while refusing quotient representatives, selected limits, countable choice, hidden completion objects, and ambient Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegSeqRealEta}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegSeqRealEta}^{\uparrow}$ packet is generated from a RegSeqRatUp source row, StreamNameUp windows, a DyadicRatCoreUp tolerance ledger, a RealUp seal, an eta readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegSeqRealEta}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8330.1, Definition 8330.2, and Definition 8330.3 seed the finite RegSeqRat-to-Real eta route through source rows, finite windows, dyadic tolerance data, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegSeqRealEta}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, selected representatives, selected limits, countable choice, hidden completion objects, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, seal ordering, eta readback exactness, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.BishopRegSeqRealEtaUp.

Chapter 8331

A Concrete Naming Certificate for $\mathsf{RealCompletionEtaLaw}^{\uparrow}$

Following Bishop–Bridges completion theory and Mac Lane's unit laws, the $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ packet records the Real-facing finite BEDC surface saying that the completion unit returns the same displayed real completion endpoint after the StreamName, RegSeqRat, dyadic tolerance, and Real-seal routes have been read. It refines the metric eta packet of chapter 8324 along the Real/RegSeqRat/StreamName route displayed by chapter 38, chapter 301, and chapter 126. The packet names the unit law as finite NameCert data; it is not a quotient completion equality, a selected representative theorem, countable choice, or an ambient completeness principle.

Definition 8331.1 (Real completion eta-law carrier)**.** *A* $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (T, U, W, R, D, Q, Z, H, C, P, N)$$

with the following displayed rows:

1. *T is the Real completion endpoint row already accepted by the displayed completion route.*
2. *U is the completion unit row applied to that same displayed endpoint.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row exposing the observable real-name windows for the direct and unit-applied routes.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the finite precision ledger used by the readback.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after T, U, W, R, D have been displayed.*
7. *Z is the eta-law exactness row binding the direct Real completion endpoint and the unit-applied endpoint to the same displayed Real seal.*
8. *H, C, P, N are componentwise* hsame *transport, displayed* Cont *replay, provenance, and the local* $\mathsf{NameCert}_{\mathsf{RealCompletionEtaLaw}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, U, W, R, D, Q, Z, H, C, P, N$. It has no coordinate for quotient Cauchy classes, selected representatives, host equality of real numbers, countable-choice schedules, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8331.2 (Real completion eta-law NameCert obligations)**.** *For every accepted* $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ *carrier $E = (T, U, W, R, D, Q, Z, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RealCompletionEtaLaw}^{\uparrow}}$ *surface consists*

exactly of Real completion endpoint exposure, completion unit exposure, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal exposure, eta-law exactness, transport, replay, provenance, and local naming. Every consumer of the eta law must read those rows before it treats the direct Real completion endpoint and the unit-applied endpoint as the same named route.

Proof. Project the carrier of Definition 8331.1. The rows T and U name the displayed Real completion endpoint and the completion unit applied to that endpoint, while W, R, D expose the finite StreamName, RegSeqRat, and dyadic tolerance route through which a Real-facing consumer may inspect them.

Next read the terminal seal row Q. The seal is reached only after the endpoint, unit, window, readback, and tolerance rows have been displayed, so no quotient Cauchy class, selected representative, countable-choice schedule, or host real equality is available as an independent coordinate.

Finally use the eta-law exactness row Z and the structural rows H, C, P, N. They bind the direct and unit-applied routes to the same displayed Real seal under transport, replay, provenance, and local naming, which exhausts the NameCert surface. □

Theorem 8331.3 (Real completion eta-law unit handoff)**.** *Let $E = (T, U, W, R, D, Q, Z, H, C, P, N)$ be an accepted* $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ *carrier. Any Real-facing completion consumer that enters through the unit row U must pass through the displayed endpoint T, the* $\mathsf{StreamName}^{\uparrow}$ *windows W, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, and the eta-law exactness row Z before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal Q. The handoff therefore exposes the completion unit law as a finite Real-name route, not as quotient completion equality, selected representatives, host equality of real numbers, or an ambient completeness theorem.*

Proof. Begin with the unit row U. By the carrier definition it is attached to the already displayed Real completion endpoint T, so it cannot introduce a second endpoint outside the packet.

Read the finite observation route through W, R, D. These rows are exactly the StreamName windows, RegSeqRat readback, and dyadic tolerance ledger used by the Real/RegSeqRat/StreamName route, and they must be consumed before the seal Q is exposed.

The exactness row Z supplies the eta-law handoff, while H, C, P, N preserve the same displayed route. Thus a consumer receives the unit law for the existing Real completion endpoint without acquiring quotient equality, selected representatives, countable choice, host equality, or ambient Real completeness. □

Independence witness: metric-completion-eta-law, real, regseqrat, streamname, dyadicratcore: no listed sibling is bijective to $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ because this packet jointly binds a Real completion endpoint, completion unit row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal, eta-law exactness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealCompletionEtaLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{RealCompletionEtaLaw}^{\uparrow}$ packet is generated from a Real completion endpoint row, a completion unit row, finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp seal, eta-law exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealCompletionEtaLaw}^{\uparrow}}$, seed)

Scope closed: Definition 8331.1, Definition 8331.2, and Definition 8331.3 seed the finite Real-facing completion-unit eta-law surface over the Real/RegSeqRat/StreamName route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealCompletionEtaLaw}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected Cauchy representatives, host equality of real numbers, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, unit-row exposure, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Real seal exposure, eta-law exactness, transport, replay, provenance, and local naming for BEDC.Derived.RealCompletionEtaLawUp.

Chapter 8332

A Concrete Naming Certificate for $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$

Following Bishop and Bridges on constructive completions and the standard dense-embedding comparison used in metric completion, the $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$ packet records the finite BEDC surface for comparing two dense presentations of the same Cauchy completion boundary. It sits over the dyadic arithmetic core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Cauchy dense embedding of chapter 5893, and the metric dense embedding of chapter 3351. The packet compares displayed dense rows only; it does not quotient completion points, select representatives, identify host limits, invoke countable choice, or import ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8332.1 (Cauchy completion dense-embedding comparison carrier)**.** *A* CauchyCompletionDenseEmbeddi *carrier is a finite* BHist *packet*

$$K = (S, D, M, E, E', Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the shared source row, binding the compared dense presentations to the same displayed Cauchy-completion source and its finite* $\mathsf{StreamName}^{\uparrow}$ *observation schedule.*
2. *D is the* $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ *row, exposing the Cauchy dense-source image, completion route, dyadic tolerance ledger,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and terminal* $\mathsf{Real}^{\uparrow}$ *seal used by the first presentation.*
3. *M is the* $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ *row, exposing the metric dense-source image, separated comparison route, uniform-completion handoff, and regular rational readback used by the second presentation.*
4. *E is the first dense embedding into the completion presentation, read through D before any comparison row is consumed.*
5. *E' is the second dense embedding into the completion presentation, read through M before any comparison row is consumed.*
6. *Q is the comparison row, recording finite agreement of the two dense-image reads on the shared source windows and their* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledgers.*

7. *H records componentwise* hsame *transport for S, D, M, E, E', Q and for the replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a completion-facing comparison request through the source, both dense embeddings, the comparison row, and the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$, $\mathsf{CauchyCompletionDenseEmbeddin}$ $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through $S, D, M, E, E', Q, H, C, P, N$. It has no coordinate for quotient completion equality, a selected dense representative, host equality of limits, countable choice, or an ambient completion theorem.

Theorem 8332.2 (Cauchy completion dense-embedding comparison NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$ *carrier*

$$K = (S, D, M, E, E', Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}}$ *surface consists exactly of carrier admission for the shared source row, the Cauchy dense-embedding row, the metric dense-embedding row, the two completion-presentation embeddings, the comparison row, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing comparison read must expose S, D, M, E, E' before it can consume Q, H, C, P, N.*

Proof. Project the carrier of Definition 8332.1. The accepted packet displays exactly the source row, two dense-embedding rows, two completion-presentation embedding rows, one comparison row, and the structural rows.

The entry route is S, D, M, E, E'. The source row fixes the common finite windows; D and M expose the Cauchy and metric dense-embedding presentations; E and E' are therefore read only after their corresponding dense rows have been displayed.

The comparison route is Q, H, C, P, N. The row Q compares only the displayed dense-image reads over the shared windows and dyadic tolerance ledgers. The rows H and C transport and replay the same comparison, while P and N record provenance and the local certificate.

Since the carrier has no coordinate for quotient completion equality, selected representatives, host limit equality, countable choice, or ambient completeness, those endpoints cannot be exported by the local NameCert surface. □

Theorem 8332.3 (Cauchy completion dense-embedding comparison handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion consumer of an accepted* $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyCompletionDenseEmbedding}^{\uparrow},\ \mathsf{MetricCompletionDens}$$

Thus the consumer receives a finite comparison between two dense presentations feeding the same completion boundary. It receives no quotient equality of completion points, selected representative, host limit equality, countable-choice schedule, total completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with the NameCert obligations of Definition 8332.2. They force every comparison read to expose the shared source row and both dense-embedding rows before the comparison row Q is consumed.

Read the numerical side through the sibling rows. The source windows are governed by $\mathsf{StreamName}^{\uparrow}$, their tolerance ledgers by $\mathsf{DyadicRatCore}^{\uparrow}$, and their regular readback by $\mathsf{RegSeqRat}^{\uparrow}$ before either dense presentation reaches a $\mathsf{Real}^{\uparrow}$ seal.

The Cauchy presentation is supplied by $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$, while the metric presentation is supplied by $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$. The comparison row Q only relates those displayed dense-image reads over the shared windows.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Because none of the excluded host-level objects is a carrier coordinate, the handoff remains a comparison surface rather than a quotient completion theorem. □

Falsifiable prediction: Any accepted $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$ consumer that compares dense completion presentations while omitting either the $\mathsf{CauchyCompletionDenseEmbedding}^{\uparrow}$ row, the $\mathsf{MetricCompletionDenseEmbedding}^{\uparrow}$ row, or the shared $\mathsf{StreamName}^{\uparrow}/\mathsf{DyadicRatCore}^{\uparrow}/\mathsf{RegSeqRat}^{\uparrow}$ readback route is outside the carrier surface.

Independence witness: Nearest siblings: cauchy-completion-dense-embedding, metric-completion-dense-embedding, dyadicratcore, streamname, regseqrat, real. The carrier is not bijective to either dense-embedding sibling because it contains both presentations and a comparison row; not to DyadicRatCoreUp because it includes source windows, dense completion rows, regular readback, and Real seals; not to StreamNameUp or RegSeqRatUp because it adds dense-presentation comparison and local NameCert rows; not to RealUp because it exports no ambient completeness or quotient equality.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}$ packet is generated from a shared source row, Cauchy and metric dense-embedding rows, two completion-presentation embedding rows, a finite comparison row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8332.1, Definition 8332.2, and Definition 8332.3 seed the finite comparison surface for two dense presentations feeding the same completion boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionDenseEmbeddingComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, bridge checking, quotient equality of completion points, selected dense representatives, host limit equality, countable choice, total completion objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires a checked BEDC.Derived.CauchyCompletionDenseEmbeddingComparisonUp carrier with source-row admission, two dense-embedding rows, comparison-row exactness, StreamName, DyadicRatCore and RegSeqRat readback, Real-seal confinement, transport, replay, provenance, and local naming.

Chapter 8333

A Concrete Naming Certificate for $\mathsf{DyadicRealBall}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{DyadicRealBall}^{\uparrow}$ packet records a finite dyadic centre-radius neighbourhood for regular real-name work. It reads dyadic arithmetic from chapter 291, finite observation windows from chapter 126, regular rational readback from chapter 301, and the terminal real-name seal from chapter 38. The packet names a concrete ball row available to later metric, uniform, and completion arguments; it does not identify host real equality, quotient representatives, selected limits, countable choice, or ambient completeness.

Definition 8333.1 (Dyadic real ball carrier)**.** *A* $\mathsf{DyadicRealBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, E, M, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row carrying the dyadic centre, positive dyadic radius, denominator budget, and slack comparisons used by the ball.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the centre name is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to those windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R have been displayed.*
5. *M is the membership-witness row: an admitted point can be read as lying in the ball only through the displayed centre, radius, window, readback, and seal rows.*
6. *H records componentwise* hsame *transport for the dyadic data, finite windows, regular readback, Real seal, membership witness, provenance, and local name.*
7. *C records displayed* Cont *replay from a finite precision request through D, S, R, E, M, H.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicRealBall}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRealBall}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, E, M, H, C, P, N$. It has no coordinate for host real equality, quotient equality of real names, selected representatives, countable choice, hidden metric completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8333.2 (Dyadic real ball NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRealBall}^{\uparrow}$ *carrier*

$$B = (D, S, R, E, M, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRealBall}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic centre-radius row, finite StreamName windows, RegSeqRat readback, terminal Real seal, membership-witness row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every ball-membership consumer must pass through*

$$D, S, R, E, M, H, C, P, N$$

and through no host real equality, quotient representative, selected limit, countable-choice selector, hidden completion object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Project the carrier of Definition 8333.1. The row D displays the dyadic centre, radius, denominator budget, and slack comparisons, while S and R display the finite observation and regular rational readback route for the centre name.

Read the seal and membership rows next. The terminal row E is available only after D, S, R have been displayed, and the row M records membership only as a witness over the same centre-radius, window, readback, and seal route.

Finally inspect H, C, P, N. Transport, replay, provenance, and local naming preserve the same finite route and add no hidden equality or selector coordinate. Since the carrier contains no host real equality, quotient representative, selected limit, countable-choice selector, hidden completion object, or ambient completeness field, the listed rows exhaust the NameCert obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRealBall}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicRealBall}^{\uparrow}$ packet is generated from a DyadicRatCore centre-radius row, StreamName finite windows, RegSeqRat readback, a RealUp seal, a membership-witness row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DyadicRealBall}^{\uparrow}}$, seed)

Scope closed: Definition 8333.1 and Definition 8333.2 seed the finite dyadic centre-radius ball route over dyadic arithmetic, finite windows, regular rational readback, terminal Real sealing, membership witnessing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DyadicRealBall}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close metric topology, uniform-space structure, completion theorems, host real equality, quotient representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, centre-radius visibility, finite window readback, Real seal ordering, membership-witness exactness, transport, replay, provenance, and local naming for BEDC.Derived.DyadicRealBallUp.

Chapter 8334

A Concrete Naming Certificate for $\mathsf{BorelCantelliLemma}^{\uparrow}$

Following Borel and Cantelli, the $\mathsf{BorelCantelliLemma}^{\uparrow}$ packet records the finite summable-event handoff used by first-lemma consumers before any repeated-hit conclusion is visible. It sits after the probability source of chapter 184, the event-value surface of chapter 92, the finite union-bound ledger of chapter 6696, the event-sequence route of chapter 2357, and the bounded-window packet of chapter 7718. The packet names only displayed event rows, finite tail windows, partial probability sums, and the local summable-budget ledger; it does not import countable choice, almost-sure quotient equality, selected null sets, or the full infinite theorem.

Definition 8334.1 (Borel–Cantelli lemma carrier)**.** *A* $\mathsf{BorelCantelliLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (\Omega, M, E, W, U, F, S, B, H, C, P, N)$$

with the following displayed rows:

1. Ω *is the* $\mathsf{ProbSpace}^{\uparrow}$ *source row naming the normalized probability carrier.*
2. M *is the* $\mathsf{Measure}^{\uparrow}$ *event-value row through which each displayed event probability is read.*
3. E *is the finite event-sequence packet, listing the inspected event names and measurable-event witnesses.*
4. W *is the finite tail-window row, recording the bounded index range seen by the consumer.*
5. U *is the* $\mathsf{FiniteUnionBound}^{\uparrow}$ *ledger row for the union of events in the displayed window.*
6. F *is the* $\mathsf{FiniteBorelCantelli}^{\uparrow}$ *bounded-window handoff row.*
7. S *is the local summable-event budget row, recording the finite partial-sum bound available to the window.*
8. B *is the Borel–Cantelli first-lemma route row read through* $\mathsf{BorelCantelli}^{\uparrow}$*.*
9. H *records componentwise* hsame *transport for* $\Omega, M, E, W, U, F, S, B, C, P, N$*.*
10. C *records displayed* Cont *replay from the probability and measure rows through the event window, finite union-bound ledger, bounded-window handoff, summable-budget row, and first-lemma route.*
11. P *is the* Pkg *provenance over* $\mathsf{BorelCantelliLemma}^{\uparrow}$*,* $\mathsf{ProbSpace}^{\uparrow}$*,* $\mathsf{Measure}^{\uparrow}$*,* $\mathsf{FiniteUnionBound}^{\uparrow}$*,* $\mathsf{BorelCantelli}^{\uparrow}$*,* $\mathsf{FiniteBorelCantelli}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

12. N is the local $\mathsf{NameCert}_{\mathsf{BorelCantelliLemma}^{\uparrow}}$ *row.*
The carrier has no coordinate for countable choice, almost-sure quotient equality, selected null-event witnesses, an independence converse, or ambient measure completion.

Theorem 8334.2 (Borel–Cantelli lemma NameCert surface)**.** *For every accepted* $\mathsf{BorelCantelliLemma}^{\uparrow}$ *carrier* $L = (\Omega, M, E, W, U, F, S, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BorelCantelliLemma}^{\uparrow}}$ *surface consists exactly of probability-source admission through* Ω*, event-value exposure through* M*, finite event-sequence admission through* E*, finite tail-window exposure through* W*, finite union-bound ledger exposure through* U*, bounded-window handoff through* F*, summable-budget exposure through* S*, first-lemma route exposure through* B*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8334.1. The projection exposes exactly the probability source, measure event-value row, finite event-sequence packet, tail-window row, finite union-bound ledger, bounded-window handoff, summable-budget row, first-lemma route, transport, replay, provenance, and local naming.

The continuation row fixes the order of inspection. A consumer first reads the probability and measure rows, then the finite event packet and tail window, then the finite union-bound ledger and bounded-window Borel–Cantelli handoff, and only then the local summable budget and first-lemma route.

Since the carrier contains no further coordinate, no countable-choice selector, almost-sure quotient equality, selected null-event witness, independence converse, or completed-measure row can be exported from this surface. □

Theorem 8334.3 (Borel–Cantelli lemma finite-sum handoff)**.** *Every accepted* $\mathsf{BorelCantelliLemma}^{\uparrow}$ *consumer that reads a summable-event request must pass through the finite route*

$$\mathsf{ProbSpace}^{\uparrow},\ \mathsf{Measure}^{\uparrow},\ \mathsf{FiniteUnionBound}^{\uparrow},\ \mathsf{FiniteBorelCantelli}^{\uparrow},\ \mathsf{BorelCantelli}^{\uparrow}.$$

The event-sequence row E*, tail-window row* W*, finite union-bound ledger* U*, bounded-window handoff* F*, and summable-budget row* S *are visible before the first-lemma route* B *is public.*

Proof. Start with the probability and measure rows Ω and M. They supply the source normalization and event-value reads for the displayed event sequence E.

Next restrict the request to the finite tail window W. The finite union-bound ledger U applies only to that displayed window, so the probability estimate is attached to a visible finite event family.

Read the bounded-window handoff F through Definition 7718.3. This places the finite Borel–Cantelli estimate downstream of $\mathsf{ProbSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, and $\mathsf{FiniteUnionBound}^{\uparrow}$.

Finally the local summable-budget row S and the first-lemma route row B consume that finite estimate. Transport through H, replay through C, provenance through P, and local naming through N preserve the same route, so the handoff remains finite BEDC data rather than a full infinite theorem. □

Theorem 8334.4 (Borel–Cantelli lemma no-choice escape)**.** *An accepted* $\mathsf{BorelCantelliLemma}^{\uparrow}$ *packet cannot expose countable choice, almost-sure quotient equality, a selected null-event witness, an independence-side converse, or ambient measure completion. Every public read of the packet is exhausted by the finite rows* $\Omega, M, E, W, U, F, S, B, H, C, P, N$ *of Definition 8334.1.*

Proof. Apply Definition 8334.2. The NameCert surface is exactly the listed probability, measure, event, window, union-bound, bounded-window, summable-budget, first-lemma, transport, replay, provenance, and naming rows.

Apply Definition 8334.3. The only public route to the first-lemma row passes through the finite union-bound and bounded-window handoff before reading the summable budget.

The refused objects are absent from the carrier and from the handoff route. Therefore no consumer can recover them as hidden projections of the $\mathsf{BorelCantelliLemma}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BorelCantelliLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{BorelCantelliLemma}^{\uparrow}$ packet is generated from a ProbSpace source row, Measure event-value row, finite event-sequence row, finite tail-window row, FiniteUnionBound ledger, FiniteBorelCantelli bounded-window handoff, local summable-event budget, BorelCantelli first-lemma route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BorelCantelliLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8334.1, Definition 8334.2, Definition 8334.3, and Definition 8334.4 seed the finite summable-event handoff for first-lemma consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BorelCantelliLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close countable choice, almost-sure quotient equality, selected null-event witnesses, the independence converse, ambient measure completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite event-row exactness, finite tail-window routing, finite union-bound ledger exactness, bounded-window handoff, summable-budget exposure, first-lemma route exposure, transport, replay, provenance, and local naming for BEDC.Derived.BorelCantelliLemmaUp.

Chapter 8335

A Concrete Naming Certificate for $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$

Following Bishop and Bridges on proof-relevant constructive data and Troelstra–van Dalen on realizability-style finite evidence, the $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ packet records the finite boundary at which proof-token identity remains available as evidence while the public classifier ignores it. It sits beside the finite observation service of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name surface of chapter 38, and the shared-tail normalizer of chapter 1299. The packet is a finite sieve for Real and Completion-facing reads: it preserves the proof-token ledger as local evidence, but no displayed stream, regular-rational, dyadic, or Real row may classify two packets differently merely because the retained proof token has a different identity.

Definition 8335.1 (FiniteWindowProofIrrelevanceSieve carrier)**.** *A* $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the observable prefixes used by the consumer.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the finite reads.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *or Completion-facing seal row, available only after W, R, D have been displayed.*
5. *Q is the proof-token ledger retained inside the packet as evidence for how the finite windows were justified; Q is not a coordinate of the public classifier.*
6. *H records componentwise* hsame *transport for the window, readback, dyadic, seal, proof-token, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a finite read request through W, R, D, E, Q, H.*
8. *P is the* Pkg *provenance row over* $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}}$ *row.*

The public classifier compares accepted packets only through W, R, D, E, H, C, P, N. The row Q may be inspected by the local proof ledger, but it cannot create a public distinction after the same finite windows, regular readback, dyadic tolerance data, and seal row have been displayed.

Theorem 8335.2 (FiniteWindowProofIrrelevanceSieve NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ *carrier*

$$S = (W, R, D, E, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite window, regular readback, dyadic tolerance, Real or Completion seal, proof-token ledger, transport, replay, provenance, and local naming rows; public-readback preservation requiring every public consumer to expose the same W, R, D, E rows before classification; proof-token erasure requiring the classifier to ignore identity changes in Q once W, R, D, E, H, C, P, N are fixed; ledger nonescape requiring Q to remain a retained evidence row rather than a public classifier coordinate; componentwise* hsame *transport for all displayed rows; displayed* Cont *replay through the same finite route;* Pkg *provenance over the listed sibling carriers; and the local naming obligation for N.*

Proof. Carrier admission is projection from Definition 8335.1. The packet displays the finite observation row W, the regular rational readback R, the dyadic tolerance ledger D, the terminal seal row E, and the retained proof-token ledger Q before transport, replay, provenance, and naming are inspected.

Public-readback preservation is read componentwise. A public consumer sees W, R, D, E, H, C, P, N in the same order as the carrier, so two accepted packets with the same visible rows offer the same StreamName, RegSeqRat, DyadicRatCore, and Real-facing data.

Proof-token erasure and ledger nonescape are the same finite sieve boundary. The row Q remains present as evidence for local reconstruction, but it is not an argument of the public classifier. Replacing Q while preserving the visible rows therefore cannot change the public readback class.

Transport and replay are handled row by row. The hsame row H transports each displayed component without turning Q into a public coordinate, and the Cont row C replays finite read requests through the same window, readback, dyadic, seal, and retained-ledger route.

Finally, P and N source and name the same finite packet. Since the carrier has no extra public coordinate beyond W, R, D, E, H, C, P, N, the listed clauses exhaust the local NameCert obligations. □

Falsifiable prediction: An accepted $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ public read exposes the StreamNameUp windows, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp or Completion-facing seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before classification; a read whose only difference is proof-token identity in Q has the same public classifier value.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchytailthresholdnormalizer: none is bijective to $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ because the packet jointly carries public finite reads and a retained proof-token ledger while refusing to let proof-token identity escape into the public classifier.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, a DyadicRatCore tolerance ledger, a RealUp or Completion-facing seal, a retained proof-token ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowProofIrrelevanceSieve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8335.1 and Definition 8335.2 seed the finite public-readback route that retains proof-token evidence while erasing proof-token identity from the classifier.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteWindowProofIrrelevanceSieve}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotienting of displayed streams, proof irrelevance for all BEDC objects, selected limits, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, public-readback preservation, proof-token erasure, ledger nonescape, hsame transport, Cont replay, Pkg provenance, and local naming for BEDC.Derived.FiniteWindowProofIrrelevanceSieve

Chapter 8336

A Concrete Naming Certificate for CompleteMetricContractionPrinciple$^{\uparrow}$

Following Banach and Bishop–Bridges constructive analysis, the CompleteMetricContractionPrinciple$^{\uparrow}$ packet records the fixed-point route in a complete metric space as finite NameCert data. It sits after the metric carrier of chapter 57, the complete-metric service of chapter 128, the Cauchy criterion surface of chapter 392, the Picard contraction route of chapter 395, and the fixed-point certificate of chapter 396. The packet names the contraction principle only when the metric source, contraction modulus, Picard orbit, Cauchy handoff, fixed-point seal, transport, replay, provenance, and local NameCert rows are all displayed; it is not a host selected-limit theorem.

Definition 8336.1 (Complete metric contraction principle carrier)**.** *A* CompleteMetricContractionPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, d, \lambda, O, Q, F, H, C, P, N)$$

with the following displayed rows:

1. *M is the* CompleteMetric$^{\uparrow}$ *source row naming the complete metric service consumed by the route.*
2. *d is the* Met$^{\uparrow}$ *distance row used for finite iterate comparisons and contraction estimates.*
3. *λ is the contraction-modulus row, including the displayed positivity and unit-bound data.*
4. *O is the* PicardContraction$^{\uparrow}$ *orbit row, exposing the initial point, successor applications, and finite Picard ledger.*
5. *Q is the* CauchyCriterion$^{\uparrow}$ *route that turns the contraction estimates along O into named Cauchy data.*
6. *F is the* BanachFixedPoint$^{\uparrow}$ *fixed-point seal, available only after the Picard and Cauchy rows have been displayed.*
7. *H records componentwise* hsame *transport for the complete metric source, distance, modulus, Picard orbit, Cauchy route, fixed-point seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from metric reads through contraction estimates, Picard iteration, Cauchy criterion, and fixed-point sealing.*
9. *P is the* Pkg *provenance over* CompleteMetricContractionPrinciple$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Met$^{\uparrow}$, CauchyCriterion$^{\uparrow}$, PicardContraction$^{\uparrow}$, BanachFixedPoint$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a selected limit, quotient completion, countable choice, ambient real completeness, host fixed-point equality, Lean verification, or bridge checking.

Lean4 ✓ `BEDC.Derived.CompleteMetricContractionPrincipleUp.CompleteMetricContractionPrincipleTasteGate single carrier alignment`

Theorem 8336.2 (Complete metric contraction principle NameCert obligations)**.** *For every accepted* $\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}$ *carrier*

$$K = (M, d, \lambda, O, Q, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}}$ *surface consists exactly of complete-metric source exposure, metric-distance exposure, contraction-modulus visibility, Picard-orbit visibility, Cauchy-Criterion route exposure, fixed-point seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8336.1. The source side is M, d, λ, O: the complete metric row supplies the service boundary, the metric row supplies distance comparisons, the modulus row supplies the strict contraction ledger, and the Picard row supplies the finite orbit.

The Cauchy row Q is downstream of those displayed data. It records the CauchyCriterion handoff for the Picard orbit, so the fixed-point seal F cannot be read before the orbit and Cauchy route are visible.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no selected limit, quotient completion, countable choice, ambient real completeness, host fixed-point equality, Lean verification, or bridge checking, the listed rows exhaust the local certificate surface. □

Theorem 8336.3 (Complete metric contraction Picard-Cauchy route)**.** *Every fixed-point read exported by an accepted* $\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{CompleteMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{PicardContraction}^{\uparrow},\ \mathsf{CauchyCriterion}^{\uparrow},\ \mathsf{BanachFixedPoint}^{\uparrow},\ \mathsf{BHist},\ \mathsf{hsame},\ \mathsf{Cont},\ \mathsf{Pkg},\ \mathsf{Name}$$

The route first exposes the complete metric source and distance row, then the contraction modulus and Picard orbit, then the CauchyCriterion handoff, and only then the BanachFixedPoint seal. It does not supply a host selected limit, a quotient completion, countable choice, ambient $\mathsf{Real}^{\uparrow}$ *completeness, or fixed-point equality outside the displayed packet.*

Proof. Begin with the accepted carrier. Its source rows M, d, λ, O are the only complete-metric, distance, modulus, and Picard coordinates available to a consumer.

Use the obligation theorem Definition 8336.2. It requires the CauchyCriterion row Q to be read from those displayed source and orbit rows before a fixed-point seal is available.

Finally read F, H, C, P, N. The fixed-point seal is transported by H, replayed by C, sourced by P, and named by N along the same finite route. Because no excluded coordinate occurs in the carrier, the exported principle is a NameCert handoff rather than a host selected-limit argument. □

Falsifiable prediction: Every accepted $\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}$ read exposes CompleteMetricUp, MetricUp, contraction modulus, PicardContractionUp, CauchyCriterionUp, BanachFixedPointUp, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any fixed-point consumer can use the seal.

Independence witness: complete metric, metric, cauchy criterion, picard contraction, banach fixed point: no listed sibling carries the whole packet $K = (M, d, \lambda, O, Q, F, H, C, P, N)$ because each sibling supplies only a source, distance, orbit, Cauchy route, or fixed-point seal while this chapter binds all rows as one complete-metric contraction-principle certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}$ packet is generated from a CompleteMetric source row, a Metric distance row, a contraction-modulus row, a PicardContraction orbit row, a CauchyCriterion route, a BanachFixedPoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8336.1, Definition 8336.2, and Definition 8336.3 seed the finite contraction-principle route over complete metric data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompleteMetricContractionPrinciple}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close a host selected-limit theorem, quotient completion, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, host fixed-point equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure asks for checked complete-metric source exposure, metric-distance exposure, contraction-modulus visibility, Picard-orbit visibility, CauchyCriterion handoff, fixed-point seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompleteMetricContractionPrincipleUp.

Chapter 8337

A Concrete Naming Certificate for $\mathsf{LocatedRealOrder}^{\uparrow}$

Following Bishop and Bridges on located order for constructive real numbers, the $\mathsf{LocatedRealOrder}^{\uparrow}$ packet records the finite BEDC surface by which order-facing real comparisons are read from displayed regular Cauchy windows. It sits over the terminal real-name seal of chapter 38, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the comparison row of chapter 1412. The packet exposes located interval and apartness evidence as finite L10 data; it does not import trichotomy, quotient real equality, selected representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Definition 8337.1 (Located real order carrier)**.** *A* $\mathsf{LocatedRealOrder}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (D, W, S, R, Q, I, A, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *observation and tolerance ledger used by all order-facing comparisons.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule that selects the displayed rational approximants.*
3. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row over the same windows and dyadic budget.*
4. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, W, S have been displayed.*
5. *Q is the* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row used to keep paired real names on the same finite comparison route.*
6. *I is the located interval row, recording a finite dyadic bracket or finite separation of brackets for the requested order comparison.*
7. *A is the apartness row, recording displayed positive separation when a strict order read is exported.*
8. *H records componentwise* hsame *transport for D, W, S, R, Q, I, A and for the structural rows.*
9. *C records displayed* Cont *replay from an order-facing request through the dyadic, window, readback, seal, comparison, interval, apartness, transport, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealOrder}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchySequenceEquivalence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. N is the local $\mathsf{NameCert}_{\mathsf{LocatedRealOrder}^{\uparrow}}$ *row.*
The local classifier reads accepted packets only through $D, W, S, R, Q, I, A, H, C, P, N$. It has no coordinate for real trichotomy, quotient real equality, selected representatives, countable choice, ambient real completeness, or an external bridge object.

Theorem 8337.2 (Located real order NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealOrder}^{\uparrow}$ *carrier*

$$O = (D, W, S, R, Q, I, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealOrder}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance ledger, finite stream windows, regular rational readback, terminal real seal, Cauchy-sequence comparison row, located interval evidence, apartness evidence, componentwise transport, displayed replay, provenance, and local naming. Every order-facing consumer must expose D, W, S, R, Q before it can consume I, A, H, C, P, N.*

Proof. Project the carrier of Definition 8337.1. The admitted packet contains exactly the numerical rows D, W, S, R, Q, I, A and the structural rows H, C, P, N.

The entry route is D, W, S, R, Q. The dyadic ledger fixes the tolerance budget, the stream schedule fixes the finite windows, the regular rational row supplies the readback, the real row supplies the terminal seal, and the Cauchy-sequence comparison row keeps paired names on one finite route.

The order route is I, A, H, C, P, N. The located interval row and apartness row are consumed only after the real and comparison rows are visible; the transport and replay rows preserve the same displayed route; the provenance and naming rows record the local certificate.

Since the carrier has no coordinate for trichotomy, quotient real equality, selected representatives, countable choice, ambient real completeness, or bridge checking, those endpoints cannot be exported by the local $\mathsf{NameCert}$ surface. □

Theorem 8337.3 (Located real order apartness handoff)**.** *Let*

$$O = (D, W, S, R, Q, I, A, H, C, P, N)$$

be an accepted $\mathsf{LocatedRealOrder}^{\uparrow}$ *carrier. Any strict order or apartness read exported from O must pass through the same* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D,* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback S, terminal* $\mathsf{Real}^{\uparrow}$ *seal R, and* $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ *comparison row Q before the apartness row A is consumed. The read exports the finite packet $D, W, S, R, Q, I, A, H, C, P, N$ and no trichotomy decision, quotient equality, selected representative, countable-choice schedule, ambient completeness theorem, or bridge certificate.*

Proof. Start from the NameCert obligations of Definition 8337.2. They force every order-facing consumer to expose the dyadic, window, readback, real-seal, and comparison rows before any interval or apartness evidence is read.

The strict order witness is the row A. It is not an independent sign oracle: it is attached to the located interval row I and therefore to the same displayed dyadic budget and finite windows used by D, W, S, R, Q.

The rows H, C, P, N transport, replay, source, and name that same packet. Because none of the excluded host-level objects is a carrier coordinate, the apartness handoff remains a finite L10 route rather than a trichotomy or quotient-equality principle. □

Theorem 8337.4 (Located real order interval route)**.** *Every interval comparison consumed through an accepted* $\mathsf{LocatedRealOrder}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CauchySequenceEquivalence}^{\uparrow} \longmapsto I, A.$$

Thus the consumer receives a located interval or displayed apartness read over one finite comparison route. It receives no quotient real equality, selected representative, trichotomy split, countable-choice stream, ambient $\mathsf{Real}^{\uparrow}$ *completeness object, or checked bridge.*

Proof. Read the numerical side through Definition 8337.1. The only tolerance source is D, the only finite schedule is W, and the only regular rational readback is S.

The terminal real row R is reached only after that finite route is displayed. The comparison row Q then aligns paired Cauchy presentations through the same finite windows before an interval read is accepted.

The rows I and A supply the interval and apartness evidence. They are therefore downstream of D, W, S, R, Q, while H, C, P, N preserve the route as one packet.

Consequently the interval route is exactly the displayed finite chain. The excluded objects would require additional carrier coordinates, so they cannot be read from an accepted $\mathsf{LocatedRealOrder}^{\uparrow}$ packet. □

Falsifiable prediction: Any accepted $\mathsf{LocatedRealOrder}^{\uparrow}$ consumer that exports an order-facing real comparison while omitting the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, $\mathsf{StreamName}^{\uparrow}$ finite window, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seal, or $\mathsf{CauchySequenceEquivalence}^{\uparrow}$ comparison row is outside the carrier surface.

Independence witness: Nearest siblings: real, streamname, regseqrat, dyadicratcore, cauchy-sequenceequivalence, and cauchy-real-apartness. The carrier is not bijective to RealUp because it adds located interval and apartness rows; not to StreamNameUp or RegSeqRatUp because it adds real-seal comparison and order evidence; not to DyadicRatCoreUp because it adds windows, readback, comparison, and local NameCert rows; not to CauchySequenceEquivalenceUp because it exports interval and apartness evidence; not to CauchyRealApartnessUp because it keeps the located order boundary as its own finite packet.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealOrder}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealOrder}^{\uparrow}$ packet is generated from a DyadicRatCore observation ledger, StreamName finite windows, RegSeqRat readback, a terminal Real seal, a CauchySequenceEquivalence comparison row, located interval and apartness evidence, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LocatedRealOrder}^{\uparrow}}$, seed)

Scope closed: Definition 8337.1, Definition 8337.2, Definition 8337.3, and Definition 8337.4 seed the finite located-order surface for real names through dyadic, stream, regular-rational, real-seal, and comparison rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{LocatedRealOrder}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Lean verification, trichotomy, quotient real equality, selected representatives, countable choice, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires a checked BEDC.Derived.LocatedRealOrderUp carrier with dyadic ledger admission, finite window readback, RegSeqRat and Real seal handoff, CauchySequenceEquivalence comparison, located interval and apartness exactness, transport, replay, provenance, and local naming.

Chapter 8338

A Concrete Naming Certificate for $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$

Following Bishop and Bridges on constructive compact metric arguments, the $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ packet records the finite radius-selector surface that turns compact-source finite-net data and pointwise continuity radii into a single uniform-radius row. It sits between the compact source chapters chapter 60 and chapter 129, the metric carrier of chapter 57, the pointwise continuity route of chapter 59, the rational lower-bound route of chapter 37, the terminal real seal of chapter 38, and the downstream uniform-modulus consumer of chapter 369. The packet is a finite NameCert carrier for Real and Completion uniform-modulus routes; it is not an open-cover compactness theorem, a sequential compactness principle, a countable-choice functional, host real equality, or an ambient Real completeness assertion.

Definition 8338.1 (Compact-source uniform-radius selector carrier)**.** *A* $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, X, M, F, T, L, Q, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, read together with the* $\mathsf{Compact}^{\uparrow}$ *compact-source row X before any radius is selected.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *triangle and distance-readback row for the source and target metrics used by the estimate.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise-radius table; each inspected compact-net center carries its displayed local continuity radius and target tolerance row.*
4. *T is the finite* $\mathsf{Met}^{\uparrow}$ *triangle row that compares an arbitrary source point with the chosen finite-net center and transports the target estimate along the metric triangle.*
5. *L is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound fold row, recording the finite minimum of the displayed positive pointwise radii.*
6. *Q is the* $\mathsf{Rat}^{\uparrow}$ *positive-radius certificate produced by the lower-bound fold.*
7. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row used when Real-facing consumers read the selected uniform radius.*

8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row that exports only the selected radius, the compact finite-net source rows, the pointwise-radius rows, the metric triangle rows, and the Real seal.*
9. *H records componentwise* hsame *transport for $K, X, M, F, T, L, Q, R, U$ and the structural rows.*
10. *C stores displayed* Cont *replay from a finite source-tolerance request through the compact source, pointwise-radius table, lower-bound fold, Real seal, and uniform-modulus handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, X, M, F, T, L, Q, R, U, H, C, P, N$. It has no coordinate for open-cover compactness, sequential compactness, countable choice, host real equality, quotient metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8338.2 (Compact-source uniform-radius selector NameCert obligations)**.** *For every accepted* $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ *carrier*

$$E = (K, X, M, F, T, L, Q, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}}$ *surface consists exactly of carrier admission, compact-source exposure through K and X, metric triangle exposure through M and T, continuous-map pointwise-radius exposure through F, rational lower-bound folding through L and Q, Real sealing through R, UniformModulus handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8338.1. The compact source rows are K and X, the analytic estimate rows are M, F, T, L, Q, R, U, and the structural rows are H, C, P, N.

The compact source is read first. Its finite-net row supplies only displayed centers and source-radius windows, so the packet cannot appeal to an open-cover compactness theorem, a sequential-compactness principle, or countable choice.

Next the pointwise-radius table F and the metric triangle row T are replayed over those displayed centers. The rational rows L and Q fold the finite list of positive pointwise radii into one lower-bound certificate, and the $\mathsf{Real}^{\uparrow}$ row R seals the selected radius for Real-facing reads.

Finally the $\mathsf{UniformModulus}^{\uparrow}$ handoff row U exports exactly that finite route, while H, C, P, N transport, replay, source, and name the same packet. Since no carrier coordinate stores host real equality, quotient metric equality, or ambient Real completeness, the listed rows exhaust the local certificate surface. □

Theorem 8338.3 (Compact-source uniform-radius selector consumer boundary)**.** *Every Real or Completion uniform-modulus consumer that reads an accepted* $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ *packet must pass through the finite route*

$$K, X, M, F, T, L, Q, R, U, H, C, P, N$$

before using the selected uniform-radius row. The consumer receives a compact finite-net source, pointwise-radius rows, metric triangle rows, a rational lower-bound fold, a Real seal, and the $\mathsf{UniformModulus}^{\uparrow}$ *handoff; it receives no open-cover compactness object, sequential compactness object, countable-choice functional, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start with the NameCert obligations. They identify $K, X, M, F, T, L, Q, R, U, H, C, P, N$ as the whole public surface of the accepted selector packet.

The Real-facing radius is downstream of the rational lower-bound rows. A consumer therefore reads L and Q before the seal R, and it cannot replace the finite fold by host real equality or by a completeness argument.

The Completion-facing uniform-modulus route is downstream of U. That row carries only the selected radius and the displayed compact-source, continuity, triangle, rational, and Real-seal data. Hence the consumer boundary is exactly the finite route above. □

Falsifiable prediction: An accepted $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ consumer that obtains a uniform-radius row without reading $K, X, M, F, T, L, Q, R, U, H, C, P, N$ refutes the selector carrier.

Independence witness: compact, compactmetric, metric, continuous, rat, real, uniformmodulus: no listed sibling is bijective to $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ because this packet jointly binds compact-source finite-net rows, pointwise-radius rows, metric triangle rows, rational lower-bound folding, a Real seal, UniformModulus handoff, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}$ packet is generated from CompactMetric and Compact finite-net source rows, ContinuousMap pointwise-radius rows, MetricSpace triangle rows, Rat lower-bound fold rows, a Real seal, UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8338.1, Definition 8338.2, and Definition 8338.3 seed the constructive compact-source radius selector consumed by Real and Completion uniform-modulus routes.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactSourceUniformRadiusSelector}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter excludes open-cover compactness, sequential compactness, countable choice, host real equality, ambient Real completeness, Lean theorem verification, and bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, pointwise-radius replay, metric triangle replay, rational lower-bound folding, Real sealing, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactSourceUniformRadiusSelectorUp.

Chapter 8339

A Concrete Naming Certificate for $\mathsf{BishopRegularCauchyTwoScale}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and explicit error estimates, the $\mathsf{BishopRegularCauchyTwoScale}^{\uparrow}$ packet records the finite two-scale estimate used when a coarse regular-Cauchy window is refined by a smaller inspection scale. It sits beside the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the finite-window induction route of chapter 8091. The packet names a displayed induction object for two-scale Cauchy estimates; it is not a selected limit, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8339.1 (Bishop regular Cauchy two-scale carrier)**.** *A* $\mathsf{BishopRegularCauchyTwoScale}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, K, k, W_0, W_1, Q_0, Q_1, D, I, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the regular-Cauchy source schedule whose estimates are inspected at two displayed scales.*
2. *K is the coarse scale row and k is the refined scale row, with the classifier requiring the refined request to be read below the coarse request through dyadic tolerance data.*
3. *W_0 and W_1 are the* $\mathsf{StreamName}^{\uparrow}$ *window rows inspected at the two scales.*
4. *Q_0 and Q_1 are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows for those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger storing the denominator budgets, slack rows, and two-scale comparison inequalities.*
6. *I is the* $\mathsf{RegularCauchyWindowInduction}^{\uparrow}$ *row that records the finite induction step from the coarse window to the refined window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after $S, K, k, W_0, W_1, Q_0, Q_1, D, I$ have been displayed.*
8. *H stores componentwise* hsame *transport for the source schedule, both scale rows, both window rows, both readback rows, the dyadic ledger, the induction row, the real seal, provenance, and local naming.*
9. *C stores displayed* Cont *replay from a finite precision request through the same rows.*

10. *P is the* Pkg *provenance over* BishopRegularCauchyTwoScale$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegularCauchyWindowInduction$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{BishopRegularCauchyTwoScale}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a completed real selected outside the displayed windows, quotient equality of streams, host real equality, countable choice, or ambient completeness.

Theorem 8339.2 (Bishop regular Cauchy two-scale obligations)**.** *For every accepted* BishopRegularCauchyTwoScale *carrier*

$$T = (S, K, k, W_0, W_1, Q_0, Q_1, D, I, E, H, C, P, N),$$

the local NameCert$_{\text{BishopRegularCauchyTwoScale}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source schedule, the two scale rows, the two* StreamName$^{\uparrow}$ *windows, the two* RegSeqRat$^{\uparrow}$ *readback rows, the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, the* RegularCauchyWindowInduction$^{\uparrow}$ *step row, the* Real$^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local name.*

Proof. Project the accepted carrier of Definition 8339.1. The rows $S, K, k, W_0, W_1, Q_0, Q_1, D, I, E, H, C, P, N$ are the complete finite packet, so carrier admission and local naming are componentwise projections.

Read the two scales next. The coarse row K and refined row k are compared only through the dyadic tolerance ledger D, and their inspected windows are exactly W_0, W_1 with readbacks Q_0, Q_1. Thus the estimate is a displayed finite relation between two windows, not a statement about an unshown completed stream.

Finally use the induction and structural rows. The row I supplies the finite-window step from chapter 8091, while H, C, P, N transport, replay, source, and name the same displayed data. Since E is reached only after those rows are present, the certificate cannot export a selected limit, quotient stream equality, countable choice, or ambient Real$^{\uparrow}$ completeness. □

Falsifiable prediction: An accepted BishopRegularCauchyTwoScale$^{\uparrow}$ consumer that reaches a Real$^{\uparrow}$ seal without reading $S, K, k, W_0, W_1, Q_0, Q_1, D, I, E, H, C, P, N$ refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-window-induction: no listed sibling supplies the joint packet containing one regular-Cauchy source schedule, two displayed scale rows, two finite window rows, two regular-rational readback rows, a dyadic two-scale tolerance ledger, a finite-window induction row, a Real seal, transport, replay, provenance, and local NameCert row.

Closure status for NameCert$_{\text{BishopRegularCauchyTwoScale}^{\uparrow}}$**.**

Constructive story: A BishopRegularCauchyTwoScale$^{\uparrow}$ packet is generated from a regular-Cauchy source schedule, coarse and refined scale rows, paired StreamName windows, paired RegSeqRat readbacks, a DyadicRatCore tolerance ledger, a RegularCauchyWindowInduction row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BishopRegularCauchyTwoScale}^{\uparrow}}$, seed)

Scope closed: Definition 8339.1 and Definition 8339.2 seed the finite two-scale Cauchy estimate route through displayed stream windows, regular-rational readback, dyadic tolerance rows, window induction, and the terminal Real-facing seal.

Formal verification: FormalStatus(NameCert$_{\text{BishopRegularCauchyTwoScale}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, Real completeness, quotient stream equality, selected limits, host real equality, or countable choice.

Upgrade path: Obligation closure requires checked carrier admission, two-scale dyadic comparison, paired window readback, finite-window induction replay, transport, provenance, and local naming for BEDC.Derived.BishopRegularCauchyTwoScaleUp.

Chapter 8340

A Concrete Naming Certificate for $\mathsf{DyadicMeshDiameter}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicMeshDiameter}^{\uparrow}$ packet names the finite diameter ledger carried by a dyadic mesh before interval-net and compactness consumers read it. It sits after the dyadic rational carrier of chapter 291, the interval-net surface of chapter 5966, the interval diameter ledger of chapter 1945, the closed bounded interval net route of chapter 1250, and the real-name seal of chapter 38. The chapter isolates the mesh-scale and diameter rows that a finite net exposes before any consumer treats the mesh as a compactness witness.

Definition 8340.1 (Dyadic mesh diameter carrier)**.** *A* $\mathsf{DyadicMeshDiameter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (M, E, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the mesh-scale row, recording the finite dyadic subdivision level used by the net.*
2. *E is the endpoint row family, listing the dyadic endpoint data inspected by adjacent mesh cells.*
3. *D is the dyadic diameter ledger, recording the displayed diameter bound attached to the mesh.*
4. *R is the refinement row, relating a finer mesh scale to the same endpoint and diameter ledger surface.*
5. *H records componentwise* hsame *transport for mesh scale, endpoint rows, diameter ledger, refinement row, replay, provenance, and local naming.*
6. *C records displayed* Cont *replay for interval-net, closed bounded interval net, and finite compactness consumers.*
7. *P is the* Pkg *provenance over* $\mathsf{DyadicMeshDiameter}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{DyadicIntervalDiameter}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicMeshDiameter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through M, E, D, R, H, C, P, N. It has no coordinate for an open-cover compactness proof, a completed real interval value, a selected limiting point, quotient equality of real names, or an unlisted mesh.

Lean4 (definition) `BEDC.Derived.DyadicMeshDiameterUp`

Theorem 8340.2 (Dyadic mesh diameter NameCert obligations)**.** *For every accepted* $\mathsf{DyadicMeshDiameter}^{\uparrow}$ *carrier*

$$W = (M, E, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicMeshDiameter}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed mesh scale, endpoint family, diameter ledger, refinement row, transport, replay, provenance, and local naming;*
2. *classifier transport by common refinement, requiring two mesh reads to compare only after both expose the shared refinement row* R *and the componentwise transport row* H*;*
3. *diameter bound exactness, requiring every interval-net diameter read to pass through the displayed dyadic ledger* D*;*
4. *refinement monotonicity, requiring a finer accepted mesh to preserve or decrease the displayed dyadic diameter bound;*
5. *ledger nonescape, requiring* P, N *to source and name no open-cover compactness proof, completed real interval value, selected limit, quotient real equality, or unlisted mesh.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8340.1. The accepted packet displays exactly one mesh-scale row, one endpoint-family row, one dyadic diameter ledger, one refinement row, and the structural rows that transport, replay, source, and name them.

Classifier transport is read through R and H. A comparison of two mesh reads must first move both packets to the displayed common refinement surface; only then can the componentwise transport row compare mesh scale, endpoint rows, and diameter ledger data.

Diameter bound exactness is read from D. The interval-net consumer therefore receives a dyadic ledger value rather than a host metric diameter or a real-valued supremum.

Refinement monotonicity is the finite ledger clause attached to R. Refining the mesh may preserve the previous displayed bound or replace it by a smaller dyadic bound, but the route contains no coordinate that can increase the bound while still naming the same accepted refinement.

Finally, P and N keep the obligation surface local to the displayed rows. Since the excluded objects are absent from the carrier, no compactness theorem, completed real value, selected limit, quotient equality, or hidden mesh can enter the local NameCert surface. □

Theorem 8340.3 (Dyadic mesh diameter refinement monotonicity)**.** *Let* $W = (M, E, D, R, H, C, P, N)$ *be an accepted* $\mathsf{DyadicMeshDiameter}^{\uparrow}$ *carrier. Any accepted refinement read through* R *and replayed through* C *exposes a diameter ledger that is the same as* D *or a dyadic bound below* D*. Thus mesh refinement can only decrease or preserve the displayed dyadic diameter bound before interval-net, closed bounded interval net, or compactness consumers read the packet.*

Proof. Project the carrier of Definition 8340.1. The only row that records a mesh diameter is D, and the only row that records a mesh refinement is R.

An accepted refinement must be replayed through C while preserving the same endpoint and provenance surface through H, P, N. Therefore the refined packet can expose only the original diameter ledger or the dyadic ledger named by the refinement row.

The NameCert obligations of Definition 8340.2 require the refinement row to preserve or lower the displayed dyadic bound. Since there is no coordinate for an external diameter operation or a hidden mesh, no larger bound can be introduced by a valid refinement read. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicMeshDiameter}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicMeshDiameter}^{\uparrow}$ packet is generated from a mesh-scale row, dyadic endpoint rows, a diameter ledger, a refinement row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicMeshDiameter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8340.1, Definition 8340.2, and Definition 8340.3 seed the finite dyadic mesh diameter route used by interval-net and compactness consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicMeshDiameter}^{\uparrow}}, \mathsf{encodedDef})$

Lean target: `BEDC.Derived.DyadicMeshDiameterUp`

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, completed RealUp interval values, selected limits, quotient real equality, ambient completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport by common refinement, diameter bound exactness, refinement monotonicity, ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicMeshDiameterUp.

Chapter 8341

A Concrete Naming Certificate for Window-Six Weight Log-Concavity

The window-six Fibonacci carrier records finite binary words with no adjacent true entries and reads their weight distribution through the polynomial

$$W_m(x) = \sum_k b(m,k)x^k,$$

where $b(m,k)$ is the number of length-m admissible words with exactly k true entries. Equivalently $b(m,k) = \binom{m-k+1}{k}$ on its natural support, and $\sum_k b(m,k) = F_{m+2}$. The BEDC carrier used here is the direct finite enumeration of those words, not the closed binomial formula.

Definition 8341.1 (Fibonacci weight coefficient)**.** *For $m, k \in \mathbb{N}$, let $b(m,k)$ be the coefficient of x^k in $W_m(x)$, computed by enumerating all length-m Boolean words, rejecting words with adjacent true entries, and counting the survivors with weight k. In Lean this coefficient is the natural number*

$$\mathsf{weightCoeff}(m,k).$$

Theorem 8341.2 (Window-six through window-ten degree-two Turan certificate)**.** *For the finite windows $m = 6, 7, 8, 9, 10$, every internal coefficient position checked by the certificate satisfies the degree-two Turan inequality*

$$b(m,k+1)b(m,k-1) \le b(m,k)^2.$$

Equivalently, the inspected coefficient rows of $W_m(x)$ are log-concave. The Lean certificate covers the nontrivial internal positions

$$\begin{aligned}
&(6,1),(6,2),\\
&(7,1),(7,2),(7,3),\\
&(8,1),(8,2),(8,3),\\
&(9,1),(9,2),(9,3),(9,4),\\
&(10,1),(10,2),(10,3),(10,4).
\end{aligned}$$

Lean4 ✓ `BEDC.Derived.Window6WeightLogConcaveTuran.window six to ten weight logconcave turan`

Proof. The proof is a finite certificate. Lean computes the admissible-word counts by recursive enumeration and then proves each inequality by an explicit natural-number slack. For example, the window $m = 6$ row is

$$(b(6,0), b(6,1), b(6,2), b(6,3)) = (1, 6, 10, 4),$$

with total $21 = F_8$. The two internal inequalities are witnessed by

$$b(6,2)b(6,0) + 26 = b(6,1)^2,$$
$$b(6,3)b(6,1) + 76 = b(6,2)^2.$$

The remaining windows are discharged in the same finite manner, using only the enumerator and natural-number slack equalities. □

Theorem 8341.3 (Finite-window RH criterion shape)**.** *The certificate of Definition 8341.2 realizes the degree-two Turan positivity shape on a Fibonacci carrier. In the classical analytic route, the Riemann Hypothesis is equivalent to the completed xi function lying in the Laguerre–Polya class, and that route is tested by finite Jensen-polynomial hyperbolicity windows; at degree two the finite positivity condition has the Turan form*

$$a_k^2 \geq a_{k-1}a_{k+1}.$$

This chapter supplies that shape only for the displayed Fibonacci coefficients, adjacent to the Laguerre–Polya packet of chapter 2363 and the RH roadmap of chapter 9239.

Proof. The statement is a scope identification. The Lean theorem supplies finite natural-number inequalities for the coefficient rows of $W_m(x)$. The Laguerre–Polya and Jensen route asks for hyperbolicity of finite polynomial windows, whose degree-two shadow is the adjacent coefficient inequality above. The carrier here is not the xi-function coefficient stream; it is the finite Fibonacci-cube weight carrier.

This is a finite-window positivity certificate on a Fibonacci carrier, not a proof of RH; it models the degree-two Turán/Jensen shape that Laguerre-Pólya (hence RH) requires. □

Falsifiable prediction: A recomputation of the Lean finite enumerator for $m = 6, 7, 8, 9, 10$ that violates any displayed internal Turan inequality refutes this packet.

Independence witness: laguerre-polya, riemann-hypothesis-roadmap, window-six-fibonacci-carrier: this packet is not bijective to the Laguerre–Polya or RH packets because it contains only finite Fibonacci-cube word enumeration, finite weight coefficients, explicit slack equalities, and the degree-two Turan shape on those coefficients.

Upgrade path: extend to higher Jensen-polynomial hyperbolicity and connect to the xi Taylor coefficients

Chapter 8342

The Window6 Weight Polynomial: A Finite-Window Positivity Ladder on a Fibonacci Carrier

The Fibonacci-cube weight polynomial $W_m(x) = \sum_k b(m,k)x^k$, with $b(m,k)$ the number of length-m no-adjacent-1 words of weight k and $\sum_k b(m,k) = F_{m+2}$, is a finite carrier for the positivity conditions that the finite-window formulation of the Riemann Hypothesis asks of the Riemann ξ function. The Laguerre–Polya route reads RH as hyperbolicity of finite Jensen windows; its degree-two shadow is coefficient log-concavity, and its stronger shadows are the Newton inequalities, Toeplitz total positivity, and full real-rootedness. This chapter records four rungs of that ladder as axiom-free finite certificates on the Fibonacci carrier, together with the structural fact that ties them to this branch's spectral-determinant constants. None of this is a proof of RH; each rung is a finite positivity witness on a Fibonacci-cube surface.

8342.1 The Ladder

The degree-two rung, coefficient log-concavity $b(m,k)^2 \geq b(m,k-1)b(m,k+1)$, is recorded separately as the degree-two log-concavity rung. The present chapter adds three sharper rungs and the recurrence that forces them.

Theorem 8342.1 (Newton ultra-log-concavity)**.** *For $m = 6, \ldots, 10$ the weight coefficients satisfy the binomial-normalised Newton inequalities*

$$b(m,k-1)\,b(m,k+1)\,(k+1)\,(n-k+1) \;\leq\; b(m,k)^2\,k\,(n-k),$$

with n the degree of W_m. This is the coefficient shadow of real-rootedness that is strictly sharper than plain log-concavity.

Lean4 ✓ `BEDC.Derived.Window6WeightUltraLogConcave.window six to ten weight newton ultra log concave`

Theorem 8342.2 (Toeplitz total positivity)**.** *For $m = 6, \ldots, 10$ the weight-coefficient sequence has nonnegative 2×2 and 3×3 Toeplitz minors, the discrete Polya-frequency strengthening that a real-rooted polynomial's coefficient sequence carries.*

Lean4 ✓ BEDC.Derived.Window6WeightToeplitzTotalPositive.window six to ten weight toeplitz total positive certificate

↪ variant BEDC.Derived.Window6WeightToeplitzTotalPositive.window six to ten weight toeplitz three total positive

Theorem 8342.3 (Fibonacci recurrence and real-rootedness)**.** *The weight coefficients obey the Fibonacci polynomial recurrence*

$$b(m+2,k+1) = b(m+1,k+1) + b(m,k),$$

that is $W_m(x) = W_{m-1}(x) + x\,W_{m-2}(x)$*, with generating function* $\sum_m W_m(x)z^m = (1-z-xz^2)^{-1}$*. At* $x = 1$ *this is the golden-mean generating function* $(1-z-z^2)^{-1}$*. The recurrence forces interlacing, hence real-rootedness of every* W_m*; the linear-times-quadratic factorisation of* W_6 *is recorded explicitly.*

Lean4 ✓ BEDC.Derived.Window6WeightFibonacciRecurrence.window six weight fibonacci recurrence

↪ variant BEDC.Derived.Window6WeightFibonacciRecurrence.window six linear quadratic factor certificate

8342.2 The Spectral-Determinant Identification

The generating function of the ladder is not a new object. With the weighted golden-mean transfer matrix

$$T(y) = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix},$$

this branch's necklace spectral determinant already records

$$\det(I - xT(y)) = 1 - x - yx^2,$$

which at $y = 1$ is the Fibonacci generating function $1 - x - x^2$ whose reciprocal produces $F_{m+2} = \mathbf{1}^\top T(1)^{m-1}\mathbf{1}$ and $L_m = \operatorname{tr} T(1)^m$. Thus W_m is the coefficient stream of $\det(I - xT(y))^{-1}$, and the branch's fine constants are the same data viewed spectrally: the golden ratio and its conjugate $\{\varphi, -1/\varphi\}$ are the eigenvalues of $T(1)$, equivalently the reciprocal poles of $1 - x - x^2$, equivalently the roots governing the metallic recurrences $t^2 - t - 1$, $t^3 - t - 1$, $t^2 - 2t - 1$, $t^3 - t^2 - 1$ that this branch has certified elsewhere.

Theorem 8342.4 (Three readings of one determinant)**.** *The finite objects*

$$\textit{fine constants} \quad = \quad \operatorname{spec} T(y), \qquad \textit{RH-carrier} \quad = \quad \textit{coefficients of } \det(I - xT(y))^{-1},$$

are two readings of the single spectral determinant $\det(I - xT(y)) = 1 - x - yx^2$*; the positivity rungs of section 8342.1 are finite-window positivity conditions on the second reading, and the metallic constants are the first reading. The reflection-positivity link deficit of a golden self-substitution word,* $\Delta_d = D_d - |\mu_d|^2 \geq 0$*, is the same* 2×2 *Gram determinant shape as the degree-two rung, on the same golden constants.*

↪ variant BEDC.Derived.Window6WeightFibonacciRecurrence.window six weight fibonacci recurrence

Falsifiable prediction: A recomputation of the Lean finite enumerator for $m = 6, \ldots, 10$ that violates any displayed Newton, Toeplitz, or recurrence identity, or a W_m with a non-real root at these lengths, refutes this packet.

Independence witness: laguerre-polya, riemann-hypothesis-roadmap, reflection-positivity: this packet is finite Fibonacci-cube word enumeration with explicit natural-number positivity witnesses and a coefficient recurrence; it is not bijective to the analytic ξ-hyperbolicity packet or to any full RH packet, and it makes no analytic transport claim to the prime channels.

Closure status for NameCert$_{Window6WeightFiniteWindowRHLadder}$.

Theory closure: TheoryGate(NameCert$_{Window6WeightFiniteWindowRHLadder}$, scopedClosed)

Scope closed: Definition 8342.1, Definition 8342.2, and Definition 8342.3 close the Newton, Toeplitz, and Fibonacci-recurrence rungs on the Fibonacci carrier for $m = 6, \ldots, 10$, and Definition 8342.4 identifies the carrier with the golden-mean spectral determinant $1 - x - yx^2$.

Formal verification: FormalStatus(NameCert$_{Window6WeightFiniteWindowRHLadder}$, theoremChecked)

Lean target: `BEDC.Derived.Window6WeightFibonacciRecurrence.window\_six\_weight\_fibonacci\_recurrence`

Bridge status: none

Not claimed: not a proof of RH; finite Fibonacci-carrier positivity ladder and a spectral-determinant identification only, with no analytic transport to the Riemann ξ coefficients or the prime channels.

Upgrade path: lift the finite Newton/Toeplitz/real-rootedness rungs to all m, then connect the golden-mean spectral determinant to the analytic ξ Jensen windows.

Chapter 8343

The Golden-Mean Ruelle Zeta: A Finite Fibonacci Transfer Certificate

The golden-mean subshift of finite type is the space of two-sided binary sequences with no two adjacent 1s; its Artin–Mazur/Bowen–Lanford dynamical zeta function is a genuine zeta, built from periodic points and carrying a primitive-orbit Euler product. This chapter records that zeta as a finite Fibonacci transfer certificate: its reciprocal is the weighted spectral determinant $1 - t - yt^2$ of the golden-mean transfer matrix, its periodic-point counts obey the Fibonacci trace recurrence, and at unit weight its poles factor over the golden ring $\mathbb{Z}[\varphi]$ into the two golden eigenvalues. This is a real zeta theorem for an infinite dynamical system whose entire zeta is controlled by a finite Fibonacci transfer operator; it is not a statement about the Riemann zeta function and not about the Riemann ξ.

8343.1 The Weighted Periodic-Point Zeta

Let CycFib_n be the set of cyclic no-adjacent-1 words of length n, and weight each word by $y^{\#1}$. With the weighted transfer matrix

$$T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix},$$

the weighted periodic-point count is $C_n(y) = \mathrm{tr}(T_y^n)$, and the dynamical zeta is

$$\zeta_{\mathrm{GM}}(t, y) = \exp\left(\sum_{n \geq 1} \frac{C_n(y)}{n}\, t^n\right) = \frac{1}{\det(I - tT_y)} = \frac{1}{1 - t - yt^2}.$$

At $y = 1$ this is the Bowen–Lanford zeta of the golden-mean shift, with the Euler product $\prod_{d \geq 1}(1 - t^d)^{-\pi_d}$ over primitive orbit counts; that product is what makes this a zeta rather than a determinant in zeta clothing.

Theorem 8343.1 (Fibonacci trace recurrence)**.** *The weighted periodic-point polynomials obey the two-term recurrence forced by $T_y^2 = T_y + yI$,*

$$C_{n+2}(y) = C_{n+1}(y) + y\, C_n(y),$$

so at $y = 1$ the counts are the Lucas trace sequence $C_n(1) = 1, 3, 4, 7, 11, 18, 29, 47, \ldots$

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanRuelleZeta.C trace recurrence`

8343.2 The Finite Zeta Certificate

Rather than begin with the analytic exponential, the finite content is the log-derivative window. With $\chi_y(t) = 1 - t - yt^2$ and $S_N(t, y) = \sum_{n=1}^{N} C_n(y)t^{n-1}$, for every $N \geq 1$

$$(1 - t - yt^2)\, S_N(t, y) = 1 + 2yt - C_{N+1}(y)\, t^N - y\, C_N(y)\, t^{N+1},$$

equivalently $S_N \equiv (1 + 2yt)/(1 - t - yt^2) \pmod{t^N}$, which together with $\zeta_{\mathrm{GM}}(0, y) = 1$ pins down $\zeta_{\mathrm{GM}}(t, y) = (1 - t - yt^2)^{-1}$. The Lean certificate multiplies the truncated trace series by $1 - t - yt^2$ as genuine polynomial arithmetic and matches the right-hand side; the $N = 6$, $y = 1$ instance is

$$(1 - t - t^2)(1 + 3t + 4t^2 + 7t^3 + 11t^4 + 18t^5) = 1 + 2t - 29t^6 - 18t^7.$$

Theorem 8343.2 (Finite log-derivative window)**.** *The order-six weighted window satisfies the polynomial identity $\chi_y(t)\, S_6(t, y) = 1 + 2yt - C_7(y)t^6 - yC_6(y)t^7$ as an equality of polynomials in y and t, verified by explicit polynomial multiplication.*

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanRuelleZeta.ruelle zeta finite certificate N6`
↪ variant `BEDC.Derived.Window6GoldenMeanRuelleZeta.ruelle zeta certificate y1 N6`

Theorem 8343.3 (Determinant reading)**.** *The reciprocal zeta equals the weighted spectral determinant of the golden-mean transfer matrix,*

$$\det(I - tT_y) = 1 - t - yt^2,$$

so the zeta and the determinant are two readings of the single Fibonacci object $1 - t - yt^2$.

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanRuelleZeta.det I minus tT`

8343.3 The Golden Pole Factorisation

Specialising to $y = 1$ and working in the golden ring $\mathbb{Z}[\varphi]$ with $\varphi^2 = \varphi + 1$, the reciprocal zeta polynomial factors into golden linear terms.

Theorem 8343.4 (Golden pole factorisation)**.** *In $\mathbb{Z}[\varphi]$,*

$$1 - t - t^2 = (1 - \varphi t)\,(1 + (\varphi - 1)t),$$

so the poles of $\zeta_{\mathrm{GM}}(t, 1)$ are exactly $t = \varphi^{-1} = \varphi - 1$ and $t = -\varphi$.

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanRuelleZeta.golden pole factorization`
↪ variant `BEDC.Derived.Window6GoldenMeanRuelleZeta.zeta pole roots`

Theorem 8343.5 (Transfer spectrum)**.** *The transfer spectrum is exactly the golden pair*

$$\operatorname{spec} T_1 = \{\varphi,\ 1 - \varphi\} = \{\varphi,\ -\varphi^{-1}\},$$

two simple real spectral roots. This is the honest "fib-RH" statement here: the reciprocal zeta polynomial of the golden-mean shift has only simple real spectral roots, controlled by a finite Fibonacci transfer operator of entropy $\log \varphi$.

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanRuelleZeta.transfer spectrum`

Falsifiable prediction: A recomputation of the Lean transfer polynomials that violates the trace recurrence $C_{n+2} = C_{n+1} + yC_n$, the finite window $\chi_y S_6 = 1 + 2yt - C_7 t^6 - yC_6 t^7$, the determinant $\det(I - tT_y) = 1 - t - yt^2$, or the golden factorisation $1 - t - t^2 = (1 - \varphi t)(1 + (\varphi - 1)t)$, refutes this packet.

Independence witness: riemann-hypothesis-roadmap, riemann-zeta: this packet is the finite Fibonacci transfer certificate of the golden-mean subshift's own dynamical zeta; it is a real zeta for an infinite dynamical system, not the Riemann zeta, not the ξ function, and it makes no analytic transport claim to the critical line or the prime channels.

Closure status for NameCert$_{Window6GoldenMeanRuelleZeta}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanRuelleZeta}$, scopedClosed)

Scope closed: Definition 8343.1, Definition 8343.2, and Definition 8343.3 close the Fibonacci trace recurrence, the order-six finite zeta certificate, and the determinant reading of the golden-mean dynamical zeta $1-t-yt^2$; Definition 8343.4 and Definition 8343.5 close the golden pole factorisation and the transfer spectrum $\{\varphi, -\varphi^{-1}\}$ over $\mathbb{Z}[\varphi]$.

Formal verification: FormalStatus(NameCert$_{Window6GoldenMeanRuelleZeta}$, theoremChecked)

Lean target: `BEDC.Derived.Window6GoldenMeanRuelleZeta.ruelle\_zeta\_finite\_certificate\_N6`

Bridge status: none

Not claimed: not a proof of the Riemann Hypothesis and not about the Riemann ξ; this is the exact dynamical zeta of the golden-mean subshift of finite type, controlled by a finite Fibonacci transfer operator, with no analytic transport to the critical line or the prime channels.

Upgrade path: connect the golden-mean transfer spectrum to the analytic golden-mean thermodynamic pressure, and study the weighted Weil-type positivity of the finite zeta certificate as a bridge toward the Laguerre–Polya windows.

Chapter 8344

The Golden-Mean Primitive-Orbit Mobius Certificate

The golden-mean subshift has a primitive-orbit Euler product behind its dynamical zeta. This chapter records the finite weighted Mobius certificate for that Euler-product side: after the divisor substitution $y \mapsto y^d$, the primitive-orbit Mobius transform is divisible by the period and has a nonnegative integral quotient through period 12.

8344.1 The Weighted Primitive-Orbit Transform

Let $T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}$ be the weighted golden-mean transfer matrix and let

$$C_n(y) = \operatorname{tr}(T_y^n)$$

be the weighted cyclic period-count polynomial. The primitive-orbit Mobius transform is

$$A_n(y) = \sum_{d|n} \mu(d)\, C_{n/d}(y^d).$$

The substitution $y \mapsto y^d$ is part of the object: an orbit with a weight contribution in the shorter quotient period is repeated d times in the length-n orbit, so its weight exponent is multiplied by d.

Theorem 8344.1 (Finite primitive-orbit integrality and positivity)**.** *For each $1 \le n \le 12$, the weighted primitive-orbit Mobius transform satisfies*

$$A_n(y) = n\, P_n(y)$$

for a polynomial $P_n(y) \in \mathbb{N}[y]$. The certified quotients are

$$\begin{aligned}
P_1 &= 1,\\
P_2 &= y,\\
P_3 &= y,\\
P_4 &= y,\\
P_5 &= y + y^2,\\
P_6 &= y + y^2,\\
P_7 &= y + 2y^2 + y^3,\\
P_8 &= y + 2y^2 + 2y^3,\\
P_9 &= y + 3y^2 + 3y^3 + y^4,\\
P_{10} &= y + 3y^2 + 5y^3 + 2y^4,\\
P_{11} &= y + 4y^2 + 7y^3 + 5y^4 + y^5,\\
P_{12} &= y + 4y^2 + 9y^3 + 8y^4 + 3y^5.
\end{aligned}$$

Thus the Euler-product exponents in this finite window are integral and nonnegative after division by the period.

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanPrimitiveOrbit.golden mean primitive orbit mobius positivity`

At $y = 1$, the values $p_n = A_n(1)/n$ are the primitive golden-mean orbit counts of exact period n in the certified window:

$$1,\ 1,\ 1,\ 1,\ 2,\ 2,\ 4,\ 5,\ 8,\ 11,\ 18,\ 25.$$

Equivalently, the corresponding Mobius numerators are

$$A_1(1), \ldots, A_{12}(1) = 1, 2, 3, 4, 10, 12, 28, 40, 72, 110, 198, 300.$$

8344.2 What This Certificate Claims

This is the finite Euler-product / primitive-orbit positivity side of the golden-mean subshift zeta; it is not a proof of the Riemann Hypothesis and not about the Riemann xi. The determinant side and the trace-Hankel positivity side certify spectral polynomial identities and finite square-sum positivity. The Mobius certificate here is different finite content: it certifies the integrality and positivity of the Euler-product exponents after the primitive-orbit divisor transform, with the essential substitution $y \mapsto y^d$.

This certificate is therefore not reducible to the determinant identity. The determinant records a reciprocal zeta polynomial and its spectral transfer reading. The primitive-orbit Mobius transform records how periodic weighted words decompose into primitive cycles and checks that the quotient exponents are actual nonnegative orbit counts in the finite window $1 \le n \le 12$.

Falsifiable prediction: A recomputation of the weighted cyclic polynomials $C_n(y)$, the Mobius values $\mu(d)$ for $d \le 12$, or the divisor substitution $y \mapsto y^d$ that changes any equality $A_n(y) = nP_n(y)$ for $1 \le n \le 12$ refutes this packet.

Independence witness: riemann-hypothesis-roadmap, riemann-zeta: this packet is the finite Euler-product primitive-orbit integrality and positivity certificate for the golden-mean subshift

only; it is not a proof of the Riemann Hypothesis, not about the Riemann ξ, and it asserts no analytic transport to the critical line or to prime-channel zeta phenomena.

Closure status for NameCert$_{Window6GoldenMeanPrimitiveOrbit}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanPrimitiveOrbit}$, scopedClosed)

Upgrade path: lift the finite $n \leq 12$ integrality to all n via a general Mobius-inversion argument, and connect the primitive-orbit exponents to the analytic golden-mean pressure

Chapter 8345

The Golden-Mean Parry Residue: A Cylinder-Resolved Finite RPF Certificate

The golden-mean subshift has a second finite certificate beyond the scalar determinant and beyond the primitive-orbit Euler product direction. This chapter records the cylinder-resolved Parry / Ruelle-Perron-Frobenius data carried by the weighted transfer matrix

$$T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}.$$

It keeps the entrywise cylinder counts, the Perron residue projector at $y = 1$, the exact secondary ψ^n error, and the formal pressure derivative. This is a finite Parry / Ruelle-Perron-Frobenius certificate for the golden-mean subshift; it is not a proof of the Riemann Hypothesis, not about the Riemann xi, and not a new Euler product.

8345.1 Cylinder-Resolved Transfer Powers

Let $F_0(y) = 0$, $F_1(y) = 1$, and

$$F_{n+2}(y) = F_{n+1}(y) + yF_n(y).$$

For $n \geq 1$, the finite matrix-power identity is

$$T_y^n = \begin{pmatrix} F_{n+1}(y) & yF_n(y) \\ F_n(y) & yF_{n-1}(y) \end{pmatrix}.$$

Thus the scalar trace is only the sum of two cylinder channels,

$$C_n(y) = \mathrm{tr}(T_y^n) = F_{n+1}(y) + yF_{n-1}(y),$$

while the two diagonal cylinders are retained separately as

$$N_0(n, y) = (T_y^n)_{00} = F_{n+1}(y), \qquad N_1(n, y) = (T_y^n)_{11} = yF_{n-1}(y).$$

The Lean certificate checks the order-eight window by direct polynomial matrix multiplication, including the entrywise data through the same recursive polynomial arithmetic used by the finite zeta packet.

Theorem 8345.1 (Cylinder-resolved finite transfer window)**.** *The weighted golden-mean transfer matrix has a checked order-eight entrywise cylinder certificate. In the list representation used by Lean, the bottom-left entry carries a trailing zero representative, while the mathematical polynomial is* $F_8(y) = 1 + 6y + 10y^2 + 4y^3$.

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanParryResidue.Ty pow cylinder 8`

8345.2 Adjugate and Pressure Shadow

The finite resolvent identity is the adjugate calculation

$$(I - tT_y)\begin{pmatrix} 1 & yt \\ t & 1-t \end{pmatrix} = (1 - t - yt^2)I_2.$$

This is more refined than the determinant alone: the adjugate remembers how the two cylinder coordinates propagate before taking the scalar determinant.

The same finite transfer data also carries the pressure derivative shadow. Differentiating the trace polynomial formally in y gives

$$\frac{d}{dy}C_n(y) = nF_{n-1}(y),$$

and therefore

$$y\,C_n'(y) = n(T_y^n)_{11}.$$

In the checked window, the identities include

$$C_4'(y) = 4(1+y), \qquad C_5'(y) = 5(1+2y), \qquad C_6'(y) = 6(1+3y+y^2),$$

and continue through the order-eight finite certificate.

Theorem 8345.2 (Adjugate and pressure derivative window)**.** *The adjugate identity for* $I - tT_y$ *and the formal derivative identities* $C_n'(y) = nF_{n-1}(y)$ *for* $2 \le n \le 8$ *are checked as exact finite polynomial computations.*

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanParryResidue.resolvent adjugate identity`
↪ variant `BEDC.Derived.Window6GoldenMeanParryResidue.pressure derivative 8`

8345.3 Golden Parry Residue

At $y = 1$, work in $\mathbb{Z}[\varphi]$ with $\varphi^2 = \varphi + 1$, put

$$\psi = 1 - \varphi, \qquad s = 2\varphi - 1,$$

and define

$$P = \begin{pmatrix} \varphi & 1 \\ 1 & \varphi - 1 \end{pmatrix}, \qquad Q = \begin{pmatrix} 1-\varphi & 1 \\ 1 & -\varphi \end{pmatrix}.$$

The denominator-cleared spectral projector statement is

$$sT^n = \varphi^n P - \psi^n Q.$$

On diagonal entries this gives the exact finite Parry-equidistribution error, with $L_n = C_n(1) = \varphi^n + \psi^n$,

$$s(T^n)_{00} = \varphi L_n - \psi^n, \qquad s(T^n)_{11} = (\varphi - 1)L_n + \psi^n.$$

The Lean certificate checks the golden spectral projector window through $n = 6$ and the two diagonal error formulas through the same window over the concrete ring $\mathbb{Z}[\varphi]$.

Theorem 8345.3 (Finite golden Parry residue)**.** *The order-six golden specialization verifies the denominator-cleared projector $sT^n = \varphi^n P - \psi^n Q$ and its diagonal $\pm\psi^n$ Parry-error formulas in $\mathbb{Z}[\varphi]$.*

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanParryResidue.golden mean parry residue certificate`

↪ variant `BEDC.Derived.Window6GoldenMeanParryResidue.golden parry spectral 6`

↪ variant `BEDC.Derived.Window6GoldenMeanParryResidue.golden parry error 6 00`

↪ variant `BEDC.Derived.Window6GoldenMeanParryResidue.golden parry error 6 11`

Falsifiable prediction: A recomputation of the finite polynomial matrix powers that changes the checked cylinder entries, the adjugate identity $(I - tT_y)\operatorname{adj}(I - tT_y) = (1 - t - yt^2)I_2$, the pressure derivative window $C_n' = nF_{n-1}$, or the golden diagonal Parry-error formulas refutes this packet.

Independence witness: determinant-side, primitive-orbit-side, riemann-hypothesis-roadmap: this packet is not reducible to the determinant side, because the scalar trace and determinant forget the Perron projector and the cylinder distribution; it is not reducible to the primitive-orbit side, because that side is the Euler product direction. This packet is a finite Parry / Ruelle-Perron-Frobenius cylinder-residue certificate for the golden-mean subshift only, not a proof of RH, not about the Riemann ξ, and not a new Euler product.

Closure status for NameCert$_{Window6GoldenMeanParryResidue}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanParryResidue}$, scopedClosed)

Scope closed: The chapter closes the finite golden-mean cylinder-power window, the adjugate resolvent identity, the pressure derivative window $C_n' = nF_{n-1}$ through $n = 8$, and the golden Parry residue diagonal error window through $n = 6$.

Upgrade path: lift the finite cylinder/residue identities to the general weighted RPF operator and connect the pressure derivative to the analytic golden-mean equilibrium state

Chapter 8346

The Golden-Mean Hankel–Turan Discriminant Identity

The golden-mean weighted trace polynomials $C_n(y) = \mathrm{tr}(T_y^n)$ for

$$T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}$$

carry a finite Hankel–Turan minor whose scalar value is exactly the discriminant of the characteristic polynomial $t^2 - t - y$. The identity is

$$C_n(y)C_{n+2}(y) - C_{n+1}(y)^2 = (-y)^n(1 + 4y).$$

At $y = 1$, where $L_n = C_n(1)$ is the Lucas trace sequence $1, 3, 4, 7, 11, 18, 29, 47, \ldots$, this specializes to

$$L_n L_{n+2} - L_{n+1}^2 = 5(-1)^n.$$

Thus the same 2×2 trace minor exposes the golden discriminant $1 + 4y$, and the unit-weight constant is $5 = \sqrt{5}^2$.

Theorem 8346.1 (Finite golden-mean Hankel–Turan certificate)**.** *For the first eight positive trace indices, the polynomial identity*

$$C_n(y)C_{n+2}(y) - C_{n+1}(y)^2 = (-y)^n(1 + 4y)$$

is verified by direct coefficient arithmetic, and the same certificate records the Lucas specialization at $n = 4$:

$$L_4 L_6 - L_5^2 = 5.$$

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanHankelTuran.golden mean hankel turan discriminant certificate`

This is a finite Hankel–Turan discriminant identity for the golden-mean trace sequence; it is not a proof of the Riemann Hypothesis and not about the Riemann xi. Its content is the scalar consequence of the second-order trace recurrence attached to $T_y^2 = T_y + yI$, recorded as explicit polynomial arithmetic. The determinant side and the trace side meet through the same characteristic polynomial $t^2 - t - y$, but this packet claims only the stated finite discriminant window and the displayed Lucas specialization.

Falsifiable prediction: A recomputation of the polynomial trace sequence that changes any coefficient of $C_n(y)C_{n+2}(y) - C_{n+1}(y)^2$ for $1 \le n \le 8$, or changes the Lucas value $L_4 L_6 - L_5^2$, refutes this certificate.

Independence witness: riemann-hypothesis-roadmap, riemann-xi: this packet is a finite Hankel–Turan discriminant identity for the golden-mean trace sequence only; it makes no Riemann Hypothesis claim and no analytic statement about the Riemann ξ function.

Closure status for NameCert$_{Window6GoldenMeanHankelTuran}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanHankelTuran}$, scopedClosed)

Scope closed: The Lean certificate closes the coefficient identities $C_n(y)C_{n+2}(y) - C_{n+1}(y)^2 = (-y)^n(1+4y)$ for $1 \le n \le 8$, together with the unit-weight Lucas discriminant instance $L_4L_6 - L_5^2 = 5$.

Chapter 8347

The Golden-Mean Zeta Denominator as a Fifth-Cyclotomic Pentagon Certificate

The golden-mean reciprocal zeta denominator $1-t-t^2$ has a finite fifth-cyclotomic lift. Let $\zeta = \zeta_5$ satisfy $\Phi_5(\zeta) = \zeta^4 + \zeta^3 + \zeta^2 + \zeta + 1 = 0$, and put

$$D_k(t,y) = 1 - \zeta^k t - y\zeta^{2k}t^2 = \det(I - \zeta^k t T_y), \qquad T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}.$$

The certificate below records the primitive fifth-cyclotomic norm of the golden-mean denominator, its scalar y-weighted norm, and the pentagon Gram bridge to the golden field. It is a finite algebraic identity in $\mathbb{Z}[\zeta_5]$ and in $\mathbb{Z}[y,t]$, not a numerical coincidence.

8347.1 The Fifth-Cyclotomic Twisted Norm

Define

$$\begin{aligned} Q_5(t,y) = 1 + t + (1+y)t^2 + (1+2y)t^3 + (1+3y+y^2)t^4 \\ - (y+2y^2)t^5 + (y^2+y^3)t^6 - y^3t^7 + y^4t^8. \end{aligned}$$

Then the scalar norm identity is

$$(1-t-yt^2)Q_5(t,y) = 1 - (1+5y+5y^2)t^5 - y^5t^{10} = \det(I - t^5T_y^5).$$

At $y=1$, the primitive cyclotomic twists collapse from $\mathbb{Z}[\zeta_5]$ to integer coefficients:

$$\prod_{k=1}^{4}(1-\zeta^k t - \zeta^{2k}t^2) = 1 + t + 2t^2 + 3t^3 + 5t^4 - 3t^5 + 2t^6 - t^7 + t^8,$$

and the full fifth norm is

$$\prod_{k=0}^{4}(1-\zeta^k t - \zeta^{2k}t^2) = 1 - 11t^5 - t^{10}.$$

The number 11 is the fifth Lucas trace $C_5(1) = \mathrm{tr}(T_1^5)$.

Theorem 8347.1 (Fifth-cyclotomic twisted norm)**.** *The four primitive ζ_5-twists of $1 - t - t^2$ multiply to $Q_5(t, 1)$, the five twists multiply to $1 - 11t^5 - t^{10}$, and the bivariate scalar identity*

$$(1 - t - yt^2)Q_5(t, y) = 1 - (1 + 5y + 5y^2)t^5 - y^5t^{10}$$

holds by finite polynomial multiplication.

Lean4 ✓ BEDC.Derived.Window6GoldenMeanCyclotomicPentagon.golden mean cyclotomic pentagon certificate

8347.2 The Pentagon Bridge

Let

$$u = \zeta + \zeta^{-1} = \zeta + \zeta^4.$$

Since

$$u^2 + u - 1 = \zeta^2 + \zeta + 1 + \zeta^{-1} + \zeta^{-2} = \zeta^{-2}\Phi_5(\zeta) = 0,$$

the real element u is $2\cos 72^\circ = (\sqrt{5} - 1)/2 = 1/\varphi$. Thus $1 + u = \varphi$ and $-u = -1/\varphi$, and the golden denominator factors in $\mathbb{Z}[\zeta_5][t]$ as

$$1 - t - t^2 = (1 - (1 + u)t)(1 + ut).$$

Equivalently, the transfer characteristic polynomial

$$x^2 - x - 1 = (x - (1 + u))(x + u)$$

has spectrum $\{1 + u, -u\} = \{\varphi, -1/\varphi\}$.

The same pentagon element appears in the Gram matrix

$$G_{ij} = \zeta^{i-j} + \zeta^{j-i}, \qquad i, j \in \mathbb{Z}/5\mathbb{Z}.$$

Its first row is

$$[2,\ u,\ -1 - u,\ -1 - u,\ u],$$

and finite multiplication gives

$$G^2 = 5G.$$

The two nontrivial Gram inner products $u = 1/\varphi$ and $-1 - u = -\varphi$ are exactly the two roots of $1 - t - t^2 = 0$.

Theorem 8347.2 (Pentagon Gram and golden factorisation)**.** *In $\mathbb{Z}[\zeta_5]$, the element $u = \zeta + \zeta^{-1}$ satisfies $u^2 + u - 1 = 0$, the golden denominator factors as*

$$1 - t - t^2 = (1 - (1 + u)t)(1 + ut),$$

and the pentagon Gram matrix $G_{ij} = \zeta^{i-j} + \zeta^{j-i}$ satisfies $G^2 = 5G$.

↪ variant BEDC.Derived.Window6GoldenMeanCyclotomicPentagon.u min poly
↪ variant BEDC.Derived.Window6GoldenMeanCyclotomicPentagon.golden denominator cyclotomic factor
↪ variant BEDC.Derived.Window6GoldenMeanCyclotomicPentagon.pentagon gram idempotent

8347.3 Scope

This is a finite cyclotomic-norm and pentagon-Gram identity bridging the golden-mean zeta to the fifth cyclotomic field; it is not a proof of the Riemann Hypothesis, not about the Riemann xi, and not a zero-line statement.

The precise Φ_5 and pentagon link is canonical at $y = 1$: the golden field is the maximal real subfield of $\mathbb{Q}(\zeta_5)$, and $u = \zeta + \zeta^{-1} = 1/\varphi$ satisfies $u^2 + u - 1 = 0$. The scalar twisted norm holds for all y, but the generic transfer spectrum lies in $\mathbb{Q}(\sqrt{1+4y})$, not canonically in the fifth cyclotomic field. The pentagon Gram identity $G^2 = 5G$ also does not by itself prove any reflection-positivity deficit theorem; that would require a separately defined reflection-positivity functional.

Falsifiable prediction: A direct finite recomputation in $\mathbb{Z}[\zeta_5]$ that violates $u^2 + u - 1 = 0$, the primitive twist product $\prod_{k=1}^{4} D_k(t,1) = Q_5(t,1)$, the full fifth norm $\prod_{k=0}^{4} D_k(t,1) = 1 - 11t^5 - t^{10}$, the bivariate scalar norm $(1 - t - yt^2)Q_5(t,y) = 1 - (1 + 5y + 5y^2)t^5 - y^5t^{10}$, the factorisation $1 - t - t^2 = (1 - (1+u)t)(1+ut)$, or $G^2 = 5G$ refutes this packet.

Independence witness: riemann-hypothesis-roadmap, riemann-zeta, reflection-positivity-deficit: this packet is the finite fifth-cyclotomic twisted norm and pentagon Gram certificate for the golden-mean zeta denominator only; it makes no claim about the Riemann ξ, the critical line, prime-channel zero statistics, or any reflection-positivity deficit theorem.

Closure status for NameCert$_{Window6GoldenMeanCyclotomicPentagon}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanCyclotomicPentagon}$, scopedClosed)

Scope closed: Definition 8347.1 closes the finite primitive and full fifth-cyclotomic twisted norm identities for the golden-mean denominator, including the scalar bivariate norm in $\mathbb{Z}[y,t]$; Definition 8347.2 closes the pentagon bridge $u^2 + u - 1 = 0$, the golden factorisation, and the Gram identity $G^2 = 5G$ in $\mathbb{Z}[\zeta_5]$.

Formal verification: FormalStatus(NameCert$_{Window6GoldenMeanCyclotomicPentagon}$, theoremChecked)

Lean target: `BEDC.Derived.Window6GoldenMeanCyclotomicPentagon.golden\_mean\_cyclotomic\_pentagon\_certificate`

Bridge status: none

Not claimed: not a proof of RH; finite fifth-cyclotomic twisted norm and pentagon Gram identities for the golden-mean zeta denominator only; the RP-deficit theorem is not proven here.

Upgrade path: extend the twisted norm to the full $\mathbb{Z}[\zeta_5][y]$ factorisation for all y, and connect the pentagon Gram to a defined reflection-positivity deficit functional.

Chapter 8348

The Golden-Mean Shift Equivalence: A Finite Presentation-Invariance Certificate

This chapter records a finite strong-shift-equivalence certificate for the golden-mean subshift zeta. The certificate does not change the dynamical system; it changes the finite presentation from the two-state transfer matrix to a three-state edge-expansion matrix and verifies that the reciprocal zeta denominator and the periodic trace window are unchanged.

8348.1 The Rectangular Factors

Let

$$R = \begin{pmatrix} 1 & y & 0 \\ 0 & 0 & 1 \end{pmatrix}, \qquad S = \begin{pmatrix} 1 & 0 \\ 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

Then the two rectangular products are

$$RS = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix} = T_y, \qquad SR = \begin{pmatrix} 1 & y & 0 \\ 0 & 0 & 1 \\ 1 & y & 0 \end{pmatrix} = E_y.$$

Thus R and S exhibit the two-state golden-mean transfer presentation T_y and the three-state edge-expansion presentation E_y as the two sides of an elementary strong-shift-equivalence datum.

8348.2 The Presentation-Invariance Certificate

The determinant side gives the same reciprocal zeta polynomial in both finite presentations:

$$\det(I_2 - tT_y) = \det(I_3 - tE_y) = 1 - t - yt^2.$$

The trace side gives the same weighted periodic-point window. For $1 \le n \le 8$, the Lean certificate computes the powers of E_y by genuine 3×3 matrix multiplication over $\mathbb{Z}[y]$ and verifies

$$\operatorname{tr}(E_y^n) = C_n(y),$$

where

$$
\begin{aligned}
C_1(y) &= 1,\\
C_2(y) &= 1 + 2y,\\
C_3(y) &= 1 + 3y,\\
C_4(y) &= 1 + 4y + 2y^2,\\
C_5(y) &= 1 + 5y + 5y^2,\\
C_6(y) &= 1 + 6y + 9y^2 + 2y^3,\\
C_7(y) &= 1 + 7y + 14y^2 + 7y^3,\\
C_8(y) &= 1 + 8y + 20y^2 + 16y^3 + 2y^4.
\end{aligned}
$$

Theorem 8348.1 (Golden-mean strong-shift-equivalence certificate)**.** *The rectangular matrices R and S satisfy $RS = T_y$ and $SR = E_y$; the two finite presentations have the common reciprocal zeta denominator $1 - t - yt^2$; and the trace window $\mathrm{tr}(E_y^n) = C_n(y)$ is checked for $1 \le n \le 8$ by explicit polynomial matrix multiplication.*

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanShiftEquivalence.golden mean shift equivalence certificate`

This is a finite presentation-invariance (strong shift equivalence) certificate for the golden-mean SFT zeta; it is not a proof of the Riemann Hypothesis and not about the Riemann xi. The point is local and finite: the determinant and trace data of the golden-mean SFT zeta survive the elementary presentation change from T_y to its edge-expansion presentation E_y. In this sense it is a finite witness for the Williams presentation-invariance principle, while remaining independent content from the determinant calculation itself.

Falsifiable prediction: A recomputation of the Lean rectangular products, determinant polynomials, or 3×3 trace powers that violates $RS = T_y$, $SR = E_y$, $\det(I_3 - tE_y) = 1 - t - yt^2$, or $\mathrm{tr}(E_y^n) = C_n(y)$ for the checked window refutes this packet.

Independence witness: riemann-hypothesis-roadmap, riemann-xi: this packet is only a finite strong-shift-equivalence presentation-invariance certificate for the golden-mean SFT zeta; it is not a proof of the Riemann Hypothesis and it is not about the Riemann xi.

Closure status for NameCert$_{Window6GoldenMeanShiftEquivalence}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanShiftEquivalence}$, scopedClosed)

Scope closed: The rectangular products $RS = T_y$ and $SR = E_y$, the common denominator $\det(I_2 - tT_y) = \det(I_3 - tE_y) = 1 - t - yt^2$, and the checked trace window $\mathrm{tr}(E_y^n) = C_n(y)$ for $1 \le n \le 8$ close the finite presentation-invariance certificate for the golden-mean SFT zeta.

Formal verification: FormalStatus(NameCert$_{Window6GoldenMeanShiftEquivalence}$, theoremChecked)

Upgrade path: extend to a general strong-shift-equivalence chain and connect to Williams classification of the golden-mean SFT

Chapter 8349

The Golden-Mean Quadratic-Algebra Capstone

The golden-mean zeta facets have a closest honest master identity, but not a single finite identity generating every certificate in the surrounding family. The organizing object is the quadratic algebra

$$Q_y = \mathbb{Z}[y][x]/(x^2 - x - y),$$

with every element written as $ax + b$ over $\mathbb{Z}[y, t]$ and conjugation $\overline{x} = 1 - x$. The root equation is $x^2 = x + y$, so multiplication reduces by

$$(ax + b)(cx + d) = (ac + ad + bc)x + (acy + bd).$$

The trace and norm are

$$\mathrm{Tr}(ax + b) = a + 2b, \qquad N(ax + b) = b^2 + ab - ya^2,$$

and hence $\mathrm{Tr}(x) = 1$ and $N(x) = -y$.

8349.1 The Master Norm Identity

The central identity is the norm computation

$$(1 - tx)(1 + t(x - 1)) = 1 - t - yt^2.$$

It is a norm identity in $Q_y[t]$: the second factor is the conjugate of $1 - tx$, because $\overline{x} = 1 - x$. Equivalently, with the regular representation

$$\rho(ax + b) = \begin{pmatrix} a + b & ya \\ a & b \end{pmatrix}, \qquad \rho(x) = T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix},$$

one has $\det \rho(ax + b) = N(ax + b)$ and $\mathrm{tr}\, \rho(ax + b) = \mathrm{Tr}(ax + b)$. The matrix form of the same identity is

$$(I - tT_y)(I + t(T_y - I)) = (1 - t - yt^2)I,$$

which is the Cayley–Hamilton reading of $T_y^2 = T_y + yI$.

Theorem 8349.1 (Quadratic-algebra capstone certificate)**.** *In the finite $\mathbb{Z}[y,t]$ model of Q_y, the root identity $x^2 = x + y$, the conjugation identity $\overline{x} = 1 - x$, the norm and trace values $N(x) = -y$ and $\mathrm{Tr}(x) = 1$, the master norm identity $(1-tx)(1+t(x-1)) = 1-t-yt^2$, the regular representation value $\rho(x) = T_y$, concrete determinant and trace readings of $\rho(x)$, six Fibonacci power identities, six Hankel–Cassini identities, and two finite truncated resolvent identities are all checked by Lean without axioms.*

Lean4 ✓ `BEDC.Derived.Window6GoldenMeanQuadraticCapstone.golden mean quadratic capstone certificate`

8349.2 Powers, Cassini, and Truncated Resolvents

Let $F_0(y) = 0$, $F_1(y) = 1$, and

$$F_{n+2}(y) = F_{n+1}(y) + yF_n(y).$$

The quadratic relation gives the finite power law

$$x^{n+1} = F_{n+1}(y)x + yF_n(y),$$

verified in Lean for the first six nontrivial instances. Taking traces gives the cyclic trace polynomials $C_n(y) = \mathrm{Tr}(x^n)$, whose specialization at $y = 1$ is the Lucas trace sequence.

The same conjugation gives the Hankel–Turan discriminant without a separate determinant argument:

$$C_n(y)C_{n+2}(y) - C_{n+1}(y)^2 = (x\overline{x})^n(x - \overline{x})^2 = (-y)^n(1 + 4y).$$

Here $x\overline{x} = -y$ and

$$(x - \overline{x})^2 = (2x - 1)^2 = 1 + 4y.$$

The capstone certificate checks this Cassini identity for $n = 1, \ldots, 6$ as polynomial data.

The finite resolvent identity is also a direct consequence of the same denominator:

$$(1 - t - yt^2)\sum_{i=0}^{N} x^i t^i = 1 + t(x - 1) - t^{N+1}x^{N+1} - yt^{N+2}x^N.$$

The Lean certificate records the concrete $N = 1$ and $N = 2$ truncations as finite polynomial computations. These truncations are not a replacement for the primitive-orbit product; they are the quadratic-algebra denominator viewed inside $Q_y[t]$.

8349.3 Honest Scope Across the Six Facets

There is no single finite identity generating all six facets; the closest honest master is the quadratic-algebra norm identity. This is the honest organizing master of the golden-mean SFT zeta facets, not a grand unification and not a proof of the Riemann Hypothesis; the independent facets remain separate certificates.

Facet	Generation by the quadratic master
A determinant/zeta/trace-recurrence	**YES directly**. The determinant, resolvent denominator, and trace recurrence come from $T_y^2 = T_y + yI$ and $\det(I - tT_y) = 1 - t - yt^2$; the $\mathbb{Z}[\varphi]$ splitting still needs $\varphi^2 = \varphi + 1$.
B Euler-product/primitive-orbit	**PARTLY**. The master gives $C_n(y) = \mathrm{Tr}(x^n)$ and therefore the input to the Mobius transform, but positivity $P_n \in \mathbb{N}[y]$ is an independent necklace-counting theorem.
C Parry/RPF/cylinder	**MOSTLY**. The power law, cylinder recurrences, and derivative identity $C_n' = nF_{n-1}$ are governed by $x^2 = x + y$; the golden spectral projector belongs to the $\mathbb{Z}[\varphi]$ specialization.
D Hankel–Turan/discriminant	**YES**. Conjugation gives $x\overline{x} = -y$ and $(x - \overline{x})^2 = 1 + 4y$, hence the Cassini–Hankel identity.
E fifth-cyclotomic/pentagon	**PARTLY**. Cyclic norms use the same norm mechanism together with $\prod_{k=0}^{4}(1 - \zeta^k a) = 1 - a^5$; the pentagon Gram relation $G^2 = 5G$ and $u^2 + u - 1 = 0$ remain independent cyclotomic geometry.
F strong-shift-equivalence	**NO**. The presentation data for strong-shift-equivalence are independent finite certificates, not consequences of the quadratic norm identity.

Thus the capstone is an organizing certificate, not a total generator. It explains why the determinant, trace recurrence, resolvent denominator, power law, and Hankel discriminant repeatedly share the same polynomial $1 - t - yt^2$, while marking the primitive-necklace positivity, golden-ring projector, pentagon geometry, and presentation data as independent inputs.

Falsifiable prediction: A recomputation of the finite $\mathbb{Z}[y, t]$ quadratic-algebra model that violates $x^2 = x + y$, $N(x) = -y$, $\mathrm{Tr}(x) = 1$, $(1 - tx)(1 + t(x - 1)) = 1 - t - yt^2$, $\rho(x) = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}$, or the checked Cassini windows refutes this packet.

Independence witness: golden-mean-facet-scope: the quadratic master does not generate the primitive-orbit positivity theorem, the $\mathbb{Z}[\varphi]$ spectral projector, the pentagon Gram geometry, the strong-shift-equivalence presentation data, or any proof of the Riemann Hypothesis.

Closure status for NameCert$_{Window6GoldenMeanQuadraticCapstone}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanQuadraticCapstone}$, scopedClosed)

Scope closed: The chapter closes the finite quadratic-algebra master identity for $Q_y = \mathbb{Z}[y][x]/(x^2 - x - y)$, its regular representation at x, six finite power and Hankel windows, and the honest facet-scope table for the golden-mean SFT zeta family.

Formal verification: FormalStatus(NameCert$_{Window6GoldenMeanQuadraticCapstone}$, theoremChecked)

Lean target: `BEDC.Derived.Window6GoldenMeanQuadraticCapstone.golden\_mean\_quadratic\_capstone\_certificate`

Bridge status: none

Not claimed: not a single-generator unification of all facets; B positivity, C/E's $\mathbb{Z}[\varphi]$/pentagon geometry, and F presentation data remain independent certificates; not a proof of RH.

Upgrade path: formalize the universal ring-hom instance over an abstract commutative base and derive each dependent facet as a corollary.

Chapter 8350

The Finite Golden-Mean Zeta Program

The golden-mean subshift of finite type, the space of two-sided binary sequences with no two adjacent 1s, has a single weighted dynamical zeta

$$\zeta(t, y) = \frac{1}{1 - t - yt^2},$$

whose reciprocal is the spectral determinant of the weighted transfer matrix $T_y = \begin{pmatrix} 1 & y \\ 1 & 0 \end{pmatrix}$. This chapter is the organizing summary of the finite, axiom-free certificate program built around that one object. It records the central algebraic identity, the table of finite facets that are shadows of it, and a frank statement of the program's boundary. It proves no new theorem; it names the completed envelope.

8350.1 The Central Norm Identity

The organizing algebra is the rank-two quadratic ring

$$Q_y = \mathbb{Z}[y][x]/(x^2 - x - y), \qquad \bar{x} = 1 - x,$$

whose regular representation of multiplication by x in the basis $(x, 1)$ is exactly T_y. The single identity from which the determinant face of the whole program descends is the quadratic norm

$$N_{Q_y/\mathbb{Z}[y]}(1 - xt) = (1 - xt)(1 - \bar{x}t) = 1 - t - yt^2,$$

equivalently the matrix form $(I - tT_y)(I + t(T_y - I)) = (1 - t - yt^2)I$, resting on the root relation $x^2 = x + y$ (that is $T_y^2 = T_y + yI$). The trace stream $C_n(y) = \mathrm{tr}(T_y^n) = \mathrm{Tr}_{Q_y}(x^n)$ and the Fibonacci-polynomial power law $x^{n+1} = F_{n+1}(y)\, x + yF_n(y)$ are the finite carriers that the individual facets read off in different ways.

Theorem 8350.1 (Organizing norm identity)**.** *In $Q_y[t]$ the quadratic norm of $1 - xt$ equals the golden-mean zeta denominator $1 - t - yt^2$, and its regular representation is the finite matrix identity $(I - tT_y)(I + t(T_y - I)) = (1 - t - yt^2)I$. Every determinant-side fact of the program is a reading of this one norm.*

↪ variant `BEDC.Derived.Window6GoldenMeanQuadraticCapstone.master norm`

8350.2 The Facet Table

Each finite facet of the program is a certificate about the same object, and the honest relation of each to the central norm is as follows.

Facet	Finite meaning	Relation to the norm i
Determinant/spectrum	$\det(I - tT_y) = 1 - t - yt^2$, $\mathbb{Z}[\varphi]$ poles	directly generated
Euler product/orbits	Mobius primitive-orbit positivity $A_n = nP_n$, $P_n \in \mathbb{N}[y]$	trace-log of the norm; posi
Parry/RPF/cylinder	T_y^n cylinder counts, $C'_n = nF_{n-1}$, golden projector	spectral specialization; the
Hankel–Turan	$C_nC_{n+2} - C_{n+1}^2 = (-y)^n(1 + 4y)$	directly the conjugate Cas
Fifth-cyclotomic/pentagon	$\prod_k(1 - \zeta^k tx)$, $u = 2\cos 72^\circ = 1/\varphi$, $G^2 = 5G$	golden specialization $y = 1$
Strong shift equivalence	$RS = T_y$, $SR = E_y$, equal zeta and traces	external dynamical invaria
Quadratic capstone	Q_y norm identity itself	the organizing algebra

The table is the honest content: the determinant, trace recurrence, resolvent denominator, power law, and Hankel discriminant repeatedly share the polynomial $1 - t - yt^2$ because they are all readings of the quadratic norm, while the primitive-necklace positivity, the golden-ring spectral projector, the pentagon Gram geometry, and the strong-shift-equivalence presentation data are genuinely independent finite inputs, not consequences of the norm.

8350.3 The Program Boundary

This is a finite algebraic and dynamical-zeta certificate program for the golden-mean subshift of finite type. It is complete as such: the shift-of-finite-type identity $\zeta(t) = 1/\det(I - tT_y)$ already controls the zeta, and the facets exhaust the main finite meanings of that determinant. It does not claim, and this program does not contain, any Riemann-Hypothesis-type analytic depth, any general subshift or sofic zeta classification, any prime-orbit asymptotics or analytic continuation, or a thermodynamic-formalism library. The golden-mean zeta is not the Riemann zeta and carries no critical line; the pentagon and $\mathbb{Z}[\varphi]$ arithmetic is exact golden-field structure, not a spectral statement about $\zeta(s)$.

Falsifiable prediction: Any finite recomputation contradicting Definition 8350.1, or a facet in the table whose displayed finite identity fails at the enumerated lengths, refutes the corresponding certificate and this summary's placement of it.

Independence witness: golden-mean-zeta-program: the six facets plus the quadratic capstone are the natural complete finite envelope of the golden-mean SFT zeta; the primitive-orbit positivity, $\mathbb{Z}[\varphi]$ spectral projector, pentagon Gram geometry, and strong-shift-equivalence presentation data are independent certificates, and nothing here is a proof of the Riemann Hypothesis or a general SFT zeta theory.

Closure status for NameCert$_{Window6GoldenMeanZetaProgramHub}$.

Theory closure: TheoryGate(NameCert$_{Window6GoldenMeanZetaProgramHub}$, scopedClosed)

Scope closed: Definition 8350.1 records the organizing quadratic norm identity, and section 8350.2 places each finite facet as a reading of it or as an independent certificate; the program is complete as a finite golden-mean-zeta certificate envelope.

Formal verification: FormalStatus(NameCert$_{Window6GoldenMeanZetaProgramHub}$, theoremChecked)

Lean target: `BEDC.Derived.Window6GoldenMeanQuadraticCapstone.golden\_mean\_quadratic\_capstone\_certificate`

Bridge status: none

Not claimed: not a proof of RH, not a general SFT or sofic zeta theory, not analytic prime-orbit asymptotics or thermodynamic formalism; the pentagon and primitive-orbit and presentation facets remain independent finite certificates.

Upgrade path: move from the finite certificate envelope to the analytic golden-mean pressure and equilibrium theory, which is outside the finite axiom-free scope of this program.

Chapter 8351

A Concrete Naming Certificate for $\mathsf{DyadicTentFunction}^{\uparrow}$

Following Schauder and Bishop–Bridges constructive approximation, the $\mathsf{DyadicTentFunction}^{\uparrow}$ packet isolates the finite tent basis element used by dyadic interpolation arguments before a consumer invokes an entire Faber–Schauder system or a polygonal approximation chapter. It sits between the rational and real readback surfaces of chapter 291 and chapter 38, the system-level construction of chapter 6414, the interpolation route of chapter 8220, and the approximation handoff of chapter 3906.

Definition 8351.1 (Dyadic tent-function carrier)**.** *A* $\mathsf{DyadicTentFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (C, S, H, L, R, E, D, A, M, P, N)$$

with the following displayed rows:

1. *C is the dyadic center row, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*.*
2. *S is the dyadic support-window row, recording the left and right dyadic endpoints.*
3. *H is the height row, normalized as the visible peak value.*
4. *L and R are the left-slope and right-slope rows, each carried by finite dyadic arithmetic.*
5. *E records endpoint vanishing and peak agreement for the three displayed dyadic breakpoints.*
6. *D is the dyadic-to-real readback row consumed before any* $\mathsf{Real}^{\uparrow}$ *graph evaluation.*
7. *A records the affine-piece admission rows for the two support halves.*
8. *M records componentwise* hsame *transport for center, support, height, slopes, endpoint rows, readback, and affine pieces.*
9. *P is the* Pkg *provenance over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{FaberSchauderSystem}^{\uparrow}$*,* $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$ $\mathsf{PiecewiseLinearApproximation}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicTentFunction}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite coefficient family, an external real-valued function object, a completed approximation theorem, or a selected ambient representative.

Theorem 8351.2 (DyadicTentFunction NameCert obligations)**.** *For the carrier of Definition 8351.1, the local* $\mathsf{NameCert}_{\mathsf{DyadicTentFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$T = (C, S, H, L, R, E, D, A, M, P, N),$$

dyadic center display through C*, support-window display through* S*, height display through* H*, slope display through* L, R*, endpoint and peak display through* E*, dyadic-to-real readback through* D*, affine-piece admission through* A*, componentwise transport through* M*, provenance through* P*, and local naming through* N*.*

Proof. Project the finite carrier. The center, support, height, slope, endpoint, readback, and affine-piece rows are all displayed before the provenance and naming rows are read.

The dyadic rows are consumed through $\mathsf{DyadicRatCore}^{\uparrow}$, while the graph-facing handoff to $\mathsf{Real}^{\uparrow}$ occurs only through the readback row D. The system and interpolation chapters may reuse this packet as one basis element, but the packet itself does not expose a Faber–Schauder family or a polygonal approximation theorem.

The structural rows preserve the same displayed rows. Thus the listed fields exhaust the local NameCert surface. □

Theorem 8351.3 (DyadicTentFunction modulus handoff)**.** *Every accepted* $\mathsf{DyadicTentFunction}^{\uparrow}$ *packet exposes a finite modulus handoff to dyadic interpolation consumers through the same support-window, slope, endpoint, and dyadic-to-real readback rows*

$$S, L, R, E, D, A, M, P, N.$$

A $\mathsf{FaberSchauderSystem}^{\uparrow}$*,* $\mathsf{DyadicPiecewiseLinearInterpolation}^{\uparrow}$*, or* $\mathsf{PiecewiseLinearApproximation}^{\uparrow}$ *consumer may use the packet as a single tent primitive only after those rows have been displayed, and cannot infer an infinite basis expansion, a global approximation bound, or a hidden real-function representative from the packet alone.*

Proof. Apply the NameCert obligations of Definition 8351.2. The support, slope, endpoint, readback, and affine-piece rows are separate displayed coordinates of the same carrier.

The interpolation-facing handoff reads S, L, R, E before it reads the real graph route through D. Transport through M preserves those rows componentwise, so refining the ambient interpolation context does not detach the tent primitive from its dyadic support and slope data.

The excluded objects are not carrier coordinates. Hence the packet supplies only the finite tent-function primitive and its modulus-facing handoff. □

Falsifiable prediction: Any interpolation consumer that reads a DyadicTentFunctionUp graph row while omitting the displayed support-window and slope rows is rejected by the local classifier.

Independence witness: Nearest siblings: faberschaudersystem, dyadicpiecewiselinearinterpolation, piecewiselinearapproximation, dyadicratcore, real. The carrier is not bijective to the system-level or approximation-level packets because it stores one finite tent primitive rather than a family, mesh, or global error ledger.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicTentFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DyadicTentFunction}^{\uparrow}$ packet is generated from dyadic center, support, height, slope, endpoint, readback, affine-piece, transport, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicTentFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter records the finite carrier and local NameCert surface for one dyadic tent primitive before system-level and approximation-level consumers read it.

Formal verification: FormalStatus(NameCert$_{\text{DyadicTentFunction}\uparrow}$, formalTarget)
Lean target: `BEDC.Derived.DyadicTentFunctionUp`
Bridge status: none
Origin: human
Not claimed: It does not close a Faber–Schauder basis theorem, uniform approximation theorem, external function equality, or bridge checking.
Upgrade path: Obligation closure requires checked carrier admission, endpoint exactness, dyadic-to-real readback, affine-piece replay, and consumer handoff for the same finite packet.

Lean4 (statement) `BEDC.Derived.DyadicTentFunctionUp`

Chapter 8352

A Concrete Naming Certificate for $\mathsf{Grassmannian}^{\uparrow}$

Following Griffiths and Harris on Grassmannians and Plucker coordinates, the $\mathsf{Grassmannian}^{\uparrow}$ packet records a finite subspace-row certificate before any consumer reads a Grassmannian as an ambient projective variety. It sits after the vector-space carrier of chapter 47, the finite matrix ledger of chapter 49, the determinant boundary of chapter 84, the alternating-word carrier of chapter 5144, and the homogeneous-coordinate surface of chapter 207. The packet names only displayed spanning rows, rank minors, wedge coordinates, projective incidence, transport, replay, provenance, and local naming; it does not select a host quotient vector space, import a scheme, assert Schubert calculus, or expose an ambient moduli object.

Definition 8352.1 (Grassmannian carrier)**.** *A* $\mathsf{Grassmannian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (V, M, D, E, Q, H, C, P, N)$$

with the following rows:

1. *V is the consumed* $\mathsf{VecSpace}^{\uparrow}$ *source row, displaying the ambient vector carrier, scalar action, and finite list of candidate generators.*
2. *M is the* $\mathsf{Mat}^{\uparrow}$ *coordinate row whose columns display the chosen finite generator table and the row operations visible to downstream consumers.*
3. *D is the* $\mathsf{Determinant}^{\uparrow}$ *minor ledger, recording the rank-window minors used to certify the displayed dimension and nonzero Plucker coordinates.*
4. *E is the* $\mathsf{ExteriorAlgebra}^{\uparrow}$ *wedge row, carrying the alternating product of the displayed generator rows and the induced coordinate table.*
5. *Q is the* $\mathsf{ProjectiveSpace}^{\uparrow}$ *homogeneous-coordinate row for the wedge coordinate, read only after V, M, D, E are visible.*
6. *H records componentwise* hsame *transport for V, M, D, E, Q and for the package and local naming rows.*
7. *C records the displayed* Cont *replay routes by which consumers read the vector row, matrix table, determinant ledger, exterior coordinate, and projective endpoint in that order.*
8. *P is the* Pkg *provenance over* $\mathsf{VecSpace}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{Determinant}^{\uparrow}$*,* $\mathsf{ExteriorAlgebra}^{\uparrow}$*,* $\mathsf{ProjectiveSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{Grassmannian}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected basis outside the displayed table, quotient subspace equality, a host projective variety, Schubert stratification, moduli functor, or scheme-theoretic Plucker ideal.

Theorem 8352.2 (Grassmannian NameCert obligations)**.** *For the carrier of Definition 8352.1, the local* $\mathsf{NameCert}_{\mathsf{Grassmannian}^{\uparrow}}$ *surface consists exactly of carrier admission for* $G = (V, M, D, E, Q, H, C, P, N)$*, vector-source exposure through* V*, matrix-coordinate exposure through* M*, determinant-rank exposure through* D*, exterior-coordinate exposure through* E*, projective-coordinate exposure through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Any accepted* $\mathsf{Grassmannian}^{\uparrow}$ *consumer must read those rows before it may cite a subspace, rank, Plucker coordinate, or homogeneous endpoint.*

Proof. Project the carrier rows. The only admitted packet is $G = (V, M, D, E, Q, H, C, P, N)$, so the local certificate can expose no data beyond those displayed coordinates.

The algebraic source is consumed in order. The vector-space row V supplies the ambient finite vector operations, the matrix row M displays the generator table, and the determinant row D certifies the rank-window minors visible in that table.

The geometric endpoint is then read through E and Q. The exterior row E turns the generator table into an alternating coordinate, and the projective row Q names its homogeneous class only after the preceding rows have been displayed.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no slot for quotient subspace equality, a host projective variety, Schubert data, a moduli functor, or a scheme-theoretic Plucker ideal, none of those objects is exported by the NameCert surface. □

Theorem 8352.3 (Grassmannian Plucker ledger)**.** *Every Plucker-facing read of an accepted* $\mathsf{Grassmannian}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{VecSpace}^{\uparrow},\ \mathsf{Mat}^{\uparrow},\ \mathsf{Determinant}^{\uparrow},\ \mathsf{ExteriorAlgebra}^{\uparrow},\ \mathsf{ProjectiveSpace}^{\uparrow},\ H,\ C,\ P,\ N.$$

The determinant minors and alternating wedge coordinate are ledger rows of the same carrier $G = (V, M, D, E, Q, H, C, P, N)$*, and the projective endpoint* Q *cannot be consumed as an independent projective variety, quotient-subspace classifier, Schubert cell, moduli point, or hidden comparison row.*

Proof. Start with Definition 8352.2. It forces every accepted read to expose the vector source, matrix table, determinant ledger, exterior coordinate, projective endpoint, and structural rows of one packet.

Read the Plucker coordinate through the determinant and exterior rows. The row D supplies exactly the visible minors of M, and the row E packages the same data as an alternating coordinate rather than as a separate ambient construction.

Now consume the projective endpoint. The row Q is available only after V, M, D, E have been projected, while H, C, P, N keep transport, replay, provenance, and local naming tied to the same finite carrier.

Thus the Plucker ledger is a row-exhaustion statement for the displayed packet. No independent projective variety, quotient-subspace equality, Schubert cell, moduli point, or hidden comparison row is present in G, so no consumer can read one from the accepted certificate. □

Falsifiable prediction: An accepted $\mathsf{Grassmannian}^{\uparrow}$ consumer that reads a Plucker coordinate or homogeneous endpoint without displaying $V, M, D, E, Q, H, C, P, N$ refutes the carrier surface.

Independence witness: vecspace, matrix, determinant, exterior-algebra, projectivespace: no listed sibling is bijective to $\mathsf{Grassmannian}^{\uparrow}$ because this packet jointly binds a vector-space source row, finite generator matrix, determinant minor ledger, exterior wedge coordinate, projective homogeneous endpoint, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{Grassmannian}^{\uparrow}}$.

Constructive story: A $\mathsf{Grassmannian}^{\uparrow}$ packet is generated from VecSpace rows, Matrix generator rows, Determinant minor rows, ExteriorAlgebra wedge rows, a ProjectiveSpace homogeneous-coordinate row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{Grassmannian}^{\uparrow}}$, seed)

Scope closed: Definition 8352.1, Definition 8352.2, and Definition 8352.3 seed the finite Grassmannian NameCert surface over displayed linear-algebra and Plucker-coordinate rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{Grassmannian}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean theorem verification, bridge checking, Schubert calculus, moduli interpretation, scheme-theoretic Plucker ideals, quotient subspace equality, or a host projective variety.

Upgrade path: Obligation closure requires checked carrier admission, vector-source exposure, matrix-coordinate exposure, determinant minor exposure, exterior-coordinate exposure, projective-coordinate exposure, transport, replay, provenance, and local naming for BEDC.Derived.GrassmannianUp.

Chapter 8353

A Concrete Naming Certificate for $\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}$

The $\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}$ packet realizes the compact-cover route in chapter 9237 as finite overlap data before a uniform-modulus consumer reads a tolerance-only handoff. It packages compact finite-cover rows, pointwise local-modulus rows, overlap compatibility, rational lower-bound data, metric-triangle rows, and the downstream $\mathsf{UniformModulus}^{\uparrow}$ handoff as one inspectable NameCert carrier.

Definition 8353.1 (Compact-uniform local-modulus nerve carrier)**.** *A* $\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, L, O, Q, T, U, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite cover-nerve row, recording the* ProbeBundle *cover names, center rows, membership rows, and finite incidence data.*
2. *L is the local-modulus row, recording pointwise modulus data attached to each bundled cover center.*
3. *O is the overlap compatibility row, recording the common-radius and common-tolerance checks on nonempty cover intersections.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *lower-bound row, recording the finite rational fold that selects a positive bound below the displayed local radii.*
5. *T is the metric-triangle row, recording source and target triangle estimates used to move from local center data to neighboring points.*
6. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exposed after B, L, O, Q, T have been read.*
7. *H records componentwise* hsame *transport for cover, local-modulus, overlap, lower-bound, triangle, uniform-modulus, provenance, and naming rows.*
8. *C records displayed* Cont *replay through cover membership, local modulus, overlap compatibility, rational lower-bound fold, metric-triangle estimate, and uniform-modulus handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CFun}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}}$ *row.*
The carrier has no coordinate for an external cover choice, a host minimum, a global modulus selected outside the finite nerve, or a completed Heine–Cantor theorem.

Theorem 8353.2 (CompactUniformLocalModulusNerve NameCert obligations)**.** *For the carrier of Definition 8353.1, the local* $\mathsf{NameCert}_{\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$K = (B, L, O, Q, T, U, H, C, P, N),$$

finite cover-nerve display through B, local-modulus display through L, overlap compatibility through O, $\mathsf{Rat}^{\uparrow}$ *lower-bound display through Q, metric-triangle display through T,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier rows. The cover nerve, local modulus, overlap compatibility, rational lower bound, triangle estimate, and uniform-modulus handoff are displayed before the structural rows are read.

The overlap row O binds local modulus data across intersecting cover entries. The lower-bound row Q is therefore a finite rational fold over displayed rows, and the metric-triangle row T is the only route from local center estimates to arbitrary nearby source points.

Finally, H, C, P, N preserve, replay, source, and name this same packet. They do not add an external cover selector or host minimum, so the listed rows exhaust the local NameCert surface. □

Theorem 8353.3 (CompactUniformLocalModulusNerve uniform-modulus handoff)**.** *Every accepted* $\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}$ *packet exposes its* $\mathsf{UniformModulus}^{\uparrow}$ *handoff only through the finite route*

$$B, L, O, Q, T, U, H, C, P, N.$$

A compact-uniform-continuity consumer may read the handoff only after cover membership, local pointwise moduli, overlap compatibility, rational lower-bound data, and metric-triangle estimates have been displayed.

Proof. Apply the NameCert obligations of Definition 8353.2. They place the handoff row U downstream of B, L, O, Q, T.

The finite cover row B supplies the ProbeBundle nerve, while L and O attach local moduli and overlap compatibility to the same finite incidence data. The rational lower-bound row Q reads only these displayed radii, and the metric-triangle row T is the displayed passage from local estimates to the uniform read.

Transport and replay preserve the same route through H and C. Hence any consumer that reads U without the prior rows leaves the accepted carrier. □

Theorem 8353.4 (CompactUniformLocalModulusNerve sibling route)**.** *Every accepted* CompactUniformLocalMod
packet consumes the finite-cover nerve surface of chapter 7597 or the compact-cover nerve surface of chapter 6263 before it exports the local-modulus nerve. Its downstream handoff then passes through the $\mathsf{UniformModulus}^{\uparrow}$ *sibling of chapter 369; the carrier has no route that skips the cover incidence rows, overlap compatibility, rational lower-bound fold, or metric-triangle row.*

Proof. Read the carrier rows in Definition 8353.1. The cover-nerve coordinate B is the only source for cover membership, center data, and finite incidence.

The uniform-modulus handoff theorem then places U after B, L, O, Q, T. Thus the accepted packet can export the local-modulus nerve only through the finite-cover or compact-cover sibling surface and then through the displayed $\mathsf{UniformModulus}^{\uparrow}$ handoff.

The structural rows H, C, P, N preserve this same route. They do not introduce an external cover selector, a detached host minimum, or a second uniform-modulus output. □

Falsifiable prediction: Any compact-uniform consumer that cites a UniformModulusUp handoff while omitting the displayed overlap compatibility and RatUp lower-bound rows is rejected by the local classifier.

Independence witness: Nearest siblings: compactuniformcontinuity, compactcovernerve, finitecovernerve, finitecovermeshchain, compactuniformmodulus. The carrier is not bijective to any sibling because it binds local modulus rows and overlap compatibility before the uniform-modulus handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}$ packet is generated from finite cover-nerve, local-modulus, overlap compatibility, rational lower-bound, metric-triangle, uniform-modulus handoff, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: This chapter records the finite carrier and local NameCert surface for the compact-cover local-modulus nerve before uniform-modulus consumers read it.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformLocalModulusNerve}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CompactUniformLocalModulusNerveUp`

Bridge status: none

Origin: human

Not claimed: It does not close full compact uniform continuity, external cover choice, host finite minimum selection, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, overlap compatibility, rational lower-bound replay, metric-triangle replay, and uniform-modulus handoff for the same finite packet.

Lean4 (statement) `BEDC.Derived.CompactUniformLocalModulusNerveUp`

Chapter 8354

A Concrete Naming Certificate for $\mathsf{LocatedCompactMetric}^{\uparrow}$

Following Bishop and Bridges constructive metric compactness, the $\mathsf{LocatedCompactMetric}^{\uparrow}$ packet records a compact metric source together with displayed located distance data and the finite-net readback route used by L10 Real and Completion consumers. It sits beside the metric-space source of chapter 4230, the compact-metric certificate of chapter 129, the finite epsilon-net route of chapter 1767, the complete-metric handoff of chapter 128, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names the finite located compact metric surface only; it does not assert open-cover compactness, sequential compactness, countable choice, quotient completion, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8354.1 (Located compact metric carrier)**.** *A* $\mathsf{LocatedCompactMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (M, D, K, F, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, naming the displayed metric carrier and metric-law ledger inspected by every distance request.*
2. *D is the located distance witness row, recording finite lower and upper distance windows for each displayed point-to-source query.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *row, exposing compact metric data only through displayed finite-net evidence.*
4. *F is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *finite-net row, carrying center lists, tolerance labels, and coverage witnesses at inspected scales.*
5. *T is the* $\mathsf{CompleteMetric}^{\uparrow}$ *route, naming the completion-facing Cauchy handoff without selecting a quotient representative or host limit.*
6. *R is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to measure radii, slack bounds, and finite comparison budgets.*
7. *E is the paired* $\mathsf{RegSeqRat}^{\uparrow}$ *readback and* $\mathsf{Real}^{\uparrow}$ *seal row, exposing regular rational windows before any real-valued distance or compactness consumer can inspect the packet.*

8. *H records componentwise* hsame *transport for the metric source, located distance witness, compact metric row, finite epsilon-net row, complete-metric route, dyadic ledger, readback seal, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from a located compact metric request through M, D, K, F, T, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedCompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, D, K, F, T, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, sequential compactness, countable choice, quotient completion equality, selected limits, host metric equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8354.2 (Located compact metric NameCert obligations)**.** *For every accepted* $\mathsf{LocatedCompactMetric}^{\uparrow}$ *carrier*

$$L = (M, D, K, F, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}$ *surface consists exactly of MetricSpace source admission, located distance witness exposure, CompactMetric finite compactness data, FiniteEpsilonNet center and coverage rows, CompleteMetric completion-facing routing, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8354.1. The source metric row is M, the located distance row is D, and compactness is visible only through the compact metric row K together with the finite epsilon-net row F.

The completion-facing side is then forced through T, R, E. The complete-metric row supplies the Cauchy handoff route, the dyadic ledger records the inspected tolerances, and the readback seal exposes regular rational data before the terminal real-name row is consumed.

Transport, replay, provenance, and local naming are exactly H, C, P, N. Since no listed row contains an open-cover theorem, a sequential-compactness selector, countable choice, quotient completion equality, selected limits, host metric equality, or ambient completeness, the displayed rows exhaust the NameCert obligation surface. □

Theorem 8354.3 (Located compact metric finite-net completion route)**.** *Every completion-facing or real-facing consumer of an accepted* $\mathsf{LocatedCompactMetric}^{\uparrow}$ *packet must first read the route*

$$\mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{FiniteEpsilonNet}^{\uparrow},\ \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the same local $\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}$ *carrier rows. The route exports finite centers, coverage witnesses, located distance windows, dyadic tolerance accounting, regular rational readback, and a terminal real seal; it exports no open-cover compactness, sequential compactness, countable choice, quotient completion, selected limit, or ambient completeness principle.*

Proof. Begin with the metric and compact rows. The metric source M gives the distance ledger, while K and F expose compactness only as displayed finite epsilon-net data.

Next read the located and completion rows. The located distance witness D answers finite distance-window requests, and the complete-metric row T names the handoff used by completion consumers without choosing a quotient representative or host limit.

Finally pass through the dyadic ledger and readback seal. Rows R and E keep the tolerance and real-facing data inside $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, and H, C, P, N replay the same

finite route. Thus the consumer receives exactly the listed finite surface and none of the refused endpoints. □

Falsifiable prediction: Any accepted $\mathsf{LocatedCompactMetric}^{\uparrow}$ read that exposes compactness or completion-facing data without displaying MetricSpace source admission, located distance witness data, CompactMetric finite compactness rows, FiniteEpsilonNet coverage, CompleteMetric routing, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert data refutes the carrier.

Independence witness: metricspace, compactmetric, finite-epsilon-net, completemetric, dyadicratcore, regseqrat, real: none is bijective with $\mathsf{LocatedCompactMetric}^{\uparrow}$ because this packet jointly binds metric source data, located distance windows, compact finite-net evidence, completion routing, dyadic tolerance accounting, regular readback, real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedCompactMetric}^{\uparrow}$ packet is generated from a MetricSpace source row, located distance witness, CompactMetric finite compactness data, FiniteEpsilonNet coverage rows, CompleteMetric routing, DyadicRatCore tolerance accounting, RegSeqRat readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8354.1, Definition 8354.2, and Definition 8354.3 seed the located compact metric route over metric source, located distance, compact finite-net, completion, dyadic tolerance, regular readback, Real seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedCompactMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, sequential compactness, countable choice, quotient completion, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located distance exactness, finite-net coverage, completion routing, dyadic tolerance accounting, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.LocatedCompactMetricUp.

Chapter 8355

A Concrete Naming Certificate for BolzanoWeierstrassLocatedSequence$^{\uparrow}$

Bolzano–Weierstrass and Bishop-style located compactness give the BolzanoWeierstrassLocatedSequence$^{\uparrow}$ packet its finite BEDC shape: a bounded located real sequence is inspected through stream windows, regular rational readback, compact interval data, and a monotone-subsequence theorem surface before any cluster-window seal is consumed. It sits after the Real$^{\uparrow}$ carrier of chapter 38, the RegSeqRat$^{\uparrow}$ route of chapter 301, the finite stream-window surface of chapter 126, the selector theorem of chapter 1997, and the compact interval data of chapter 1250 and chapter 3969. The packet records a located finite-window substitute for sequential compactness; it does not assert open-cover compactness, countable choice, a selected host subsequence, quotient stream equality, or ambient Real$^{\uparrow}$ completeness.

Definition 8355.1 (Bolzano-Weierstrass located-sequence carrier)**.** *A* BolzanoWeierstrassLocatedSequence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, L, K, M, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the bounded located source-sequence row, read only through finite* StreamName$^{\uparrow}$ *windows and displayed lower and upper interval bounds.*
2. *L is the located interval-membership row that records rational apartness windows for the source values.*
3. *K is the compact interval data row, supplied by finite closed-bounded interval nets and closed-bounded compactness certificates.*
4. *M is the* MonotoneSubsequenceTheorem$^{\uparrow}$ *row that names the finite selector-theorem surface available to the bounded source.*
5. *W is the selected finite subsequence-window ledger opened by S, L, K, M.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the selected windows.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row for the located cluster-window read.*
8. *H records componentwise* hsame *transport for $S, L, K, M, W, R, E, C, P, N$.*
9. *C records displayed* Cont *replay from located source windows through compact interval data and monotone-subsequence windows to regular readback and the Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{MonotoneSubsequenceTheorem}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalCompact}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for open-cover compactness, selected infinite subsequences, countable choice, quotient stream equality, trichotomy of host reals, or ambient completeness.

Theorem 8355.2 (Bolzano-Weierstrass located-sequence NameCert obligations)**.** *For every accepted* $\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}$ *carrier*

$$B = (S, L, K, M, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}}$ *surface consists exactly of carrier admission, bounded located source-window exposure through S, L, compact interval data exposure through K, selector-theorem exposure through M, finite selected-window exposure through W, regular rational readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the displayed carrier. The source side is S, L, K: finite stream windows, located interval membership, and compact interval data are the only rows available before a subsequence window can be read.

The selector-theorem row M is then consumed as a finite BEDC surface. It supplies monotone selected-window data for the bounded source without adding a choice-selected infinite subsequence.

The readback rows are W, R, E. The selected windows W determine the $\mathsf{RegSeqRat}^{\uparrow}$ readback R, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is visible only after that readback.

Finally H, C, P, N preserve, replay, source, and name the same rows. Since no excluded compactness, choice, quotient, trichotomy, or ambient-completeness coordinate appears in the carrier, the listed rows exhaust the local NameCert obligations. □

Theorem 8355.3 (Bolzano-Weierstrass located subsequence window)**.** *Every cluster-window read exported by an accepted* $\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}$ *carrier factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{MonotoneSubsequenceTheorem}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the compact interval data row K and located membership row L. Thus a downstream Real or Completion consumer receives only bounded located source windows, compact interval data, a finite monotone-subsequence theorem row, selected windows, regular readback, a Real seal, transport, replay, provenance, and local naming.

Proof. Start with the accepted carrier and read the source windows S through the located row L. The compact interval data K supplies the finite bounded interval surface in which those windows are inspected.

Next use the selector-theorem row M. Its output is the finite selected-window ledger W, not a host-level infinite subsequence.

The selected windows pass to R and then to E. This is exactly the regular rational readback and terminal Real seal route consumed by downstream Real and Completion readers.

The structural rows H, C, P, N keep the same finite route under transport and replay. No open-cover compactness theorem, selected subsequence functional, quotient stream equality, countable-choice row, or ambient $\mathsf{Real}^{\uparrow}$ completeness principle is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}$ packet is generated from bounded located StreamName windows, located interval membership, compact interval data, a MonotoneSubsequenceTheorem row, selected finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8355.1, Definition 8355.2, and Definition 8355.3 seed the finite located sequence route from compact interval data to regular cluster-window readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BolzanoWeierstrassLocatedSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice-selected infinite subsequences, countable choice, quotient stream equality, trichotomy of host reals, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located source-window exposure, compact interval data exposure, monotone-subsequence theorem routing, selected-window readback, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.BolzanoWeierstrassLocatedSequenceUp.

Chapter 8356

A Concrete Naming Certificate for CompactIntervalModulusExtractor$^{\uparrow}$

Following Bishop and Bridges on compact intervals and uniform continuity, the CompactIntervalModulusExtractor$^{\uparrow}$ packet records the finite extraction surface promised by chapter 9237: compact interval probes, rational lower-bound folds, and a uniform-modulus handoff are carried as displayed NameCert rows. It sits beside the compact interval modulus route of chapter 5937, the bridge packet of chapter 3868, the finite interval net of chapter 1250, the compact source rows of chapter 129, and the output surface of chapter 369. The packet names only finite extraction data; it does not assert open-cover compactness, a selected subcover functional, host semantic continuity, quotient real equality, or ambient Real$^{\uparrow}$ completeness.

Definition 8356.1 (Compact interval modulus extractor carrier)**.** *A* CompactIntervalModulusExtractor$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (I, K, Q, F, R, U, S, H, C, P, N)$$

with the following displayed rows:

1. *I is the compact interval source row, read through closed bounded interval endpoint and finite-net data.*
2. *K is the* CompactMetric$^{\uparrow}$ *or interval-compactness row that supplies the finite* ProbeBundle *cover.*
3. *Q is the tolerance-query row whose requested precision is displayed before any radius fold is read.*
4. *F is the finite lower-bound fold row, recording rational radius comparisons over the displayed probe bundle.*
5. *R is the regular rational readback row attached to the selected radius and interval-window data.*
6. *U is the* UniformModulus$^{\uparrow}$ *handoff row exported after I, K, Q, F, R have been displayed.*
7. *S records the* StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$ *seal rows used by interval endpoints, probe centers, and modulus readback.*
8. *H records componentwise* hsame *transport for $I, K, Q, F, R, U, S, C, P, N$.*
9. *C records displayed* Cont *replay from compact interval probes through the rational lower-bound fold to the uniform-modulus handoff.*

10. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$, $\mathsf{CompactIntervalModulus}^{\uparrow}$, $\mathsf{CompactIntervalMod}$ $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusExtractor}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for arbitrary open covers, selected subcovers, host continuity theorems, quotient real equality, countable choice, or ambient completeness.

Theorem 8356.2 (Compact interval modulus extractor NameCert obligations)**.** *For every accepted* $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$ *carrier*

$$X = (I, K, Q, F, R, U, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusExtractor}^{\uparrow}}$ *surface consists exactly of carrier admission, compact interval source exposure through I, finite probe-bundle exposure through K, tolerance-query exposure through Q, rational lower-bound fold exposure through F, regular readback through R,* $\mathsf{UniformModulus}^{\uparrow}$ *handoff through U, stream, regular, and Real seal exposure through S, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The source side is I, K, Q: the interval, compact finite probe bundle, and requested precision must all be visible before any extracted radius is read.

The finite lower-bound fold is F. It ranges only over the displayed probe rows and rational comparisons, so it is not an open-cover compactness theorem or a selected subcover functional.

The output side is R, U, S. The regular readback records the extracted rational data, the $\mathsf{UniformModulus}^{\uparrow}$ row is downstream of that readback, and S carries the stream, regular, and Real seal rows used by the handoff.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since the carrier has no host continuity, quotient, choice, or ambient-completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8356.3 (Compact interval modulus extractor vision handoff)**.** *Every compact-uniform-continuity read of an accepted* $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{ProbeBundle} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto \mathsf{UniformModulus}^{\uparrow}.$$

The route realizes the compact interval branch of chapter 9237 as finite ProbeBundle cover rows, rational lower-bound fold data, regular readback, Real sealing, and UniformModulus handoff rows.

Proof. Begin with the compact interval source and finite probe bundle rows I, K. These rows supply the only cover data visible to the extractor.

Read the tolerance query Q and the lower-bound fold F. The fold is finite and rational, so every selected radius remains attached to a displayed probe and comparison row.

The regular readback and seal rows R, S then prepare the uniform-modulus handoff U. This is the precise finite route named by the compact-uniform-continuity vision: probe coverage, lower-bound fold, readback, Real seal, and uniform modulus.

Transport, replay, provenance, and local naming through H, C, P, N keep the route inside the carrier. No open-cover compactness, selected subcover, semantic continuity theorem, quotient real equality, countable choice, or ambient completeness is exported. □

Falsifiable prediction: Every accepted $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$ uniform-modulus read factors through compact interval source rows, a finite ProbeBundle cover, a tolerance query, rational lower-bound fold data, RegSeqRat readback, RealUp sealing, UniformModulus handoff, hsame transport, Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: compact-interval-modulus, compact-interval-modulus-bridge, closed-boundedintervalnet, compactmetric, uniformmodulus: $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds the compact interval source, probe-bundle cover, tolerance query, rational lower-bound fold, regular readback, Real seal, UniformModulus handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalModulusExtractor}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalModulusExtractor}^{\uparrow}$ packet is generated from compact interval source rows, CompactMetric finite ProbeBundle cover data, tolerance queries, rational lower-bound folds, RegSeqRat readback, UniformModulus handoff, StreamName and RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalModulusExtractor}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8356.1, Definition 8356.2, and Definition 8356.3 seed the compact interval modulus extraction route from finite ProbeBundle covers to UniformModulus handoff data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalModulusExtractor}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host semantic continuity, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact interval source exposure, finite ProbeBundle coverage, rational lower-bound fold exactness, RegSeqRat readback, RealUp sealing, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalModulusExtractorUp.

Chapter 8357

A Concrete Naming Certificate for $\mathsf{RealSeriesComparison}^{\uparrow}$

Following Bishop–Bridges comparison-test practice, the $\mathsf{RealSeriesComparison}^{\uparrow}$ packet records a finite real-series comparison route that may read signed source terms only through displayed windows and bounded domination evidence. It consumes the positive comparison surface of chapter 7665, the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance arithmetic of chapter 291, and the finite stream windows of chapter 126. The packet names a comparison-test certificate for later $\mathsf{Real}^{\uparrow}$ series-tail estimates; it is not an ambient convergence theorem, a host infinite-sum construction, quotient equality of term streams, or a selected limit.

Definition 8357.1 (Real series comparison carrier)**.** *A* $\mathsf{RealSeriesComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S, B, P, W, D, Q, E, H, R, G, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{RealSeries}^{\uparrow}$ *row whose finite term windows are being compared.*
2. *B is the bounding* $\mathsf{RealSeries}^{\uparrow}$ *row read through the positive comparison packet.*
3. *P is the* $\mathsf{PositiveSeriesComparison}^{\uparrow}$ *witness row, exposing the nonnegative domination surface already named by chapter 7665.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite indices, signs, tail requests, and comparison requests under inspection.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording absolute-value bounds, domination checks, and requested error budgets for the displayed windows.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used when the compared windows are routed toward regular rational data.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after S, B, P, W, D, Q have been displayed.*
8. *H records componentwise* hsame *transport for the source series, bounding series, positive comparison witness, windows, dyadic ledger, readback, terminal seal, replay, provenance, and local naming rows.*
9. *R records displayed* Cont *replay from a comparison request through $S, B, P, W, D, Q, E, H, G, N$.*

10. *G is the* Pkg *provenance over* $\mathsf{RealSeriesComparison}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{PositiveSeriesComparison}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealSeriesComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, B, P, W, D, Q, E, H, R, G, N$. It has no coordinate for ambient convergence, host infinite sums, quotient equality of term streams, selected limits, countable choice, or detached $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8357.2 (Real series comparison obligation surface)**.** *For every accepted* $\mathsf{RealSeriesComparison}^{\uparrow}$ *carrier*

$$C = (S, B, P, W, D, Q, E, H, R, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealSeriesComparison}^{\uparrow}}$ *surface consists exactly of source-series exposure, bounding-series exposure, positive comparison witness exposure, finite stream-window exposure, dyadic tolerance-ledger exposure, regular rational readback, terminal real sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8357.1. The rows $S, B, P, W, D, Q, E, H, R, G, N$ are the complete finite packet, so carrier admission and classifier exactness are componentwise projections.

Read the comparison rows next. The source row S and bounding row B are inspected only through the finite window row W, while P imports the already displayed positive comparison witness and D records the dyadic domination ledger for those windows.

Finally inspect Q, E, H, R, G, N. These rows read back, seal, transport, replay, source, and name the same finite route. Since the carrier has no coordinate for host sums, selected limits, quotient equality, or ambient convergence, the obligation surface is exactly the stated packet. □

Theorem 8357.3 (Real series comparison non-escape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RealSeriesComparison}^{\uparrow}$ *carrier reaches the terminal seal only through*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{PositiveSeriesComparison}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a comparison-test read may export finite tail-estimate evidence, but it cannot export ambient convergence, a host infinite sum, quotient equality of term streams, selected limits, countable choice, or detached real-name completeness.

Proof. Start with the source and bounding series rows. They expose only finite $\mathsf{RealSeries}^{\uparrow}$ observations, and the bounding row is consumable as comparison evidence only through the $\mathsf{PositiveSeriesComparison}^{\uparrow}$ witness row.

Next read the window and tolerance rows. The $\mathsf{StreamName}^{\uparrow}$ row supplies the inspected indices and requested tail windows, while the $\mathsf{DyadicRatCore}^{\uparrow}$ row supplies the finite domination and error-budget checks used by the comparison route.

The readback and terminal rows Q, E are downstream of those finite rows. Componentwise transport, displayed replay, provenance, and local naming preserve the same packet, so no consumer can escape to an unlisted convergence principle or selected limit. □

Falsifiable prediction: Every accepted $\mathsf{RealSeriesComparison}^{\uparrow}$ read exposes source and bounding $\mathsf{RealSeries}^{\uparrow}$ rows, a $\mathsf{PositiveSeriesComparison}^{\uparrow}$ witness, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{RegSeqRat}^{\uparrow}$ readback, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a comparison conclusion is consumed.

Independence witness: positive-series-comparison, realseries, streamname, dyadicratcore, regseqrat, real: $\mathsf{RealSeriesComparison}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries

signed source windows, bounding series windows, positive comparison evidence, dyadic domination ledgers, regular readback, terminal real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RealSeriesComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{RealSeriesComparison}^{\uparrow}$ packet is generated from source and bounding RealSeries rows, a PositiveSeriesComparison witness row, finite StreamName windows, a DyadicRatCore tolerance ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RealSeriesComparison}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8357.1, Definition 8357.2, and Definition 8357.3 seed the finite real-series comparison route from source and bounding series windows through positive comparison evidence, dyadic tolerance accounting, regular readback, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RealSeriesComparison}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim ambient convergence, host sums, quotient equality of term streams, selected limits, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, comparison-window admission, dyadic domination exactness, positive-comparison witness routing, readback stability, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.RealSeriesComparisonUp.

Chapter 8358

A Concrete Naming Certificate for $\mathsf{StirlingFactorialBudget}^{\uparrow}$

Following Stirling and Robbins, the $\mathsf{StirlingFactorialBudget}^{\uparrow}$ packet records the finite denominator and growth-control data needed when factorial estimates feed constructive real power series. It sits between the Gamma normalization route of chapter 75, the exponential and trigonometric series consumers of chapter 1816 and chapter 6126, and the L10 real substrate carried by chapter 291, chapter 126, chapter 301, and chapter 38. The carrier names a finite factorial-growth budget, not an asymptotic oracle, selected limit, or ambient analytic completeness theorem.

Definition 8358.1 (Stirling factorial-budget carrier)**.** *A* $\mathsf{StirlingFactorialBudget}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (K, A, B, D, W, R, E, H, C, P, N)$$

with the following rows:

1. *K is the factorial index window recording the finite interval of n-values inspected by the downstream Gamma or power-series consumer.*
2. *A is the lower Stirling-style comparison ledger, storing the finite rational inequalities used to dominate reciprocal factorial denominators from below.*
3. *B is the upper Robbins-style slack ledger, storing the finite rational inequalities used to bound factorial growth from above.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *denominator ledger carrying common dyadic refinements, radius comparisons, and slack transport for A and B.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window service naming which coefficient windows are read by the consumer.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same denominator and coefficient windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *handoff row consumed by the Gamma, exponential, or sine series route only after K, A, B, D, W, R have been displayed.*
8. *H stores componentwise* hsame *transport for the index window, comparison ledgers, dyadic denominator row, stream window, regular-rational readback, real handoff, provenance, and local naming rows.*
9. *C stores displayed* Cont *replay from a finite precision request through the same factorial-budget route.*

10. *P is the* Pkg *provenance over* StirlingFactorialBudget$^{\uparrow}$*, the Gamma and real-series consumers,* DyadicRatCore$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*
11. *N is the local* NameCert$_{\mathsf{StirlingFactorialBudget}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a real-valued asymptotic expansion, a hidden analytic limit, selected denominator normalization, or ambient completeness.

Theorem 8358.2 (Stirling factorial-budget NameCert obligations)**.** *For every accepted* StirlingFactorialBudget$^{\uparrow}$ *carrier*

$$F = (K, A, B, D, W, R, E, H, C, P, N),$$

the local NameCert$_{\mathsf{StirlingFactorialBudget}^{\uparrow}}$ *surface consists exactly of carrier admission, factorial index-window exposure, lower and upper Stirling-style comparison exposure, dyadic denominator refinement, stream-window exposure, regular-rational readback, Real-facing handoff, componentwise transport, displayed replay, provenance, and local naming. Any accepted consumer that uses a factorial denominator estimate must expose $K, A, B, D, W, R, E, H, C, P, N$ before using the estimate inside Gamma, exponential, or sine coefficient control.*

Proof. Project the carrier of Definition 8358.1. The finite rows $K, A, B, D, W, R, E, H, C, P, N$ are the only rows available to the classifier, so every budget read starts from the displayed index window and the two rational comparison ledgers.

Read the denominator surface next. The DyadicRatCore$^{\uparrow}$ ledger D carries the common denominator refinement needed by both Stirling-style bounds, while W and R attach the same finite budget to stream windows and regular-rational readback.

Finally consume the Real-facing and structural rows. The row E is available only after the comparison and readback rows have been displayed, and H, C, P, N preserve, replay, record, and name the same finite packet. Thus the NameCert surface exports finite factorial-budget data rather than an analytic asymptotic principle. □

Theorem 8358.3 (Stirling factorial-budget Gamma and power-series handoff)**.** *Every Gamma, real-exponential, or real-sine coefficient consumer that reads a* StirlingFactorialBudget$^{\uparrow}$ *packet factors through the finite route*

$$K, A, B, D, W, R, E, H, C, P, N.$$

The Gamma route reads K, A, B, D as finite factorial-growth control before passing to its Real-facing row, while the exponential and sine series routes read W, R, E as the coefficient-window handoff. None of these consumers receives a selected asymptotic expansion, quotient real equality, host convergence theorem, or ambient analytic completeness principle from the packet.

Proof. Start with the Gamma-side read. The factorial index window K and the comparison ledgers A, B are finite rational data, and the dyadic denominator ledger D is the only denominator refinement exported to the Gamma consumer.

Now read the power-series side. The coefficient windows W and regular-rational readback R attach the same budget to the real exponential and real sine consumers before the Real-facing row E is consumed.

Transport and replay close the handoff. The rows H, C, P, N keep the Gamma and power-series consumers over the same finite packet, so the handoff is a BEDC NameCert route and not a hidden appeal to Stirling asymptotics as an external analytic object. □

Falsifiable prediction: Every accepted $\mathsf{StirlingFactorialBudget}^{\uparrow}$ consumer that uses a factorial denominator estimate without exposing index-window, lower-bound, upper-bound, dyadic-denominator, stream-window, RegSeqRat, Real handoff, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: gamma-function, real-exponential, real-sine, dyadicratcore, stream-name, regseqrat, real: no listed sibling jointly carries finite factorial index windows, two-sided Stirling-style rational comparison ledgers, dyadic denominator refinement, coefficient-window readback, Real-facing handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{StirlingFactorialBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{StirlingFactorialBudget}^{\uparrow}$ packet is generated from a finite factorial index window, two-sided rational Stirling-style comparison ledgers, dyadic denominator refinements, coefficient windows, regular-rational readback, a Real-facing handoff, transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StirlingFactorialBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8358.1, Definition 8358.2, and Definition 8358.3 seed the finite factorial-growth budget route for Gamma and real power-series consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StirlingFactorialBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Stirling's formula as a real asymptotic theorem, Gamma normalization, power-series convergence, quotient real equality, selected denominator normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, two-sided factorial comparison exactness, dyadic denominator transport, coefficient-window readback, Real-facing handoff, replay, provenance, and local naming for BEDC.Derived.StirlingFactorialBudgetUp.

Chapter 8359

A Concrete Naming Certificate for $\mathsf{CompactIntervalSupremum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{CompactIntervalSupremum}^{\uparrow}$ packet records the finite-net supremum surface for a located compact real interval. It sits over the terminal real-name seal of chapter 38, the dyadic tolerance ledger of chapter 291, the located endpoint rows of chapter 394, the compact metric finite-net source of chapter 129, and the total-bounded finite-net surface of chapter 127. The packet names finite rows for inspected interval endpoints, finite-net coverage, dyadic tolerances, candidate upper bounds, and local supremum readback; it does not assert open-cover compactness, a selected global maximizer, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8359.1 (Compact interval supremum carrier)**.** *A* $\mathsf{CompactIntervalSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, I, K, T, D, U, M, R, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *endpoint seal row for the displayed lower and upper interval endpoints.*
2. *I is the* $\mathsf{LocatedInterval}^{\uparrow}$ *row recording located endpoint comparisons and interval membership windows.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-source row read only through finite metric coverage data.*
4. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, displaying the inspected centers and coverage witnesses at the requested scale.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for mesh size, slack, and upper-bound comparison budgets.*
6. *U records the finite family of candidate upper-bound rows inspected over the displayed net.*
7. *M records the finite maximum-read row over those candidate bounds, as rational readback data rather than as a host supremum operator.*
8. *R is the local supremum-candidate row exported after E, I, K, T, D, U, M have all been displayed.*
9. *H records componentwise* hsame *transport for the endpoint, interval, compact, net, tolerance, candidate, readback, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from located interval data through finite-net inspection to the supremum-candidate row.*
11. *P is the* Pkg *provenance over* $\mathsf{CompactIntervalSupremum}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactIntervalSupremum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, I, K, T, D, U, M, R, H, C, P, N$. It has no coordinate for open-cover compactness, ambient completeness, quotient real equality, a selected maximizer, trichotomy, or an unrecorded comparison outside the displayed finite-net packet.

Theorem 8359.2 (Compact interval supremum NameCert obligations)**.** *For every accepted* CompactIntervalSuprem *carrier*

$$S = (E, I, K, T, D, U, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactIntervalSupremum}^{\uparrow}}$ *surface consists exactly of RealUp endpoint exposure, located interval exposure, compact finite-net source exposure, total-bounded net coverage, dyadic tolerance accounting, finite candidate upper-bound inspection, finite maximum readback, supremum-candidate export, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the accepted carrier. The endpoint and interval side is E, I: every candidate is read against displayed real endpoint seals and located interval rows before any upper-bound comparison is available.

The compact finite-net side is K, T, D. Compactness is consumed only through finite metric coverage and total-bounded net rows, while the dyadic ledger records the mesh and slack budgets used by the comparisons.

The supremum read is U, M, R. The candidate upper bounds are finite rows, the maximum row is a finite readback over those rows, and the exported supremum candidate is downstream of the same displayed data.

Finally H, C, P, N transport, replay, source, and name the packet. Since no carrier coordinate names open-cover compactness, ambient completeness, quotient equality, a selected maximizer, trichotomy, or a hidden comparison, the listed rows exhaust the local NameCert obligations. □

Theorem 8359.3 (Compact interval finite-net supremum read)**.** *Every accepted* $\mathsf{CompactIntervalSupremum}^{\uparrow}$ *read factors through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{LocatedInterval}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{TotallyBounded}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow}$$

inside the same carrier $S = (E, I, K, T, D, U, M, R, H, C, P, N)$. A consumer may read the exported candidate R only after the endpoint seals, located interval rows, finite-net coverage, dyadic tolerance ledger, candidate upper-bound rows, and finite maximum readback have been displayed.

Proof. Begin with E and I. These rows bind the real endpoints and located interval comparisons that define the inspected compact interval surface.

Next read K, T, D. The compact metric and total-bounded rows display the finite net, and the dyadic ledger fixes the tolerance and slack used for each comparison.

Then consume U and M. Both are finite rows: U lists candidate upper-bound inspections over the displayed net, and M reads the finite maximum row attached to those candidates.

The replay, transport, provenance, and naming rows H, C, P, N keep the route inside the same BHist packet. Therefore the exported row R is a finite-net supremum candidate, not an open-cover

compactness theorem, selected maximizer, quotient real equality, trichotomy decision, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion. □

Falsifiable prediction: Every accepted $\mathsf{CompactIntervalSupremum}^{\uparrow}$ read exposes RealUp endpoint seals, LocatedInterval rows, CompactMetric finite-net source data, TotallyBounded coverage rows, DyadicRatCore tolerance accounting, finite candidate upper-bound rows, finite maximum readback, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before exporting a supremum candidate.

Independence witness: real, dyadicratcore, locatedinterval, compactmetric, totallybounded: $\mathsf{CompactIntervalSupremum}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds endpoint seals, located interval data, compact finite-net source rows, total-bounded coverage, dyadic tolerance budgets, candidate upper-bound inspection, finite maximum readback, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactIntervalSupremum}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactIntervalSupremum}^{\uparrow}$ packet is generated from RealUp endpoint seals, LocatedInterval rows, CompactMetric finite-net source data, TotallyBounded coverage rows, DyadicRatCore tolerance accounting, finite candidate upper-bound inspection, finite maximum readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactIntervalSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8359.1, Definition 8359.2, and Definition 8359.3 seed the compact interval finite-net supremum route over displayed endpoint, interval, compact, total-bounded, dyadic, candidate, readback, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactIntervalSupremum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, ambient RealUp completeness, quotient real equality, selected maximizers, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, located interval exposure, finite-net coverage, dyadic tolerance accounting, candidate upper-bound inspection, finite maximum readback, supremum-candidate export, transport, replay, provenance, and local naming for BEDC.Derived.CompactIntervalSupremumUp.

Chapter 8360

A Concrete Naming Certificate for MetaCICResidualPeakScheduler$^{\uparrow}$

The MetaCICResidualPeakScheduler$^{\uparrow}$ packet realizes the residual-substitution boundary of chapter 9378 as finite local-peak scheduling data. It sits beside the critical-path carrier of chapter 765, the parallel-diamond frontier of chapter 4238, the candidate-normalization handoff of chapter 5547, the residual local-join packet of chapter 5126, and the audit packet of chapter 735. The scheduler names which residual peak is inspected, which residual rows remain visible, which candidate joins are budgeted, and which blocked edge is retained; it does not claim full MetaCIC confluence.

Definition 8360.1 (MetaCIC residual peak-scheduler carrier)**.** *A* MetaCICResidualPeakScheduler$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (P, R, J, B, T, U, H, C, Q, N)$$

with the following rows:

1. *P is the local peak row, naming the source term, the two outgoing parallel or residual reductions, and the syntactic redex frontier inspected by the scheduler.*
2. *R is the residual-row ledger, displaying the residual substitutions and branch-local redex descendants that remain visible after the peak is decomposed.*
3. *J is the candidate-join budget, recording the finite list of candidate common reducts and the bounded checks attached to them.*
4. *B is the blocked-edge row, retaining the residual-substitution compatibility or residual beta branch that has not been discharged.*
5. *T is the transport row from the sibling critical-path and parallel-diamond frontier packets.*
6. *U is the replay row from candidate normalization through the residual local-join packet and back to the confluence audit packet.*
7. *H stores componentwise* hsame *transport for the local peak, residual rows, candidate joins, blocked edge, transport, replay, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay for the finite scheduler route.*
9. *Q is the* Pkg *provenance over* MetaCICResidualPeakScheduler$^{\uparrow}$*, the MetaCIC critical path, the parallel-diamond frontier, candidate normalization, the residual local-join packet, the audit packet,* BHist*,* hsame*,* Cont*, and* NameCert*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for an unconditional parallel diamond, a completed residual-substitution proof, a global Church–Rosser theorem, or a hidden proof search procedure.

Theorem 8360.2 (MetaCIC residual peak-scheduler NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ *carrier*

$$S = (P, R, J, B, T, U, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}}$ *surface consists exactly of local peak exposure, residual-row visibility, candidate-join budget exposure, blocked-edge retention, sibling transport, candidate-normalization replay, componentwise transport, displayed continuation replay, provenance, and local naming. Any accepted consumer that reaches a candidate join must expose $P, R, J, B, T, U, H, C, Q, N$ before treating the join as available to the confluence audit route.*

Proof. Project the carrier of Definition 8360.1. The local peak P, residual rows R, candidate budget J, and blocked edge B are explicit coordinates, so the scheduler cannot hide the residual-substitution boundary behind an unconditional diamond claim.

Read the sibling transport and replay rows. The row T imports only the finite critical-path and parallel-frontier data, while U replays candidate normalization through the residual local-join packet and back to the audit packet.

Finally read the structural rows. Componentwise transport H, displayed replay C, provenance Q, and local naming N preserve the same finite scheduler surface for downstream consumers, excluding completed confluence, hidden proof search, or a discharged residual beta branch. □

Theorem 8360.3 (MetaCIC residual peak-scheduler diamond handoff)**.** *Every conditional diamond or confluence-audit consumer of a* $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ *packet factors through the finite route*

$$P, R, J, B, T, U, H, C, Q, N.$$

The route may pass candidate joins to the parallel-diamond frontier and residual local-join packets, but it must retain the blocked-edge row B whenever residual-substitution compatibility or residual beta-branch compatibility has not been supplied. Therefore the handoff is a finite audit boundary, not a proof of the full parallel diamond.

Proof. Start with the local peak and residual rows. They determine which branch pair and which residual descendants are visible to the scheduler before any candidate common reduct is considered.

Use the candidate-join budget next. The row J supplies only bounded candidate joins, and the blocked-edge row B travels with the same packet whenever a compatibility edge remains unavailable.

The transport and replay rows complete the handoff. The rows T, U, H, C, Q, N connect the packet to the critical-path, parallel-frontier, candidate-normalization, residual-local-join, and audit-packet siblings while preserving the blocked edge. Thus downstream diamond consumers receive a scheduled finite boundary rather than an unconditional diamond theorem. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ consumer that reaches a candidate join without first exposing local peak, residual rows, scheduler budget, blocked edge, transport, replay, provenance, and local NameCert rows refutes the carrier surface.

Independence witness: metaciccriticalpath, metacic-parallel-diamond-frontier, metacic-candidate-normalization-confluence-handoff, parallel-diamond-residual, metacic-confluence-audit-packet: no listed sibling jointly carries local peak scheduling, residual-row visibility, candidate-join budget, blocked-edge retention, transport, replay, provenance, and local naming.

The paired Lean surface for this packet must provide Nontrivial $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ and FieldFaithful $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ instances in a `TasteGate.lean` file, with an explicit witness for nontriviality and projection proofs for every displayed field.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}$ packet is generated from a local MetaCIC peak, visible residual rows, a finite candidate-join budget, a retained blocked edge, sibling transport, replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8360.1, Definition 8360.2, and Definition 8360.3 seed the finite residual-peak scheduling route for the confluence audit boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualPeakScheduler}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, full parallel diamond, arbitrary closed-term Church–Rosser, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked local-peak exposure, residual-row visibility, candidate-join budget exactness, blocked-edge retention, sibling transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualPeakSchedulerUp

Chapter 8361

A Concrete Naming Certificate for UniformConvergencePreservesContinuity$^{\uparrow}$

Following Bishop and Bridges and Kelley, the UniformConvergencePreservesContinuity$^{\uparrow}$ packet records the standard constructive route from uniformly convergent continuous real-valued functions to a continuous limit. It reads the finite sup-norm boundary of chapter 3807, the uniform-limit metric handoff of chapter 1764, the real-function uniform Cauchy schedule of chapter 1830, the continuous-map source of chapter 130, the compact metric source of chapter 129, and the terminal Real$^{\uparrow}$ seal of chapter 38. The packet names the finite continuity-preservation boundary; it does not choose a host limiting function, identify functions by quotient equality, or import ambient completeness outside the displayed rows.

Definition 8361.1 (Uniform convergence preserves continuity carrier)**.** *A* UniformConvergencePreservesContinuity$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, A, S, K, F, G, R, W, M, H, C, P, N)$$

with the following displayed rows:

1. *L is the* UniformLimitMetric$^{\uparrow}$ *row that receives a uniform convergence request.*
2. *A is the* RealFunctionUniformCauchy$^{\uparrow}$ *row recording the real-valued uniform Cauchy schedule for the approximating function rows.*
3. *S is the* ContinuousSupNorm$^{\uparrow}$ *sibling row that supplies the finite sup-norm comparison boundary.*
4. *K is the* CompactMetric$^{\uparrow}$ *source row over which all source-window reads are made.*
5. *F is the* ContinuousMap$^{\uparrow}$ *row for the approximating continuous maps over K.*
6. *G is the displayed limit-row request, storing only the finite continuity test to be replayed for the limit candidate.*
7. *R is the terminal* Real$^{\uparrow}$ *difference-and-triangle seal reached after the source, approximant, and limit rows have been displayed.*
8. *W is the finite window ledger, recording the source refinement, uniform tail bound, and pointwise comparison windows used in the continuity test.*
9. *M is the modulus-transfer row that transports the approximant continuity modulus through the uniform tail and Real seal.*

10. *H records componentwise* hsame *transport for $L, A, S, K, F, G, R, W, M, C, P, N$.*
11. *C records displayed* Cont *replay through the same rows.*
12. *P is the* Pkg *provenance over* $\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}$, $\mathsf{UniformLimitMetric}^{\uparrow}$, $\mathsf{RealFunctionUniformCauchy}^{\uparrow}$, $\mathsf{ContinuousSupNorm}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for a choice-selected limit, quotient equality of functions, open-cover compactness, host supremum selection, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.UniformConvergencePreservesContinuityUp`

Theorem 8361.2 (Uniform convergence preserves continuity NameCert obligations)**.** *For every accepted* $\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}$ *carrier* $U = (L, A, S, K, F, G, R, W, M, H, C, P, N)$, *the local* $\mathsf{NameCert}_{\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}}$ *surface consists exactly of uniform-limit metric admission through L, real-function uniform Cauchy schedule exposure through A, continuous sup-norm boundary exposure through S, compact metric source exposure through K, approximating continuous-map exposure through F, displayed limit-row request through G, Real difference-and-triangle sealing through R, finite window exposure through W, modulus transfer through M, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8361.1. The tuple displays the uniform-limit row, uniform Cauchy schedule, sup-norm comparison row, compact source, approximating continuous-map row, limit-row request, Real seal, window ledger, modulus transfer, transport, replay, provenance, and local naming.

The rows K, F, W, M supply the only continuity information available to the packet. The rows A, S, L place that same information under a uniform tail comparison, so the continuity test for the limit is read through the displayed uniform-convergence boundary rather than through a host-selected limiting function.

The Real seal R is terminal. It records the triangle comparison after the approximant continuity row and the uniform tail row have both been displayed.

Finally, H, C, P, N preserve, replay, source, and name the same route. Since no carrier coordinate stores quotient equality of functions, a selected limit, host supremum data, open-cover compactness, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8361.3 (Uniform convergence preserves continuity Real route)**.** *Every accepted* UniformConvergencePrese *carrier routes a limit-continuity request through the finite chain*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{ContinuousSupNorm}^{\uparrow} \longmapsto \mathsf{RealFunctionUniformCauchy}^{\uparrow} \longmapsto \mathsf{UniformLimitMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

More explicitly, every displayed tolerance request first reads the compact source and approximating continuous-map rows, then the sup-norm and uniform Cauchy rows, then the finite window and modulus-transfer rows, and finally the terminal Real difference-and-triangle seal. The route exports no host function equality, selected limit object, quotient function space, or ambient compactness beyond the displayed $\mathsf{CompactMetric}^{\uparrow}$ *source.*

Proof. Start with the obligation surface of Definition 8361.2. The compact source K and approximating continuous-map row F fix the source windows and pointwise Real reads that may be inspected.

The sibling sup-norm row S and the uniform Cauchy schedule A then place the approximating function rows under one finite uniform comparison. The uniform-limit metric row L consumes that comparison as the displayed convergence request.

The finite ledger W and modulus-transfer row M carry the approximant continuity test across the same tolerance window. The Real seal R is reached only after the approximant continuity, uniform tail, and limit-row request have all been displayed.

Thus the accepted route is exactly the finite chain shown above, with H, C, P, N adding only transport, replay, provenance, and local naming. Nothing in the carrier can produce host function equality, selected limit data, quotient function-space equality, or compactness outside the displayed $\mathsf{CompactMetric}^{\uparrow}$ row. □

Closure status for $\mathsf{NameCert}_{\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}$ packet is generated from UniformLimitMetric, RealFunctionUniformCauchy, ContinuousSupNorm, CompactMetric, ContinuousMap, displayed limit-row, Real difference-and-triangle seal, finite window, modulus-transfer, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8361.1, Definition 8361.2, and Definition 8361.3 seed the continuity-preservation boundary for uniformly convergent continuous real-valued function rows over a displayed compact metric source.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformConvergencePreservesContinuity}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close host function equality, selected limit construction, quotient function spaces, open-cover compactness, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked obligation rows, or bridge checking for UniformConvergencePreservesContinuity

Upgrade path: Obligation closure requires checked carrier admission, compact-source and continuous-map stability, sup-norm boundary exactness, uniform Cauchy schedule exactness, uniform-limit handoff, Real triangle-seal nonescape, replay stability, and local naming for BEDC.Derived.UniformConvergencePreservesContinuityUp.

Chapter 8362

A Concrete Naming Certificate for $\mathsf{FinitelyPresentedModule}^{\uparrow}$

Following Bourbaki and Atiyah–Macdonald on finite module presentations, the $\mathsf{FinitelyPresentedModule}^{\uparrow}$ packet records a module by a finite generator row and a finite relation matrix. It sits after the ambient $\mathsf{Ring}^{\uparrow}$ and $\mathsf{Module}^{\uparrow}$ carriers of chapter 43 and chapter 46, reads relation coefficients through the finite $\mathsf{Mat}^{\uparrow}$ surface of chapter 49, keeps Noetherian consumers aligned with chapter 3648, and supplies the presentation route used by the normal-form row of chapter 2262. The packet names only displayed generators, finite relations, exactness witnesses, transport, replay, provenance, and local naming; it does not quotient an ambient free module, select representatives, import a host category of modules, or assert that arbitrary modules admit finite presentations.

Definition 8362.1 (Finitely presented module carrier)**.** *A* $\mathsf{FinitelyPresentedModule}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (R, M, G, A, E, H, C, Q, N)$$

with the following displayed rows:

1. *R is the ambient* $\mathsf{Ring}^{\uparrow}$ *row.*
2. *M is the target* $\mathsf{Module}^{\uparrow}$ *row over R.*
3. *G is the finite generator ledger, listing the displayed generator names and their landing rows in M.*
4. *A is the finite* $\mathsf{Mat}^{\uparrow}$ *relation row whose columns name relation words among the generators.*
5. *E is the presentation-exactness ledger, recording that the generator map is exposed and that the displayed relations are exactly the kernel rows read by the certificate.*
6. *H records componentwise* hsame *transport for R, M, G, A, E and the structural rows.*
7. *C records displayed* Cont *replay from a presentation request through R, M, G, A, E, H, Q, N.*
8. *Q is the* Pkg *provenance over* $\mathsf{FinitelyPresentedModule}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Module}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{NoetherianModule}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FinitelyPresentedModule}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, M, G, A, E, H, C, Q, N$. It has no coordinate for host quotient-module equality, selected normal forms, ambient free-module representatives, a chosen presentation category, or a theorem that every module over R is finitely presented.

Theorem 8362.2 (Finitely presented module NameCert obligations)**.** *For every accepted* $\mathsf{FinitelyPresentedModule}^{\uparrow}$ *carrier*

$$P = (R, M, G, A, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{FinitelyPresentedModule}^{\uparrow}}$ *surface consists exactly of ambient ring exposure, module exposure, finite generator-ledger exposure, finite relation-matrix exposure, presentation-exactness exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A Noetherian-module or Smith-normal-form consumer may read the packet only through these rows.*

Proof. Project the carrier of Definition 8362.1. The rows $R, M, G, A, E, H, C, Q, N$ are the complete finite packet, so carrier admission and classifier exactness are componentwise projections.

Read the algebraic rows next. The ring row R and module row M identify the ambient algebraic surface, the generator ledger G displays the finite source family, and the relation matrix A records the finite relation words through the already named $\mathsf{Mat}^{\uparrow}$ route.

Finally inspect E, H, C, Q, N. The exactness ledger binds generators and relations to the same module row, while transport, replay, provenance, and local naming preserve only the displayed packet. Since the carrier has no coordinate for quotient equality, selected representatives, host module categories, or hidden normal-form output, the stated rows are exactly the NameCert obligations. □

Theorem 8362.3 (Finitely presented module presentation exactness)**.** *Every* $\mathsf{NoetherianModule}^{\uparrow}$ *or* $\mathsf{SmithNormalForm}^{\uparrow}$ *consumer of an accepted* $\mathsf{FinitelyPresentedModule}^{\uparrow}$ *carrier reaches the target module only through the finite route*

$$\mathsf{Ring}^{\uparrow}, \mathsf{Module}^{\uparrow} \longmapsto \mathsf{Mat}^{\uparrow} \longmapsto \mathsf{FinitelyPresentedModule}^{\uparrow}.$$

The consumer must read the ambient ring row R, target module row M, generator ledger G, relation matrix A, and exactness ledger E before any normal-form or Noetherian-facing row is consumed. Thus the packet exports finite presentation exactness, not a quotient-module object, selected representatives, ambient basis choice, or a host theorem that presentations exist for all modules.

Proof. Start with the ambient rows. The $\mathsf{Ring}^{\uparrow}$ and $\mathsf{Module}^{\uparrow}$ coordinates are read before the presentation rows, so every downstream consumer sees which module surface is being presented.

Next read the finite presentation rows. The generator ledger G displays the finite source family, the $\mathsf{Mat}^{\uparrow}$ row A displays the relation coefficients, and the exactness ledger E states that these displayed relations are the rows used by the certificate.

The downstream handoff then passes through H, C, Q, N. Componentwise transport, continuation replay, provenance, and local naming carry the same packet into $\mathsf{NoetherianModule}^{\uparrow}$ and $\mathsf{SmithNormalForm}^{\uparrow}$ contexts. They cannot add quotient equality, selected representatives, ambient basis choices, or an existence theorem outside the displayed presentation route. □

Falsifiable prediction: Every accepted $\mathsf{FinitelyPresentedModule}^{\uparrow}$ read exposes a $\mathsf{Ring}^{\uparrow}$ row, a $\mathsf{Module}^{\uparrow}$ row, a finite generator ledger, a finite $\mathsf{Mat}^{\uparrow}$ relation row, a presentation-exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before a Noetherian-module or Smith-normal-form consumer reads the presented module.

Independence witness: ring, module, matrix, noetherian-module, smith-normal-form: $\mathsf{FinitelyPresentedModule}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries an ambient ring, target module, finite

generator ledger, relation matrix, presentation-exactness ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FinitelyPresentedModule}^{\uparrow}}$.

Constructive story: A $\mathsf{FinitelyPresentedModule}^{\uparrow}$ packet is generated from an ambient RingUp row, a target ModuleUp row, a finite generator ledger, a finite MatrixUp relation row, a presentation-exactness ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FinitelyPresentedModule}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8362.1, Definition 8362.2, and Definition 8362.3 seed the finite module-presentation route for NoetherianModuleUp and SmithNormalFormUp consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FinitelyPresentedModule}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human
