Not claimed: This chapter does not claim quotient-module equality, selected representatives, ambient basis choice, universal finite presentability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, generator-ledger exposure, relation-matrix exposure, presentation-exactness routing, Noetherian consumer boundary, Smith-normal-form handoff, transport, replay, provenance, and local naming for BEDC.Derived.FinitelyPresentedModuleUp.

Chapter 8363

A Concrete Naming Certificate for $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ packet records the finite modulus data by which a displayed Cauchy cluster is read before a Real or Completion consumer reaches a seal. It sits after the terminal real-name surface of chapter 38, the regular rational readback of chapter 301, the finite stream-window route of chapter 126, the dyadic tolerance core of chapter 291, and the finite cluster-window sibling of chapter 8035. It also reads the Cauchy-filter cluster sibling of chapter 1734 when a filter-facing completion route supplies the cluster source. The packet supplies a finite cluster-modulus interface without choice-selected subsequences, quotient representatives, host completeness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8363.1 (Bishop Cauchy cluster modulus carrier)**.** *A* $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (R, S, Q, D, K, F, B, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *source seal whose completion-facing cluster read is being controlled.*
2. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *schedule of inspected windows for the cluster read.*
3. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same inspected windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the dyadic radii, comparison slack, and arithmetic budget used by the cluster-modulus checks.*
5. *K is the* $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$ *cluster-window row, recording the finite cells and overlap checks available to the Real-facing consumer.*
6. *F is the optional* $\mathsf{CauchyFilterCluster}^{\uparrow}$ *handoff row used when the same cluster source is supplied by a displayed Cauchy-filter route.*
7. *B is the Bishop cluster-modulus ledger. It records, for each displayed tolerance request, the finite window bound and cluster-cell coverage needed before the downstream completion read may proceed.*
8. *H records componentwise* hsame *transport for the Real seal, stream schedule, regular readback, dyadic tolerance ledger, cluster-window row, filter-cluster handoff, modulus ledger, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the route*

$$S, Q, D \longmapsto K, F \longmapsto B \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteRealCauchyCluster}^{\uparrow}$, $\mathsf{CauchyFilterCluster}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyClusterModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, S, Q, D, K, F, B, H, C, P, N$. It has no coordinate for a selected subsequence, quotient Cauchy representative, host limit, countable choice, or ambient completeness principle.

Theorem 8363.2 (Bishop Cauchy cluster modulus NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ *carrier*

$$M = (R, S, Q, D, K, F, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyClusterModulus}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed Real seal, stream schedule, regular readback, dyadic tolerance ledger, cluster-window row, optional filter-cluster handoff, modulus ledger, transport, replay, provenance, and local naming rows;*
2. *stream-window exposure through S, requiring every modulus request to cite inspected finite windows;*
3. *regular-readback exposure through Q, requiring each inspected window to have a displayed rational readback before it participates in the modulus ledger;*
4. *dyadic-tolerance exactness through D, requiring the tolerance request, comparison slack, and arithmetic budget to be read from the same dyadic core;*
5. *cluster-window coverage through K, and through F when the source is filter-facing, requiring the modulus ledger to cite only displayed cluster cells;*
6. *Bishop modulus ledger exactness through B, requiring each tolerance request to return a finite window bound and cluster-cell coverage row before the Real or Completion consumer reads R;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No obligation is discharged by a selected subsequence, quotient representative, host limit, countable choice, or ambient completeness for $\mathsf{Real}^{\uparrow}$.

Proof. Project the carrier rows from Definition 8363.1. The finite observation data are exactly S, Q, D, while K and F are the only cluster-source rows available to the packet.

The modulus ledger B is downstream from those rows. Hence a tolerance request can be accepted only after the stream windows, regular readbacks, dyadic tolerance budget, and cluster-window cells have been displayed.

The Real-facing row R is not a selected limit or quotient representative. It is the seal consumed after the finite cluster-modulus ledger has supplied a window bound and coverage row for the displayed request.

Finally H, C, P, N preserve, replay, source, and name the same finite route. Since no coordinate stores subsequence choice, host completeness, or a hidden Cauchy representative, the listed rows exhaust the local NameCert surface. □

Theorem 8363.3 (Bishop Cauchy cluster modulus completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{FiniteRealCauchyCluster}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with the $\mathsf{CauchyFilterCluster}^{\uparrow}$ *sibling available only as a displayed cluster-source handoff. The consumer receives a Bishop modulus ledger over finite windows and cluster cells, not a choice-selected subsequence, quotient Cauchy representative, host limit, or ambient real-completeness theorem.*

Proof. Start with the obligation theorem Definition 8363.2. It places the stream schedule S, regular readback Q, dyadic tolerance ledger D, and cluster-window row K before the modulus ledger B and the Real seal R.

The finite cluster source is supplied by chapter 8035. When the source is filter-facing, chapter 1734 supplies only the displayed handoff row F; it does not add a second Real seal or a selected limit.

The structural rows H, C, P, N preserve the same route. Therefore the completion-facing read receives a finite cluster-modulus ledger over displayed windows and cluster cells, and no hidden subsequence or quotient representative can be consumed. □

Falsifiable prediction: A $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ consumer that reads a Real or Completion cluster seal without displaying StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, FiniteRealCauchyCluster cells, the Bishop modulus ledger, transport, replay, provenance, and local naming exits the accepted carrier.

Independence witness: real, regseqrat, streamname, dyadicratcore, finite-real-cauchy-cluster, cauchy-filter-cluster: no listed sibling is bijective with $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ because this packet binds tolerance-indexed finite window bounds to cluster-cell coverage before the Real or Completion seal is read.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyClusterModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyClusterModulus}^{\uparrow}$ packet is generated from a RealUp source seal, finite StreamName windows, RegSeqRat readback rows, DyadicRatCore tolerance rows, FiniteRealCauchyCluster cells, an optional CauchyFilterCluster handoff, a Bishop cluster-modulus ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyClusterModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8363.1, Definition 8363.2, and Definition 8363.3 seed the finite cluster-modulus route over displayed Real, RegSeqRat, StreamName, DyadicRatCore, FiniteRealCauchyCluster, CauchyFilterCluster, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyClusterModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subsequence selection, quotient Cauchy representatives, host limits, countable choice, ambient RealUp completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular-readback exposure, dyadic-tolerance exactness, cluster-window coverage, filter-cluster handoff, Bishop modulus ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyClusterModulusUp.

Chapter 8364

A Concrete Naming Certificate for $\mathsf{PanitchpakdiHyperconvexInjectivity}^{\uparrow}$

Following Aronszajn and Panitchpakdi, the $\mathsf{PanitchpakdiHyperconvexInjectivity}^{\uparrow}$ packet records the finite boundary where hyperconvex ball-intersection data may be read as an injective metric-extension interface. It sits over the hyperconvex metric row of chapter 4013, the injective-envelope route of chapter 6810, the isometric embedding handoff of chapter 439, the metric source of chapter 57, the complete-metric seal of chapter 128, and the terminal real-radius rows of chapter 38. The packet names only displayed finite extension boundaries; it does not assert arbitrary-family intersections, choice-selected injective hull points, quotient completions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8364.1 (Panitchpakdi hyperconvex injectivity carrier)**.** *A* $\mathsf{PanitchpakdiHyperconvexInjectivity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, H, E, I, K, R, T, C, Q, N)$$

with the following displayed rows:

1. *M is the common* $\mathsf{Met}^{\uparrow}$ *source row whose point and distance requests are inspected by all downstream rows.*
2. *H is the* $\mathsf{HyperconvexMetric}^{\uparrow}$ *ball-family row, including displayed closed balls, real radii, pairwise compatibility, and the finite intersection handoff.*
3. *E is the finite injective-extension row, recording a displayed one-step metric extension boundary over the same source rather than a selected host hull point.*
4. *I is the* $\mathsf{IsometricEmbedding}^{\uparrow}$ *handoff row, keeping the source-to-extension distance-preserving route visible before any extension consumer is admitted.*
5. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row attached to the same metric source and read only after the ball-family and embedding rows have been displayed.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *radius and distance row used by the ball-family inequalities, extension budgets, and isometric comparison.*
7. *T records componentwise* hsame *transport for the metric source, hyperconvex row, finite-extension row, isometric handoff, complete-metric seal, real-radius row, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from metric observations through ball-family compatibility, extension admissibility, isometric embedding handoff, complete-metric sealing, and real-radius readback.*

9. *Q is the* Pkg *provenance over* PanitchpakdiHyperconvexInjectivity$^{\uparrow}$, HyperconvexMetric$^{\uparrow}$, InjectiveEnvelopeMetric$^{\uparrow}$, IsometricEmbedding$^{\uparrow}$, Met$^{\uparrow}$, CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{PanitchpakdiHyperconvexInjectivity}^{\uparrow}}$ *row.*

The carrier has no coordinate for arbitrary ball-family intersections, choice-selected injective hull points, quotient completion representatives, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8364.2 (Panitchpakdi hyperconvex injectivity NameCert obligations)**.** *For every accepted* PanitchpakdiHyperconvexInjectivity$^{\uparrow}$ *carrier $P = (M, H, E, I, K, R, T, C, Q, N)$, the local* NameCert$_{\text{PanitchpakdiHyperconvexInjectivity}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, common-source exposure through M, hyperconvex finite ball-family exposure through H, finite injective-extension exposure through E, isometric embedding handoff through I, complete-metric sealing through K, real-radius and distance readback through R, componentwise* hsame *transport through T, displayed* Cont *replay through C,* Pkg *provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 8364.1. The packet exposes exactly the metric source M, hyperconvex ball-family row H, finite extension row E, isometric handoff I, complete-metric seal K, real-radius row R, and structural rows T, C, Q, N.

Read the ball-family side first. The row H imports only the finite hyperconvex route of chapter 4013: displayed closed balls, real radii, pairwise compatibility, and the finite intersection handoff over the common metric source.

Read the extension side next. The row E records the finite injective-extension boundary and is consumed through the injective-envelope neighbour of chapter 6810; the row I keeps the isometric embedding handoff visible before the extension is treated as distance preserving.

Finally inspect K, R, T, C, Q, N. The complete-metric and real-radius rows seal the same displayed route, while transport, replay, provenance, and local naming preserve the packet without adding a selected hull point, quotient completion representative, arbitrary-family intersection, choice selector, or ambient completeness theorem. □

Falsifiable prediction: Every accepted PanitchpakdiHyperconvexInjectivity$^{\uparrow}$ read that treats finite hyperconvex ball data as an injective metric-extension boundary must first expose the displayed metric source, hyperconvex ball-family row, finite extension row, isometric embedding handoff, complete-metric seal, real-radius row, transport, replay, provenance, and local naming.

Independence witness: hyperconvex-metric, injective-envelope-metric, isometric-embedding, metric, completemetric, real: no listed sibling supplies the whole packet $P = (M, H, E, I, K, R, T, C, Q, N)$, because each sibling contributes only a metric source, ball-intersection handoff, envelope route, embedding route, completion seal, or real-radius seal while this chapter binds the Panitchpakdi injectivity boundary across all six faces.

Closure status for NameCert$_{\text{PanitchpakdiHyperconvexInjectivity}^{\uparrow}}$.

Constructive story: A PanitchpakdiHyperconvexInjectivity$^{\uparrow}$ packet is generated from a displayed MetricSpace source, HyperconvexMetric finite ball-family row, finite injective-extension row, IsometricEmbedding handoff, CompleteMetric seal, Real radius and distance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{PanitchpakdiHyperconvexInjectivity}^{\uparrow}}$, seed)

Scope closed: Definition 8364.1 and Definition 8364.2 seed the finite boundary between hyperconvex ball-intersection data and injective metric-extension reads.

Formal verification: FormalStatus(NameCert$_{\mathsf{PanitchpakdiHyperconvexInjectivity}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, arbitrary-family intersections, choice-selected injective hull points, quotient completions, countable choice, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, hyperconvex ball-family exposure, finite extension exposure, isometric handoff, complete-metric sealing, Real radius readback, transport, replay, provenance, and local naming for the same packet.

Chapter 8365

A Concrete Naming Certificate for $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$

Following Bishop and Bridges-style constructive analysis, the $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ packet records the finite fusion route by which a nested dyadic interval stream supplies one regular rational readback before the terminal $\mathsf{Real}^{\uparrow}$ name is consumed. It sits after the dyadic endpoint and comparison rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name boundary of chapter 38. The packet names only the displayed prefix, shrinking-width, fusion, readback, transport, replay, provenance, and local naming rows; it is not a quotient stream, a selected host limit, a countable-choice selector, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8365.1 (Nested dyadic interval fusion carrier)**.** *A* $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, D, W, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the nested dyadic interval prefix row, storing the finite chain of left and right endpoint cells.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and width ledger for those cells, including the displayed containment and shrinking-width comparisons.*
3. *W is the fusion-window row, selecting the common finite prefix that every downstream read must inspect.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation schedule attached to the same prefix.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row formed from the scheduled dyadic observations.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *terminal seal row, available only after I, D, W, S, R have been displayed.*
7. *H records componentwise* hsame *transport for the interval prefix, dyadic ledger, fusion window, stream schedule, regular readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a fusion request through I, D, W, S, R, E and then through the structural rows.*
9. *P is the* Pkg *provenance over* $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NestedDyadicIntervalFusion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, W, S, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected completed limits, host real equality, countable choice, trichotomy, or ambient real completeness.

Theorem 8365.2 (Nested dyadic interval fusion NameCert obligations)**.** *For every accepted* $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ *carrier*

$$F = (I, D, W, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NestedDyadicIntervalFusion}^{\uparrow}}$ *surface consists exactly of nested-prefix exposure through I, dyadic endpoint and width exposure through D, common fusion-window exposure through W, finite observation scheduling through S, regular rational readback through R, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8365.1. The projection exposes the finite interval prefix, dyadic ledger, fusion window, schedule, regular readback, real seal, transport, replay, provenance, and naming rows.

The analytic rows are ordered. The dyadic ledger D can be read only after a prefix I is displayed, the fusion window W restricts all later observations to a common finite prefix, and the stream schedule S names the observations allowed inside that prefix.

The regular and real-facing rows are downstream. The readback row R is formed from the scheduled dyadic observations, and the terminal seal E is available only after that readback is displayed.

The structural rows H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no quotient stream, selected limit, host real equality, choice, trichotomy, or ambient completeness coordinate, the listed rows exhaust the local certificate. □

Theorem 8365.3 (Nested dyadic interval fusion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ *packet factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

using the finite rows $I, D, W, S, R, E, H, C, P, N$. The handoff exposes a common nested dyadic prefix and one regular rational readback route before the terminal seal is consumed; it does not expose quotient real equality, a selected host limit, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations. They force a Real-facing consumer to expose I, D, W, S, R before the seal row E is available.

Read the sibling surfaces in order. The dyadic rational core supplies endpoint and width comparisons for D, the stream-name interface supplies the finite observation schedule S, and the regular rational interface supplies the readback row R.

Finally consume the terminal seal through $\mathsf{Real}^{\uparrow}$. The rows H, C, P, N preserve the same finite fusion route under transport, replay, provenance, and local naming, so no downstream consumer can replace the route by a quotient stream, a selected limit, or an ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ read displays the nested dyadic prefix, DyadicRatCore endpoint ledger, common fusion window, StreamName schedule,

RegSeqRat readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any Real-facing consumer can use the terminal seal.

Independence witness: dyadicratcore, streamname, regseqrat, real: none is bijective to NestedDyadicIntervalFusio because only this packet binds a common nested dyadic prefix, a fusion window, scheduled observations, regular rational readback, terminal real sealing, transport, replay, provenance, and local naming as one finite route.

Closure status for $\mathsf{NameCert}_{\mathsf{NestedDyadicIntervalFusion}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedDyadicIntervalFusion}^{\uparrow}$ packet is generated from nested dyadic interval prefixes, DyadicRatCore endpoint and width rows, one common fusion window, StreamName finite observations, RegSeqRat readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedDyadicIntervalFusion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8365.1, Definition 8365.2, and Definition 8365.3 seed the finite nested dyadic interval fusion route from displayed dyadic prefix data to a Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedDyadicIntervalFusion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, host real equality, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic prefix exposure, fusion-window scheduling, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.NestedDyadicIntervalFusionUp.

Chapter 8366

A Concrete Naming Certificate for $\mathsf{MoreraTheorem}^{\uparrow}$

Following Morera and Bishop–Bridges constructive complex analysis, the $\mathsf{MoreraTheorem}^{\uparrow}$ packet names the finite theorem-shaped route by which triangle-contour integral vanishing is read as a holomorphic handoff. It sits beside the complex-analysis carrier of chapter 76, the holomorphic output surface of chapter 68, the finite contour window of chapter 587, the complex limit rows of chapter 65, and the real tolerance ledger of chapter 38. The packet records only displayed triangle contours, finite contour-integral rows, local complex-limit evidence, real tolerance comparisons, transport, replay, provenance, and local naming; it does not import analytic continuation, a host path-integral theory, open-cover compactness, selected primitives, quotient path equality, or classical choice.

Definition 8366.1 (Morera theorem carrier)**.** *A* $\mathsf{MoreraTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (A, H, T, W, L, R, Z, E, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{CplxAnalytic}^{\uparrow}$ *context row, naming the complex neighbourhood and the displayed analytic-read request.*
2. *H is the* $\mathsf{Holomorphic}^{\uparrow}$ *handoff row that may be exported only after the triangle-contour vanishing rows have been inspected.*
3. *T is the finite triangle-contour row, recording three* $\mathsf{Complex}^{\uparrow}$ *vertex histories, oriented edge rows, and the bounded family of triangle windows to be tested.*
4. *W is the* $\mathsf{ContourSumWindow}^{\uparrow}$ *row, recording the finite contour-window ledger and the local sum requests for the triangle boundaries.*
5. *L is the* $\mathsf{CplxLim}^{\uparrow}$ *row, recording the local limiting comparison that turns the finite contour-window data into the analytic handoff.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *tolerance row, recording positive rational bounds, modulus comparisons, and real-valued estimates used by the finite windows.*
7. *Z is the zero-contour row, displaying that each accepted triangle-window integral request is sealed at* $0_{\mathsf{Complex}^{\uparrow}}$ *inside the finite ledger.*

8. *E records componentwise* hsame *transport for analytic context, holomorphic handoff, triangle contours, contour windows, complex limits, real tolerances, zero rows, provenance, and naming.*
9. *C records displayed* Cont *replay from triangle-window admission through zero-contour sealing and the holomorphic handoff.*
10. *P is the* Pkg *provenance over* $\mathsf{MoreraTheorem}^{\uparrow}$, $\mathsf{CplxAnalytic}^{\uparrow}$, $\mathsf{Holomorphic}^{\uparrow}$, $\mathsf{ContourSumWindow}^{\uparrow}$, $\mathsf{CplxLim}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MoreraTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, H, T, W, L, R, Z, E, C, P, N$. It has no coordinate for a selected primitive, analytic continuation, an ambient path integral, a quotient path space, an open-cover compactness proof, or a classical-choice schedule.

Theorem 8366.2 (Morera theorem NameCert obligations)**.** *For every accepted* $\mathsf{MoreraTheorem}^{\uparrow}$ *carrier $M = (A, H, T, W, L, R, Z, E, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MoreraTheorem}^{\uparrow}}$ *surface consists exactly of* $\mathsf{CplxAnalytic}^{\uparrow}$ *context admission through A,* $\mathsf{Holomorphic}^{\uparrow}$ *handoff exposure through H, finite triangle-contour display through T,* $\mathsf{ContourSumWindow}^{\uparrow}$ *ledger display through W,* $\mathsf{CplxLim}^{\uparrow}$ *limiting comparison through L,* $\mathsf{Real}^{\uparrow}$ *tolerance comparison through R, zero-contour sealing through Z, componentwise* hsame *transport through E, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8366.1. The analytic rows are A, H, T, W, L, R, Z, and the structural rows are E, C, P, N.

The triangle-contour row T and contour-window row W expose the finite integral requests before the holomorphic handoff is read. The zero row Z seals those requests at $\mathsf{0}_{\mathsf{Complex}^{\uparrow}}$ inside the displayed window, rather than by an ambient path-integral theorem.

The complex-limit row L and real tolerance row R supply the constructive limiting and estimate data consumed by the handoff H. Transport, replay, provenance, and local naming preserve the same packet, so no selected primitive, analytic-continuation principle, quotient path equality, or classical-choice schedule can be read from the carrier. □

Theorem 8366.3 (Morera theorem contour-window route)**.** *Every complex-analysis consumer that reads an accepted* $\mathsf{MoreraTheorem}^{\uparrow}$ *packet must factor the read through the finite route*

$$A, T, W, R, Z, L \longmapsto H \longmapsto E, C, P, N.$$

The theorem-shaped content is the displayed passage from finite triangle-contour vanishing to the $\mathsf{Holomorphic}^{\uparrow}$ *handoff over the named* $\mathsf{CplxAnalytic}^{\uparrow}$ *context. It is not an analytic-continuation theorem, a hidden primitive selector, a host contour-integral object, a quotient path equality, or an open-cover compactness principle.*

Proof. Begin with the accepted carrier. The rows A, T, W display the complex-analysis context, triangle contours, and contour-window ledger before any handoff is exposed.

The real tolerance row R and zero-contour row Z then bind the finite estimates and vanishing certificates for the same triangle windows. The complex-limit row L is read after those rows, so the limiting comparison remains attached to the finite contour-window surface.

Finally H exports the holomorphic handoff, while E, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for the excluded ambient objects, every accepted consumer remains on the finite contour-window route. □

Falsifiable prediction: Any $\mathsf{MoreraTheorem}^{\uparrow}$ consumer that exports a $\mathsf{Holomorphic}^{\uparrow}$ handoff while omitting the displayed $\mathsf{ContourSumWindow}^{\uparrow}$, $\mathsf{CplxLim}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows is rejected by the local classifier.

Independence witness: complexanalytic, holomorphic, contoursumwindow, complexlimit, real: $\mathsf{MoreraTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite triangle-contour vanishing, contour-window ledgers, complex-limit comparisons, real tolerance rows, holomorphic handoff, transport, replay, provenance, and local naming into one theorem-shaped packet.

Closure status for $\mathsf{NameCert}_{\mathsf{MoreraTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{MoreraTheorem}^{\uparrow}$ packet is generated from ComplexAnalytic context rows, Holomorphic handoff rows, triangle-contour rows, ContourSumWindow ledgers, ComplexLimit comparisons, Real tolerance rows, zero-contour seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MoreraTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8366.1, Definition 8366.2, and Definition 8366.3 seed the finite Morera theorem contour-window route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MoreraTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, analytic continuation, selected primitives, host path integration, open-cover compactness, quotient path equality, or classical choice for $\mathsf{MoreraTheorem}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, triangle-contour display, contour-window exactness, ComplexLimit comparison, Real tolerance replay, zero-contour sealing, Holomorphic handoff, transport, replay, provenance, and local naming for BEDC.Derived.MoreraTheoremUp.

Chapter 8367

A Concrete Naming Certificate for BishopCompletionUniquenessPrinciple$^{\uparrow}$

Following Bishop and Bridges constructive completion theory, the BishopCompletionUniquenessPrinciple$^{\uparrow}$ packet records the textbook uniqueness principle for completion presentations as finite BEDC NameCert data. It sits after the criterion surface of chapter 3404, the located uniqueness boundary of chapter 7277, the regular Cauchy completion uniqueness route of chapter 1782, and the regular Cauchy representative uniqueness route of chapter 3390. The packet gives L10 Real and Completion consumers one finite uniqueness surface; it does not assert quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient Real$^{\uparrow}$ completeness.

Definition 8367.1 (Bishop completion uniqueness principle carrier)**.** *A* BishopCompletionUniquenessPrinciple$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (B, L, C, R, S, Q, D, E, H, K, P, N)$$

with the following displayed rows:

1. *B is the* BishopCompletionCriterion$^{\uparrow}$ *row exposing the completion-admission criterion before any uniqueness read is available.*
2. *L is the* LocatedCompletionUniqueness$^{\uparrow}$ *row recording the located uniqueness comparison for the same displayed completion source.*
3. *C is the* RegularCauchyCompletionUniqueness$^{\uparrow}$ *row recording the regular Cauchy completion uniqueness route.*
4. *R is the* RegularCauchyUniqueness$^{\uparrow}$ *row comparing representative regular Cauchy names before the terminal seal is consumed.*
5. *S is the paired* StreamName$^{\uparrow}$ *finite-window row inspected by the criterion and both uniqueness routes.*
6. *Q is the paired* RegSeqRat$^{\uparrow}$ *regular rational readback row extracted from those finite windows.*
7. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used by the displayed comparison routes.*
8. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after B, L, C, R, S, Q, D have been displayed.*

9. *H records componentwise* hsame *transport for the criterion, located uniqueness, regular completion uniqueness, representative uniqueness, window, readback, tolerance, seal, continuation, provenance, and local naming rows.*
10. *K records displayed* Cont *replay from a completion uniqueness request back through B, L, C, R, S, Q, D, E.*
11. *P is the* Pkg *provenance over* $\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}$, $\mathsf{BishopCompletionCriterion}^{\uparrow}$, $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}}$ *row naming the displayed principle and its permitted completion consumers.*

The classifier compares accepted carriers only through these rows and their replay paths. It has no coordinate for quotient completion equality, selected limits, countable choice, host equality, proof-irrelevant representative collapse, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8367.2 (Bishop completion uniqueness principle NameCert obligations)**.** *For every accepted* $\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}$ *carrier*

$$U = (B, L, C, R, S, Q, D, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}}$ *surface consists exactly of criterion admission through B, located uniqueness exposure through L, regular Cauchy completion uniqueness exposure through C, representative regular Cauchy uniqueness exposure through R, finite StreamName window admission through S, RegSeqRat readback through Q, DyadicRatCore tolerance comparison through D, Real seal nonescape through E, componentwise hsame transport through H, displayed Cont replay through K, Pkg provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8367.1. The analytic rows are exactly B, L, C, R, S, Q, D, E, and the structural rows are H, K, P, N.

The completion-admission criterion is read first. Row B supplies the Bishop completion criterion, so a uniqueness-facing consumer cannot enter the completion boundary without the displayed finite criterion surface.

The uniqueness comparison is then forced through the three displayed sibling routes. Row L supplies located completion uniqueness, row C supplies regular Cauchy completion uniqueness, and row R supplies regular Cauchy representative uniqueness over the same finite source.

The finite source rows bind those sibling routes to concrete data. Rows S, Q, D expose the StreamName windows, RegSeqRat readback, and DyadicRatCore tolerance ledger used by the criterion and the uniqueness comparisons before the terminal Real seal E is available.

Finally H, K, P, N transport, replay, source, and name the same route. Since the excluded quotient, selection, host-equality, choice, representative-collapse, and ambient-completeness objects have no carrier coordinate, none can be exported by the local NameCert surface. □

Theorem 8367.3 (Bishop completion uniqueness principle finite route)**.** *Every completion-facing uniqueness read exported by an accepted* $\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}$ *carrier factors through the ordered finite route*

$$\mathsf{BishopCompletionCriterion}^{\uparrow},\ \mathsf{LocatedCompletionUniqueness}^{\uparrow},\ \mathsf{RegularCauchyCompletionUniqueness}^{\uparrow},\ \mathsf{RegularCauchyU}$$

Thus the L10 Real and Completion consumer receives uniqueness only as a displayed NameCert route through the completion criterion, located uniqueness, regular Cauchy completion uniqueness, representative uniqueness, finite windows, regular rational readback, and dyadic tolerance data.

Proof. Use Definition 8367.2 to identify the complete local obligation surface. Any exported uniqueness read must consume B, L, C, R, S, Q, D before the seal row E is visible.

The first four rows bind the principle to existing completion uniqueness packets. The criterion row B admits the completion-facing read, while L, C, R record the located, regular completion, and representative uniqueness routes over the same displayed source.

The finite source rows prevent escape from the displayed route. Rows S, Q, D expose the finite windows, regular rational readback, and dyadic tolerance ledger used by the sibling uniqueness routes.

The terminal rows add no new analytic object. Row E is only a Real seal, and H, K, P, N only transport, replay, source, and name the route, so the exported read cannot become quotient completion equality, a selected limit, countable choice, host equality, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}$ uniqueness read must expose $\mathsf{BishopCompletionCriterion}^{\uparrow}$, $\mathsf{LocatedCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyCompletionUniqueness}^{\uparrow}$, $\mathsf{RegularCauchyUniqueness}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, a terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: bishopcompletioncriterion, locatedcompletionuniqueness, regularcauchycompletionuniqueness, regularcauchyuniqueness, streamname, regseqrat, dyadicratcore, real: BishopCompletionUnic is not bijective to any listed sibling because it jointly carries the completion criterion, located uniqueness, regular completion uniqueness, representative uniqueness, finite windows, regular rational readback, dyadic tolerance ledger, Real seal, transport, replay, provenance, and local naming while refusing quotient completion equality and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}$ packet is generated from a BishopCompletionCriterion row, LocatedCompletionUniqueness row, RegularCauchyCompletionUniqueness row, RegularCauchyUniqueness row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance ledger, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8367.1, Definition 8367.2, and Definition 8367.3 seed the finite L10 completion uniqueness principle over BishopCompletionCriterion, LocatedCompletionUniqueness, RegularCauchyCompletionUniqueness, RegularCauchyUniqueness, StreamName, RegSeqRat, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCompletionUniquenessPrinciple}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completion equality, selected limits, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, sibling uniqueness exposure, finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance comparison, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 8368

A Concrete Naming Certificate for MetaCICCandidateResidualJoinBudget$^{\uparrow}$

The MetaCICCandidateResidualJoinBudget$^{\uparrow}$ packet realizes the finite candidate-residual join-budget branch of chapter 9378. It sits between the parallel-diamond frontier of chapter 4238, the confluence audit packet of chapter 735, and the residual-substitution boundary of chapter 2181. The packet records typed residual windows, candidate join budgets, closed-shape guards, obstruction retention, TasteGate-facing instance requirements, transport, replay, provenance, and local naming before a confluence-facing consumer may read a local join attempt.

Definition 8368.1 (MetaCIC candidate residual join budget carrier)**.** *A* MetaCICCandidateResidualJoinBudget$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (T, R, B, Q, D, O, I, H, C, P, N)$$

with the following displayed rows:

1. *T is the typed-window row, naming the closed or shape-limited MetaCIC source window being inspected.*
2. *R is the residual-substitution row, recording the residual frontier that remains visible before a candidate join can be consumed.*
3. *B is the finite budget row, recording unary fuel, inspected critical-pair identifiers, and the local residual-join search bound.*
4. *Q is the candidate-join row, naming the displayed common-reduct attempt and its budgeted replay trace.*
5. *D is the closed-shape guard row, separating the admitted closed-normal or bounded-shape branch from the unclosed residual-substitution boundary.*
6. *O is the obstruction row, retaining any missing residual-substitution compatibility, parallel-diamond input, or closed-confluence premise as visible data.*
7. *I is the TasteGate instance row, stating that Lean-side gate discharge must provide* Nontrivial *and* FieldFaithful *instances for the candidate residual-budget surface.*
8. *H records componentwise* hsame *transport for typed-window, residual-substitution, budget, candidate-join, guard, obstruction, instance, provenance, and naming rows.*

9. *C records displayed* Cont *replay from typed-window admission through residual inspection, budgeted candidate join, obstruction retention, and the instance row.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose displayed residual window, budget, candidate join, guard, obstruction, instance, transport, replay, provenance, and naming rows agree componentwise. It has no coordinate for global confluence, unrestricted residual-substitution compatibility, subject reduction, quotient syntax equality, evaluator equality, or a hidden join oracle.

Theorem 8368.2 (MetaCIC candidate residual join budget NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$ *carrier* $J = (T, R, B, Q, D, O, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}}$ *surface consists exactly of typed-window exposure through T, residual-substitution exposure through R, finite budget exposure through B, candidate-join exposure through Q, closed-shape guard exposure through D, obstruction retention through O, TasteGate instance disclosure through I, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8368.1. The confluence-facing rows are T, R, B, Q, D, O, I, and the structural rows are H, C, P, N.

The typed-window row T and residual-substitution row R are read before the finite budget B and candidate join Q. Thus a local join attempt remains attached to the residual frontier named by the confluence audit map.

The guard row D and obstruction row O then keep the closed-shape branch separate from missing substitution-compatibility and parallel-diamond inputs. The instance row I records the Nontrivial and FieldFaithful requirements that a Lean TasteGate must discharge before the packet can be promoted beyond a candidate budget.

Finally H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate exports global confluence, subject reduction, quotient syntax equality, evaluator equality, or a hidden join oracle, the listed rows exhaust the local NameCert surface. □

Theorem 8368.3 (MetaCIC candidate residual join budget non-escape)**.** *Every confluence-facing consumer of an accepted* $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$ *packet receives the finite route*

$$T, R, B, Q, D, O, I, H, C, P, N.$$

The route may be handed to $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, $\mathsf{MetaCICConfluenceAuditPacket}^{\uparrow}$, *and* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$ *consumers only as candidate residual-join budget evidence with the obstruction row still visible. It cannot be repacked as full confluence, subject reduction, unrestricted residual-substitution compatibility, quotient syntax equality, or evaluator equality.*

Proof. Start with the NameCert obligations of Definition 8368.2. They expose the typed window, residual frontier, finite budget, candidate join, guard, obstruction, instance row, and structural rows as one packet.

The candidate row Q is downstream of both the residual row R and budget row B. Therefore a consumer sees a budgeted join attempt, not an unrestricted common-reduct theorem.

The obstruction row O is transported and replayed together with D and I. Hence the handoff to the parallel-diamond frontier, confluence audit packet, or residual-substitution boundary preserves the missing-premise boundary and the TasteGate instance requirements. □

Falsifiable prediction: Any $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$ consumer that exports a candidate join while omitting the residual-substitution row, budget row, obstruction row, or Nontrivial and FieldFaithful TasteGate instance requirements is rejected by the local classifier.

Independence witness: Nearest siblings: MetaCICParallelDiamondFrontier, MetaCICConfluenceAuditPacket, MetaCICResidualSubstitutionBoundary. The packet is not bijective to any sibling because it binds typed residual windows, finite candidate-join budgets, closed-shape guards, obstruction retention, TasteGate instance requirements, transport, replay, provenance, and local naming into one confluence-audit object.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$ packet is generated from typed-window rows, residual-substitution rows, finite budget rows, candidate-join rows, closed-shape guards, obstruction rows, TasteGate instance requirements, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8368.1, Definition 8368.2, and Definition 8368.3 seed the finite candidate residual-join budget route for the MetaCIC confluence audit map.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, full confluence, subject reduction, unrestricted residual-substitution compatibility, quotient syntax equality, evaluator equality, or hidden join selection for $\mathsf{MetaCICCandidateResidualJoinBudget}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, typed-window exposure, residual-substitution exposure, budget replay, candidate-join admission, closed-shape guard retention, obstruction retention, TasteGate instance disclosure, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICCandidateResidualJoinBudgetUp.

Chapter 8369

A Concrete Naming Certificate for MetaCICAuditSynthesisRouter$^{\uparrow}$

The MetaCICAuditSynthesisRouter$^{\uparrow}$ packet realizes the audit-synthesis route of section 9376.7 as one finite router over subject-reduction, confluence, normalization, substitution, decidability, blocker, and open-input rows. It sits beside the audit-synthesis packet of chapter 776, the critical-path packet of chapter 765, the confluence audit packet of chapter 735, the normalization frontier of chapter 892, and the discharge-obligation ledger of chapter 717. The router names a finite audit handoff; it preserves the open-input boundary instead of claiming subject reduction, confluence, normalization, decidability, closed consistency, quotient syntax equality, evaluator soundness, or MetaCIC kernel consistency.

Definition 8369.1 (MetaCIC audit-synthesis router carrier)**.** *A* MetaCICAuditSynthesisRouter$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (S, C, N, U, D, B, O, K, F, H, T, P, L)$$

with the following displayed rows:

1. *S is the subject-reduction route row, recording the obstruction boundary and the discharge rows that remain required before closed subject reduction could be consumed.*
2. *C is the confluence route row, recording the conditional confluence audit surface, critical-pair rows, local-join rows, and retained residual-substitution premises.*
3. *N is the normalization route row, recording candidate-mediated strong-normalization evidence, bounded normal endpoints, and the normal-frontier handoff.*
4. *U is the substitution route row, recording closed-substitution, binder-budget, residual, and open-input side conditions that must remain visible to the router.*
5. *D is the decidability route row, recording bounded conversion, typed-checker, and finite observation data without turning them into global decidability.*
6. *B is the blocker row, recording the closed-normal branch, the subject-reduction obstruction, and the consistency boundary that prevents the route from becoming a closed consistency theorem.*
7. *O is the open-input row, recording inputs, premises, sockets, and side conditions that are intentionally not discharged by the router.*

8. *K is the critical-path row, read through* $\mathsf{MetaCICCriticalPath}^{\uparrow}$ *as the source ledger tying the preceding rows to the MetaCIC audit-synthesis route.*
9. *F is the field-faithfulness readiness row, recording that future TasteGate work must keep $S, C, N, U, D, B, O, K, H$ as separate carrier fields.*
10. *H records componentwise* hsame *transport for every route row, the critical-path row, field-faithfulness readiness, replay, provenance, and local naming.*
11. *T records displayed* Cont *replay from the audit-synthesis request through the seven route rows, the critical-path source, the open-input boundary, and the local name.*
12. *P is the* Pkg *provenance over the audit-synthesis packet, critical-path packet, confluence audit packet, normalization frontier, discharge-obligation ledger,* BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
13. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}}$ *row.*

The classifier compares accepted routers only through $S, C, N, U, D, B, O, K, F, H, T, P, L$. It has no coordinate for premise-free subject reduction, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, quotient syntax equality, host evaluator soundness, closed consistency, or MetaCIC kernel consistency.

Theorem 8369.2 (MetaCIC audit-synthesis router obligations)**.** *For every accepted* $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ *carrier*

$$R = (S, C, N, U, D, B, O, K, F, H, T, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}}$ *surface consists exactly of subject-reduction route exposure, confluence route exposure, normalization route exposure, substitution route exposure, decidability route exposure, blocker retention, open-input retention, critical-path sourcing, field-faithfulness readiness, componentwise transport, displayed replay, provenance, local naming, and non-escape from premise-free subject reduction, unrestricted Church–Rosser, candidate-free normalization, global beta-conversion decidability, quotient syntax equality, host evaluator soundness, closed consistency, and MetaCIC kernel consistency.*

Proof. Project the carrier of Definition 8369.1. The route rows S, C, N, U, D expose the five audit families separately, so the router has no coordinate that merges their conclusions into one theorem.

The blocker and open-input rows are then read as boundaries. Row B keeps the closed-normal branch and subject-reduction obstruction visible, while O records the sockets and premises that remain outside the router.

The critical-path row K sources the route without discharging those boundaries. The field-faithfulness readiness row F records that future TasteGate evidence must preserve every displayed field rather than ignore a route coordinate.

Finally, H, T, P, L transport, replay, source, and name the same finite packet. Since no row supplies premise-free subject reduction, unrestricted Church–Rosser, candidate-free normalization, global decidability, quotient equality, evaluator soundness, closed consistency, or kernel consistency, the listed rows exhaust the local certificate surface. □

Theorem 8369.3 (MetaCIC audit-synthesis router non-escape)**.** *Every consumer of an accepted* $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ *packet must read the finite route*

$$S, C, N, U, D \longmapsto B, O, K, F \longmapsto H, T, P, L.$$

The resulting handoff may coordinate subject-reduction, confluence, normalization, substitution, decidability, blocker, and open-input rows as audit data, but it cannot export subject reduction, confluence, normalization, decidability, closed consistency, quotient syntax equality, evaluator soundness, or MetaCIC kernel consistency as closed theorems.

Proof. Begin with the NameCert obligations of Definition 8369.2. They place every public read downstream of the five route rows S, C, N, U, D.

The blocker and open-input rows are not optional. A consumer that omits B loses the closed-normal and subject-reduction obstruction boundary, and a consumer that omits O loses the premises and sockets that the route intentionally leaves open.

The critical-path and field-faithfulness rows keep the handoff source-local. Row K points back to the displayed MetaCIC critical path, while F records the future requirement that no classifier may ignore one of the displayed fields.

Thus the structural rows H, T, P, L can only replay the finite audit-synthesis router. They cannot create any of the closed theorem endpoints excluded by the carrier. □

Falsifiable prediction: A purported $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ read is refuted if it exports subject reduction, confluence, normalization, decidability, closed consistency, quotient syntax equality, evaluator soundness, or MetaCIC kernel consistency without displaying the subject-reduction, confluence, normalization, substitution, decidability, blocker, open-input, critical-path, transport, replay, provenance, and local naming rows.

Independence witness: metacicauditsynthesispacket, metaciccriticalpath, metacicconfluenceauditpacket, metacicnormalizationfrontier, metacicdischargeobligationledger: none is bijective to $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ because this packet jointly carries subject-reduction, confluence, normalization, substitution, decidability, blocker, open-input, critical-path, field-faithfulness readiness, transport, replay, provenance, and local NameCert rows.

The Lean TasteGate follow-up for $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ must provide explicit Nontrivial MetaCICAuditS and FieldFaithful $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ instances. These instances must preserve $S, C, N, U, D, B, O, K, F,$ as separate fields before any checked carrier-alignment theorem can serve as a public gate.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}$ packet is generated from subject-reduction, confluence, normalization, substitution, decidability, blocker, open-input, critical-path, field-faithfulness readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8369.1, Definition 8369.2, and Definition 8369.3 seed the finite MetaCIC audit-synthesis router and its open-input non-escape boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICAuditSynthesisRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, unrestricted confluence, candidate-free normalization, global beta-conversion decidability, quotient syntax equality, evaluator soundness, closed consistency, Lean verification, bridge checking, or MetaCIC kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, seven-row audit route exposure, blocker retention, open-input retention, critical-path sourcing, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICAuditSynthesisRouterUp.

Chapter 8370

A Concrete Naming Certificate for $\mathsf{SchurDecomposition}^{\uparrow}$

Following Schur and standard finite-dimensional spectral theory, the $\mathsf{SchurDecomposition}^{\uparrow}$ packet records the finite route by which a displayed square matrix is read through a unitary change-of-basis ledger, an upper-triangular row, and a diagonal spectral readback. It consumes the matrix carrier of chapter 49, the linear-map surface of chapter 48, the inner-product rows of chapter 86, the unitary-row discipline of chapter 219, and the real-spectrum boundary of chapter 3816. The packet names only finite matrix, unitary, triangular, spectral, transport, replay, provenance, and local NameCert data; it does not import host diagonalization, quotient matrix equality, a selected eigenbasis outside the displayed rows, or ambient spectral theory.

Definition 8370.1 (Schur decomposition carrier)**.** *A* $\mathsf{SchurDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (A, F, U, T, \Delta, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the source square-matrix row, read through* $\mathsf{Mat}^{\uparrow}$ *and the underlying* $\mathsf{LinMap}^{\uparrow}$ *action surface.*
2. *F is the scalar-field or complex-real spectrum boundary row, exposing the finite scalar readback interface used by the diagonal entries.*
3. *U is the unitary change-of-basis ledger, read through* $\mathsf{InnerProduct}^{\uparrow}$ *and* $\mathsf{UnitaryGroup}^{\uparrow}$*.*
4. *T is the upper-triangular matrix ledger obtained after the displayed unitary change of basis.*
5. *Δ is the diagonal spectral readback row, listing the diagonal scalar reads of T through the spectrum boundary F.*
6. *E is the residual triangular exactness row saying that the displayed source matrix is replayed by the U, T route and that no off-ledger remainder is exported.*
7. *H records componentwise* hsame *transport for the source matrix, scalar boundary, unitary ledger, triangular ledger, diagonal readback, exactness row, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the source matrix through the scalar boundary, unitary change of basis, triangular ledger, diagonal spectral readback, and residual exactness row.*
9. *P is the* Pkg *provenance over* $\mathsf{SchurDecomposition}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{UnitaryGroup}^{\uparrow}$*,* $\mathsf{RealSpectrum}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{SchurDecomposition}^{\uparrow}}$ *row.*

The classifier accepts only packets displaying all ten rows. It has no coordinate for a host eigenbasis, quotient matrix equality, normal diagonalization, selected spectral ordering outside Δ, or an ambient theorem asserting that every host matrix has been decomposed.

Theorem 8370.2 (Schur decomposition NameCert obligations)**.** *For every accepted* $\mathsf{SchurDecomposition}^{\uparrow}$ *carrier*

$$D = (A, F, U, T, \Delta, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SchurDecomposition}^{\uparrow}}$ *surface consists exactly of source matrix admission for A, scalar or spectrum-boundary admission for F, unitary-ledger admission for U, upper-triangular ledger admission for T, diagonal spectral readback for Δ, residual triangular exactness for E, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through P, and local naming through N.*

No Schur decomposition obligation is stored outside these rows.

Proof. Project the accepted carrier. The source row A is the only matrix being named, and F is the only scalar or spectrum boundary through which diagonal entries may be read.

The unitary and triangular data are displayed separately. The ledger U records the change-of-basis route, while T records the upper-triangular matrix obtained on that route.

The diagonal readback Δ and exactness row E then tie the spectrum-facing entries and triangular residual to the same replay path. The support rows H, C, P, N transport, replay, source, and name this finite route, so the listed rows exhaust the local NameCert obligations. □

Theorem 8370.3 (Schur decomposition unitary triangular handoff)**.** *Every finite-dimensional spectral, matrix-factorization, or linear-map consumer of an accepted* $\mathsf{SchurDecomposition}^{\uparrow}$ *carrier must first read*

$$A, F, U, T, \Delta, E, H, C, P, N.$$

The unitary handoff is visible only through U after the source matrix row A and scalar boundary F have been displayed, and the triangular handoff is visible only through T, Δ, E after that unitary ledger has been read. The handoff exports no host eigenbasis, quotient matrix equality, unrestricted diagonalization theorem, or selected ordering of spectrum entries outside the displayed diagonal ledger.

Proof. Start from an accepted carrier. The consumer first reads A and F, so the matrix and scalar boundary are fixed before any change-of-basis row is available.

The unitary row U then supplies the displayed change-of-basis ledger. Since the carrier has no other change-of-basis coordinate, any spectral or factorization consumer must pass through this ledger.

Finally T, Δ, E expose the upper-triangular matrix, the diagonal spectral readback, and the residual exactness row on the same route. Transport, replay, provenance, and local naming through H, C, P, N preserve the route and add no host-level diagonalization or quotient equality. □

Theorem 8370.4 (Schur decomposition spectrum non-escape)**.** *Every spectrum-boundary read from an accepted* $\mathsf{SchurDecomposition}^{\uparrow}$ *carrier factors through the displayed diagonal ledger Δ and the residual triangular exactness row E after the source matrix, scalar boundary, unitary ledger, and upper-triangular ledger have already been read. A consumer cannot detach a diagonal entry from $A, F, U, T, \Delta, E, H, C, P, N$ and treat it as an ambient host eigenvalue, a quotient representative, or a hidden spectral selector.*

Proof. Read the carrier rows in order. The diagonal spectral ledger Δ appears only after the source matrix, scalar boundary, unitary ledger, and upper-triangular ledger have been displayed.

The exactness row E keeps the diagonal readback attached to the residual triangular route. It does not provide a second spectral interface or a host eigenvalue selector.

The structural rows H, C, P, N preserve that same finite route. Hence every spectrum-facing consumer remains inside the displayed packet and cannot obtain quotient representatives, hidden eigenvalue choices, or an ambient spectral theorem from the carrier. □

Lean4 (statement) `BEDC.Derived.SchurDecompositionUp`

Closure status for $\mathsf{NameCert}_{\mathsf{SchurDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{SchurDecomposition}^{\uparrow}$ packet is generated from a source MatrixUp row, scalar or RealSpectrumUp boundary, unitary change-of-basis ledger, upper-triangular matrix ledger, diagonal spectral readback, residual exactness row, hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SchurDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8370.1, Definition 8370.2, Definition 8370.3, and Definition 8370.4 seed the finite Schur decomposition packet over matrix, linear-map, inner-product, unitary, spectrum, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SchurDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host diagonalization, quotient matrix equality, selected eigenbasis construction, spectral ordering outside the displayed ledger, or ambient finite-dimensional spectral theory.

Upgrade path: Obligation closure requires checked source-matrix admission, scalar-boundary admission, unitary-ledger exactness, triangular-ledger exactness, diagonal spectral readback, residual non-escape, transport stability, replay stability, and NameCert obligations for BEDC.Derived.SchurDecompositionUp.

Chapter 8371

A Concrete Naming Certificate for $\mathsf{IntegralTest}^{\uparrow}$

Following Hardy's treatment of convergence tests and the Bishop–Bridges constructive reading of monotone real functions, the $\mathsf{IntegralTest}^{\uparrow}$ packet records the textbook integral test as finite NameCert data for Real and Completion consumers. It sits beside the narrower $\mathsf{CauchyIntegralTest}^{\uparrow}$ route of chapter 2259, the source-series surface of chapter 1581, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names the finite comparison route from a nonnegative decreasing tail to a convergence handoff; it does not choose an improper integral value, select an infinite sum, quotient partial-sum streams, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8371.1 (IntegralTest carrier)**.** *An* $\mathsf{IntegralTest}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, F, W, D, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RealSeries}^{\uparrow}$ *source row, exposing the inspected nonnegative tail only through finite partial-sum windows.*
2. *F is the monotone real-function comparison row, recording the decreasing majorant or minorant data used by the integral test.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row for the series tail and the matching integral cells.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for endpoint, mesh, and tail-budget comparisons.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed tail windows and dyadic tolerances.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached from Q and from no independent completed-sum coordinate.*
7. *H records componentwise* hsame *transport for the source series, comparison function, windows, dyadic budgets, readback, and seal.*
8. *C records displayed* Cont *replay for the same comparison route.*
9. *P is the* Pkg *provenance over* $\mathsf{IntegralTest}^{\uparrow}$, $\mathsf{CauchyIntegralTest}^{\uparrow}$, $\mathsf{RealSeries}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{IntegralTest}^{\uparrow}}$ *row.*

The carrier has no coordinate for a selected improper integral, a host infinite sum, quotient equality of series names, countable choice, trichotomy, or ambient completeness.

Theorem 8371.2 (IntegralTest NameCert obligations)**.** *For every accepted* $\mathsf{IntegralTest}^{\uparrow}$ *carrier* $I = (S, F, W, D, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{IntegralTest}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet,* $\mathsf{RealSeries}^{\uparrow}$ *source exposure through* S*, monotone comparison exposure through* F*, finite* $\mathsf{StreamName}^{\uparrow}$ *tail-window exposure through* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure through* D*,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through* Q*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The rows of Definition 8371.1 are precisely the series source, monotone comparison function, finite windows, dyadic tolerances, regular readback, terminal seal, transport, replay, provenance, and local naming rows.

The comparison part is finite: S exposes only inspected series tails, F exposes only the monotone comparison data, W names the windows, and D names the dyadic budgets. The readback row Q is therefore downstream of displayed tail and integral-cell data.

The terminal row E can then be read only after Q has been exposed. The structural rows H, C, P, N transport, replay, source, and name the same route, so the local certificate contains exactly the listed obligations and no host summation or ambient completeness row. □

Theorem 8371.3 (IntegralTest Cauchy series handoff)**.** *Every accepted* $\mathsf{IntegralTest}^{\uparrow}$ *carrier hands convergence evidence to Real and Completion consumers only through the displayed route*

$$\mathsf{RealSeries}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{CauchyIntegralTest}^{\uparrow}$ *sibling supplies the narrower Cauchy-tail comparison corridor, while* $\mathsf{IntegralTest}^{\uparrow}$ *keeps the general textbook comparison surface visible as its own finite carrier. The handoff exports no selected infinite sum, selected improper integral, quotient stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the carrier rows. The source series row S and comparison row F are not endpoint seals; they only expose finite tail and monotone comparison data.

Use Definition 8371.2. It places W, D, Q, E after the source and comparison rows, so every endpoint-facing read must pass through finite windows, dyadic budgets, and regular rational readback before the Real seal is visible.

The $\mathsf{CauchyIntegralTest}^{\uparrow}$ route is a compatible sibling because it supplies the Cauchy-tail corridor for the same kind of integral comparison. This chapter keeps the broader $\mathsf{IntegralTest}^{\uparrow}$ carrier distinct: the provenance row cites the sibling but the route is still exhausted by $S, F, W, D, Q, E, H, C, P, N$.

Since no carrier coordinate stores a selected sum, improper integral value, quotient stream equality, choice schedule, or ambient completeness principle, none can be exported by the handoff. □

Falsifiable prediction: An accepted $\mathsf{IntegralTest}^{\uparrow}$ packet that reaches a $\mathsf{Real}^{\uparrow}$ seal without first exposing the $\mathsf{RealSeries}^{\uparrow}$ source row, monotone comparison row, finite $\mathsf{StreamName}^{\uparrow}$ window row, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, and $\mathsf{RegSeqRat}^{\uparrow}$ readback refutes the carrier surface.

Independence witness: cauchy-integral-test, realseries, regseqrat, dyadicratcore, real: no listed sibling supplies the whole packet $I = (S, F, W, D, Q, E, H, C, P, N)$, because each sibling contributes only a Cauchy-tail corridor, source-series row, regular readback, dyadic tolerance ledger, or terminal seal while this chapter binds them into one integral-test NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{IntegralTest}^{\uparrow}}$.

Constructive story: An $\mathsf{IntegralTest}^{\uparrow}$ packet is generated from a RealSeriesUp source row, a monotone comparison-function row, finite StreamNameUp windows, a DyadicRatCore tolerance ledger, RegSeqRatUp readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntegralTest}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8371.1, Definition 8371.2, and Definition 8371.3 seed the finite integral-test carrier, local NameCert obligations, and Cauchy-series handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntegralTest}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected improper integrals, selected infinite sums, quotient series equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, monotone comparison exposure, finite-window exposure, dyadic tolerance confinement, regular readback, terminal seal scope, transport, replay, provenance, and local naming for BEDC.Derived.IntegralTestUp.

Chapter 8372

A Concrete Naming Certificate for $\mathsf{FiniteSelectionCorrespondence}^{\uparrow}$

Following Berge and Aliprantis–Border on finite correspondences and measurable selection language, the $\mathsf{FiniteSelectionCorrespondence}^{\uparrow}$ packet records only finite displayed selection rows. It sits beside the metric source of chapter 57, the compact metric ledger of chapter 129, the set-like membership surface of chapter 3668, the finite transport-plan route of chapter 5197, and the distribution ledger of chapter 186. The packet is a finite correspondence interface; it does not export a global selector, countable choice, measurable-selection theorem, optimizer, or ambient completion.

Definition 8372.1 (Finite selection correspondence carrier)**.** *A* $\mathsf{FiniteSelectionCorrespondence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, K, S, W, R, D, H, C, P, N)$$

with the following visible rows:

1. *M is the displayed* $\mathsf{Met}^{\uparrow}$ *source row;*
2. *K is an optional* $\mathsf{CompactMetric}^{\uparrow}$ *finite-support or finite-net ledger read by compact consumers;*
3. *S is the* $\mathsf{SetLike}^{\uparrow}$ *graph row listing finite source points and finite admissible value rows;*
4. *W is the displayed selection-window table, whose entries are finite pairs already present in S;*
5. *R is the readback row consumed by finite* $\mathsf{Wasserstein}^{\uparrow}$ *and* $\mathsf{Distribution}^{\uparrow}$ *interfaces;*
6. *D is the refusal ledger recording that no global selector, countable-choice schedule, optimizer, or measurable-selection theorem is exported;*
7. *H records componentwise* hsame *transport for the metric, compact, graph, window, readback, refusal, provenance, and naming rows;*
8. *C records displayed* Cont *replay from graph rows to finite windows and from windows to downstream finite consumers;*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteSelectionCorrespondence}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{Wasserstein}^{\uparrow}$, $\mathsf{Distribution}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSelectionCorrespondence}^{\uparrow}}$ *row.*

The classifier compares accepted packets componentwise by hsame *on these rows.*

Lean4 (statement) `BEDC.Derived.FiniteSelectionCorrespondenceUp`

Theorem 8372.2 (Finite selection correspondence obligation surface)**.** *For every accepted* FiniteSelectionCorrespon*carrier* $F = (M, K, S, W, R, D, H, C, P, N)$*, the local obligation surface consists exactly of the displayed metric source, compact-support ledger, set-like graph row, finite selection windows, downstream readback row, refusal ledger, componentwise transport, replay, provenance, and local naming rows. Any finite transport, compact metric, or distribution consumer must read* S *and* W *before consuming* R*, and* D *remains visible on every route, so no choice principle or selected global function is exported.*

Proof. Project the carrier of Definition 8372.1. The only admissible correspondence data are the finite graph row S and the finite selection-window table W over the displayed metric source M and optional compact row K.

The downstream readback row R is attached to those finite rows. A Wasserstein$^{\uparrow}$ or Distribution$^{\uparrow}$ consumer may therefore receive a finite support or finite provenance route, but it must receive it through the listed S, W, R coordinates rather than through a hidden selector.

Finally read the structural rows. The componentwise hsame row H, the displayed Cont replay row C, the Pkg provenance P, and the local NameCert row N preserve the same finite route, while D records the refusal of global selection, countable choice, optimizer extraction, and measurable-selection principles. Hence the displayed rows exhaust the finite selection correspondence obligation surface. □

Falsifiable prediction: An accepted FiniteSelectionCorrespondence$^{\uparrow}$ consumer that reads a selected value without first exposing the finite graph row S and finite selection window W, or that exports a global selector after reading D, is outside the carrier surface.

Independence witness: metric, compactmetric, setlike, wasserstein, distribution: no listed sibling supplies the joint finite correspondence packet with displayed metric source, compact-support ledger, set-like graph row, finite selection windows, transport and distribution readback, refusal ledger, componentwise transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{FiniteSelectionCorrespondence}^{\uparrow}}$**.**

Theory closure: TheoryGate(NameCert$_{\text{FiniteSelectionCorrespondence}^{\uparrow}}$, seed)

Scope closed: Definition 8372.1 and Definition 8372.2 seed the finite displayed correspondence interface over Metric, CompactMetric, SetLike, Wasserstein, Distribution, transport, replay, provenance, and local NameCert rows.

Constructive story: A FiniteSelectionCorrespondence$^{\uparrow}$ packet is generated from a displayed Metric source row, optional CompactMetric finite-support row, SetLike graph row, finite selection-window table, downstream readback row, refusal ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Formal verification: FormalStatus(NameCert$_{\text{FiniteSelectionCorrespondence}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.FiniteSelectionCorrespondenceUp`

Bridge status: none

Not claimed: This chapter does not close global selectors, measurable selection, optimizer existence, countable choice, ambient measure completion, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite graph-window exhaustion, downstream readback preservation, refusal-ledger nonescape, Nontrivial, and FieldFaithful instances for BEDC.Derived.FiniteSelectionCorrespondenceUp.

Chapter 8373

A Concrete Naming Certificate for $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$

Following Bishop and Bridges-style completion discipline, the $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$ packet records a separated Cauchy completion as displayed regular rational names with an explicit separation seal. It sits after the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the completion interface of chapter 95, the separated-completion surface of chapter 1612, and the terminal real-name seal of chapter 38. The packet is quotient-free: equality is read through displayed regular windows and separation evidence rather than through an ambient quotient of Cauchy streams.

Definition 8373.1 (SeparatedCauchyCompletion carrier)**.** *A* $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (R, W, D, C, E, Q, H, T, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row for the regular rational Cauchy name.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which consumers inspect R.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for window comparison and separation tests.*
4. *C is the* $\mathsf{Completion}^{\uparrow}$ *handoff row recording that the displayed name is completion-facing.*
5. *E is the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *seal that turns zero-distance comparison into displayed sameness without quotienting streams.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row reached only through R, W, D, C, E.*
7. *H records componentwise* hsame *transport for the regular name, schedule, dyadic ledger, completion row, separated seal, and real readback.*
8. *T records displayed* Cont *replay for the same finite route.*
9. *P is the* Pkg *provenance over* $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Completion}^{\uparrow}$, $\mathsf{SeparatedCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletion}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient class of Cauchy streams, a selected host limit, countable choice, trichotomy, or ambient completeness outside the displayed route.

Theorem 8373.2 (SeparatedCauchyCompletion NameCert obligations)**.** *For every accepted* SeparatedCauchyComp *carrier* $S = (R, W, D, C, E, Q, H, T, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, regular rational source exposure through* R*, finite* $\mathsf{StreamName}^{\uparrow}$ *window exposure through* W*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure through* D*, completion handoff through* C*, separated-completion sealing through* E*, terminal* $\mathsf{Real}^{\uparrow}$ *readback through* Q*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* T*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The displayed rows of Definition 8373.1 are precisely the regular rational source, finite window schedule, dyadic tolerance ledger, completion handoff, separated seal, real readback, transport, replay, provenance, and local naming rows.

The separation step is finite because it can only read the windows named by W and the dyadic tolerances recorded in D. The completion row C therefore receives a regular rational name together with its explicit tolerance route, not an ambient quotient object.

The separated seal E is downstream of that route, and Q can be read only after E has been exposed. The structural rows H, T, P, N preserve the same route under transport, replay, sourcing, and naming, so the local certificate contains exactly the listed obligations. □

Theorem 8373.3 (SeparatedCauchyCompletion regular-sequence scope)**.** *Every completion-facing consumer of an accepted* $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Completion}^{\uparrow} \longmapsto \mathsf{SeparatedCompletion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *row supplies the displayed regular name, the* $\mathsf{StreamName}^{\uparrow}$ *row supplies finite windows, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row supplies comparison tolerances, the* $\mathsf{Completion}^{\uparrow}$ *row records the completion-facing handoff, the* $\mathsf{SeparatedCompletion}^{\uparrow}$ *row records the separation seal, and the* $\mathsf{Real}^{\uparrow}$ *row is the only terminal readback. The route exports no quotient stream, selected host limit, countable-choice schedule, trichotomy, or ambient completeness theorem.*

Proof. Begin with the carrier rows. The source row R and window row W expose only finite pieces of the regular rational name, while D records the dyadic comparisons available at those windows.

Use Definition 8373.2. It places the completion handoff C after R, W, D and the separated seal E after the completion-facing data, so a consumer cannot reach the Real readback before the displayed separation evidence is visible.

Finally read Q through the structural rows H, T, P, N. Since the carrier has no coordinate for quotient streams, selected host limits, countable choice, trichotomy, or ambient completeness, the regular-sequence scope is exhausted by the displayed route. □

Falsifiable prediction: An accepted $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$ packet whose $\mathsf{Real}^{\uparrow}$ readback is consumed without exposing the $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ finite windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, $\mathsf{Completion}^{\uparrow}$ handoff, and $\mathsf{SeparatedCompletion}^{\uparrow}$ seal refutes the carrier surface.

Independence witness: regseqrat, streamname, dyadicratcore, completion, separatedcompletion, real: no listed sibling supplies the whole packet $S = (R, W, D, C, E, Q, H, T, P, N)$, because each sibling contributes only a regular name, finite windows, dyadic tolerances, completion handoff, separation seal, or terminal real readback while this chapter binds them into one quotient-free NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SeparatedCauchyCompletion}^{\uparrow}$ packet is generated from a RegSeqRatUp source row, StreamNameUp finite windows, a DyadicRatCore tolerance ledger, a CompletionUp handoff, a SeparatedCompletionUp seal, a

RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SeparatedCauchyCompletion}\uparrow}$, seed)

Scope closed: Definition 8373.1, Definition 8373.2, and Definition 8373.3 seed the quotient-free separated Cauchy completion carrier, local NameCert obligations, and regular-sequence consumer scope.

Formal verification: FormalStatus(NameCert$_{\mathsf{SeparatedCauchyCompletion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, countable choice, trichotomy, ambient RealUp completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, regular rational source exposure, finite-window exposure, dyadic tolerance confinement, completion handoff, separated seal scope, Real readback, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCauchyCompletionUp.

Chapter 8374

A Concrete Naming Certificate for CompactCoverOrderBound$^{\uparrow}$

Following the constructive Heine–Cantor cover discipline, the CompactCoverOrderBound$^{\uparrow}$ packet records a finite overlap bound for the compact-uniform-continuity route. It sits beside the compact source certificate of chapter 60, the uniform-continuity carrier of chapter 388, the finite star-refinement route of chapter 6997, the mesh-chain cover route of chapter 7769, the local-modulus nerve of chapter 8353, and the tolerance-only handoff of chapter 369. The packet names bounded-overlap cover rows before a uniform modulus is read; it does not choose an optimal cover, a least Lebesgue number, or an ambient compactness principle.

Definition 8374.1 (CompactCoverOrderBound carrier)**.** *A* CompactCoverOrderBound$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, C, S, M, B, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the* Compact$^{\uparrow}$ *source row exposing the finite cover only through displayed compact data.*
2. *C is the finite cover row, read as bundled centers, radii, or cells rather than as an ambient open-cover object.*
3. *S is the star-refinement and mesh-chain row that records which cover cells may meet after refinement.*
4. *M is the pointwise local-modulus row consumed by compact-uniform-continuity arguments.*
5. *B is the finite cover-order bound row: for each displayed cell, it lists the finite family of neighboring cells allowed to overlap it.*
6. *U is the downstream* UniformModulus$^{\uparrow}$ *handoff row reached through the bound B and the local-modulus row M.*
7. *H records componentwise* hsame *transport for the compact source, cover, refinement, local-modulus, bound, and uniform-modulus rows.*
8. *T records displayed* Cont *replay for the same finite cover-order route.*
9. *P is the* Pkg *provenance over* CompactCoverOrderBound$^{\uparrow}$, Compact$^{\uparrow}$, CompactUniformContinuity$^{\uparrow}$, FiniteCoverStarRefinementModulus$^{\uparrow}$, FiniteCoverMeshChain$^{\uparrow}$, CompactUniformLocalModulusNerve$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{CompactCoverOrderBound}^{\uparrow}}$ *row.*
The carrier has no coordinate for an optimal subcover, a least Lebesgue number, an infinite locally finite family, countable choice, or an external compactness oracle.

Theorem 8374.2 (CompactCoverOrderBound NameCert obligations)**.** *For every accepted* CompactCoverOrderBou *carrier $O = (K, C, S, M, B, U, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactCoverOrderBound}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, compact source exposure through K, finite cover exposure through C, star-refinement and mesh-chain exposure through S, local-modulus exposure through M, finite cover-order bound exposure through B, uniform-modulus handoff through U, componentwise* hsame *transport through H, displayed* Cont *replay through T, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows of Definition 8374.1 are precisely the compact source, finite cover, refinement mesh, local-modulus, order-bound, uniform-modulus, transport, replay, provenance, and naming rows.

The cover-order row is finite because B records only the displayed neighboring cells allowed by C and S. No proof step ranges over an arbitrary open cover or over an infinite locally finite family.

The uniform-modulus handoff U is downstream of the local-modulus row M and the finite overlap bound B. The structural rows H, T, P, N preserve the same bounded-overlap route, so the local certificate contains exactly the listed obligations. □

Theorem 8374.3 (CompactCoverOrderBound uniform-modulus scope)**.** *Every uniform-modulus consumer of an accepted* $\mathsf{CompactCoverOrderBound}^{\uparrow}$ *carrier reads the finite route*

$$\mathsf{Compact}^{\uparrow} \longmapsto \mathsf{FiniteCoverStarRefinementModulus}^{\uparrow} \longmapsto \mathsf{FiniteCoverMeshChain}^{\uparrow} \longmapsto \mathsf{CompactUniformLocalModulusNe}$$

The cover-order bound row B is consumed before the $\mathsf{UniformModulus}^{\uparrow}$ *handoff U, and it confines the handoff to bounded-overlap finite cover rows. The route exports no optimal cover, least Lebesgue number, infinite cover selection, countable-choice schedule, or external compactness oracle.*

Proof. Begin with the compact source row K and the finite cover row C. These rows expose a displayed finite family, not an arbitrary open-cover quantifier.

Use Definition 8374.2. The obligation surface places the star-refinement row S, local-modulus row M, and cover-order bound row B before any uniform-modulus read is available.

Finally read U through H, T, P, N. The transport and replay rows preserve the same finite neighboring-cell list, while provenance and naming keep the route tied to the displayed carrier. Since no other cover-selection coordinate exists, the uniform-modulus scope is exactly the bounded-overlap finite cover route. □

Falsifiable prediction: An accepted $\mathsf{CompactCoverOrderBound}^{\uparrow}$ packet whose $\mathsf{UniformModulus}^{\uparrow}$ handoff is consumed without first exposing the finite cover row, star-refinement row, local-modulus row, and cover-order bound row refutes the carrier surface.

Independence witness: compact, compactuniformcontinuity, finite-cover-star-refinement-modulus, finite-cover-mesh-chain, compact-uniform-local-modulus-nerve, uniformmodulus: no listed sibling supplies the whole packet $O = (K, C, S, M, B, U, H, T, P, N)$, because each sibling contributes only compact source data, a uniform-continuity route, star-refinement data, mesh-chain data, local-modulus nerve data, or terminal uniform-modulus handoff while this chapter binds them into one bounded-overlap NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactCoverOrderBound}^{\uparrow}}$.

Constructive story: A CompactCoverOrderBound$^{\uparrow}$ packet is generated from a CompactUp source row, finite cover rows, star-refinement and mesh-chain rows, a local-modulus row, a finite cover-order bound row, a UniformModulusUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactCoverOrderBound}^{\uparrow}}$, seed)

Scope closed: Definition 8374.1, Definition 8374.2, and Definition 8374.3 seed the bounded-overlap finite cover carrier, local NameCert obligations, and uniform-modulus consumer scope.

Formal verification: FormalStatus(NameCert$_{\text{CompactCoverOrderBound}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close optimal finite covers, least Lebesgue numbers, infinite cover selection, countable choice, ambient compactness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact source exposure, finite cover exposure, refinement exposure, local-modulus exposure, cover-order bound confinement, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactCoverOrderBoundUp.

Chapter 8375

A Concrete Naming Certificate for $\mathsf{DyadicCutStability}^{\uparrow}$

Bishop-style located cut stability asks that a located lower-and-upper cut presentation remain stable when finite dyadic tolerance rows, regular rational readback, and the terminal real-name seal are replayed through the same certificate surface. The $\mathsf{DyadicCutStability}^{\uparrow}$ packet records that stability as finite BEDC data. It sits after the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the Dedekind real carrier of chapter 3629, and the located cut real carrier of chapter 3773. The packet names a stability route for displayed cuts; it does not assert Dedekind completeness, quotient equality of real names, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8375.1 (Dyadic cut stability carrier)**.** *A* $\mathsf{DyadicCutStability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, D, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *L is the rounded lower-cut row, recording finite lower witnesses and the rounded-lower readback used by a located cut consumer.*
2. *U is the rounded upper-cut row, recording finite upper witnesses and the rounded-upper readback used by the same consumer.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback row, storing dyadic width requests, comparison windows, and the finite tolerance ledger linking L and U.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *witness row, translating the dyadic ledger into regular rational observations before the real seal is exposed.*
5. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after L, U, D, Q have been displayed.*
6. *H stores componentwise* hsame *transport for the rounded lower cut, rounded upper cut, dyadic ledger, regular-rational witness, real seal, replay, provenance, and local naming rows.*
7. *C stores displayed* Cont *replay from located-cut inspection through L, U, D, Q, R, H.*
8. *P is the* Pkg *provenance over* $\mathsf{DyadicCutStability}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DedekindReal}^{\uparrow}$, $\mathsf{LocatedCutReal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicCutStability}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, D, Q, R, H, C, P, N$. It has no coordinate for a host Dedekind supremum, quotient equality of real names, a selected cut representative, trichotomy, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8375.2 (Dyadic cut stability NameCert obligations)**.** *For an accepted* $\mathsf{DyadicCutStability}^{\uparrow}$ *packet $S = (L, U, D, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{DyadicCutStability}^{\uparrow}}$ *obligations are exhausted by rounded lower-cut exposure through L, rounded upper-cut exposure through U,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and readback through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *witness readback through Q,* $\mathsf{Real}^{\uparrow}$ *sealing through R, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8375.1. The accepted packet displays exactly the lower cut, upper cut, dyadic tolerance, regular rational witness, real seal, transport, replay, provenance, and naming rows.

Read the cut rows first. The lower and upper rows are rounded before the dyadic tolerance row is consumed, so a located-cut consumer receives both sides of the cut as finite data rather than as a detached real equality claim.

Next use D, Q, R. The dyadic ledger records the finite comparison windows, the regular rational row reads those windows as regular observations, and the real seal is reached only after those rows have been displayed.

Finally apply H, C, P, N. These rows preserve and replay the same packet under componentwise transport, package the cited sibling chapters, and expose the local name. Since the carrier has no further coordinate, the listed rows exhaust the local $\mathsf{NameCert}$ obligations. □

Theorem 8375.3 (Dyadic cut stability transport)**.** *Every* $\mathsf{DyadicCutStability}^{\uparrow}$ *transport read preserves the rounded lower-cut row L, rounded upper-cut row U, dyadic tolerance row D, regular rational witness row Q, real seal row R, componentwise* hsame *row H, displayed* Cont *replay row C, provenance row P, and local* $\mathsf{NameCert}$ *row N before any located-cut consumer reads stability. The transport exports no Dedekind completeness theorem, quotient real equality, trichotomy, selected representative, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with the NameCert obligations of Definition 8375.2. They force every accepted read to display $L, U, D, Q, R, H, C, P, N$ before the local name is consumed.

Use the sibling route recorded in P. The dyadic tolerance core supplies D, the regular rational chapter supplies Q, the real chapter supplies R, and the Dedekind and located-cut chapters supply the cut-facing provenance for L and U.

Transport is then componentwise through H and replayed through C. These rows can preserve the displayed lower and upper cut data together with their dyadic and regular-rational readback, but they cannot create a new coordinate for a host completion or quotient equality.

Thus every located-cut stability consumer reads the same finite packet before it reaches the stability conclusion. The excluded completeness, equality, trichotomy, representative, choice, and ambient real-completion claims are not carrier rows. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCutStability}^{\uparrow}$ read that omits a rounded lower cut, rounded upper cut, dyadic tolerance ledger, RegSeqRat witness, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, or local NameCert row is outside the carrier surface.

Independence witness: dyadicratcore, regseqrat, real, dedekind-real, located-cut-real: none is bijective to DyadicCutStabilityUp because the packet jointly carries rounded lower and upper

cut rows, dyadic tolerance/readback, regular rational witness, Real seal, hsame transport, Cont replay, Pkg provenance, and one local NameCert row while refusing quotient equality and ambient completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCutStability}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCutStability}^{\uparrow}$ packet is generated from rounded lower-cut rows, rounded upper-cut rows, DyadicRatCore tolerance and readback rows, RegSeqRat witness rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCutStability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8375.1, Definition 8375.2, and Definition 8375.3 seed the finite located-cut stability route over DyadicRatCore, RegSeqRat, Real, Dedekind real, located cut real, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCutStability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Lean verification, bridge checking, Dedekind completeness, quotient equality of real names, trichotomy, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked rounded lower-cut exposure, rounded upper-cut exposure, DyadicRatCore tolerance/readback, RegSeqRat witness readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.DyadicCutStabilityUp.

Chapter 8376

A Concrete Naming Certificate for $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$

Following Bishop and Bridges constructive completion theory and the Kelley presentation of completion as a reflective boundary, the $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$ packet records the finite retraction surface from displayed Cauchy-completion data back to regular Cauchy real names. It sits after the completion retraction packet of chapter 1921, the finite name windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names only a finite NameCert retraction route; it does not assert quotient completion, selected representatives, countable choice, host equality of completed objects, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8376.1 (Regular Cauchy completion retraction carrier)**.** *A* $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, W, S, D, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ *source row, exposing the completion-facing retraction request before any regular readback is consumed.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the retraction.*
3. *S is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the finite regularity and comparison budgets.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, W, S, D have been displayed.*
6. *H records componentwise* hsame *transport for the retraction row, windows, readback, dyadic ledger, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a completion-facing read back through K, W, S, D, E.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$, $\mathsf{CauchyCompletionRetraction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows and their replay paths. It has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8376.2 (Regular Cauchy completion retraction NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$ *carrier*

$$T = (K, W, S, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}}$ *surface consists exactly of completion-retraction admission through* K*, finite StreamName window exposure through* W*, RegSeqRat readback through* S*, DyadicRatCore tolerance comparison through* D*, Real seal nonescape through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8376.1. The analytic rows are exactly K, W, S, D, E, while H, C, P, N transport, replay, source, and name that same finite packet.

The retraction row is read first. Row K supplies the completion-facing retraction request, but it is not a quotient-completion equality or a selected representative.

The regular source rows then control the readback. Rows W, S, D expose finite stream windows, regular rational data, and dyadic tolerance budgets before the terminal seal row E is available.

Finally H, C, P, N preserve the same route. Since the excluded quotient, representative, choice, host-equality, and ambient-completeness objects have no carrier coordinate, none can become a local NameCert obligation. □

Theorem 8376.3 (Regular Cauchy completion retraction Real seal route)**.** *Every accepted* RegularCauchyCompletic *completion-facing read reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed route*

$$\mathsf{CauchyCompletionRetraction}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus a Real or Completion consumer reads the retraction as finite regular-Cauchy NameCert data through $K, W, S, D, E, H, C, P, N$*, not as quotient completion, a selected representative, countable choice, host equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with Definition 8376.2. It places every exported retraction read inside the rows $K, W, S, D, E, H, C, P, N$.

The source row K attaches the route to chapter 1921. The window and readback rows W, S attach it to the finite StreamName and RegSeqRat surfaces of chapter 126 and chapter 301.

The dyadic ledger D supplies the finite tolerance comparison used before the terminal seal E is consumed. The structural rows only transport, replay, source, and name that route.

Therefore every accepted consumer reaches $\mathsf{Real}^{\uparrow}$ through the displayed regular-Cauchy surface and cannot replace it by quotient completion equality, selected representatives, countable choice, host equality, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}$ packet that exposes a terminal $\mathsf{Real}^{\uparrow}$ seal without first displaying the $\mathsf{CauchyCompletionRetraction}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, and $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger refutes the carrier surface.

Independence witness: cauchy-completion-retraction, streamname, regseqrat, dyadicratcore, real: no listed sibling supplies the whole finite packet $T = (K, W, S, D, E, H, C, P, N)$, because each sibling contributes only the retraction request, finite windows, regular readback, tolerance comparison, or terminal seal while this chapter binds them into one regular-Cauchy completion retraction surface.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompletionRetraction}^{\uparrow}}$**.**

Constructive story: A RegularCauchyCompletionRetraction$^{\uparrow}$ packet is generated from a CauchyCompletionRetraction source row, StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance comparison, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompletionRetraction}^{\uparrow}}$, seed)

Scope closed: Definition 8376.1, Definition 8376.2, and Definition 8376.3 seed the finite retraction route from Cauchy completion data to regular Cauchy real-name data.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompletionRetraction}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host equality of completed objects, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-retraction admission, finite-window exposure, regular readback, dyadic tolerance comparison, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompletionRetractionUp.

Chapter 8377

A Concrete Naming Certificate for $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and explicit tail estimates, the $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ packet records the finite ledger used when a fixed tail-window budget is reparametrized before regular rational readback. It sits beside the finite schedules of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the cofinal reindexing route of chapter 6960, the tail-map route of chapter 7209, and the subsequence surface of chapter 381. The packet names only a fixed finite tail-window reparametrization ledger; it is not quotient stream equality, not a selected subsequence choice, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8377.1 (Regular Cauchy tail reparametrization carrier)**.** *A* $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, W, M, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *window row naming the finite regular-Cauchy observations available before the reparametrization is read.*
2. *W is the target tail-window row. It records the finite target tail budget and the source tail window to which the current request is sent.*
3. *M is the monotone finite reparametrization ledger. It records the displayed order comparisons and target-to-source request map for the fixed window W.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the precision budget, slack conversions, and tail-window comparison data used by M.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after S, W, M, D have been displayed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the regular rational readback has consumed the fixed reparametrized tail window.*
7. *H records componentwise* hsame *transport for the source window, target tail-window, monotone ledger, dyadic tolerance row, readback row, Real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tail precision request through W, then M, then S, then D, R, E.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegularCauchyReindexing}^{\uparrow}$, $\mathsf{CofinalReindexing}^{\uparrow}$, $\mathsf{RegularCauchySubsequence}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyTailReparametrization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected subsequence choice, trichotomy of reals, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8377.2 (Regular Cauchy tail reparametrization NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ *carrier*

$$T = (S, W, M, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyTailReparametrization}^{\uparrow}}$ *surface consists exactly of carrier admission for the source* $\mathsf{StreamName}^{\uparrow}$ *window, target tail-window, monotone finite reparametrization ledger,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. The obligations require every readback request to pass through the fixed target tail-window and its monotone finite ledger before any dyadic tolerance, regular rational value, or Real seal is consumed.*

Proof. Project the carrier of Definition 8377.1. The rows S, W, M, D, R, E are the complete analytic route, while H, C, P, N only transport, replay, source, and name that route.

The target tail-window W is fixed before the reparametrization ledger is read. The row M supplies the finite monotone target-to-source request map for that window, so the packet does not choose a subsequence or appeal to a global cofinal selector.

After W and M have fixed the inspected source window, the dyadic tolerance row D supplies the precision budget for the regular rational readback R. The terminal seal E is downstream of the same displayed data, so no quotient stream equality, selected subsequence choice, trichotomy, host equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness row can be exported. □

Theorem 8377.3 (Regular Cauchy tail reparametrization fixed-window route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ *carrier factors through the finite route*

$$W \longmapsto M \longmapsto S \longmapsto D \longmapsto R \longmapsto E.$$

The route is a fixed tail-window specialization of the sibling reindexing and subsequence packets: it keeps the source $\mathsf{StreamName}^{\uparrow}$ *window, target tail-window, finite monotone ledger, dyadic tolerance row, regular rational readback, and terminal Real seal visible. It exports no quotient stream equality, selected subsequence choice, trichotomy, host real equality, countable-choice row, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a consumer of the seal row E. The NameCert obligations of Definition 8377.2 place E after R, and place R after the source window S, dyadic tolerance row D, target tail-window W, and monotone finite ledger M.

The sibling chapters identify the surrounding interfaces. The $\mathsf{RegularCauchyReindexing}^{\uparrow}$ and $\mathsf{CofinalReindexing}^{\uparrow}$ routes expose cofinal reindexing data, while $\mathsf{RegularCauchySubsequence}^{\uparrow}$ exposes subsequence-facing monotone-cofinal data. This packet uses only the fixed-window part of that surface, so it has no coordinate from which a selected subsequence or quotient stream equality could be read.

The structural rows H, C, P, N preserve the same finite route. Therefore every Real-facing read factors through the displayed ledger and stops at the terminal seal without adding trichotomy, host equality, countable choice, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ seal without reading $W, M, S, D, R, E, H, C, P, N$ refutes the fixed tail-window carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-reindexing, cofinal-reindexing, regular-cauchy-subsequence: no listed sibling supplies the joint packet containing one source StreamName window, one fixed target tail-window, one monotone finite reparametrization ledger, one dyadic tolerance row, one RegSeqRat readback, one Real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyTailReparametrization}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyTailReparametrization}^{\uparrow}$ packet is generated from a source StreamName window, a target tail-window, a monotone finite reparametrization ledger, a DyadicRatCore tolerance row, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailReparametrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8377.1, Definition 8377.2, and Definition 8377.3 seed the fixed tail-window reparametrization route from displayed StreamName windows through dyadic tolerance and RegSeqRat readback to the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyTailReparametrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected subsequence choice, trichotomy, host real equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fixed target tail-window exposure, monotone finite ledger stability, dyadic tolerance exactness, RegSeqRat readback ordering, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyTailReparametrizationUp.

Chapter 8378

A Concrete Naming Certificate for $\mathsf{SturmSeparation}^{\uparrow}$

Following Sturm and Coddington–Levinson on zero separation for scalar second-order equations, the $\mathsf{SturmSeparation}^{\uparrow}$ packet records the finite BEDC surface by which two displayed solution-window rows witness alternating zero windows before any global solution theorem is used. It sits beside the real-name boundary of chapter 38, the regular rational readback of chapter 301, the dyadic arithmetic ledger of chapter 291, the local ODE source of chapter 193, the interval carrier of chapter 56, and the continuous-map handoff of chapter 130. It also consumes the Sturm sequence, comparison, and root-count siblings of chapter 2079, chapter 2338, and chapter 3612. The packet names separation data as displayed rows only; it is not global ODE completeness, a selected classical solution curve, quotient real equality, sign trichotomy, or hidden choice.

Definition 8378.1 (Sturm separation carrier)**.** *A* $\mathsf{SturmSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (O, I, F, G, Z, A, B, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the* $\mathsf{Ode}^{\uparrow}$ *source row for the scalar second-order equation and its local solution-window request.*
2. *I is the* $\mathsf{Interval}^{\uparrow}$ *row naming the inspected compact interval and its left, middle, and right subwindows.*
3. *F and G are two* $\mathsf{ContinuousMap}^{\uparrow}$ *solution-observation rows over the interval window.*
4. *Z is the zero-window ledger, recording the displayed zeros of F and the adjacent zero-search windows for G.*
5. *A is the alternation ledger, recording which G zero-window is read between adjacent F zero-windows and which F zero-window is read between adjacent G zero-windows.*
6. *B is the* $\mathsf{SturmComparison}^{\uparrow}$ *coefficient and comparison handoff row.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and tolerance ledger for the zero windows and comparison inequalities.*
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint, coefficient, and solution-observation windows.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after $O, I, F, G, Z, A, B, D, R$ are displayed.*
10. *H records componentwise* hsame *transport for the ODE, interval, solution rows, zero ledgers, comparison rows, dyadic ledger, readback, seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a separation request through the ODE source, interval window, solution observations, zero ledgers, comparison handoff, dyadic and regular readbacks, and Real seal.*
12. *P is the* Pkg *provenance over* $\mathsf{SturmSeparation}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{Interval}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{SturmSequence}^{\uparrow}$, $\mathsf{SturmComparison}^{\uparrow}$, $\mathsf{SturmRootCount}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{SturmSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for global ODE completeness, host solution equality, excluded-middle sign trichotomy, quotient real equality, or a selected classical solution curve.

Theorem 8378.2 (Sturm separation NameCert obligations)**.** *For every accepted* $\mathsf{SturmSeparation}^{\uparrow}$ *carrier*

$$S = (O, I, F, G, Z, A, B, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SturmSeparation}^{\uparrow}}$ *surface consists exactly of carrier admission, ODE-source exposure, interval-window exposure, two continuous solution-observation rows, zero-window exposure, alternation-ledger exposure, Sturm comparison handoff, dyadic endpoint and tolerance accounting, regular rational readback, terminal Real sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8378.1. The rows O, I, F, G are the only displayed source rows, so a separation read cannot inspect a host solution space before the local ODE, interval, and continuous-map observations are opened.

Read the zero data through Z and the alternation data through A. These rows record finite adjacent windows rather than an ambient zero set or a trichotomy oracle.

Use the Sturm comparison handoff row B together with the dyadic and regular readback rows D, R. They place coefficient comparisons, endpoint tolerances, and solution observations on the same finite windows before the terminal seal E is available.

Finally H, C, P, N transport, replay, source, and name the same packet. Since no displayed coordinate names global completeness, host solution equality, quotient real equality, hidden choice, or selected classical curves, those objects are not local NameCert obligations. □

Theorem 8378.3 (Sturm separation zero interlacing route)**.** *Every accepted* $\mathsf{SturmSeparation}^{\uparrow}$ *zero-interlacing read factors through the displayed route*

$$O, I, F, G \longmapsto Z, A \longmapsto B, D, R \longmapsto E \longmapsto H, C, P, N.$$

The route exposes one local ODE source, one inspected interval, two continuous solution-observation rows, finite zero-window and alternation ledgers, the Sturm comparison handoff, dyadic endpoint accounting, regular rational readback, a terminal Real seal, transport, replay, provenance, and local naming. It exports no global ODE completeness theorem, selected solution curve, quotient real equality, sign trichotomy, or hidden choice principle.

Proof. Start with a consumer of zero separation. The ODE source row O and interval row I must be displayed before any solution observation is read, and the two solution rows F, G are available only as $\mathsf{ContinuousMap}^{\uparrow}$ observations over that interval.

The zero-window ledger Z then names the inspected adjacent windows. The alternation ledger A records the finite interlacing claim by pointing from each displayed zero-window of one solution row to the displayed search window of the other.

Apply the Sturm comparison handoff B with the dyadic and regular readback rows D, R. This binds coefficient comparisons, endpoint tolerances, and solution-window readbacks to the same finite route before the $\mathsf{Real}^{\uparrow}$ seal E is readable.

The structural rows H, C, P, N preserve and name that route. Hence every accepted zero-interlacing read is the finite packet above, with no appeal to global completeness, selected solution curves, quotient real equality, sign trichotomy, or hidden choice. □

Falsifiable prediction: An accepted $\mathsf{SturmSeparation}^{\uparrow}$ consumer that reads zero separation without first displaying $O, I, F, G, Z, A, B, D, R, E, H, C, P, N$ refutes the carrier surface.

Independence witness: real, regseqrat, dyadicratcore, ode, interval, continuousmap, sturmsequence, sturmcomparison, sturmrootcount: no listed sibling supplies the joint packet containing one ODE source, one interval window, two continuous solution-observation rows, zero-window and alternation ledgers, Sturm comparison handoff, dyadic endpoint accounting, regular rational readback, Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{SturmSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{SturmSeparation}^{\uparrow}$ packet is generated from an OdeUp source row, an IntervalUp window, two ContinuousMap solution-observation rows, zero-window and alternation ledgers, a SturmComparison handoff, DyadicRatCore endpoint accounting, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SturmSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8378.1, Definition 8378.2, and Definition 8378.3 seed the finite zero-interlacing route for displayed scalar ODE solution windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SturmSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close classical global ODE completeness, selected solution curves, quotient real equality, sign trichotomy, hidden choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ODE and interval exposure, continuous solution-window exposure, zero-window exactness, alternation-ledger exactness, Sturm comparison handoff, dyadic and regular readback discipline, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.SturmSeparationUp.

Chapter 8379

A Concrete Naming Certificate for MetaCICSubjectReductionResidualFence$^{\uparrow}$

The MetaCICSubjectReductionResidualFence$^{\uparrow}$ packet realizes the dependent-codomain obstruction frontier of chapter 9377 as finite discharge, residual, normalization-frontier, obstruction-retention, transport, replay, provenance, and local naming rows. It consumes the obstruction-retention row of chapter 731 and the normalization-frontier rows of chapter 892 before any subject-reduction consumer can read the fence; it remains adjacent to the discharge route of chapter 718, the closed application argument-stability boundary of chapter 6177, and the beta-substitution preservation packet of chapter 716. The packet names the residual fence that remains after the independent-codomain application case has been separated from the dependent-codomain counterexample; it does not claim closed subject reduction, discharge any of the four hypotheses, or hide the obstruction boundary.

Definition 8379.1 (MetaCIC subject-reduction residual fence carrier)**.** *A* MetaCICSubjectReductionResidualFence$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (D, R, K, O, T, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the discharge-interface row, naming the four simultaneous subject-reduction obligations* BetaSubstitutionPreservation*,* AppArgTypeStable*,* LamDomainSubjectReduction*, and* PiDomainSubjectRedu
2. *R is the residual dependent-codomain row, retaining the application-argument reduction case where substituting the reduct into the codomain changes the displayed result type.*
3. *K is the candidate-normalization frontier row, recording the closed-normal and candidate evidence that remains usable without converting the residual fence into a subject-reduction theorem.*
4. *O is the obstruction-retention row, carrying the checked dependent-codomain counterexample and the unavailable closed subject-reduction statement as visible boundary data.*
5. *T is the transport row from closed application argument stability, beta-substitution preservation, subject-reduction discharge, and normalization-frontier siblings into this fence.*
6. *Q is the replay row, recording the finite route from the obstruction map through candidate normalization and back to the four-obligation discharge interface.*
7. *H records componentwise* hsame *transport for the discharge, residual, candidate-normalization, obstruction, transport, replay, provenance, and naming rows.*

8. *C records displayed* Cont *replay for the fence route.*
9. *P is the* Pkg *provenance over* MetaCICSubjectReductionResidualFence$^{\uparrow}$, SubjectReductionDischarge$^{\uparrow}$, BetaSubstitutionPreservation$^{\uparrow}$, MetaCICNormalizationFrontier$^{\uparrow}$, ClosedAppArgumentStability$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}}$ *row.*

The classifier accepts exactly packets whose residual fence, obstruction-retention row, transport route, replay route, provenance, and local naming agree componentwise. It has no coordinate for unconditional closed subject reduction, a discharged dependent-codomain theorem, quotient syntax equality, hidden normalization, or a silent proof of any missing discharge row.

Theorem 8379.2 (MetaCIC subject-reduction residual fence NameCert obligations)**.** *For every accepted* MetaCICSubjectReductionResidualFence$^{\uparrow}$ *carrier*

$$F = (D, R, K, O, T, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}}$ *surface consists exactly of four-obligation discharge exposure through D, dependent-codomain residual exposure through R, candidate-normalization frontier exposure through K, obstruction retention through O, sibling transport through T, replay through Q, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8379.1. The rows D, R, K, O are the only mathematical rows available before transport and replay are read, so a consumer cannot extract closed subject reduction from the packet.

Read the residual row R against the obstruction row O. The residual row retains the dependent-codomain application boundary, while O keeps the checked counterexample and the unavailable closed statement visible.

Read the candidate-normalization row K and transport row T. They allow the already checked normalization-side evidence and sibling discharge routes to be cited only as finite rows, not as replacements for the four simultaneous discharge obligations.

Finally Q, H, C, P, N replay, transport, source, and name the same fence. Since no carrier coordinate discharges the missing hypotheses or erases the obstruction, the listed rows exhaust the local NameCert obligations. □

Theorem 8379.3 (MetaCIC subject-reduction residual fence non-escape)**.** *Every subject-reduction consumer of an accepted* MetaCICSubjectReductionResidualFence$^{\uparrow}$ *packet receives the finite route*

$$D, R, K, O, T, Q, H, C, P, N.$$

The route may cite subjectreductiondischarge, metacic-subject-reduction-obstruction, metacic-normalization-frontier, closed-app-argument-stability, and betasubstitutionpreservation only as displayed rows. It cannot be consumed as an unconditional subject-reduction theorem, a closed dependent-codomain preservation proof, a completed candidate-normalization proof of subject reduction, or an erased obstruction boundary.

Proof. Start with the discharge row D. It names the four simultaneous inputs consumed by the parameterised subject-reduction theorem and does not identify them with one another.

The residual and obstruction rows R, O are then read together. They retain the dependent-codomain counterexample and prevent the independent-codomain application case from being treated as the full application-argument congruence discharge.

Use the candidate-normalization and transport rows K, T. These rows connect the fence to the normalization frontier, closed application argument-stability boundary, beta-substitution preservation packet, and subject-reduction discharge route, while keeping every cited object as a finite row.

The replay and structural rows Q, H, C, P, N preserve that same packet. Thus the accepted consumer receives a residual fence, not a hidden proof of closed subject reduction. □

Theorem 8379.4 (MetaCIC residual fence sibling route)**.** *Any residual-fence read of an accepted* $\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ *packet that reaches the audit-synthesis rows of chapter 776 must first pass through the subject-reduction boundary of chapter 721. The route remains local to the fence: it records the order in which audit-synthesis data may be consumed, and it does not assert closed subject reduction, dependent-codomain preservation, candidate normalization as a preservation theorem, or discharge of the four simultaneous hypotheses.*

Proof. Project the accepted fence carrier $F = (D, R, K, O, T, Q, H, C, P, N)$. The residual row R and obstruction-retention row O are visible before any audit-synthesis consumer can read the replay row.

Read the subject-reduction boundary sibling first. The boundary chapter supplies the finite place where the subject-reduction obstruction is exposed as boundary data rather than as a completed theorem, so the fence can hand R, O to downstream audit rows only after that boundary is visible.

Then read the audit-synthesis packet. Its rows may summarize the surrounding MetaCIC audit surface, but within this fence they are consumed through T, Q, H, C, P, N as transport, replay, provenance, and naming data for the same residual route.

Thus a consumer reaching audit-synthesis data has already passed through the subject-reduction boundary. Since no carrier coordinate erases R, O or discharges D, the route remains a local dependency route rather than a proof of subject reduction. □

Falsifiable prediction: A MetaCIC consumer that reads $\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ as closed subject reduction while omitting any of subjectreductiondischarge, metacic-subject-reduction-obstruction, metacic-normalization-frontier, closed-app-argument-stability, or betasubstitutionpreservation refutes the residual-fence classifier.

Independence witness: subjectreductiondischarge, metacic-subject-reduction-obstruction, metacic-normalization-frontier, closed-app-argument-stability, betasubstitutionpreservation: no listed sibling is bijective to $\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ because this packet jointly carries discharge, residual, candidate-normalization, obstruction-retention, transport, replay, provenance, and local naming rows.

The paired Lean surface for this packet must provide $\mathsf{Nontrivial}\ \mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ instances in a `TasteGate.lean` file before any verified TasteGate route can be claimed.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}$ packet is generated from a four-obligation discharge row, a dependent-codomain residual row, a candidate-normalization frontier row, an obstruction-retention row, sibling transport, replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8379.1, Definition 8379.2, and Definition 8379.3 seed the finite residual-fence route for the dependent-codomain subject-reduction obstruction.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICSubjectReductionResidualFence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, any of the four discharge obligations, dependent-codomain preservation, candidate normalization as a preservation theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, four-obligation discharge exposure, residual-row retention, candidate-normalization frontier exposure, obstruction retention, transport, replay, provenance, local naming, and Lean TasteGate Nontrivial and FieldFaithful instances for BEDC.Derived.MetaCICSubjectReductionResidualFenceUp.

Chapter 8380

A Concrete Naming Certificate for $\mathsf{AsymptoticCompactness}^{\uparrow}$

Following Hale and Temam, the $\mathsf{AsymptoticCompactness}^{\uparrow}$ packet records the dynamical compactness condition that long-time tails of a dissipative evolution admit compact finite-window capture. In BEDC form it consumes the dynamical-system certificate of chapter 195, the metric certificate of chapter 57, the compactness certificate of chapter 60, and the stream-window naming surface of chapter 126. The packet is a finite NameCert carrier for tail capture; it is not an ambient compactness theorem for the whole phase space and not a hidden choice principle for selecting convergent subsequences.

Definition 8380.1 (Asymptotic compactness packet carrier)**.** *An* $\mathsf{AsymptoticCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (D, M, K, S, T, W, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DynSystem}^{\uparrow}$ *flow row whose long-time orbit tail is being read;*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *phase-distance row used to compare tail windows;*
3. *K is the* $\mathsf{Compact}^{\uparrow}$ *candidate capture row for the selected finite tail window;*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule naming the finite sequence of requested tail times;*
5. *T is the absorbing-tail row, recording that all sufficiently late windows selected by S are routed into the compact candidate row K;*
6. *W is the finite-window attractor ledger, storing the compact capture window, its metric tolerance rows, and the associated dynamical endpoints;*
7. *H records componentwise* hsame *transport for the dynamical, metric, compact, stream, tail, and window rows;*
8. *C records displayed* Cont *replay from an orbit-tail request through D, M, K, S, T, W, H;*
9. *P is the* Pkg *provenance over* $\mathsf{DynSystem}^{\uparrow}$*,* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{Compact}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{AsymptoticCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, M, K, S, T, W, H, C, P, N$. It has no coordinate for a compact whole phase space, a selected limit point, a host-level sequential compactness principle, or a global attractor object outside the displayed finite ledger.

Theorem 8380.2 (Asymptotic compactness absorbing tail carrier)**.** *Every accepted* $\mathsf{AsymptoticCompactness}^{\uparrow}$ *carrier exposes an absorbing-tail row T before any compact read is consumed. Concretely, a downstream consumer may read the compact row K only as a capture surface for tail windows selected by the stream schedule S and produced by the dynamical row D under the metric row M. Thus the carrier records finite tail capture rather than compactness of the entire phase carrier.*

Theorem 8380.3 (Asymptotic compactness finite-window attractor ledger)**.** *For every accepted* $\mathsf{AsymptoticCompactness}^{\uparrow}$ *carrier*

$$A = (D, M, K, S, T, W, H, C, P, N),$$

the finite-window attractor ledger W is exhausted by the compact capture row K, the stream-selected tail windows from S, the dynamical endpoints produced by D, the metric tolerance comparisons from M, and the structural rows H, C, P, N. Agreement on those rows cannot be repacked as a selected limit, a full global attractor, a compact phase-space certificate, or a choice-backed subsequence selector.

Theorem 8380.4 (Asymptotic compactness NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{AsymptoticCompactness}^{\uparrow}}$ *obligation surface consists exactly of carrier admission for $D, M, K, S, T, W, H, C, P, N$, classifier transport through the displayed* hsame *rows, continuation replay through C, provenance through P, absorbing-tail exposure through T, finite-window attractor ledger exposure through W, and local naming through N. No consumer-visible row claims a selected orbit limit, a compact ambient phase space, or a global attractor outside the finite BEDC packet.*

Independence witness: dynsystem, metric, compact, streamname: none is bijective to $\mathsf{AsymptoticCompactness}^{\uparrow}$ because this packet jointly carries dynamical flow rows, metric tolerance rows, compact capture rows, stream-selected tail windows, absorbing-tail exposure, finite-window attractor ledger rows, transport, replay, provenance, and local NameCert data.

Closure status for $\mathsf{NameCert}_{\mathsf{AsymptoticCompactness}^{\uparrow}}$.

Constructive story: An $\mathsf{AsymptoticCompactness}^{\uparrow}$ packet is generated from dynamical-system flow rows, metric comparison rows, compact capture rows, stream-selected tail windows, absorbing-tail exposure, finite-window attractor ledgers, componentwise transport, displayed continuation replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{AsymptoticCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 8380.1, Definition 8380.2, Definition 8380.3, and Definition 8380.4 name the finite tail-capture carrier and its immediate obligation rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{AsymptoticCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not construct a global attractor, select convergent subsequences, prove compactness of the whole phase space, or bridge-check the dynamical compactness packet.

Upgrade path: Obligation closure requires checked carrier admission, classifier transport, absorbing-tail exactness, finite-window ledger exactness, replay, provenance, and local naming for the same packet.

Chapter 8381

A Concrete Naming Certificate for $\mathsf{BishopLocatedBallCover}^{\uparrow}$

Following Bishop and Bridges constructive metric analysis, the $\mathsf{BishopLocatedBallCover}^{\uparrow}$ packet records a finite located ball-cover route for L10 Real and Completion consumers. It sits after the dyadic radius core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the displayed metric and cover siblings of chapter 57, chapter 8085, and chapter 8117. The packet names a finite located cover witness only; it does not claim open-cover compactness, choice, trichotomy, quotient real equality, selected subcovers, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8381.1 (Bishop located ball cover carrier)**.** *A* $\mathsf{BishopLocatedBallCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (M, Q, W, R, E, L, H, C, P, N)$$

with the following displayed rows:

1. *M is the displayed* $\mathsf{Met}^{\uparrow}$ *or completion-facing metric source whose ball membership comparisons are inspected.*
2. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *radius ledger, carrying the positive dyadic radii, tolerance refinements, and overlap budgets for the cover rows.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation window through which points, centers, and requested radii are exposed.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational distance and radius comparisons used by the locatedness test.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the dyadic radius row, finite window row, and regular rational readback have been displayed.*
6. *L is the located cover ledger. For each inspected window it names a finite ball entry, its center row, its dyadic radius, and the comparison showing that the inspected point is either inside the displayed ball or separated from the complementary inspected window.*
7. *H records componentwise* hsame *transport for the metric source, radius ledger, finite windows, readback, seal, located cover ledger, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a ball-cover request through M, Q, W, R, E, L, H.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedBallCover}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteOpenBallCover}^{\uparrow}$, $\mathsf{RationalBallCover}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedBallCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, Q, W, R, E, L, H, C, P, N$. It has no coordinate for an arbitrary open cover, a host compactness theorem, a selected subcover, countable choice, quotient real equality, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.BishopLocatedBallCoverUp`

Theorem 8381.2 (Bishop located ball cover NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedBallCover}^{\uparrow}$ *carrier $B = (M, Q, W, R, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedBallCover}^{\uparrow}}$ *surface consists exactly of metric-source admission, dyadic radius admission, finite observation-window exposure, regular rational readback, terminal real sealing, located cover ledger exposure, componentwise transport, displayed replay, provenance, and local naming for the rows $M, Q, W, R, E, L, H, C, P, N$.*

Proof. Project the carrier of Definition 8381.1. The analytic rows are M, Q, W, R, E, L, while H, C, P, N only transport, replay, source, and name that displayed route.

The located cover ledger L can be read only together with the metric source M, dyadic radius ledger Q, finite window W, and regular rational readback R. Thus each cover claim is witnessed by finite rows already present in the carrier.

Finally the terminal seal E is downstream of those rows, and the structural rows preserve the same finite route. Since the carrier has no coordinate for compactness, selected subcovers, countable choice, quotient equality, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8381.3 (Bishop located ball cover radius locality)**.** *Every radius read in an accepted* $\mathsf{BishopLocatedBallCover}^{\uparrow}$ *packet factors through the dyadic ledger Q before the cover ledger L or terminal seal E can be consumed. A consumer may refine a displayed radius by a finite dyadic tolerance row, but it cannot replace Q by a global real-order decision, trichotomy branch, quotient real equality, or ambient completeness principle.*

Proof. Read the carrier rows. Radius data appear only in Q, and the finite observation row W determines which radius and center entries are visible for the current request.

The regular rational readback R interprets the dyadic radius comparisons before the located cover ledger L is read. Therefore every radius-facing consumer receives a finite dyadic route rather than an ambient real-order oracle.

The seal E and the structural rows H, C, P, N remain downstream of Q, W, R, L. They preserve the displayed route and add no trichotomy, quotient equality, selected subcover, choice principle, or ambient completeness witness. □

Theorem 8381.4 (Bishop located ball cover finite-window realizer)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopLocatedBallCover}^{\uparrow}$ *carrier must first read the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The located ball-cover row L is realized only over that route: the displayed dyadic radii, finite observations, regular rational comparisons, and terminal real seal are consumed before any cover-facing conclusion is exported.

Proof. Start from a Real or Completion consumer of B. The consumer can reach the terminal seal only through Q, W, R, E, because these are the dyadic, window, readback, and seal rows present in the carrier.

The located cover ledger L is attached to the same route. It records finite ball entries and local comparisons for inspected windows, so it realizes the cover surface without selecting an external subcover or quotient representative.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same finite route. Hence the Real-facing output remains confined to the displayed dyadic-window-readback-seal path and exports no open-cover compactness, choice, trichotomy, quotient real equality, selected limit, or ambient completeness principle. □

Falsifiable prediction: An accepted $\mathsf{BishopLocatedBallCover}^{\uparrow}$ consumer that reaches a cover-facing $\mathsf{Real}^{\uparrow}$ seal without exposing $Q, W, R, E, L, H, C, P, N$ refutes the carrier of Definition 8381.1.

Independence witness: dyadicratcore, streamname, regseqrat, real, finite-open-ball-cover, rational-ball-cover, metric: no listed sibling supplies the joint packet containing one metric source, one dyadic radius ledger, finite observation windows, regular rational readback, terminal Real seal, located cover ledger, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedBallCover}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedBallCover}^{\uparrow}$ packet is generated from a Metric source row, DyadicRatCore radius ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, a located ball-cover ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedBallCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8381.1, Definition 8381.2, Definition 8381.3, and Definition 8381.4 seed the finite located ball-cover route through dyadic radii, finite StreamName windows, RegSeqRat readback, and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedBallCover}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.BishopLocatedBallCoverUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, choice, trichotomy, quotient real equality, selected subcovers, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic radius locality, finite-window realization, RegSeqRat readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedBallCoverUp.

Chapter 8382

A Concrete Naming Certificate for $\mathsf{BishopDiagonalCompletion}^{\uparrow}$

Following Bishop and Bridges constructive completion, the $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ packet records the finite diagonal route by which rational regular names, dyadic tolerances, and inspected stream windows are organized before a terminal Real-facing seal is exposed. It sits after the dyadic arithmetic ledger of chapter 291, the finite observation surface of chapter 126, the regular rational readback of chapter 301, the effective Cauchy completion route of chapter 5930, and the terminal real-name seal of chapter 38. The packet names a diagonal completion interface; it is not quotient stream equality, a selected limit representative, countable choice, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8382.1 (Bishop diagonal completion carrier)**.** *A* $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, S, R, \Delta, E, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic scales, rational slack rows, and comparison budgets for the diagonal requests.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected rational-name windows at the scales displayed by D.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular Cauchy readback row obtained from the inspected windows and the dyadic tolerance ledger.*
4. *Δ is the diagonal schedule row, listing the finite request order by which later windows reuse earlier tolerance and readback data.*
5. *E is the* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *route row, exposing the completion-facing handoff that consumes D, S, R, Δ before any terminal seal is visible.*
6. *L is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the effective completion route has displayed the diagonal windows and regular rational readback.*
7. *H records componentwise* hsame *transport for the dyadic, stream-window, regular-readback, diagonal-schedule, effective-completion, Real-seal, replay, provenance, and naming rows.*
8. *C records the displayed* Cont *replay from a diagonal completion request through $D, S, R, \Delta, E, L, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{BishopDiagonalCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, \Delta, E, L, H, C, P, N$. It has no coordinate for quotient representatives, hidden limit selection, countable-choice schedules, host equality of reals, or an unmediated completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8382.2 (Bishop diagonal completion NameCert obligations)**.** *For every accepted* BishopDiagonalCompleti *carrier $B = (D, S, R, \Delta, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite stream-window exposure, regular rational readback, diagonal schedule display, effective Cauchy completion routing, Real-seal handoff, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier coordinates. The rows D, S, R, Δ, E, L display the finite dyadic tolerance data, inspected name windows, regular Cauchy readback, diagonal request schedule, effective completion route, and terminal Real-facing seal.

The structural rows H, C, P, N then transport, replay, source, and name the same packet. They do not add quotient representatives, selected limits, countable-choice data, host equality, or an ambient completeness witness.

Since the carrier has no coordinate outside $D, S, R, \Delta, E, L, H, C, P, N$, every accepted local NameCert obligation is one of the listed rows, and every listed row is explicitly present in the accepted packet. □

Theorem 8382.3 (Bishop diagonal completion regular seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ *carrier is reached through displayed finite diagonal windows and regular rational readback. More precisely, any Real-facing consumer factors through the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{EffectiveCauchyCompletion}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

with the diagonal schedule row Δ governing which displayed windows are consumed before the effective completion route is read.

Proof. Begin with a Real-facing consumer of B. Carrier admission gives access to the terminal seal only as the row L in the same finite packet as D, S, R, Δ, E.

Replay the continuation row C. The request first reads the dyadic tolerance ledger D, opens the finite $\mathsf{StreamName}^{\uparrow}$ windows S, obtains the $\mathsf{RegSeqRat}^{\uparrow}$ regular readback R, and consults the diagonal schedule Δ that records the inspected finite window order.

Only after that displayed route is available can the effective completion row E be consumed and the terminal seal L be read. Componentwise transport and package provenance preserve the same order, so no host limit operation can bypass the finite diagonal windows or the regular rational readback. □

Theorem 8382.4 (Bishop diagonal completion no quotient nonescape)**.** *No accepted* $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ *packet exports quotient stream equality, a selected representative of a Cauchy class, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness. Any such datum is outside the local carrier unless it is re-expressed through the displayed dyadic, stream-window, regular-readback, diagonal-schedule, effective-completion, Real-seal, transport, replay, provenance, and naming rows.*

Proof. Inspect the classifier of Definition 8382.1. It compares accepted packets only through the ten displayed rows $D, S, R, \Delta, E, L, H, C, P, N$.

The excluded data are not among those coordinates. The regular seal route also forces every Real-facing read through the dyadic, finite-window, regular-readback, diagonal-schedule, and effective-completion route before the terminal seal is visible.

Therefore an export using quotient equality, selected representatives, countable choice, host equality, or ambient completeness has left the accepted $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ surface rather than escaping from it. □

Falsifiable prediction: Every accepted BishopDiagonalCompletionUp Real-facing read factors through DyadicRatCore tolerance data, StreamName finite windows, RegSeqRat regular readback, a displayed diagonal schedule, EffectiveCauchyCompletion routing, a RealUp seal, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, effective-cauchy-completion, real: $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries dyadic tolerances, finite windows, regular readback, a diagonal schedule, effective Cauchy completion routing, Real sealing, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDiagonalCompletion}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat regular Cauchy readback, a diagonal schedule row, an EffectiveCauchyCompletion route, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8382.1, Definition 8382.2, Definition 8382.3, and Definition 8382.4 seed the finite diagonal completion route through dyadic tolerance, finite stream-window, regular-readback, effective-completion, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDiagonalCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite-window readback, regular Cauchy diagonal routing, effective completion handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopDiagonalCompletionUp.

Chapter 8383

A Concrete Naming Certificate for $\mathsf{RegularCauchyLimsup}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLimsup}^{\uparrow}$ packet records the finite upper-tail envelope available from a displayed regular Cauchy rational source before any Real-facing consumer reads a terminal value. It sits over the limsup boundary of chapter 768, the located upper-envelope route of chapter 7935, the bounded upper-envelope packet of chapter 7101, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet names an L10 completion-facing upper-tail envelope; it does not import host limsup, quotient stream equality, countable choice, selected subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8383.1 (Regular Cauchy limsup carrier)**.** *A* $\mathsf{RegularCauchyLimsup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (S, W, R, D, L, B, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row, recording the displayed regular Cauchy rational name whose upper tail is being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite tail windows made visible to the upper-envelope request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback row, binding the windows from W to regular rational values and tail tolerances.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic precision, slack, and comparison budgets for the envelope read.*
5. *L is the* $\mathsf{Limsup}^{\uparrow}$ *and* $\mathsf{LocatedLimsup}^{\uparrow}$ *upper-envelope row, exposing the finite tail-upper surface and the located comparison tests available at the displayed precision.*
6. *B is the* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *comparison row, recording the bounded upper-envelope handoff over the same source row S and the same displayed tail windows.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, R, D, L, B have all been displayed.*
8. *H records componentwise* hsame *transport for the source, windows, readback, dyadic ledger, upper-envelope, bounded-comparison, Real-seal, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from an upper-tail request through*

$$S \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow L \longrightarrow B \longrightarrow E \longrightarrow H \longrightarrow P \longrightarrow N.$$

10. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLimsup}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Limsup}^{\uparrow}$, $\mathsf{LocatedLimsup}^{\uparrow}$, $\mathsf{BoundedRealLimsup}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLimsup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, R, D, L, B, E, H, C, P, N$. It has no coordinate for quotient stream equality, a host-selected limsup value, a chosen cofinal subsequence, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8383.2 (Regular Cauchy limsup NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLimsup}^{\uparrow}$ *carrier*

$$U = (S, W, R, D, L, B, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLimsup}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source sequence,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Limsup}^{\uparrow}$ *and* $\mathsf{LocatedLimsup}^{\uparrow}$ *upper-envelope row,* $\mathsf{BoundedRealLimsup}^{\uparrow}$ *comparison row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier rows of Definition 8383.1. The analytic rows S, W, R, D, L, B, E display the source name, finite windows, regular rational readback, dyadic tolerance ledger, upper-envelope request, bounded comparison row, and terminal Real seal in that order.

The structural rows H, C, P, N transport, replay, source, and name the same packet. They do not add a quotient stream, a selected cofinal subsequence, a host limsup, countable choice, or ambient Real completeness.

Since the classifier has no coordinate outside $S, W, R, D, L, B, E, H, C, P, N$, every local NameCert obligation is one of the listed rows, and every listed row is visible in the accepted carrier. □

Theorem 8383.3 (Regular Cauchy limsup Real seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchyLimsup}^{\uparrow}$ *carrier is reached through displayed regular-Cauchy upper-tail data. More precisely, every Real or Completion-facing read factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{LocatedLimsup}^{\uparrow} \longrightarrow \mathsf{BoundedRealLimsup}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

with the same source sequence row S and the same displayed tail windows W governing the upper-envelope comparison.

Proof. Let a Real or Completion-facing consumer read an accepted carrier U. The terminal value is available only as the row E, and E is downstream of the source row S, window row W, readback row R, dyadic tolerance ledger D, upper-envelope row L, and bounded comparison row B.

Replay the continuation row C. The consumer first opens the finite $\mathsf{StreamName}^{\uparrow}$ windows, then reads regular rational tail values through $\mathsf{RegSeqRat}^{\uparrow}$, and then consults the dyadic ledger before the located and bounded upper-envelope rows are available.

Componentwise transport H and provenance P preserve the same order. Therefore the Real seal cannot bypass the displayed regular-Cauchy tail rows or import a host limsup, quotient stream equality, countable choice, selected subsequence, or ambient completeness witness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLimsup}^{\uparrow}$ Real-facing read exposes a source sequence, StreamName windows, RegSeqRat tail readbacks, a DyadicRatCore tolerance ledger, Limsup and LocatedLimsup upper-envelope data, a BoundedRealLimsup comparison row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any upper-tail endpoint is visible.

Independence witness: limsup, located-limsup, bounded-real-limsup, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyLimsup}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a regular Cauchy source, finite windows, rational tail readback, dyadic tolerances, located upper-envelope data, bounded upper-envelope comparison, Real sealing, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLimsup}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLimsup}^{\uparrow}$ packet is generated from a regular Cauchy source sequence, StreamName windows, RegSeqRat tail readbacks, a DyadicRatCore tolerance ledger, Limsup and LocatedLimsup upper-envelope rows, a BoundedRealLimsup comparison row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimsup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8383.1, Definition 8383.2, and Definition 8383.3 seed the finite regular-Cauchy upper-tail envelope route through displayed windows, rational readback, dyadic tolerances, located and bounded limsup rows, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLimsup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host limsup, quotient stream equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coverage, RegSeqRat readback, DyadicRatCore tolerance exposure, located upper-envelope exactness, bounded comparison, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLimsupUp.

Chapter 8384

A Concrete Naming Certificate for $\mathsf{CauchyProductTopology}^{\uparrow}$

Following Bourbaki and Kelley on finite product topologies, the $\mathsf{CauchyProductTopology}^{\uparrow}$ packet records the product-topology read available when each coordinate is presented by a constructive Cauchy real name. It sits after the finite topology certificate of chapter 2000, the Cauchy coordinate-projection certificate of chapter 2076, and the completion-projection certificate of chapter 5824. The packet gives finite Cauchy-name product consumers a topology-facing coordinate read without importing quotient product equality, selected stream representatives, ambient completeness, or host product spaces.

Definition 8384.1 (Cauchy product topology carrier)**.** *A* $\mathsf{CauchyProductTopology}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (P, R, Q, W, A, S, H, C, G, N)$$

with the following displayed rows:

1. *P is the* $\mathsf{ProductTopology}^{\uparrow}$ *finite product-topology row naming the coordinate-window topology surface.*
2. *R is the* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *coordinate-projection readback row.*
3. *Q is the* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *completion-facing projection row.*
4. *W is the finite family of* $\mathsf{StreamName}^{\uparrow}$ *windows used by the coordinate Cauchy names.*
5. *A is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row attached to the displayed windows.*
6. *S is the pair of* $\mathsf{Real}^{\uparrow}$ *seal rows reached from the regular readbacks.*
7. *H records componentwise* hsame *transport for topology, projection, completion, stream-window, regular-readback, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each product-coordinate topology request through $P, R, Q, W, A, S, H, G, N$.*
9. *G is the* Pkg *provenance over* $\mathsf{CauchyProductTopology}^{\uparrow}$, $\mathsf{ProductTopology}^{\uparrow}$, $\mathsf{RegularCauchyProductProjection}^{\uparrow}$, $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyProductTopology}^{\uparrow}}$ *row.*

The carrier predicate asserts exactly that these rows form one finite product-topology read over Cauchy real-name coordinates. It has no coordinate for quotient product equality, selected stream representatives, host product spaces, global completeness, choice of representatives, Lean verification, or bridge checking.

Theorem 8384.2 (Cauchy product topology NameCert obligations)**.** *For every accepted* $\mathsf{CauchyProductTopology}^{\uparrow}$ *carrier*

$$T = (P, R, Q, W, A, S, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyProductTopology}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet, product-topology exposure through* P*, regular Cauchy product projection exposure through* R*, completion projection exposure through* Q*, finite stream-window exposure through* W*, regular-rational readback through* A*, real-name sealing through* S*, componentwise transport through* H*, displayed replay through* C*, provenance through* G*, and local naming through* N*.*

Proof. Project the carrier of Definition 8384.1. Its rows are precisely the topology row, projection rows, stream-window rows, regular-rational readback, real seals, and structural certificate rows listed in the statement.

Read the three sibling certificates. The $\mathsf{ProductTopology}^{\uparrow}$ chapter supplies the finite product-window topology row, chapter 2076 supplies the coordinate Cauchy projection row, and chapter 5824 supplies the completion-facing projection row.

Finally replay through H, C, G, N. These rows transport, replay, source, and name the already displayed route, so the local certificate cannot add quotient product equality, selected stream representatives, host product spaces, global completeness, or a Lean-side verification claim. □

Theorem 8384.3 (Cauchy product topology finite product readback)**.** *Every finite product-coordinate topology read exported by an accepted* $\mathsf{CauchyProductTopology}^{\uparrow}$ *carrier factors through*

$$P, R, Q, W, A, S, H, C, G, N$$

in that order: the $\mathsf{ProductTopology}^{\uparrow}$ *window is exposed before the* $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ *and* $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$ *projection rows are consumed, the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks are displayed before the* $\mathsf{Real}^{\uparrow}$ *seals, and the final route is preserved only by* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming.*

Proof. Start with the accepted packet T from Definition 8384.1. Since P is the only product-topology row, every coordinate topology read must expose P before any Cauchy projection or completion projection can be consumed.

Use the projection certificates cited in the introduction. The regular Cauchy projection row R reads finite coordinate windows, and the completion projection row Q preserves that coordinate route at the completion-facing boundary.

Then read the real-name source. The finite windows W feed the regular-rational row A, and A feeds the terminal real seals S; no selected stream representative or quotient product equality is present in the carrier.

The structural rows H, C, G, N preserve and name the same finite route. Hence the exported read is the displayed Cauchy-name product topology route, not an ambient product space, host completeness theorem, or bridge-checked object. □

Falsifiable prediction: Every accepted $\mathsf{CauchyProductTopology}^{\uparrow}$ read displays the $\mathsf{ProductTopology}^{\uparrow}$ finite product window, $\mathsf{RegularCauchyProductProjection}^{\uparrow}$ coordinate readback, $\mathsf{CauchyProductCompletionProjection}^{\uparrow}$

completion projection, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, $\mathsf{Real}^{\uparrow}$ seals, hsame transport, Cont replay, Pkg provenance, and local NameCert before a product-coordinate topology consumer can use the route.

Independence witness: product-topology, regular-cauchy-product-projection, cauchy-product-completion-projection, streamname, regseqrat, real: $\mathsf{CauchyProductTopology}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries product-topology windows, regular Cauchy projection readback, completion projection, finite stream windows, regular-rational readback, real seals, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyProductTopology}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyProductTopology}^{\uparrow}$ packet is generated from a ProductTopology finite window row, RegularCauchyProductProjection coordinate readback, CauchyProductCompletionProjection completion-facing row, StreamName windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyProductTopology}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8384.1, Definition 8384.2, and Definition 8384.3 seed the finite product-topology route over Cauchy real-name coordinates.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyProductTopology}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient product equality, selected stream representatives, ambient product spaces, global completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite product-window exposure, coordinate projection readback, completion projection exposure, stream-window accounting, regular-rational readback, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyProductTopologyUp.

Chapter 8385

A Concrete Naming Certificate for $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$ packet records the finite limit-facing interface by which a regular rational Cauchy name is admitted as a separated completion limit without claiming ambient $\mathsf{Real}^{\uparrow}$ completeness. It consumes the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. It also sits downstream of the quotient-free separated completion surface of chapter 8373.

Definition 8385.1 (Separated Cauchy completion limit carrier)**.** *A* $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, E, H, T, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording the inspected stages of the Cauchy name.*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to those windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare the displayed windows.*
4. Q *is the separated completion-limit row, recording that the named regular Cauchy data has passed the zero-distance boundary inside the displayed route.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after* S, R, D, Q *have been exposed.*
6. H *records componentwise* hsame *transport for the window, readback, tolerance, separated-limit, Real seal, provenance, and local naming rows.*
7. T *records the displayed continuity boundary*

$$\mathsf{Cont}(L) = \mathsf{Cont}(S, R, D, Q, E, H).$$

8. P *records*

$$\mathsf{Pkg}(L) = \mathsf{Pkg}(\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}$$

9. N *is the local* $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, E, H, T, P, N$. It has no coordinate for quotient stream equality, selected host limits, choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.SeparatedCauchyCompletionLimitUp`

Theorem 8385.2 (Separated Cauchy completion limit NameCert obligations)**.** *For every accepted* $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$ *carrier*

$$L = (S, R, D, Q, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the displayed packet L;*
2. *finite observation exposure through the* $\mathsf{StreamName}^{\uparrow}$ *row S;*
3. *regular rational readback through the* $\mathsf{RegSeqRat}^{\uparrow}$ *row R;*
4. *dyadic comparison confinement through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row D;*
5. *separated completion-limit sealing through Q;*
6. *terminal* $\mathsf{Real}^{\uparrow}$ *readback through E, reachable only after S, R, D, Q have been displayed;*
7. *componentwise transport, continuity replay, provenance, and local naming through H, T, P, N.*

Thus the packet names a separated completion-limit interface, not a proof that every Cauchy object in an ambient Real carrier has a selected limit.

Proof. Project the carrier of Definition 8385.1. The finite-window row S, regular rational readback row R, and dyadic tolerance row D expose the only data through which a consumer may inspect the Cauchy name.

The separated-limit row Q is downstream of that finite route. It records the displayed zero-distance boundary for this packet rather than a quotient class of streams or a host-selected Real element.

Finally read the terminal Real seal E through H, T, P, N. These structural rows preserve and name the same displayed route, so the NameCert surface contains exactly the listed obligations and exports no ambient completeness principle. □

Theorem 8385.3 (Separated Cauchy completion limit uniqueness route)**.** *If two accepted* SeparatedCauchyComplet *packets agree componentwise on S, R, D, Q, H, T, P, N by* hsame*, then every* $\mathsf{Real}^{\uparrow}$*-facing consumer reads the same displayed limit route through E. The comparison is made through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{SeparatedCauchyCompletionLimit}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and does not invoke quotient equality of Cauchy streams, trichotomy, countable choice, a selected host limit, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the shared rows S, R, D, Q, H, T, P, N. The window, readback, and dyadic tolerance rows determine the displayed Cauchy route available to both packets.

Use Definition 8385.2. It places the separated-limit row Q after the common finite data and the terminal Real seal E after Q, so a Real-facing consumer cannot bypass the displayed comparison boundary.

Transport by H and replay by T preserve the same finite route, while P and N name it locally. Since the carrier contains no quotient, choice, trichotomy, selected host-limit, or ambient-completeness coordinate, the uniqueness route is exhausted by the displayed seal path. □

Falsifiable prediction: An accepted $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$ packet whose $\mathsf{Real}^{\uparrow}$ seal is read without first exposing $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{RegSeqRat}^{\uparrow}$ readback, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, and the separated-limit row Q refutes the carrier surface.

Independence witness: streamname, regseqrat, dyadicratcore, real, separated-cauchy-completion: no listed sibling supplies the whole packet $L = (S, R, D, Q, E, H, T, P, N)$, because each sibling contributes only finite windows, regular rational readback, dyadic tolerances, a Real seal, or separated completion context while this chapter binds them into one limit-facing NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}$ packet is generated from StreamNameUp finite windows, RegSeqRatUp readback, a DyadicRatCoreUp tolerance ledger, a separated completion-limit row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8385.1, Definition 8385.2, and Definition 8385.3 seed the finite separated Cauchy completion-limit interface over window, readback, tolerance, separated-limit, Real-seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SeparatedCauchyCompletionLimit}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected host limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular rational readback, dyadic tolerance confinement, separated-limit sealing, Real readback, transport, replay, provenance, and local naming for BEDC.Derived.SeparatedCauchyCompletionLimitUp.

Chapter 8386

A Concrete Naming Certificate for $\mathsf{RegularSequenceTailMetric}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy sequences and constructive completion, the $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ packet records the finite tail-metric surface by which regular rational names are compared before a terminal real-name seal is visible. It sits after the dyadic tolerance core of chapter 291, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the public finite fusion route of chapter 693, and the terminal real-name seal of chapter 38. The packet names a tail metric for displayed regular sequences only; it does not assert ambient completeness of $\mathsf{Real}^{\uparrow}$, quotient stream equality, countable choice, trichotomy, or selected representatives of completed real names.

Definition 8386.1 (Regular sequence tail metric carrier)**.** *A* $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (D, W, R, F, M, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic scale at which two tails are compared.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite tail windows inspected at the requested scale.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational sequence values visible on those windows.*
4. *F is the* $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$ *fusion row, recording that the window, readback, tolerance, and terminal seal are consumed through one finite L10 route.*
5. *M is the tail-metric row, storing the displayed rational bound for the tail comparison obtained from D, W, R, F.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the tail-metric row has been displayed.*
7. *H records componentwise* hsame *transport for $D, W, R, F, M, E, C, P, N$.*
8. *C records the displayed* Cont *replay from a tail comparison request through $D, W, R, F, M, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RegularSequenceTailMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyWindowFusion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{RegularSequenceTailMetric}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $D, W, R, F, M, E, H, C, P, N$. It has no coordinate for quotient equality of streams, a chosen limit representative, countable choice over tails, trichotomy of real names, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8386.2 (Regular sequence tail metric NameCert obligations)**.** *For every accepted* RegularSequenceTailMe *carrier*

$$T = (D, W, R, F, M, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularSequenceTailMetric}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance exposure, finite tail-window exposure, regular rational readback, regular Cauchy window fusion, displayed tail-metric bounding, terminal* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Lean4 ✓ `BEDC.Derived.RegularSequenceTailMetricUp.RegularSequenceTailMetricTasteGate single carrier alignment`

Proof. Project the carrier of Definition 8386.1. The displayed coordinates are precisely $D, W, R, F, M, E, H, C, P, N$

The comparison-facing rows are D, W, R, F, M. The dyadic tolerance row sets the scale, the stream row supplies finite tail windows, the regular readback row supplies rational values on those windows, the fusion row keeps those reads on one L10 route, and the metric row records the resulting bound.

The seal and structural rows E, H, C, P, N preserve, replay, source, and name the same displayed route. Since the carrier has no quotient, choice, trichotomy, selected-representative, or ambient-completeness coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 8386.3 (Regular sequence tail metric tail stability)**.** *Let*

$$T = (D, W, R, F, M, E, H, C, P, N)$$

and

$$T' = (D, W', R', F', M, E, H', C', P', N')$$

be accepted $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ *packets with the same dyadic tolerance row D, tail-metric row M, and terminal* $\mathsf{Real}^{\uparrow}$ *seal row E. If (W', R', F') is displayed as a cofinal tail of (W, R, F) inside the accepted packet data, then T and T' export the same finite tail-metric handoff through M and E. Neither packet exports quotient stream equality, a selected representative, countable choice, trichotomy, or ambient completeness.*

Proof. Start with Definition 8386.2. Both packets expose their dyadic tolerance, tail windows, regular readbacks, fusion rows, tail-metric rows, and terminal seals before the structural rows are consumed.

Because (W', R', F') is a displayed cofinal tail of (W, R, F), the second packet changes only the visible finite tail window and its regular readback route. The shared dyadic tolerance D and metric row M keep the requested comparison scale and bound fixed.

The terminal seal row E is reached only after M is displayed. The structural rows transport, replay, source, and name the same handoff, so passing to the displayed cofinal tail preserves the exported tail-metric surface.

The excluded data are not carrier coordinates in either packet. Thus no quotient stream equality, selected representative, countable choice, trichotomy, or ambient completeness can be exported by the tail replacement. □

Theorem 8386.4 (Regular sequence tail metric RegSeqRat handoff)**.** *Every accepted* $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ *comparison consumed by a* $\mathsf{Real}^{\uparrow}$ *or completion-facing reader factors through the route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{RegularCauchyWindowFusion}^{\uparrow} \longrightarrow \mathsf{RegularSequenceTailMetr}$$

The $\mathsf{RegSeqRat}^{\uparrow}$ *row supplies the rational regular readback used by the tail metric row* M*, and the later seal row* E *is unreadable until that finite handoff has been displayed.*

Proof. Project an accepted carrier $T = (D, W, R, F, M, E, H, C, P, N)$. The rows D, W, R, F, M, E are ordered as dyadic tolerance, stream window, regular rational readback, finite fusion route, tail metric, and terminal real-name seal.

Apply Definition 8386.2. It requires every accepted comparison to expose D, W, R, F, M, E before H, C, P, N can package the result.

The row R is the only $\mathsf{RegSeqRat}^{\uparrow}$ readback coordinate in the carrier. Therefore the metric row M can only be read through the displayed regular rational values supplied by R and the finite window supplied by W.

Finally the row E is a seal for that already displayed route. Since no other completion, quotient, selected-limit, choice, or trichotomy coordinate exists in the packet, every $\mathsf{Real}^{\uparrow}$ or completion-facing reader factors through the stated finite handoff. □

Falsifiable prediction: Every accepted RegularSequenceTailMetricUp comparison exposes DyadicRatCore tolerance data, StreamName finite tail windows, RegSeqRat regular rational readback, RegularCauchyWindowFusion routing, a displayed tail-metric bound, a RealUp seal, transport, replay, provenance, and local naming before any Real-facing consumer reads the result.

Independence witness: dyadicratcore, streamname, regseqrat, regularcauchywindowfusion, real: $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ is not bijective to any listed sibling because it carries the displayed tail-metric row M between regular rational readback and the terminal Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceTailMetric}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceTailMetric}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance row, StreamName finite tail-window row, RegSeqRat regular readback row, RegularCauchyWindowFusion route row, tail-metric row, RealUp seal row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceTailMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8386.1, Definition 8386.2, Definition 8386.3, and Definition 8386.4 seed the finite tail-metric surface between regular rational readback and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceTailMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close RealUp completeness, quotient stream equality, selected representatives, countable choice, trichotomy, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exposure, finite tail-window exposure, regular readback, fusion routing, tail-metric bounding, terminal Real seal scope, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceTailMetricUp.

Chapter 8387

A Concrete Naming Certificate for $\mathsf{KrawczykOperator}^{\uparrow}$

Following Krawczyk and Moore–Kearfott–Cloud interval analysis, the $\mathsf{KrawczykOperator}^{\uparrow}$ packet records the finite preconditioned interval operator used to validate and narrow boxes for nonlinear zero searches. It separates the Krawczyk image from the surrounding $\mathsf{IntervalNewton}^{\uparrow}$ row of chapter 1570: the operator is a named L10 certificate whose arithmetic is read through chapter 302, whose Newton comparison route is read through chapter 223, whose enclosure provenance may use the Taylor rows of chapter 442, and whose rational and real readback passes through chapter 301 and chapter 38.

Definition 8387.1 (Krawczyk operator carrier)**.** *A* $\mathsf{KrawczykOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, F, J, A, R, M, I, V, H, C, P, N)$$

with the following displayed rows:

1. *B is the input interval box, including the coordinate boxes and their* $\mathsf{IntervalArithmetic}^{\uparrow}$ *endpoint rows.*
2. *F is the interval enclosure of the function values on B, read only through interval-arithmetic operation rows.*
3. *J is the interval matrix or slope enclosure for the derivative data over B.*
4. *A is the approximate inverse or preconditioner row attached to the chosen center.*
5. *R is the center and residual row, recording the displayed center c and the preconditioned residual $AF(c)$.*
6. *M is the interval matrix row for $I - AJ$, including its interval product and subtraction ledger.*
7. *I is the Krawczyk image row, recording the displayed enclosure $c - AF(c) + (I - AJ)(B - c)$.*
8. *V is the containment and narrowing validation row, recording whether $I \subseteq B$, $I \cap B$, or the refused containment boundary is the public result.*
9. *H records componentwise* hsame *transport for boxes, enclosures, derivative rows, preconditioners, residuals, interval matrices, Krawczyk images, and validation rows.*
10. *C records displayed* Cont *replay from interval arithmetic to the image computation, from validation to narrowing, and from readback rows to the public certificate.*

11. *P is the* Pkg *provenance over* $\mathsf{KrawczykOperator}^{\uparrow}$, $\mathsf{IntervalArithmetic}^{\uparrow}$, $\mathsf{IntervalNewton}^{\uparrow}$, $\mathsf{NewtonIteration}^{\uparrow}$, $\mathsf{TaylorModel}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{KrawczykOperator}^{\uparrow}}$ *row.*

The carrier exports only the displayed interval operator and its validation ledger. It does not assert host existence of a zero, global uniqueness, floating-point semantics, differentiability outside the supplied slope row, quotient real equality, or ambient Real completeness.

Theorem 8387.2 (Krawczyk operator NameCert obligations)**.** *For every accepted* $\mathsf{KrawczykOperator}^{\uparrow}$ *carrier*

$$K = (B, F, J, A, R, M, I, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KrawczykOperator}^{\uparrow}}$ *surface consists exactly of carrier admission, box exposure through B, function enclosure exposure through F, derivative or slope enclosure exposure through J, preconditioner exposure through A, center and residual exposure through R, interval matrix exposure through M, Krawczyk image exposure through I, containment or narrowing validation through V, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The only arithmetic rows available to a Krawczyk read are the displayed box, function enclosure, derivative or slope enclosure, preconditioner, residual, interval matrix, image, and validation rows.

The interval-arithmetic route computes F, J, M, and I inside the same finite packet. The row A is only a displayed approximate inverse or preconditioner, and R is only the center-residual ledger attached to that preconditioner.

Validation is read through V. It records containment, narrowing by intersection, or refusal of containment without adding a root-existence theorem or a uniqueness theorem.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for host zeros, global uniqueness, floating-point semantics, quotient real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8387.3 (Krawczyk operator interval-Newton handoff)**.** *Every* $\mathsf{IntervalNewton}^{\uparrow}$ *consumer that uses a* $\mathsf{KrawczykOperator}^{\uparrow}$ *packet must read the Krawczyk route*

$$B, F, J, A, R, M, I, V, H, C, P, N$$

before treating a correction row as a validated enclosure. The handoff supplies the named image $I = c - AF(c) + (I - AJ)(B - c)$ and the containment or narrowing validation row V to the interval-Newton packet; it supplies no solver oracle, host zero selection, global uniqueness claim, floating-point semantics, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the interval-Newton correction boundary of chapter 1570. That chapter may consume a Krawczyk correction row, but the row is public only after the box, enclosure, derivative, and validation data have been displayed.

The present carrier names those data as B, F, J, A, R, M, I, V. The interval-arithmetic rows compute the residual and image, while the $\mathsf{NewtonIteration}^{\uparrow}$ and $\mathsf{TaylorModel}^{\uparrow}$ provenance rows record how the displayed derivative or slope data were obtained.

The rational and real readback remains finite. Any $\mathsf{RegSeqRat}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ consumer reaches the image and validation rows only through the displayed replay and provenance rows C, P together with the transport and local name H, N.

Thus the interval-Newton consumer receives a named finite operator certificate rather than an unnamed correction row. Since no carrier field selects a zero or proves global uniqueness, the handoff remains an interval validation route. □

Falsifiable prediction: Every accepted $\mathsf{KrawczykOperator}^{\uparrow}$ read exposes the box, function enclosure, derivative or slope enclosure, preconditioner, center-residual row, interval matrix row, Krawczyk image, validation ledger, transport, replay, provenance, and local NameCert row before an interval-Newton consumer can use the correction.

Independence witness: intervalnewton, intervalarithmetic, newtoniteration, taylormodel, regseqrat, real: $\mathsf{KrawczykOperator}^{\uparrow}$ is not bijective to any listed sibling because it binds the preconditioned residual, interval matrix $I - AJ$, Krawczyk image, containment-or-narrowing validation, arithmetic replay, rational readback, real-name readback, provenance, and local naming into one operator certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{KrawczykOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{KrawczykOperator}^{\uparrow}$ packet is generated from an interval box, function enclosure, derivative or slope enclosure, approximate inverse or preconditioner, center-residual row, interval matrix row, Krawczyk image, containment or narrowing validation row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KrawczykOperator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8387.1, Definition 8387.2, and Definition 8387.3 seed the finite L10 Krawczyk operator certificate and its interval-Newton consumer boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KrawczykOperator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host zero existence, global uniqueness, floating-point semantics, differentiability beyond the displayed slope row, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Lean closure requires carrier admission, interval-arithmetic image formation, containment or narrowing validation, RegSeqRat and Real readback nonescape, interval-Newton handoff, transport, replay, provenance, and local naming for BEDC.Derived.KrawczykOperatorUp.

Chapter 8388

A Concrete Naming Certificate for IntervalNewtonKrawczyk$^{\uparrow}$

Following Krawczyk and Moore–Kearfott–Cloud interval analysis, the IntervalNewtonKrawczyk$^{\uparrow}$ packet records the bridge between interval Newton correction rows and Krawczyk validation rows as finite BEDC data. It sits between the interval-Newton carrier of chapter 1570 and the preconditioned operator carrier of chapter 8387. Its purpose is to expose the exact handoff by which a displayed interval box, interval-arithmetic enclosure, Newton correction, Krawczyk image, Taylor or slope remainder, rational readback, real-name seal, transport, replay, provenance, and local naming row jointly validate a narrowing certificate without adding a solver oracle, host zero selection, floating-point semantics, quotient real equality, or ambient Real$^{\uparrow}$ completeness.

Definition 8388.1 (Interval Newton–Krawczyk carrier)**.** *An* IntervalNewtonKrawczyk$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (I, K, A, N, T, R, E, H, C, P, L)$$

with the following displayed rows:

1. *I is the accepted* IntervalNewton$^{\uparrow}$ *row carrying the displayed interval box, function enclosure, derivative or slope enclosure, correction row, containment ledger, and validated readback boundary.*
2. *K is the accepted* KrawczykOperator$^{\uparrow}$ *row carrying the preconditioned residual, interval matrix, Krawczyk image, and containment or narrowing validation ledger.*
3. *A is the* IntervalArithmetic$^{\uparrow}$ *operation row through which both I and K read endpoint operations, interval products, interval sums, and inclusion tests.*
4. *N is the* NewtonIteration$^{\uparrow}$ *correction-provenance row used by the interval Newton side.*
5. *T is the* TaylorModel$^{\uparrow}$ *or displayed slope-remainder row used by the Krawczyk side when the derivative enclosure is read through finite Taylor data.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to the validated enclosure.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row exposed only after I, K, A, N, T, R have been displayed.*
8. *H records componentwise* hsame *transport for interval Newton, Krawczyk, arithmetic, Newton, Taylor, rational readback, real seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from interval arithmetic through the Newton and Krawczyk validations into the rational and real readback rows.*

10. *P is the* Pkg *provenance over* IntervalNewtonKrawczyk$^{\uparrow}$, IntervalNewton$^{\uparrow}$, KrawczykOperator$^{\uparrow}$, IntervalArithmetic$^{\uparrow}$, NewtonIteration$^{\uparrow}$, TaylorModel$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{IntervalNewtonKrawczyk}^{\uparrow}}$ *row.*

The local classifier compares accepted packets only through the visible rows $I, K, A, N, T, R, E, H, C, P, L$.

Theorem 8388.2 (Interval Newton–Krawczyk NameCert obligations)**.** *For every accepted* IntervalNewtonKrawczyk *carrier*

$$V = (I, K, A, N, T, R, E, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{IntervalNewtonKrawczyk}^{\uparrow}}$ *surface consists exactly of interval-Newton exposure through I, Krawczyk-operator exposure through K, interval-arithmetic exposure through A, Newton correction provenance through N, Taylor or slope-remainder provenance through T,* RegSeqRat$^{\uparrow}$ *readback through R,* Real$^{\uparrow}$ *seal delivery through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8388.1. The interval Newton side is available only through I, and the Krawczyk side is available only through K.

Read the arithmetic rows next. The row A supplies the interval endpoint operations for both validations, N records the Newton correction provenance, and T records the Taylor or slope-remainder provenance used by the Krawczyk image.

The readback rows are then forced by the displayed order. The rational readback R and real seal E can be consumed only after the interval Newton and Krawczyk rows have exposed the same box, correction, image, and containment data.

The rows H, C, P, L transport, replay, source, and name this finite route. Since the carrier has no extra coordinate, solver oracles, host zero selection, floating-point semantics, quotient real equality, and ambient Real completeness are outside the local certificate. □

Theorem 8388.3 (Interval Newton–Krawczyk validation handoff)**.** *Every accepted* IntervalNewtonKrawczyk$^{\uparrow}$ *validation handoff from interval Newton to a Krawczyk read is routed through*

IntervalNewton$^{\uparrow}$, KrawczykOperator$^{\uparrow}$, IntervalArithmetic$^{\uparrow}$, NewtonIteration$^{\uparrow}$, TaylorModel$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHi

In an accepted carrier $V = (I, K, A, N, T, R, E, H, C, P, L)$, a downstream consumer may read the validated enclosure only after the interval Newton correction row, Krawczyk image row, interval-arithmetic operation row, Newton provenance row, Taylor or slope-remainder row, rational readback row, real seal row, transport row, replay row, provenance row, and local naming row have all been displayed.

Proof. Start from the NameCert obligations of Definition 8388.2. They identify the full finite surface $I, K, A, N, T, R, E, H, C, P, L$ and place the interval Newton and Krawczyk rows before any readback row.

Use the interval Newton sibling of chapter 1570. Its correction row is accepted only with the displayed box, containment ledger, interval-arithmetic route, validated readback boundary, and local naming row.

Use the Krawczyk operator sibling of chapter 8387. Its image and containment rows are accepted only after the preconditioned residual, interval matrix, arithmetic replay, validation ledger, transport, provenance, and local name have been exposed.

The present carrier intersects those sibling surfaces at $A, N, T, R, E, H, C, P, L$. Thus the downstream consumer receives a single finite validation route rather than two unrelated certificates.

Because no field stores a solver oracle, host-selected zero, floating-point semantics, quotient real equality, or ambient Real completeness, the handoff exports only the stated BEDC rows. □

Falsifiable prediction: An $\mathsf{IntervalNewtonKrawczyk}^{\uparrow}$ packet that exposes a Krawczyk image without the interval Newton correction row, interval-arithmetic row, Newton provenance row, Taylor or slope-remainder row, and rational-to-real readback route is not accepted.

Independence witness: intervalnewton, krawczykoperator, intervalarithmetic, newtoniteration, taylormodel, regseqrat, real: the bridge packet is not bijective to any listed sibling because it binds both the interval Newton correction and the Krawczyk image to the same arithmetic, provenance, readback, transport, replay, package, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{IntervalNewtonKrawczyk}^{\uparrow}}$.

Constructive story: An $\mathsf{IntervalNewtonKrawczyk}^{\uparrow}$ packet is generated from an IntervalNewton row, KrawczykOperator row, IntervalArithmetic row, NewtonIteration provenance row, TaylorModel or slope-remainder row, RegSeqRat readback row, RealUp seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IntervalNewtonKrawczyk}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8388.1, Definition 8388.2, and Definition 8388.3 seed the finite bridge surface joining interval Newton correction rows to Krawczyk validation rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IntervalNewtonKrawczyk}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host zero existence, global uniqueness, floating-point semantics, quotient real equality, ambient Real completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, interval-arithmetic soundness, Newton correction provenance, Krawczyk image validation, Taylor or slope-remainder provenance, RegSeqRat readback, RealUp seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.IntervalNewtonKrawczykUp.

Chapter 8389

A Concrete Naming Certificate for $\mathsf{BishopLocatedConvexHull}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ packet records finite located convex-hull approximation data as BEDC naming evidence. It sits over the real-name seal of chapter 38, the metric carrier of chapter 57, the convex membership surface of chapter 208, the compact finite-read boundary of chapter 60, the polytope witness rows of chapter 209, and the bounded-support convex-hull route of chapter 2347. The packet names a finite approximation surface for located convex hulls; it does not import host convex-hull equality, selected closest points, quotient subsets, ambient $\mathsf{Real}^{\uparrow}$ completeness, or countable choice.

Definition 8389.1 (Bishop located convex-hull carrier)**.** *A* $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (R, M, C, K, P, A, W, D, Q, H, T, S, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal through which tolerances, coefficients, and metric radii are read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *ambient row carrying the distance reads used by the located approximation.*
3. *C is the* $\mathsf{ConvexSet}^{\uparrow}$ *source row naming the convex family under inspection.*
4. *K is the* $\mathsf{Compact}^{\uparrow}$ *finite-read boundary for the inspected source window.*
5. *P is the* $\mathsf{Polytope}^{\uparrow}$ *finite witness row that stores the displayed approximating hull.*
6. *A is the* $\mathsf{CaratheodoryConvexHull}^{\uparrow}$ *bounded-support handoff row.*
7. *W records the located tolerance window and the finite mesh radius used by the approximation read.*
8. *D records the displayed distance-to-hull comparison rows, read only through R, M, C, K, P, A, W.*
9. *Q records the finite coefficient ledger for the approximating convex combination.*
10. *H records componentwise* hsame *transport for the real, metric, convex, compact, polytope, support, window, distance, coefficient, continuation, provenance, and naming rows.*
11. *T is the displayed* Cont *replay from a tolerance request through the same finite rows.*
12. *S is the* Pkg *provenance over* $\mathsf{BishopLocatedConvexHull}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Polytope}^{\uparrow}$, $\mathsf{CaratheodoryConvexHull}^{\uparrow}$, BHist, hsame, Cont, *and local* NameCert *rows.*

13. N is the local $\mathsf{NameCert}_{\mathsf{BishopLocatedConvexHull}^{\uparrow}}$ *row.*
The carrier has no coordinate for host convex-hull equality, a selected nearest point, quotient subset equality, ambient completeness, separation, or countable choice.

Theorem 8389.2 (Bishop located convex-hull NameCert obligations)**.** *For the carrier of Definition 8389.1, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedConvexHull}^{\uparrow}}$ *surface consists exactly of carrier exposure for L, real and metric readback through R, M, convex-source exposure through C, compact finite-read exposure through K, polytope approximation exposure through P, Caratheodory bounded-support exposure through A, tolerance-window exposure through W, distance-comparison exposure through D, coefficient-ledger exposure through Q, componentwise transport through H, displayed continuation replay through T, package provenance through S, and local naming through N. Classifier stability is tested only by replaying those displayed rows under* hsame *transport.*

Theorem 8389.3 (Bishop located convex-hull finite approximation)**.** *Every accepted* $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ *packet exposes a finite approximation route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{ConvexSet}^{\uparrow},\ \mathsf{Compact}^{\uparrow},\ \mathsf{Polytope}^{\uparrow},\ \mathsf{CaratheodoryConvexHull}^{\uparrow}$$

before any located convex-hull distance read is available. The tolerance row W, distance row D, and coefficient row Q therefore witness a finite located approximation of the convex hull, not a host equality of hulls, a selected closest point, quotient subset equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Falsifiable prediction: An accepted $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ consumer that reads a located convex-hull approximation without the displayed real, metric, convex, compact, polytope, Caratheodory, tolerance, distance, and coefficient rows refutes the carrier surface.

Independence witness: real, metric, convexset, compact, polytope, caratheodory-convex-hull: no listed sibling is bijective to $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ because this packet jointly binds finite located tolerance windows, metric distance comparisons, compact finite-read boundaries, polytope approximants, bounded-support hull rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedConvexHull}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedConvexHull}^{\uparrow}$ packet is generated from real-name scalar reads, a metric ambient row, a convex source row, a compact finite-read boundary, a polytope approximant, a Caratheodory bounded-support handoff, located tolerance and distance rows, a coefficient ledger, componentwise transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedConvexHull}^{\uparrow}}$, seed)

Scope closed: Definition 8389.1, Definition 8389.2, and Definition 8389.3 bind the finite located approximation carrier and its NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedConvexHull}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.BishopLocatedConvexHullUp`

Bridge status: none

Not claimed: This chapter does not close host convex-hull equality, nearest-point selection, quotient subset equality, separation, ambient Real completeness, countable choice, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, located distance comparison, finite approximation exactness, support handoff, transport, provenance, and local naming for BEDC.Derived.BishopLocatedConvexHullUp.

Chapter 8390

A Concrete Naming Certificate for $\mathsf{FiniteIntervalChainSelection}^{\uparrow}$

Following Bishop and Bridges on nested intervals and constructive real approximation, the FiniteIntervalChainSelecti packet records the finite L10 surface by which a nested dyadic interval chain exposes a cofinal inspected subchain before Real and Completion consumers read a limit-facing seal. It sits over the dyadic arithmetic of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name boundary of chapter 38, and the nested interval selector route of chapter 6784. The packet names only the finite displayed rows needed by downstream Bolzano–Weierstrass, nested-interval, and completion arguments; it is not countable choice, quotient stream equality, a selected host limit, interval compactness, or real trichotomy.

Definition 8390.1 (Finite interval chain selection carrier)**.** *A* $\mathsf{FiniteIntervalChainSelection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (I, C, D, W, R, E, H, T, P, N)$$

with the following displayed rows:

1. *I is the nested dyadic interval row, recording the finite list of retained endpoint pairs and the inclusion certificates between adjacent rows.*
2. *C is the cofinal unary index row, recording the inspected stages and the monotone refinement map from requested windows to retained interval rows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter-budget row, carrying dyadic upper bounds for retained interval lengths at the inspected stages.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing exactly the queried stages of the chain and cofinal map.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same windows, so endpoint and midpoint observations are regular rational reads rather than host real values.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the nested row, cofinal row, diameter ledger, stream window, and regular readback have been displayed.*
7. *H records componentwise* hsame *transport for the nested rows, cofinal index row, diameter ledger, window, readback, seal, provenance, replay, and local naming rows.*
8. *T records displayed* Cont *replay from a requested precision through C, D, W, R, E and back to the structural rows.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteIntervalChainSelection}^{\uparrow}$, $\mathsf{NestedInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntervalChainSelection}^{\uparrow}}$ *row.*

The carrier exports this finite chain-selection packet and no coordinate for a countable-choice functional, quotient stream equality, host-selected limit, trichotomy of real endpoints, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8390.2 (Finite interval chain selection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntervalChainSelection}^{\uparrow}$ *carrier*

$$S = (I, C, D, W, R, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntervalChainSelection}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed nested dyadic interval row, cofinal unary index row, diameter-budget row, stream window, regular readback, terminal seal, transport, replay, provenance, and local naming data;*
2. *nesting preservation, requiring every retained row of I exposed through C to remain included in the preceding displayed dyadic interval row;*
3. *cofinal refinement, requiring every requested window in W to be met by some unary index of C whose dyadic diameter budget in D is within the requested tolerance;*
4. *Real seal handoff, requiring the terminal* $\mathsf{Real}^{\uparrow}$ *row E to be consumed only after I, C, D, W, R have been displayed and replayed through H, T, P, N;*
5. *nonescape from countable choice, quotient streams, selected host limits, trichotomy, interval compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8390.1. Its analytic rows are exactly the nested dyadic interval row I, cofinal index row C, diameter-budget row D, finite stream window W, regular rational readback R, and terminal Real seal E.

Nesting preservation and cofinal refinement are read from I, C, D, W. The retained interval rows are finite BHist rows, and the cofinal map is a displayed unary index row, so every refinement request is witnessed inside the packet before any Real-facing read is available.

The Real seal handoff then factors through R and E. Regular rational readback supplies the endpoint and midpoint observations for the same finite windows, while E is terminal in the route through $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Finally, H, T, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for countable choice, quotient stream equality, a host-selected limit, real trichotomy, interval compactness, or ambient completeness, the local certificate cannot export any of those principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntervalChainSelection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntervalChainSelection}^{\uparrow}$ packet is generated from nested dyadic interval rows, a cofinal unary index row, a DyadicRatCoreUp diameter-budget ledger, StreamNameUp finite windows, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteIntervalChainSelection}^{\uparrow}}$, seed)

Scope closed: Definition 8390.1 and Definition 8390.2 seed the finite L10 chain-selection route from nested dyadic interval rows through cofinal inspected windows, dyadic diameter budgets, regular rational readback, and the RealUp seal.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteIntervalChainSelection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim countable choice, quotient stream equality, selected host limits, real trichotomy, interval compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, nesting preservation, cofinal refinement, diameter-budget exactness, RealUp seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteIntervalChainSelectio

Chapter 8391

A Concrete Naming Certificate for $\mathsf{LUDecomposition}^{\uparrow}$

Following Golub and Van Loan on matrix computations, the $\mathsf{LUDecomposition}^{\uparrow}$ packet records Gaussian elimination as a finite lower-upper factorization ledger. It consumes the matrix carrier of chapter 49, the vector-space source of chapter 47, the linear-map presentation of chapter 48, the determinant boundary of chapter 84, and the rank accounting surface of chapter 3438. The packet names only displayed pivot rows, row-update ledgers, triangular factors, determinant sign and diagonal-product handoffs, rank-sensitive zero-pivot boundaries, transport, replay, provenance, and local NameCert data; it does not import host Gaussian elimination, quotient matrix equality, selected inverses outside the pivot ledger, or an ambient matrix algorithm.

Definition 8391.1 (LU decomposition carrier)**.** *An* $\mathsf{LUDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (V, A, \Pi, E, L_0, U_0, S, D, R, H, C, P, N)$$

with the following displayed rows:

1. *V is the finite* $\mathsf{VecSpace}^{\uparrow}$ *source and target row on which the matrix acts.*
2. *A is the consumed* $\mathsf{Mat}^{\uparrow}$ *row for the square matrix being factored, together with its* $\mathsf{LinMap}^{\uparrow}$ *action readback.*
3. *Π is the permutation and pivot-order ledger, listing the finite pivot rows and the row exchanges actually used.*
4. *E is the elimination ledger. For each pivot stage it records the displayed multiplier row, the affected row interval, and the resulting entry-update equations.*
5. *L_0 is the lower-triangular factor row, with unit diagonal entries and multiplier entries read only from E.*
6. *U_0 is the upper-triangular factor row produced by the same pivot sequence.*
7. *S is the triangular exactness row saying that the displayed permutation of A is replayed by the product L_0U_0 through the same matrix and linear-map rows.*
8. *D is the determinant boundary row, carrying the permutation sign and the diagonal-product readback through* $\mathsf{Determinant}^{\uparrow}$*.*
9. *R is the rank-sensitive boundary row, read through* $\mathsf{RankNullity}^{\uparrow}$*, that records where a zero-pivot branch stops, swaps, or exposes rank deficiency.*

10. *H records componentwise* hsame *transport for the vector-space, matrix, pivot, elimination, triangular-factor, exactness, determinant, rank, replay, provenance, and local-name rows.*
11. *C records displayed* Cont *replay from an LU-facing consumer back through $V, A, \Pi, E, L_0, U_0, S, D, R, H$.*
12. *P is the* Pkg *provenance over* $\mathsf{LUDecomposition}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{RankNullity}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{LUDecomposition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host field-inversion oracle, quotient row-equivalence theorem, unlogged pivot choice, selected inverse matrix, spectral decomposition, or ambient Gaussian-elimination procedure.

Theorem 8391.2 (LU decomposition NameCert obligations)**.** *For every accepted* $\mathsf{LUDecomposition}^{\uparrow}$ *carrier*

$$L = (V, A, \Pi, E, L_0, U_0, S, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LUDecomposition}^{\uparrow}}$ *surface consists exactly of finite vector-space admission through V, matrix and linear-map admission through A, pivot-order admission through Π, elimination-ledger admission through E, lower-triangular and upper-triangular factor admission through L_0, U_0, triangular exactness through S, determinant boundary readback through D, rank-sensitive zero-pivot boundary readback through R, componentwise transport through H, displayed replay through C, sibling provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows V and A display the finite vector-space, matrix, and linear-map surface before any pivot row is visible.

The pivot and elimination data are then exactly Π, E. These rows determine the multiplier entries in L_0 and the updated upper-triangular entries in U_0, so no separate elimination trace or hidden inverse can be read.

The rows S, D, R attach the triangular product, determinant handoff, and rank-sensitive boundary to the same displayed route. Finally H, C, P, N transport, replay, source, and name only those rows. Hence the listed inventory exhausts the local NameCert obligations. □

Theorem 8391.3 (LU decomposition pivot ledger)**.** *Every finite linear-system, determinant, rank, or matrix-factorization consumer of an accepted* $\mathsf{LUDecomposition}^{\uparrow}$ *packet must first read the pivot route*

$$V, A, \Pi, E, L_0, U_0, S, D, R, H, C, P, N.$$

At each stage the pivot row in Π precedes the multiplier and row-update rows in E, and the lower and upper triangular factors expose only entries recorded by that same finite route.

Proof. Start with the carrier projection. The source vector-space and matrix rows fix the finite domain in which pivoting can be read.

Read Π before E. The pivot order and row-exchange ledger determine which update rows are admissible, while E records the multipliers and row transformations that later appear in L_0 and U_0.

The triangular exactness and support rows then preserve the same route. Since the carrier contains no additional pivot-choice coordinate, no consumer can replace this route by a host Gaussian-elimination algorithm, quotient row-equivalence theorem, or selected inverse outside the ledger. □

Theorem 8391.4 (LU decomposition triangular factor route)**.** *The triangular factor read exported by an accepted* $\mathsf{LUDecomposition}^{\uparrow}$ *packet factors through*

$$\mathsf{Mat}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{LinMap}^{\uparrow} \longmapsto \Pi, E, L_0, U_0, S \longmapsto H, C, P, N.$$

The row L_0 *is lower triangular with unit diagonal because its off-diagonal entries are the displayed multiplier rows from* E*, and the row* U_0 *is upper triangular because every lower-entry cancellation is recorded in the same elimination ledger.*

Proof. Read the matrix, vector-space, and linear-map sources. These rows determine the square finite matrix presentation against which a triangular factorization can be checked.

Next read the pivot and elimination ledgers. The lower factor receives only the multiplier entries already named in E, and the upper factor receives only the updated rows produced by replaying those same elimination equations.

The exactness row S ties the displayed product L_0U_0 to the permuted source matrix. The support rows H, C, P, N preserve that factor route and add no host equality of matrices, unlogged row operation, or external triangularization theorem. □

Theorem 8391.5 (LU decomposition determinant boundary)**.** *Every determinant read from an accepted* $\mathsf{LUDecomposition}^{\uparrow}$ *packet factors through the permutation sign row in* Π*, the upper-triangular diagonal row of* U_0*, the triangular exactness row* S*, and the determinant handoff row* D*. The read is therefore a displayed boundary through* $\mathsf{Determinant}^{\uparrow}$*, not a host determinant algorithm or an unrestricted row-operation principle.*

Proof. Begin with the pivot ledger. The row Π records the finite permutation and hence the sign contribution available to the determinant boundary.

Read the triangular rows next. Since L_0 has unit diagonal by the displayed elimination ledger, the determinant contribution is routed through the diagonal entries of U_0 together with the exactness row S.

The handoff row D is the only determinant-facing coordinate in the carrier. Transport and replay through H, C, P, N preserve that coordinate, so a consumer cannot obtain an ambient determinant computation, hidden row-equivalence theorem, or quotient matrix equality from the LU packet. □

Falsifiable prediction: An accepted $\mathsf{LUDecomposition}^{\uparrow}$ consumer is refuted if it reads a triangular factor, determinant boundary, or rank-sensitive zero-pivot result without first exposing the displayed $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{RankNullity}^{\uparrow}$, pivot, elimination, exactness, transport, replay, provenance, and local-name rows.

Independence witness: matrix, vecspace, linearmap, determinant, ranknullity: none is bijective to $\mathsf{LUDecomposition}^{\uparrow}$ because the LU packet jointly carries a pivot ledger, an elimination ledger, two triangular factor rows, determinant-boundary data, rank-sensitive zero-pivot data, and structural support rows.

Closure status for $\mathsf{NameCert}_{\mathsf{LUDecomposition}^{\uparrow}}$.

Constructive story: An $\mathsf{LUDecomposition}^{\uparrow}$ packet is generated from MatrixUp, VecSpaceUp, and LinearMapUp source rows, a finite permutation and pivot ledger, displayed elimination-update equations, lower and upper triangular factor rows, triangular exactness, DeterminantUp sign and diagonal-product readback, RankNullityUp zero-pivot boundary data, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{LUDecomposition}^{\uparrow}}$, seed)

Scope closed: Definition 8391.1, Definition 8391.2, Definition 8391.3, Definition 8391.4, and Definition 8391.5 seed the finite LU factorization route over matrix, vector-space, linear-map, determinant, rank-nullity, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{LUDecomposition}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host Gaussian elimination, quotient row-equivalence, arbitrary pivot selection outside the displayed ledger, inverse-matrix construction, spectral decomposition, or ambient matrix-algorithm correctness.

Upgrade path: Obligation closure requires checked carrier admission, pivot-ledger exactness, elimination-update replay, triangular-factor exactness, determinant boundary soundness, rank-sensitive zero-pivot boundary soundness, transport, replay, provenance, and local naming for BEDC.Derived.LUDecompositionUp.

Chapter 8392

A Concrete Naming Certificate for $\mathsf{FiniteTailSandwich}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteTailSandwich}^{\uparrow}$ packet records the finite tail-squeeze data by which a middle regular rational name is read between lower and upper tail rows at a common dyadic budget. It sits over the arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational sequence interface of chapter 301, the terminal real seal of chapter 38, and the two-sided regular-Cauchy bracketing route of chapter 5874. The packet gives Real-and-Completion arguments a displayed finite tail sandwich without using quotient sequence equality, selected subsequences, host limits, or ambient completeness.

Definition 8392.1 (Finite tail sandwich carrier)**.** *A* $\mathsf{FiniteTailSandwich}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (L, M, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower tail row, naming the inspected lower* $\mathsf{RegSeqRat}^{\uparrow}$ *values and their finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
2. *M is the middle tail row, naming the inspected middle* $\mathsf{RegSeqRat}^{\uparrow}$ *values that are to be squeezed.*
3. *U is the upper tail row, naming the inspected upper* $\mathsf{RegSeqRat}^{\uparrow}$ *values and their finite* $\mathsf{StreamName}^{\uparrow}$ *windows.*
4. *D is the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *budget ledger, recording the shared tail index, tolerance cell, lower–middle comparison, middle–upper comparison, and upper–lower width bound for each displayed read.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window ledger proving that L, M, U are read on the same finite tail schedule.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row through which downstream regular-Cauchy consumers reread the middle row only after the two-sided tail comparisons have been exposed.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached after the lower, middle, upper, budget, window, and readback rows have been replayed.*
8. *H records componentwise* hsame *transport for L, M, U, D, W, R, E and the structural rows.*
9. *C records displayed* Cont *replay routes for rereading the same finite sandwich data.*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteTailSandwich}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTailSandwich}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for host real equality, quotient stream equality, a selected cofinal subsequence, trichotomy, a least upper bound, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8392.2 (Finite tail sandwich NameCert obligations)**.** *For every accepted* $\mathsf{FiniteTailSandwich}^{\uparrow}$ *carrier $F = (L, M, U, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteTailSandwich}^{\uparrow}}$ *surface consists of carrier admission for the lower, middle, and upper tail rows; common-window exposure through W; common dyadic-budget visibility through D; regular rational readback through R; terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport; displayed* Cont *replay;* Pkg *provenance; and local naming. No obligation may replace these rows by a host limit, quotient sequence equality, selected subsequence, trichotomy, or ambient completeness.*

Proof. Project the carrier of Definition 8392.1. The analytic rows are exactly L, M, U, D, W, R, E, so every admissible obligation must be read from the displayed lower, middle, upper, budget, window, readback, and seal coordinates.

The common-tail condition is enforced by W and D. The window row fixes the finite tail schedule shared by the three regular rational rows, while the dyadic ledger records the lower–middle and middle–upper comparisons at the same tolerance cell.

The structural rows H, C, P, N preserve this inventory. Transport keeps the same component rows visible, continuation replay rereads them in the displayed order, provenance names the packet source, and the local name records no additional analytic coordinate. Hence the listed rows exhaust the local NameCert surface and exclude the non-constructive escape routes named in the statement. □

Theorem 8392.3 (Finite tail sandwich RegSeqRat handoff)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of the middle row in an accepted* $\mathsf{FiniteTailSandwich}^{\uparrow}$ *packet factors through the displayed route*

$$L \longmapsto M \longmapsto U \longmapsto D \longmapsto W \longmapsto R \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

In particular, the handoff exposes a finite lower–middle–upper tail squeeze at a common dyadic budget, not a host limit, quotient sequence equality, selected subsequence, or ambient completeness principle.

Proof. Begin with the lower, middle, and upper rows L, M, U. They supply only finite $\mathsf{RegSeqRat}^{\uparrow}$ reads and finite $\mathsf{StreamName}^{\uparrow}$ windows, so the middle row is never detached from its two bounding rows.

Next read D and W. The dyadic ledger stores the two-sided comparison and width budget at the inspected tolerance, while the window ledger records that all three rows are read on the same finite tail schedule.

Only after those rows are visible can a consumer reach R and E. The readback row makes the middle regular rational name available to downstream regular-Cauchy consumers, and the terminal seal exposes the Real-facing boundary. The structural rows H, C, P, N then transport, replay, source, and name precisely the same route, so no host limit or completeness coordinate is introduced. □

The chapter is the finite-tail sibling of the broader regular-Cauchy sandwich certificate in chapter 5874. That sibling records the two-sided regular-Cauchy bracketing route as a full certificate; the present packet isolates the common-tail budget, window, and middle-row readback used when a later Real-and-Completion argument only needs the finite squeeze data.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTailSandwich}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTailSandwich}^{\uparrow}$ packet is generated from lower, middle, and upper RegSeqRat tail rows, a common DyadicRatCore budget ledger, StreamName windows, RegSeqRat readback, a terminal Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTailSandwich}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8392.1, Definition 8392.2, and Definition 8392.3 seed the finite lower–middle–upper tail squeeze surface for Real-and-Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTailSandwich}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, quotient sequence equality, selected subsequences, host limits, trichotomy, least-upper-bound reasoning, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, common-tail window exposure, dyadic two-sided budget visibility, RegSeqRat readback, Real seal routing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTailSandwichUp.

Chapter 8393

A Concrete Naming Certificate for $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$

Following Bishop and Bridges, a regular completion argument uses a displayed modulus before it treats a Cauchy name as completion-facing data. The $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ packet records that finite modulus surface between the dyadic arithmetic of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the effective Cauchy completion carrier of chapter 5930, and the terminal real-name seal of chapter 38. The packet names the regularity budget that a completion consumer may inspect; it is not a quotient of Cauchy streams, a selected host limit, countable choice, trichotomy, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8393.1 (Bishop regular completion-modulus carrier)**.** *A* $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (D, S, R, C, E, B, H, T, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, listing the dyadic radii and comparison rows used by the requested completion precision.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, exposing exactly the inspected entries of the regular Cauchy name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the same stream window and dyadic tolerance ledger.*
4. *C is the* $\mathsf{EffectiveCauchyCompletion}^{\uparrow}$ *admission row, recording that the displayed windows and tolerances form the completion-facing Cauchy route.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after D, S, R, C have all been displayed.*
6. *B is the Bishop regularity-modulus row, assigning each requested precision a finite inspection bound and a dyadic tolerance budget.*
7. *H records componentwise* hsame *transport for the dyadic ledger, stream window, regular readback, completion row, Real seal, modulus row, replay, provenance, and local naming.*
8. *T records displayed* Cont *replay from a precision request through B, D, S, R, C, E.*

9. *P is the* Pkg *provenance over* BishopRegularCompletionModulus$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, EffectiveCauchyCompletion$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopRegularCompletionModulus}^{\uparrow}}$ *row.*

The carrier exports only this finite modulus packet. It has no coordinate for quotient stream equality, a selected representative in a host completion, an infinite choice functional, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8393.2 (Bishop regular completion-modulus NameCert obligations)**.** *For every accepted* BishopRegularCompletionModulus$^{\uparrow}$ *carrier*

$$M = (D, S, R, C, E, B, H, T, P, N),$$

the local NameCert$_{\text{BishopRegularCompletionModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the dyadic tolerance ledger, stream window, regular readback, effective-completion admission, Real seal, Bishop modulus, transport, replay, provenance, and local naming rows;*
2. *finite-window adequacy, requiring every precision request in B to open the displayed S window before the regular readback row R is consumed;*
3. *dyadic tolerance exactness, requiring the row D to supply the budget used by both R and the completion admission row C;*
4. *Real seal nonescape, requiring E to be read only after D, S, R, C, B have been displayed and replayed through H, T, P, N;*
5. *exclusion of quotient stream equality, selected completed representatives, countable choice, trichotomy, and ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8393.1. Its analytic rows are exactly D, S, R, C, E, B, with H, T, P, N supplying transport, replay, provenance, and local naming.

The modulus row B is the only row assigning a finite inspection bound to a requested precision. Once B is read, the consumer must open the corresponding stream window S and dyadic tolerance ledger D before it can consume the regular readback row R.

The completion-facing row C is downstream of D, S, R, B. Thus the packet presents an effective Cauchy completion route through displayed finite data rather than through a quotient of Cauchy names.

Finally, the terminal seal E is reached only after the same rows have been replayed. Since the carrier contains no coordinate for quotient equality, a selected host representative, countable choice, trichotomy, or ambient completeness, those principles are outside the local certificate. □

Theorem 8393.3 (Bishop regular completion-modulus window route)**.** *Every* BishopRegularCompletionModulus$^{\uparrow}$ *precision request first factors through the* StreamName$^{\uparrow}$ *finite-window row and the* RegSeqRat$^{\uparrow}$ *readback row of chapter 126 and chapter 301. The dyadic tolerance ledger of chapter 291 supplies the same finite budget before the request may be treated as an* EffectiveCauchyCompletion$^{\uparrow}$ *admission.*

Proof. Apply Definition 8393.2. The finite-window adequacy clause makes S the first observation row opened by a precision request, and the dyadic tolerance exactness clause makes D the budget row shared by the readback and completion admission.

The row R reads the displayed window as regular rational data, while C is available only after D, S, R, B. Therefore the effective-completion route cannot bypass the StreamName and RegSeqRat sibling rows. □

Theorem 8393.4 (Bishop regular completion-modulus Real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ *packet reads the route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{EffectiveCauchyCompletion}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $D, S, R, C, E, B, H, T, P, N$*. The route supplies a finite regular completion-modulus witness and no completed-real theorem, quotient representative, selected limit, countable-choice functional, trichotomy, or ambient completeness principle.*

Proof. Apply Definition 8393.3. The route already forces the precision request through dyadic tolerance, finite stream inspection, regular rational readback, and effective-completion admission.

The Real seal nonescape clause of Definition 8393.2 places E after those rows and after the Bishop modulus row B. Rows H, T, P, N preserve and replay the same displayed route.

Hence a Real-facing consumer receives only the finite regular completion-modulus packet. Any claim about completed-real existence, quotient representatives, selected limits, countable choice, trichotomy, or ambient completeness is absent from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ read exposes a DyadicRatCore tolerance ledger, StreamName finite-window row, RegSeqRat readback row, EffectiveCauchyCompletion admission row, RealUp seal, Bishop modulus row, transport, replay, provenance, and local naming.

Independence witness: dyadicratcore, streamname, regseqrat, effective-cauchy-completion, real: $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ is not identical to any listed sibling because it binds the precision-to-window modulus before effective completion admission and terminal RealUp sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRegularCompletionModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRegularCompletionModulus}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance ledger, StreamName finite windows, RegSeqRat readback, EffectiveCauchyCompletion admission, RealUp seal, Bishop regularity modulus, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8393.1, Definition 8393.2, Definition 8393.3, and Definition 8393.4 seed the finite regular completion-modulus route from precision requests to the terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRegularCompletionModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim completed-real existence, quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window adequacy, dyadic tolerance exactness, effective-completion admission, RealUp seal nonescape, replay, provenance, and local naming for BEDC.Derived.BishopRegularCompletion

Chapter 8394

A Concrete Naming Certificate for $\mathsf{CompactUniformGraphModulus}^{\uparrow}$

Following Bishop and Bridges on compact metric spaces and uniform continuity, the $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ packet records the finite graph-evaluation route by which a continuous map on a compact source yields a displayed uniform-modulus handoff. It sits over the compact finite-net rows of chapter 129, the distance rows of chapter 57, the graph and pointwise-modulus rows of chapter 130, the uniform-modulus consumer of chapter 369, and the value readback route through chapter 126, chapter 301, and chapter 38. The packet names the compact graph-modulus bridge as finite NameCert data; it is not open-cover compactness, a host function graph, a selected net point outside the carrier, quotient equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8394.1 (Compact uniform graph-modulus carrier)**.** *A* $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (K, M, F, P, U, S, R, E, H, C, Q, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, listing the compact source centers and coverage witnesses inspected by the graph-modulus read.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *source-and-target distance row used to compare source points, selected centers, and target values.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph-evaluation row, recording the finite pointwise graph windows opened at the centers of K.*
4. *P is the pointwise-modulus row attached to the same graph windows.*
5. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained by folding the compact-net and pointwise-modulus data into a single tolerance budget.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for graph values and tolerance reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed stream windows.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for value-facing consumers.*
9. *H records componentwise* hsame *transport for compact, metric, graph, pointwise-modulus, uniform-modulus, stream, readback, Real-seal, replay, provenance, and naming rows.*

10. *C records displayed* Cont *replay from a requested tolerance through K, M, F, P, U, S, R, E.*
11. *Q is the* Pkg *provenance over* $\mathsf{CompactUniformGraphModulus}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformGraphModulus}^{\uparrow}}$ *row.*

The carrier exports no coordinate for a host graph subset, open-cover compactness proof, global choice of centers, quotient equality of maps, selected modulus outside U, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8394.2 (Compact uniform graph-modulus NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ *carrier*

$$G = (K, M, F, P, U, S, R, E, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformGraphModulus}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for compact finite-net, metric, continuous graph, pointwise-modulus, uniform-modulus, stream-window, regular readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *graph-window adequacy, requiring each graph value used by F and P to be exposed through the displayed finite window S and read back through R;*
3. *compact fold exactness, requiring the uniform-modulus row U to be obtained only from the compact finite-net row K, metric row M, graph row F, and pointwise-modulus row P;*
4. *Real seal nonescape, requiring the terminal row E to be consumed only after K, M, F, P, U, S, R have all been displayed and replayed through H, C, Q, N;*
5. *exclusion of host graph subsets, open-cover compactness, global center choice, quotient map equality, selected external moduli, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8394.1. The analytic rows are precisely K, M, F, P, U, S, R, E, and the structural rows H, C, Q, N preserve and replay the same route.

The graph-window adequacy clause forces pointwise graph reads through S and R. Thus a continuous-map value is consumed as finite StreamName and RegSeqRat data, not as a host graph element.

The compact fold exactness clause then makes U downstream from the compact finite net K, metric comparisons M, graph values F, and pointwise moduli P. This is the finite graph-modulus route used by the compact-uniform-continuity construction.

Finally, E is terminal and only Real-facing. Since no row stores open-cover compactness, a host graph subset, a global choice functional, quotient map equality, an external selected modulus, or ambient completeness, the local certificate cannot export those principles. □

Theorem 8394.3 (Compact uniform graph-modulus finite route)**.** *Every* $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ *consumer factors through the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

before reading a value-facing or modulus-facing conclusion. In particular, the compact finite-net row, graph-evaluation row, pointwise-modulus row, uniform-modulus row, and Real seal are all displayed rows of the same packet.

Proof. Apply Definition 8394.2. Carrier admission lists the compact, metric, graph, pointwise-modulus, uniform-modulus, stream, readback, and Real-seal rows as the whole analytic surface.

Graph-window adequacy routes value reads through S and R. Compact fold exactness routes the modulus read through K, M, F, P before U is available.

The terminal Real seal is then downstream of the same finite rows. Therefore any value-facing or modulus-facing consumer receives the displayed graph-modulus route and no detached compactness or host graph object. □

Theorem 8394.4 (Compact uniform graph-modulus Real seal)**.** *For an accepted* $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ *carrier, every* $\mathsf{Real}^{\uparrow}$ *value read and every* $\mathsf{UniformModulus}^{\uparrow}$ *handoff is bounded by the displayed compact-net, metric, graph-evaluation, pointwise-modulus, stream-window, and regular-readback rows. The packet can be cited by compact-uniform-continuity consumers, but it exports no open-cover compactness theorem, host graph subset, quotient map equality, selected external modulus, global choice of centers, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply Definition 8394.3. The value read has already passed through S, R, E, and the modulus handoff has already passed through K, M, F, P, U.

Rows H, C, Q, N add only componentwise transport, replay, provenance, and local naming. They do not add a host graph, a separate open-cover compactness proof, or a choice functional.

Thus the Real-facing and uniform-modulus-facing conclusions are bounded by the displayed finite packet. Claims about host graph subsets, quotient equality of maps, selected external moduli, global center choice, or ambient completeness lie outside the certificate. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ read exposes compact finite-net, metric, continuous graph, pointwise-modulus, uniform-modulus, StreamName, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Independence witness: compactmetric, metric, continuousmap, uniformmodulus, streamname, regseqrat, real: $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ is not identical to any listed sibling because it binds finite graph-evaluation rows and pointwise moduli into a compact uniform-modulus handoff before terminal RealUp sealing.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformGraphModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformGraphModulus}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, Metric distance rows, ContinuousMap graph-evaluation rows, pointwise-modulus rows, a UniformModulus handoff, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformGraphModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8394.1, Definition 8394.2, Definition 8394.3, and Definition 8394.4 seed the compact graph-evaluation route from compact finite nets and pointwise moduli to a UniformModulus and RealUp handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformGraphModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, host graph subsets, quotient equality of maps, selected external moduli, global center choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph-window adequacy, compact fold exactness, UniformModulus handoff, RealUp seal nonescape, replay, provenance, and local naming for BEDC.Derived.CompactUniformGraphModulu

Chapter 8395

A Concrete Naming Certificate for $\mathsf{BishopLocatedCompactness}^{\uparrow}$

Following Bishop–Bridges constructive compactness, the $\mathsf{BishopLocatedCompactness}^{\uparrow}$ packet records the finite-net and located-distance certificate by which a constructive compact metric source can be consumed without changing into an open-cover principle. It sits after the complete metric service of chapter 128, the finite-net surface of chapter 127, the located subset interface of chapter 1541, the ambient metric-space carrier of chapter 4230, and the real-name boundary of chapter 38. Completion and compact-metric consumers receive a displayed located finite-net package, not open-cover compactness, not sequential compactness without choice-like data, and not host selected limit points.

Definition 8395.1 (Bishop located compactness carrier)**.** *A* $\mathsf{BishopLocatedCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, C, T, L, W, R, D, E, H, Q, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the distance classifier and metric-law ledger used by every finite-net request.*
2. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, available only as the displayed Cauchy-readback boundary for completion-facing consumers.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, storing finite center bundles, coverage-distance rows, and rational tolerance comparisons.*
4. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row for the compact-facing located subset or whole-space admission surface.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that names the finite observation schedule for net and distance reads.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for regular rational distance and tolerance data.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger row for dyadic radius and coverage comparisons.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for displayed distance or modulus outputs.*
9. *H records componentwise* hsame *transport for the metric, complete, finite-net, located-set, stream, rational, dyadic, real, replay, provenance, and local naming rows.*
10. *Q records displayed* Cont *replay from a compactness tolerance request through $M, C, T, L, W, R, D, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedCompactness}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for arbitrary open covers, selected subsequences, host compact subsets, quotient completion, or chosen limit points.

Theorem 8395.2 (Bishop located compactness net obligations)**.** *For every accepted* $\mathsf{BishopLocatedCompactness}^{\uparrow}$ *carrier*

$$K = (M, C, T, L, W, R, D, E, H, Q, P, N),$$

each compactness-facing read must first expose the metric source M, the complete-metric service row C, the totally bounded finite-net row T, the located-set row L, the stream window W, the regular-rational readback R, the dyadic ledger D, and the real seal E, together with the support rows H, Q, P, N. The resulting surface is a Bishop-style located finite-net certificate for downstream compact-metric and completion routes.

Proof. Project the carrier of Definition 8395.1. The finite-net data are exactly the $\mathsf{TotallyBounded}^{\uparrow}$ row T, the located-distance data are exactly the $\mathsf{LocatedSet}^{\uparrow}$ row L, and both are typed over the same $\mathsf{Met}^{\uparrow}$ source M.

The completion-facing service is read only through C. It supplies the displayed Cauchy boundary for later consumers, while W, R, D, E provide the finite stream, regular-rational, dyadic, and real-seal readbacks attached to the net and located-distance rows.

The support rows H, Q, P, N preserve this route by componentwise transport, displayed replay, provenance, and local naming. Since the carrier has no coordinate for open-cover compactness, choice-free sequential compactness, or selected host limit points, the obligation surface is exhausted by the displayed finite-net projection. □

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedCompactness}^{\uparrow}$ read exposes MetricSpace, CompleteMetric, TotallyBounded, LocatedSet, StreamName, RegSeqRat, DyadicRatCore, Real, transport, replay, provenance, and local NameCert rows before any compactness-facing conclusion is consumed.

Independence witness: CompleteMetric, TotallyBounded, LocatedSet, MetricSpace, StreamName, RegSeqRat, DyadicRatCore, and Real: no listed sibling is bijective to $\mathsf{BishopLocatedCompactness}^{\uparrow}$ because this packet jointly carries the finite-net cover, located-distance admission, completion-facing service, rational and dyadic readback, real seal, transport, replay, provenance, and local naming route while refusing open-cover compactness and selected limit points.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedCompactness}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedCompactness}^{\uparrow}$ packet is generated from a MetricSpace source row, CompleteMetric service row, TotallyBounded finite-net row, LocatedSet distance row, StreamName window, RegSeqRat readback, DyadicRatCore ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedCompactness}^{\uparrow}}$, seed)

Scope closed: Definition 8395.1 and Definition 8395.2 seed the constructive located finite-net certificate over the metric, completion, total-boundedness, located-set, stream, rational, dyadic, Real, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, sequential compactness without choice-like data, selected limit points, quotient completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net projection, located-distance routing, completion service exposure, StreamName and RegSeqRat readback, DyadicRatCore ledgering, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedCompactnessUp.

Chapter 8396

A Concrete Naming Certificate for $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ packet records the finite route by which a regular sequence displays a cluster witness before a Real or Completion consumer reads a seal. It sits over the regular-sequence source of chapter 5965, the finite observation windows of chapter 5916, the cofinal extraction route of chapter 5125, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet names a displayed cluster witness for a regular-sequence source without countable choice, quotient equality of sequence names, host compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8396.1 (Regular-sequence cluster-witness carrier)**.** *A* $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (S, F, E, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *source row, retaining the regular-sequence classifier and the source-window names used by the cluster read.*
2. *F is the* $\mathsf{FiniteStream}^{\uparrow}$ *window ledger, recording the finite source windows inspected for the cluster witness.*
3. *E is the* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *cofinal extraction row, naming the monotone cofinal schedule by which the displayed windows are read.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic radii and comparison slack used in the cluster-window checks.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the rational observations read from the extracted windows.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, consumed only after S, F, E, D, R have been displayed.*
7. *H records componentwise* hsame *transport for the source, finite windows, extractor, dyadic tolerance, regular readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the route*

$$S, F, E, D, R \longmapsto Q.$$

9. *P is the* Pkg *provenance over* RegularSequenceClusterWitness$^{\uparrow}$, RegularSequenceSpace$^{\uparrow}$, FiniteStream$^{\uparrow}$, CauchySubsequenceExtractor$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{RegularSequenceClusterWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, F, E, D, R, Q, H, C, P, N$. It has no coordinate for a choice-selected subsequence, quotient equality of sequence names, a detached cluster point, host compactness, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8396.2 (Regular-sequence cluster-witness NameCert obligations)**.** *For every accepted* RegularSequenceClusterWitness$^{\uparrow}$ *carrier*

$$W = (S, F, E, D, R, Q, H, C, P, N),$$

the local NameCert$_{\text{RegularSequenceClusterWitness}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed regular-sequence source, finite windows, cofinal extractor, dyadic tolerance row, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *source-window exposure, requiring every cluster observation to cite the same* RegularSequenceSpace$^{\uparrow}$ *source row S and a displayed* FiniteStream$^{\uparrow}$ *window row F;*
3. *cofinal extraction exposure, requiring the selected windows to pass through the* CauchySubsequenceExtractor$^{\uparrow}$ *row E before any readback is used;*
4. *dyadic-tolerance exactness, requiring every cluster comparison to use the displayed* DyadicRatCore$^{\uparrow}$ *row D;*
5. *regular-readback exactness, requiring the comparison values to be read from the* RegSeqRat$^{\uparrow}$ *row R rather than from host sequence equality;*
6. *Real-seal nonescape, requiring Q to be consumed only after the source, finite windows, extractor, tolerance, and readback rows have been displayed;*
7. *componentwise transport, continuation replay, package provenance, and local naming through H, C, P, N.*

No obligation is discharged by choice, quotient sequence equality, host compactness, or ambient completeness.

Lean4 ✓ `BEDC.Derived.RegularSequenceClusterWitnessUp.RegularSequenceClusterWitnessTasteGate`
`single carrier alignment`

Proof. Project the accepted carrier $W = (S, F, E, D, R, Q, H, C, P, N)$. The available observation data are exactly the regular-sequence source, finite stream windows, cofinal extractor, dyadic tolerance row, regular rational readback, and terminal Real seal.

The source-window and extractor obligations follow from the placement of S, F, E. A cluster observation has no independent schedule row unless it first cites the regular-sequence source, a finite window ledger, and the cofinal extraction route.

The comparison obligations are then forced through D and R. The dyadic tolerance row supplies the comparison radius, while the regular rational readback supplies the displayed values inspected inside that radius.

Finally Q is downstream from those rows, and H, C, P, N preserve, replay, source, and name the same finite packet. Since no excluded object is a coordinate of W, the listed rows exhaust the local NameCert surface. □

Theorem 8396.3 (Regular-sequence cluster-witness Real-completion handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ *packet reads the finite route*

$$\mathsf{RegularSequenceSpace}^{\uparrow} \longmapsto \mathsf{FiniteStream}^{\uparrow} \longmapsto \mathsf{CauchySubsequenceExtractor}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \mapsto$$

The handoff supplies a displayed cluster witness over finite windows and a cofinal extractor; it does not select a cluster point, identify quotient sequence names, invoke countable choice, or use host compactness or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularSequenceClusterWitnessUp.RegularSequenceClusterWitnessRealCompletionHandoff`

Proof. Start with the obligation theorem Definition 8396.2. It places the source row S, finite-window ledger F, cofinal extractor E, tolerance row D, and readback row R before the Real seal Q.

The sibling routes provide the stated handoff surface. The regular-sequence space supplies the source classifier, the finite-stream chapter supplies inspected windows, and the cofinal extractor supplies the displayed monotone schedule before any rational readback is consumed.

The dyadic and regular-rational rows then determine the finite comparison read. Transport, replay, provenance, and local naming preserve that route, so the completion-facing consumer receives only the displayed cluster-witness packet and none of the excluded endpoints. □

Theorem 8396.4 (Regular-sequence cluster-witness monotone extraction)**.** *For every accepted* $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ *carrier*

$$W = (S, F, E, D, R, Q, H, C, P, N),$$

each cluster-facing read exposes the cofinal extractor row E *as a monotone finite-window schedule over the* $\mathsf{FiniteStream}^{\uparrow}$ *ledger* F *before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R *or terminal* $\mathsf{Real}^{\uparrow}$ *seal* Q *is consumed.*

Proof. Project the carrier of Definition 8396.1. Its displayed row order is $S, F, E, D, R, Q, H, C, P, N$, and the replay row records the route

$$S, F, E, D, R \longmapsto Q.$$

Apply Definition 8396.2. The source-window exposure row places every cluster observation over the same source row S and finite-window row F, while the cofinal extraction exposure row requires the selected windows to pass through E before any readback is used.

The regular-readback and Real-seal clauses are downstream of that projection. Thus R can only read rational observations after the monotone finite-window schedule has been displayed over F, and Q can only be consumed after the source, finite windows, extractor, tolerance, and readback rows have already appeared. □

Lean4 ✓ `BEDC.Derived.RegularSequenceClusterWitnessUp.RegularSequenceClusterWitnessCarrier monotone extraction`

Falsifiable prediction: A $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ consumer that reaches a Real or Completion cluster read without displaying the regular-sequence source, finite stream windows, cofinal

extractor, dyadic tolerance row, regular rational readback, transport, replay, provenance, and local naming exits the accepted carrier.

Independence witness: regular-sequence-space, finite-stream, cauchy-subsequence-extractor, dyadicratcore, regseqrat, real: no listed sibling is bijective with $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ because this packet jointly binds source regularity, finite windows, cofinal extraction, dyadic tolerance, rational readback, terminal seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularSequenceClusterWitness}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularSequenceClusterWitness}^{\uparrow}$ packet is generated from a RegularSequenceSpace source row, FiniteStream windows, a CauchySubsequenceExtractor cofinal extraction row, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularSequenceClusterWitness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8396.1, Definition 8396.2, and Definition 8396.3 seed the finite cluster-witness route over displayed regular-sequence, finite-window, cofinal-extractor, dyadic-tolerance, rational-readback, Real, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularSequenceClusterWitness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected cluster points, quotient sequence equality, countable choice, host compactness, ambient RealUp completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exposure, cofinal extraction exposure, dyadic-tolerance exactness, regular-readback exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularSequenceClusterWitnessUp.

Chapter 8397

A Concrete Naming Certificate for $\mathsf{CholeskyDecomposition}^{\uparrow}$

Following Cholesky and Golub–Van Loan, the $\mathsf{CholeskyDecomposition}^{\uparrow}$ packet records positive-definite matrix factorization as finite BEDC data over displayed matrix, inner-product, triangular-factor, and diagonal-positivity rows. It consumes the matrix carrier of chapter 49, the positive-definite inner-product route of chapter 86, the triangular ledger of chapter 8391, the orthogonal factorization comparison of chapter 4240, and the spectral comparison surface of chapter 6037. The packet names only a displayed positive-definite factorization route; it does not import a host numerical algorithm, quotient matrix equality, pivot selection outside the certificate, an analytic square-root choice, or an ambient completeness principle.

Definition 8397.1 (Cholesky decomposition carrier)**.** *A* $\mathsf{CholeskyDecomposition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (M, P, L, D, R, H, C, Q, N)$$

with the following visible rows:

1. *M is the displayed square matrix source, read through the finite row and column interface of* $\mathsf{Mat}^{\uparrow}$*.*
2. *P is the positive-definite witness row, recording the* $\mathsf{InnerProduct}^{\uparrow}$ *comparison and the finite Gram positivity checks available to the factorization consumer.*
3. *L is the lower-triangular factor row, carrying the finite entries and triangular-zero ledger.*
4. *D is the diagonal-positivity row, recording that the diagonal entries used by the triangular factor are positive displayed scalars.*
5. *R is the reconstruction ledger asserting that the displayed matrix source is recovered from the lower-triangular factor, its transpose-facing read, and the diagonal positivity data.*
6. *H records componentwise* hsame *transport for the source, positivity, triangular, diagonal, reconstruction, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from the matrix and positivity rows to the factor row, and from the factor row to the reconstruction ledger.*
8. *Q is the* Pkg *provenance over* $\mathsf{CholeskyDecomposition}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{InnerProduct}^{\uparrow}$*,* $\mathsf{LUDecomposition}^{\uparrow}$*,* $\mathsf{QRDecomposition}^{\uparrow}$*,* $\mathsf{SingularValueDecomposition}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{CholeskyDecomposition}^{\uparrow}}$ *row.*
The classifier compares accepted packets componentwise by the displayed rows. No coordinate stores a host floating-point routine, quotient matrix equality, selected pivoting outside the packet, a global spectral theorem, or an unrestricted square-root operation.

Theorem 8397.2 (Cholesky decomposition NameCert obligations)**.** *For every accepted* $\mathsf{CholeskyDecomposition}^{\uparrow}$ *carrier*

$$X = (M, P, L, D, R, H, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{CholeskyDecomposition}^{\uparrow}}$ *surface consists exactly of matrix-source admission through M, positive-definite exposure through P, lower-triangular factor exposure through L, diagonal positivity through D, reconstruction through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, sibling provenance through Q, and local naming through N.*

Proof. Project the carrier of Definition 8397.1. The only mathematical rows before structural transport are M, P, L, D, R, so every accepted read must expose the matrix source, positive-definite witness, lower-triangular factor, diagonal positivity, and reconstruction ledger.

The structural rows H and C preserve those same displayed rows under transport and replay. They do not introduce a second factorization, a host equality principle, or an algorithmic pivot choice.

Finally Q and N record sibling provenance and the local naming row. Since no other coordinate is present, the listed rows exhaust the local NameCert obligations. □

Theorem 8397.3 (Cholesky decomposition positive-definite route)**.** *Every positive-definite matrix-factorization consumer of an accepted* $\mathsf{CholeskyDecomposition}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Mat}^{\uparrow} \longrightarrow \mathsf{InnerProduct}^{\uparrow} \longrightarrow \mathsf{LUDecomposition}^{\uparrow} \longrightarrow \mathsf{QRDecomposition}^{\uparrow} \longrightarrow \mathsf{SingularValueDecomposition}^{\uparrow}$$

through the displayed rows $M, P, L, D, R, H, C, Q, N$. The Cholesky read therefore exports a lower-triangular positive-diagonal reconstruction certificate, not a host numerical routine, quotient matrix equality, selected pivoting rule, analytic square-root choice, or ambient spectral-completion theorem.

Proof. Start with the matrix source and positive-definite witness rows M and P. They force the consumer to read a displayed finite matrix and the finite positivity checks before any triangular factor can be inspected.

Next read the triangular and diagonal rows L and D. The lower-triangular shape is tied to the LU-style triangular ledger, while the positive diagonal row keeps the Cholesky factor distinct from a generic triangular decomposition.

Finally inspect the reconstruction and structural rows R, H, C, Q, N. They replay the same factorization route and record the QR and singular-value comparison surfaces only as sibling provenance. Thus the exported object is the displayed positive-definite Cholesky route and nothing outside the finite certificate. □

Falsifiable prediction: An accepted $\mathsf{CholeskyDecomposition}^{\uparrow}$ consumer is refuted if it reads a positive-definite factorization without first exposing the MatrixUp source, InnerProductUp positivity witness, lower-triangular factor, diagonal-positivity row, reconstruction ledger, transport, replay, provenance, and local naming rows.

Independence witness: matrix, innerproduct, lu-decomposition, qr-decomposition, singular-value-decomposition: none is bijective to $\mathsf{CholeskyDecomposition}^{\uparrow}$ because the Cholesky packet

jointly carries positive-definite witness data, lower-triangular factor data, diagonal positivity, reconstruction, and structural certificate rows.

Closure status for $\mathsf{NameCert}_{\mathsf{CholeskyDecomposition}^{\uparrow}}$.

Constructive story: A $\mathsf{CholeskyDecomposition}^{\uparrow}$ packet is generated from a displayed MatrixUp source, an InnerProductUp positive-definite witness row, a lower-triangular factor row, a diagonal-positivity row, a reconstruction ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CholeskyDecomposition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8397.1, Definition 8397.2, and Definition 8397.3 seed the finite positive-definite triangular factorization route over MatrixUp, InnerProductUp, LUDecompositionUp, QRDecompositionUp, SingularValueDecompositionUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CholeskyDecomposition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host numerical Cholesky algorithms, quotient matrix equality, selected pivoting outside the packet, analytic square-root choice, spectral completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-definite witness exposure, triangular-factor exposure, diagonal-positivity exposure, reconstruction replay, transport, provenance, and local naming for BEDC.Derived.CholeskyDecom

Chapter 8398

A Concrete Naming Certificate for $\mathsf{ParacompactLocallyFinite}^{\uparrow}$

Following Bourbaki and Dugundji on paracompact covers and locally finite refinements, the ParacompactLocallyFinit packet records the finite BEDC handoff by which a displayed paracompact cover request is read as a locally finite cover ledger. It sits between the paracompact refinement carrier of chapter 1963, the locally finite cover surface of chapter 7245, and the indexed-open topology rows of chapter 88. The packet names only the displayed cover request, refinement assignment, local finite windows, transport, replay, provenance, and local NameCert rows needed by later partition-of-unity consumers; it does not assert a full partition of unity, a choice-selected refinement theorem, arbitrary subcover extraction, host powerset equality, or open-cover compactness.

Definition 8398.1 (Paracompact locally finite carrier)**.** *A* $\mathsf{ParacompactLocallyFinite}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (T, A, Q, R, L, W, I, H, C, S, N)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row, exposing the indexed open operations on which the cover request and local windows are read.*
2. *A is the displayed open-cover request row, naming the cover cells before any refinement or local-finiteness read is available.*
3. *Q is the* $\mathsf{Paracompact}^{\uparrow}$ *refinement source row, carrying the finite paracompact packet whose locally finite refinement ledger is being handed off.*
4. *R is the refinement-assignment row, listing the displayed refinement cells and their assignment back into the cover request A.*
5. *L is the* $\mathsf{LocallyFiniteCover}^{\uparrow}$ *ledger row, recording the local neighbourhood windows and finite incidence lists used to read the refinement as locally finite.*
6. *W is the coverage and containment row, recording that the displayed refinement covers the same source region as A and that every refinement cell is contained in its assigned cover cell.*
7. *I is the downstream interface row consumed by* $\mathsf{PartitionOfUnity}^{\uparrow}$ *only as support-window data, with no weight or sum-to-one coordinate.*

8. *H records componentwise* hsame *transport for the topology, cover request, paracompact source, refinement assignment, locally finite ledger, coverage, downstream interface, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a paracompact cover request through $T, A, Q, R, L, W, I, H, S, N$.*
10. *S is the* Pkg *provenance over* ParacompactLocallyFinite$^{\uparrow}$, Paracompact$^{\uparrow}$, LocallyFiniteCover$^{\uparrow}$, Topology$^{\uparrow}$, PartitionOfUnity$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\mathsf{ParacompactLocallyFinite}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, A, Q, R, L, W, I, H, C, S, N$. It has no coordinate for a selected host-indexed refinement family, arbitrary subcover choice, partition-of-unity weights, countable choice, quotient open equality, or a global paracompactness theorem detached from the displayed packet.

Theorem 8398.2 (Paracompact locally finite NameCert obligations)**.** *For every accepted* ParacompactLocallyFinite *carrier*

$$P = (T, A, Q, R, L, W, I, H, C, S, N),$$

the local NameCert$_{\mathsf{ParacompactLocallyFinite}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the topology source, cover request, paracompact source, refinement assignment, locally finite ledger, coverage and containment row, downstream interface, transport, replay, provenance, and local naming;*
2. *topology and cover exposure, requiring every refinement read to display T and A before any locally finite ledger is consumed;*
3. *paracompact-source exposure, requiring the refinement assignment R to be read through the displayed* Paracompact$^{\uparrow}$ *packet Q;*
4. *local-finiteness exactness, requiring L to expose the neighbourhood windows and finite incidence lists supplied by* LocallyFiniteCover$^{\uparrow}$ *before the refinement can be used as locally finite;*
5. *coverage and containment exactness, requiring W to record both coverage of the displayed source region and containment inside assigned cover cells;*
6. *downstream-interface discipline, requiring I to expose only support-window data for* PartitionOfUnity$^{\uparrow}$ *and no weights or sum-to-one rows;*
7. hsame, Cont, Pkg, *and local* NameCert *stability, requiring H, C, S, N to preserve exactly the listed rows.*

No local obligation for the paracompact-to-locally-finite handoff is stored outside these rows.

Proof. Carrier admission is projection from Definition 8398.1. The accepted tuple displays exactly the topology source, open-cover request, paracompact packet, refinement assignment, locally finite ledger, coverage and containment row, downstream support interface, transport, replay, provenance, and local naming.

Topology and cover exposure are forced by row order. A refinement read starts with T and A, so the handoff cannot begin from an unlogged host-indexed cover family.

Paracompact-source exposure is the projection to Q and R. The refinement assignment is usable only as a row transported from the displayed Paracompact$^{\uparrow}$ packet, with each refinement cell assigned back into the cover request.

Local-finiteness exactness is the projection to L. The row records neighbourhood windows and finite incidence lists in the sense of chapter 7245; the existence of a refinement family alone is not read as local finiteness.

Coverage and containment are read from W, while the downstream support boundary is read from I. These rows make the handoff available to later partition-of-unity work only as cover and support-window data, not as weights, sums, or selected functions.

Finally H, C, S, N transport, replay, source, and name the same finite route. Since the classifier has no further coordinate, selected refinements, arbitrary subcover choice, partition-of-unity data, countable choice, quotient open equality, and detached global paracompactness cannot be exported by the local certificate. □

Theorem 8398.3 (Paracompact locally finite handoff route)**.** *Every accepted* $\mathsf{ParacompactLocallyFinite}^{\uparrow}$ *packet exports the finite route*

$$\mathsf{Topology}^{\uparrow} \longrightarrow \mathsf{Paracompact}^{\uparrow} \longrightarrow \mathsf{LocallyFiniteCover}^{\uparrow}$$

before any partition-of-unity consumer may read support-window data from it. The exported route is a handoff from displayed paracompact refinement rows to displayed locally finite cover windows; it is not a choice-based refinement theorem, an arbitrary open-cover compactness theorem, a full partition of unity, or an ambient point-set topology construction.

Proof. Begin with the carrier of Definition 8398.1. The rows T, A, Q display the topology, cover request, and paracompact source before the refinement assignment is available.

Use the obligation theorem Definition 8398.2. It forces the refinement assignment R, locally finite ledger L, and coverage row W to remain visible before a consumer reads the handoff.

The downstream interface row I is only support-window data. It may be consumed by $\mathsf{PartitionOfUnity}^{\uparrow}$ after the locally finite route is displayed, but the carrier contains no weight, sum-to-one, selected-function, or arbitrary subcover coordinate.

The structural rows H, C, S, N preserve this order, so every exported read factors through the displayed topology, paracompact refinement, and locally finite cover surfaces. □

Closure status for $\mathsf{NameCert}_{\mathsf{ParacompactLocallyFinite}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ParacompactLocallyFinite}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8398.1, Definition 8398.2, and Definition 8398.3 seed the finite topology, paracompact refinement, locally finite cover, coverage, support-interface, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ParacompactLocallyFinite}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full partition-of-unity construction, choice-based refinement selection, arbitrary subcover extraction, open-cover compactness, quotient open equality, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, topology and cover exposure, paracompact-source exposure, local-finiteness exactness, coverage and containment exactness, downstream-interface discipline, transport stability, replay stability, and non-escape proofs for BEDC.Derived.ParacompactLocallyFiniteUp.

Constructive story: A $\mathsf{ParacompactLocallyFinite}^{\uparrow}$ packet is generated from a $\mathsf{Topology}^{\uparrow}$ source row, an open-cover request row, a $\mathsf{Paracompact}^{\uparrow}$ refinement source row, a refinement assignment, a $\mathsf{LocallyFiniteCover}^{\uparrow}$ local-window ledger, coverage and containment data, a $\mathsf{PartitionOfUnity}^{\uparrow}$ support interface, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8399

A Concrete Naming Certificate for $\mathsf{MaxFlowMinCut}^{\uparrow}$

Following Ford–Fulkerson and the finite network-flow tradition, the $\mathsf{MaxFlowMinCut}^{\uparrow}$ packet records the displayed certificate surface for maximum-flow/minimum-cut duality as finite BEDC data. It sits after the residual-capacity and cut rows of chapter 233, the alternating-incidence discipline of chapter 234, the directed graph carrier of chapter 118, the finite list accounting surface of chapter 36, and the natural-number ledger of chapter 28. The packet names a feasible flow, residual reachability ledger, displayed cut, augmenting-path refusal, value/capacity comparison, transport, replay, provenance, and local certificate; it is not a host optimization theorem, not quotient equality of flows, and not an unbounded search principle.

Definition 8399.1 (Max-flow min-cut carrier)**.** *A* $\mathsf{MaxFlowMinCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (G, s, t, U, F, R, A, K, V, M, L, H, C, P, N)$$

with the following displayed rows:

1. *G is the* $\mathsf{Graph}^{\uparrow}$ *and* $\mathsf{NetworkFlow}^{\uparrow}$ *source row, carrying the finite directed graph, source and sink endpoints, and edge inventory.*
2. *s and t are the distinguished endpoint rows for the inspected flow problem.*
3. *U is the capacity ledger, recording the displayed capacity bound for every inspected edge.*
4. *F is the feasible-flow row, exposing edge-flow values, conservation checks, and the flow-value history through* $\mathsf{NetworkFlow}^{\uparrow}$*.*
5. *R is the residual reachability row, recording exactly which vertices are reached from s by residual arcs in the displayed finite residual graph.*
6. *A is the augmenting-path audit row, whose positive entries are finite path witnesses and whose terminal entry is the displayed refusal of any remaining s–t residual path.*
7. *K is the cut row obtained from the residual reachability boundary, with crossing-edge saturation and reverse-edge zero-flow checks displayed edge by edge.*
8. *V is the* $\mathsf{Nat}^{\uparrow}$ *value/capacity comparison ledger, recording that the flow value and the displayed cut capacity have the same finite unary total.*
9. *M is the* $\mathsf{Matching}^{\uparrow}$ *sibling row, exposing the same alternating-path and saturated-boundary discipline to bipartite matching and cover consumers.*

10. *L records the* $\mathsf{List}^{\uparrow}$ *accounting discipline for path lists, reachable-vertex lists, cut-edge lists, and fold-order witnesses.*
11. *H records componentwise* hsame *transport for source, endpoints, capacity, flow, residual reachability, augmenting audit, cut, value ledger, matching sibling, list accounting, replay, provenance, and local naming rows.*
12. *C records displayed* Cont *replay from a max-flow/min-cut query through $G, s, t, U, F, R, A, K, V, M, L, H$.*
13. *P is the* Pkg *provenance over* $\mathsf{MaxFlowMinCut}^{\uparrow}$, $\mathsf{NetworkFlow}^{\uparrow}$, $\mathsf{Matching}^{\uparrow}$, $\mathsf{Graph}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{MaxFlowMinCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a host max-flow theorem, selected optimizer outside the packet, infinite graph, quotient flow equality, or choice over augmenting paths.

Theorem 8399.2 (Max-flow min-cut NameCert obligations)**.** *For every accepted* $\mathsf{MaxFlowMinCut}^{\uparrow}$ *carrier*

$$X = (G, s, t, U, F, R, A, K, V, M, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{MaxFlowMinCut}^{\uparrow}}$ *surface consists exactly of network-flow source admission through G, endpoint exposure through s, t, capacity exposure through U, feasible-flow exposure through F, residual reachability through R, augmenting-path audit through A, cut exposure through K, value/capacity comparison through V, matching sibling exposure through M, list accounting through L, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8399.1. The source, endpoint, capacity, feasible-flow, residual, augmenting, cut, value, matching, and list rows are exactly $G, s, t, U, F, R, A, K, V, M, L$.

The feasible-flow row F is read only after the source and capacity rows. The residual reachability row R and augmenting audit row A then inspect the finite residual graph determined by the same G, s, t, U, F data, so the audit cannot detach from the displayed network.

The cut row K is obtained from the terminal residual boundary. The value ledger V compares the flow value to the capacity of that same cut, while the matching sibling row M exposes the alternating-route discipline without replacing the packet by a matching oracle.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since no carrier coordinate stores a host max-flow theorem, selected optimizer, quotient flow equality, infinite graph, or choice over paths, the listed rows exhaust the NameCert obligations. □

Theorem 8399.3 (Max-flow min-cut augmenting cut handoff)**.** *Every duality-facing consumer of an accepted* $\mathsf{MaxFlowMinCut}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{NetworkFlow}^{\uparrow},\ \mathsf{Matching}^{\uparrow},\ \mathsf{Graph}^{\uparrow},\ \mathsf{List}^{\uparrow},\ \mathsf{Nat}^{\uparrow} \longmapsto G, s, t, U, F, R, A, K, V, M, L, H, C, P, N.$$

The handoff states only that the displayed feasible flow has no displayed residual augmenting path and that the residual boundary cut has the same displayed finite value. It exports no global optimizer, no hidden residual network, no quotient equality of flows, and no theorem for infinite networks.

Proof. Begin with Definition 8399.2. A duality-facing consumer must expose G, s, t, U, F before it can inspect either an augmenting path or a cut boundary.

Next read R and A. If A contains a positive augmenting witness, it is a finite path list in the displayed residual graph. If the terminal audit row refuses such a path, that refusal is recorded against the same residual reachability boundary R.

Now read K, V, M, L. The cut row K is the boundary determined by R, the value ledger V compares the displayed flow value with the displayed cut capacity, the matching row M keeps the alternating-route sibling visible, and the list row L supplies the finite inventories used by all folds.

Transport, replay, provenance, and local naming through H, C, P, N preserve that route. Thus the consumer receives a finite augmenting-path/cut certificate and no stronger host max-flow/min-cut endpoint. □

Falsifiable prediction: A purported $\mathsf{MaxFlowMinCut}^{\uparrow}$ consumer is refuted if it reaches a maximum-flow/minimum-cut conclusion while omitting any of the displayed network source, endpoints, capacity, feasible-flow, residual reachability, augmenting audit, cut, value/capacity, matching sibling, list accounting, transport, replay, provenance, or local NameCert rows.

Independence witness: networkflow, matching, graph, list, nat: no listed sibling is bijective to $\mathsf{MaxFlowMinCut}^{\uparrow}$ because this packet jointly carries feasible-flow rows, residual reachability, augmenting-path audit, cut boundary, value/capacity comparison, matching sibling exposure, finite list accounting, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{MaxFlowMinCut}^{\uparrow}}$.

Constructive story: A $\mathsf{MaxFlowMinCut}^{\uparrow}$ packet is generated from NetworkFlowUp source rows, endpoint rows, capacity rows, feasible-flow rows, residual reachability rows, augmenting-path audit rows, cut rows, NatUp value/capacity ledgers, MatchingUp sibling rows, ListUp accounting rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MaxFlowMinCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8399.1, Definition 8399.2, and Definition 8399.3 seed the finite augmenting-path and cut-certificate route over network-flow, matching, graph, list, natural-number, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MaxFlowMinCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host max-flow theorem, selected optimizers for arbitrary networks, infinite-network duality, quotient equality of flows, hidden residual networks, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint exposure, capacity exposure, feasible-flow exposure, residual reachability exactness, augmenting-path refusal, cut-boundary saturation, value/capacity comparison, Matching and List sibling handoffs, transport, replay, provenance, and local naming for BEDC.Derived.MaxFlowMinCutUp.

Chapter 8400

A Concrete Naming Certificate for MetaCICBoundedConversionFrontier$^{\uparrow}$

The MetaCICBoundedConversionFrontier$^{\uparrow}$ packet realizes the decidability audit map of chapter 9379 as a bounded finite conversion-checker boundary. It is distinct from the conversion-facing frontier of chapter 4097: this packet names the checker fuel, normalization endpoint, comparison row, refusal ledger, transport, replay, provenance, and local certificate before any broader decidability frontier can be cited. It sits beside the bounded equality checker of chapter 752, the fuel trace of chapter 3889, the bounded conversion bridge of chapter 3439, and the normal-form consistency seal of chapter 740.

Falsifiable prediction: Every accepted MetaCICBoundedConversionFrontier$^{\uparrow}$ read exposes checker fuel, bounded normalizer endpoints, structural comparison, finished-normal evidence, bridge handoff, consistency seal, refusal, transport, replay, provenance, and local NameCert rows before any conversion-frontier conclusion is consumed.

Independence witness: bounded-normal-equality-checker, metacic-fuel-trace, bounded-normal-conversion-bridge, normal-form-consistency-seal, metacic-decidable-conversion-frontier: the equality checker records comparison output without the full refusal ledger; the fuel trace records normalization budget without the bridge and seal pair; the bridge compares finished normal forms without naming the checker packet; the seal records closed normal-form safety without the local fuel ledger; and the decidable conversion frontier is a broader consumer of bounded rows. None is bijective to MetaCICBoundedConversionFrontier$^{\uparrow}$.

Definition 8400.1 (MetaCIC bounded conversion frontier carrier)**.** *A* MetaCICBoundedConversionFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (Q, F, N, E, S, R, D, H, C, P, L)$$

with the following displayed rows:

1. *Q is the bounded checker row, recording the two closed terms, the finite fuel value, and the Boolean comparison produced by the checker.*
2. *F is the* MetaCICFuelTrace$^{\uparrow}$ *row, exposing the exact bounded normalizer schedule used by Q.*
3. *N is the bounded normalizer endpoint row, recording the two computed normal forms and the finished-normal evidence available at that fuel.*

4. *E is the structural equality row, reading the endpoint comparison through* Term.*eq rather than through quotient syntax equality.*
5. *S is the* $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$ *row, packaging the local bounded normal-equality check as a finite NameCert surface.*
6. *R is the* $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$ *row, transporting a positive bounded comparison to the finished-normal conversion boundary when the displayed endpoint evidence is present.*
7. *D is the refusal row, naming the excluded endpoints: global closed conversion decidability, arbitrary-fuel completeness, evaluator equality, subject reduction, confluence, quotient syntax equality, and kernel consistency.*
8. *H records componentwise* hsame *transport for checker, fuel, endpoint, comparison, checker-surface, bridge, refusal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a bounded conversion query through Q, F, N, E, S, R, D, H.*
10. *P is the* Pkg *provenance over* $\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, $\mathsf{NormalFormConsistencySeal}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* $\mathsf{NameCert}_{\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, F, N, E, S, R, D, H, C, P, L$. It has no coordinate for global conversion decidability, arbitrary-fuel completeness, evaluator equality, subject reduction, confluence, quotient syntax equality, or kernel consistency.

Theorem 8400.2 (MetaCIC bounded conversion frontier obligations)**.** *For every accepted* MetaCICBoundedConvers *carrier*

$$B = (Q, F, N, E, S, R, D, H, C, P, L),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}}$ *surface consists exactly of checker exposure through Q, fuel-trace exposure through F, endpoint exposure through N, structural comparison through E, bounded equality-checker exposure through S, bounded bridge exposure through R, refusal retention through D, componentwise transport through H, displayed replay through C, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8400.1. Rows Q, F, N, E, S, R, D are the bounded checker, fuel, endpoint, comparison, checker-surface, bridge, and refusal data.

The checker row Q is read only with its fuel trace F and endpoint row N. The comparison row E therefore compares displayed bounded normal forms, not quotient syntax objects or evaluator outputs.

The bounded equality-checker row S and bridge row R keep positive comparison data inside the finished-normal boundary. The refusal row D remains part of the same packet and prevents the bounded result from becoming global conversion decidability.

Finally H, C, P, L transport, replay, source, and name the same finite rows. Since no carrier coordinate stores arbitrary-fuel completeness, subject reduction, confluence, evaluator equality, quotient syntax equality, or kernel consistency, the listed rows exhaust the NameCert obligations. □

Theorem 8400.3 (MetaCIC bounded conversion frontier nonescape)**.** *Every positive read exported by an accepted* $\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}$ *carrier factors through*

$\mathsf{MetaCICFuelTrace}^{\uparrow}$, $\mathsf{BoundedNormalEqualityChecker}^{\uparrow}$, $\mathsf{BoundedNormalConversionBridge}^{\uparrow}$, NormalFormConsistencySe

The read is a finite bounded conversion-checker certificate. It does not export global closed conversion decidability, arbitrary-fuel completeness, evaluator equality, subject reduction, confluence, quotient syntax equality, or kernel consistency.

Proof. Start with Definition 8400.2. A positive read must expose the checker row Q, the fuel trace F, the endpoint row N, and the structural comparison row E before the bounded equality-checker row can be consumed.

Next read the bridge row R. It is attached to the same finished-normal endpoint evidence and to the normal-form consistency seal named in the provenance row P, so it transports only the displayed bounded comparison.

The refusal row D is then still present. It names the global endpoints that the bounded checker does not supply, including closed conversion decidability, arbitrary-fuel completeness, evaluator equality, subject reduction, confluence, quotient syntax equality, and kernel consistency.

Transport and replay through H, C, P, L preserve this boundary. Hence the packet can feed the broader decidability frontier, but it cannot itself be cited as a global conversion decider. □

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}$ packet is generated from bounded checker rows, MetaCICFuelTraceUp rows, bounded normalizer endpoint rows, Term.eq comparison rows, BoundedNormalEqualityCheckerUp rows, BoundedNormalConversionBridgeUp rows, refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8400.1, Definition 8400.2, and Definition 8400.3 seed the finite bounded conversion-checker frontier over checker, fuel, endpoint, comparison, bridge, refusal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedConversionFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global closed conversion decidability, arbitrary-fuel completeness, evaluator equality, subject reduction, confluence, quotient syntax equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, checker exposure, fuel-trace exactness, endpoint exposure, Term.eq comparison, bounded equality-checker compatibility, bridge compatibility, refusal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICBoundedConversionFrontierUp.

Chapter 8401

A Concrete Naming Certificate for $\mathsf{BishopUniformStructure}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley on uniform spaces, the $\mathsf{BishopUniformStructure}^{\uparrow}$ packet records the finite entourage-filter substrate used by the L10 Real and Completion route. It sits between the general entourage discipline of chapter 339, the Real-induced route of chapter 1624, the Cauchy-filter surface of chapter 333, and the completion-facing criteria of chapter 1506. The chapter names only Bishop-style finite uniform-structure data: entourages, filter refinement, Cauchy compatibility, transport, replay, provenance, and local naming.

Definition 8401.1 (Bishop uniform-structure carrier)**.** *A* $\mathsf{BishopUniformStructure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, E, F, R, C, D, S, Q, H, K, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row naming the finite entourage basis, diagonal requests, symmetry requests, and composition requests accepted by the uniform surface.*
2. *E is the entourage-filter row, recording finite upward-closure and finite-intersection witnesses for the displayed entourage family.*
3. *F is the* $\mathsf{CauchyFilter}^{\uparrow}$ *compatibility row for consumers that read Cauchy data through the entourage filter.*
4. *R is the* $\mathsf{RealUniformStructure}^{\uparrow}$ *comparison row, used only when a Real-induced uniformity supplies the source entourages.*
5. *C is the completion handoff row that names* $\mathsf{MetricCompletion}^{\uparrow}$ *or sibling completion consumers as readers of the already displayed uniform data.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger when the source uniformity is metric or Real-induced.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by sequential or completion-facing consumers.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
9. *H records componentwise* hsame *transport for the uniform, entourage-filter, Cauchy-filter, Real-uniform, completion, tolerance, window, readback, replay, provenance, and local naming rows.*
10. *K records displayed* Cont *replay through the same route.*

11. *P is the* Pkg *provenance over* $\mathsf{BishopUniformStructure}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformStructure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, E, F, R, C, D, S, Q, H, K, P, N$. The carrier has no coordinate for Real completeness, selected limits, quotient uniformities, countable choice, open-cover compactness, or quotient equality of completion points.

Theorem 8401.2 (Bishop uniform-structure NameCert obligations)**.** *For every accepted* $\mathsf{BishopUniformStructure}^{\uparrow}$ *carrier*

$$B = (U, E, F, R, C, D, S, Q, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopUniformStructure}^{\uparrow}}$ *surface consists exactly of uniform-source admission, entourage-filter exposure, Cauchy-filter compatibility, optional Real-induced comparison, completion handoff ordering, tolerance-ledger exposure, finite-window readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through the rows of B.*

Proof. Project the carrier of Definition 8401.1. The uniform data are exactly U, E: a finite entourage source and the filter witnesses that make those entourages usable by downstream requests.

The Cauchy and completion rows are downstream of that source. A Cauchy-filter consumer reads F only after the entourage-filter row E is displayed, and a completion consumer reads C only as a named reader of the same route.

When the source is Real-induced, the comparison row R and tolerance ledger D supply the finite bridge to chapter 1624. The window and readback rows S, Q expose sequential observations only after the uniform route has been displayed.

The structural rows H, K, P, N transport, replay, source, and name this finite route. Since no listed row stores Real completeness, selected limits, quotient uniformities, countable choice, open-cover compactness, or quotient equality of completion points, none of those objects can discharge a local NameCert obligation. □

Theorem 8401.3 (Bishop filter-entourage induction)**.** *Let $B = (U, E, F, R, C, D, S, Q, H, K, P, N)$ be an accepted* $\mathsf{BishopUniformStructure}^{\uparrow}$ *carrier. Any finite induction over accepted entourage-filter requests preserves the route*

$$\mathsf{UniformSpace}^{\uparrow},\ E,\ \mathsf{CauchyFilter}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow}$$

and, when the source row is Real-induced, preserves the comparison route through $\mathsf{RealUniformStructure}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, *and* $\mathsf{RegSeqRat}^{\uparrow}$. *The induction exports no Real completeness, selected limit, quotient uniformity, open-cover compactness, or quotient equality of completion points.*

Proof. The base case is a single displayed entourage request. Carrier admission gives the request through U and its filter witness through E, so the Cauchy row F and the completion row C can only read the already displayed uniform surface.

For upward closure, the accepted refinement is another row of the same entourage-filter packet E. Transport through H and replay through K preserve the source row U and keep the Cauchy-filter handoff downstream of the displayed refinement.

For finite intersections, the induction step reads both prior requests from E and records the intersected request as another finite filter witness. The handoff to F and C is therefore still a handoff from the same uniform source, not a new quotient uniformity.

If R is present as the Real-induced comparison row, each inductive step also keeps the tolerance ledger D and the finite observations S, Q attached to the same route. Thus Real-uniform consumers receive only the displayed comparison and readback data.

No induction case creates a coordinate outside $U, E, F, R, C, D, S, Q, H, K, P, N$. Real completeness, selected limits, quotient uniformities, open-cover compactness, and quotient equality of completion points are absent throughout the induction. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformStructure}\uparrow}$.

Constructive story: A $\mathsf{BishopUniformStructure}^{\uparrow}$ packet is generated from a UniformSpace source row, finite entourage-filter witnesses, CauchyFilter compatibility, optional RealUniformStructure comparison, completion handoff ordering, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformStructure}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8401.1, Definition 8401.2, and Definition 8401.3 seed the L10 route from Bishop-style entourage filters to Real and completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformStructure}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, selected limits, quotient uniformities, countable choice, open-cover compactness, quotient equality of completion points, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage-filter exactness, Cauchy-filter compatibility, Real-induced comparison, completion handoff ordering, tolerance exposure, finite-window readback, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformStructureUp.

Chapter 8402

A Concrete Naming Certificate for $\mathsf{AbelTransformation}^{\uparrow}$

Following Abel and Hardy, the $\mathsf{AbelTransformation}^{\uparrow}$ packet records the finite boundary identity that rewrites a displayed coefficient-weighted tail through partial sums, adjacent coefficient differences, and endpoint terms. It sits beside the finite summation-by-parts surface of chapter 5796, the Abel summation route of chapter 1763, the Abel-test consumer of chapter 1496, and the Dirichlet-test consumer of chapter 1497. The packet names only a displayed Abel-transform window; it does not import infinite sums, selected limits, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8402.1 (Abel transformation carrier)**.** *An* $\mathsf{AbelTransformation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, P, C, \Delta, B, W, T, R, D, E, H, K, Q, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{Series}^{\uparrow}$ *source row, exposing the inspected finite term window and its partial-sum cells.*
2. *P is the partial-sum row used by the Abel transform on the same finite interval.*
3. *C is the coefficient-window row, naming the scalar coefficients paired with the partial sums.*
4. *Δ is the adjacent-difference ledger for the coefficient window.*
5. *B is the boundary-term row, recording the two endpoint products of the displayed window.*
6. *W is the finite transform row, collecting the boundary terms and interior difference-weighted partial sums.*
7. *T is the convergence-test handoff row consumed by* $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *or* $\mathsf{DirichletTest}^{\uparrow}$.
8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from W and the displayed handoff.*
9. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the additions, subtractions, products, and endpoint comparisons in W.*
10. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after $S, P, C, \Delta, B, W, T, R, D$ have been displayed.*
11. *H records componentwise* hsame *transport for the source, partial-sum, coefficient, difference, boundary, transform, handoff, readback, dyadic, endpoint, replay, provenance, and local naming rows.*

12. *K records displayed* Cont *replay of the route*

$$S, P, C, \Delta, B, W, T, R, D \longmapsto E.$$

13. *Q is the* Pkg *provenance over* $\mathsf{AbelTransformation}^{\uparrow}$, $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

14. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, P, C, \Delta, B, W, T, R, D, E, H, K, Q, N$. It has no coordinate for an infinite sum, selected limit, quotient series equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8402.2 (Abel transformation NameCert obligations)**.** *For every accepted* $\mathsf{AbelTransformation}^{\uparrow}$ *carrier*

$$A = (S, P, C, \Delta, B, W, T, R, D, E, H, K, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed finite packet; source and partial-sum exposure through S and P; coefficient-window and adjacent-difference exposure through C and Δ; boundary-term exactness through B; transform-row exactness through W; convergence-test handoff through T; regular readback, dyadic accounting, and endpoint sealing through R, D, E; and transport, replay, provenance, and local naming through H, K, Q, N.*

Proof. Project the accepted carrier. The projection exposes exactly the rows $S, P, C, \Delta, B, W, T, R, D, E, H, K, Q, N$ so every local naming obligation is attached to one displayed coordinate.

The analytic rows are finite. The source row S and partial-sum row P display the inspected cumulative sums, the coefficient row C displays the paired coefficients, Δ displays adjacent differences, and B displays the endpoint products determined by the same window.

The transform row W is then forced by those rows. It records the finite Abel-transform boundary and interior difference-weighted partial-sum terms, so a convergence-test consumer can read T only after the transform data have been displayed.

Finally R, D, E, H, K, Q, N preserve and seal the same route. Because the carrier has no coordinate for infinite summation, selected limits, quotient series equality, countable choice, trichotomy, or ambient real completeness, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}$ surface. □

Theorem 8402.3 (Abel transformation summation handoff)**.** *Every accepted* $\mathsf{AbelTransformation}^{\uparrow}$ *packet hands a convergence-test consumer only the finite route*

$$\mathsf{SummationByParts}^{\uparrow} \longmapsto S, P, C, \Delta, B, W, T \longmapsto R, D, E, H, K, Q, N.$$

The downstream $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, *and* $\mathsf{DirichletTest}^{\uparrow}$ *chapters may consume the displayed transform row, but they receive no infinite sum, selected limit, quotient series equality, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness from this packet.*

Proof. Begin with the summation-by-parts dependency. The packet reads the same finite identity surface as chapter 5796, but specializes the visible handoff to the Abel-transform row W.

The Abel-facing consumers then read only T. An $\mathsf{AbelSummation}^{\uparrow}$ consumer uses the transform window as a summation boundary, an $\mathsf{AbelTest}^{\uparrow}$ consumer combines it with its coefficient-control rows, and a $\mathsf{DirichletTest}^{\uparrow}$ consumer combines it with bounded partial sums and tail estimates. In each case the contribution of this chapter remains the displayed finite packet.

The regular and real-facing route is downstream of W and T. Rows R, D, E read back, account for, and seal the same finite transform, while H, K, Q, N transport, replay, source, and name that route. No excluded summation or completeness datum is present in the carrier. □

Falsifiable prediction: An accepted $\mathsf{AbelTransformation}^{\uparrow}$ consumer that reaches an $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ row without reading the displayed source, partial-sum, coefficient, adjacent-difference, boundary, transform, and handoff rows refutes the carrier surface.

Independence witness: summation-by-parts, abel-summation, abel-test, dirichlet-test, series, regseqrat, dyadicratcore, real: no listed sibling supplies the whole fourteen-row packet $A = (S, P, C, \Delta, B, W, T, R, D, E, H, K, Q, N)$, because each sibling contributes only an identity surface, transform consumer, convergence-test consumer, source series, regular readback, dyadic ledger, or endpoint seal while this chapter binds the finite Abel-transform window itself.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}$.

Constructive story: An $\mathsf{AbelTransformation}^{\uparrow}$ packet is generated from a SeriesUp finite source row, partial-sum windows, coefficient windows, adjacent-difference rows, boundary-term rows, a finite Abel-transform row, AbelSummation/AbelTest/DirichletTest handoff rows, RegSeqRat readback, DyadicRatCore tolerance accounting, a RealUp endpoint seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8402.1, Definition 8402.2, and Definition 8402.3 seed the finite Abel-transform identity packet over $\mathsf{SummationByParts}^{\uparrow}$, $\mathsf{AbelSummation}^{\uparrow}$, $\mathsf{AbelTest}^{\uparrow}$, $\mathsf{DirichletTest}^{\uparrow}$, $\mathsf{Series}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelTransformation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close infinite summation, quotient series equality, selected convergence witnesses, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite Abel-transform exactness, convergence-test handoff, regular readback, dyadic accounting, endpoint sealing, transport and replay stability, provenance exhaustion, and TasteGate field faithfulness for BEDC.Derived.AbelTransformationUp.

Chapter 8403

A Concrete Naming Certificate for $\mathsf{BishopChainConnected}^{\uparrow}$

Following Bishop and Bridges on constructive connectedness of intervals, the $\mathsf{BishopChainConnected}^{\uparrow}$ packet records interval chain-connectedness as finite NameCert data over located interval rows, dyadic interval-net cells, finite chain ledgers, and Real-facing readbacks. It sits next to the metric chain-connected route of chapter 2050, consumes the finite interval-net surface of chapter 5966, and reads its Real-facing source rows through chapter 126, chapter 301, and chapter 38. The packet gives downstream interval and intermediate-value consumers a chain witness surface without invoking open-cover compactness, quotient equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8403.1 (Bishop chain-connected carrier)**.** *A* $\mathsf{BishopChainConnected}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, A, Z, D, J, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval row, including the named endpoints, locatedness witnesses for endpoint comparisons, and the interval side on which the chain is read.*
2. *A is the endpoint-pair row whose members are to be joined inside the located interval surface.*
3. *Z is the finite chain ledger. It lists the inspected chain nodes, adjacency witnesses, and the finite successor route from the first endpoint row to the second endpoint row.*
4. *D is the dyadic tolerance and endpoint-arithmetic ledger used by the chain steps.*
5. *J is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row that supplies the finite dyadic interval-net cells through which the chain route is inspected.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for endpoint names, chain nodes, and cell endpoints.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those same windows and dyadic tolerances.*
8. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, A, Z, D, J, W, R have been displayed.*
9. *H records componentwise* hsame *transport for the interval row, endpoint pair, chain ledger, dyadic data, interval-net cells, windows, readbacks, Real seal, and structural rows.*
10. *C records displayed* Cont *replay of the finite route*

$$I, A, Z, D, J \longmapsto W, R \longmapsto Q, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{BishopChainConnected}^{\uparrow}$, $\mathsf{ChainConnectedMetric}^{\uparrow}$, $\mathsf{DyadicIntervalNet}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopChainConnected}^{\uparrow}}$ *row.*

The carrier exports only this displayed finite packet. It has no coordinate for open-cover compactness, quotient equality of real names, a selected global path, countable choice, trichotomy, or ambient completeness.

Theorem 8403.2 (Bishop chain-connected NameCert obligations)**.** *For every accepted* $\mathsf{BishopChainConnected}^{\uparrow}$ *carrier* $B = (I, A, Z, D, J, W, R, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopChainConnected}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *interval admission: the located interval row I and endpoint-pair row A are displayed before any chain read;*

2. *finite chain ledger: the chain nodes, adjacency rows, and successor route are exhausted by the finite ledger Z;*

3. *dyadic cell support: every chain step reads the dyadic arithmetic row D and the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row J before it reaches a Real-facing boundary;*

4. *source readback: endpoint and cell observations pass through the common* $\mathsf{StreamName}^{\uparrow}$ *window W and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the terminal* $\mathsf{Real}^{\uparrow}$ *seal Q is consumed;*

5. *structural provenance: H, C, P, N transport, replay, source, and locally name only the displayed rows of the carrier.*

No NameCert obligation is stored outside these rows.

Lean4 ✓ `BEDC.Derived.BishopChainConnectedUp.BishopChainConnectedCarrier namecert obligations`

Proof. Carrier admission is projection from Definition 8403.1. The located interval row, endpoint pair, finite chain ledger, dyadic arithmetic, interval-net cells, window, readback, Real seal, and structural rows are all coordinates of the same finite packet.

The chain obligation is finite because Z supplies the only allowed node and adjacency list. A consumer can replay a chain step only by reading a displayed successor entry of Z together with the dyadic support rows D and J.

The Real-facing obligation is downstream. The StreamName window W and RegSeqRat readback R are read before Q, and the structural rows H, C, P, N preserve that ordering componentwise. Since the carrier has no coordinate for open covers, quotient equality, choice, trichotomy, or completeness, none of those principles can be exported by the NameCert surface. □

Theorem 8403.3 (Bishop chain-connected interval handoff)**.** *Every interval-facing consumer of an accepted* $\mathsf{BishopChainConnected}^{\uparrow}$ *carrier must read the located interval row I, endpoint pair A, finite chain ledger Z, dyadic tolerance and endpoint-arithmetic row D,* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row J,* $\mathsf{StreamName}^{\uparrow}$ *window W,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal Q in that displayed order. The handoff may then pass the packet to Real interval, compact interval, or intermediate-value consumers as a finite chain-connected source, but it may not replace the source by open-cover compactness, host real equality, quotient stream equality, selected paths, countable choice, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.BishopChainConnectedUp.BishopChainConnectedCarrier interval handoff`

Proof. Start with the obligation theorem Definition 8403.2. It forces every accepted interval read to expose the located interval and endpoint-pair rows before a chain witness is consumed.

Next read the finite chain and dyadic support rows. The ledger Z supplies the chain nodes and adjacency route, while D and the interval-net row J provide the dyadic endpoint arithmetic and finite cell incidence needed by each step.

Finally pass through the source readback rows W, R, Q and the structural rows H, C, P, N. This is the same Real-facing order used by the dyadic interval-net route of chapter 5966 and the metric chain-connected sibling chapter 2050. Thus downstream interval consumers receive a displayed finite chain-connected packet and no ambient compactness, equality, choice, or completeness endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopChainConnected}\uparrow}$.

Constructive story: A $\mathsf{BishopChainConnected}^{\uparrow}$ packet is generated from a located interval row, endpoint-pair row, finite chain ledger, dyadic endpoint arithmetic, DyadicIntervalNet cells, StreamName windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopChainConnected}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8403.1, Definition 8403.2, and Definition 8403.3 seed the Bishop chain-connected interval route over located interval rows, finite chain ledgers, dyadic interval-net cells, StreamName windows, RegSeqRat readbacks, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopChainConnected}\uparrow}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.BishopChainConnectedUp.BishopChainConnectedCarrier\_namecert\_obligations`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient equality of real names, selected global paths, countable choice, trichotomy, ambient RealUp completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite chain-ledger replay, dyadic interval-net support, StreamName and RegSeqRat readback routing, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.BishopChainConnectedUp.

Chapter 8404

A Concrete Naming Certificate for $\mathsf{ConstructiveRiemannSum}^{\uparrow}$

Following Bishop and Bridges on constructive integration, the $\mathsf{ConstructiveRiemannSum}^{\uparrow}$ packet records a finite Riemann-sum surface over tagged dyadic partitions. It sits over the dyadic arithmetic core of chapter 291, the regular rational tolerance readback of chapter 301, the terminal real-name seal of chapter 38, and the pointwise source-map rows of chapter 130. The packet names the displayed finite sum only; it does not assert integrability, Darboux equivalence, mesh convergence, selected refining partitions, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8404.1 (Constructive Riemann sum carrier)**.** *A* $\mathsf{ConstructiveRiemannSum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (E, T, F, D, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the endpoint row. It records a finite increasing list of dyadic endpoints and the adjacent half-open cells read by the partition surface.*
2. *T is the tag row. It records one displayed dyadic tag inside each cell named by E.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *readback row. It records the pointwise evaluations requested at the tags and the source-continuity provenance inspected before those values are used.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row. It records dyadic cell widths, dyadic tag comparisons, finite products of displayed values with displayed widths, and the finite dyadic sum replay.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance row. It records the regular rational window through which the dyadic sum is read before a real-facing consumer accepts the value.*
6. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the endpoint, tag, map, arithmetic, and regular rational rows have been displayed.*
7. *H records componentwise* hsame *transport for endpoint, tag, map, dyadic arithmetic, regular tolerance, real seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay for the route*

$$E, T, F, D \longmapsto R \longmapsto Q.$$

9. *P is the* Pkg *provenance over* $\mathsf{ConstructiveRiemannSum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannSum}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for host integrability, supremum or infimum data, quotient function equality, countable choice, selected mesh sequences, or ambient completeness.

Lean4 (definition) `BEDC.Derived.ConstructiveRiemannSumUp`

Theorem 8404.2 (Constructive Riemann sum NameCert obligations)**.** *For every accepted* ConstructiveRiemannSum *carrier $S = (E, T, F, D, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannSum}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed endpoint list, tag list,* $\mathsf{ContinuousMap}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic replay,* $\mathsf{RegSeqRat}^{\uparrow}$ *tolerance readback,* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *route,* Pkg *provenance, and local naming; refinement stability for partitions obtained by inserting finitely many dyadic endpoints and retagging through displayed dyadic comparisons; sample transport along the H rows; dyadic finite-sum replay through D; terminal real handoff through R, Q; and ledger non-escape through P, N.*

Proof. Carrier admission is projection from Definition 8404.1. The tuple displays exactly the endpoint, tag, map, dyadic arithmetic, regular readback, real seal, transport, replay, provenance, and local naming rows, so every obligation begins with one of $E, T, F, D, R, Q, H, C, P, N$.

Refinement stability remains finite. Inserting dyadic endpoints only replaces the endpoint row by a longer displayed list and asks T for tags inside the new cells; the dyadic comparisons needed to validate those tags are already rows of D.

The sampled values are transported through H and replayed through C. Thus a consumer reads tag evaluations from F before using dyadic widths and products from D, and the finite sum has no source outside the displayed tagged partition.

The real-facing handoff is terminal. The dyadic sum passes through the regular rational tolerance row R before reaching the seal Q, and the provenance and naming rows P, N expose no hidden integrability theorem, selected mesh sequence, quotient equality, or completeness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveRiemannSum}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveRiemannSum}^{\uparrow}$ packet is generated from finite dyadic endpoints, displayed tags, ContinuousMap point readback, DyadicRatCore width and product arithmetic, RegSeqRat tolerance readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ConstructiveRiemannSum}^{\uparrow}}$, seed)

Scope closed: Definition 8404.1 and Definition 8404.2 seed the finite tagged dyadic partition surface and its dyadic-sum, regular-readback, and real-seal handoff.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ConstructiveRiemannSum}^{\uparrow}}$, encodedDef)

Lean target: `BEDC.Derived.ConstructiveRiemannSumUp`

Bridge status: none

Not claimed: This chapter does not close Riemann integrability, Darboux equivalence, mesh-limit convergence, selected refining partitions, quotient equality of maps, ambient RealUp completeness, checked obligation rows, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite refinement stability, sample transport, dyadic finite-sum replay, RegSeqRat tolerance readback, Real handoff, provenance, and local naming for BEDC.Derived.ConstructiveRiemannSu

Chapter 8405

A Concrete Naming Certificate for $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$

Fekete's subadditive lemma and Bishop–Bridges constructive sequence reasoning supply the traditional source for the $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$ packet: a displayed subadditive sequence is read through finite normalized-average windows before any lower-envelope or completion-facing consumer may inspect a Real boundary. The packet sits beside the subadditive-average carrier of chapter 2013, the limsup route of chapter 768, the regular rational readback of chapter 301, the finite stream window surface of chapter 126, the dyadic arithmetic core of chapter 291, and the terminal real-name seal of chapter 38. It records the lemma as finite NameCert data, not as a host infimum principle, quotient stream equality, trichotomy, countable choice, or ambient completeness theorem.

Definition 8405.1 (Fekete subadditive lemma carrier)**.** *A* $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, A, Q, T, I, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source-sequence row naming the inspected sequence windows.*
2. *A is the subadditivity ledger, listing each displayed decomposition comparison used by the lemma route.*
3. *Q is the normalized-average row, carrying the finite rational and dyadic denominator windows read from S and A.*
4. *T is the tail-window row, recording the cofinal finite tails over which the normalized averages are compared.*
5. *I is the tail-infimum readback row, storing only the lower-envelope data exposed by Q and T.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row reached after the tail-infimum readback is visible.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached after the regular rational handoff.*
8. *H records componentwise* hsame *transport for the source, subadditivity, average, tail, infimum-readback, handoff, seal, replay, provenance, and naming rows.*
9. *C records displayed* Cont *replay through the route*

$$S, A \longmapsto Q \longmapsto T \longmapsto I \longmapsto R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$, $\mathsf{FeketeSubadditive}^{\uparrow}$, $\mathsf{Limsup}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FeketeSubadditiveLemma}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, A, Q, T, I, R, E, H, C, P, N$. It has no coordinate for a global infimum operator, quotient stream equality, selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8405.2 (Fekete subadditive lemma NameCert obligations)**.** *For every accepted* $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$ *carrier*

$$L = (S, A, Q, T, I, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FeketeSubadditiveLemma}^{\uparrow}}$ *surface consists exactly of source-window admission through S, subadditivity-ledger exposure through A, normalized-average comparison through Q, cofinal tail-window exposure through T, tail-infimum readback through I, regular rational handoff through R, Real seal exposure through E, componentwise transport through H, displayed replay through C, package provenance through P, local naming through N, and non-escape for global infima, selected limits, quotient streams, trichotomy, countable choice, and ambient completeness.*

Proof. Project the carrier of Definition 8405.1. The mathematical rows are exactly the source windows S, subadditivity ledger A, normalized-average row Q, tail-window row T, tail-infimum readback I, regular handoff R, and Real seal E.

The subadditivity content is read before the tail boundary. Rows S and A supply the inspected sequence values and decomposition comparisons, while Q records only the normalized averages computed from those displayed rows.

The tail readback is then forced through T and I. The row T supplies the cofinal finite windows, and I records the lower-envelope readback visible on those windows without adding a global infimum operator.

Finally R, E, H, C, P, N transport, replay, source, and name the same route. Since none of the displayed rows stores a selected limit, quotient stream equality, trichotomy, countable choice, or ambient completeness theorem, the listed rows exhaust the local NameCert obligations. □

Theorem 8405.3 (Fekete subadditive lemma tail-infimum route)**.** *Every Real or completion-facing read of an accepted* $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$ *carrier factors through the finite route*

$$S, A \longmapsto Q \longmapsto T \longmapsto I \longmapsto R \longmapsto E.$$

The tail-infimum row I may be read only after the source sequence, subadditivity ledger, normalized-average comparisons, and cofinal tail windows have been displayed. Thus a downstream $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Limsup}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer receives a finite lower-envelope route rather than a quotient sequence, selected limit, host infimum, trichotomy decision, countable-choice schedule, or ambient completeness witness.*

Proof. Start from the carrier projection. Rows $S, A, Q, T, I, R, E, H, C, P, N$ are the only public rows, and I is positioned downstream of the source, subadditivity, normalized-average, and tail-window data.

Apply the NameCert obligations of Definition 8405.2. They make S, A, Q, T visible before I, so the lower-envelope readback is computed from displayed finite comparisons rather than from a host infimum principle.

The regular rational and Real-facing rows are later in the same route. A $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Limsup}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ consumer can read R and E only after the tail-infimum row has already been exposed.

Transport and replay preserve the route componentwise through H and C, while P and N fix provenance and naming. Therefore no consumer can bypass the displayed route with quotient streams, selected limits, trichotomy, countable choice, or ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FeketeSubadditiveLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{FeketeSubadditiveLemma}^{\uparrow}$ packet is generated from source-sequence windows, a subadditivity ledger, normalized-average comparisons, cofinal tail windows, tail-infimum readback, regular rational handoff, Real seal exposure, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FeketeSubadditiveLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8405.1, Definition 8405.2, and Definition 8405.3 seed the finite route from subadditive sequence windows to tail-infimum readback for Real and completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FeketeSubadditiveLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a global infimum operator, quotient sequence equality, selected limits, trichotomy, countable choice, ambient Real completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subadditivity-ledger exposure, normalized-average comparison, cofinal tail-window exposure, tail-infimum readback, regular rational handoff, Real seal exposure, transport, replay, provenance, and local naming for BEDC.Derived.FeketeSubadditiveLemmaUp.

Chapter 8406

A Concrete Naming Certificate for $\mathsf{CompactOpenEquicontinuity}^{\uparrow}$

Following Kelley and Bishop–Bridges on compact-open topology and equicontinuous families, the $\mathsf{CompactOpenEquicontinuity}^{\uparrow}$ packet records the finite compact-family certificate by which compact source windows, continuous-map graph rows, equicontinuity-family witnesses, and uniform-modulus handoffs are read together before an Arzela–Ascoli consumer may inspect a compact-open family. It sits over the compact metric source of chapter 129, the graph-and-modulus rows of chapter 130, the family-wide equicontinuity surface of chapter 413, the finite tolerance handoff of chapter 369, and the compact-family consumer of chapter 412. The packet names a compact-open equicontinuity boundary as displayed NameCert data; it is not a host compact-open topology, a selected subnet, quotient equality of functions, countable choice, or ambient completeness of a function space.

Definition 8406.1 (Compact-open equicontinuity carrier)**.** *A* $\mathsf{CompactOpenEquicontinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, A, U, O, S, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, listing the finite compact windows and coverage entries through which the compact-open inspection is performed.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *family graph row, recording the finite graph evaluations visible on those compact windows.*
3. *A is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row, carrying the family-wide local equicontinuity witnesses attached to the same compact windows.*
4. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row obtained from the compact-window and family-equicontinuity data.*
5. *O is the compact-open observation ledger: a finite list of compact-window requests, tolerance requests, and graph-value windows that the consumer may inspect.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for graph values and tolerance reads.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those stream windows.*
8. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for value-facing and tolerance-facing reads.*

9. *H records componentwise* hsame *transport for compact-window, continuous-map, equicontinuity-family, uniform-modulus, observation, stream, readback, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the route*

$$K, F, A, O \longmapsto U, S, R, Q, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CompactOpenEquicontinuity}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOpenEquicontinuity}^{\uparrow}}$ *row.*

The carrier exports only these displayed rows. It has no coordinate for a host compact-open topology, function-space compactness theorem, selected convergent subnet, quotient equality of functions, countable choice, external modulus oracle, or ambient completeness.

Theorem 8406.2 (Compact-open equicontinuity NameCert obligations)**.** *For every accepted* CompactOpenEquicon *carrier*

$$E = (K, F, A, U, O, S, R, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOpenEquicontinuity}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *compact-window admission, requiring every compact-open request to expose the compact metric row K and the finite observation ledger O before any family read is consumed;*

2. *continuous-family exposure, requiring graph values to be read through the* $\mathsf{ContinuousMap}^{\uparrow}$ *row F, the stream window S, the regular readback row R, and the terminal Real seal Q;*

3. *equicontinuity synchronization, requiring the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row A and the* $\mathsf{UniformModulus}^{\uparrow}$ *row U to share the compact-window and tolerance requests listed by O;*

4. *structural stability, requiring H, C, P, N to transport, replay, source, and locally name only the displayed rows of the carrier;*

5. *exclusion of host compact-open topology, selected subnets, quotient function equality, countable choice, external modulus choice, function-space compactness, and ambient completeness.*

No NameCert obligation is stored outside these rows.

Proof. Project the carrier of Definition 8406.1. The compact-window data are exactly K and O, so any compact-open request begins with the displayed finite compact source and its inspection ledger.

The family values are then read through F, S, R, Q. This places every visible graph value behind the ContinuousMap row, StreamName window, RegSeqRat readback, and terminal Real seal, not behind a host function graph or quotient equality of maps.

The equicontinuity synchronization clause reads A and U over the same ledger O. Thus the family-wide equicontinuity witness and the downstream uniform-modulus handoff are tied to the compact windows already exposed by K.

Finally, H, C, P, N only transport, replay, source, and locally name the displayed rows. Since no row stores host compact-open topology, selected subnets, quotient function equality, countable choice, external modulus choice, function-space compactness, or ambient completeness, none of those objects can discharge a local NameCert obligation. □

Theorem 8406.3 (Compact-open equicontinuity Ascoli handoff)**.** *Every* ArzelaAscoli$^{\uparrow}$ *or compact-family consumer of an accepted* CompactOpenEquicontinuity$^{\uparrow}$ *carrier must read the compact metric row K, continuous-map family row F, equicontinuity-family row A, uniform-modulus handoff U, compact-open observation ledger O, stream window S, regular readback row R, terminal Real seal Q, and structural rows H, C, P, N in the displayed dependency order. The handoff may cite the packet as the compact-open equicontinuity boundary for the family, but it may not replace that boundary by host compact-open topology, a selected convergent subnet, quotient equality of functions, countable choice, a function-space compactness theorem, or ambient completeness.*

Proof. Start with the obligation theorem Definition 8406.2. It forces every compact-family read to expose K and O before the family graph or equicontinuity rows are consumed.

Next read the ContinuousMap and equicontinuity rows. The graph values pass through F, S, R, Q, while the family-wide equicontinuity data pass through A and the shared uniform-modulus handoff U.

The Ascoli-facing boundary is then the structural replay of the same finite route. Rows H, C, P, N preserve the order from compact windows to graph values, equicontinuity witnesses, and uniform-modulus output, so the consumer receives a displayed compact-open equicontinuity packet and no extra function-space compactness or choice-selected convergence object. □

Falsifiable prediction: Every accepted CompactOpenEquicontinuity$^{\uparrow}$ read exposes compact metric, continuous-map, equicontinuity-family, uniform-modulus, compact-open observation, StreamName, RegSeqRat, RealUp, transport, replay, provenance, and local naming rows.

Independence witness: compactmetric, continuousmap, equicontinuityfamily, uniformmodulus, arzelaascoli: CompactOpenEquicontinuity$^{\uparrow}$ is not identical to any listed sibling because it binds compact-open observation ledgers to family-wide equicontinuity and a uniform-modulus handoff before an Arzela–Ascoli consumer reads the family boundary.

Closure status for NameCert$_{\text{CompactOpenEquicontinuity}^{\uparrow}}$.

Constructive story: A CompactOpenEquicontinuity$^{\uparrow}$ packet is generated from CompactMetric finite-window rows, ContinuousMap graph rows, EquicontinuityFamily witnesses, a UniformModulus handoff, a compact-open observation ledger, StreamName windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactOpenEquicontinuity}^{\uparrow}}$, seed)

Scope closed: Definition 8406.1, Definition 8406.2, and Definition 8406.3 seed the compact-open equicontinuity route from compact windows and continuous family graphs to a UniformModulus and ArzelaAscoli-facing handoff.

Formal verification: FormalStatus(NameCert$_{\text{CompactOpenEquicontinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host compact-open topology, selected convergent subnets, quotient equality of functions, countable choice, external modulus choice, function-space compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, continuous-family exposure, equicontinuity synchronization, compact-open observation exactness, UniformModulus handoff, RealUp seal ordering, replay, provenance, and local naming for BEDC.Derived.CompactOpenEquicontinuityUp.

Chapter 8407

A Concrete Naming Certificate for $\mathsf{FiniteOscillationCover}^{\uparrow}$

Following Bishop–Bridges compact metric analysis and the Heine–Cantor finite-cover route, the $\mathsf{FiniteOscillationCover}^{\uparrow}$ packet records the finite rows by which compact finite-net data and pointwise continuous-map control become an oscillation cover visible to uniform-continuity consumers. It sits over the compact metric source of chapter 129, the continuous-map surface of chapter 130, the dyadic tolerance core of chapter 291, the uniform-modulus consumer of chapter 369, and the terminal real-name seal of chapter 38. The packet names finite cover rows and finite oscillation bounds; it does not assert open-cover compactness, select points by choice, identify maps by host equality, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8407.1 (Finite oscillation cover carrier)**.** *A* $\mathsf{FiniteOscillationCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (K, F, D, C, R, U, H, T, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net source row, including the displayed centers, radii, metric comparisons, and finite coverage ledger;*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose pointwise continuity data are read at the listed centers and their displayed neighborhoods;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the requested dyadic oscillation bound and the finite comparisons used by the cover;*
4. *C is the finite oscillation-cover row, listing the accepted cover cells, their center witnesses, their source-side radius rows, and their cellwise oscillation bounds;*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *readback seal for value comparisons when the oscillation bound is read in real-valued form;*
6. *U is the downstream* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row visible after the finite cover and oscillation rows have been displayed;*
7. *H records componentwise* hsame *transport for compact, continuous-map, dyadic, finite-cover, real-readback, uniform-modulus, provenance, and naming rows;*
8. *T records displayed* Cont *replay for finite-net coverage, pointwise continuity reads, dyadic tolerance comparisons, and uniform-modulus handoff;*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteOscillationCover}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationCover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, D, C, R, U, H, T, P, N$. No coordinate stores a host open-cover theorem, a choice-selected subcover, a hidden global modulus, quotient function equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8407.2 (Finite oscillation cover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteOscillationCover}^{\uparrow}$ *carrier $O = (K, F, D, C, R, U, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteOscillationCover}^{\uparrow}}$ *surface consists exactly of compact finite-net exposure through K, continuous-map pointwise reads through F, dyadic tolerance accounting through D, finite oscillation-cover cells through C, optional real-valued comparison sealing through R, uniform-modulus handoff through U, componentwise transport through H, displayed replay through T, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8407.1. The compact source, continuous-map row, dyadic tolerance, finite cover, real readback, uniform handoff, transport, replay, provenance, and local name are all displayed coordinates of one finite packet.

The compact and continuity rows are read before the cover row. The source row K supplies the finite centers and coverage ledger, while F supplies the pointwise continuity data attached to those displayed neighborhoods.

The dyadic and real rows then bound the oscillation read. The row D records the requested tolerance and finite comparisons, and R seals any real-valued comparison without adding an ambient completeness principle.

Finally C and U expose the finite oscillation cover and its downstream uniform-modulus handoff. The rows H, T, P, N preserve that route under transport, replay, provenance, and local naming, and no other obligation is available to the classifier. □

Theorem 8407.3 (Finite oscillation cover finite-subcover route)**.** *Every consumer that reads a* $\mathsf{FiniteOscillationCover}^{\uparrow}$ *packet as a compact-uniform-continuity input must factor through the displayed finite route*

$$K \longmapsto F \longmapsto D \longmapsto C \longmapsto R \longmapsto U \longmapsto H, T, P, N.$$

Thus the consumer receives a finite compact-metric coverage ledger, pointwise continuous-map rows, dyadic tolerance comparisons, finite oscillation cells, real-valued comparison seals when requested, and a $\mathsf{UniformModulus}^{\uparrow}$ *handoff, but it receives no open-cover compactness theorem, no choice-selected subcover, no hidden global modulus, no quotient map equality, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the compact source row K. It displays the finite-net coverage data used by the packet, so the consumer reads a listed finite coverage ledger rather than an external open-cover principle.

Read the continuous-map and dyadic rows next. The row F supplies pointwise control at the listed centers, and D supplies the dyadic tolerance comparisons that determine the accepted oscillation cells.

Project the cover row C. Its cells, center witnesses, radius rows, and oscillation bounds are the only finite subcover data available to the consumer; no selector outside the displayed list is present.

The real seal R and uniform handoff U are downstream of those finite rows. Transport, replay, provenance, and naming through H, T, P, N preserve exactly the same route, so the packet exports finite oscillation-cover data and refuses the excluded host principles. □

Falsifiable prediction: An accepted $\mathsf{FiniteOscillationCover}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying CompactMetric finite-net data, ContinuousMap pointwise rows, DyadicRatCore tolerance comparisons, finite oscillation-cover cells, optional RealUp comparison seals, transport, replay, provenance, and local naming.

Independence witness: compactmetric, continuousmap, dyadicratcore, real, uniformmodulus: none is bijective to $\mathsf{FiniteOscillationCover}^{\uparrow}$ because the packet binds compact finite-net coverage, pointwise continuity, dyadic tolerance accounting, finite oscillation cells, real-valued comparison seals, and a uniform-modulus handoff into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteOscillationCover}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteOscillationCover}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise rows, DyadicRatCore tolerance comparisons, finite oscillation-cover cells, RealUp comparison seals, a UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteOscillationCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8407.1, Definition 8407.2, and Definition 8407.3 seed the finite oscillation-cover packet for compact-uniform-continuity consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteOscillationCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, choice-selected subcovers, hidden global moduli, quotient function equality, ambient RealUp completeness, Lean verification, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked compact finite-net exposure, continuous-map pointwise reads, dyadic tolerance accounting, finite oscillation-cover rows, real comparison seals, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteOscillationCoverUp.

Chapter 8408

A Concrete Naming Certificate for $\mathsf{OscillationDerivative}^{\uparrow}$

Following Lebesgue and Baire, the $\mathsf{OscillationDerivative}^{\uparrow}$ packet records the finite-window derivative step by which a real-valued function on a displayed metric source exposes its local oscillation boundary before any rank, Baire-one, or discontinuity consumer reads the data. It sits over the $\mathsf{Met}^{\uparrow}$ source of chapter 57, the $\mathsf{ContinuousMap}^{\uparrow}$ function-surface row of chapter 130, the $\mathsf{Real}^{\uparrow}$ value seal of chapter 38, the Baire-one oscillation neighbours chapter 8067 and chapter 8106, and the downstream oscillation-rank route of chapter 7961. The packet names only a displayed finite derivative window; it does not construct a transfinite rank, choose neighbourhood bases by countable choice, identify functions by quotient equality, or import ambient completeness.

Definition 8408.1 (OscillationDerivative carrier)**.** *An* $\mathsf{OscillationDerivative}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (F, X, W, O, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the function-surface row, read through* $\mathsf{ContinuousMap}^{\uparrow}$ *or an adjacent real-valued function packet, naming the displayed source-to-*$\mathsf{Real}^{\uparrow}$ *value observations.*
2. *X is the* $\mathsf{Met}^{\uparrow}$ *source row, carrying the visible metric comparisons and named source points used by the derivative request.*
3. *W is the metric/Real finite-window row: it pairs a finite neighbourhood schedule around the inspected source points with the* $\mathsf{Real}^{\uparrow}$ *value windows read from F.*
4. *O is the oscillation-bound row, recording the displayed lower and upper value comparisons and the rational bound tested inside W.*
5. *R is the refinement ledger, recording which finite neighbourhood windows survive the derivative step and which are discarded at the displayed bound.*
6. *H records componentwise* hsame *transport for the function surface, metric source, finite windows, oscillation bounds, refinement ledger, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from an oscillation-derivative request through F, X, W, O, R and then through the structural rows.*
8. *P is the* Pkg *provenance over* $\mathsf{OscillationDerivative}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

9. N is the local $\mathsf{NameCert}_{\mathsf{OscillationDerivative}^{\uparrow}}$ *row.*
The carrier has no coordinate for a completed derivative hierarchy, a selected neighbourhood basis, quotient equality of functions, point-set measurability, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.OscillationDerivativeUp.TasteGate.OscillationDerivativeTasteGate single carrier alignment`

Theorem 8408.2 (OscillationDerivative NameCert obligations)**.** *For every accepted* $\mathsf{OscillationDerivative}^{\uparrow}$ *carrier* $D = (F, X, W, O, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OscillationDerivative}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; function-surface admission through* F*; metric-source compatibility through* X*; finite neighbourhood and value-window admission through* W*; oscillation-bound exactness through* O*; refinement-ledger exactness through* R*; componentwise transport stability through* H*; displayed replay through* C*; provenance through* P*; and local naming through* N*.*

Proof. Carrier admission is projection from Definition 8408.1. The accepted packet exposes exactly the rows $F, X, W, O, R, H, C, P, N$, so each local NameCert obligation must be read from one of these rows.

The analytic rows are read in finite order. The function-surface row F supplies the displayed real-valued observations, the metric row X supplies the source comparisons, and the finite-window row W binds neighbourhood inspection to the value windows already visible through F.

The derivative step is then the route through O and R. The oscillation-bound row records the tested lower and upper value comparisons at a rational bound, while the refinement ledger records only the displayed surviving and discarded windows.

Transport and replay preserve that route. The rows H and C cannot add a completed hierarchy, selected neighbourhood basis, quotient function equality, countable choice, point-set measurability, or ambient completeness principle, while P and N source and name only the listed packet. Hence the displayed rows exhaust the local certificate surface. □

Theorem 8408.3 (OscillationDerivative finite-window handoff)**.** *Every Baire-one, oscillation-rank, or discontinuity-boundary consumer of an accepted* $\mathsf{OscillationDerivative}^{\uparrow}$ *carrier factors through the finite route*

$$F, X, W, O, R \longmapsto H, C, P, N.$$

Thus the consumer may inspect the displayed function surface, metric source, finite neighbourhood schedule, Real value windows, oscillation-bound row, and refinement ledger, but it receives no completed rank hierarchy, no quotient function equality, no selected neighbourhood basis, no point-set measurability theorem, no countable-choice principle, and no ambient real-completion theorem.

Proof. Start with a consumer of the refinement row R. Carrier admission makes R available only after the function surface F, metric source X, finite window W, and oscillation-bound row O have been displayed.

Replay the continuation row C. The request opens the source and function-surface data, reads the named finite neighbourhood schedule, inspects the corresponding $\mathsf{Real}^{\uparrow}$ value windows, and only then exposes the oscillation-bound and refinement rows.

The handoff is therefore the stated finite route. Componentwise transport through H preserves the same rows, and P, N source and name only that packet. None of the excluded host objects can be recovered from the carrier. □

Falsifiable prediction: Every accepted $\mathsf{OscillationDerivative}^{\uparrow}$ consumer that exports a derivative-window row must display the ContinuousMap or function-surface row, MetricSpace source row, finite neighbourhood schedule, RealUp value windows, oscillation-bound row, refinement ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming before any Baire-one, oscillation-rank, or discontinuity-boundary handoff is available.

Independence witness: continuousmap, metricspace, real, baire-one-uniform-oscillation, baire-one-modulus, oscillation-rank: no listed sibling supplies the whole nine-row packet $D = (F, X, W, O, R, H, C, P, N)$, because each sibling contributes only the function surface, metric source, value seal, Baire-one oscillation window, modulus companion, or rank consumer while this chapter binds the derivative-window refinement ledger into one local NameCert carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{OscillationDerivative}^{\uparrow}}$.

Constructive story: An $\mathsf{OscillationDerivative}^{\uparrow}$ packet is generated from a function-surface row, MetricSpace source row, finite neighbourhood and RealUp value windows, an oscillation-bound row, a refinement ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OscillationDerivative}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8408.1, Definition 8408.2, and Definition 8408.3 seed the finite-window oscillation-derivative certificate over displayed function-surface, metric-source, Real-value, oscillation-bound, refinement-ledger, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OscillationDerivative}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.OscillationDerivativeUp.TasteGate.OscillationDerivativeTasteGate\_single\_carrier\_alig`

Bridge status: none

Not claimed: This chapter does not close completed derivative hierarchies, transfinite ranks, quotient function equality, selected neighbourhood bases, point-set measurability, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, axiom purity, or bridge checking.

Upgrade path: Obligation closure asks for checked carrier admission, function-surface admission, metric-source compatibility, finite-window admission, oscillation-bound exactness, refinement-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.OscillationDerivativeUp.

Chapter 8409

A Concrete Naming Certificate for $\mathsf{SardRegularValue}^{\uparrow}$

Following Sard and standard differential-topology treatments, the $\mathsf{SardRegularValue}^{\uparrow}$ packet records the finite regular-value consumer surface for displayed manifold chart rows, smooth-map rows, derivative finite-jet rows, the finite Sard jet packet of chapter 3644, terminal $\mathsf{Real}^{\uparrow}$ readback through chapter 38, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert data. It sits beside the charted manifold carrier of chapter 96 and consumes only finite window evidence; it does not claim full Sard measure theory, host smooth topology, a transversality theorem, or choice-selected regular values.

Definition 8409.1 (Sard regular-value carrier)**.** *A* $\mathsf{SardRegularValue}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (M, F, D, J, V, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart row naming the source and target chart windows in which the candidate value is inspected.*
2. *F is the smooth-map observation row, containing only the displayed map values and chart restrictions consumed by the packet.*
3. *D is the derivative finite-jet row, recording the derivative windows and rank reads used to test regularity.*
4. *J is the* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ *support row that supplies the finite critical-window exclusion surface.*
5. *V is the candidate value-window row whose regular-value status is being consumed.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row for the displayed value after the finite chart and jet route has been replayed.*
7. *H records componentwise* hsame *transport for the chart, map, derivative, Sard-jet, value-window, readback, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a regular-value request through $M, F, D, J, V, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{SardRegularValue}^{\uparrow}$, $\mathsf{SardTheoremFiniteJet}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SardRegularValue}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these ten rows. It has no coordinate for ambient measure-zero data, host smooth-function spaces, selected values, global transversality, or a standard bridge.

Theorem 8409.2 (Sard regular-value NameCert obligations)**.** *For every accepted* $\mathsf{SardRegularValue}^{\uparrow}$ *carrier* $R = (M, F, D, J, V, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SardRegularValue}^{\uparrow}}$ *surface consists exactly of chart admission through* M*, smooth-map observation through* F*, derivative finite-jet admission through* D*, finite critical-window support through* J*, candidate value exposure through* V*, terminal* $\mathsf{Real}^{\uparrow}$ *readback through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8409.1. Its rows $M, F, D, J, V, E, H, C, P, N$ are the whole accepted packet, so every regular-value read begins as finite BHist data.

The differential-topology part is confined to M, F, D, J, V. The chart row and smooth-map row expose the finite windows, the derivative row records the rank reads, the Sard finite-jet row supplies the critical-window support, and the value row names the candidate window.

The readback and structure rows preserve that same route. The row E seals the displayed value as $\mathsf{Real}^{\uparrow}$, while H, C, P, N transport, replay, source, and name the packet without adding host measure theory, global transversality, selected regular values, or a smooth-function-space quotient. □

Theorem 8409.3 (Sard regular-value critical-window handoff)**.** *Every consumer of an accepted* $\mathsf{SardRegularValue}^{\uparrow}$ *packet that asks whether a displayed value window is regular must first read the route*

$$M \longmapsto F \longmapsto D \longmapsto J \longmapsto V \longmapsto E$$

with structural support H, C, P, N*. The row* J *is the only handoff to* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$*, so the consumer receives finite critical-window exclusion data rather than a full Sard measure theorem, host topology on smooth maps, or a choice-selected regular value.*

Proof. Begin with the chart and map rows M, F. They name the displayed source and target windows and the finite observations available to the regular-value consumer.

Next read D, J, V. The derivative row supplies the rank-facing finite-jet data, the Sard finite-jet row records the critical-window support from chapter 3644, and the value row identifies the inspected target window.

Finally replay the terminal value through E and the structural rows. The route stays inside the displayed carrier and therefore cannot export ambient measure-zero reasoning, host smooth topology, global transversality, or a selected regular value. □

Falsifiable prediction: Every accepted $\mathsf{SardRegularValue}^{\uparrow}$ consumer must expose $\mathsf{Manifold}^{\uparrow}$, smooth-map finite observations, derivative finite-jet rows, $\mathsf{SardTheoremFiniteJet}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$ readback, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows before any regular-value result is consumed.

Independence witness: sard-theorem-finite-jet, manifold, real: $\mathsf{SardRegularValue}^{\uparrow}$ is not bijective to any listed sibling because it binds a candidate value-window consumer to chart, map, derivative, finite critical-window support, terminal real readback, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SardRegularValue}^{\uparrow}}$.

Constructive story: A SardRegularValue$^{\uparrow}$ packet is generated from Manifold chart rows, smooth-map observation rows, derivative finite-jet rows, a SardTheoremFiniteJetUp support row, candidate value-window rows, a terminal RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{SardRegularValue}\uparrow}$, seed)

Scope closed: Definition 8409.1, Definition 8409.2, and Definition 8409.3 seed the finite regular-value certificate over chart, map, derivative, Sard finite-jet, value-window, readback, transport, replay, provenance, and naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{SardRegularValue}\uparrow}$, unformalized)

Lean target: `BEDC.Derived.SardRegularValueUp`

Bridge status: none

Not claimed: This chapter does not claim the full Sard measure theorem, transversality, choice-selected regular values, host smooth topology, Lean theorem checking, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, derivative finite-jet admission, Sard finite-jet handoff, candidate value-window exposure, terminal Real readback, transport stability, replay, provenance, and local naming for the displayed packet.

Chapter 8410

A Concrete Naming Certificate for $\mathsf{SardTheorem}^{\uparrow}$

Following Sard's theorem in differential topology, the $\mathsf{SardTheorem}^{\uparrow}$ packet names the theorem-level consumer surface that reads the finite critical-window certificate of chapter 3644 together with the regular-value consumer route of chapter 8409. It sits over the charted manifold carrier of chapter 96 and the terminal Real seal of chapter 38. The packet records the finite BEDC route by which critical-value exclusion and regular-value readback are consumed together; it does not claim the classical measure-zero Sard theorem, a transversality theorem, a host smooth-topology argument, or choice-selected regular values.

Definition 8410.1 (Sard theorem carrier)**.** *A* $\mathsf{SardTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, J, R, V, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *chart row that names the source and target chart windows read by the theorem-level consumer.*
2. *J is the* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ *support row carrying the finite derivative-jet, rank-defect, and critical-value window evidence.*
3. *R is the* $\mathsf{SardRegularValue}^{\uparrow}$ *row that consumes the finite critical-window support as a regular-value read.*
4. *V is the displayed value-window row whose critical or regular status is inspected.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *readback row used to expose the finite value-window comparison.*
6. *H records componentwise* hsame *transport for M, J, R, V, E and the structural rows below.*
7. *C records displayed* Cont *replay through the chart, finite-jet, regular-value, value-window, and Real rows.*
8. *P is the* Pkg *provenance over* $\mathsf{SardTheorem}^{\uparrow}$, $\mathsf{SardTheoremFiniteJet}^{\uparrow}$, $\mathsf{SardRegularValue}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SardTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for Lebesgue measure, transversality, a host topology on smooth maps, a selected regular value, or an ambient differentiability theorem.

Theorem 8410.2 (Sard theorem NameCert obligations)**.** *For every accepted* $\mathsf{SardTheorem}^{\uparrow}$ *carrier* $S = (M, J, R, V, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SardTheorem}^{\uparrow}}$ *surface consists exactly of chart admission through* M*, finite-jet critical-window support through* J*, regular-value consumption through* R*, displayed value-window exposure through* V*, terminal* $\mathsf{Real}^{\uparrow}$ *readback through* E*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier $S = (M, J, R, V, E, H, C, P, N)$. The chart row M fixes the finite manifold windows available to the theorem-level read, while the finite-jet row J supplies the derivative, rank-defect, and critical-window evidence.

Next read the regular-value row R together with the inspected value window V. The regular-value route of chapter 8409 consumes the finite critical-window support of chapter 3644, so the theorem-level packet uses exactly the displayed handoff rather than an ambient measure argument.

Finally read E, H, C, P, N. The Real row seals the finite value-window comparison, and the structural rows transport, replay, source, and name the same packet. Since the excluded host coordinates are absent from the carrier, they cannot discharge any local NameCert obligation. □

Theorem 8410.3 (Sard theorem critical-value route)**.** *Every consumer of an accepted* $\mathsf{SardTheorem}^{\uparrow}$ *packet that asks for a theorem-level critical-value or regular-value read must first traverse the finite route*

$$M \longmapsto J \longmapsto R \longmapsto V \longmapsto E$$

with structural support H, C, P, N*. The consumer receives the finite* $\mathsf{SardTheoremFiniteJet}^{\uparrow}$ *and* $\mathsf{SardRegularValue}^{\uparrow}$ *rows over* $\mathsf{Manifold}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$*, not a full measure-theoretic Sard theorem, transversality theorem, host smooth-topology surface, or choice-selected regular value.*

Proof. Begin with the charted manifold row M. It names the source and target windows before any critical-value request can be inspected.

Apply the finite-jet packet of chapter 3644. The row J exposes derivative-jet, rank-defect, value-window, and local regularity data as finite certificate rows.

Use the regular-value consumer of chapter 8409. The row R can read regularity only through the finite critical-window support supplied by J, and the inspected value window V reaches the terminal Real readback E through the same displayed route.

The structural rows H, C, P, N preserve the packet under transport, replay, provenance, and local naming. No omitted host coordinate can supply measure-zero reasoning, transversality, smooth-topology closure, or a selected regular value. □

Falsifiable prediction: Every accepted $\mathsf{SardTheorem}^{\uparrow}$ consumer must expose $\mathsf{Manifold}^{\uparrow}$, $\mathsf{SardTheoremFiniteJet}^{\uparrow}$, $\mathsf{SardRegularValue}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and local $\mathsf{NameCert}$ rows before any theorem-level critical-value or regular-value read is public.

Independence witness: sard-theorem-finite-jet, sard-regular-value, manifold, real: $\mathsf{SardTheorem}^{\uparrow}$ is not bijective to any listed sibling because it binds theorem-level chart admission, finite critical-window support, regular-value consumption, value-window readback, terminal Real sealing, transport, replay, provenance, and local naming in one carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{SardTheorem}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SardTheorem}^{\uparrow}$ packet is generated from Manifold chart rows, a SardTheoremFiniteJetUp finite critical-window support row, a SardRegularValueUp consumer row, a displayed value-window row, a terminal RealUp readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SardTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 8410.1, Definition 8410.2, and Definition 8410.3 seed the theorem-level finite route through manifold chart rows, Sard finite-jet support, regular-value consumption, value-window exposure, Real readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{SardTheorem}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.SardTheoremUp`

Bridge status: none

Not claimed: This chapter does not claim full measure-theoretic Sard, transversality, host smooth topology, choice-selected regular values, Lean theorem checking, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-jet support, regular-value consumption, value-window exposure, Real readback, transport stability, replay, provenance, and local naming for the displayed packet.

Chapter 8411

A Concrete Naming Certificate for $\mathsf{MetricDerivedSet}^{\uparrow}$

Following Kuratowski and Bourbaki on derived sets in metric spaces, the $\mathsf{MetricDerivedSet}^{\uparrow}$ packet records the finite BEDC route by which a displayed subset exposes points whose every punctured metric neighbourhood meets that subset. It sits beside the metric carrier of chapter 57, the closure interface of chapter 3342, the metric sequential limit-point route of chapter 8015, the finite sequence windows of chapter 126, the regular rational readbacks of chapter 301, and the terminal real seal of chapter 38. The packet is a conservative L10 neighbour of closure and sequential-limit evidence; it does not choose cluster points, identify quotient streams, import open-cover compactness, use countable choice, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8411.1 (Metric derived-set carrier)**.** *A* $\mathsf{MetricDerivedSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, S, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the ambient* $\mathsf{Met}^{\uparrow}$ *row, including the point classifier, distance-observation rows, and finite metric-law ledger used by the neighbourhood tests.*
2. *S is the subset row whose accumulation boundary is being inspected.*
3. *Q is the punctured-ball witness ledger: each displayed radius request records a candidate point, a positive puncture condition, a subset witness row, and a metric-distance read showing the witness lies in the requested punctured ball.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window surface used to read candidate names, subset witnesses, and inspected radius windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the metric-distance and radius comparisons carried by Q and W.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the metric, subset, punctured-ball, window, and readback rows have been displayed.*
7. *H records componentwise* hsame *transports for M, S, Q, W, R, E and for the provenance and local naming rows.*
8. *C records displayed* Cont *replay from metric and subset reads through punctured-ball witnesses, finite windows, regular rational readback, and the terminal Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{MetricDerivedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{MetricDerivedSet}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through these displayed rows. It has no coordinate for an open-cover compactness theorem, a selected cluster point, quotient equality of sequences or subsets, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8411.2 (Metric derived-set NameCert obligations)**.** *For every accepted* $\mathsf{MetricDerivedSet}^{\uparrow}$ *carrier $D = (M, S, Q, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MetricDerivedSet}^{\uparrow}}$ *surface consists exactly of metric-source admission through M, subset admission through S, punctured-ball witness coverage through Q, finite StreamName window visibility through W, RegSeqRat readback through R, Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The metric row, subset row, punctured-ball witness ledger, finite windows, regular rational readbacks, and terminal Real seal are the only mathematical rows exposed to a consumer.

The punctured-ball clause is finite because Q records the inspected radius requests and their displayed subset witnesses. Each witness is read through W and each distance comparison is read through R before the Real seal E is available.

The structural rows H, C, P, N preserve the same route under transport, replay, provenance, and local naming. Since the carrier has no compactness, selector, quotient, choice, or completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8411.3 (Metric derived-set L10 handoff)**.** *Every closure-facing or sequential-limit-point consumer of an accepted* $\mathsf{MetricDerivedSet}^{\uparrow}$ *packet must first read the finite route through* $\mathsf{Met}^{\uparrow}$, $\mathsf{MetricClosure}^{\uparrow}$, $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$. *In carrier terms, the rows $M, S, Q, W, R, E, H, C, P, N$ must remain visible before the consumer treats the packet as derived-set evidence for a displayed subset. The handoff exports punctured-ball witness data and finite readback seals, not open-cover compactness, selected cluster points, quotient equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8411.2. They place the metric row, subset row, punctured-ball witness ledger, finite windows, rational readbacks, Real seal, transport, replay, provenance, and local naming in one displayed packet.

For a closure-facing read, the packet first exposes the same metric and subset rows used by $\mathsf{MetricClosure}^{\uparrow}$, then replaces a bare candidate-limit read with the punctured-ball ledger Q. The finite windows W, regular rational readback R, and Real seal E keep the closure evidence inside displayed BEDC rows.

For a sequential-limit-point read, the packet exposes the same finite observation discipline used by $\mathsf{MetricSequentialLimitPoint}^{\uparrow}$: sequence or witness windows are read through $\mathsf{StreamName}^{\uparrow}$, distance comparisons through $\mathsf{RegSeqRat}^{\uparrow}$, and terminal comparisons through $\mathsf{Real}^{\uparrow}$ before the derived-set consumer may inspect the punctured-ball witness.

The refused principles require rows absent from D. No coordinate supplies an open-cover compactness theorem, a selected cluster point, quotient equality, countable choice, or ambient Real completeness, so the L10 handoff is exactly the finite route stated above. □

Falsifiable prediction: Every accepted $\mathsf{MetricDerivedSet}^{\uparrow}$ read exposes one Metric row, one subset row, one punctured-ball witness ledger, finite StreamName windows, RegSeqRat readbacks,

one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any derived-set consumer is public.

Independence witness: metric, metric-closure, metric-sequential-limit-point, streamname, regseqrat, real: $\mathsf{MetricDerivedSet}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a subset row and punctured-ball witness ledger over the metric, window, readback, seal, transport, replay, provenance, and local naming surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MetricDerivedSet}^{\uparrow}}$.

Constructive story: A $\mathsf{MetricDerivedSet}^{\uparrow}$ packet is generated from a Metric row, a subset row, a punctured-ball witness ledger, finite StreamName windows, RegSeqRat readbacks, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetricDerivedSet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8411.1, Definition 8411.2, and Definition 8411.3 seed the finite metric derived-set route between metric closure and metric sequential limit-point consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetricDerivedSet}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.MetricDerivedSetUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected cluster points, quotient equality, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem checking, axiom cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, punctured-ball witness coverage, finite-window visibility, regular rational readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.MetricDerivedSetU

Lean4 (statement) `BEDC.Derived.MetricDerivedSetUp`

Chapter 8412

A Concrete Naming Certificate for $\mathsf{ApartnessCut}^{\uparrow}$

Following Bishop and Bridges, an apartness cut is a cut-shaped real observation whose positive separation information is displayed before any real-order or completion consumer may inspect it. The $\mathsf{ApartnessCut}^{\uparrow}$ packet sits beside the located-cut route of chapter 404, the located real-number route of chapter 6640, the dyadic tolerance ledger of chapter 291, the stream-window source of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. It records a constructive apartness-facing cut as finite BEDC data, not as trichotomy, quotient-cut equality, selected comparisons, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8412.1 (Apartness cut carrier)**.** *An* $\mathsf{ApartnessCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (L, U, K, S, R, D, E, Q, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower cut-observation row, containing only finite rational lower observations and their downward-use discipline.*
2. *U is the upper cut-observation row, containing only finite rational upper observations and their upward-use discipline.*
3. *K is the located-cut row, read through* $\mathsf{LocatedCut}^{\uparrow}$ *and carrying displayed gap witnesses between lower and upper observations.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *request schedule for the inspected cut windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row exposed after S.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for radii, endpoint gaps, and dyadic comparison slack.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after K, S, R, D have been displayed.*
8. *Q is the apartness-facing query row: it records positive separation requests and their displayed rational witnesses, but it does not decide equality or trichotomy.*
9. *H records componentwise* hsame *transport for the lower, upper, located-cut, stream, regular-rational, dyadic, real-seal, apartness-query, replay, provenance, and naming rows.*
10. *C records displayed* Cont *replay from an apartness query through $L, U, K, S, R, D, E, Q, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{ApartnessCut}^{\uparrow}$, $\mathsf{LocatedCut}^{\uparrow}$, $\mathsf{LocatedRealNumber}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ApartnessCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, K, S, R, D, E, Q, H, C, P, N$. It has no coordinate for cut quotients, real trichotomy, a selected apartness oracle, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.ApartnessCutUp.ApartnessCutTasteGate single carrier alignment`

Theorem 8412.2 (Apartness cut NameCert obligations)**.** *For every accepted* $\mathsf{ApartnessCut}^{\uparrow}$ *carrier $A = (L, U, K, S, R, D, E, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ApartnessCut}^{\uparrow}}$ *surface consists exactly of carrier admission, lower- and upper-cut observation exposure, located-cut gap visibility, stream-window scheduling, regular-rational readback, dyadic tolerance exactness, terminal* $\mathsf{Real}^{\uparrow}$ *seal nonescape, apartness-query exposure, componentwise* hsame *transport, displayed* Cont *replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8412.1. The rows $L, U, K, S, R, D, E, Q, H, C, P, N$ are the complete local inventory available to an accepted packet.

The cut-side rows are finite. Lower and upper observations meet only through the located-cut row K, so a consumer cannot replace the displayed gap witnesses by a quotient cut or by an ambient order object.

The real-facing route then passes through the stream schedule S, the regular rational readback R, the dyadic tolerance ledger D, and only then the terminal seal E. The apartness-query row Q reads positive separation evidence along that same route; it does not add equality, trichotomy, or a selected comparison oracle.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since no excluded object is a coordinate of the carrier, the listed rows exhaust the local certificate obligations. □

Theorem 8412.3 (Apartness cut L10 handoff)**.** *Every Phase Real or Completion consumer of an accepted* $\mathsf{ApartnessCut}^{\uparrow}$ *packet must read apartness-cut evidence through the displayed route*

$$\mathsf{LocatedCut}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

with the lower and upper cut rows, apartness-query row Q, and the displayed BHist, hsame, Cont, Pkg, *and* NameCert *support retained. The handoff exports a constructive apartness-cut source for* $\mathsf{Real}^{\uparrow}$ *apartness and order work, not trichotomy, quotient-cut equality, countable choice, selected limits, or ambient real completeness.*

Proof. Start from the NameCert obligations of Definition 8412.2. They force the lower row, upper row, located gap row, stream schedule, regular readback, dyadic tolerance ledger, Real seal, and apartness-query row to remain visible before any public read is available.

Use the located-cut sibling chapter 404 and the located real-number sibling chapter 6640 as the readback discipline for finite cut and located real observations. The new packet keeps that discipline while making the positive separation query Q an explicit coordinate.

The L10 route consumes only the displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows after the located-cut witness has been shown. Structural rows H, C, P, N preserve the route under transport, replay, provenance, and local naming.

Thus the handoff supplies the constructive apartness-facing boundary needed by Real and Completion consumers. Because none of trichotomy, quotient-cut equality, countable choice, selected limits, or ambient completeness is present as a carrier row, none is exported by the handoff. □

Falsifiable prediction: Every accepted $\mathsf{ApartnessCut}^{\uparrow}$ read exposes lower and upper cut observations, a LocatedCut gap witness, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a terminal Real seal, an apartness-query row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row before any Real-facing apartness or order consumer may inspect it.

Independence witness: dyadicratcore, streamname, regseqrat, real, locatedcut, located-real-number: no listed sibling is bijective with $\mathsf{ApartnessCut}^{\uparrow}$ because this packet jointly binds lower and upper cut observations, located gap witnesses, stream windows, regular rational readback, dyadic tolerance data, a terminal Real seal, apartness-query evidence, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{ApartnessCut}^{\uparrow}}$.

Constructive story: An $\mathsf{ApartnessCut}^{\uparrow}$ packet is generated from lower and upper cut observations, a LocatedCut gap row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, a terminal Real seal, an apartness-query row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ApartnessCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8412.1, Definition 8412.2, and Definition 8412.3 seed the finite constructive apartness-cut route over DyadicRatCore, StreamName, RegSeqRat, Real, LocatedCut, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ApartnessCut}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.ApartnessCutUp.ApartnessCutTasteGate\_single\_carrier\_alignment`

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient-cut equality, selected apartness or comparison oracles, countable choice, selected limits, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-cut gap visibility, stream-window scheduling, regular-rational readback, dyadic tolerance exactness, Real seal nonescape, apartness-query exposure, transport, replay, provenance, and local naming for BEDC.Derived.ApartnessCutUp.

Chapter 8413

A Concrete Naming Certificate for $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$

Following Bishop and Bridges on explicit real-name bounds and finite approximation windows, the $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ packet records the finite Archimedean witness window that a Real and Completion consumer must read before a terminal real-name seal is exposed. It sits over the finite stream surface of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the sequential Archimedean handoff of chapter 8278. The packet names a bounded witness-window route; it is not trichotomy, quotient stream equality, a selected completed representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8413.1 (Sequential Archimedean window carrier)**.** *A* $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (R, i, Q, D, A, G, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *name whose bounded sequential observation is being prepared.*
2. *i is the unary* $\mathsf{Nat}^{\uparrow}$ *request row naming the observation scale.*
3. *Q is the* $\mathsf{Rat}^{\uparrow}$ *Archimedean witness row visible at the request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row presenting the same witness for window consumers.*
5. *A is the finite* $\mathsf{StreamName}^{\uparrow}$ *window opened by the request and witness rows.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback extracted from the same window.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after i, Q, D, A, G have been displayed.*
8. *H records componentwise* hsame *transport for the real name, request, witness rows, finite window, regular readback, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from the request through the finite window, regular readback, witness rows, and terminal seal.*
10. *P is the* Pkg *provenance over* $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$, $\mathsf{SequentialArchimedeanReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanWindow}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through $R, i, Q, D, A, G, E, H, C, P, N$. It has no coordinate for trichotomy, quotient stream equality, a selected completed representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.SequentialArchimedeanWindowUp.SequentialArchimedeanWindowTasteGate single carrier alignment`

Theorem 8413.2 (Sequential Archimedean window NameCert obligations)**.** *For every accepted* $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ *carrier*

$$W = (R, i, Q, D, A, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanWindow}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed real name, unary request, rational witness, dyadic tolerance, finite stream window, regular readback, Real seal, componentwise transport, continuation replay, provenance, and local naming rows; request-window compatibility binding i, Q, D to the same window A that produces G; witness coherence binding Q and D to one finite Archimedean bound; seal ordering requiring E to be read only after i, Q, D, A, G; and non-escape excluding trichotomy, quotient stream equality, selected completed representatives, countable choice, ambient Real completeness, Lean verification, and bridge checking.*

Proof. Project the carrier of Definition 8413.1. The rows $R, i, Q, D, A, G, E, H, C, P, N$ are the complete packet inventory, so carrier admission and local naming introduce no hidden object.

The request-window compatibility clause follows from the displayed order. The unary request i and witness rows Q, D open the finite window A, and the readback G is extracted from that same window before the seal E can be consumed.

Witness coherence is componentwise. The rational witness Q and dyadic tolerance row D describe one Archimedean bound for the same request, and H and C transport and replay that bound without allocating another witness row.

Finally the seal-ordering and non-escape clauses use the absence of further coordinates. Since E is the only terminal $\mathsf{Real}^{\uparrow}$ seal and the carrier has no row for trichotomy, quotient stream equality, selected completed representatives, countable choice, ambient completeness, Lean verification, or bridge checking, every accepted consumer remains inside the displayed finite route. □

Theorem 8413.3 (Sequential Archimedean window Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ *carrier*

$$W = (R, i, Q, D, A, G, E, H, C, P, N)$$

must read the unary request i, the rational witness Q, the dyadic tolerance row D, the finite window A, and the regular readback G before it may read the terminal seal E. The handoff is therefore a finite Archimedean witness-window route from $\mathsf{SequentialArchimedeanReal}^{\uparrow}$ *to* $\mathsf{Real}^{\uparrow}$ *consumers, not a completeness principle or a selected representative of a completed stream.*

Proof. Read the accepted carrier. The only Real-facing seal row is E, and it is stored after the request, witness, window, and readback rows i, Q, D, A, G.

Apply Definition 8413.2. Its seal-ordering clause requires the request-window compatibility and witness-coherence rows before any consumer-visible seal read.

The provenance row P names the sibling route through $\mathsf{SequentialArchimedeanReal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$, while H and C preserve the same displayed rows under

transport and replay. Hence the Real handoff exports exactly the finite witness window and not trichotomy, quotient stream equality, selected completed representatives, countable choice, or ambient Real completeness. □

Falsifiable prediction: Every accepted $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ Real-facing read exposes a RealUp name, a NatUp unary request, RatUp and DyadicRatCoreUp Archimedean witness rows, a StreamNameUp finite window, RegSeqRatUp readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row before the terminal seal is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real, sequential-archimedean-real: $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a unary request, rational and dyadic Archimedean witness rows, finite stream windows, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming while refusing trichotomy, quotient stream equality, selected completed representatives, countable choice, and Real completeness.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentialArchimedeanWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentialArchimedeanWindow}^{\uparrow}$ packet is generated from a RealUp name, a NatUp unary request, RatUp and DyadicRatCoreUp Archimedean witness rows, a StreamNameUp finite window, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentialArchimedeanWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8413.1, Definition 8413.2, and Definition 8413.3 seed the finite Archimedean witness-window route before RealUp consumers read a terminal seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SequentialArchimedeanWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close trichotomy, quotient stream equality, selected completed representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, request-window compatibility, rational-dyadic witness coherence, Real-seal ordering, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.SequentialArchimedeanW

Chapter 8414

A Concrete Naming Certificate for $\mathsf{EntourageCompletion}^{\uparrow}$

Following Bishop and Bridges' constructive completion discipline, Kelley's uniform-space entourages, and Bourbaki's filter-facing uniformity language, the $\mathsf{EntourageCompletion}^{\uparrow}$ packet names the finite route by which an entourage base can be read as completion data without quotienting Cauchy filters or selecting limits. It sits between the Cauchy-filter surface of chapter 333, the finite stream windows of chapter 126, the regular rational sequence route of chapter 301, the dyadic ledger of chapter 291, and the terminal Real seal of chapter 38.

Definition 8414.1 (Entourage completion carrier)**.** *An* $\mathsf{EntourageCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (U, F, B, S, R, D, W, H, C, P, N)$$

with the following rows:

1. *U is a displayed uniformity row whose entourages are read as finite neighborhood relations rather than as a completed quotient space.*
2. *F is a* $\mathsf{CauchyFilter}^{\uparrow}$ *source row whose Cauchy condition is opened only through named entourage requests.*
3. *B is an entourage-base row, assigning each accepted request a finite base entourage and its monotone refinement ledger.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-observation row used to expose observable names before a completion-facing consumer reads the route.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular readback row and D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by Real-facing consumers.*
6. *W is a common-window row tying the Cauchy-filter read and the stream read to the same displayed entourage budget.*
7. *H records componentwise* hsame *transport for the uniformity, filter, entourage-base, stream, regularity, dyadic, window, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an entourage request through B, W, S, R, D and then toward the terminal* $\mathsf{Real}^{\uparrow}$ *seal.*
9. *P is the* Pkg *provenance over* $\mathsf{EntourageCompletion}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{EntourageCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. The carrier has no coordinate for quotient filters, host uniform spaces, selected limits, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8414.2 (Entourage completion NameCert obligations)**.** *The local* $\mathsf{NameCert}_{\mathsf{EntourageCompletion}^{\uparrow}}$ *surface for an accepted carrier* $E = (U, F, B, S, R, D, W, H, C, P, N)$ *consists exactly of carrier admission, entourage-base exposure, Cauchy-filter source exposure, finite StreamName observation, RegSeqRat readback, DyadicRatCore tolerance control, common-window routing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No NameCert clause is stored outside the displayed rows* $U, F, B, S, R, D, W, H, C, P, N$.

Proof. Project the carrier of Definition 8414.1. Its listed coordinates are the whole local packet, so carrier admission and local naming are read directly from the displayed tuple.

The entourage-base row B opens the uniform request before the filter source row F is consumed. The common-window row W then binds that filter read to the same finite stream, regularity, and dyadic tolerance route used by S, R, D.

The structural rows H, C, P, N preserve and name this route without adding a new object. Since quotient filters, selected limits, countable choice, host uniform equality, and ambient Real completeness are absent from the carrier, they cannot occur as local NameCert obligations. □

Theorem 8414.3 (Entourage completion Cauchy-filter handoff)**.** *Every* $\mathsf{CauchyFilter}^{\uparrow}$ *consumer of an accepted* $\mathsf{EntourageCompletion}^{\uparrow}$ *packet must first expose the displayed uniformity row, entourage-base row, common window, StreamName observations, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The handoff exports Cauchy-filter data only as the finite route*

$$U, F, B, W, S, R, D, H, C, P, N \longmapsto \mathsf{CauchyFilter}^{\uparrow}.$$

It exports no quotient filter, selected limit, cofinal-choice schedule, host uniform equality, or detached completion point.

Proof. Start from the source row F in the carrier. The filter is not inspected by an ambient limit operation; it is opened only after the uniformity row U and entourage-base row B have named the finite request.

Next bind the read to the common window. The row W routes the same request through the finite observation row S, the regular readback row R, and the dyadic tolerance ledger D before any completion-facing consumer can reuse the filter data.

Finally replay the route through H, C, P, N. These rows transport, continue, source, and name the displayed packet, and no excluded quotient, selected limit, choice schedule, host uniform equality, or detached completion point is available in the carrier. □

Theorem 8414.4 (Entourage completion Real-route nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{EntourageCompletion}^{\uparrow}$ *packet passes through the same displayed route*

$$\mathsf{CauchyFilter}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{BHist}, \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

The terminal Real seal is reached only after the entourage request, Cauchy filter source, finite stream window, regular readback, dyadic tolerance ledger, and common-window rows have been displayed. The read exports no quotient filters, selected limits, countable choice, host real equality, host uniform space equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the Cauchy-filter handoff of Definition 8414.3. It forces the entourage and Cauchy-filter source rows to remain visible before the completion-facing route is consumed.

Then read the L10 rows. StreamName observations, RegSeqRat regularity, and the DyadicRatCore tolerance ledger form the finite bridge from the displayed entourage request to the terminal Real seal.

The structural rows keep the bridge inside the packet. Componentwise hsame transport and displayed Cont replay preserve the same route, while Pkg and NameCert record its provenance and local name. Since the carrier contains none of the excluded host-level or choice-level data, the Real-facing read cannot escape the displayed route. □

Falsifiable prediction: Every accepted $\mathsf{EntourageCompletion}^{\uparrow}$ read factors through $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows before any completion-facing consumer can inspect a terminal seal.

Closure status for $\mathsf{NameCert}_{\mathsf{EntourageCompletion}^{\uparrow}}$.

Constructive story: An $\mathsf{EntourageCompletion}^{\uparrow}$ packet is generated from a displayed uniformity row, CauchyFilter source row, entourage-base row, StreamName finite observations, RegSeqRat readback, DyadicRatCore tolerance ledger, a common-window row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{EntourageCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8414.1, Definition 8414.2, Definition 8414.3, and Definition 8414.4 seed the constructive entourage-completion route over displayed CauchyFilterUp, StreamNameUp, RegSeqRatUp, DyadicRatCoreUp, RealUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{EntourageCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, quotient filters, selected limits, countable choice, host uniform-space equality, host real equality, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, entourage-base exposure, Cauchy-filter handoff, common-window stability, Real-route nonescape, and TasteGate field faithfulness for BEDC.Derived.EntourageCompletionUp.

Chapter 8415

A Concrete Naming Certificate for $\mathsf{BoundedRealInfimum}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BoundedRealInfimum}^{\uparrow}$ packet records the lower-cut side of a bounded real sequence as finite BEDC naming data. It sits beside the bounded sequence surface of chapter 1415, the bounded lower-cut observation discipline of chapter 1440, the dyadic rational ledger of chapter 291, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet gives L10 Real-and-Completion consumers a reusable lower-bound certificate without importing a host infimum, quotient stream equality, choice of subsequence, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8415.1 (Bounded real infimum carrier)**.** *A* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, L, D, Q, T, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{BoundedRealSequence}^{\uparrow}$ *source row whose finite windows, bound ledger, and displayed* $\mathsf{Real}^{\uparrow}$ *entries are inspected.*
2. *L is the* $\mathsf{BoundedRealLowerCut}^{\uparrow}$ *lower-cut schedule, recording finite lower observations for the bounded source.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare lower-cut observations with displayed rational budgets.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows consumed by the lower-cut route.*
5. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal naming the candidate lower-bound value only after S, L, D, Q have been replayed.*
6. *H records componentwise* hsame *transport for the bounded source, lower-cut schedule, dyadic ledger, rational readback, terminal seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *routes by which consumers replay the bounded sequence row, lower-cut schedule, dyadic ledger, regular readback, terminal real seal, transports, provenance, and local naming row.*
8. *P is the* Pkg *provenance over* $\mathsf{BoundedRealInfimum}^{\uparrow}$, $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRealInfimum}^{\uparrow}}$ *row.*
The carrier stores a finite lower-bound route for bounded real sequences. It has no coordinate for a host infimum, quotient equality of streams, a selected subsequence, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Definition 8415.2 (Bounded real infimum classifier)**.** *Two* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *carriers*

$$I = (S, L, D, Q, T, H, C, P, N) \qquad \text{and} \qquad I' = (S', L', D', Q', T', H', C', P', N')$$

are classified as the same displayed infimum packet exactly when the bounded sequence rows expose the same finite source windows, the lower-cut schedules expose the same accepted lower observations, the dyadic ledgers carry the same rational comparison budgets, the regular readback rows expose the same finite rational windows, the terminal $\mathsf{Real}^{\uparrow}$ *seals are transported by the displayed* hsame *data, the continuation routes replay the same lower-bound path, and the provenance and local NameCert rows name the same* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *surface. The classifier is rowwise over* $S, L, D, Q, T, H, C, P, N$ *and does not identify packets by host infima, quotient stream equality, selected subsequences, trichotomy, or Real completeness.*

Theorem 8415.3 (Bounded real infimum NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *carrier* $I = (S, L, D, Q, T, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRealInfimum}^{\uparrow}}$ *surface consists of carrier formation for the nine displayed rows, classifier stability for Definition 8415.2, lower-cut schedule exactness through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*, dyadic tolerance accounting through* $\mathsf{DyadicRatCore}^{\uparrow}$*, regular rational readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8415.1. Its rows are exactly the bounded source, lower-cut schedule, dyadic ledger, regular readback, terminal seal, transport, replay, provenance, and local naming data.

Use the classifier of Definition 8415.2. It compares accepted packets only by those displayed rows, so a consumer cannot replace the packet by a host-level infimum or by an equality of ambient streams.

The lower-cut, dyadic, regular-readback, and terminal-seal obligations are then row projections. The structural rows H, C, P, N preserve and name the same finite route, and no carrier coordinate contains subsequence choice, trichotomy, or ambient completeness. □

Theorem 8415.4 (Bounded real infimum lower-bound scope)**.** *Every consumer of an accepted* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *packet receives a lower-bound claim only after the bounded sequence row* S*, bounded lower-cut schedule* L*, dyadic tolerance ledger* D*, regular rational readback* Q*, and terminal* $\mathsf{Real}^{\uparrow}$ *seal* T *have been displayed. The lower-bound read is therefore the finite route*

$$S \longmapsto L \longmapsto D \longmapsto Q \longmapsto T \longmapsto H, C, P, N$$

rather than a host infimum, selected subsequence, quotient stream equality, trichotomy, or Real completeness principle.

Proof. Begin with S. The bounded source row supplies the only sequence-facing data available to the packet, and it is read through the bounded-sequence surface.

Next read L, D, Q. The lower-cut schedule exposes the accepted lower observations, the dyadic ledger records finite comparison budgets, and the regular readback row exposes the rational windows consumed by those budgets.

Only after those rows are visible can a consumer reach T. The structural rows transport, replay, source, and name the same displayed route, so the lower-bound claim cannot escape to any excluded host-level principle. □

Theorem 8415.5 (Bounded real infimum greatest lower-cut scope)**.** *The greatest-lower-cut information exported by an accepted* $\mathsf{BoundedRealInfimum}^{\uparrow}$ *carrier is scoped to the displayed lower-cut route* $S, L, D, Q, T, H, C, P, N$*. A consumer may compare lower observations through* $\mathsf{BoundedRealLowerCut}^{\uparrow}$*, spend dyadic budgets through* $\mathsf{DyadicRatCore}^{\uparrow}$*, read regular rational windows through* $\mathsf{RegSeqRat}^{\uparrow}$*, and reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal, but it may not replace that route by a completed host infimum or by a quotient-level stream argument.*

Proof. Apply the NameCert obligation surface of Definition 8415.3. It exposes the lower-cut schedule, dyadic ledger, regular readback row, and terminal seal as separate obligations of the accepted packet.

Use the lower-bound scope theorem, Definition 8415.4. It orders the consumer route from the bounded source through the lower-cut and rational rows before the terminal seal is available.

Finally inspect the carrier inventory. Since host infima, quotient stream equality, selected subsequences, trichotomy, and ambient $\mathsf{Real}^{\uparrow}$ completeness are absent from the packet, the exported greatest-lower-cut surface remains the finite displayed route. □

Falsifiable prediction: Every accepted $\mathsf{BoundedRealInfimum}^{\uparrow}$ lower-bound read factors through $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{BoundedRealLowerCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows before any consumer can inspect the candidate lower-bound seal.

Independence witness: boundedrealsequence, bounded-real-lower-cut, dyadicratcore, regseqrat, real: $\mathsf{BoundedRealInfimum}^{\uparrow}$ is not bijective to any listed sibling because it binds the bounded source, lower-cut schedule, dyadic budget, regular rational readback, terminal Real seal, transport, replay, provenance, and local NameCert rows into one lower-bound packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRealInfimum}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedRealInfimum}^{\uparrow}$ packet is generated from a bounded real sequence source, a bounded lower-cut schedule, a DyadicRatCore tolerance ledger, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transports, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedRealInfimum}^{\uparrow}}$, seed)

Scope closed: Definition 8415.1, Definition 8415.2, Definition 8415.3, Definition 8415.4, and Definition 8415.5 seed the finite lower-bound surface for bounded real sequences.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedRealInfimum}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim a host infimum, quotient stream equality, selected subsequences, trichotomy, Real completeness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, lower-cut schedule exactness, dyadic tolerance accounting, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.BoundedRealInfimumUp.

Chapter 8416

A Concrete Naming Certificate for $\mathsf{ConstantRankTheorem}^{\uparrow}$

Following Spivak and Lee on the constant rank theorem, the $\mathsf{ConstantRankTheorem}^{\uparrow}$ packet records the finite theorem-level route from a displayed smooth map, a stable rank window, and derivative-control data to a local normal-form read. It sits beside the derivative carrier of chapter 122, the inverse-function theorem route of chapter 6206, the implicit-function theorem route of chapter 6354, the finite observation surface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the BEDC certificate a differential-topology consumer inspects before using a local normal form; it does not import a host smooth-manifold primitive, quotient chart equality, ambient choice of coordinates, or bridge verification.

Definition 8416.1 (Constant rank theorem carrier)**.** *A* $\mathsf{ConstantRankTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (F, R, D, I, G, L, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the displayed map row, including source and target coordinate windows, base point, target value, and the finite classifier for the theorem read.*
2. *R is the rank-window row, recording the inspected minor, its nonvanishing witness, the neighbouring minor constraints, and the radius over which the rank is displayed as constant.*
3. *D is the* $\mathsf{Derivative}^{\uparrow}$ *control row for the displayed map on the same source and target windows.*
4. *I is the* $\mathsf{InverseFunctionTheorem}^{\uparrow}$ *handoff row used to isolate the invertible coordinate block supplied by R and D.*
5. *G is the* $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$ *handoff row used to solve the complementary coordinate equations inside the same local window.*
6. *L is the local normal-form row, recording the source chart, target chart, rank projection, zero complementary coordinates, and the route by which the normal-form read is obtained from F, R, D, I, G.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row for source coordinates, target coordinates, rank-window tests, and endpoint reads.*
8. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational approximation data exposed by S and used by the derivative and rank-window comparisons.*

9. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for every real-facing coordinate, derivative, rank, and normal-form read.*
10. *H records componentwise* hsame *transport for the map, rank-window, derivative, inverse-function, implicit-function, normal-form, observation, readback, seal, replay, provenance, and naming rows.*
11. *C records displayed* Cont *replay through*

$$F, R, D, I, G, L, S, Q, E \longmapsto \mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}.$$

12. *P is the* Pkg *provenance over* $\mathsf{ConstantRankTheorem}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{InverseFunctionTheorem}^{\uparrow}$, $\mathsf{ImplicitFunctionTheorem}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, R, D, I, G, L, S, Q, E, H, C, P, N$. The carrier has no coordinate for a host constant-rank theorem, an ambient smooth-manifold structure, selected chart germs, quotient equality of maps, unrecorded coordinate choices, global submersion or immersion theorems, Lean theorem checking, or bridge checking.

Theorem 8416.2 (Constant rank theorem NameCert obligations)**.** *For every accepted* $\mathsf{ConstantRankTheorem}^{\uparrow}$ *carrier*

$$T = (F, R, D, I, G, L, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed map row, rank-window exactness through R, derivative-control exposure through D, inverse-function handoff through I, implicit-function handoff through G, local normal-form exposure through L, finite StreamName observations through S, RegSeqRat readback through Q, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 8416.1. The rows F, R, D are the only source of the displayed map, constant-rank window, and derivative-control data.

The theorem handoffs are then forced. The row I exposes the inverse-function theorem route for the invertible block selected by the rank window, while G exposes the implicit-function theorem route for the complementary equations. The normal-form row L is downstream of those two handoffs and cannot be read before them.

The observation and completion rows come last. Stream observations S feed the regular rational readback Q, and E seals the Real-facing coordinate and derivative reads. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so no host constant-rank theorem, manifold primitive, selected chart germ, quotient equality, unrecorded coordinate choice, global submersion theorem, or bridge check is present. □

Theorem 8416.3 (Constant rank theorem local normal-form route)**.** *Every accepted* $\mathsf{ConstantRankTheorem}^{\uparrow}$ *local normal-form read factors through the finite route*

$$\mathsf{Derivative}^{\uparrow} \longmapsto \mathsf{InverseFunctionTheorem}^{\uparrow} \longmapsto \mathsf{ImplicitFunctionTheorem}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Rea}$$

as instantiated by D, I, G, S, Q, E together with the displayed map row F, rank-window row R, and local normal-form row L. A consumer may read local source and target chart data, the rank projection, zero complementary coordinates, finite observations, regular rational readback, terminal

Real sealing, componentwise transport, displayed replay, provenance, and local naming; it may not read a host smooth-manifold theorem, quotient chart equality, selected chart germ, untracked coordinate choice, global immersion or submersion theorem, or normalization oracle.

Proof. Start with the accepted carrier $T = (F, R, D, I, G, L, S, Q, E, H, C, P, N)$. The displayed map and rank-window rows fix the coordinate block and the local radius, while D supplies the derivative-control data in the same window.

The local theorem route first uses I to isolate the invertible block and then uses G to solve the complementary coordinate equations. The row L records the resulting source chart, target chart, rank projection, and zero complementary coordinates only after those handoffs are visible.

The finite observation route then reads source, target, rank, and endpoint data through S, rational comparisons through Q, and Real-facing coordinates through E. Transport, replay, provenance, and local naming preserve the same path through H, C, P, N. Since the carrier has no host theorem, manifold primitive, quotient chart equality, chart-germ selector, untracked coordinate choice, global theorem, or oracle coordinate, the normal-form read is exhausted by the displayed BEDC rows. □

Falsifiable prediction: Every accepted $\mathsf{ConstantRankTheorem}^{\uparrow}$ local normal-form read exposes one displayed map row, one rank-window row, one Derivative control row, one InverseFunctionTheorem handoff, one ImplicitFunctionTheorem handoff, one local normal-form row, StreamName observations, RegSeqRat readback, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: derivative, inverse-function-theorem, implicit-function-theorem, streamname, regseqrat, real: $\mathsf{ConstantRankTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries rank-window data, derivative control, inverse and implicit theorem handoffs, local normal-form data, finite observation, rational readback, terminal Real sealing, transport, replay, provenance, and local naming as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstantRankTheorem}^{\uparrow}$ packet is generated from a displayed map row, rank-window row, Derivative control row, InverseFunctionTheorem handoff, ImplicitFunctionTheorem handoff, local normal-form row, StreamName observations, RegSeqRat readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8416.1, Definition 8416.2, and Definition 8416.3 seed the finite theorem-level local normal-form route over rank-window, derivative, theorem-handoff, observation, regular rational, and Real completion rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstantRankTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host constant-rank theorems, ambient smooth-manifold primitives, selected chart germs, quotient chart equality, unrecorded coordinate choices, global immersion or submersion theorems, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rank-window exactness, derivative-control exposure, inverse-function handoff, implicit-function handoff, local normal-form exposure, Real completion routing, provenance exactness, and local naming for BEDC.Derived.ConstantRankTheoremUp.

Chapter 8417

A Concrete Naming Certificate for $\mathsf{SpeckerTheorem}^{\uparrow}$

Following Specker and the Bishop–Bridges treatment of constructive real analysis, the $\mathsf{SpeckerTheorem}^{\uparrow}$ packet records the finite NameCert boundary of the classical-looking assertion that a bounded monotone rational sequence need not provide a located supremum as constructive data. It sits after the $\mathsf{SpeckerSequence}^{\uparrow}$ carrier of chapter 1406, the Markov-sensitive refusal surface of chapter 1666, the terminal real-name seal of chapter 38, the regular rational route of chapter 301, and the dyadic tolerance ledger of chapter 291. The chapter records the theorem as a boundary object for Real and Completion consumers; it does not assert ambient $\mathsf{Real}^{\uparrow}$ completeness, real trichotomy, quotient stream equality, countable choice, or a selected completed real.

Definition 8417.1 (Specker theorem carrier)**.** *A* $\mathsf{SpeckerTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, M, R, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *S is the accepted* $\mathsf{SpeckerSequence}^{\uparrow}$ *source row carrying the monotone bounded rational stream.*
2. *M is the* $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$ *refusal row that keeps negative finite inspection from becoming a global principle.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the displayed rational windows of S.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the rational bounds and cut tests used in the theorem boundary.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal available only after S, R, D and the refusal row M have been displayed.*
6. *L is the located-supremum absence ledger, recording that no located comparison witness for the supremum is present in the packet.*
7. *H records componentwise* hsame *transport for the source, refusal, readback, dyadic, seal, absence, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the Specker source through regular readback, dyadic tolerance inspection, Markov-boundary refusal, and the terminal seal.*
9. *P is the* Pkg *provenance over* $\mathsf{SpeckerTheorem}^{\uparrow}$, $\mathsf{SpeckerSequence}^{\uparrow}$, $\mathsf{MarkovPrincipleBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{SpeckerTheorem}^\uparrow}$ *row.*
The classifier compares accepted packets only through $S, M, R, D, E, L, H, C, P, N$. It has no coordinate for an ambient completion theorem, real trichotomy, quotient equality of real names, countable choice, Markov's principle as a rule, or a selected supremum.

Theorem 8417.2 (Specker theorem NameCert obligations)**.** *For every accepted* $\mathsf{SpeckerTheorem}^\uparrow$ *carrier $T = (S, M, R, D, E, L, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{SpeckerTheorem}^\uparrow}$ *surface consists exactly of Specker-source admission through S, Markov-boundary refusal through M, regular rational readback through R, dyadic tolerance accounting through D, terminal Real sealing through E, located-supremum absence through L, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8417.1. Its analytic rows are precisely the Specker source, the Markov-boundary refusal, the regular readback, the dyadic tolerance ledger, the Real seal, and the located-supremum absence ledger.

The Specker source row is read through the existing boundary of Definition 1406.2 and Definition 1406.7. The Markov row is read through Definition 1666.2 and Definition 1666.3, so negative inspection remains named data rather than an imported rule.

The remaining rows are structural. Componentwise transport, continuation replay, provenance, and local naming preserve the displayed route and do not add a located supremum, quotient equality, countable-choice selector, trichotomy branch, or ambient completion coordinate. Thus the listed rows exhaust the NameCert obligations. □

Theorem 8417.3 (Specker theorem Real-completion boundary)**.** *Every Real or Completion consumer of an accepted* $\mathsf{SpeckerTheorem}^\uparrow$ *carrier must read the route*

$$\mathsf{SpeckerSequence}^\uparrow \longmapsto \mathsf{RegSeqRat}^\uparrow \longmapsto \mathsf{DyadicRatCore}^\uparrow \longmapsto \mathsf{MarkovPrincipleBoundary}^\uparrow \longmapsto \mathsf{Real}^\uparrow$$

together with the located-supremum absence row L and the structural rows H, C, P, N. The packet may be cited as the Specker theorem boundary, but it cannot be consumed as completeness of $\mathsf{Real}^\uparrow$*, real trichotomy, quotient stream equality, countable choice, Markov's principle as a rule, or a selected completed supremum.*

Proof. Start with the $\mathsf{SpeckerSequence}^\uparrow$ source row. By the SpeckerSequence exposure and non-located supremum boundary, S supplies finite monotone bounded rational windows and no located-supremum witness.

Next read the regular and dyadic rows. The rows R and D expose the regular rational readback and the tolerance ledger used by a completion-facing consumer, but they remain finite displayed rows rather than a host completion operator.

Now read the Markov-boundary row M and the absence ledger L. The Markov boundary keeps finite negative inspection from becoming a global rule, while L records the missing located comparison witness for the supremum. The terminal seal E is therefore only a boundary seal for this displayed route.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since no coordinate contains ambient completeness of $\mathsf{Real}^\uparrow$, trichotomy, quotient equality, countable choice, Markov's principle as a rule, or a selected completed supremum, no Real or Completion consumer can read such data from the carrier. □

Falsifiable prediction: Every $\mathsf{SpeckerTheorem}^\uparrow$ Real or Completion read factors through a SpeckerSequence source row, a RegSeqRat readback row, a DyadicRatCore tolerance ledger, a

MarkovPrincipleBoundary refusal row, a terminal RealUp seal, a located-supremum absence row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: speckersequence, markov-principle-boundary, regseqrat, dyadicratcore, real: $\mathsf{SpeckerTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly stores the theorem-level boundary tying a Specker source, regular and dyadic readback, Markov-sensitive refusal, a Real seal, and a located-supremum absence ledger into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SpeckerTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{SpeckerTheorem}^{\uparrow}$ packet is generated from a SpeckerSequence source row, MarkovPrinciple-Boundary refusal row, RegSeqRat readback, DyadicRatCore tolerance ledger, a terminal RealUp seal, a located-supremum absence ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SpeckerTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8417.1, Definition 8417.2, and Definition 8417.3 seed the finite theorem boundary separating Specker-source data from ambient Real completeness or trichotomy claims.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SpeckerTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, real trichotomy, quotient stream equality, countable choice, Markov's principle as a rule, selected completed suprema, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligations, Real-completion boundary nonescape, transport and replay stability, provenance, and local naming for BEDC.Derived.SpeckerTheoremUp.

Chapter 8418

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealSegment}^{\uparrow}$

Following Bishop–Bridges constructive analysis, $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ names the finite certificate surface for a located real interval whose endpoints are presented by regular rational data and whose order evidence is explicitly displayed. The packet sits over the $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, and $\mathsf{LocatedRealOrder}^{\uparrow}$ siblings of chapter 291, chapter 126, chapter 301, chapter 38, **??**, and chapter 8337. It gives later located-interval and completion arguments a routed endpoint packet, not a classical interval object.

Definition 8418.1 (Bishop located real segment carrier)**.** *A* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, R, O, S, Q, D, E, H, C, P, N)$$

with the following displayed rows:

1. *L and R are endpoint rows, each naming a left or right* $\mathsf{Real}^{\uparrow}$ *endpoint through the same finite packet rather than through host real equality.*
2. *O is the located-order evidence row, read through* $\mathsf{LocatedReal}^{\uparrow}$ *and* $\mathsf{LocatedRealOrder}^{\uparrow}$*, stating that the displayed left endpoint is below the displayed right endpoint at the requested finite tolerances.*
3. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row used to inspect endpoint names.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to those windows.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording endpoint radii, comparison budgets, and dyadic inclusion tests.*
6. *E is the pair of terminal* $\mathsf{Real}^{\uparrow}$ *seals reached after S, Q, D, O have been replayed.*
7. *H records componentwise* hsame *transport for endpoint rows, located-order evidence, stream windows, regular readbacks, dyadic tolerances, terminal seals, and structural rows.*
8. *C records the displayed* Cont *routes by which consumers replay the endpoint, order, window, readback, tolerance, seal, transport, provenance, and local naming rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{LocatedRealOrder}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealSegment}^{\uparrow}}$ *row.*

The carrier stores a located segment boundary as finite endpoint and order data. It has no coordinate for Real completeness, trichotomy, quotient real equality, selected representatives, or open-cover compactness.

Definition 8418.2 (Bishop located real segment classifier)**.** *Two* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ *carriers*

$$I = (L, R, O, S, Q, D, E, H, C, P, N) \qquad \textit{and} \qquad I' = (L', R', O', S', Q', D', E', H', C', P', N')$$

are classified as the same displayed located segment exactly when the left and right endpoint rows match componentwise, the located-order rows expose the same endpoint order boundary, the stream windows inspect the same finite endpoint prefixes, the regular rational readbacks and dyadic tolerance ledgers carry the same comparison budgets, the terminal $\mathsf{Real}^{\uparrow}$ *seals are transported by the displayed* hsame *data, and the continuation, provenance, and local NameCert rows name the same* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ *packet. The classifier is rowwise over* $L, R, O, S, Q, D, E, H, C, P, N$ *and does not identify intervals by quotient real equality, selected representatives, trichotomy, or a host subset of the real line.*

Theorem 8418.3 (Bishop located real segment NameCert obligations)**.** *For an accepted* $\mathsf{BishopLocatedRealSegmen}$ *carrier* $I = (L, R, O, S, Q, D, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealSegment}^{\uparrow}}$ *surface consists of seven finite obligation rows:*

1. *carrier formation for the two endpoint rows, located-order evidence, finite stream windows, regular rational readbacks, dyadic tolerance ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seals, transports, continuations, provenance, and local naming data;*
2. *classifier stability for the componentwise comparison of Definition 8418.2;*
3. *endpoint order stability, stating that the displayed located-order row is transported together with the endpoint rows and dyadic comparison budgets;*
4. *stream-window readback, stating that endpoint prefixes are inspected only through the* $\mathsf{StreamName}^{\uparrow}$ *and* $\mathsf{RegSeqRat}^{\uparrow}$ *rows;*
5. *dyadic tolerance exactness, stating that interval inclusion and endpoint comparison checks use only the displayed* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger;*
6. *terminal seal routing, stating that endpoint consumers reach the two* $\mathsf{Real}^{\uparrow}$ *seals only after the window, readback, tolerance, and located-order rows have been replayed;*
7. *ledger non-escape, excluding Real completeness, trichotomy, quotient real equality, selected representatives, and open-cover compactness.*

Proof. Carrier formation is projection from Definition 8418.1. The packet displays exactly the endpoint rows, located-order evidence, finite stream windows, regular readbacks, dyadic tolerance ledger, terminal seals, transport rows, continuation routes, provenance, and local name.

Classifier stability follows from Definition 8418.2. Transport along H may replace visible rows only by rows with the same endpoint order boundary, the same stream windows, and the same dyadic comparison budgets, while C preserves the replay order.

The readback and exactness rows are the displayed roles of S, Q, D, O. The stream row exposes endpoint prefixes, the regular row reads them as rational approximants, the dyadic ledger records the finite tolerances, and the located-order row binds those comparisons to the endpoint boundary.

Terminal seal routing is the role of E. A consumer may read the left or right real endpoint only after the stream, regular, dyadic, and located-order rows have been replayed.

The non-escape row follows from the carrier inventory. No displayed field carries Real completeness, trichotomy, quotient real equality, selected representatives, or open-cover compactness. □

Theorem 8418.4 (Bishop located real segment endpoint order stability)**.** *Let $I = (L, R, O, S, Q, D, E, H, C, P, N)$ be an accepted* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ *carrier. Every endpoint-facing transport of I preserves the located order row O together with the endpoint rows L, R and dyadic tolerance ledger D. Hence the transported packet remains a located segment certificate and cannot turn into an unordered pair of real names, a trichotomy witness, or a quotient interval.*

Proof. Project L, R, O, D, H from the carrier of Definition 8418.1. The endpoint rows and located-order row are displayed in the same packet, and the dyadic tolerance ledger records the finite comparison budgets attached to them.

Use the classifier of Definition 8418.2. It compares accepted packets by the componentwise endpoint, order, stream, readback, tolerance, seal, transport, replay, provenance, and naming rows, not by a host subset or quotient equality of real names.

The transport row H therefore preserves the order boundary whenever it transports the endpoints. Since C, P, N replay and source the same finite packet, no consumer obtains an unordered pair, a trichotomy decision, or a quotient interval from the transported carrier. □

Theorem 8418.5 (Bishop located real segment Real seal non-escape)**.** *An accepted* $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ *packet exposes its endpoints only as the terminal* $\mathsf{Real}^{\uparrow}$ *seals E reached through the displayed route*

$$S \longmapsto Q \longmapsto D \longmapsto O \longmapsto E \longmapsto H \longmapsto C \longmapsto P \longmapsto N.$$

In particular, it does not export Real completeness, trichotomy, quotient real equality, selected representatives, or open-cover compactness.

Proof. The only endpoint-facing value coordinate in the carrier is E. The rows S, Q, D, O supply the stream windows, regular rational readbacks, dyadic tolerances, and located-order evidence that must be replayed before E is consumed.

Continuation replay through C follows the displayed route, and componentwise transport through H preserves the same endpoint and order rows. Provenance through P and local naming through N record the packet as a $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ certificate.

Since no carrier field stores the excluded principles, the terminal seals cannot be read as a completeness theorem, trichotomy decision, quotient real equality, selected representative, or open-cover compactness principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealSegment}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealSegment}^{\uparrow}$ packet is generated from two RealUp endpoint rows, located-order evidence, finite StreamName windows, RegSeqRat readbacks, a DyadicRatCore tolerance ledger, terminal RealUp seals, componentwise hsame transports, Cont replay routes, package provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopLocatedRealSegment}^{\uparrow}}$, seed)

Scope closed: Definition 8418.1, Definition 8418.2, Definition 8418.3, Definition 8418.4, and Definition 8418.5 seed the finite located real segment surface over displayed endpoint, order, stream, regular rational, dyadic, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopLocatedRealSegment}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Real completeness, trichotomy, quotient real equality, selected representatives, open-cover compactness, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier formation, classifier stability, endpoint order stability, stream-window readback, dyadic tolerance exactness, terminal seal routing, and Real seal non-escape for the displayed packet.

Chapter 8419

A Concrete Naming Certificate for $\mathsf{VanKampen}^{\uparrow}$

Following Seifert and van Kampen, the $\mathsf{VanKampen}^{\uparrow}$ packet records the finite cover-generator route by which local loop data over a path-connected open cover is handed to a fundamental-group presentation consumer. It sits beside the homotopy surface of chapter 156, the finite based-loop algebra of chapter 3368, the open-cover carrier of chapter 6731, the path-connected source of chapter 6885, and the group operation surface of chapter 41. The certificate names cover rows, overlap rows, local path-loop rows, generator rows, relation rows, and a downstream $\mathsf{FundamentalGroup}^{\uparrow}$ consumer route; it does not import a quotient group, a host group presentation theorem, selected representatives of homotopy classes, or ambient path-space equality.

Definition 8419.1 ($\mathsf{VanKampen}^{\uparrow}$ finite cover-generator carrier)**.** *A* $\mathsf{VanKampen}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Pi = (X, x_0, U, O, A, L, G, R, F, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient topological source row and x_0 is the displayed basepoint row. The source must expose the* $\mathsf{PathConnectedSpace}^{\uparrow}$ *route that makes every inspected open row reachable from x_0 by finite path data.*
2. *U is the finite open-cover row family, read through the open-cover surface of chapter 6731. Each member row records its open test, basepoint-reachability witness, and finite cover index.*
3. *O is the overlap row family. It lists the nonempty pairwise and finite multi-overlap windows whose path components are inspected before a relation row is accepted.*
4. *A is the local path-loop row family. Its entries are based paths, transported basepoints, and local loop rows read through the deformation classifier of chapter 156.*
5. *L is the local fundamental-group row family. Each entry records the* $\mathsf{FundamentalGroup}^{\uparrow}$ *packet carried by one cover member or overlap component, together with the inclusion route back to X.*
6. *G is the generator ledger. It records one finite generator row for each admitted local loop or overlap transfer whose image is exported to the global consumer.*
7. *R is the relation ledger. It records the finite overlap identifications, conjugation-by-path adjustments, and null-loop seals that the global consumer must read before classifying the generated group row.*

8. *F is the* $\mathsf{FundamentalGroup}^{\uparrow}$ *consumer row. It receives only the displayed generator and relation rows G, R together with their source paths and homotopy comparisons, not a host quotient group.*
9. *H records componentwise* hsame *transport for $X, x_0, U, O, A, L, G, R, F, C, P, N$.*
10. *C records displayed* Cont *replay for open-cover admission, overlap admission, path-loop readback, local fundamental-group readback, generator export, relation export, and the global consumer handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{VanKampen}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{OpenCover}^{\uparrow}$, $\mathsf{PathConnectedSpace}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{FundamentalGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{VanKampen}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through the displayed cover, overlap, path-loop, generator, relation, consumer, transport, replay, provenance, and naming rows. Thus the packet is a finite cover-generator certificate, not a completed quotient presentation of $\pi_1(X, x_0)$.

Theorem 8419.2 ($\mathsf{VanKampen}^{\uparrow}$ NameCert obligations)**.** *For every accepted* $\mathsf{VanKampen}^{\uparrow}$ *carrier*

$$\Pi = (X, x_0, U, O, A, L, G, R, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{VanKampen}^{\uparrow}}$ *surface consists exactly of source admission for X, x_0 through* $\mathsf{PathConnectedSpace}^{\uparrow}$, *finite open-cover admission through U, overlap-window admission through O, local path-loop admission through A, local* $\mathsf{FundamentalGroup}^{\uparrow}$ *admission through L, generator export through G, relation export through R, target handoff through F, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every* $\mathsf{Group}^{\uparrow}$ *or* $\mathsf{FundamentalGroup}^{\uparrow}$ *consumer of the packet must inspect those rows before it may read the generated global algebraic surface.*

Proof. Carrier admission is projection from Definition 8419.1. The rows $X, x_0, U, O, A, L, G, R, F, H, C, P, N$ expose the topological source, basepoint, cover windows, overlap windows, local path-loop data, local fundamental-group data, generator and relation ledgers, consumer handoff, transport, replay, provenance, and local name.

The source side is forced before any algebraic read. The $\mathsf{PathConnectedSpace}^{\uparrow}$ row supplies the displayed route from x_0 to each inspected cover member, while U and O supply the finite open-cover and overlap windows. The local loop rows in A are then read through $\mathsf{Homotopy}^{\uparrow}$, so every generator has a visible path and deformation provenance.

The algebraic side is only a consumer surface. The local $\mathsf{FundamentalGroup}^{\uparrow}$ rows in L produce finite loop-composition data, and G, R export exactly the generator and relation endpoints the global consumer may inspect. Since F receives these rows through H, C, P, N, no step introduces a host quotient group, an uncarried presentation, or a selected homotopy-class representative. □

Theorem 8419.3 ($\mathsf{VanKampen}^{\uparrow}$ cover-generator handoff)**.** *Let $\Pi = (X, x_0, U, O, A, L, G, R, F, H, C, P, N)$ be an accepted* $\mathsf{VanKampen}^{\uparrow}$ *carrier. Any downstream* $\mathsf{FundamentalGroup}^{\uparrow}$ *consumer of the global cover-generated surface factors through the finite route*

$$X, x_0, U, O, A, L, G, R, H, C, P, N \longmapsto F.$$

The consumer may read the displayed generators, overlap relations, conjugating path rows, and null-loop seals, but it cannot replace them by a host Seifert–van Kampen theorem, a quotient group presentation outside BHist, *or an ambient path-component equality.*

Proof. Begin with the cover and overlap rows. The open-cover ledger U and overlap ledger O determine which local path-loop rows in A are eligible for export, and the path-connected source row keeps the transport from x_0 visible.

Read the local algebraic rows next. Each local row in L is already a $\mathsf{FundamentalGroup}^{\uparrow}$ packet, so its loop composition, inverse, identity, and homotopy comparison data are finite NameCert rows. The generator ledger G selects only endpoints carried by those local rows.

Finally consume the relation ledger R through F. The relation rows list the overlap identifications and conjugating paths that the global consumer is allowed to use. Componentwise transport H, displayed replay C, provenance P, and the local name N keep this route inside the same finite packet, so the handoff supplies a cover-generated boundary without importing the ambient quotient theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{VanKampen}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{VanKampen}^{\uparrow}}$, seed)

Scope closed: Definition 8419.1, Definition 8419.2, and Definition 8419.3 seed the finite cover, overlap, path-loop, local fundamental-group, generator, relation, consumer, transport, replay, provenance, and local naming surface for the Seifert–van Kampen cover-generator packet.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{VanKampen}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host Seifert–van Kampen theorem, quotient group presentations, selected loop-class representatives, universal covers, monodromy actions, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite open-cover admission, overlap-window admission, path-loop admission, local fundamental-group admission, generator export, relation export, target handoff, transport, replay, provenance, and local naming for BEDC.Derived.VanKampenUp.

Constructive story: A $\mathsf{VanKampen}^{\uparrow}$ packet is generated from a displayed topological source and basepoint, finite open-cover rows, overlap rows, path-loop rows, local FundamentalGroupUp rows, generator rows, relation rows, a FundamentalGroupUp consumer row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8420

A Concrete Naming Certificate for $\mathsf{HarmonicFunction}^{\uparrow}$

Following Weyl and Bishop–Bridges, the $\mathsf{HarmonicFunction}^{\uparrow}$ packet records the finite NameCert surface of a harmonic-function read over a compact metric chart. It sits over the terminal real-name rows of chapter 38, the metric carrier of chapter 57, the compact finite-net surface of chapter 129, the graph and modulus rows of chapter 130, and the local differential-equation vocabulary of $\mathsf{Pde}^{\uparrow}$. The packet names a constructive finite-means harmonicity certificate only; it does not assert global Dirichlet solvability, classical smoothness, distributional equality, unique continuation, maximum principle completeness, quotient equality of functions, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8420.1 (Harmonic-function carrier)**.** *A* $\mathsf{HarmonicFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (R, M, K, F, L, A, V, E, T, C, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{Real}^{\uparrow}$ *value row, exposing the real-name windows consumed by the function values.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *chart row, recording the source distance comparisons used by ball and boundary reads.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-window row for the compact chart windows on which the certificate is inspected.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *graph row, recording the pointwise function reads and their local continuity witnesses.*
5. *L is the* $\mathsf{Pde}^{\uparrow}$ *Laplace row, naming the displayed local equation $\Delta F = 0$ only through finite stencil, ball, or chart data.*
6. *A is the averaging row. It records the finite boundary samples, weights, tolerances, and mean-value readback requested around each inspected ball.*
7. *V is the verification row requiring the displayed Laplace row and averaging row to agree on every accepted inspection window.*
8. *E records componentwise* hsame *transport for real values, metric balls, compact windows, continuous graph reads, Laplace rows, averaging rows, verification rows, replay, provenance, and local naming.*

9. *T records displayed* Cont *replay for the route*

$$R, M, K, F, L, A \longmapsto V \longmapsto E, C, P, N.$$

10. *C is the consumer handoff row for local Dirichlet, mean-value, and PDE-facing requests that accept only the displayed finite route.*

11. *P is the* Pkg *provenance over* $\mathsf{HarmonicFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HarmonicFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these twelve rows. It has no coordinate for a host smooth function, selected Poisson kernel, global boundary-value solution, distributional equality, quotient map equality, excluded-middle regularity argument, or ambient completeness principle.

Theorem 8420.2 (Harmonic-function NameCert obligations)**.** *For every accepted* $\mathsf{HarmonicFunction}^{\uparrow}$ *carrier*

$$H = (R, M, K, F, L, A, V, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HarmonicFunction}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for* $\mathsf{Real}^{\uparrow}$ *values,* $\mathsf{Met}^{\uparrow}$ *chart distances,* $\mathsf{CompactMetric}^{\uparrow}$ *finite windows,* $\mathsf{ContinuousMap}^{\uparrow}$ *graph reads,* $\mathsf{Pde}^{\uparrow}$ *Laplace rows, averaging rows, verification rows, transport, replay, consumer handoff, provenance, and local naming;*

2. *metric-ball exactness, requiring every averaging window and Laplace stencil to be attached to the same displayed chart row M and compact window row K;*

3. *continuity compatibility, requiring every value consumed by L or A to be exposed first through F and read through R;*

4. *Laplace–mean agreement, requiring V to compare the displayed* $\mathsf{Pde}^{\uparrow}$ *Laplace row with the finite averaging row before any harmonic read is exported;*

5. *non-escape of host smoothness, global Dirichlet solvability, selected Poisson kernels, distributional equality, quotient equality of functions, choice principles, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier of Definition 8420.1. The analytic rows are precisely R, M, K, F, L, A, V, and the structural rows E, T, C, P, N preserve, replay, hand off, source, and name the same finite route.

Metric-ball exactness is local. The row M supplies the distance comparisons for balls and boundaries, while K supplies the compact finite windows on which those comparisons are inspected. Thus neither L nor A can choose a detached chart.

Continuity compatibility then forces every value read through the graph row F and the real row R before a Laplace or averaging check may consume it. The verification row V is the only row that compares the displayed $\mathsf{Pde}^{\uparrow}$ equation with the finite mean-value data.

Finally, E, T, C, P, N add only transport, replay, consumer routing, provenance, and local naming. Since the carrier has no row for a host smooth function, global boundary-value solution, selected kernel, quotient equality, choice principle, or ambient completeness theorem, those claims cannot be exported by the NameCert surface. □

Theorem 8420.3 (Harmonic-function mean-value route)**.** *Every accepted* $\mathsf{HarmonicFunction}^{\uparrow}$ *mean-value or local Dirichlet read factors through*

$$\mathsf{Real}^{\uparrow},\ \mathsf{Met}^{\uparrow},\ \mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{Pde}^{\uparrow}$$

before it reaches the consumer handoff row. In particular, the exported harmonicity read is the displayed agreement between a finite Laplace row and a finite averaging row inside the same compact metric chart, not a host-theoretic solution operator.

Proof. Apply Definition 8420.2. Carrier admission lists the real, metric, compact, continuous-map, PDE, averaging, and verification rows as the entire analytic surface.

The metric-ball exactness and continuity compatibility clauses bind those rows to the same chart and graph reads. Hence a mean-value read cannot bypass R, M, K, F before inspecting L and A.

The verification row V then compares the Laplace and averaging displays, and the handoff row C exports only the route replayed by E, T and sourced by P, N. Therefore a local Dirichlet or harmonicity consumer receives finite NameCert data rather than a global solution operator, selected kernel, quotient function, or ambient completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{HarmonicFunction}^{\uparrow}$ packet exposes RealUp value rows, MetricSpaceUp chart rows, CompactMetricUp finite windows, ContinuousMapUp graph rows, PdeUp Laplace rows, finite averaging rows, verification rows, transport, replay, consumer handoff, provenance, and local naming.

Independence witness: real, metricspace, compactmetric, continuousmap, pde: $\mathsf{HarmonicFunction}^{\uparrow}$ is not identical to any listed sibling because it binds finite mean-value rows and local Laplace rows into one compact metric chart certificate before exporting harmonic-function reads.

Closure status for $\mathsf{NameCert}_{\mathsf{HarmonicFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HarmonicFunction}^{\uparrow}$ packet is generated from RealUp value rows, MetricSpaceUp chart distance rows, CompactMetricUp finite windows, ContinuousMapUp graph rows, PdeUp Laplace rows, finite averaging rows, a Laplace–mean verification row, componentwise hsame transport, displayed Cont replay, a consumer handoff row, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HarmonicFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8420.1, Definition 8420.2, and Definition 8420.3 seed the compact metric finite-means packet for local harmonic-function reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HarmonicFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global Dirichlet solvability, classical smoothness, distributional equality, unique continuation, maximum principle completeness, selected Poisson kernels, quotient equality of maps, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-ball exactness, continuity compatibility, Laplace–mean agreement, consumer handoff, provenance, and local naming for BEDC.Derived.HarmonicFunctionUp.

Chapter 8421

A Concrete Naming Certificate for $\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}$

The $\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}$ packet realizes the local stop-face classifier route of subsection 9462.28.17 as finite BEDC NameCert data. It consumes the six-coordinate source atlas of chapter 2234, the stop-face suffix surface of chapter 1374, the codon-window spectral inverse sibling of chapter 2161, and the deterministic transition-matrix rows of chapter 2245. The packet records the $\mathrm{U}+\mathrm{RR}$ face, the local suffix classifier $00, 01, 10, 11$, the exclusion of UGG as the 11 corner, and the surviving stop rows UAA, UAG, and UGA; it is not a global no-11 predicate, a full genetic-code table, an amino-acid classifier, a stochastic readthrough model, or a quotient codon semantics.

Definition 8421.1 (Codon-window stop-face classifier carrier)**.** *A* $\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (W, A, U, S, X, D, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{CodonSixBitWindow}^{\uparrow}$ *source-window row exposing the six-bit codon coordinates and Flat6 readback.*
2. *A is the two-axis atlas row naming the* $\mathrm{U}, \mathrm{C}, \mathrm{A}, \mathrm{G}$ *base reads used by the codon-window bridge.*
3. *U is the face-selection row. It selects the local* $\mathrm{U}+\mathrm{RR}$ *square before any stop decision is inspected.*
4. *S is the suffix-coordinate row. It displays the four local family suffixes* $00, 01, 10, 11$ *inside the selected face.*
5. *X is the* $\mathsf{StopCodonZeckendorfSuffix}^{\uparrow}$ *legality row, retaining exactly the* $X_2 = \{00, 01, 10\}$ *suffixes.*
6. *D is the stop-decision row. It maps* $00, 01, 10$ *to the stop rows* $\mathrm{UAA}, \mathrm{UAG}, \mathrm{UGA}$ *and maps* 11 *to the excluded* UGG *corner.*
7. *E records componentwise* hsame *transport for source windows, atlas rows, face rows, suffix rows, legality rows, decision rows, replay, provenance, and local naming.*
8. *H records displayed* Cont *replay for the route*

$$W, A, U, S \longmapsto X, D \longmapsto E, C, P, N.$$

9. *C is the classifier handoff row used by local stop-face consumers that accept only the displayed finite route.*

10. *P is the* Pkg *provenance over* $\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}$, $\mathsf{CodonSixBitWindow}^{\uparrow}$, $\mathsf{StopCodonZeckendorfSuffi}$ $\mathsf{CodonWindowSpectralInverse}^{\uparrow}$, $\mathsf{CodonTransitionMatrix}^{\uparrow}$, *the codon-window-six bridge,* BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}}$ *row.*

*The classifier compares accepted packets only through these eleven rows. It has no coordinate for a global flattened no-*11 *predicate, a full translation table, amino-acid class identity, stochastic readthrough, quotient codon equality, selected biological code tables, or global biological universality.*

Theorem 8421.2 (Codon-window stop-face classifier NameCert obligations)**.** *For every accepted* $\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}$ *carrier*

$$F = (W, A, U, S, X, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CodonWindowStopFaceClassifier}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for six-bit source windows, two-axis atlas rows, local face selection, suffix-coordinate rows, suffix-legality rows, stop-decision rows, transport, replay, classifier handoff, provenance, and local naming;*

2. *source-atlas exactness, requiring every local stop-face read to pass through W and A before a suffix is classified;*

3. *face locality, requiring the decision row to be attached to the selected* $\mathrm{U} + \mathrm{RR}$ *square U rather than to the whole flattened six-bit window;*

4. *suffix exactness, requiring S and X to retain* $00, 01, 10$ *and exclude only* 11 *inside that face;*

5. *stop-decision determinacy, requiring D to export exactly* UAA, UAG, *and* UGA *as stop rows while keeping* UGG *outside the stop class;*

6. *non-escape of global no-*11 *classification, full genetic-code tables, amino-acid classifiers, stochastic readthrough, quotient codon equality, selected biological code tables, and biological universality claims.*

Proof. Project the accepted carrier of Definition 8421.1. The visible analytic rows are W, A, U, S, X, D, and the structural rows E, H, C, P, N preserve, replay, hand off, source, and locally name the same finite route.

Source-atlas exactness comes first. The six-bit source row W and atlas row A expose the codon window before any face or suffix classifier can be read.

Face locality is then enforced by U. The suffix rows S and X are attached only to the selected $\mathrm{U} + \mathrm{RR}$ square, so the classifier cannot become a global no-11 predicate on the flattened six-bit string.

The decision row D is deterministic over the displayed suffixes: it exports $00, 01, 10$ as UAA, UAG, and UGA stop rows and keeps 11 as the excluded UGG corner. Since the refused biological objects have no carrier coordinate and no replay edge, the listed rows exhaust the local NameCert surface. □

Theorem 8421.3 (Codon-window stop-face exclusion route)**.** *Every accepted* CodonWindowStopFaceClassifier$^{\uparrow}$ *read factors through*

CodonSixBitWindow$^{\uparrow}$, StopCodonZeckendorfSuffix$^{\uparrow}$, CodonWindowSpectralInverse$^{\uparrow}$, CodonTransitionMatrix$^{\uparrow}$

as sibling evidence before it may export a local stop decision. The exported decision is the finite U + RR *face classifier that excludes* UGG *and retains* UAA*,* UAG*, and* UGA*, not the global no-adjacent predicate of Definition 9462.1090.*

Proof. Apply Definition 8421.2. Carrier admission forces the read through W, A, U, S, X, D before any handoff row can be consumed.

The sibling route is finite. The source row W is the six-coordinate atlas packet, the legality row X is the stop-suffix packet, and the provenance row P names the spectral-inverse and transition-matrix consumers that inspect the same stop face.

By suffix exactness and stop-decision determinacy, only $00, 01, 10$ are exported as stop rows. The 11 suffix is the UGG corner and remains outside the stop class.

Thus the classifier is local to the selected face. It records the cannot-claim boundary of Definition 9462.1090 as concrete NameCert data, rather than importing a global flattened predicate or a full biological translation table. □

Falsifiable prediction: Every accepted CodonWindowStopFaceClassifier$^{\uparrow}$ packet exposes CodonSixBitWindowUp source rows, two-axis atlas rows, U+RR face selection, suffix coordinates, StopCodonZeckendorfSuffixUp legality, stop-decision rows, transport, replay, classifier handoff, provenance, and local naming. A packet that classifies stop codons by global no-adjacent-11 on the flattened six-bit window fails the face-locality row.

Independence witness: codon-six-bit-window, stopcodonzeckendorfsuffix, codon-window-spectral-inverse, codon-transition-matrix: CodonWindowStopFaceClassifier$^{\uparrow}$ is not identical to any listed sibling because it binds source atlas, local face selection, suffix legality, and deterministic UGG exclusion into one local stop-face classifier packet.

Closure status for NameCert$_{\text{CodonWindowStopFaceClassifier}^{\uparrow}}$**.**

Constructive story: A CodonWindowStopFaceClassifier$^{\uparrow}$ packet is generated from CodonSixBitWindowUp source rows, two-axis atlas rows, a U+RR face-selection row, suffix-coordinate rows, StopCodonZeckendorfSuffixUp legality rows, a deterministic stop-decision row, componentwise hsame transport, displayed Cont replay, a classifier handoff row, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CodonWindowStopFaceClassifier}^{\uparrow}}$, seed)

Scope closed: Definition 8421.1, Definition 8421.2, and Definition 8421.3 seed the local U+RR stop-face classifier and its UGG exclusion route.

Formal verification: FormalStatus(NameCert$_{\text{CodonWindowStopFaceClassifier}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close global flattened no-adjacent classification, full genetic-code table identity, amino-acid classifiers, stochastic readthrough, quotient codon equality, selected biological code tables, biological universality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-atlas exactness, face locality, suffix exactness, stop-decision determinacy, transport, replay, provenance, and local naming for BEDC.Derived.CodonWindowStopFaceClassifierUp.

Chapter 8422

A Concrete Naming Certificate for $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$

Following Riemann, Darboux, and Bishop–Bridges constructive analysis, the $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ packet records the finite uniform-partition route by which a displayed real-valued integrand is admitted to a Riemann-integrability criterion. It sits after the real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the criterion surface of chapter 8064, and the compact-continuity route of chapter 7133. The packet names a finite equal-mesh integrability surface; it does not import host-level limits of partitions, quotient equality of functions, countable choice, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8422.1 (Riemann integrability uniform-partition carrier)**.** *A* $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (I, F, M, E, S, Q, R, D, T, H, C, P, N)$$

with the following displayed rows:

1. *I is the* $\mathsf{Real}^{\uparrow}$ *closed-interval source row, exposing the two endpoint seals and the admitted interval direction.*
2. *F is the integrand readback row, storing only displayed evaluation windows on the interval source.*
3. *M is the uniform mesh row, recording a positive dyadic mesh-width and a finite cell count.*
4. *E is the equal-cell ledger, listing the uniform partition cells and their endpoint coverage through I and M.*
5. *S is the finite Riemann-sum row, read through the same cells and the displayed integrand windows.*
6. *Q is the* $\mathsf{RiemannSumCriterion}^{\uparrow}$ *comparison row, recording the finite criterion request over the displayed uniform mesh.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the sum values and comparison tolerances.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for mesh size, oscillation budget, and rational error comparison.*
9. *T is the terminal handoff row, by which a* $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$ *or integration-facing consumer may read the accepted uniform-partition criterion.*

10. *H records componentwise* hsame *transport for interval, integrand, mesh, cells, sums, criterion, rational readback, dyadic tolerance, terminal handoff, replay, provenance, and local naming rows.*

11. *C records displayed* Cont *replay of the route*

$$I, F, M, E \longmapsto S \longmapsto Q \longmapsto R, D \longmapsto T.$$

12. *P is the* Pkg *provenance over* $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RiemannSumCriterion}^{\uparrow}$, $\mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

13. *N is the local* $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, F, M, E, S, Q, R, D, T, H, C, P, N$. It has no coordinate for a host partition limit, selected refining sequence, quotient function equality, measure completion, countable choice, or ambient real completeness.

Theorem 8422.2 (Riemann integrability uniform-partition obligations)**.** *For every accepted* RiemannIntegrabilityUn *carrier*

$$U = (I, F, M, E, S, Q, R, D, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}}$ *surface consists exactly of interval admission, integrand-window exposure, uniform-mesh admission, equal-cell endpoint coverage, finite Riemann-sum readback, Riemann-sum criterion comparison, regular rational readback, dyadic tolerance accounting, terminal consumer handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8422.1. The rows I, F, M, E expose the interval, integrand windows, uniform mesh, and equal cells before any sum or criterion is read.

The integration-facing data are then S and Q. The finite sum row S is tied to the same equal-cell ledger, and the criterion row Q is the only place where the Riemann-sum comparison is recorded.

The numerical boundary is R and D. Regular rational readback and dyadic tolerances are displayed before the terminal row T is available to consumers.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier contains no host partition limit, selected refining sequence, quotient function equality, measure-completion row, countable-choice selector, or ambient completeness theorem, the listed rows exhaust the local obligations. □

Theorem 8422.3 (Uniform-partition criterion non-escape)**.** *Every accepted* $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ *consumer that reads a Riemann-integrability claim factors through the finite route*

$$\mathsf{Real}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{RiemannSumCriterion}^{\uparrow},\ \mathsf{ContinuousCompactRiemannIntegrability}^{\uparrow}$$

as displayed by I, R, D, Q, T and by the structural rows H, C, P, N. No consumer may replace that route by a host partition-limit theorem, quotient equality of functions, a selected sequence of refinements, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with an accepted consumer read. By the carrier definition, the only terminal handoff is T, and it is downstream of the interval, integrand, mesh, equal-cell, sum, criterion, rational, and dyadic tolerance rows.

Use the criterion row Q to locate the Riemann-sum comparison inside the sibling surface of chapter 8064. The comparison does not stand alone; it reads the same finite uniform cells and sum row.

Read the numerical rows through R and D. These rows keep sum values, mesh bounds, and tolerances in $\mathsf{RegSeqRat}^{\uparrow}$ and $\mathsf{DyadicRatCore}^{\uparrow}$ form before any $\mathsf{Real}^{\uparrow}$ terminal seal is consumed.

The terminal consumer may then connect to the compact-continuity route of chapter 7133, but only through the displayed handoff T. The structural rows H, C, P, N preserve the same packet, so no excluded host object is available. □

Falsifiable prediction: An accepted $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ consumer that reaches a Riemann-integrability claim without displaying the uniform mesh, equal cells, finite sum row, Riemann-sum criterion row, regular rational readback, dyadic tolerance row, terminal handoff, transport, replay, provenance, and local naming rows refutes the carrier surface.

Independence witness: real, regseqrat, dyadicratcore, riemann-sum-criterion, continuous-compact-riemann-integrability: no listed sibling is bijective with $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ because this packet binds the uniform mesh, equal-cell ledger, finite Riemann-sum readback, criterion comparison, rational and dyadic tolerance boundary, terminal handoff, transport, replay, provenance, and local naming rows as one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}}$.

Constructive story: A $\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}$ packet is generated from a RealUp interval source row, displayed integrand windows, a uniform mesh row, an equal-cell ledger, finite Riemann-sum readback, a RiemannSumCriterion comparison row, RegSeqRat readback, a DyadicRatCore tolerance row, terminal consumer handoff, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8422.1, Definition 8422.2, and Definition 8422.3 seed the finite uniform-partition Riemann-integrability surface over Real, RegSeqRat, DyadicRatCore, RiemannSumCriterion, compact-continuity, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannIntegrabilityUniformPartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host Riemann integration theorem, host partition limits, selected refining sequences, quotient function equality, measure completion, countable choice, open-cover compactness, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-mesh exactness, equal-cell endpoint coverage, finite Riemann-sum readback, criterion comparison, rational and dyadic tolerance nonescape, terminal handoff, transport, replay, provenance, and local naming for BEDC.Derived.RiemannIntegrabilityUniformPartitionUp.

Chapter 8423

A Concrete Naming Certificate for $\mathsf{LocatedBisectionLimit}^{\uparrow}$

Following Bishop and Bridges on interval bisection and constructive real approximation, the $\mathsf{LocatedBisectionLimit}^{\uparrow}$ packet names the finite certificate surface by which a retained located bisection route is read as a terminal $\mathsf{Real}^{\uparrow}$ seal. It sits over the source located-interval bisection packet of chapter 1711, the bisection-to-Cauchy handoff of chapter 8207, the dyadic tolerance ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet records a finite route from located bisection data to a Real seal; it does not select an infinite branch, identify quotient streams, assert trichotomy, invoke countable choice, or claim ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8423.1 (Located bisection limit carrier)**.** *A* $\mathsf{LocatedBisectionLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, B, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the located interval source row, read through the* $\mathsf{LocatedIntervalBisection}^{\uparrow}$ *surface and carrying the displayed endpoint, radius, locator, and retained-window data for the requested bisection depth.*
2. *B is the retained bisection branch ledger. It records the finite left-or-right branch prefix, the retained child intervals, and the source agreement with I.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *midpoint and diameter budget row. It stores the displayed midpoint cells, dyadic width bounds, and tolerance comparisons used by the retained branch ledger.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row listing the finite bisection stages and endpoint approximants inspected by a downstream request.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row formed from the retained dyadic centers and the diameter budgets displayed in D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal. It is exposed only after I, B, D, S, R have been displayed and replayed.*
7. *H records componentwise* hsame *transport for the source interval, retained branch ledger, dyadic midpoint and diameter budget, StreamName windows, RegSeqRat readback, terminal Real seal, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from a finite approximation request through the located interval source, retained branch ledger, dyadic budget, StreamName windows, RegSeqRat readback, and terminal Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{LocatedBisectionLimit}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{BisectionCauchy}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedBisectionLimit}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, B, D, S, R, E, H, C, P, N$. It has no coordinate for an infinite branch object, quotient stream equality, host real equality, trichotomy, countable choice, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8423.2 (Located bisection limit NameCert obligations)**.** *For every accepted* $\mathsf{LocatedBisectionLimit}^{\uparrow}$ *carrier*

$$L = (I, B, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedBisectionLimit}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the located interval source, retained bisection branch ledger, dyadic midpoint and diameter budget, finite stream windows, regular rational readback, terminal Real seal, componentwise transport, replay, provenance, and local naming rows;*

2. *source agreement, requiring the retained branch ledger B to read its initial interval and locator data from I;*

3. *dyadic diameter control, requiring every retained child interval in B to display midpoint and width information through D before any readback row is exposed;*

4. *finite-window extraction, requiring S to list only bisection stages and endpoint approximants already displayed by I, B, D;*

5. *regular-readback handoff, requiring R to read retained centers under the dyadic error budgets supplied by D before the terminal seal E is exposed;*

6. *transport, replay, provenance, and naming stability through H, C, P, N;*

7. *non-escape, excluding selected infinite branches, quotient stream equality, host real equality, trichotomy, countable choice, selected representatives, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness from the local certificate.*

No NameCert obligation is stored outside $I, B, D, S, R, E, H, C, P, N$.

Proof. Carrier admission is projection from Definition 8423.1. The packet displays the located source interval, retained branch ledger, dyadic budget, stream windows, regular readback, terminal seal, and structural rows.

Source agreement is inherited from the located-interval bisection route of chapter 1711. The branch ledger has no independent interval source; it can only retain child intervals below the displayed row I.

Dyadic diameter control follows the bisection-to-Cauchy route of chapter 8207 and the tolerance ledger of chapter 291. Each retained stage displays a midpoint and width before a downstream window may inspect it.

The finite-window and regular-readback obligations are supplied by chapter 126 and chapter 301. The window row selects only displayed stages, and the readback row turns those stages into regular rational data with the same dyadic budget.

Finally the terminal handoff is the $\mathsf{Real}^{\uparrow}$ seal of chapter 38, transported and replayed through H, C, P, N. Since the carrier has no row for the excluded branch, quotient, choice, trichotomy, host-equality, or completeness objects, the listed rows exhaust the local NameCert surface. □

Theorem 8423.3 (Located bisection limit Real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{LocatedBisectionLimit}^{\uparrow}$ *carrier must pass through the finite route*

$$I, B, D \longmapsto S, R \longmapsto E, H, C, P, N.$$

The consumer receives located interval data, a retained bisection branch ledger, dyadic midpoint and diameter budgets, finite StreamName windows, RegSeqRat readback, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and a local* NameCert *row before the terminal Real seal can be consumed. The handoff exports no selected infinite branch, quotient stream equality, host real equality, trichotomy, countable choice, selected representative, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with the source and branch rows. The source row I gives the located interval data, while B displays the finite retained branch ledger below that source. This is the public bisection surface supplied by chapter 1711.

Next read the dyadic budget row D. The midpoint and diameter comparisons in D are the data used by the bisection-Cauchy route of chapter 8207 to control the retained centers.

Then the finite observation and regular readback rows S, R expose only already displayed bisection stages. Their StreamName and RegSeqRat roles are the same finite-window and regular-rational roles described in chapter 126 and chapter 301.

Finally E, H, C, P, N seal and name the route. The terminal $\mathsf{Real}^{\uparrow}$ seal is reached only after the source, branch, dyadic, window, and readback rows have been replayed, as in chapter 38. No excluded branch, quotient, host-equality, trichotomy, choice, selected-representative, or completeness row is present, so no Real-facing consumer can bypass the displayed handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedBisectionLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedBisectionLimit}^{\uparrow}$ packet is generated from a LocatedIntervalBisection source row, a retained bisection branch ledger, DyadicRatCore midpoint and diameter budgets, StreamName finite windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedBisectionLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8423.1, Definition 8423.2, and Definition 8423.3 seed the finite located-bisection route from source interval and dyadic branch rows to regular Cauchy readback and terminal Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedBisectionLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, selected infinite branches, quotient stream equality, trichotomy, countable choice, host real equality, selected representatives, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source agreement, dyadic diameter control, finite-window extraction, regular-readback handoff, Real-seal handoff, and non-escape for BEDC.Derived.LocatedBisectionLimitUp.

Chapter 8424

A Concrete Naming Certificate for $\mathsf{TotallyBoundedReal}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{TotallyBoundedReal}^{\uparrow}$ packet records a finite-net real-object certificate for Real and Completion consumers. It sits beside the real-name seal of chapter 38, the metric source of chapter 57, the finite-net source of chapter 127, the dyadic tolerance ledger of chapter 291, and the compact-metric consumer of chapter 129. The packet names a totally bounded real row only through displayed finite nets, regular rational windows, dyadic radii, and real seals; it is not open-cover compactness, a quotient completion, a selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8424.1 (TotallyBoundedReal carrier)**.** *A* $\mathsf{TotallyBoundedReal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (E, M, T, D, W, Q, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording the endpoint real-name boundary exposed to downstream Real and Completion consumers.*
2. *M is the metric row on the displayed real-name surface, with distance requests, endpoint classifiers, and comparison histories read through the same finite packet.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net row, including the displayed center bundle, membership rows, coverage witnesses, and mesh ledger.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by the metric and finite-net rows for positive radius requests.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row that exposes only the regular observation prefixes used to inspect the real names.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows attached to W and D.*
7. *H records componentwise* hsame *transport for the real seal, metric row, finite-net row, dyadic ledger, finite windows, rational readbacks, replay, provenance, and local name.*
8. *C records displayed* Cont *replay from a tolerance request through D, then through the finite-net row T, the metric row M, the stream window W, the rational readback Q, and finally the real seal E.*

9. *P is the* Pkg *provenance over* $\mathsf{TotallyBoundedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedReal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their componentwise transports. It has no coordinate for open-cover compactness, selected subcovers, quotient real equality, selected limits, trichotomy, countable choice, or ambient Real completeness.

Theorem 8424.2 (TotallyBoundedReal NameCert obligations)**.** *For an accepted* $\mathsf{TotallyBoundedReal}^{\uparrow}$ *carrier $R = (E, M, T, D, W, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedReal}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the real seal, metric row, totally bounded finite-net row, dyadic tolerance ledger, stream window, regular rational readback, transport, replay, provenance, and local naming rows;*
2. *finite-net exactness, requiring every positive tolerance request to read the center bundle, membership rows, coverage witnesses, and mesh ledger displayed by T;*
3. *real-window exactness, requiring every Real-facing read to pass through the finite observation row W, the regular rational readback row Q, and the dyadic tolerance ledger D before the seal E is consumed;*
4. *metric compatibility, requiring the distance comparisons in M to use the same dyadic radii and real-name windows displayed by D, W, Q, E;*
5. *transport and replay stability, requiring H and C to preserve the ordered route from tolerance request to finite net, metric comparison, rational readback, and real seal;*
6. *provenance non-escape, requiring P and N to name only the displayed rows and to export no open-cover compactness, selected subcover, quotient equality, selected limit, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8424.1. The packet exposes exactly the real seal, metric row, finite-net row, dyadic tolerance ledger, stream window, regular rational readback, transport, replay, provenance, and local name.

Finite-net exactness is read from T. A positive tolerance request can reach only the displayed center bundle, membership rows, coverage witnesses, and mesh ledger carried by the $\mathsf{TotallyBounded}^{\uparrow}$ row.

Real-window exactness and metric compatibility are read together. The stream window W, regular rational readback Q, and dyadic ledger D display the real-name observations before the seal E is exposed, while the metric row M uses those same windows and radii for every comparison.

Finally inspect H, C, P, N. Transport and replay preserve the displayed route, and provenance names only the listed rows. Since the carrier has no coordinate for open-cover compactness, selected subcovers, quotient equality, selected limits, trichotomy, countable choice, or ambient Real completeness, none of those objects can be exported. □

Theorem 8424.3 (TotallyBoundedReal finite-net handoff)**.** *Every* $\mathsf{CompactMetric}^{\uparrow}$*, Real, or Completion consumer of an accepted* $\mathsf{TotallyBoundedReal}^{\uparrow}$ *carrier*

$$R = (E, M, T, D, W, Q, H, C, P, N)$$

reads the totally bounded real object through the finite route

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{TotallyBounded}^{\uparrow} \longmapsto \mathsf{Met}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For each positive tolerance request, the consumer receives a displayed dyadic radius from D, a finite center bundle from T, metric comparisons from M, a regular rational window from W, Q, and the terminal real seal E. The handoff exports no open-cover compactness, selected subcover, quotient real equality, selected limit, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the tolerance request. The replay row C sends it first to the dyadic ledger D, so every radius and comparison budget is displayed before a finite-net row can be read.

Next read the finite-net row T and the metric row M. The center bundle, membership rows, coverage witnesses, and mesh ledger provide the total-bounded source, while the metric comparisons use exactly the dyadic radii already displayed by D.

The Real-facing portion then passes through the finite window W and the regular rational readback Q before reaching the seal E. Thus a downstream compact-metric, Real, or Completion consumer sees a real object only after the finite net and the rational-window evidence have been exposed.

Transport, replay, provenance, and local naming through H, C, P, N preserve that route. The packet therefore hands off finite-net real data without adding any open-cover compactness, selected subcover, quotient real equality, selected limit, trichotomy, countable choice, or ambient Real completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedReal}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedReal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8424.1, Definition 8424.2, and Definition 8424.3 seed the finite-net real-object certificate over RealUp, MetricUp, TotallyBoundedUp, DyadicRatCoreUp, StreamNameUp, RegSeqRatUp, CompactMetricUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedReal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net exactness, real-window exactness, metric compatibility, transport stability, replay stability, and provenance non-escape for BEDC.Derived.TotallyBoundedRealUp.

Constructive story: A $\mathsf{TotallyBoundedReal}^{\uparrow}$ packet is generated from a Real seal, metric row, totally bounded finite-net row, dyadic tolerance ledger, finite stream window, regular rational readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 8425

A Concrete Naming Certificate for $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$

Following Bishop and Bridges on constructive sequential compactness, the $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$ packet records the finite-window subsequence route that can be consumed before any full compactness or completeness theorem is available. It sits beside the finite source interfaces of chapter 5916 and chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal seal of chapter 38, and the real Bolzano–Weierstrass and sequential compactness routes of chapter 5350 and chapter 5935. The packet names a bounded finite source window and a displayed subsequence schedule; it is not a host subsequence selector, countable-choice principle, quotient stream equality, open-cover compactness theorem, or ambient $\mathsf{Real}^{\uparrow}$ completeness assertion.

Definition 8425.1 (Finite subsequence compactness carrier)**.** *A* $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (F, S, L, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the finite source-window row, listing the bounded block of source observations available to the compactness consumer.*
2. *S is the subsequence schedule row, recording only the displayed monotone index cells selected inside F.*
3. *L is the compact or located source row, exposing the finite compact support, located interval, or finite-net witness from which the schedule is read.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the scheduled observations.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic mesh, comparison radius, and readback precision used by R.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, S, L, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the source window, subsequence schedule, compact source, readback, tolerance, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a finite compactness request through F, S, L, R, D, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteSubsequenceCompactness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, S, L, R, D, E, H, C, P, N$. It has no coordinate for a host-selected infinite subsequence, quotient stream equality, countable choice, open-cover compactness, or ambient real completeness.

Theorem 8425.2 (Finite subsequence compactness NameCert obligations)**.** *For every accepted* $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$ *carrier*

$$K = (F, S, L, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteSubsequenceCompactness}^{\uparrow}}$ *surface consists exactly of finite source-window admission through F, subsequence schedule visibility through S, compact or located source exposure through L,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, dyadic tolerance accounting through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8425.1. The only rows available to a compactness consumer are $F, S, L, R, D, E, H, C, P, N$.

The source and schedule rows are finite. Row F exposes the inspected source block, row S records the monotone schedule inside that block, and row L supplies the displayed compact or located support before any readback is public.

The analytic read proceeds through R, D, E. The regular rational row reads only scheduled observations, the dyadic row fixes the tolerance ledger, and the Real seal is downstream from both.

Finally H, C, P, N preserve and name the same route. Since the carrier has no coordinate for host subsequence selection, quotient stream equality, countable choice, open-cover compactness, or ambient real completeness, the listed rows exhaust the local obligation surface. □

Theorem 8425.3 (Finite subsequence Real-seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read exported by an accepted* $\mathsf{FiniteSubsequenceCompactness}^{\uparrow}$ *carrier must pass through the finite source window F, subsequence schedule S, compact or located source row L,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D before the terminal seal E can be consumed. The route exports a displayed finite-window subsequence packet and no selected infinite subsequence, quotient stream equality, countable choice, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start from the obligation surface of Definition 8425.2. It places F, S, L before any regular rational or real-facing read.

The readback rows R and D then account for the scheduled rational observations and the dyadic tolerance used to compare them. Therefore a Real-facing consumer cannot reach E without first reading the displayed finite source and schedule route.

The structural rows H, C, P, N transport, replay, source, and name that same route. They add no hidden selector, quotient stream, choice principle, open-cover compactness theorem, or ambient completeness object, so Real-seal access remains finite-window local. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteSubsequenceCompactness}^{\uparrow}}$ **·**
Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteSubsequenceCompactness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8425.1, Definition 8425.2, and Definition 8425.3 seed the finite-window subsequence compactness route through finite source windows, displayed schedules, compact or located support, RegSeqRat readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteSubsequenceCompactness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host subsequence selection, quotient stream equality, countable choice, open-cover compactness, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite source-window visibility, subsequence-schedule monotonicity, compact-source exposure, RegSeqRat readback, dyadic tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteSubsequenceCompactnessUp.

Constructive story: A FiniteSubsequenceCompactness$^{\uparrow}$ packet is generated from a finite source window, a displayed subsequence schedule, compact or located source support, RegSeqRat readback, DyadicRatCore tolerance, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8426

A Concrete Naming Certificate for $\mathsf{FiniteWindowSubcover}^{\uparrow}$

Following Bishop finite subcover and finite-net arguments, the $\mathsf{FiniteWindowSubcover}^{\uparrow}$ packet records the Real-completeness subcover route as explicit windows rather than as an ambient Heine–Borel theorem. It realizes the route of chapter 9238 through displayed $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ rows. The packet is a finite-window NameCert surface for later completion consumers; it does not assert general open-cover compactness, arbitrary subcover selection, countable choice, quotient stream equality, or full ambient Real completeness. The sibling route through chapter 5916, chapter 126, chapter 301, chapter 291, and chapter 38 supplies the finite candidate stream, observation windows, regular rational readback, dyadic tolerance ledger, and terminal Real seal consumed by this packet.

Definition 8426.1 (Finite-window subcover carrier)**.** *A* $\mathsf{FiniteWindowSubcover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (U, F, S, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *U is the displayed cover-request row, naming the finite family of cover cells and the requested observation budget.*
2. *F is the* $\mathsf{FiniteStream}^{\uparrow}$ *source row, exposing the finite list of candidate cover cells and sampled source points.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the source observations and cover-membership reads are opened.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational endpoints, radii, or membership thresholds visible in S.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording the finite mesh, overlap, and radius comparisons.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after F, S, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the cover request, finite stream, window, readback, tolerance, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a Real-completeness finite-window request through U, F, S, R, D, E, H.*

9. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowSubcover}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowSubcover}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, F, S, R, D, E, H, C, P, N$. It has no coordinate for a host open-cover object, arbitrary subcover selector, countable choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Theorem 8426.2 (Finite-window subcover NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowSubcover}^{\uparrow}$ *carrier*

$$B = (U, F, S, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteWindowSubcover}^{\uparrow}}$ *surface consists exactly of cover-request visibility through U, finite source and candidate-cell exposure through F,* $\mathsf{StreamName}^{\uparrow}$ *window reads through S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R, dyadic tolerance accounting through D, terminal* $\mathsf{Real}^{\uparrow}$ *sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8426.1. The packet exposes only $U, F, S, R, D, E, H, C, P, N$.

The cover-facing data are finite. Row U fixes the request, row F lists the displayed candidates, and row S opens only the inspected StreamName windows.

The numerical readback stays within R, D, E. The regular rational row reads the displayed endpoints or thresholds, the dyadic row supplies the finite tolerance ledger, and the Real seal is downstream from those rows.

Transport, replay, provenance, and local naming preserve this route without adding a host open-cover object, arbitrary subcover selector, countable-choice witness, quotient real equality, or ambient Real-completeness theorem. □

Theorem 8426.3 (Heine–Borel finite-window subcover route)**.** *Every subcover read exported by an accepted* $\mathsf{FiniteWindowSubcover}^{\uparrow}$ *carrier stays inside the displayed finite windows $U, F, S, R, D, E, H, C, P, N$. In particular, cover-cell membership is read through* $\mathsf{FiniteStream}^{\uparrow}$ *and* $\mathsf{StreamName}^{\uparrow}$*, rational thresholds are read through* $\mathsf{RegSeqRat}^{\uparrow}$*, tolerance comparisons are read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, and the terminal value is sealed through* $\mathsf{Real}^{\uparrow}$*. The route does not assert general open-cover compactness, arbitrary subcover selection, countable choice, quotient stream equality, or ambient Real completeness.*

Proof. Begin with Definition 8426.2. It forces the cover request, finite candidate list, and source observation windows to be displayed before any subcover-facing read is public.

Next read the numerical rows. The rational thresholds in R and dyadic comparisons in D are attached to the same finite StreamName windows, so no cover membership can be imported from outside U, F, S.

Finally consume the Real seal E only after the finite readback route has been displayed. The support rows H, C, P, N preserve that route uniformly, and the carrier contains no coordinate for the excluded open-cover, selector, choice, quotient, or ambient-completeness principles. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowSubcover}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowSubcover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8426.1, Definition 8426.2, and Definition 8426.3 seed the finite-window subcover route through cover requests, FiniteStream candidates, StreamName windows, RegSeqRat readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowSubcover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close general open-cover compactness, arbitrary subcover selection, countable choice, quotient stream equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite candidate visibility, StreamName window exactness, RegSeqRat readback, DyadicRatCore tolerance accounting, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteWindowSubcoverUp.

Constructive story: A FiniteWindowSubcover$^{\uparrow}$ packet is generated from a cover request, a FiniteStream candidate list, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8427

A Concrete Naming Certificate for $\mathsf{WhitneyExtension}^{\uparrow}$

Following Whitney's extension theorem for compatible finite jets on closed subsets of Euclidean space, the $\mathsf{WhitneyExtension}^{\uparrow}$ packet records the finite BEDC handoff from a displayed jet surface to extension-facing consumers. It sits after the finite-jet compatibility surface of chapter 3679, the finite Taylor enclosure rows of chapter 442, and the manifold carrier of chapter 96. The packet names only the rows by which a finite jet table, remainder ledger, chart window, transport, replay, provenance, and local naming are made available to downstream derivative or smooth-manifold consumers; it is not a host theorem selecting an arbitrary global smooth extension.

Definition 8427.1 (Whitney extension carrier)**.** *A* $\mathsf{WhitneyExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$W = (J, T, M, E, R, H, C, P, N)$$

with the following displayed rows:

1. *J is the* $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$ *compatibility row, including the closed-set classifier, finite jet table, and Whitney comparison ledger already exposed by the finite-jet chapter.*
2. *T is the* $\mathsf{TaylorModel}^{\uparrow}$ *local Taylor-row handoff, retaining only displayed center, finite coefficient, and remainder-enclosure data needed to read local polynomial approximants.*
3. *M is the* $\mathsf{Manifold}^{\uparrow}$ *or Euclidean chart-window row on which the finite jet and Taylor rows are interpreted.*
4. *E is the extension-handoff ledger, recording which jet requests are eligible for derivative-facing or smooth-manifold consumers after J, T, M have been displayed.*
5. *R is the readback row for derivative, smooth-chart, and validated-local-model consumers.*
6. *H records componentwise* hsame *transport for J, T, M, E, R, C, P, N.*
7. *C records displayed* Cont *replay from a finite extension request through J, T, M, E, R, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{WhitneyExtension}^{\uparrow}$, $\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}$, $\mathsf{TaylorModel}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{WhitneyExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $J, T, M, E, R, H, C, P, N$. It has no coordinate for a selected smooth function, arbitrary global extension operator, compactness theorem, quotient equality, choice principle, or ambient completeness claim.

Theorem 8427.2 (Whitney extension NameCert obligations)**.** *For every accepted* $\mathsf{WhitneyExtension}^{\uparrow}$ *carrier* $W = (J, T, M, E, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{WhitneyExtension}^{\uparrow}}$ *surface consists exactly of carrier admission for the rows named in Definition 8427.1, finite-jet compatibility inherited through* J*, Taylor-row handoff through* T*, chart-window exposure through* M*, extension-handoff eligibility through* E*, derivative or smooth-chart readback through* R*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the accepted carrier. The only analytic source is the finite Whitney jet row J, and the only local approximation source is the Taylor-model row T over the displayed chart window M.

The extension-handoff row E is downstream of those three sources. It records that a consumer may request the displayed extension-facing data only after the finite compatibility, Taylor remainder, and chart rows are visible in the same packet.

The readback row R exposes exactly that handoff to derivative or smooth-chart consumers. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same route and add no hidden extension object. □

Theorem 8427.3 (Whitney extension jet handoff)**.** *Every derivative-facing, validated-local-model, or smooth-chart consumer reading an accepted* $\mathsf{WhitneyExtension}^{\uparrow}$ *packet must factor through the displayed route*

$$\mathsf{WhitneyExtensionFiniteJet}^{\uparrow}, \mathsf{TaylorModel}^{\uparrow}, \mathsf{Manifold}^{\uparrow} \longmapsto E \longmapsto R \longmapsto H, C, P, N.$$

The consumer receives the finite jet compatibility surface, Taylor-row local approximation data, chart-window interpretation, and extension-handoff ledger. It receives no arbitrary global smooth extension, no selected representative function, no compactness theorem, no quotient equality, no cover choice, and no ambient completeness principle.

Proof. Begin with a consumer read. By Definition 8427.1, the consumer can inspect only J, T, M before reaching the extension-handoff ledger E.

Read E next. It is a finite row stating that the displayed jet and Taylor data can be handed to the requested derivative-facing or smooth-chart endpoint; it does not contain a host extension function.

Finally pass through R, H, C, P, N. These rows expose, transport, replay, source, and name the same finite handoff. Since the carrier has no coordinate for a global smooth extension or selected representative, every consumer route remains inside the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{WhitneyExtension}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{WhitneyExtension}^{\uparrow}}$, seed)

Scope closed: Definition 8427.1, Definition 8427.2, and Definition 8427.3 seed the finite Whitney extension handoff over finite jets, Taylor rows, manifold chart windows, readback, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{WhitneyExtension}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close the classical global Whitney extension theorem, a selected smooth extension operator, compactness, arbitrary choice, quotient equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-jet compatibility, Taylor-row handoff, chart-window exposure, extension-handoff eligibility, readback, transport, replay, provenance, and local naming for BEDC.Derived.WhitneyExtensionUp.

Constructive story: A $\mathsf{WhitneyExtension}^{\uparrow}$ packet is generated from a WhitneyExtensionFiniteJetUp compatibility row, a TaylorModelUp local Taylor row, a ManifoldUp chart window, an extension-handoff ledger, derivative or smooth-chart readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8428

A Concrete Naming Certificate for $\mathsf{StratifiableSpace}^{\uparrow}$

Following Borges and Engelking on stratifiable spaces, the $\mathsf{StratifiableSpace}^{\uparrow}$ packet records the finite neighborhood-stratum route by which closed-set data are turned into open refinements visible to topology consumers. It sits beside the topological carrier of chapter 88, the metric-refinement surface of chapter 57, the open-cover carrier of chapter 6731, and the locally finite cover route of chapter 8398. The certificate names only the displayed stratum rows, monotone refinement comparisons, and downstream cover handoff; it does not import a host metrization theorem, paracompactness theorem, selected point neighborhoods, countable choice, or ambient lattice equality.

Definition 8428.1 ($\mathsf{StratifiableSpace}^{\uparrow}$ neighborhood-stratum carrier)**.** *A* $\mathsf{StratifiableSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, F, G, M, U, R, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the underlying* $\mathsf{Topology}^{\uparrow}$ *source row, including the finite open-set tests used by the packet.*
2. *F is the closed-request row family. Each entry names the closed row whose neighborhoods are to be stratified.*
3. *G is the stratum ledger. For every displayed closed row and finite index, it records an open neighborhood row $G(F, n)$.*
4. *M is the monotonicity ledger, recording the displayed implication from $F_0 \subseteq F_1$ to $G(F_0, n) \subseteq G(F_1, n)$ and the nesting comparison from $G(F, n+1)$ to $G(F, n)$.*
5. *U is the separation ledger. It records that each closed row F remains inside the corresponding open stratum and that exterior witnesses are kept outside some finite stratum window.*
6. *R is the refinement handoff row for open-cover consumers. It exposes the finite cover rows obtained from the visible strata.*
7. *L is the locally finite route row, read through chapter 8398 only after G, M, U, R have been displayed.*
8. *H records componentwise* hsame *transport for $X, F, G, M, U, R, L, C, P, N$.*
9. *C records displayed* Cont *replay for topology admission, closed-row admission, stratum reads, monotone comparison, separation readback, refinement export, locally finite handoff, and the local naming row.*

10. *P is the* Pkg *provenance over* StratifiableSpace$^{\uparrow}$, Topology$^{\uparrow}$, Met$^{\uparrow}$, OpenCover$^{\uparrow}$, ParacompactLocallyFinite$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{StratifiableSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, F, G, M, U, R, L, H, C, P, N$. It has no coordinate for a host metrization theorem, an ambient paracompactness theorem, arbitrary neighborhood choice, or equality of open-set lattices outside the displayed finite rows.

Theorem 8428.2 (StratifiableSpace$^{\uparrow}$ NameCert obligations)**.** *For every accepted* StratifiableSpace$^{\uparrow}$ *carrier*

$$S = (X, F, G, M, U, R, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StratifiableSpace}^{\uparrow}}$ *surface consists exactly of topology-source admission through X, closed-request visibility through F, open-stratum exposure through G, monotone and nesting comparison through M, separation readback through U, cover-refinement export through R, locally finite handoff through L, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8428.1. The displayed rows expose the topological source, closed requests, strata, monotone comparisons, separation witnesses, refinement handoff, locally finite route, transport, replay, provenance, and local name.

The stratum obligations are local to F, G, M, U. The closed row is visible before any open neighborhood is read, the stratum ledger supplies the indexed open rows, and the monotonicity ledger records the two comparisons needed by downstream cover consumers.

The cover-facing data are exported only after the stratum route has been displayed. Rows R and L hand the finite refinement surface to open-cover and locally finite consumers, while H, C, P, N preserve the same finite packet without importing a host metrization theorem, arbitrary choices of neighborhoods, or ambient equality of topological lattices. □

Theorem 8428.3 (Metric-topology refinement handoff)**.** *Let $S = (X, F, G, M, U, R, L, H, C, P, N)$ be an accepted* StratifiableSpace$^{\uparrow}$ *carrier. Every metric-style neighborhood refinement read exported by S factors through the finite route*

$$X, F, G, M, U, H, C, P, N \longmapsto R \longmapsto L.$$

In particular, a downstream topology or cover-refinement consumer may read the displayed closed rows, open strata, monotone comparisons, separation windows, and refinement handoff, but it cannot replace them by a host metrization theorem, an arbitrary open-cover selector, or a paracompactness theorem outside the packet.

Proof. Start with the topology source row X and the closed-request rows F. They fix the only closed sets whose neighborhoods the packet is allowed to expose.

Read the stratum data next. The rows G, M, U display the open neighborhoods, the monotone and nesting comparisons, and the finite separation windows, so every refinement read has a visible stratum witness.

Finally pass through R and L. The refinement row exports the finite cover data, and the locally finite row is reached only through the displayed refinement route. Componentwise transport, replay, provenance, and local naming keep the handoff inside the same BHist packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{StratifiableSpace}^{\uparrow}}$.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StratifiableSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8428.1, Definition 8428.2, and Definition 8428.3 seed the finite neighborhood-stratum route through topology source rows, closed requests, indexed open strata, monotone comparisons, separation windows, cover refinement, locally finite handoff, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{StratifiableSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close metrization, paracompactness, arbitrary neighborhood selection, equality of ambient open-set lattices, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, closed-request visibility, open-stratum exposure, monotone comparison, separation readback, cover-refinement export, locally finite handoff, transport, replay, provenance, and local naming for BEDC.Derived.StratifiableSpaceUp.

Constructive story: A StratifiableSpace$^{\uparrow}$ packet is generated from a topology source, closed-request rows, indexed open-stratum rows, monotone and nesting comparison rows, separation rows, a cover-refinement handoff, a locally finite route, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8429

A Concrete Naming Certificate for FiniteCauchyCompletenessCriterion$^{\uparrow}$

Following Bishop–Bridges constructive analysis, the FiniteCauchyCompletenessCriterion$^{\uparrow}$ packet records a finite criterion object for reading Cauchy data into the Real$^{\uparrow}$ seal boundary without asserting ambient completeness. It sits after the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the convergence-route surface of chapter 1509, the Bolzano–Cauchy branch of chapter 1913, and the terminal real-name seal of chapter 38. The certificate names the finite rows by which a completion-facing consumer may inspect Cauchy convergence data; it is not a quotient of streams, a selected limit, countable choice, trichotomy, open-cover compactness, or full Real$^{\uparrow}$ completeness.

Definition 8429.1 (Finite Cauchy completeness criterion carrier)**.** *A* FiniteCauchyCompletenessCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, R, D, G, B, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *finite-window schedule naming exactly the observed Cauchy tail requests.*
2. *R is the* RegSeqRat$^{\uparrow}$ *readback row produced from those windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger recording the dyadic radii, comparison cells, and finite precision budget.*
4. *G is the* CauchyConvergenceCriterion$^{\uparrow}$ *criterion row that certifies convergence readiness for the displayed readback and tolerance data.*
5. *B is the* BolzanoCauchy$^{\uparrow}$ *branch row, available only as a finite companion route for located Cauchy evidence.*
6. *E is the terminal* Real$^{\uparrow}$ *seal row reached only after S, R, D, G, B have been displayed.*
7. *H records componentwise* hsame *transport for the window, readback, tolerance, criterion, Bolzano–Cauchy branch, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from each finite tail request through S, R, D, G, B, E, H.*
9. *P is the* Pkg *provenance over* FiniteCauchyCompletenessCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, CauchyConvergenceCriterion$^{\uparrow}$, BolzanoCauchy$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through these displayed rows. It contains no coordinate for host Cauchy completeness, quotient stream equality, selected representatives, countable choice, trichotomy, open-cover compactness, or an ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Lean4 (statement) `BEDC.Derived.FiniteCauchyCompletenessCriterionUp`

Theorem 8429.2 (Finite Cauchy completeness criterion NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}$ *carrier* $K = (S, R, D, G, B, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyC}}$ *surface consists exactly of carrier admission for the finite StreamName window, regular rational readback, dyadic tolerance ledger, convergence-criterion row, Bolzano–Cauchy branch row, Real seal row, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8429.1. Its displayed coordinates are precisely $S, R, D, G, B, E, H, C, P, N$.

The analytic read is finite before it is real-facing. Row S fixes the observed tail window, R supplies only the corresponding regular rational readback, and D supplies the dyadic tolerance cells attached to that window.

The criterion and branch rows are downstream of the same finite data. The convergence-criterion row G and Bolzano–Cauchy row B may be read only after S, R, D have been exposed, and the Real seal E is downstream from those rows.

Transport, replay, provenance, and local naming preserve this route. Since the carrier has no coordinate for host completeness, quotient streams, selected representatives, countable choice, trichotomy, open-cover compactness, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8429.3 (Finite Cauchy completeness criterion Real seal route)**.** *Every* $\mathsf{Real}^{\uparrow}$*- or completion-facing read of an accepted* $\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyConvergenceCriterion}^{\uparrow} \longmapsto \mathsf{BolzanoCauchy}^{\uparrow} \longmapsto \mathsf{Real}$$

The read consumes the same window row S, readback row R, tolerance ledger D, criterion row G, branch row B, seal row E, transport row H, replay row C, provenance row P, and local name row N before any terminal Real seal is public.

Proof. Begin with the finite window. The carrier gives S as the only source of Cauchy tail observations, so a Real-facing consumer cannot inspect an unbounded stream before the finite schedule is displayed.

Next read R and D. The regular rational row supplies the displayed values, and the dyadic ledger supplies the radii and comparison cells used by the criterion.

Now consume the criterion and branch rows. The convergence row G records readiness for the displayed Cauchy data, while B supplies only the finite Bolzano–Cauchy companion route; neither row introduces a selected limit or an ambient completeness theorem.

Finally the seal row E is reached through H, C, P, N. These structural rows preserve the same finite route, so the public Real seal has no bypass around S, R, D, G, B. □

Theorem 8429.4 (Finite Cauchy completeness criterion nonescape)**.** *An accepted* $\mathsf{FiniteCauchyCompletenessCriteric}$ *packet exports no ambient completeness principle. Any consumer that reaches* $\mathsf{Real}^{\uparrow}$ *through the packet can read only the finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, Cauchy convergence criterion row, Bolzano–Cauchy branch row, Real seal boundary, transport, replay, provenance, and local NameCert rows displayed by the carrier.*

Proof. Apply the NameCert obligations of Definition 8429.2. They identify the complete local surface of the accepted packet.

Apply the Real seal route of Definition 8429.3. Every completion-facing read reaches $\mathsf{Real}^{\uparrow}$ only through $S, R, D, G, B, E, H, C, P, N$.

The carrier definition contains no further coordinate. Therefore a consumer cannot extract quotient stream equality, a selected limit, countable choice, trichotomy, open-cover compactness, host Cauchy completeness, or ambient Real completeness from this packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}$ packet is generated from finite StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a Cauchy convergence criterion row, a Bolzano–Cauchy branch row, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8429.1, Definition 8429.2, Definition 8429.3, and Definition 8429.4 seed the finite criterion route from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, Cauchy convergence evidence, Bolzano–Cauchy branch data, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyCompletenessCriterion}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FiniteCauchyCompletenessCriterionUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, trichotomy, open-cover compactness, host Cauchy completeness, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, regular rational readback, dyadic tolerance accounting, convergence-criterion handoff, Bolzano–Cauchy branch routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCauchyCompletenessCriterionUp.

Chapter 8430

A Concrete Naming Certificate for $\mathsf{FiniteNetFan}^{\uparrow}$

Following Brouwer and Bishop–Bridges finite-net arguments, the $\mathsf{FiniteNetFan}^{\uparrow}$ packet records a finite ProbeBundle fan handoff for total-boundedness and compact-uniform consumers. It sits between the finite-net source of chapter 127, the compact-metric consumer of chapter 129, the dyadic tolerance ledger of chapter 291, the finite stream-name window of chapter 126, the regular-rational readback of chapter 301, and the terminal real seal of chapter 38. The packet names a finite fan of mesh-controlled probes; it is not open-cover compactness, selected subcover extraction, quotient real equality, countable choice, trichotomy, or ambient Real completeness.

Definition 8430.1 (FiniteNetFan carrier)**.** *A* $\mathsf{FiniteNetFan}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, D, J, W, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{ProbeBundle}^{\uparrow}$ *center bundle, recording the finite family of probe centers, membership rows, and bundle indices used by the net.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *mesh-radius ledger, recording the positive dyadic tolerance and every comparison budget consumed by the fan.*
3. *J is the finite fan-refinement row, listing the bounded refinement branches, parent-child mesh inclusions, and coverage witnesses read from the finite net.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which each probe center and refinement branch exposes only the finite observations requested by D.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows attached to W and to the dyadic mesh ledger.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the center and branch observations after B, D, J, W, Q have been displayed.*
7. *H records componentwise* hsame *transport for the center bundle, mesh radius, fan refinement, window, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a tolerance request through D, then through B, J, W, Q, E, H.*
9. *P is the* Pkg *provenance over* $\mathsf{FiniteNetFan}^{\uparrow}$, $\mathsf{ProbeBundle}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteNetFan}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows and their componentwise transports. It has no coordinate for open-cover compactness, a selected subcover, quotient real equality, a hidden completion theorem, countable choice, trichotomy, or ambient Real completeness.

Theorem 8430.2 (FiniteNetFan NameCert obligations)**.** *For an accepted* $\mathsf{FiniteNetFan}^{\uparrow}$ *carrier* $F = (B, D, J, W, Q, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteNetFan}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, center-bundle visibility through B, mesh-radius accounting through D, finite fan-refinement visibility through J, StreamName window exactness through W, RegSeqRat readback through Q, terminal Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 8430.1. The packet exposes exactly the center bundle, mesh-radius ledger, finite fan-refinement row, window row, readback row, Real seal, transport, replay, provenance, and local name.

The finite-net obligations are read from B, D, J. The bundle B displays the centers, D displays the mesh radius and comparison budget, and J displays the bounded refinement branches and coverage witnesses.

The Real-facing obligations are read from W, Q, E. StreamName windows expose the finite observations, RegSeqRat readback turns those windows into regular rational rows, and the Real seal is downstream of that readback.

Finally H, C, P, N preserve and name the route. Since no carrier coordinate names open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, or ambient Real completeness, none of those data can be exported by the local certificate. □

Theorem 8430.3 (FiniteNetFan ProbeBundle handoff)**.** *Every total-boundedness, compact-metric, Real, or compact-uniform consumer of an accepted* $\mathsf{FiniteNetFan}^{\uparrow}$ *carrier*

$$F = (B, D, J, W, Q, E, H, C, P, N)$$

reads a finite fan only through the route

$$\mathsf{ProbeBundle}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

For each positive mesh request, the consumer receives the displayed probe centers from B, the dyadic mesh radius from D, the finite refinement branches from J, the finite observation windows from W, the regular rational readback from Q, and the terminal seal from E.

Proof. Induct over the finite ProbeBundle fan recorded by B and J. The empty branch has no exported center, and the carrier still exposes the mesh ledger D, structural rows, and local name before a consumer can read the packet.

For a branch extension, project the next probe center from B and the next refinement row from J. The mesh comparison for that branch is read from D, so the branch cannot be consumed as a detached point selection.

The branch then passes through W, Q, E. The StreamName window supplies only the finite observations requested by the mesh ledger, RegSeqRat readback records the regular rational values, and the Real seal is terminal for that branch.

Transport, replay, provenance, and local naming through H, C, P, N preserve the same route for every branch. Thus total-boundedness and compact-uniform consumers receive finite ProbeBundle fan data without importing open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, or ambient Real completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteNetFan}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteNetFan}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8430.1, Definition 8430.2, and Definition 8430.3 seed the finite ProbeBundle fan handoff through center bundles, dyadic mesh radii, finite fan refinements, StreamName windows, RegSeqRat readback, Real sealing, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteNetFan}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected subcovers, quotient real equality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ProbeBundle center visibility, dyadic mesh accounting, finite fan-refinement exactness, StreamName window exactness, RegSeqRat readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteNetFanUp.

Constructive story: A $\mathsf{FiniteNetFan}^{\uparrow}$ packet is generated from a ProbeBundle center bundle, dyadic mesh-radius ledger, finite fan-refinement row, StreamName windows, RegSeqRat readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Chapter 8431

A Concrete Naming Certificate for $\mathsf{BorelLebesgueCover}^{\uparrow}$

Following Bishop–Bridges constructive analysis and the Borel–Lebesgue finite-cover theorem for closed intervals, the $\mathsf{BorelLebesgueCover}^{\uparrow}$ packet records the finite subcover boundary as BEDC NameCert data. It sits after the interval compactness surface of chapter 1379, the closed-bounded interval net of chapter 1250, the located interval-cover row of chapter 1885, and the rational readback rows of chapter 291, chapter 126, chapter 301, and chapter 38. The packet names the finite subcover certificate available for a displayed interval cover; it does not import general open-cover compactness, selected subcovers, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8431.1 (Borel–Lebesgue cover carrier)**.** *A* $\mathsf{BorelLebesgueCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, K, L, D, S, Q, R, F, H, C, P, N)$$

where:

- I *is the displayed* $\mathsf{HeineBorelInterval}^{\uparrow}$ *closed-interval source.*
- K *is the* $\mathsf{ClosedBoundedIntervalNet}^{\uparrow}$ *finite interval-net row over the same endpoints.*
- L *is the* $\mathsf{LocatedIntervalCover}^{\uparrow}$ *row whose located cover tests are available on the displayed interval net.*
- D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare interval endpoints, cover radii, and finite-net refinements.*
- S *is the* $\mathsf{StreamName}^{\uparrow}$ *inspection schedule for the finite cover windows.*
- Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same schedule and dyadic ledger.*
- R *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the interval endpoints and cover radii read through* D, S, Q*.*
- F *is the finite subcover-boundary row: it records that the displayed finite window covers the interval source through* I, K, L, D, S, Q, R*.*
- H, C, P, N *are the componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{BorelLebesgueCover}^{\uparrow}}$ *rows.*

The carrier exports no arbitrary open-cover compactness principle, no selected subcover outside F*, no quotient real equality, and no ambient completeness field for* $\mathsf{Real}^{\uparrow}$*.*

Theorem 8431.2 (Borel–Lebesgue cover NameCert obligations)**.** *For the carrier of Definition 8431.1, the local* $\mathsf{NameCert}_{\mathsf{BorelLebesgueCover}^{\uparrow}}$ *surface consists exactly of carrier admission for* B*, interval-source exposure through* I*, closed-bounded net exposure through* K*, located-cover exposure through* L*, dyadic and regular readback through* D, S, Q, R*, finite subcover-boundary exposure through* F*, and structural replay through* H, C, P, N*. No NameCert read may replace those rows by general open-cover compactness, a choice-selected subcover, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier. Its displayed coordinates are precisely $I, K, L, D, S, Q, R, F, H, C, P, N$, with the interval source, interval-net row, located-cover row, rational readback rows, finite subcover boundary, and structural rows all present before the local name is read.

The NameCert obligation for interval exposure reads I, K, L together: the closed interval, finite net, and located cover are not separate ambient principles. The rational obligation then routes endpoint and radius comparisons through D, S, Q, R.

Finally F, H, C, P, N record the finite subcover boundary, transport, replay, provenance, and local naming surface. Since no coordinate stores arbitrary open-cover compactness, a selected subcover oracle, quotient real equality, or ambient Real completeness, the local NameCert surface cannot export them. □

Theorem 8431.3 (Borel–Lebesgue cover finite-subcover boundary)**.** *Every consumer of an accepted* $\mathsf{BorelLebesgueCover}^{\uparrow}$ *packet receives a finite subcover boundary only after the rows*

$$\mathsf{HeineBorelInterval}^{\uparrow},\quad \mathsf{ClosedBoundedIntervalNet}^{\uparrow},\quad \mathsf{LocatedIntervalCover}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{StreamName}^{\uparrow},\quad \mathsf{R}$$

have been displayed inside the same carrier and replayed through F, H, C, P, N*. The exported finite boundary is therefore a packet-local certificate over the displayed interval cover, not a claim of general open-cover compactness, selected subcovers, quotient real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the carrier and NameCert obligations. They place the interval source I, interval-net row K, located-cover row L, dyadic ledger D, inspection schedule S, regular readback Q, and Real seal R before the finite boundary row F.

The finite boundary row records coverage only for the displayed window over that source. Transport and replay through H and C preserve the same rows, while P and N record provenance and local naming for the same packet.

Thus a downstream compact-uniform-continuity or interval-cover consumer can read the finite subcover boundary only through the displayed packet. The excluded compactness, selected-subcover, quotient-equality, and completeness claims have no carrier coordinate. □

Falsifiable prediction: A $\mathsf{BorelLebesgueCover}^{\uparrow}$ consumer is refuted if it exports a finite subcover without displaying the Heine–Borel interval source, closed-bounded interval net, located interval cover, dyadic ledger, stream window, regular readback, Real seal, finite boundary row, transport, replay, provenance, and local naming rows.

Independence witness: heineborelinterval, closedboundedintervalnet, locatedintervalcover, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{BorelLebesgueCover}^{\uparrow}$, because this packet binds the displayed interval source, located cover, rational readback, and finite subcover boundary as one NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BorelLebesgueCover}^{\uparrow}}$**.**

Constructive story: A BorelLebesgueCover$^{\uparrow}$ packet is generated from a Heine–Borel interval source, a closed-bounded interval net, a located interval-cover row, dyadic tolerance arithmetic, stream-window inspection, regular-rational readback, a Real seal, a finite subcover-boundary row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{BorelLebesgueCover}^{\uparrow}}$, seed)

Scope closed: Definition 8431.1, Definition 8431.2, and Definition 8431.3 introduce the finite subcover packet boundary over HeineBorelInterval$^{\uparrow}$, ClosedBoundedIntervalNet$^{\uparrow}$, LocatedIntervalCover$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus(NameCert$_{\text{BorelLebesgueCover}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim general open-cover compactness, selected subcovers, quotient real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located cover exposure, dyadic and regular readback, finite subcover-boundary exactness, and non-escape from general compactness or selected-subcover principles.

Chapter 8432

A Concrete Naming Certificate for $\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}$

Following Bishop-style constructive analysis, the $\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}$ packet records finite oscillation control on explicit rational windows before any compact-continuity argument is allowed to consume a Real-facing value. It sits over the dyadic tolerance ledger of chapter 291, the observation interface of chapter 126, the regular rational readback of chapter 301, the terminal real-name surface of chapter 38, and the finite-window consumer route of chapter 8426. The packet names a local gauge for explicit interval windows; it does not assert open-cover compactness, trichotomy, quotient equality, selected suprema, or full $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8432.1 (Constructive real oscillation gauge carrier)**.** *A* $\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (I, L, U, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval-window row. It names a displayed rational interval, its finite subwindows, and the requested local observation budget.*
2. *L is the local lower-oscillation row. It records the displayed lower rational bounds for the values visible on each window of I.*
3. *U is the local upper-oscillation row. It records the displayed upper rational bounds for the same windows, with no appeal to a selected supremum.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row. It records the dyadic tolerance, mesh, and comparison ledger used to compare the displayed bounds in L and U.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *readback row through which the finite windows and sampled value names are opened.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regularity row. It records the regular rational readback attached to the sampled values and the dyadic tolerance ledger.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after I, L, U, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for the interval window, lower and upper oscillation bounds, dyadic tolerance, StreamName readback, RegSeqRat regularity, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay from a finite oscillation request through I, L, U, D, S, R, E, H.*
10. *P is the* Pkg *provenance over* $\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{FiniteWindowSubcover}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, L, U, D, S, R, E, H, C, P, N$. It has no coordinate for an ambient open cover, trichotomy on reals, quotient equality of names, selected supremum or infimum, arbitrary subcover selection, or full $\mathsf{Real}^{\uparrow}$ *completeness proof.*

Theorem 8432.2 (Constructive real oscillation gauge NameCert obligations)**.** *For every accepted* $\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}$ *carrier*

$$G = (I, L, U, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ConstructiveRealOscillationGauge}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the interval-window, local lower-bound, local upper-bound, dyadic tolerance, StreamName readback, RegSeqRat regularity, terminal Real seal, transport, replay, provenance, and local naming rows;*
2. *window coherence, requiring L and U to name bounds only for the subwindows displayed by I;*
3. *dyadic oscillation accounting, requiring D to display the tolerance comparisons that make each local spread $U - L$ visible as dyadic data;*
4. *regular readback, requiring S and R to expose only the finite sampled names and regular rational approximants attached to the displayed windows;*
5. *Real-seal nonescape, requiring E to be consumed only after the window, bound, tolerance, StreamName, and RegSeqRat rows have been replayed;*
6. *transport, replay, provenance, and naming stability through H, C, P, N;*
7. *refusal of open-cover compactness, trichotomy, quotient equality, selected suprema, arbitrary subcover selection, and full* $\mathsf{Real}^{\uparrow}$ *completeness as local certificate data.*

No NameCert obligation is stored outside $I, L, U, D, S, R, E, H, C, P, N$.

Proof. Carrier admission is projection from Definition 8432.1. The packet displays exactly the interval-window, lower-bound, upper-bound, dyadic tolerance, StreamName readback, RegSeqRat regularity, Real seal, and structural rows.

Window coherence follows because the lower and upper rows are indexed by the displayed subwindows in I. There is no independent global cover or ambient compactness row from which additional windows could be imported.

Dyadic oscillation accounting is read through the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger of chapter 291. The spread between the displayed upper and lower rational bounds is public only when the tolerance comparisons are recorded in D.

The finite readback route is supplied by chapter 126 and chapter 301. Row S opens the sampled names, and row R records the regular rational approximants attached to those names.

Finally E, H, C, P, N seal and name the route as a local certificate. The carrier has no row for trichotomy, quotient equality, selected suprema, arbitrary subcover selection, or full Real completeness, so those principles cannot enter the local NameCert surface. □

Theorem 8432.3 (Constructive real oscillation modulus extraction)**.** *Every modulus read exported by an accepted* ConstructiveRealOscillationGauge$^{\uparrow}$ *carrier is extracted from the finite route*

$$I, L, U, D \longmapsto S, R \longmapsto E, H, C, P, N.$$

Given a requested dyadic tolerance already displayed in D, the extracted local modulus names only those subwindows of I whose lower and upper rational rows L, U have StreamName readback through S, RegSeqRat regularity through R, and terminal Real sealing through E. The extraction exports no open-cover compactness principle, trichotomy decision, quotient equality, selected supremum, arbitrary subcover selector, or full Real$^{\uparrow}$ *completeness proof.*

Proof. Start with the displayed request in I and the bound rows L, U. These rows determine the candidate subwindows and the rational lower and upper oscillation bounds visible to the packet.

Read the dyadic tolerance row D. A local modulus can be named only where D records the finite comparison between the requested tolerance and the displayed spread between L and U.

Next pass through S and R. The StreamName row opens the sampled windows and value names, while the RegSeqRat row records the regular rational approximants needed by the Real-facing read.

Finally consume the seal and structural rows E, H, C, P, N. The resulting modulus is local to the displayed finite packet and therefore cannot carry an ambient compactness theorem, a trichotomy decision, quotient equality, a selected extremum, an arbitrary subcover selector, or full Real completeness. □

Closure status for NameCert$_{\text{ConstructiveRealOscillationGauge}^{\uparrow}}$.

Constructive story: A ConstructiveRealOscillationGauge$^{\uparrow}$ packet is generated from interval windows, local lower and upper oscillation bounds, a DyadicRatCore tolerance ledger, StreamName readback, RegSeqRat regularity, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{ConstructiveRealOscillationGauge}^{\uparrow}}$, seed)

Scope closed: Definition 8432.1, Definition 8432.2, and Definition 8432.3 seed the finite local oscillation-control route from explicit interval windows to Real-seal consumers.

Formal verification: FormalStatus(NameCert$_{\text{ConstructiveRealOscillationGauge}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, trichotomy, quotient equality, selected suprema, arbitrary subcover selection, full Real$^{\uparrow}$ completeness, Lean verification, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window coherence, dyadic oscillation accounting, StreamName readback, RegSeqRat regularity, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.ConstructiveRealOscillationGaugeUp.

Chapter 8433

A Concrete Naming Certificate for $\mathsf{GoodCover}^{\uparrow}$

Following Leray's good-cover method and the Bott–Tu and Hatcher presentations of cover nerves, the $\mathsf{GoodCover}^{\uparrow}$ packet records the finite BEDC surface of a cover whose visible nonempty finite intersections are contractible along displayed rows. It sits between the open-cover carrier of chapter 6731, the finite open-cover nerve of chapter 7481, the finite cover nerve of chapter 7597, the compact cover nerve rows used by $\mathsf{CompactCoverNerve}^{\uparrow}$, and the Cech nerve packet of chapter 6755. The packet is a finite good-cover ledger; it is not the nerve theorem, not a selected homotopy equivalence, not an ambient triangulation theorem, and not host contractibility of arbitrary intersections.

Definition 8433.1 (Good-cover carrier)**.** *A* $\mathsf{GoodCover}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (T, O, F, I, K, N, S, H, C, P, L)$$

with the following displayed rows:

1. *T is the* $\mathsf{Topology}^{\uparrow}$ *source row naming the open-set ambient surface.*
2. *O is the* $\mathsf{OpenCover}^{\uparrow}$ *row giving the displayed cover members.*
3. *F is the* $\mathsf{FiniteOpenCover}^{\uparrow}$ *or finite cover row fixing the finite index window.*
4. *I is the finite-intersection ledger for every nonempty displayed subwindow of F.*
5. *K is the good-intersection row recording contractible-cell evidence for each nonempty entry of I.*
6. *N is the nerve-face row shared with* $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{CompactCoverNerve}^{\uparrow}$, *and* $\mathsf{CechNerve}^{\uparrow}$ *consumers.*
7. *S is the* $\mathsf{SimplicialComplex}^{\uparrow}$ *export row for the finite nerve faces.*
8. *H records componentwise* hsame *transport for the topology, cover, finite index, intersection, good-intersection, nerve, simplicial, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from finite cover reads through the intersection and nerve rows.*
10. *P is the* Pkg *provenance over* $\mathsf{GoodCover}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{OpenCover}^{\uparrow}$, $\mathsf{FiniteOpenCover}^{\uparrow}$, $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{CechNerve}^{\uparrow}$, $\mathsf{SimplicialComplex}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. L is the local $\mathsf{NameCert}_{\mathsf{GoodCover}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, O, F, I, K, N, S, H, C, P, L$. It has no coordinate for selected points in intersections, ambient homotopy equivalence, quotient realization equality, a global triangulation, open-cover compactness, or the nerve theorem.

Theorem 8433.2 (Good-cover NameCert obligations)**.** *For every accepted* $\mathsf{GoodCover}^{\uparrow}$ *carrier $G = (T, O, F, I, K, N, S, H, C, P, L)$, the local* $\mathsf{NameCert}_{\mathsf{GoodCover}^{\uparrow}}$ *surface consists exactly of topology-source exposure, open-cover exposure, finite index exposure, nonempty finite-intersection ledger exposure, good-intersection contractible-cell exposure, nerve-face exposure, simplicial-complex handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8433.1. Rows T, O, F expose the topological source, displayed cover, and finite index window before any intersection can be read.

The finite-intersection ledger I lists only displayed nonempty subwindows. The good-intersection row K attaches contractible-cell evidence to those ledger entries, and the nerve row N records the corresponding finite faces.

The simplicial export S is downstream of I, K, N. Transport, replay, provenance, and local naming are supplied by H, C, P, L, so no host nerve theorem, selected point, quotient realization, or global triangulation is part of the local certificate surface. □

Theorem 8433.3 (Good-cover finite-intersection nerve route)**.** *Every* $\mathsf{FiniteOpenCoverNerve}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{CompactCoverNerve}^{\uparrow}$, *or* $\mathsf{CechNerve}^{\uparrow}$ *consumer that reads an accepted* $\mathsf{GoodCover}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{Topology}^{\uparrow} \longmapsto \mathsf{OpenCover}^{\uparrow} \longmapsto \mathsf{FiniteOpenCover}^{\uparrow} \longmapsto I \longmapsto K \longmapsto N \longmapsto \mathsf{SimplicialComplex}^{\uparrow}.$$

The consumer receives only the displayed cover rows, finite-intersection rows, contractible-cell rows, nerve-face rows, transport, replay, provenance, and local $\mathsf{NameCert}$ *evidence. It does not receive the nerve theorem, an ambient homotopy equivalence, a selected realization map, arbitrary open-cover compactness, quotient point equality, or global homology computation.*

Proof. Start with the finite cover source. A nerve-facing consumer can read N only after the cover member rows O and finite index row F have been exposed over the topology row T.

Next read the intersection data. The ledger I records exactly the displayed nonempty finite intersections, while K records the good-cover evidence attached to those intersections. Thus the nerve face row is determined by finite ledger data rather than by a host compactness or choice principle.

Finally apply the structural rows H, C, P, L. They transport, replay, source, and name the same route into the finite-open-cover, finite-cover, compact-cover, and Cech nerve siblings. Since the carrier has no coordinate for a nerve theorem or ambient homotopy equivalence, the route stops at the displayed finite nerve and simplicial-complex surface. □

Falsifiable prediction: An accepted $\mathsf{GoodCover}^{\uparrow}$ consumer that exports a nerve-theorem equivalence while omitting the displayed finite-intersection ledger I or good-intersection row K is not reading this carrier.

Independence witness: open-cover, finite-open-cover-nerve, finite-cover-nerve, compact-cover-nerve, cech-nerve: none is bijective with $\mathsf{GoodCover}^{\uparrow}$ because this packet jointly carries finite cover rows, nonempty finite-intersection rows, good-intersection contractible-cell evidence, nerve-face

export, transport, replay, provenance, and local naming while refusing the nerve theorem and ambient realization equality.

Closure status for $\mathsf{NameCert}_{\mathsf{GoodCover}^{\uparrow}}$.

Constructive story: A $\mathsf{GoodCover}^{\uparrow}$ packet is generated from a TopologyUp source row, OpenCoverUp cover rows, a finite cover index, a finite-intersection ledger, good-intersection contractible-cell evidence, nerve-face rows, a SimplicialComplexUp export row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GoodCover}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8433.1, Definition 8433.2, and Definition 8433.3 seed the finite good-cover surface linking open-cover, finite-cover-nerve, compact-cover-nerve, and Cech nerve consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GoodCover}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close the nerve theorem, selected intersection points, ambient homotopy equivalence, quotient realization equality, global triangulation, host open-cover compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite cover exposure, intersection-ledger exactness, good-intersection evidence, nerve-face handoff, simplicial export, transport, replay, provenance, and local naming for BEDC.Derived.GoodCoverUp.

Chapter 8434

A Concrete Naming Certificate for $\mathsf{NormalizationBudgetTrace}^{\uparrow}$

The $\mathsf{NormalizationBudgetTrace}^{\uparrow}$ packet realizes the strong-normalization boundary of chapter 9370 as finite trace data for a total host reading a possibly universal substrate. It sits beside the step-indexed trace carrier of chapter 8123, the total-host fuel handoff of chapter 962, the reduction-fuel boundary of chapter 970, the MetaCIC normalization frontier of chapter 892, and the normalization audit map of chapter 9383. The packet names only finite fuel, finite prefix, endpoint, refusal, replay, provenance, and local naming rows; it does not assert global strong normalization, substrate halting, a divergence oracle, quotient trace equality, or host evaluation completeness.

Definition 8434.1 (Normalization budget trace carrier)**.** *A* $\mathsf{NormalizationBudgetTrace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (T, F, P, E, R, A, H, C, Q, N)$$

with the following displayed rows:

1. *T is the typed host term or substrate-state window being inspected.*
2. *F is the finite fuel row bounding the normalization read.*
3. *P is the finite prefix trace row produced under that fuel.*
4. *E is the endpoint row, recording either a displayed normal endpoint or the last bounded substrate state.*
5. *R is the refusal row for requests that ask for global strong normalization, unbounded halting, divergence detection, or evidence-free endpoint production.*
6. *A is the audit-route row linking the packet to chapter 9370 and chapter 9383.*
7. *H records componentwise* hsame *transport for the term, fuel, prefix, endpoint, refusal, audit, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the bounded fuel request through the finite prefix to the endpoint or refusal row.*
9. *Q is the* Pkg *provenance over* $\mathsf{NormalizationBudgetTrace}^{\uparrow}$, $\mathsf{StepIndexedTrace}^{\uparrow}$, $\mathsf{TotalHostFuelHandoff}^{\uparrow}$, $\mathsf{ReductionFuelBoundary}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{NormalizationBudgetTrace}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $T, F, P, E, R, A, H, C, Q, N$. It has no coordinate for an unbounded reduction, a host evaluator oracle, quotient trace equality, substrate halting, divergence detection, global strong normalization, or completed MetaCIC normalization.

Theorem 8434.2 (Normalization budget trace NameCert obligations)**.** *For every accepted* NormalizationBudgetTra *carrier $B = (T, F, P, E, R, A, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{NormalizationBudgetTrace}^{\uparrow}}$ *surface consists exactly of term-window exposure, finite fuel exposure, prefix-trace exposure, endpoint or bounded-state exposure, refusal-ledger exposure, audit-route exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8434.1. The rows T, F, P, E provide the only computational data: a term or substrate window, a finite fuel bound, a finite prefix, and the endpoint reached inside that bound.

The refusal row R records every request whose target is not carried by the finite packet. In particular, global strong normalization, unbounded substrate halting, divergence detection, and evidence-free endpoint production have no exported coordinate.

The audit row A places the bounded read inside the strong-normalization and MetaCIC audit routes. The structural rows H, C, Q, N transport, replay, source, and name that same finite route, so the listed rows exhaust the local NameCert surface. □

Theorem 8434.3 (Normalization budget trace total-host boundary)**.** *Every total-host or MetaCIC normalization consumer of an accepted* $\mathsf{NormalizationBudgetTrace}^{\uparrow}$ *packet factors through the finite route*

$$T \longmapsto F \longmapsto P \longmapsto E \longmapsto R \longmapsto A.$$

The consumer may read bounded fuel, a finite prefix, a displayed endpoint or bounded last state, the refusal ledger, the audit route, transport, replay, provenance, and local NameCert *evidence. It receives no global strong-normalization theorem, no substrate halting oracle, no divergence detector, no quotient trace equality, and no host evaluator completeness row.*

Proof. Start with the total-host discipline of the vision chapter. A BEDC consumer can inspect the substrate or MetaCIC normalization route only through a finite fuel row, so F must be displayed before any prefix or endpoint row is read.

Next read P and E. The prefix row records the bounded trace, and the endpoint row records only what is visible under that fuel. If the consumer asks beyond those rows, the request lands in the refusal ledger R rather than producing an unbounded normalization claim.

Finally use A, H, C, Q, N. The audit route keeps the packet attached to the strong-normalization and MetaCIC normalization maps, while transport, replay, provenance, and local naming preserve the same finite bounded trace. Since no carrier coordinate names halting, divergence, quotient trace equality, or evaluator completeness, the total-host boundary is exactly the displayed route. □

Falsifiable prediction: An accepted $\mathsf{NormalizationBudgetTrace}^{\uparrow}$ consumer that exports global strong normalization while omitting finite fuel F, finite prefix P, endpoint row E, or refusal row R is not reading this carrier.

Independence witness: step-indexed-trace, totalhostfuelhandoff, reductionfuelboundary, metacicnormalizationfrontier, metacic-normalization-audit-map: no listed sibling is bijective with NormalizationBudgetTra because this packet jointly carries the term window, finite fuel, prefix trace, endpoint row, refusal ledger, audit route, transport, replay, provenance, and local naming as one bounded total-host trace.

Closure status for $\mathsf{NameCert}_{\mathsf{NormalizationBudgetTrace}^{\uparrow}}$.

Constructive story: A $\mathsf{NormalizationBudgetTrace}^{\uparrow}$ packet is generated from a typed host or substrate-state window, finite fuel, finite prefix trace, endpoint or bounded-state row, refusal ledger, audit-route row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NormalizationBudgetTrace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8434.1, Definition 8434.2, and Definition 8434.3 seed the finite total-host budget trace for normalization and substrate-boundary consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NormalizationBudgetTrace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global strong normalization, unbounded substrate halting, divergence detection, quotient trace equality, host evaluator completeness, completed MetaCIC normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, fuel exposure, prefix exactness, endpoint or refusal exactness, audit-route handoff, transport, replay, provenance, and local naming for BEDC.Derived.NormalizationBudgetTraceUp.

Chapter 8435

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealFunction}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedRealFunction}^{\uparrow}$ packet records a located real-valued function as displayed finite input-location requests and regular real output rows, not as a host function or quotient map. It sits between the terminal real-name seal of chapter 38, the located real input boundary of chapter 1933, the regular rational readback of chapter 301, the finite observation interface of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet gives Real and Completion consumers a function-facing surface whose inputs, output approximants, tolerances, transports, and local name remain finite BEDC rows.

Definition 8435.1 (Bishop located real function carrier)**.** *A* $\mathsf{BishopLocatedRealFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, Q, L, D, S, R, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the input real-name row, opened only through the* $\mathsf{Real}^{\uparrow}$ *seal named by the packet.*
2. *Q is the locatedness request row, sourced through* $\mathsf{LocatedReal}^{\uparrow}$*, that records the finite positive/negative separation tests allowed for the input.*
3. *L is the local input-window ledger. It records which located input cells are served by the packet and which tolerance request each cell answers.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for the input request, output request, slack, and comparison budget.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation window opened before the output is read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to S and D.*
7. *O is the displayed output real-name seal reached only after Q, L, D, S, R have been exposed.*
8. *H records componentwise* hsame *transport for the input seal, locatedness requests, local windows, dyadic tolerances, StreamName windows, RegSeqRat readback, output seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a located input request through the same rows.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealFunction}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{LocatedReal}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFunction}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, Q, L, D, S, R, O, H, C, P, N$. It has no coordinate for general continuity, ambient $\mathsf{Real}^{\uparrow}$ *completeness, host function equality, quotient equality of real names, countable choice, or a selected global modulus.*

Theorem 8435.2 (Bishop located real function NameCert obligations)**.** *For every accepted* BishopLocatedRealFunc *carrier*

$$F = (X, Q, L, D, S, R, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, located-input admission through Q, local window exactness through L, dyadic tolerance accounting through D, StreamName window exactness through S, RegSeqRat output readback through R, output Real-seal nonescape through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 8435.1. The packet exposes exactly the input seal, locatedness request row, local input-window ledger, dyadic tolerance ledger, StreamName window, RegSeqRat readback, output seal, transport, replay, provenance, and local name.

The located-input obligations are read through Q, L, D. The locatedness row Q determines which finite input separation tests are allowed, L records the served local windows, and D fixes the tolerance and comparison budget for those requests.

The output obligations are read through S, R, O. StreamName opens only finite observations, RegSeqRat records the regular rational output approximants attached to those observations, and the output Real seal is downstream of that readback.

Finally H, C, P, N preserve and name the same route. Since no coordinate stores general continuity, host function equality, quotient equality, countable choice, a selected global modulus, or ambient Real completeness, none of those principles is exported by the local NameCert surface. □

Theorem 8435.3 (Bishop located real function located-output stability)**.** *Every accepted* BishopLocatedRealFunctio *read that serves a located input request through*

$$F = (X, Q, L, D, S, R, O, H, C, P, N)$$

must expose the same located input row Q, local window ledger L, dyadic tolerance ledger D, finite StreamName window S, RegSeqRat readback R, and output Real seal O before the output value is consumed. Refining a served input window may add displayed rows inside L, S, R, but the public output read remains the same packet route through H, C, P, N and cannot be presented as a host function value, quotient equality class, selected limit, general continuity theorem, or completeness witness.

Proof. Start with the located input request. Row Q supplies the locatedness data, while L records the finite input windows to which the packet responds.

Read the dyadic tolerance ledger D. It fixes the input and output precision budget, so a refinement must remain inside the displayed comparison route rather than changing the function packet.

Next pass through S, R, O. The StreamName and RegSeqRat rows expose finite output approximants, and the terminal Real seal is consumed only after those rows are visible.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Therefore a located-output read is stable under displayed finite refinement, but it never becomes host function equality, quotient equality, general continuity, selected completion data, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealFunction}^{\uparrow}$ packet is generated from a RealUp input seal, LocatedRealUp request rows, local input windows, a DyadicRatCoreUp tolerance ledger, StreamNameUp finite windows, RegSeqRatUp output readback, a RealUp output seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8435.1, Definition 8435.2, and Definition 8435.3 seed the located real-valued function packet over displayed RealUp, LocatedRealUp, RegSeqRatUp, StreamNameUp, DyadicRatCoreUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealFunction}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.BishopLocatedRealFunctionUp`

Bridge status: none

Not claimed: This chapter does not claim general continuity, ambient $\mathsf{Real}^{\uparrow}$ completeness, host function equality, quotient equality of real names, countable choice, selected limits, Lean theorem checking, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located-input admission, local window exactness, dyadic tolerance accounting, StreamName window exactness, RegSeqRat output readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealFunctionUp.

Chapter 8436

A Concrete Naming Certificate for $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$

Following Grothendieck's Tohoku paper and Weibel's homological algebra account, the GrothendieckSpectralSequenc packet records the finite NameCert surface for the classical composite-derived-functor spectral sequence. It sits after the abelian-category carrier of chapter 176, the category, functor, and natural-transformation rows of chapter 61, chapter 62, and chapter 63, the derived-functor spine of chapter 177, and the page ledger of chapter 178. The packet names only the displayed composite-functor source, acyclicity ledger, page rows, filtration target, transport, replay, provenance, and local naming data; it is not a host proof of the full Grothendieck spectral sequence and does not claim convergence beyond the finite route recorded below.

Definition 8436.1 (Grothendieck spectral sequence carrier)**.** *A* $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, C, F, G_0, \eta, D, E, P, T, H, R, Q, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row in which exactness, injective or acyclic resolutions, and homology reads are interpreted.*
2. *C is the* $\mathsf{Cat}^{\uparrow}$ *dependency row for the source, middle, and target categories of the composite construction.*
3. *F and G_0 are the two* $\mathsf{Functor}^{\uparrow}$ *rows whose composite is being inspected.*
4. *η is the* $\mathsf{NatTrans}^{\uparrow}$ *comparison row recording the displayed compatibility data used by the composite-functor route.*
5. *D is the* $\mathsf{DerivedFunctor}^{\uparrow}$ *row for the inner and outer derived-functor reads, including the resolution, degree, cycle-boundary, and* Cont *ledgers visible to downstream consumers.*
6. *E is the* $\mathsf{SpectralSeq}^{\uparrow}$ *page row, carrying the displayed E_2 page, differential rows, successor-page route, and filtration readback boundary.*
7. *P is the finite acyclicity and resolution-compatibility ledger that allows the inner derived-functor row to feed the outer derived-functor row.*
8. *T is the target filtration row, recording only the displayed filtration boundary of the composite derived functor.*

9. *H records componentwise* hsame *transport for the abelian, category, functor, natural-transformation, derived-functor, spectral-sequence, acyclicity, target-filtration, replay, provenance, and local naming rows.*
10. *R records displayed* Cont *replay from the composite source through F, G_0, η, D, P, E, T.*
11. *Q is the* Pkg *provenance over* $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{DerivedFunctor}^{\uparrow}$, $\mathsf{SpectralSeq}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{GrothendieckSpectralSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, C, F, G_0, \eta, D, E, P, T, H, R, Q, N$. It has no coordinate for host derived-category equality, a global convergence theorem, chosen resolutions outside the displayed ledger, exactness beyond the acyclicity row, or quotient equality of pages.

Theorem 8436.2 (Grothendieck spectral sequence NameCert obligations)**.** *For every accepted* $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$ *carrier $G = (A, C, F, G_0, \eta, D, E, P, T, H, R, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{GrothendieckSpec}}$ *surface consists exactly of carrier admission for those thirteen rows; source exposure through* $\mathsf{AbelianCat}^{\uparrow}$ *and* $\mathsf{Cat}^{\uparrow}$*; functorial exposure through the two* $\mathsf{Functor}^{\uparrow}$ *rows and the* $\mathsf{NatTrans}^{\uparrow}$ *comparison row; derived-functor exposure through D; spectral-sequence page exposure through E; acyclicity and resolution compatibility through P; target-filtration exposure through T; componentwise* hsame *transport through H; displayed* Cont *replay through R;* Pkg *provenance through Q; and local naming through N.*

Proof. Project the carrier of Definition 8436.1. The only source rows are A, C, F, G_0, η, and the only homological rows are D, E, P, T.

Read the functorial source first. The category and abelian-category rows type the two functors and the natural-transformation comparison, so the composite route is a displayed BEDC route rather than an ambient functor category.

Next read the homological ledger. The derived-functor row D supplies the inner and outer derived reads, P records the acyclicity and resolution-compatibility budget, E records the spectral-sequence page ledger, and T records the target filtration boundary.

Finally use H, R, Q, N. Transport, replay, provenance, and local naming preserve exactly those displayed rows. Since no carrier coordinate stores a host convergence theorem, chosen external resolution, derived-category equality, or quotient page equality, those data are not NameCert obligations of the packet. □

Theorem 8436.3 (Grothendieck spectral sequence derived-functor route)**.** *Every derived-functor consumer of an accepted* $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$ *packet must factor through the finite route*

$$\mathsf{AbelianCat}^{\uparrow},\ \mathsf{Cat}^{\uparrow},\ \mathsf{Functor}^{\uparrow},\ \mathsf{NatTrans}^{\uparrow} \longmapsto \mathsf{DerivedFunctor}^{\uparrow} \longmapsto \mathsf{SpectralSeq}^{\uparrow} \longmapsto T, H, R, Q, N.$$

The route exposes the composite source, the acyclicity ledger, the page ledger, and the target-filtration boundary before any derived-functor output is read. It does not export a host Grothendieck spectral sequence theorem, global convergence assertion, selected resolution outside P, or quotient equality of spectral-sequence pages.

Proof. Begin with the NameCert obligations of Definition 8436.2. They force every read through the abelian and categorical source rows, the two functor rows, and the natural-transformation comparison row before any derived-functor or spectral-sequence row is consumed.

The derived-functor handoff is then the row D. It is scoped by the existing $\mathsf{DerivedFunctor}^{\uparrow}$ surface and by the acyclicity and resolution-compatibility row P, so the consumer receives only displayed resolution, degree, cycle-boundary, and continuation ledgers.

The spectral-sequence handoff is the row E, followed by the target filtration row T. These rows are read through the existing $\mathsf{SpectralSeq}^{\uparrow}$ page ledger and do not add a separate convergence theorem.

Finally H, R, Q, N preserve, replay, source, and name the same route. Thus the accepted consumer sees a finite composite-derived-functor packet and no unlisted host-level exactness or convergence data. □

Falsifiable prediction: Every accepted $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$ consumer that reads a target-filtration row must first expose the $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{DerivedFunctor}^{\uparrow}$, $\mathsf{SpectralSeq}^{\uparrow}$, acyclicity, BHist, hsame, Cont, Pkg, and NameCert rows listed in the carrier.

Independence witness: abelian category, category, functor, natural transformation, derived functor, spectral sequence: none is bijective to $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$, because this packet binds the composite-functor source, acyclicity ledger, derived-functor handoff, page ledger, and target-filtration boundary into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{GrothendieckSpectralSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{GrothendieckSpectralSequence}^{\uparrow}$ packet is generated from AbelianCatUp source rows, CategoryUp source rows, two FunctorUp rows, a NatTransUp comparison row, a DerivedFunctorUp handoff, a SpectralSeqUp page ledger, an acyclicity and resolution-compatibility ledger, a target-filtration row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GrothendieckSpectralSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8436.1, Definition 8436.2, and Definition 8436.3 seed the finite composite-derived-functor spectral-sequence route over the displayed dependency rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GrothendieckSpectralSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host derived-category equality, a full Grothendieck spectral sequence theorem, global convergence, selected external resolutions, quotient page equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, composite-functor source exposure, acyclicity-ledger exactness, derived-functor handoff, spectral-sequence page routing, target-filtration nonescape, transport, replay, provenance, and local naming for BEDC.Derived.GrothendieckSpectralSequenceUp.

Chapter 8437

A Concrete Naming Certificate for RegularCauchyCompactnessCriterion$^{\uparrow}$

Following Bishop and Bridges constructive compactness criteria, the RegularCauchyCompactnessCriterion$^{\uparrow}$ packet records the finite route by which regular Cauchy real data are admitted to a compactness read. It sits after the finite window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, the interval finite-net surface of chapter 1379, and the finite Cauchy completion criterion of chapter 8429. The packet names a criterion surface for Real and Completion consumers; it does not import sequential compactness, open-cover compactness, quotient stream equality, selected cluster points, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8437.1 (Regular Cauchy compactness criterion carrier)**.** *A* RegularCauchyCompactnessCriterion$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, Q, D, R, C, W, H, P, N)$$

with the following displayed rows:

1. *S is the* StreamName$^{\uparrow}$ *finite-window row that records which name windows are inspected before the compactness read.*
2. *Q is the* RegSeqRat$^{\uparrow}$ *readback row for the regular rational data exposed by those windows.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row controlling mesh size, Cauchy radius, and comparison budget.*
4. *R is the terminal* Real$^{\uparrow}$ *seal row reached only after S, Q, D have been displayed.*
5. *C is the compact finite-window witness row, read through the public finite-net interval export of chapter 1379.*
6. *W is the finite-window extraction row that records the inspected window and net-cell data consumed by a compactness query.*
7. *H records componentwise* hsame *transport for S, Q, D, R, C, W, P, N.*
8. *P is the displayed* Cont *replay and* Pkg *provenance over* RegularCauchyCompactnessCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, HeineBorelInterval$^{\uparrow}$, FiniteCauchyCompletenessCriterion$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}}$ *row.*
The carrier predicate asserts exactly that the compactness criterion is read from these finite rows. It has no coordinate for sequential compactness, open-cover compactness, a selected subsequence, a selected cluster point, quotient equality of real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8437.2 (Regular Cauchy compactness criterion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}$ *carrier* $K = (S, Q, D, R, C, W, H, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row,* $\mathsf{Real}^{\uparrow}$ *seal row, compact finite-window witness row, finite-window extraction row, componentwise* hsame *transport, displayed* Cont *replay with* Pkg *provenance, and local naming. No obligation row may be discharged by host compactness, sequential compactness, open-cover compactness, quotient stream equality, selected representatives, countable choice, or ambient Real completeness.*

Proof. Project the carrier of Definition 8437.1. Its displayed coordinates are exactly $S, Q, D, R, C, W, H, P, N$, so carrier admission and local naming can only inspect those rows.

Read the L10 source rows in order. The finite windows S expose the regular rational readback Q, the dyadic tolerance row D controls the Cauchy and mesh budgets, and the terminal real seal R is downstream of those displayed rows.

Now read the compactness side. The row C is a compact finite-window witness through the Heine–Borel interval finite-net surface, and W records the actual extraction window consumed by the query. Transport, replay, provenance, and local naming preserve that same finite route, so the excluded compactness and choice principles have no carrier coordinate. □

Theorem 8437.3 (Regular Cauchy compactness criterion finite-window extraction)**.** *Every compactness read of an accepted* $\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}$ *carrier factors through the finite extraction route*

$$S, Q, D, R, C, W, H, P, N.$$

In particular, the read consumes StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, the Real seal, the Heine–Borel finite-net witness, the displayed extraction window, transport, replay, provenance, and local naming before it can expose compactness data. It is therefore a finite-window extraction, not sequential compactness, not open-cover compactness, and not an appeal to ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8437.2. They identify the complete local surface of an accepted carrier, so a compactness read cannot leave the rows $S, Q, D, R, C, W, H, P, N$.

Use the Real-facing route next. Rows S, Q, D provide finite observation, regular rational readback, and tolerance accounting before the terminal seal R is available.

Finally apply the compact finite-net rows C, W. The public finite-net interval export supplies the compact witness as displayed net data, while W records the finite extraction actually inspected by the consumer. Since neither row contains a selected subsequence, an open-cover subcover choice, quotient stream equality, or an ambient completeness theorem, the compactness read is exactly the stated finite-window extraction. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularCauchyCompactnessCriterion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a terminal RealUp seal, a compact finite-window witness, a finite-window extraction row, componentwise hsame transport, displayed Cont replay with Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyCompactnessCriterion}\uparrow}$, seed)

Scope closed: Definition 8437.1, Definition 8437.2, and Definition 8437.3 seed the finite compactness criterion route over StreamName, RegSeqRat, DyadicRatCore, Real, Heine–Borel interval, and finite Cauchy completion data.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyCompactnessCriterion}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim sequential compactness, open-cover compactness, selected subcovers, selected cluster points, quotient equality of real names, countable choice, Lean verification, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exactness, regular rational read-back, dyadic tolerance accounting, Real seal routing, Heine–Borel finite-net handoff, finite Cauchy completion handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyCompactnessCriterionUp.

Chapter 8438

A Concrete Naming Certificate for $\mathsf{SpectralSequenceComparison}^{\uparrow}$

Following Weibel and McCleary on spectral-sequence comparison theorems, the $\mathsf{SpectralSequenceComparison}^{\uparrow}$ packet records the finite NameCert surface by which displayed page data in $\mathsf{SpectralSeq}^{\uparrow}$ can be compared before any downstream derived-functor spectral-sequence consumer reads it. It sits after the spectral-sequence page carrier of chapter 178, the homology carrier of chapter 98, the abelian-category carrier of chapter 176, the derived-functor spine of chapter 177, and the composite-derived-functor packet of chapter 8436. The packet names only the displayed source pages, comparison rows, page-stability ledger, filtration boundary, transport, replay, provenance, and local naming data; it does not claim convergence, exactness beyond the recorded rows, or a host-level comparison theorem.

Definition 8438.1 (Spectral sequence comparison carrier)**.** *A* $\mathsf{SpectralSequenceComparison}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$C = (S_0, S_1, H_0, A, D, F, L, T, R, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two* $\mathsf{SpectralSeq}^{\uparrow}$ *page carriers being compared, including their page objects, differential rows, successor-page routes, and filtration readback boundaries.*
2. *H_0 is the* $\mathsf{Homology}^{\uparrow}$ *readback row for the pagewise cycles, boundaries, and induced homology rows visible in the comparison.*
3. *A is the* $\mathsf{AbelianCat}^{\uparrow}$ *source row in which the page objects, differentials, and homology reads are interpreted.*
4. *D is the* $\mathsf{DerivedFunctor}^{\uparrow}$ *consumer row that records how the compared pages feed derived-functor data.*
5. *F is the pagewise comparison row, listing the displayed maps or rowwise* hsame *transports used between corresponding page entries.*
6. *L is the finite page-stability ledger. It records the range of pages, bidegrees, differential compatibility checks, and filtration-boundary agreements that are actually inspected.*
7. *T records componentwise* hsame *transport for $S_0, S_1, H_0, A, D, F, L$ and the structural rows.*

8. *R records displayed* Cont *replay from the source page rows through the comparison row and the page-stability ledger.*
9. *P is the* Pkg *provenance over* SpectralSequenceComparison$^{\uparrow}$, SpectralSeq$^{\uparrow}$, Homology$^{\uparrow}$, AbelianCat$^{\uparrow}$, DerivedFunctor$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* NameCert$_{\text{SpectralSequenceComparison}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S_0, S_1, H_0, A, D, F, L, T, R, P, N$. It has no coordinate for global convergence, an ambient equality of spectral sequences, quotient equality of pages, selected resolutions, exact-couple data not displayed in L, or a host comparison theorem.

Theorem 8438.2 (Spectral sequence comparison NameCert obligations)**.** *For every accepted* SpectralSequenceComparison$^{\uparrow}$ *carrier $C = (S_0, S_1, H_0, A, D, F, L, T, R, P, N)$, the local* NameCert$_{\text{SpectralSequenceCompar}}$ *surface consists exactly of carrier admission for those eleven rows; page exposure through the two* SpectralSeq$^{\uparrow}$ *rows; homology readback through H_0; abelian source exposure through A; derived-functor consumer exposure through D; displayed pagewise comparison through F; page-stability and filtration-boundary exposure through L; componentwise* hsame *transport through T; displayed* Cont *replay through R;* Pkg *provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8438.1. Its only spectral-sequence inputs are the displayed page rows S_0 and S_1, and its only ambient source rows are H_0, A, D.

Read the pagewise comparison next. The row F lists the inspected maps or transports between corresponding page entries, while L records the finite page range, bidegree range, differential compatibility checks, and filtration-boundary agreements used by the comparison.

Finally use T, R, P, N. Transport, replay, provenance, and local naming preserve exactly the listed rows. Since no coordinate stores a global convergence theorem, ambient equality of spectral sequences, quotient page equality, selected resolution, or host comparison theorem, none of those data is a NameCert obligation of the packet. □

Theorem 8438.3 (Spectral sequence comparison page stability)**.** *Every downstream* DerivedFunctor$^{\uparrow}$ *or* GrothendieckSpectralSequence$^{\uparrow}$ *consumer of an accepted* SpectralSequenceComparison$^{\uparrow}$ *packet must read the finite route*

$$S_0, S_1, H_0, A \longmapsto F, L \longmapsto D, T, R, P, N$$

before it may use the comparison as page-stability data. The route exposes the two SpectralSeq$^{\uparrow}$ *page carriers, homology readback, abelian source row, pagewise comparison row, and stability ledger before any derived-functor or composite-derived-functor consumer reads the result. It exports no convergence theorem, quotient equality of pages, selected external resolution, countable choice, or ambient spectral-sequence equality.*

Proof. Begin with the NameCert obligations of Definition 8438.2. They force every comparison read to expose the two spectral-sequence page packets, the homology readback row, and the abelian source row before the derived-functor consumer row is available.

The comparison data is then finite. The row F supplies the displayed pagewise maps or transports, and L records the inspected page range, bidegree range, differential compatibility, and filtration-boundary agreement. A downstream consumer therefore receives a stability ledger rather than an unbounded comparison theorem.

Finally replay the structural rows T, R, P, N. These rows transport and name the same finite packet for DerivedFunctor$^{\uparrow}$ and GrothendieckSpectralSequence$^{\uparrow}$ consumers, so the public route has no coordinate for convergence, quotient page equality, selected resolutions, countable choice, or ambient spectral-sequence equality. □

Falsifiable prediction: Every accepted $\mathsf{SpectralSequenceComparison}^{\uparrow}$ consumer that reads page-stability data must first expose the two $\mathsf{SpectralSeq}^{\uparrow}$ page carriers, $\mathsf{Homology}^{\uparrow}$, $\mathsf{AbelianCat}^{\uparrow}$, $\mathsf{DerivedFunctor}^{\uparrow}$, comparison, stability-ledger, BHist, hsame, Cont, Pkg, and NameCert rows listed in the carrier.

Independence witness: spectral sequence, homology, abelian category, derived functor, Grothendieck spectral sequence: none is bijective to $\mathsf{SpectralSequenceComparison}^{\uparrow}$, because this packet binds two page carriers, homology readback, abelian source data, a pagewise comparison row, a finite stability ledger, and a derived-functor handoff into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SpectralSequenceComparison}^{\uparrow}}$.

Constructive story: A $\mathsf{SpectralSequenceComparison}^{\uparrow}$ packet is generated from two SpectralSeqUp page rows, HomologyUp readback, an AbelianCatUp source row, a DerivedFunctorUp consumer row, a pagewise comparison row, a finite page-stability ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{SpectralSequenceComparison}^{\uparrow}}$, seed)

Scope closed: Definition 8438.1, Definition 8438.2, and Definition 8438.3 seed the finite comparison route over displayed spectral-sequence page data.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{SpectralSequenceComparison}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim convergence, a host spectral-sequence comparison theorem, quotient page equality, selected external resolutions, countable choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, page exposure, homology readback, abelian source exposure, derived-functor handoff, pagewise comparison, page-stability routing, transport, replay, provenance, and local naming for BEDC.Derived.SpectralSequenceComparisonUp.

Chapter 8439

A Concrete Naming Certificate for $\mathsf{BrouwerChoiceSequence}^{\uparrow}$

Following Brouwer and Bishop–Bridges, the $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ packet records finite displayed choice-sequence data routed through Brouwer spread admission and the L10 countable-name surfaces. It sits between the choice-sequence surface of chapter 1482, the spread-prefix discipline of chapter 1677, the finite stream-name interface of chapter 126, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet gives Real and Completion consumers a displayed finite bridge from choice-sequence observations to spread-admissible name reads without importing countable choice, quotient streams, selected infinite branches, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8439.1 (Brouwer choice-sequence carrier)**.** *A* $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, A, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite schedule row listing the choice-sequence questions and precision requests that have been opened.*
2. *W is the displayed prefix-window row, recording only the finite choice-sequence answers visible to the packet.*
3. *A is the answer-ledger row, pairing every displayed question in S with its answer in W.*
4. *T is the* $\mathsf{BrouwerSpread}^{\uparrow}$ *admissibility row, certifying that the displayed prefix window is accepted by the spread route before any downstream read occurs.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the admitted prefix window and its finite stream-name handoff.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, A, T, R have been displayed.*
7. *H records componentwise* hsame *transport for the schedule, prefix window, answer ledger, spread-admissibility, readback, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay for opening the choice-sequence window, checking spread admission, handing the window to* $\mathsf{StreamName}^{\uparrow}$*, reading* $\mathsf{RegSeqRat}^{\uparrow}$*, and sealing through* $\mathsf{Real}^{\uparrow}$*.*
9. *P is the* Pkg *provenance over* $\mathsf{BrouwerChoiceSequence}^{\uparrow}$*,* $\mathsf{ChoiceSequence}^{\uparrow}$*,* $\mathsf{BrouwerSpread}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerChoiceSequence}^{\uparrow}}$ *row.*

The local classifier compares accepted carriers only through $S, W, A, T, R, E, H, C, P, N$. It has no coordinate for a completed host function, quotient stream equality, countable choice, a selected infinite branch, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8439.2 (Brouwer choice-sequence NameCert obligations)**.** *For the carrier of Definition 8439.1, the local* $\mathsf{NameCert}_{\mathsf{BrouwerChoiceSequence}^{\uparrow}}$ *surface consists of nine finite obligations:*

1. *carrier admission exposes exactly the rows $S, W, A, T, R, E, H, C, P, N$;*
2. *prefix stability preserves the visible window W and answer ledger A under later finite schedule extension;*
3. *spread admissibility reads the* $\mathsf{BrouwerSpread}^{\uparrow}$ *row T before any stream-name or regular-rational handoff;*
4. *StreamName handoff consumes only the displayed finite prefix window and answer ledger;*
5. *RegSeqRat and Real boundary rows expose R before the terminal seal E;*
6. *componentwise transport preserves S, W, A, T, R, E along H;*
7. *continuation replay reads the same finite route through C;*
8. *provenance records the choice-sequence, spread, stream-name, regular-rational, and Real siblings through P;*
9. *the ledger refuses completed host functions, quotient streams, countable choice, selected infinite branches, and ambient Real completeness as certificate data.*

Proof. Carrier admission is projection from Definition 8439.1. The displayed packet has exactly the schedule, prefix-window, answer-ledger, spread-admissibility, readback, seal, transport, replay, provenance, and local naming rows.

Prefix stability follows from the classifier. Since S, W, A are visible rows and no hidden tail coordinate exists, later finite inspection can preserve the already displayed prefix only by preserving those rows.

Spread admissibility and the StreamName handoff are read in order through T and then the finite window data. The regular-rational row R and terminal seal E are downstream of that admitted route.

Finally, H, C, P, N provide transport, replay, provenance, and local naming for the same finite packet. The refusal clause is the absence of any coordinate for completed host functions, quotient streams, countable choice, selected infinite branches, or ambient Real completeness. □

Theorem 8439.3 (Brouwer choice-sequence spread-stream handoff)**.** *Every consumer of an accepted* $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ *carrier first reads the* $\mathsf{ChoiceSequence}^{\uparrow}$ *rows S, W, A and the* $\mathsf{BrouwerSpread}^{\uparrow}$ *row T before any* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *handoff is public. The downstream route is therefore*

$$\mathsf{ChoiceSequence}^{\uparrow} \longmapsto \mathsf{BrouwerSpread}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow},$$

with the concrete packet rows $S, W, A, T, R, E, H, C, P, N$ displayed along the way.

Proof. Start with the NameCert obligations of Definition 8439.2. They require carrier admission, prefix stability, and spread admissibility before the stream-name handoff is consumed.

The carrier definition places R after the admitted spread row and makes E a terminal seal after the regular-rational readback. Thus a Real-facing consumer cannot reach E without first reading S, W, A, T, R.

The transport, replay, provenance, and local naming rows preserve the same order for every consumer. Hence the handoff factors through the displayed choice-sequence and Brouwer-spread rows before StreamName, RegSeqRat, or Real data become public. □

Falsifiable prediction: An accepted $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ read is refuted if it reaches $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ data without first displaying the finite choice-sequence rows S, W, A and the $\mathsf{BrouwerSpread}^{\uparrow}$ admissibility row T.

Independence witness: choice-sequence, brouwer-spread, streamname, regseqrat, real: $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ is not bijective to any sibling because it binds finite choice-sequence questions, displayed answers, spread-prefix admission, L10 countable-name handoff, regular-rational readback, Real sealing, transport, replay, provenance, and local NameCert rows in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerChoiceSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerChoiceSequence}^{\uparrow}$ packet is generated from finite choice-sequence schedule rows, displayed prefix windows, answer ledgers, BrouwerSpread admission, StreamName handoff, RegSeqRat readback, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerChoiceSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8439.1, Definition 8439.2, and Definition 8439.3 seed the finite route from displayed choice-sequence prefixes through Brouwer spread admission, StreamName handoff, RegSeqRat readback, and Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerChoiceSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close completed host functions, quotient stream equality, countable choice, selected infinite branches, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix stability, spread admissibility, StreamName handoff, RegSeqRat and Real boundary, transport, replay, provenance, and local naming for BEDC.Derived.BrouwerChoiceSequenceUp.

Lean4 (statement) `BEDC.Derived.BrouwerChoiceSequenceUp`

Chapter 8440

A Concrete Naming Certificate for $\mathsf{TotallyBoundedReflection}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{TotallyBoundedReflection}^{\uparrow}$ packet records the finite precompact-reflection surface by which a uniform carrier exposes total-bounded schedules before any completion or compactness consumer reads it. It sits over the uniform source of chapter 339, the entourage basis of chapter 1819, the finite-net surface of chapter 127, the stream observation rows of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a finite reflection carrier for later completion and compact-metric routes; it does not assert open-cover compactness, a selected Cauchy limit, quotient equality, countable choice, or ambient completeness.

Definition 8440.1 (Totally bounded reflection carrier)**.** *A* $\mathsf{TotallyBoundedReflection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (U, E, T, S, Q, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *source row whose uniform carrier is being reflected.*
2. *E is the* $\mathsf{EntourageBase}^{\uparrow}$ *row naming the finite entourage requests available to downstream consumers.*
3. *T is the* $\mathsf{TotallyBounded}^{\uparrow}$ *finite-net schedule for each displayed entourage request.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *observation row recording the finite stream windows by which net centers and coverage witnesses are inspected.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same observation windows when rational radii or distances must be read.*
6. *A is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the entourage, net, stream, and regular-rational rows have been displayed.*
7. *H records componentwise* hsame *transport for $U, E, T, S, Q, A, C, P, N$.*
8. *C records displayed* Cont *replay from a precompact-reflection request through U, E, T, S, Q, A and then through the support rows.*
9. *P is the* Pkg *provenance over* $\mathsf{TotallyBoundedReflection}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{TotallyBoundedReflection}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through the displayed tuple $U, E, T, S, Q, A, H, C, P, N$. It has no coordinate for open-cover compactness, a selected completion point, quotient real equality, countable choice, or ambient complete uniform space data.

Theorem 8440.2 (Totally bounded reflection NameCert obligations)**.** *For every accepted* TotallyBoundedReflection *carrier*

$$R = (U, E, T, S, Q, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TotallyBoundedReflection}^{\uparrow}}$ *surface consists exactly of uniform-source admission, entourage-basis exposure, total-bounded finite-net scheduling, stream-window inspection, regular-rational readback, Real seal non-escape, componentwise transport, displayed replay, provenance, and local naming. Every completion-facing or compact-metric consumer must read $U, E, T, S, Q, A, H, C, P, N$ before it treats the source as precompact.*

Proof. Project the carrier of Definition 8440.1. The rows U, E, T expose the uniform source, the entourage basis, and the finite total-bounded schedules before any reflected route can be consumed.

The stream and regular-rational rows S, Q provide the only observation and radius readback interface. The Real seal row A is downstream of those rows, so a consumer cannot replace the displayed net schedule by quotient real equality or by a selected completion point.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no carrier coordinate stores open-cover compactness, a choice-selected subcover, countable choice, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{TotallyBoundedReflection}^{\uparrow}$ consumer that exports a precompact reflection must display the $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{EntourageBase}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, transport, replay, provenance, and local NameCert rows.

Independence witness: uniformspace, entourage-base, totallybounded, streamname, regseqrat, real: no listed sibling is bijective to $\mathsf{TotallyBoundedReflection}^{\uparrow}$ because this packet jointly binds a uniform carrier, entourage requests, finite-net schedules, stream windows, regular-rational readback, Real seal non-escape, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedReflection}^{\uparrow}}$.

Constructive story: A $\mathsf{TotallyBoundedReflection}^{\uparrow}$ packet is generated from UniformSpace source data, EntourageBase request rows, TotallyBounded finite-net schedules, StreamName observation windows, RegSeqRat readback, a Real seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{TotallyBoundedReflection}^{\uparrow}}$, seed)

Scope closed: Definition 8440.1 and Definition 8440.2 seed the finite precompact-reflection surface for later completion and compact-metric consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{TotallyBoundedReflection}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, selected completion points, quotient real equality, countable choice, Lean verification, bridge checking, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, entourage-basis exposure, finite-net scheduling, stream-window inspection, regular-rational readback, Real seal non-escape, transport, replay, provenance, and local naming for BEDC.Derived.TotallyBoundedReflectionUp.

Chapter 8441

A Concrete Naming Certificate for $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed located upper-cut presentation may be read through regular Cauchy and Real-seal data without turning that read into a Dedekind construction or an ambient completeness principle. It sits over the located-cut real route of chapter 3773, the two-sided located Dedekind cut packet of chapter 7256, the regular-Cauchy located-cut handoff of chapter 7018, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a local upper-cut criterion for Real and Completion consumers; it does not construct a Dedekind real, select a quotient-completion limit, or assert trichotomy.

Definition 8441.1 (Bishop located upper-cut criterion carrier)**.** *A* $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (L, A, D, I, Q, R, S, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-cut row, listing the finite lower observations used by the criterion and the downward-closure witnesses actually opened by the request.*
2. *A is the upper-cut row, listing the finite upper observations, upper stability cells, and upper-side witnesses used by the criterion.*
3. *D is the locatedness witness row. For each displayed interval request $a < b$, it records the local decision that either a lower observation lies below b or an upper observation lies above a.*
4. *I is the dyadic interval-test row over* $\mathsf{DyadicRatCore}^{\uparrow}$*, carrying endpoint cells, radius cells, comparison slack, and the finite gap requests consumed by D.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *compatibility row, exposing the regular rational readback that compares the cut observations against the displayed dyadic tests.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after L, A, D, I, Q have been displayed.*
7. *S records the handoff route from the regular-Cauchy located-cut surface to the terminal Real seal.*

8. *H stores componentwise* hsame *transport for lower rows, upper rows, locatedness witnesses, dyadic tests, regular-rational compatibility, Real sealing, replay, provenance, and local naming.*
9. *C stores displayed* Cont *replay for the route*

$$L, A, D, I, Q \longmapsto R.$$

10. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$, $\mathsf{LocatedCutReal}^{\uparrow}$, $\mathsf{LocatedDedekindCut}^{\uparrow}$, $\mathsf{RegularCauchyLocatedCut}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, A, D, I, Q, R, S, H, C, P, N$. It has no coordinate for quotient completion, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8441.2 (Bishop located upper-cut criterion obligations)**.** *For every accepted* BishopLocatedUpperCutCrite *carrier $U = (L, A, D, I, Q, R, S, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}}$ *surface consists exactly of finite lower-cut row exposure, finite upper-cut row exposure, locatedness-witness exposure, dyadic interval-test exactness,* $\mathsf{RegSeqRat}^{\uparrow}$ *compatibility,* $\mathsf{Real}^{\uparrow}$ *seal ordering, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may cite the located-cut real packet, the located Dedekind cut packet, and the regular-Cauchy located-cut packet only through those displayed rows.*

Proof. Project the accepted carrier. The cut-facing data are exactly the lower row L, upper row A, and locatedness row D.

The dyadic and regular-rational rows then determine the numerical read. The interval tests I provide the endpoint and slack ledger, while Q supplies the regular-rational compatibility row read by the Real-facing consumer.

Finally R, S, H, C, P, N seal, route, transport, replay, source, and name the same finite packet. Since no quotient completion, selected limit, trichotomy branch, countable-choice schedule, or ambient-completeness witness is a coordinate of U, those objects are not NameCert obligations. □

Theorem 8441.3 (Bishop located upper-cut criterion locatedness)**.** *Every accepted* BishopLocatedUpperCutCriterio *packet answers each displayed interval request $a < b$ only through the locatedness row D and the dyadic interval-test row I. The answer may expose a lower-side observation below b or an upper-side observation above a, but it may not decide all cuts by trichotomy, choose an external representative, or replace the displayed interval test by host real order.*

Proof. Begin with the locatedness row D in the carrier. Its entries are indexed by the interval requests actually displayed by the packet.

The dyadic interval-test row I supplies the endpoint and slack data for those requests, so every locatedness read remains tied to finite dyadic cells. Transport and replay through H and C preserve only those indexed cells.

Thus the packet gives a local locatedness criterion. It does not contain a global order decision, a representative selector, or a host real comparison row, so none can be exported by an accepted read. □

Theorem 8441.4 (Bishop located upper-cut criterion Real-seal handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ *carrier reaches the terminal seal only through*

$$\mathsf{LocatedCutReal}^{\uparrow} \longmapsto \mathsf{LocatedDedekindCut}^{\uparrow} \longmapsto \mathsf{RegularCauchyLocatedCut}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto$$

The handoff exposes finite lower and upper cut rows, locatedness witnesses, dyadic interval tests, regular-Cauchy compatibility, Real sealing, hsame *transport,* Cont *replay,* Pkg *provenance, and local NameCert data; it exports no Dedekind real construction, quotient completion, selected limit, trichotomy, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use the obligation theorem to expose $L, A, D, I, Q, R, S, H, C, P, N$. The lower and upper rows supply the cut presentation, while D and I provide the displayed located interval tests.

The regular-Cauchy and regular-rational reads then pass through Q before the Real seal R is available. The handoff row S names the same route through the located-cut and regular-Cauchy located-cut siblings cited above.

The excluded endpoints are absent from the carrier inventory. Therefore a Real or Completion consumer receives only the displayed finite criterion route and cannot read a Dedekind construction, quotient completion, selected limit, trichotomy branch, countable-choice schedule, or ambient completeness principle from this packet. □

Falsifiable prediction: A $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ consumer that reaches a Real or Completion handoff without displaying the lower row, upper row, locatedness witnesses, dyadic interval tests, regular-rational compatibility, Real seal, transport, replay, provenance, and local naming exits the accepted carrier.

Independence witness: located-cut-real, located-dedekind-cut, regular-cauchy-located-cut, dyadicratcore, regseqrat, real: $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds lower and upper cut rows, locatedness witnesses, dyadic interval tests, regular-Cauchy compatibility, terminal Real sealing, transport, replay, provenance, and one local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}$ packet is generated from finite lower and upper cut rows, locatedness witnesses, dyadic interval tests, RegSeqRat compatibility, a RealUp seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8441.1, Definition 8441.2, Definition 8441.3, and Definition 8441.4 seed the finite Bishop located upper-cut criterion route for regular Cauchy and Real-seal consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedUpperCutCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Dedekind real construction, quotient completion, selected limits, trichotomy, countable choice, ambient RealUp completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, locatedness witnesses, dyadic interval-test exactness, RegSeqRat compatibility, Real-seal ordering, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.BishopLocatedUpperCutCriterionUp.

Chapter 8442

A Concrete Naming Certificate for $\mathsf{FiniteDyadicBisection}^{\uparrow}$

Following Bishop–Bridges constructive bisection and nested interval practice, the $\mathsf{FiniteDyadicBisection}^{\uparrow}$ packet records a finite dyadic interval-halving computation as BEDC NameCert data. It sits after the dyadic endpoint rows of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the nested dyadic fusion route of chapter 8365. The packet supplies Real and Completion arguments with a finite bisection carrier without importing open-cover compactness, a selected host limit, quotient streams, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8442.1 (Finite dyadic bisection carrier)**.** *A* $\mathsf{FiniteDyadicBisection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (I, D, M, L, R, S, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval-chain row, recording the input dyadic endpoint pair and each retained dyadic child interval.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger, storing the displayed endpoint comparisons, width budget, and dyadic denominator data for every row of I.*
3. *M is the midpoint split row, computed from the current dyadic endpoints through the same ledger D.*
4. *L is the selected left-child row when the displayed finite test keeps the left half.*
5. *R is the selected right-child row when the displayed finite test keeps the right half.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row opened for the endpoint, midpoint, and selected-child observations.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row formed from those finite windows and dyadic tolerance cells.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, D, M, L, R, S, Q have been displayed.*
9. *H records componentwise* hsame *transport for the interval chain, dyadic ledger, midpoint split, selected child row, window, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a finite bisection request through I, D, M, L, R, S, Q, E and then through the structural rows.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteDyadicBisection}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteDyadicBisection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, D, M, L, R, S, Q, E, H, C, P, N$. It has no coordinate for an infinite bisection tree, quotient stream equality, a selected completed real, open-cover compactness, trichotomy, countable choice, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.FiniteDyadicBisectionUp.FiniteDyadicBisectionTasteGate single carrier alignment`

Theorem 8442.2 (Finite dyadic bisection NameCert obligations)**.** *For every accepted* $\mathsf{FiniteDyadicBisection}^{\uparrow}$ *carrier*

$$B = (I, D, M, L, R, S, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteDyadicBisection}^{\uparrow}}$ *surface consists exactly of finite interval-chain exposure through I, dyadic endpoint and width exposure through D, midpoint split exposure through M, selected-child exposure through L or R, finite observation scheduling through S, regular rational readback through Q, terminal real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8442.1. The projection exposes the finite interval chain, dyadic ledger, midpoint split, selected child rows, finite observation window, regular rational readback, Real seal, transport, replay, provenance, and naming rows.

The analytic rows are ordered. The endpoint ledger D can be read only after the current finite interval row I is displayed, and the midpoint split M is computed from that ledger.

The selected-child rows are finite alternatives inside the same packet. The left row L and right row R are not host choices; they are displayed child rows whose source endpoint and midpoint data remain in I, D, M.

The downstream rows S, Q, E then expose only finite windows, regular rational readback, and the terminal Real seal. The structural rows H, C, P, N transport, replay, source, and name the same route, so the listed rows exhaust the local certificate. □

Theorem 8442.3 (Finite dyadic bisection induction route)**.** *Every finite induction over an accepted* $\mathsf{FiniteDyadicBisection}^{\uparrow}$ *packet proceeds by the displayed route*

$$I, D \longmapsto M \longmapsto L, R \longmapsto S, Q, E, H, C, P, N.$$

The base step reads the initial dyadic endpoint row and the first width budget. Each successor step consumes the current endpoint row, computes the midpoint split, selects one displayed child row, and then replays the same $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *downstream route. The induction exports no infinite branch selector, quotient stream equality, selected host limit, open-cover compactness, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use induction on the finite interval-chain row I. In the base case, the packet displays the initial dyadic endpoints and width budget through D, so the downstream rows cannot be read before that finite row is visible.

For the successor step, assume the current finite prefix has been read through I, D. The midpoint row M is computed from the displayed dyadic endpoints, and the retained child is recorded by one of the finite rows L or R.

The observation and completion-facing rows are downstream from this selected child. The $\mathsf{StreamName}^{\uparrow}$ window S opens only the endpoint and midpoint observations named by the finite step, the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q reads that window, and the $\mathsf{Real}^{\uparrow}$ seal E is consumed only after Q is displayed.

Finally H, C, P, N preserve the same finite route under transport, replay, provenance, and local naming. Since the carrier contains no infinite branch selector, quotient stream, selected limit, compactness principle, or completeness coordinate, the induction remains a finite bisection route. □

Falsifiable prediction: Every accepted $\mathsf{FiniteDyadicBisection}^{\uparrow}$ Real-facing read exposes a finite dyadic interval chain, DyadicRatCore endpoint ledger, midpoint split, selected child row, StreamName finite window, RegSeqRat readback, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before the terminal seal is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, real, nested-dyadic-interval-fusion: $\mathsf{FiniteDyadicBisection}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite dyadic interval-chain, midpoint split, selected child row, downstream readback, Real seal, transport, replay, provenance, and local naming as one finite bisection packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDyadicBisection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDyadicBisection}^{\uparrow}$ packet is generated from finite dyadic interval-chain rows, DyadicRatCore endpoint and width rows, midpoint split rows, selected child rows, StreamName finite observations, RegSeqRat readback, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDyadicBisection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8442.1, Definition 8442.2, and Definition 8442.3 seed the finite dyadic bisection route from displayed dyadic endpoint data to a Real-facing readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDyadicBisection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, infinite branch selection, quotient stream equality, selected host limits, trichotomy, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, midpoint splitting, selected-child stability, StreamName scheduling, RegSeqRat readback, Real handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDyadicBisectionUp.

Chapter 8443

A Concrete Naming Certificate for $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ packet records the finite branch tree by which Real and Completion arguments may inspect finitely many possible local choices without importing a countable-choice schedule. It sits after the finite stream observations of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the regular Cauchy criterion surface of chapter 1611, and the terminal real-name seal of chapter 38. The packet gives diagonal, tail, and criterion arguments a named finite-choice surface; it does not choose an infinite branch, select a limit, quotient streams, decide trichotomy, or assert ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8443.1 (Finite-window choice-tree carrier)**.** *A* $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, W, R, D, G, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the finite branch-tree row, listing the root, the displayed child cells, the finite depth bound, and the local branch labels opened by the request.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite stream observations attached to each displayed branch cell.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from those windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, carrying the dyadic radii, comparison cells, and finite precision budget attached to each branch cell.*
5. *G is the* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *row, exposing only the criterion checks that were requested on the displayed windows and dyadic tolerances.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, W, R, D, G have been displayed.*
7. *H records componentwise* hsame *transport for branch cells, window rows, readback rows, dyadic tolerances, criterion checks, Real sealing, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay for the finite route*

$$B, W, R, D, G \longmapsto E.$$

9. *P is the* Pkg *provenance over* $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowChoiceTree}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, W, R, D, G, E, H, C, P, N$. It has no coordinate for a countable-choice schedule, an infinite selected branch, quotient stream equality, selected limits, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8443.2 (Finite-window choice-tree NameCert obligations)**.** *For every accepted* $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ *carrier $T = (B, W, R, D, G, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{FiniteWindowChoiceTree}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier formation, requiring the branch tree B to be finite and every exposed child cell to be named inside the same* BHist *packet;*
2. *branch-window stability, requiring every read of a branch cell to pass through the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row W and its* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R;*
3. *dyadic tolerance exposure, requiring each criterion check to expose the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D before it may read the* $\mathsf{RegularCauchyCriterion}^{\uparrow}$ *row G;*
4. hsame *and* Cont *transport, requiring H and C to preserve the same finite branch, window, readback, tolerance, criterion, and Real-seal rows under replay;*
5. *ledger refusal, requiring the packet to refuse countable choice, infinite selected branches, selected limits, quotient streams, trichotomy, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness as available coordinates.*

Proof. Project the accepted carrier of Definition 8443.1. Its branch data are exactly the finite row B, so the packet begins with named finite cells rather than an infinite choice object.

The analytic observations then pass through W, R, D, G. The stream windows and regular rational readbacks supply the observed values, while the dyadic row supplies the precision ledger consumed by the regular Cauchy criterion row.

The Real-facing read is downstream from the same rows. The seal E is not available until the branch tree, windows, readbacks, dyadic tolerances, and criterion checks have all been displayed.

Finally H, C, P, N transport, replay, source, and name the finite route. Since the carrier contains no coordinate for countable choice, selected limits, quotient streams, trichotomy, or ambient Real completeness, those objects cannot become local NameCert obligations. □

Theorem 8443.3 (Finite-window choice-tree Real handoff)**.** *Every Real or Completion read exported by an accepted* $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ *packet factors through*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The finite branch tree only indexes which displayed windows, readbacks, dyadic tolerances, and criterion rows are consumed; it does not provide a global branch selector or a completeness theorem.

Proof. Start with the branch tree row B. It indexes a finite family of displayed cells and supplies no data outside that finite family.

For each exposed cell, read the rows W, R, D, G in order. These rows give the stream window, regular rational readback, dyadic tolerance, and criterion check used by the Real-facing route.

The seal row E is then reached through the same displayed data, and H, C, P, N preserve the route under transport, replay, provenance, and local naming. No separate selector or completeness coordinate is present, so no such object can be exported. □

Falsifiable prediction: A $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ consumer that exports a Real or Completion read while omitting the finite branch tree, stream windows, RegSeqRat readbacks, dyadic tolerance row, regular Cauchy criterion row, Real seal, transport, replay, provenance, or local naming exits the accepted carrier.

Independence witness: streamname, regseqrat, dyadicratcore, regularcauchycriterion, real: $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds a finite branch tree, displayed stream windows, regular rational readbacks, dyadic tolerance exposure, criterion checks, Real sealing, transport, replay, provenance, and one local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteWindowChoiceTree}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteWindowChoiceTree}^{\uparrow}$ packet is generated from a finite branch tree, displayed StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RegularCauchyCriterion checks, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteWindowChoiceTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8443.1, Definition 8443.2, and Definition 8443.3 seed the finite branch-window route for Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteWindowChoiceTree}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, infinite selected branches, selected limits, quotient streams, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, branch-window stability, dyadic tolerance exposure, regular Cauchy criterion handoff, Real seal nonescape, hsame transport, Cont replay, provenance, and local naming for BEDC.Derived.FiniteWindowChoiceTreeUp.

Chapter 8444

A Concrete Naming Certificate for $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$

Following Bishop and Bridges on located real sequences and regular Cauchy real names, the $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ packet records the finite calibration row that lets a located real-sequence consumer pass from inspected stream windows to regular rational readback and then to a terminal real-name seal. It sits beside the finite stream windows of chapter 126, the regular rational route of chapter 301, the terminal real-name surface of chapter 38, the Bishop located sequence packet of chapter 7766, and the located real sequence source of chapter 1984. The calibration is finite L10 data; it is not quotient equality of streams, selected convergence, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8444.1 (Bishop located real sequence calibration carrier)**.** *A* $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (S, B, L, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row of inspected finite sequence windows.*
2. *B is the* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *row naming the Bishop-style located sequence surface that supplies the locatedness request.*
3. *L is the* $\mathsf{LocatedRealSequence}^{\uparrow}$ *row recording the located real-name component windows used by the same request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the inspected windows and locatedness data.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from S, B, L, D.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the regular rational readback has been displayed.*
7. *H records componentwise* hsame *transport for S, B, L, D, R, E and for the structural rows.*
8. *C records displayed* Cont *replay from a calibration request through the same finite rows.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{BishopLocatedSequence}^{\uparrow}$, $\mathsf{LocatedRealSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}}$ *row.*

The classifier is rowwise over $S, B, L, D, R, E, H, C, P, N$. It compares only displayed stream windows, located-sequence rows, located-real component windows, dyadic tolerances, regular rational readbacks, real seals, transport, replay, provenance, and local naming.

Theorem 8444.2 (Bishop located real sequence calibration obligations)**.** *For every accepted* $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ *carrier* $K = (S, B, L, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedRea}}$ *surface consists of five finite obligation rows:*

1. *stream-window admission, requiring the consumer to begin at the displayed* $\mathsf{StreamName}^{\uparrow}$ *row* S*;*
2. *located-sequence alignment, requiring the* $\mathsf{BishopLocatedSequence}^{\uparrow}$ *row* B *and the* $\mathsf{LocatedRealSequence}^{\uparrow}$ *row* L *to describe the same inspected request;*
3. *tolerance calibration, requiring the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *to bind the displayed windows and locatedness rows before any rational readback is consumed;*
4. *readback and seal routing, requiring the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *to precede the terminal* $\mathsf{Real}^{\uparrow}$ *row* E*;*
5. *structural replay, requiring* H, C, P, N *to preserve the same finite route under componentwise transport, continuation replay, provenance, and local naming.*

No obligation row supplies quotient stream equality, selected convergence, trichotomy, countable choice, host real equality, or ambient real completeness.

Proof. Carrier admission is projection from Definition 8444.1. The analytic rows are S, B, L, D, R, E, and the structural rows are H, C, P, N.

The alignment obligations bind the two sequence views. The $\mathsf{BishopLocatedSequence}^{\uparrow}$ row records the Bishop locatedness route, while the $\mathsf{LocatedRealSequence}^{\uparrow}$ row records the located real-name component windows for the same inspected request.

The tolerance and readback rows are downstream. The dyadic ledger D calibrates the displayed windows before the regular rational row R is read, and the terminal seal E is reached only after that readback.

Finally H, C, P, N transport, replay, source, and name the same route. Since none of the excluded principles appears as a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8444.3 (Bishop located real sequence calibration L10 route)**.** *Every Real-and-Completion consumer of an accepted* $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BishopLocatedSequence}^{\uparrow} \longmapsto \mathsf{LocatedRealSequence}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Re}$$

together with the displayed BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows. The route is a calibration surface between finite windows, located sequence data, regular rational readback, and the real seal; it is not a completeness theorem or a quotient-real equality.*

Proof. Start with the obligation rows of Definition 8444.2. They force each consumer to expose the stream window row, the two located sequence rows, the dyadic tolerance ledger, the regular rational readback, and the terminal real seal in that order.

Use the rowwise classifier of Definition 8444.1. Componentwise transport preserves the displayed route, so a transported consumer cannot replace it by quotient streams or by a selected convergence witness.

The structural rows then close the finite replay. The route is sourced by P, replayed by C, transported by H, and named by N, so the consumer reaches only the displayed $\mathsf{Real}^{\uparrow}$ seal. □

Lean4 (statement) `BEDC.Derived.BishopLocatedRealSequenceCalibrationUp`

Falsifiable prediction: Every accepted $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ consumer displays StreamName windows, Bishop located sequence data, LocatedRealSequence component windows, DyadicRatCore tolerances, RegSeqRat readback, Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before it reads a Real-facing result.

Independence witness: streamname, regseqrat, real, bishoplocatedsequence, locatedrealsequence: $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ is not bijective to any listed sibling because it packages the calibration between located sequence data, located real-sequence rows, dyadic tolerance, rational readback, and the terminal real seal as one finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}$ packet is generated from finite StreamName windows, BishopLocatedSequence data, LocatedRealSequence component windows, DyadicRatCore tolerances, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8444.1, Definition 8444.2, and Definition 8444.3 seed the finite calibration route between located sequence data, regular rational readback, and a terminal Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopLocatedRealSequenceCalibration}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected convergence, trichotomy, countable choice, host real equality, ambient Real completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Lean closure requires checked carrier admission, located-sequence alignment, dyadic tolerance calibration, RegSeqRat handoff, Real-seal nonescape, transport replay, provenance, and local naming for BEDC.Derived.BishopLocatedRealSequenceC

Chapter 8445

A Concrete Naming Certificate for $\mathsf{FordCircle}^{\uparrow}$

Following Hardy and Wright on Farey fractions and the classical Ford-circle construction, the $\mathsf{FordCircle}^{\uparrow}$ packet records a reduced rational boundary point together with its tangent upper-half-plane circle as finite Farey and horoball NameCert data. It realizes the Farey-horoball branch of chapter 9463 beside the finite Farey sequence rows of chapter 1759, the Farey approximation route of chapter 8081, and the hyperbolic horoball carrier of chapter 7843. The packet names only displayed rational, radius, tangency, horoball, transport, replay, provenance, and local naming rows; it is not a quotient real circle, not a host Euclidean tangent theorem, and not a global hyperbolic-plane completion.

Definition 8445.1 (FordCircle carrier)**.** *A* $\mathsf{FordCircle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (Q, D, R, T, U, H, C, P, N)$$

with the following displayed rows:

1. *Q is the reduced rational center row, naming coprime integer numerator and positive denominator data over the rational boundary line.*
2. *D is the positive denominator row, recording the denominator witness used by the circle radius and by Farey-neighbour tests.*
3. *R is the dyadic reciprocal-square radius row, storing the displayed radius corresponding to the classical value $1/(2D^2)$ as rational and dyadic readback data.*
4. *T is the tangency ledger. It records the finite Farey determinant tests that witness equality of the boundary tangency point and exact tangency between neighbouring Ford circles.*
5. *U is the upper-half-plane and horoball row. It places the circle as a boundary-tangent horoball read whose base is Q and whose height is read from R.*
6. *H records componentwise* hsame *transport for the reduced rational center, denominator, radius, tangency ledger, upper-half-plane or horoball row, continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a Farey or hyperbolic-boundary consumer through Q, D, R, T, U, H, P, N.*
8. *P is the* Pkg *provenance row over* $\mathsf{FareySequence}^{\uparrow}$*,* $\mathsf{HyperbolicHoroball}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Rat}^{\uparrow}$*,* $\mathsf{Int}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{FordCircle}^{\uparrow}}$ *row.*

The local classifier compares two accepted packets only through these rows. It has no coordinate for ambient Euclidean circle equality, real quotient centers, selected real representatives, a completed hyperbolic plane, or a host geometry theorem about all tangent circles.

Theorem 8445.2 (FordCircle NameCert obligations)**.** *For every accepted* $\mathsf{FordCircle}^{\uparrow}$ *carrier*

$$F = (Q, D, R, T, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FordCircle}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier formation for the reduced rational center, positive denominator, dyadic reciprocal-square radius, Farey tangency ledger, upper-half-plane or horoball row, transport, replay, provenance, and local naming data;*
2. *radius stability, requiring the radius row R to be transported together with the same denominator row D and not recomputed from an external real-circle representative;*
3. *Farey tangency exactness, requiring the tangency ledger T to expose the determinant and adjacency rows consumed by neighbouring-circle reads;*
4. *horoball embedding route, requiring the upper-half-plane row U to be read downstream of Q, D, R, T and upstream of the structural rows H, C, P, N;*
5. *nonescape from host real-circle equality, excluding ambient Euclidean circle equality, quotient real centers, selected representatives, global hyperbolic-plane completion, and an unlogged tangent-circle theorem.*

Proof. Project the carrier of Definition 8445.1. The rows $Q, D, R, T, U, H, C, P, N$ display the reduced rational center, denominator, radius, tangency data, horoball placement, componentwise transport, replay, provenance, and local name.

Radius stability is componentwise. The denominator row D and the dyadic reciprocal-square radius row R move together under H, and any consumer replay through C must read R as part of the same packet.

Farey tangency exactness is supplied by the ledger T. The packet records the determinant and adjacency data before a neighbouring-circle read can be consumed, so tangency is not imported from an ambient real-circle theorem.

Finally the horoball row U is downstream of the rational and radius rows. The package and NameCert rows P, N name this displayed route, while the absent host objects have no coordinate in the carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{FordCircle}^{\uparrow}}$.

Constructive story: A $\mathsf{FordCircle}^{\uparrow}$ packet is generated from a reduced rational center, positive denominator, dyadic reciprocal-square radius, Farey tangency ledger, upper-half-plane or horoball row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FordCircle}^{\uparrow}}$, seed)

Scope closed: Definition 8445.1 and Definition 8445.2 seed the finite Ford-circle surface linking Farey rational data with hyperbolic horoball reads.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FordCircle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host Euclidean circle equality, quotient real-center equality, global hyperbolic-plane completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius stability, Farey tangency exactness, horoball embedding, transport, replay, provenance, and local naming for BEDC.Derived.FordCircleUp.

Chapter 8446

A Concrete Naming Certificate for KolmogorovMaximalInequality$^{\uparrow}$

Following Kolmogorov and Bishop–Bridges finite probability estimates, the KolmogorovMaximalInequality$^{\uparrow}$ packet records the finite partial-sum maximal-window route behind Kolmogorov's maximal inequality. It sits after the probability source of chapter 184, the measurable random-variable rows of chapter 185, the one-row Chebyshev tail carrier of chapter 6592, the finite Boole ledger of chapter 6696, the weak-law finite-average packet of chapter 4373, and the terminal real-name seal of chapter 38. The packet is a finite maximal-window certificate for displayed prefixes; it is not a countable-choice selector, almost-sure quotient, measure-completion object, host limit theorem, or ambient Real$^{\uparrow}$ completeness principle.

Definition 8446.1 (Kolmogorov maximal inequality carrier)**.** *A* KolmogorovMaximalInequality$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (\Omega, X, S, B, C, U, R, H, K_0, P, N)$$

with the following displayed rows:

1. Ω *is the* ProbSpace$^{\uparrow}$ *source row carrying the event classifier and total-mass normalization.*
2. X *is the finite* RandomVar$^{\uparrow}$ *prefix row, listing the displayed variables* $X_1, \ldots, X_n$ *over the same probability source.*
3. S *is the partial-sum window row, recording the displayed sums* $S_k = X_1 + \cdots + X_k$ *for* $1 \le k \le n$.
4. B *is the maximum-threshold row, naming the positive* Real$^{\uparrow}$ *threshold and the event* $\max_{1 \le k \le n} |S_k| \ge B$ *as a finite window over* S.
5. C *is the Chebyshev tail-row family, one displayed* ChebyshevInequality$^{\uparrow}$ *read for each stopped partial-sum window needed by the maximal estimate.*
6. U *is the* FiniteUnionBound$^{\uparrow}$ *ledger that joins the finitely many exposed tail rows into the maximal-window event bound.*
7. R *is the* Real$^{\uparrow}$ *bound seal reached only after* Ω, X, S, B, C, U *have been displayed.*
8. H *records componentwise* hsame *transport for the source, prefix, partial-sum, threshold, Chebyshev, finite-union, bound, replay, provenance, and local naming rows.*
9. K_0 *records displayed* Cont *replay of the finite maximal-window route.*

10. *P is the* Pkg *provenance over* KolmogorovMaximalInequality$^{\uparrow}$, ProbSpace$^{\uparrow}$, RandomVar$^{\uparrow}$, ChebyshevInequality$^{\uparrow}$, FiniteUnionBound$^{\uparrow}$, WeakLawLargeNumbers$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{KolmogorovMaximalInequality}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $\Omega, X, S, B, C, U, R, H, K_0, P, N$. It has no coordinate for countable choice, almost-sure quotient equality, measure completion, a host-side limiting theorem, an infinite stopping-time selector, or ambient real completeness.

Theorem 8446.2 (Kolmogorov maximal inequality NameCert obligations)**.** *For every accepted* KolmogorovMaximalInequality$^{\uparrow}$ *carrier*

$$K = (\Omega, X, S, B, C, U, R, H, K_0, P, N),$$

the local NameCert$_{\text{KolmogorovMaximalInequality}^{\uparrow}}$ *surface consists exactly of probability-source exposure through Ω, finite random-variable prefix exposure through X, partial-sum window exactness through S, maximum-threshold exposure through B, Chebyshev tail-row exposure through C, finite-union ledger exposure through U, terminal real-bound sealing through R, componentwise transport through H, displayed replay through K_0, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8446.1. The projection exposes the probability source, finite random-variable prefix, partial-sum windows, maximum-threshold row, Chebyshev tail rows, finite-union ledger, Real bound seal, transport, replay, provenance, and local naming.

The prefix rows are ordered. The partial sums in S can be read only from the displayed prefix $X_1, \ldots, X_n$ over the source Ω, and the maximal event in B is a finite event window over those displayed sums.

The tail rows are downstream from that window. Each row of C is a Chebyshev read for one displayed stopped partial-sum prefix, while U records the finite union-bound ledger over exactly those rows.

The endpoint R is therefore a real-bound seal for the finite maximal event named by B. The structural rows H, K_0, P, N transport, replay, source, and name the same route, so no unlisted measure completion, countable selector, almost-sure quotient, host limit, or ambient completeness coordinate remains. □

Theorem 8446.3 (Kolmogorov partial-sum window bound)**.** *Every accepted* KolmogorovMaximalInequality$^{\uparrow}$ *maximal-window read factors through the finite route*

$$\Omega, X, S, B \longmapsto C \longmapsto U \longmapsto R \longmapsto H, K_0, P, N.$$

For each displayed prefix length n and threshold row B, the route first opens the finite partial-sum windows $S_1, \ldots, S_n$, then applies the Chebyshev tail rows in C to the stopped window pieces, then composes those finitely many rows through the FiniteUnionBound$^{\uparrow}$ *ledger U, and only then exposes the* Real$^{\uparrow}$ *bound seal R. Thus the maximal-window estimate is available to weak-law, concentration, and later strong-law-facing consumers as finite BEDC data, not as an almost-sure, countable-choice, measure-completion, host-limit, or ambient-completeness principle.*

Proof. Use induction on the displayed prefix length in X. In the base case, the packet exposes the empty or one-term partial-sum window through Ω, X, S, and the threshold row B names the only finite maximal event that can be inspected.

For the successor step, extend the displayed prefix by one RandomVar$^{\uparrow}$ row. The new partial-sum row is appended to S, while the already displayed prefix sums remain available through the same componentwise hsame transport.

Now open the tail-row family C. Each stopped prefix event is a finite Chebyshev request over the same probability source and the same displayed partial-sum data; no countable family or stopping-time selector is introduced.

The finite-union ledger U then composes exactly the rows supplied by C. This is the Boole-inequality step of chapter 6696, so the maximal event remains a finite union of displayed tail events.

Finally read the $\mathsf{Real}^{\uparrow}$ seal R and the structural rows H, K_0, P, N. The seal is downstream from the finite prefix, Chebyshev rows, and union ledger, while the structural rows preserve the same route for weak-law and concentration consumers. Since the carrier contains no coordinate for almost-sure quotient equality, measure completion, countable choice, host limits, or ambient real completeness, the partial-sum maximal bound stays inside finite BEDC data. □

Falsifiable prediction: Every accepted $\mathsf{KolmogorovMaximalInequality}^{\uparrow}$ maximal-window read exposes a ProbSpace source row, finite RandomVar prefix, partial-sum window row, maximum-threshold row, Chebyshev tail rows, finite-union ledger, RealUp bound seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before the bound is consumed.

Independence witness: probspace, randomvar, chebyshev-inequality, finite-union-bound, weak-law-large-numbers, real: $\mathsf{KolmogorovMaximalInequality}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite probability source, random-variable prefix, partial-sum maximal window, Chebyshev tail family, finite-union ledger, terminal real-bound seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KolmogorovMaximalInequality}^{\uparrow}}$.

Constructive story: A $\mathsf{KolmogorovMaximalInequality}^{\uparrow}$ packet is generated from a probability source row, finite random-variable prefix, partial-sum window rows, a maximum-threshold row, Chebyshev tail rows, a finite-union ledger, a RealUp bound seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KolmogorovMaximalInequality}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8446.1, Definition 8446.2, and Definition 8446.3 seed the finite partial-sum maximal-window route over probability, random-variable, Chebyshev, finite-union, RealUp, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KolmogorovMaximalInequality}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close almost-sure convergence, countable-choice selection, measure completion, quotient event equality, host limiting theorems, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite prefix exposure, partial-sum window exactness, maximum-threshold exposure, Chebyshev tail-row stability, finite-union ledger composition, Real bound nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KolmogorovMaximalInequalityUp.

Chapter 8447

A Concrete Naming Certificate for $\mathsf{OrderConvexSubspace}^{\uparrow}$

Following Bourbaki and Bishop-style ordered-space practice, the $\mathsf{OrderConvexSubspace}^{\uparrow}$ packet records an order-convex subspace as finite NameCert data over a constructive ordered carrier. It sits after the relational source of chapter 52, the antisymmetric surface of chapter 53, the located interval boundary of chapter 1709, the constructive real order of chapter 1716, and the Real readback route of chapter 38. The packet gives interval and completion-facing consumers a named order-convex restriction surface without importing host subset equality, quotient subspaces, classical trichotomy, selected suprema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8447.1 (OrderConvexSubspace carrier)**.** *An* $\mathsf{OrderConvexSubspace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (P, S, I, T, R, H, C, Q, N)$$

with the following displayed rows:

1. *P is the ordered source row, read through* $\mathsf{Preorder}^{\uparrow}$ *or* $\mathsf{Poset}^{\uparrow}$*, with its carrier, order relation, and classifier exposed before the subspace row is used.*
2. *S is the subset-membership row, recording the finite membership classifier for the inspected subspace without identifying it with host set equality.*
3. *I is the interval-closure row: whenever accepted elements a, b of S satisfy $a \leq x \leq b$ in the source order, the inspected element x is admitted by the same membership classifier.*
4. *T is the order-transport row, recording that componentwise* hsame *transport preserves source order comparisons and the subset-membership classifier.*
5. *R is the interval handoff row to* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$*, exposing only the located interval windows and regular rational readbacks needed by Real-facing consumers.*
6. *H records componentwise* hsame *transport for P, S, I, T, R and the structural rows below.*
7. *C records displayed* Cont *replay through the ordered source, membership classifier, interval-closure row, order transport, and Real or RegSeqRat handoff.*
8. *Q is the* Pkg *provenance over* $\mathsf{OrderConvexSubspace}^{\uparrow}$*,* $\mathsf{Preorder}^{\uparrow}$*,* $\mathsf{Poset}^{\uparrow}$*,* $\mathsf{LocatedRealInterval}^{\uparrow}$*,* $\mathsf{CauchyRealOrder}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{OrderConvexSubspace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient subset equality, host carrier equality, trichotomy of the source order, selected endpoints, or ambient real completeness.

Theorem 8447.2 (OrderConvexSubspace NameCert obligations)**.** *For every accepted* $\mathsf{OrderConvexSubspace}^{\uparrow}$ *carrier* $O = (P, S, I, T, R, H, C, Q, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OrderConvexSubspace}^{\uparrow}}$ *surface consists exactly of carrier admission for the ordered source, subset-membership classifier, interval-closure row, order-transport row, Real or RegSeqRat interval handoff, componentwise transport, displayed replay, provenance, and local naming rows. No obligation may be discharged by quotienting the subset, replacing membership by host set equality, invoking classical trichotomy, selecting endpoints externally, or importing ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8447.1. The source row P gives the displayed preorder or poset data, while S gives the finite membership classifier for the inspected subspace.

The interval row I is the only closure coordinate. It admits an inspected middle point only through the displayed comparisons $a \leq x \leq b$ and the accepted endpoint memberships, so no host subset equality or quotient subspace can discharge the local obligation.

The transport and handoff rows T, R, H, C, Q, N keep the same source order, membership classifier, interval closure, Real or RegSeqRat readback, replay, provenance, and naming surface visible to consumers. Since trichotomy, endpoint selection, and ambient completeness are absent from the packet, they cannot serve as NameCert obligations. □

Theorem 8447.3 (OrderConvexSubspace interval transport)**.** *Every accepted interval read through an* $\mathsf{OrderConvexSubspace}^{\uparrow}$ *packet factors through*

$$P, S, I, T \longmapsto R \longmapsto H, C, Q, N.$$

Thus a Real or RegSeqRat interval consumer may use the subspace only after reading the ordered source, subset-membership classifier, interval-closure row, order-transport row, terminal interval handoff, transport, replay, provenance, and local NameCert data.

Proof. Start with the ordered source and membership rows. The row P exposes the $\mathsf{Preorder}^{\uparrow}$ or $\mathsf{Poset}^{\uparrow}$ comparisons, and S exposes the subspace membership classifier.

Apply the interval-closure row I and order-transport row T. Together they make the middle-point admission invariant under the displayed source-order comparisons and componentwise transport.

Finally read the handoff row R before the structural rows H, C, Q, N. The interval consumer therefore receives a finite BEDC route from ordered membership to Real or RegSeqRat windows, not a host theorem about convex subsets or completed ordered spaces. □

Falsifiable prediction: An $\mathsf{OrderConvexSubspace}^{\uparrow}$ read that omits the subset-membership classifier, interval-closure row, order-transport row, or Real/RegSeqRat handoff is not accepted by the local NameCert.

Independence witness: preorder, poset, located-real-interval, cauchy-real-order, regseqrat, real: $\mathsf{OrderConvexSubspace}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the ordered source, subset-membership classifier, interval-closure row, order transport, interval readback, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{OrderConvexSubspace}^{\uparrow}}$**.**

Constructive story: An OrderConvexSubspace$^{\uparrow}$ packet is generated from an ordered source row, subset-membership classifier, interval-closure row, order-transport row, Real or RegSeqRat interval handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{OrderConvexSubspace}^{\uparrow}}$, seed)

Scope closed: Definition 8447.1, Definition 8447.2, and Definition 8447.3 seed the finite order-convex subspace route through ordered source, membership, interval closure, order transport, interval handoff, structural replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{OrderConvexSubspace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient subset equality, host carrier equality, trichotomy, selected endpoints, ambient Real$^{\uparrow}$ completeness, Lean theorem checking, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, subset-membership stability, interval-closure routing, order-transport stability, Real or RegSeqRat interval handoff, transport stability, replay stability, provenance, and local naming for BEDC.Derived.OrderConvexSubspaceUp.

Chapter 8448

A Concrete Naming Certificate for BishopCauchyModulusCalculus$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the BishopCauchyModulusCalculus$^{\uparrow}$ packet records the finite calculus used to compose, meet, shift, and replay displayed Cauchy moduli before a regular-Cauchy real-name consumer reads a seal. It sits beside the dyadic tolerance core of chapter 291, the finite-window name surface of chapter 126, the regular rational readback of chapter 301, the checked arithmetic packet of chapter 1485, and the terminal real-name surface of chapter 38. The packet names a local L10 tool for regular-Cauchy modulus arithmetic; it does not assert quotient equality of real names, a selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real$^{\uparrow}$ completeness.

Definition 8448.1 (Bishop Cauchy modulus calculus carrier)**.** *A* BishopCauchyModulusCalculus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (D, S, R, A, M, J, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger, recording the dyadic radii, comparison cells, and finite precision budget used by the calculus.*
2. *S is the* StreamName$^{\uparrow}$ *finite-window row whose observed windows provide the source data for each modulus read.*
3. *R is the* RegSeqRat$^{\uparrow}$ *readback row obtained from those windows.*
4. *A is the* CauchyModulusArithmetic$^{\uparrow}$ *arithmetic row, exposing the sum, product, diagonal, and shared-threshold operations already accepted by that sibling packet.*
5. *M is the displayed meet row, recording the common threshold schedule used to compare two modulus requests in the same dyadic ledger.*
6. *J is the shift row, recording finite index shifts and replay offsets for the displayed windows.*
7. *E is the terminal* Real$^{\uparrow}$ *seal row, reachable only after D, S, R, A, M, J have been displayed.*
8. *H records componentwise* hsame *transport for the tolerance, window, readback, arithmetic, meet, shift, seal, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay for each finite calculus operation through D, S, R, A, M, J, E, H.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalculus}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $D, S, R, A, M, J, E, H, C, P, N$. No coordinate stores a completed real, quotient equality of names, a selected limit, countable choice, trichotomy, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8448.2 (Bishop Cauchy modulus calculus NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$ *carrier*

$$K = (D, S, R, A, M, J, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalculus}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance ledger, finite StreamName windows, regular rational readback, Cauchy modulus arithmetic row, displayed meet row, finite shift row, Real seal row, componentwise transport, displayed replay, provenance, and local naming. The obligation surface requires every compose, meet, shift, and replay read to expose the same dyadic ledger D, window row S, readback row R, arithmetic row A, meet row M, shift row J, and structural rows H, C, P, N before the seal E is public.*

Proof. Project the carrier of Definition 8448.1. Its displayed coordinates are exactly $D, S, R, A, M, J, E, H, C, P, N$, so carrier admission and local naming have no additional source.

The arithmetic read is finite before it is Real-facing. The dyadic ledger D fixes the tolerances, the window row S fixes the inspected observations, and the regular rational readback R supplies the values used by the modulus operations.

The calculus rows are downstream of those data. The arithmetic row A supplies the accepted sum, product, diagonal, and shared-threshold operations from the Cauchy modulus arithmetic packet; the meet row M and shift row J record only the displayed threshold and index-offset data needed to replay those operations.

Finally the seal row E is read only through H, C, P, N. Since the carrier has no coordinate for quotient equality, selected limits, countable choice, trichotomy, compactness, or ambient Real completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8448.3 (Bishop Cauchy modulus calculus operation laws)**.** *Every accepted* BishopCauchyModulusCalculus *packet exposes compose, meet, shift, and replay laws only along the finite route*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyModulusArithmetic}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The compose and meet laws reuse the same dyadic tolerance ledger and shared-threshold row; the shift law reindexes only displayed finite windows; the replay law transports the same rows through hsame, Cont, Pkg, *and the local* NameCert *row. None of these laws exports quotient real equality, a selected limit, countable choice, trichotomy, open-cover compactness, or ambient Real completeness.*

Proof. Begin with the NameCert obligations of Definition 8448.2. They require every calculus read to expose $D, S, R, A, M, J, H, C, P, N$ before a Real-facing seal is available.

For compose and meet, read A together with the meet row M. The arithmetic row supplies the accepted operation surface, while M forces both modulus requests to share the displayed dyadic threshold.

For shift, read J against the same S and R rows. The shift changes only the finite index window and replay offset; it does not create a new stream, a quotient name, or a selected limit.

For replay, use H, C, P, N. Componentwise transport and displayed continuation replay preserve the same finite route, and provenance plus local naming keep the calculus laws inside the accepted packet. □

Theorem 8448.4 (Bishop Cauchy modulus calculus L10 handoff)**.** *Every L10 Real or Completion consumer of an accepted* $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$ *packet must read the dyadic tolerance ledger, StreamName windows, RegSeqRat readback, Cauchy modulus arithmetic row, displayed meet row, finite shift row, componentwise transport, displayed replay, provenance, and local naming before using a regular-Cauchy modulus calculation. The handoff supplies a finite local tool for regular-Cauchy modulus arithmetic and does not close Real completeness, quotient equality of names, countable choice, selected limits, or an open-cover compactness principle.*

Proof. Start from the operation laws of Definition 8448.3. They place every compose, meet, shift, and replay read inside the displayed route through dyadic tolerances, finite windows, regular readback, arithmetic, transport, replay, provenance, and local naming.

The Real-facing consumer may then inspect the seal row E only after the same rows have been displayed. This keeps the calculation as an L10 handoff for regular-Cauchy modulus arithmetic rather than a theorem of ambient Real completeness.

The excluded principles have no row in the carrier. Quotient real equality, selected limits, countable choice, trichotomy, and open-cover compactness therefore cannot be extracted from the handoff. □

Falsifiable prediction: An accepted $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$ consumer is refuted if it uses a compose, meet, shift, replay, Real, or Completion read without displaying the dyadic tolerance ledger, finite StreamName windows, RegSeqRat readback, CauchyModulusArithmetic row, meet row, shift row, transport, replay, provenance, and local naming evidence.

Independence witness: dyadicratcore, streamname, regseqrat, cauchy-modulus-arithmetic, real: no listed sibling is bijective with $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$ because this packet jointly carries tolerance ledgers, finite windows, rational readback, modulus arithmetic, meet thresholds, shift offsets, Real sealing, transport, replay, provenance, and local naming as one finite calculus surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalculus}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyModulusCalculus}^{\uparrow}$ packet is generated from DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, a CauchyModulusArithmetic row, displayed meet and shift rows, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalculus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8448.1, Definition 8448.2, Definition 8448.3, and Definition 8448.4 seed the finite L10 modulus-calculus route over dyadic tolerances, finite windows, regular readback, arithmetic, meet, shift, Real sealing, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyModulusCalculus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient equality of real names, selected limits, countable choice, trichotomy, open-cover compactness, ambient Real completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic tolerance exactness, StreamName window exposure, RegSeqRat readback exactness, arithmetic-row handoff, meet and shift replay, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopCauchyModulusCalculusUp.

Chapter 8449

A Concrete Naming Certificate for $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$

Following Banach and Bishop–Bridges, the $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$ packet records a separable Banach-space presentation whose dense data are inspected through finite stream windows before the completion service is read. It sits over the Banach carrier of **??**, the norm rows of chapter 89, the complete-metric boundary of chapter 128, the density route of chapter 1809, and the finite real-name infrastructure of chapter 126 and chapter 301. The packet names a constructive countably dense realization inside a complete normed carrier; it does not choose limits, quotient Cauchy classes, dense enumerants outside the displayed code, countable choice, Hahn–Banach data, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8449.1 (Finite-realized separable Banach space carrier)**.** *A* $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (B, N, M, D, S, R, E, H, C, P, L)$$

with the following displayed rows:

1. *B is the ambient* $\mathsf{BanachSpace}^{\uparrow}$ *carrier row, including its vector, norm, Cauchy, completion, and separated-comparison service.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *readback row used by dense-code and Cauchy-window consumers.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *row induced by the Banach norm and exposed before completion-facing density is public.*
4. *D is the* $\mathsf{RealSeparability}^{\uparrow}$ *dense-code admission row, listing the accepted countable dense codes and the finite windows by which those codes are inspected.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule for reading dense-code observations.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the same stream windows and norm tolerances.*
7. *E is the terminal real-name seal reached by the norm and density reads.*
8. *H records componentwise* hsame *transport for B, N, M, D, S, R, E and the local certificate rows.*
9. *C records displayed* Cont *replay for Banach, norm, dense-code, stream-window, regular-rational, real-seal, and completion reads.*

10. *P is the* Pkg *provenance over* FiniteRealizedSeparableBanachSpace$^{\uparrow}$, BanachSpace$^{\uparrow}$, Norm$^{\uparrow}$, CompleteMetric$^{\uparrow}$, RealSeparability$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *L is the local* NameCert$_{\text{FiniteRealizedSeparableBanachSpace}^{\uparrow}}$ *row.*

The carrier has no coordinate for a choice-selected dense enumeration, an external completion object, quotient real equality, selected Cauchy limits, Hahn–Banach functionals, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8449.2 (Finite-realized separable Banach space NameCert obligations)**.** *For every accepted* FiniteRealizedSeparableBanachSpace$^{\uparrow}$ *carrier*

$$F = (B, N, M, D, S, R, E, H, C, P, L),$$

the local NameCert$_{\text{FiniteRealizedSeparableBanachSpace}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *carrier: the packet displays the* BanachSpace$^{\uparrow}$ *carrier B, its* Norm$^{\uparrow}$ *readback N, and the induced* CompleteMetric$^{\uparrow}$ *row M before any separability or completion read is available;*
2. *dense-code admission: the* RealSeparability$^{\uparrow}$ *row D admits only displayed dense codes, read through the finite* StreamName$^{\uparrow}$ *windows S and the* RegSeqRat$^{\uparrow}$ *rational readback R;*
3. *norm/Cauchy stability: componentwise transport H and replay C preserve the same norm, dense-code, stream-window, and regular-rational rows under every accepted Cauchy request;*
4. *completion seal: completion-facing consumers reach the terminal real-name seal E only after the Banach, complete-metric, dense-code, stream, and regular-rational rows have been displayed;*
5. *no-choice ledger: provenance P and local name L record that the packet exports no selected dense enumeration, countable-choice branch, quotient completion equality, selected limit, Hahn–Banach datum, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8449.1. The Banach, norm, and complete-metric rows provide the only complete normed-space data available to a consumer.

The dense-code obligation is then read through D, S, R. The separability row admits only displayed codes, the stream row supplies finite observation windows, and the regular rational row attaches those windows to norm tolerances before the terminal real-name seal is reached.

Stability is the role of H and C. Since they transport and replay the same displayed coordinates, they cannot introduce a second dense enumeration, a detached completion object, or an off-ledger Cauchy limit.

The completion seal is therefore the row E read after B, N, M, D, S, R. Provenance and local naming, P, L, close the no-choice ledger by recording the absence of selected dense enumerants, countable choice, quotient completion equality, Hahn–Banach data, and ambient real-completeness coordinates. □

Closure status for NameCert$_{\text{FiniteRealizedSeparableBanachSpace}^{\uparrow}}$.

Constructive story: A FiniteRealizedSeparableBanachSpace$^{\uparrow}$ packet is generated from an ambient Banach carrier, norm and complete-metric rows, displayed separability codes, finite stream windows, regular rational readback, a terminal real-name seal, componentwise transport, replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteRealizedSeparableBanachSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8449.1 and Definition 8449.2 bind the displayed carrier, dense-code admission, norm/Cauchy stability, completion seal, and no-choice ledger.

Formal verification: FormalStatus(NameCert$_{\text{FiniteRealizedSeparableBanachSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a Lean theorem, a standard bridge, a selected dense enumeration, quotient Banach completion equality, Hahn–Banach, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Formal verification should encode the carrier rows and prove the five NameCert obligations without adding choice, quotient completion equality, selected limits, or ambient real-completeness coordinates.

Chapter 8450

A Concrete Naming Certificate for $\mathsf{Dvoretsky}^{\uparrow}$

Following Dvoretsky and Milman, the $\mathsf{Dvoretsky}^{\uparrow}$ packet records the finite-section surface by which a Banach-space carrier exposes a Hilbert-comparable finite-dimensional section with a displayed Banach–Mazur distortion ledger. It sits over the Banach-space source of **??**, the distance ledger of chapter 7979, the norm carrier of chapter 89, the Hilbert comparison surface of chapter 91, and the convex admissibility rows of chapter 208. The packet names only the finite BEDC handoff for a selected finite section and its distortion witness; it is not an ambient theorem asserting uniform Euclidean sections for every host Banach space.

Definition 8450.1 (Dvoretsky finite-section carrier)**.** *A* $\mathsf{Dvoretsky}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (B, N, S, D, H, C, P, L)$$

with the following displayed rows:

1. *B is the Banach and norm source row, read through the* $\mathsf{BanachSpace}^{\uparrow}$ *and* $\mathsf{Norm}^{\uparrow}$ *certificates.*
2. *N is the finite-dimensional section row, naming the finite subspace, coordinate window, and section inclusion under the same norm source.*
3. *S is the Hilbert comparison row, recording the finite Euclidean model and the comparison map to the selected section.*
4. *D is the* $\mathsf{BanachMazurDistance}^{\uparrow}$ *distortion ledger for the comparison between N and S.*
5. *H records componentwise* hsame *transport for the Banach source, section row, Hilbert comparison, distortion ledger, provenance, and local name.*
6. *C records displayed* Cont *replay from the Banach source through the finite section, Hilbert comparison, and distortion ledger.*
7. *P is the* Pkg *provenance over* $\mathsf{BanachSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{BanachMazurDistance}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
8. *L is the local* $\mathsf{NameCert}_{\mathsf{Dvoretsky}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host infinite-dimensional compactness theorem, selected global basis, quotient Banach space, unrestricted finite-codimensional projection, classical choice schedule, or ambient Euclideanization principle.

Theorem 8450.2 (Dvoretsky NameCert obligations)**.** *For the carrier of Definition 8450.1, the local* $\mathsf{NameCert}_{\mathsf{Dvoretsky}^{\uparrow}}$ *surface consists exactly of Banach and norm source exposure through* B*, finite-dimensional section exposure through* N*, Hilbert comparison through* S*, Banach–Mazur distortion readback through* D*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* L*.*

Proof. Project the finite packet $Q = (B, N, S, D, H, C, P, L)$. The first four rows display the mathematical content: source normed Banach data, the finite section, the Hilbert comparison row, and the distortion ledger.

Read the structural rows next. The transport row H compares the displayed rows componentwise, while C replays only the route from source to section, from section to Hilbert comparison, and from comparison to distortion ledger.

Finally inspect P and L. They source and name the same finite packet, and neither supplies an additional compactness, basis-selection, quotient, choice, or global Euclideanization row. Hence the listed rows exhaust the local NameCert surface. □

Theorem 8450.3 (Dvoretsky finite-dimensional section handoff)**.** *Every accepted* $\mathsf{Dvoretsky}^{\uparrow}$ *consumer that reads a Hilbert-comparable finite section must first expose the Banach and norm source row* B*, the finite-dimensional section row* N*, the Hilbert comparison row* S*, the Banach–Mazur distortion ledger* D*, and the structural rows* H, C, P, L*. The handoff reaches downstream Banach, Hilbert, convex, or distortion consumers only through this finite route.*

Proof. Start from the carrier. A finite-section read is stored in N, but the row is attached to the Banach and norm source B and to the Hilbert comparison row S inside the same packet.

Apply the NameCert obligations of Definition 8450.2. They place the distortion ledger D after the section and comparison rows, and they keep H, C, P, L as preservation, replay, provenance, and naming data for the same route.

Thus a consumer cannot read a Hilbert-comparable section as a detached host subspace or as an unrecorded Euclidean model. It receives the displayed finite section only after B, N, S, D, H, C, P, L have been exposed. □

Theorem 8450.4 (Dvoretsky non-escape)**.** *An accepted* $\mathsf{Dvoretsky}^{\uparrow}$ *packet exports no host Banach-space compactness theorem, no selected global basis, no quotient representative, no unrestricted projection, no classical choice schedule, and no ambient assertion that all finite-dimensional sections are Euclidean. Every finite-section claim available from the packet is routed through* B, N, S, D, H, C, P, L*.*

Proof. Inspect the carrier coordinates. The only rows present are the Banach and norm source, finite section, Hilbert comparison, Banach–Mazur distortion ledger, transport, replay, provenance, and local naming rows.

Use Definition 8450.3. Any downstream consumer must pass through the displayed section and distortion handoff before using the finite Hilbert comparison.

The excluded principles are not rows of the packet. Since H, C, P, L only preserve and name the same finite route, no host compactness theorem, global basis selector, quotient representative, unrestricted projection, choice schedule, or ambient Euclideanization principle can escape from the certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{Dvoretsky}^{\uparrow}}$**.**

Constructive story: A $\mathsf{Dvoretsky}^{\uparrow}$ packet is generated from a Banach and norm source row, a finite-dimensional section row, a Hilbert comparison row, a Banach–Mazur distortion ledger, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{Dvoretsky}\uparrow}$, seed)

Scope closed: Definition 8450.1, Definition 8450.2, Definition 8450.3, and Definition 8450.4 seed the finite-section NameCert surface over Banach, norm, Hilbert, convex, and Banach–Mazur distance rows.

Formal verification: FormalStatus(NameCert$_{\text{Dvoretsky}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close the full analytic Dvoretsky theorem, host compactness, global basis selection, quotient representatives, unrestricted projections, choice, Lean verification, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-section exposure, Hilbert comparison stability, Banach–Mazur distortion readback, transport, replay, provenance, local naming, and non-escape for BEDC.Derived.DvoretskyUp.

Chapter 8451

A Concrete Naming Certificate for $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$

Following Bishop and Bridges, constructive diagonal arguments over regular rational names first synchronize dyadic tolerances and finite stream windows, then expose a regular readback before any real-name seal is available. The $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ packet records that finite L10 route as NameCert data. It sits after the dyadic tolerance rows of chapter 291, the finite-window interface of chapter 126, the regular rational readback of chapter 301, the diagonal-limit route of chapter 6002, and the terminal real-name seal of chapter 38. The packet supplies Real and Completion consumers with a finite dyadic diagonal schedule; it is not quotient stream equality, a selected representative, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8451.1 (Dyadic Cauchy diagonal carrier)**.** *A* $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (D_0, S, R, G, E, H, C, P, N)$$

with the following displayed rows:

1. D_0 *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance schedule, recording the denominator scale, slack cells, and comparison ledger used by every diagonal read.*
2. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window family, exposing only the source windows requested by the dyadic tolerance schedule.*
3. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from the displayed windows and tolerance ledger.*
4. G *is the regular Cauchy diagonal row, recording the synchronized diagonal request before the terminal real-name seal is visible.*
5. E *is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after* D_0, S, R, G *have been displayed.*
6. H *records componentwise* hsame *transport for the dyadic schedule, finite windows, regular readback, diagonal row, real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay from each Real or Completion request through* D_0, S, R, G, E, H, P, N.
8. P *is the* Pkg *provenance over* $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalLimit}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. N *is the local* $\mathsf{NameCert}_{\mathsf{DyadicCauchyDiagonal}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D_0, S, R, G, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable-choice schedules, trichotomy, host real equality, ambient completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.DyadicCauchyDiagonalUp.DyadicCauchyDiagonalUp`

Theorem 8451.2 (Dyadic Cauchy diagonal NameCert obligations)**.** *For every accepted* $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ *carrier*

$$D = (D_0, S, R, G, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicCauchyDiagonal}^{\uparrow}}$ *surface consists exactly of carrier admission for the dyadic tolerance schedule, finite stream windows, regular rational readback, regular Cauchy diagonal row, terminal Real seal, componentwise transport, displayed replay, package provenance, and local naming rows.*

Proof. Project the carrier of Definition 8451.1. The displayed tuple $D_0, S, R, G, E, H, C, P, N$ is the entire public surface, so carrier admission is exactly admission of those nine rows.

The analytic rows are ordered. The dyadic tolerance schedule D_0 determines which finite windows S may be opened, and the readback row R is assembled only from those windows and tolerance cells.

The diagonal row G then records the synchronized regular Cauchy request. Only after G is displayed may the terminal $\mathsf{Real}^{\uparrow}$ seal E be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since no further coordinate is present, no quotient stream, selected representative, countable-choice schedule, trichotomy row, host real equality, ambient completion object, or ambient real-completeness principle can become a local NameCert obligation. □

Theorem 8451.3 (Dyadic Cauchy diagonal RegSeqRat handoff)**.** *Every Real or Completion consumer of an accepted* $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ *carrier first reads the finite handoff*

$$D_0, S \longmapsto R \longmapsto G \longmapsto E \longmapsto H, C, P, N.$$

Thus the diagonal route hands off a $\mathsf{RegSeqRat}^{\uparrow}$ *readback before the regular Cauchy diagonal row and terminal real seal are available.*

Proof. Start with a consumer request. The carrier exposes no direct seal coordinate, so the request first enters the dyadic tolerance schedule D_0 and the finite-window row S.

Those rows determine the regular rational readback R. The diagonal row G is downstream of that readback, so it cannot be consumed until the RegSeqRat handoff is visible.

The real seal E and the structural rows H, C, P, N preserve this displayed route under transport, replay, provenance, and local naming. Therefore every Real or Completion consumer receives the finite handoff stated above. □

Theorem 8451.4 (Dyadic Cauchy diagonal nonescape)**.** *An accepted* $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ *carrier exports no quotient stream equality, selected representative, countable-choice schedule, trichotomy row, host real equality, ambient completion object, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Inspect the carrier rows in Definition 8451.1. The only analytic rows are the dyadic tolerance schedule, finite stream windows, regular rational readback, regular Cauchy diagonal row, and terminal real seal.

The remaining rows are structural: transport, replay, provenance, and local naming. They can preserve or replay the displayed finite route, but they do not introduce a new analytic coordinate.

Any excluded object would need a readable row distinct from $D_0, S, R, G, E, H, C, P, N$. No such row exists in the carrier, so the excluded objects cannot escape through the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ Real or Completion read factors through a DyadicRatCore tolerance schedule, StreamName finite-window family, RegSeqRat readback, regular Cauchy diagonal row, RealUp seal, hsame transport, Cont replay, Pkg provenance, and local NameCert row before the terminal seal is consumed.

Independence witness: dyadicratcore, streamname, regseqrat, regular-cauchy-diagonal-limit, real: $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the dyadic tolerance schedule, finite windows, regular rational readback, diagonal route, real seal, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicCauchyDiagonal}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicCauchyDiagonal}^{\uparrow}$ packet is generated from a DyadicRatCore tolerance schedule, StreamName finite windows, RegSeqRat readback, a regular Cauchy diagonal row, a RealUp terminal seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicCauchyDiagonal}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8451.1, Definition 8451.2, Definition 8451.3, and Definition 8451.4 seed the finite dyadic diagonal route from tolerance schedules through RegSeqRat readback to a terminal RealUp seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicCauchyDiagonal}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, ambient completion, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window coverage, dyadic tolerance exactness, RegSeqRat handoff, diagonal-row stability, Real seal non-escape, componentwise transport, displayed replay, and local naming for BEDC.Derived.DyadicCauchyDiagonalUp.

Chapter 8452

A Concrete Naming Certificate for $\mathsf{HairyBall}^{\uparrow}$

Following Brouwer and Hopf-style tangent-field obstruction theorems, the $\mathsf{HairyBall}^{\uparrow}$ packet records the finite BEDC surface by which a tangent vector-field obstruction on an even sphere is named. It reads the circle boundary discipline of chapter 58, the degree obstruction row of chapter 3745, the finite chart source of chapter 96, the tangent-bundle rows of chapter 210, and the terminal real seal of chapter 38. The packet stores only displayed rows; it does not import a host tangent field, quotient equality of sphere points, selected zeros, compactness by open covers, or an ambient classical degree theorem.

Definition 8452.1 (Hairy-ball carrier)**.** *A* $\mathsf{HairyBall}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, T, V, Z, D, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the sphere-source row, recording the displayed even-sphere chart and boundary data read through* $\mathsf{Manifold}^{\uparrow}$ *and the circle source of chapter 58.*
2. *T is the tangent-bundle row over S, read through* $\mathsf{VectorBundle}^{\uparrow}$ *and carrying only the displayed fibre and transition data needed for tangent reads.*
3. *V is the vector-field row, recording the finite local vector assignments and their compatibility with T.*
4. *Z is the zero-obstruction row, recording the finite ledger that blocks a nowhere-zero export from the displayed field data.*
5. *D is the Brouwer-degree and Euler-obstruction row, read through* $\mathsf{BrouwerDegree}^{\uparrow}$ *and used only as the finite obstruction ledger for the displayed sphere route.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the scalar comparison consumed by the obstruction.*
7. *H records componentwise* hsame *transports for S, T, V, Z, D, R and the structural rows.*
8. *C records the displayed* Cont *replay order by which consumers read the sphere source, tangent bundle, vector field, zero obstruction, degree obstruction, real seal, transports, provenance, and local naming.*
9. *P is the* Pkg *provenance over* $\mathsf{HairyBall}^{\uparrow}$, $\mathsf{S}^{1\uparrow}$, $\mathsf{BrouwerDegree}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{VectorBundle}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{HairyBall}^\uparrow}$ *row.*
The carrier has no coordinate for a host vector field, a selected zero, quotient equality of sphere points, unrestricted compactness, or a classical tangent-bundle theorem outside the displayed rows.

Lean4 (statement) `BEDC.Derived.HairyBallUp`

Theorem 8452.2 (Hairy-ball NameCert obligations)**.** *For every accepted* $\mathsf{HairyBall}^\uparrow$ *carrier* $Q = (S, T, V, Z, D, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HairyBall}^\uparrow}$ *surface consists exactly of sphere-source admission, tangent-bundle exposure, vector-field row exposure, zero-obstruction retention, Brouwer-degree and Euler-obstruction routing, terminal* $\mathsf{Real}^\uparrow$ *sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 8452.1. The rows S, T, V expose the sphere, tangent-bundle, and vector-field data before any obstruction is read.

The rows Z, D, R then bind the obstruction surface. The zero-obstruction row records the blocked nowhere-zero export, the Brouwer-degree and Euler row supplies the displayed obstruction ledger, and the terminal real row seals the scalar comparison consumed by that ledger.

Finally use H, C, P, N. Componentwise transport preserves the same displayed rows, continuation replay fixes their order, provenance names the sibling certificates, and the local NameCert row packages the finite surface. No missing coordinate can supply a host vector field, selected zero, quotient equality, compactness principle, or ambient degree theorem. □

Theorem 8452.3 (Hairy-ball tangent-field route)**.** *Every tangent-field consumer of an accepted* $\mathsf{HairyBall}^\uparrow$ *packet must factor through the route*

$$S \longmapsto T \longmapsto V \longmapsto Z \longmapsto D \longmapsto R \longmapsto H \longmapsto C \longmapsto P \longmapsto N$$

before reading the displayed obstruction. The exported route is therefore a finite tangent-field obstruction packet over $\mathsf{Manifold}^\uparrow$*,* $\mathsf{VectorBundle}^\uparrow$*,* $\mathsf{BrouwerDegree}^\uparrow$*,* $\mathsf{Real}^\uparrow$*, and* $\mathsf{S}^{1\uparrow}$ *rows, not a host theorem selecting a zero or a nowhere-zero vector field.*

Proof. Start with S and T. The sphere-source row fixes the displayed chart and boundary data, and the tangent-bundle row fixes the fibre reads over that same source.

Next read V, Z, D, R. The vector-field row is consumed only as local data over T; the zero-obstruction and degree rows record the obstruction ledger; and the real seal is downstream of those rows rather than an independent host comparison.

The structural rows H, C, P, N preserve the same order. Transport, replay, provenance, and naming can repack the displayed packet, but they cannot introduce a selected zero, quotient equality of sphere points, an unrestricted compactness argument, or a classical tangent-field theorem outside the finite carrier. □

Closure status for $\mathsf{NameCert}_{\mathsf{HairyBall}^\uparrow}$**.**

Constructive story: A $\mathsf{HairyBall}^\uparrow$ packet is generated from a sphere-source row, tangent-bundle row, vector-field row, zero-obstruction row, Brouwer-degree and Euler-obstruction row, terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HairyBall}^\uparrow}$, seed)

Scope closed: Definition 8452.1, Definition 8452.2, and Definition 8452.3 seed the finite tangent-field obstruction route for HairyBallUp.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HairyBall}^\uparrow}$, formalTarget)

Bridge status: none

Not claimed: This chapter does not claim a selected zero, a nowhere-zero vector field, quotient equality of sphere points, unrestricted compactness, Lean verification of the obstruction theorem, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, tangent-bundle exposure, vector-field row exposure, zero-obstruction retention, degree-obstruction routing, real-seal routing, transport, replay, provenance, and local naming for BEDC.Derived.HairyBallUp.

Chapter 8453

A Concrete Naming Certificate for $\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Kelley filter-base terminology, the FiniteCauchyFilterBasisRefine packet records the finite common-refinement layer used by the L10 Cauchy-filter route before located or regular completion consumers read the basis. It sits after the basis generator of chapter 1501 and the finite meet packet of chapter 1958, and before the located filter route of chapter 1661. Its readback support passes through the stream windows of chapter 126, the regular rational rows of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The chapter names a finite refinement packet only; it does not complete a quotient filter, select a limit, invoke countable choice, identify host equality, decide trichotomy, or assume ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8453.1 (Finite Cauchy filter basis refinement carrier)**.** *A* $\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (B, R, D, M, S, H, C, P, N)$$

with the following displayed rows:

1. *B is the source* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row whose finite basis elements are being compared.*
2. *R is the refinement request row. It names the finite pair or finite family of basis requests that must be jointly refined before a located or regular completion consumer may read them.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to the same requests, including the displayed radius and inclusion budget used to compare regular rational observations.*
4. *M is the finite meet and common-refinement witness, read through* $\mathsf{CauchyFilterMeet}^{\uparrow}$*, that names a displayed basis element refining every request recorded in R.*
5. *S is the support row carrying the* $\mathsf{StreamName}^{\uparrow}$ *windows and* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks used by B, R, D, M.*
6. *H records componentwise* hsame *transport for B, R, D, M, S and for the continuation, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a refinement request through the support row S, the tolerance ledger D, the meet witness M, and then the downstream located or regular consumer boundary.*

8. *P is the* Pkg *provenance over* FiniteCauchyFilterBasisRefinement$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, CauchyFilterMeet$^{\uparrow}$, LocatedCauchyFilter$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* NameCert$_{\text{FiniteCauchyFilterBasisRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, R, D, M, S, H, C, P, N$. It has no coordinate for completed filters, quotient Cauchy names, selected representatives, countable-choice schedules, trichotomy decisions, host real equality, or ambient completeness of Real$^{\uparrow}$.

Theorem 8453.2 (Finite Cauchy filter basis refinement NameCert obligations)**.** *For every accepted* FiniteCauchyFilterBasisRefinement$^{\uparrow}$ *carrier $K = (B, R, D, M, S, H, C, P, N)$, the local* NameCert$_{\text{FiniteCauchyFilter}}$ *surface consists exactly of carrier admission for the source basis row, refinement request row, dyadic tolerance ledger, finite meet witness, stream and regular-rational support row, componentwise transport, displayed replay, provenance, and local naming. Every located or regular completion-facing consumer must first read B, R, D, M, S and then pass through H, C, P, N before any downstream filter or* Real$^{\uparrow}$ *seal is inspected.*

Proof. Project the carrier of Definition 8453.1. Its mathematical rows are exactly the source basis B, refinement request R, tolerance ledger D, meet witness M, and support row S.

The support row is not an independent completion principle. It only displays the StreamName$^{\uparrow}$ windows and RegSeqRat$^{\uparrow}$ readbacks that the basis, request, tolerance, and meet rows already use.

The structural rows H, C, P, N transport, replay, source, and name that route. Since no carrier coordinate stores a completed filter, quotient name, selected limit, choice schedule, trichotomy decision, host real equality, or ambient completeness proof, the listed rows exhaust the local NameCert obligations. □

Theorem 8453.3 (Finite Cauchy filter basis refinement common refinement)**.** *Let $K = (B, R, D, M, S, H, C, P, N)$ be an accepted* FiniteCauchyFilterBasisRefinement$^{\uparrow}$ *carrier. Every request listed in R has a displayed common refinement read through the meet row M, and that refinement is checked against the same stream windows, regular rational readbacks, and dyadic tolerance ledger carried by S and D. Thus a consumer receives a finite common-refinement certificate, not a completed filter object or a choice of limit.*

Proof. Read the request row R together with the basis row B. The accepted carrier requires these requests to be basis-level requests over the same displayed observation surface.

Apply the meet row M. It supplies the common-refinement witness through CauchyFilterMeet$^{\uparrow}$, so every listed request is refined by a displayed basis element before the consumer sees a downstream filter boundary.

Finally replay the witness through S, D, H, C, P, N. The stream windows, regular rational readbacks, and dyadic tolerances remain visible, while the structural rows add only transport, replay, provenance, and local naming. Hence the certificate is finite and does not select a completed filter or limit. □

Theorem 8453.4 (Finite Cauchy filter basis refinement Real seal boundary)**.** *Every* Real$^{\uparrow}$*-facing read exposed by an accepted* FiniteCauchyFilterBasisRefinement$^{\uparrow}$ *packet factors through the finite route*

CauchyFilterBasis$^{\uparrow}$, CauchyFilterMeet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, LocatedCauchyFilter$^{\uparrow}$, Real$^{\uparrow}$.

The route may hand a common-refinement certificate to located or regular completion consumers, but it cannot turn that certificate into quotient filter equality, selected convergence, countable choice, host equality of real names, trichotomy, or ambient completeness of Real$^{\uparrow}$.

Proof. Start from the NameCert obligations of Definition 8453.2. They force every downstream read to expose the basis, request, tolerance, meet, and support rows before structural replay is available.

Use common refinement from Definition 8453.3. The meet witness is a finite basis-level certificate checked against the same stream, regular rational, and dyadic rows; it is not a completed filter or a selected limit.

The only real-facing route in the provenance row passes through the located filter boundary and then the terminal $\mathsf{Real}^{\uparrow}$ seal. Since the carrier has no coordinate for quotient filters, selected convergence, choice, host equality, trichotomy, or ambient completeness, the Real-facing read remains a boundary handoff rather than a completeness principle. □

Falsifiable prediction: Every accepted $\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}$ consumer that claims a basis refinement must display a $\mathsf{CauchyFilterBasis}^{\uparrow}$ row, a refinement request row, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, a $\mathsf{CauchyFilterMeet}^{\uparrow}$ witness, $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ support rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Independence witness: cauchy-filter-basis, cauchy-filter-meet, located-cauchy-filter, stream-name, regseqrat, dyadicratcore, real: no listed sibling is bijective to $\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}$ because this packet jointly binds source basis data, a refinement request, a dyadic tolerance ledger, a finite meet witness, readback support, downstream handoff provenance, transport, replay, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}$ packet is generated from a CauchyFilterBasis row, a finite refinement request row, a DyadicRatCore tolerance ledger, a CauchyFilterMeet common-refinement witness, StreamName and RegSeqRat support rows, componentwise hsame transport, displayed Cont replay, package provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8453.1, Definition 8453.2, Definition 8453.3, and Definition 8453.4 seed the finite common-refinement packet between raw Cauchy filter bases and located or regular completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteCauchyFilterBasisRefinement}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient filters, selected limits, countable choice, host equality, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, common-refinement witness exactness, readback support preservation, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteCauchyFilterBasisRefinemen

Chapter 8454

A Concrete Naming Certificate for $\mathsf{PringsheimTauberian}^{\uparrow}$

Following Pringsheim on positive term series and Hardy's account of Tauberian theory, the $\mathsf{PringsheimTauberian}^{\uparrow}$ packet records the finite route by which a Pringsheim-positive real series may pass from Abel boundary data and a Tauberian side ledger back to ordinary real-series readback. It sits after the positive-series source of chapter 2080, the Pringsheim convergence surface of chapter 6261, the Hardy–Littlewood Tauberian handoff of chapter 1932, the Tauberian remainder boundary of chapter 1991, the Abel summation route of chapter 1763, the real-series source of chapter 1581, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet is a finite NameCert surface for a positive-series Tauberian route; it is not an ambient theorem about arbitrary series, quotient series equality, selected limits, trichotomy, countable choice, open-cover compactness, or host $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8454.1 (Pringsheim-Tauberian carrier)**.** *A* $\mathsf{PringsheimTauberian}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (S, C, A, B, T, M, R, E, H, K, P, N)$$

whose rows have the following roles.

1. *S is the* $\mathsf{PringsheimPositiveRealSeries}^{\uparrow}$ *source row, displaying positive real-series coefficients and finite partial-sum windows.*
2. *C is the* $\mathsf{PringsheimConvergence}^{\uparrow}$ *convergence row, recording the ordinary Pringsheim-facing partial-sum readback admitted for the inspected positive series.*
3. *A is the* $\mathsf{AbelSummation}^{\uparrow}$ *row, displaying summation-by-parts and radial Abel boundary windows for the same source row.*
4. *B is the Abel boundary row supplied by the* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ *route.*
5. *T is the Tauberian side row, supplied either by the* $\mathsf{HardyLittlewoodTauberian}^{\uparrow}$ *tail ledger or by the* $\mathsf{TauberianRemainder}^{\uparrow}$ *remainder ledger.*
6. *M is the comparison row tying the Abel boundary, the Tauberian side row, and the ordinary partial-sum readback to one finite tolerance request.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the ordinary series endpoint.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached by the ordinary readback.*

9. *H records componentwise* hsame *transport for positive-series rows, Abel rows, Tauberian side rows, ordinary readback, Real sealing, replay, provenance, and local naming.*
10. *K records displayed* Cont *replay from a requested precision through the Abel boundary and Tauberian side row to the ordinary readback and Real seal.*
11. *P is the* Pkg *provenance over* PringsheimTauberian$^{\uparrow}$, PringsheimPositiveRealSeries$^{\uparrow}$, PringsheimConvergence$^{\uparrow}$, HardyLittlewoodTauberian$^{\uparrow}$, TauberianRemainder$^{\uparrow}$, AbelSummation$^{\uparrow}$, RealSeries$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* NameCert$_{\text{PringsheimTauberian}^{\uparrow}}$ *row.*

Theorem 8454.2 (Pringsheim-Tauberian NameCert obligations)**.** *For every accepted* PringsheimTauberian$^{\uparrow}$ *carrier $Q = (S, C, A, B, T, M, R, E, H, K, P, N)$, the local* NameCert$_{\text{PringsheimTauberian}^{\uparrow}}$ *surface consists exactly of carrier admission for that twelve-row packet, positive-series exposure through S, Pringsheim convergence exposure through C, Abel summation exposure through A, Abel boundary exposure through B, Tauberian side exposure through T, comparison exposure through M, regular rational readback through R, Real sealing through E, and transport, replay, provenance, and local naming through H, K, P, N.*

Proof. Project the carrier of Definition 8454.1. Its analytic rows are precisely S, C, A, B, T, M, R, E, and its structural rows are precisely H, K, P, N.

Read the source rows first. The positive-series row S supplies the coefficients and finite partial sums, while C supplies the ordinary Pringsheim-facing convergence readback. The Abel row A and boundary row B then expose only radial and summation-by-parts data for the same source.

Next inspect the Tauberian rows. The side row T and comparison row M are the only coordinates that relate the Abel boundary to the ordinary readback, and R, E are the only endpoint coordinates. Componentwise transport, displayed replay, provenance, and local naming therefore preserve the same finite surface and supply no hidden host theorem. □

Theorem 8454.3 (Pringsheim-Tauberian Abel handoff)**.** *Every ordinary real-series endpoint exported by an accepted* PringsheimTauberian$^{\uparrow}$ *carrier factors through the finite route*

$$S, C \longmapsto A, B \longmapsto T, M \longmapsto R, E \longmapsto H, K, P, N.$$

Thus an Abel-facing read becomes an ordinary positive-series read only after the displayed Tauberian side row and comparison row have been replayed through the same hsame *and* Cont *surface.*

Proof. Begin with the positive source and ordinary convergence rows S, C. They display the partial-sum window and the Pringsheim-facing readback that any endpoint consumer must cite.

Then apply the Abel summation and Hardy–Littlewood boundary routes. The rows A, B expose Abel data, but they do not by themselves export ordinary convergence; they are boundary data for the Tauberian stage.

Finally use the Tauberian side row T and comparison row M. These rows connect the Abel boundary to the regular rational readback R and terminal Real seal E, while H, K, P, N transport, replay, source, and name the same finite packet. Hence the endpoint cannot be obtained from quotient series equality, selected limits, countable choice, trichotomy, open-cover compactness, or ambient Real completeness. □

Falsifiable prediction: An accepted PringsheimTauberian$^{\uparrow}$ consumer that reaches a Real$^{\uparrow}$ seal without first reading the PringsheimPositiveRealSeries$^{\uparrow}$ row, AbelSummation$^{\uparrow}$ row, Tauberian side row, comparison row, and RegSeqRat$^{\uparrow}$ readback row refutes the carrier surface.

Independence witness: pringsheim-positive-real-series, pringsheim-convergence, hardy-littlewood-tauberian, tauberian-remainder, abel-summation, realseries, regseqrat, real: no listed sibling supplies the whole twelve-row packet $Q = (S, C, A, B, T, M, R, E, H, K, P, N)$, because each sibling contributes only a positive-series source, convergence readback, Abel boundary, Tauberian side ledger, summation route, regular readback, seal face, or structural row while this chapter binds them into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PringsheimTauberian}\uparrow}$.

Constructive story: A PringsheimTauberian$^{\uparrow}$ packet is generated from a Pringsheim-positive real-series row, a Pringsheim convergence row, Abel summation rows, Abel boundary rows, Tauberian side-condition rows, comparison rows, RegSeqRat readback, a RealUp seal, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PringsheimTauberian}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8454.1, Definition 8454.2, and Definition 8454.3 seed the finite positive-series Tauberian route over Pringsheim, AbelSummation, HardyLittlewoodTauberian, TauberianRemainder, RegSeqRat, RealSeries, and RealUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PringsheimTauberian}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient Tauberian theory, arbitrary real-series convergence, quotient series equality, selected limits, trichotomy, countable choice, open-cover compactness, Lean verification, or bridge checking.

Upgrade path: A formal route can encode the twelve-row carrier and prove the finite NameCert obligation surface, Abel handoff theorem, and Real seal nonescape for BEDC.Derived.PringsheimTauberianUp.

Chapter 8455

A Concrete Naming Certificate for $\mathsf{NewmanLemma}^{\uparrow}$

Following Newman on terminating abstract reduction systems, the $\mathsf{NewmanLemma}^{\uparrow}$ packet records the finite BEDC surface by which local confluence and normalization evidence can be routed toward confluence-facing MetaCIC consumers. It sits beside the traditional Church–Rosser packet of chapter 6198 and reads the MetaCIC normalization-confluence bridge of chapter 1190, the normalization frontier of chapter 892, and the parallel-diamond frontier of chapter 4238. The packet names a handoff from terminating local peaks to a bounded confluence route; it is not an unconditional Church–Rosser theorem, a subject-reduction theorem, quotient syntax equality, evaluator equality, or kernel consistency.

Definition 8455.1 (Newman lemma carrier)**.** *A* $\mathsf{NewmanLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (T, L, W, J, B, O, H, C, P, M)$$

with the following displayed rows:

1. *T is the terminating or strongly normalizing measure row for the displayed reduction source.*
2. *L is the local-confluence row, exposing only finite one-step peak data for the same source.*
3. *W is the well-founded descent ledger that forces every iterated peak analysis to consume a smaller displayed row.*
4. *J is the local join budget extracted from L under the descent row W.*
5. *B is the MetaCIC bridge row, read through* $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$ *and carrying only normalization-confluence correspondence data.*
6. *O is the obstruction row recording that subject reduction, quotient syntax equality, host evaluator equality, and unrestricted Church–Rosser remain outside the packet.*
7. *H records componentwise* hsame *transport for T, L, W, J, B, O and the structural rows.*
8. *C records displayed* Cont *replay from a confluence-facing request through $T, L, W, J, B, O, H, P, M$.*
9. *P is the* Pkg *provenance over* $\mathsf{NewmanLemma}^{\uparrow}$, $\mathsf{ChurchRosser}^{\uparrow}$, $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *M is the local* $\mathsf{NameCert}_{\mathsf{NewmanLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $T, L, W, J, B, O, H, C, P, M$. There is no coordinate for a global confluence oracle, a subject-reduction discharge, quotient equality of terms, evaluator equality, or a consistency endpoint.

Theorem 8455.2 (Newman lemma NameCert obligations)**.** *For every accepted* $\mathsf{NewmanLemma}^{\uparrow}$ *carrier* $N = (T, L, W, J, B, O, H, C, P, M)$*, the local* $\mathsf{NameCert}_{\mathsf{NewmanLemma}^{\uparrow}}$ *surface consists exactly of termination evidence, local-confluence exposure, well-founded descent, local-join budgeting, MetaCIC bridge routing, obstruction retention, componentwise transport, displayed replay, provenance, and local naming through the displayed rows.*

Proof. Project the carrier of Definition 8455.1. The rows T, L, W, J expose the traditional Newman ingredients: termination, local confluence, descent, and local joins for the same displayed source.

The bridge row B then fixes the only MetaCIC-facing route. It reads normalization-confluence correspondence data through the existing bridge packet rather than inventing a detached confluence theorem.

Finally use O, H, C, P, M. The obstruction row records the missing global claims, while transport, replay, provenance, and local naming preserve the same finite route. Since no further coordinate is present, the NameCert surface cannot supply subject reduction, quotient term equality, evaluator equality, unrestricted Church–Rosser, or kernel consistency. □

Theorem 8455.3 (Newman local-confluence normalization handoff)**.** *Every confluence-facing consumer of an accepted* $\mathsf{NewmanLemma}^{\uparrow}$ *carrier first reads the finite handoff*

$$T, L \longmapsto W \longmapsto J \longmapsto B \longmapsto O, H, C, P, M.$$

Thus local confluence is consumed only under the displayed normalization or termination row, and the resulting join budget is handed to the MetaCIC normalization-confluence bridge before any confluence conclusion is visible.

Proof. Start with the rows T and L. The local peak row is readable only for the same source whose terminating measure is displayed by T.

Next consume W and J. The descent ledger orders the finite peak analysis, and the local join budget records the bounded join data produced by that analysis.

The bridge and structural rows then close the handoff route. Row B passes the bounded join budget to the normalization-confluence bridge, while O, H, C, P, M retain the obstruction boundary, replay order, provenance, and local naming. □

Theorem 8455.4 (Newman MetaCIC route)**.** *Any MetaCIC use of* $\mathsf{NewmanLemma}^{\uparrow}$ *factors through the sibling route*

$\mathsf{ChurchRosser}^{\uparrow}$, $\mathsf{MetaCICNormalizationConfluenceBridge}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, $\mathsf{MetaCICParallelDiamondI}$

The Newman packet may therefore serve as a finite local-confluence and normalization handoff, but it does not discharge subject reduction, residual substitution compatibility, full closed confluence, quotient syntax equality, evaluator equality, or kernel consistency.

Proof. Read the provenance row P of Definition 8455.1. It names the Church–Rosser sibling, the normalization-confluence bridge, the normalization frontier, and the parallel-diamond frontier as the only MetaCIC-facing dependencies.

The analytic rows T, L, W, J, B are then consumed along that provenance route. They can produce a bounded local-confluence handoff under termination, and they can feed the bridge row, but they do not add the missing subject-reduction or residual-substitution premises.

The obstruction and structural rows preserve this boundary. Hence the route remains a finite Newman-style handoff inside the displayed MetaCIC dependency lattice. □

Closure status for $\mathsf{NameCert}_{\mathsf{NewmanLemma}\uparrow}$.

Constructive story: A $\mathsf{NewmanLemma}^{\uparrow}$ packet is generated from termination evidence, local-confluence exposure, well-founded descent, local-join budgeting, MetaCIC bridge routing, obstruction retention, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NewmanLemma}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8455.1, Definition 8455.2, Definition 8455.3, and Definition 8455.4 seed the finite Newman handoff from terminating local confluence into the MetaCIC normalization-confluence route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NewmanLemma}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close subject reduction, residual substitution compatibility, full closed confluence, quotient syntax equality, evaluator equality, Lean verification, bridge checking, or kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, local-confluence exposure, well-founded descent, local-join budgeting, MetaCIC bridge routing, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.NewmanLemmaUp.

Chapter 8456

A Concrete Naming Certificate for MetaCICResidualNormalFormBudgetRouter$^{\uparrow}$

The MetaCICResidualNormalFormBudgetRouter$^{\uparrow}$ packet realizes a residual normal-form budget route for MetaCIC as finite candidate-mediated NameCert data. It sits beside the typed normal-form scheduler of chapter 6617, the residual diamond budget of chapter 7407, the residual join budget of chapter 7378, the normal-endpoint budget of chapter 4292, and the candidate-normalization confluence handoff of chapter 5547. The router stores the finite rows by which a residual pair, candidate gate, normal-form scheduler budget, and endpoint seal are read before a confluence-facing handoff is public; it is not a global normalization theorem, subject-reduction theorem, unrestricted residual diamond, quotient syntax equality, evaluator equality, or kernel-consistency certificate.

Definition 8456.1 (MetaCIC residual normal-form budget router carrier)**.** *A* MetaCICResidualNormalFormBudgetR *carrier is a finite* BHist *packet*

$$R = (W, D, J, S, E, Q, O, H, C, P, N)$$

with the following displayed rows:

1. *W is the typed residual window row, recording the closed typed source, residual pair, and bounded comparison window.*
2. *D is the residual-diamond budget row, read through* MetaCICResidualDiamondBudget$^{\uparrow}$ *and retaining the finite local-diamond checker surface.*
3. *J is the residual-join budget row, read through* MetaCICResidualJoinBudget$^{\uparrow}$ *and recording the candidate join that the checker may inspect.*
4. *S is the typed normal-form scheduler row, read through* MetaCICTypedNormalFormScheduler$^{\uparrow}$ *and exposing candidate-gate and scheduler-budget data.*
5. *E is the normal-endpoint budget row, read through* MetaCICNormalEndpointBudget$^{\uparrow}$ *and sealing the finished normal endpoint available to bounded comparison.*
6. *Q is the candidate-normalization confluence handoff row, read through* MetaCICCandidateNormalizationConfluenc *only after W, D, J, S, E have been displayed.*
7. *O is the obstruction row, retaining failed candidate gates, exhausted scheduler budgets, blocked residual pairs, missing endpoint seals, and failed bounded local joins.*
8. *H records componentwise* hsame *transport for W, D, J, S, E, Q, O and the structural rows.*

9. *C records displayed* Cont *replay from a residual normal-form request through* $W, D, J, S, E, Q, O, H, P, N$.
10. *P is the* Pkg *provenance over* MetaCICResidualNormalFormBudgetRouter$^{\uparrow}$, MetaCICTypedNormalFormScheduler$^{\uparrow}$, MetaCICResidualDiamondBudget$^{\uparrow}$, MetaCICResidualJoinBudget$^{\uparrow}$, MetaCICNormalEndpointBudget$^{\uparrow}$, MetaCICCandidateNormalizationConfluenceHandoff$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* NameCert$_{\text{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}}$ *row.*

The classifier compares accepted router packets only through $W, D, J, S, E, Q, O, H, C, P, N$. It has no coordinate for unrestricted residual substitution, global strong normalization, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency.

Theorem 8456.2 (MetaCIC residual normal-form budget router obligations)**.** *For every accepted* MetaCICResidualNormalFormBudgetRouter$^{\uparrow}$ *carrier*

$$R = (W, D, J, S, E, Q, O, H, C, P, N),$$

the local NameCert$_{\text{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}}$ *surface consists exactly of typed residual-window admission, residual-diamond budget exposure, residual-join budget exposure, typed scheduler budget routing, normal-endpoint sealing, candidate-normalization confluence handoff, obstruction retention, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8456.1. The accepted packet displays exactly $W, D, J, S, E, Q, O, H, C, P, N$, so the NameCert surface is exhausted by those rows.

The residual rows W, D, J are read before any normal-form endpoint is public. They bind the typed window, local-diamond budget, and candidate join budget to the same residual pair.

The scheduler and endpoint rows S, E then expose candidate-gate, finite scheduler, and finished endpoint data. The handoff row Q can be consumed only after those rows are visible.

Finally O, H, C, P, N retain the obstruction boundary and preserve the displayed route under transport, replay, provenance, and local naming. Since no further coordinate is present, the packet cannot export unrestricted residual substitution, global normalization, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency. □

Theorem 8456.3 (MetaCIC residual normal-form router handoff)**.** *Every candidate-mediated confluence consumer of an accepted* MetaCICResidualNormalFormBudgetRouter$^{\uparrow}$ *packet first reads the finite route*

$$W \longmapsto D, J \longmapsto S \longmapsto E \longmapsto Q \longmapsto O, H, C, P, N.$$

Thus residual diamond and residual join budgets are consumed before the typed normal-form scheduler and normal-endpoint budget, and the candidate-normalization confluence handoff is visible only after those budget rows have been displayed.

Proof. Start with the typed residual window W. It fixes the closed typed source, residual pair, and bounded comparison window for the whole route.

Next read D and J. These rows expose the residual-diamond and residual-join budgets without turning them into a premise-free confluence theorem.

Then consume S, E, Q. The scheduler row supplies candidate-gate and budget data, the endpoint row seals the finished normal endpoint, and the handoff row exports only the candidate-mediated confluence boundary that can read those budgets.

The obstruction and structural rows keep the same boundary public. They record missing gates, exhausted budgets, blocked residuals, failed endpoint seals, failed joins, transport, replay, provenance, and local naming. □

Falsifiable prediction: Any accepted $\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}$ confluence-facing read that exposes Q without first displaying typed residual window W, residual-diamond budget D, residual-join budget J, typed scheduler budget S, endpoint seal E, obstruction O, transport H, replay C, provenance P, and local naming N is outside the carrier surface.

Independence witness: metacic-typed-normal-form-scheduler, metacic-residual-diamond-budget, metacic-residual-join-budget, metacic-normal-endpoint-budget, metacic-candidate-normalization-confluence-handoff: no listed sibling is bijective with $\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}$ because this packet jointly carries a typed residual window, residual-diamond budget, residual-join budget, scheduler budget, endpoint seal, candidate-normalization handoff, obstruction, transport, replay, provenance, and local NameCert rows.

Lean TasteGate work for $\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}$ must supply Nontrivial and FieldFaithful instances so the residual window, residual-diamond budget, residual-join budget, scheduler budget, endpoint seal, handoff, obstruction, replay, provenance, and local naming rows remain distinguishable.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}$ packet is generated from a typed residual window, residual-diamond budget, residual-join budget, typed normal-form scheduler budget, normal-endpoint seal, candidate-normalization confluence handoff, obstruction row, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8456.1, Definition 8456.2, and Definition 8456.3 seed the finite residual normal-form budget route through typed residual windows, residual-diamond and residual-join budgets, scheduler budgets, endpoint seals, candidate handoff, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICResidualNormalFormBudgetRouter}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close unrestricted residual substitution, global strong normalization, subject reduction, unrestricted residual diamond, quotient syntax equality, evaluator equality, Lean proof obligations, bridge checking, or kernel consistency.

Upgrade path: Obligation closure requires checked carrier admission, typed residual-window exposure, residual-diamond budget exposure, residual-join budget exposure, scheduler-budget routing, endpoint sealing, handoff exactness, Nontrivial and FieldFaithful instances, obstruction retention, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICResidualNormalFormBudgetRouterUp.

Chapter 8457

A Concrete Naming Certificate for $\mathsf{LocatedRealTailMajorant}^{\uparrow}$

Following Bishop and Bridges constructive analysis, a located real is read through explicit finite approximations, displayed error bounds, and a named handoff into the real-number surface rather than through an ambient completed object. The $\mathsf{LocatedRealTailMajorant}^{\uparrow}$ packet records the finite tail-majorant route that a Real-and-Completion consumer uses after the regular-Cauchy tail rows of chapter 5900 and the tail-bound rows of chapter 2071, while still reading finite windows through chapter 126, dyadic tolerances through chapter 291, regular rational names through chapter 301, located upper witnesses through chapter 6098, and the terminal real-name seal through chapter 38. The packet names a displayed majorant threshold for located reads; it does not quotient streams, select limits, invoke countable choice, use trichotomy, or appeal to ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8457.1 (Located real tail-majorant carrier)**.** *A* $\mathsf{LocatedRealTailMajorant}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, D, T, B, R, U, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected prefixes and tail windows of the located real name.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row listing the dyadic precision requests used by the tail comparison.*
3. *T is the* $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$ *threshold row, giving an explicit index after which the inspected regular-Cauchy tail is bounded by the displayed dyadic request.*
4. *B is the* $\mathsf{CauchyTailBound}^{\uparrow}$ *comparison row, recording the finite inequality check that turns the threshold into a bound usable by downstream consumers.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational name attached to the same windows and tolerances.*
6. *U is the* $\mathsf{LocatedSequenceSupremum}^{\uparrow}$ *handoff row, exposing the located upper comparison needed when a consumer asks for a majorant of all later inspected values.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, D, T, B, R, U have been consumed.*
8. *H records componentwise* hsame *transport for the stream, dyadic, threshold, bound, regular-rational, located-supremum, and real-seal rows.*

9. *C records displayed* Cont *replay order for the finite tail-majorant route.*
10. *P is the* Pkg *provenance over* $\mathsf{LocatedRealTailMajorant}^{\uparrow}$, $\mathsf{RegularCauchyTailMajorant}^{\uparrow}$, $\mathsf{CauchyTailBound}^{\uparrow}$, $\mathsf{LocatedSequenceSupremum}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealTailMajorant}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected limit values, host real equality, countable choice, trichotomy, a detached supremum object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8457.2 (Located real tail-majorant NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealTailMajorant}^{\uparrow}$ *carrier*

$$L = (S, D, T, B, R, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealTailMajorant}^{\uparrow}}$ *surface consists exactly of finite StreamName-window exposure through S, dyadic tolerance exposure through D, explicit tail-majorant threshold exposure through T, Cauchy tail-bound comparison through B, regular-rational readback through R, LocatedSequenceSupremum handoff through U, terminal Real seal exposure through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The rows $S, D, T, B, R, U, E, H, C, P, N$ are the only public coordinates available to the local certificate, so every obligation must be read from one of these displayed finite rows.

Read the numerical rows first. The finite windows in S say which tail entries are inspected, the dyadic row D fixes the requested tolerances, the threshold row T gives the explicit majorant index, and the comparison row B records the finite inequalities witnessing that the tail after T is bounded at those tolerances.

Read the handoff rows next. The regular-rational row R supplies the RegSeqRat readback attached to the same windows, while U exposes the located-sequence-supremum comparison that lets a downstream located consumer ask for a majorant without selecting a completed supremum.

Finally inspect E, H, C, P, N. The Real seal is reachable only after the stream, dyadic, threshold, bound, regular-rational, and located-supremum rows have been consumed, and the structural rows preserve, replay, package, and name the same finite route. Thus the displayed packet exhausts the local NameCert obligations. □

Theorem 8457.3 (Located real tail-majorant Real handoff)**.** *Every Real-facing consumer of an accepted* $\mathsf{LocatedRealTailMajorant}^{\uparrow}$ *packet must reach the terminal* $\mathsf{Real}^{\uparrow}$ *seal through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyTailMajorant}^{\uparrow} \longmapsto \mathsf{CauchyTailBound}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Loc}$$

Consequently the consumer obtains a finite located tail-majorant threshold and its dyadic comparison rows before it can read the Real seal. No quotient stream, selected limit, detached supremum, host equality, countable-choice schedule, trichotomy, or ambient completeness principle is exported by the handoff.

Proof. Start from the obligation surface of Definition 8457.2. The Real seal row E is not an independent coordinate; it is named after the finite stream windows S, dyadic tolerances D, threshold row T, tail-bound comparison B, regular-rational readback R, and located-supremum handoff U.

The regular-Cauchy tail-majorant and Cauchy tail-bound rows keep the numerical estimate finite. They expose an explicit threshold and the dyadic inequalities checked at the requested tolerances, rather than a completed tail object or a choice-selected limiting value.

The RegSeqRat and LocatedSequenceSupremum rows then provide the Real-facing readback. They let a consumer compare located upper information against the same finite windows and tolerance rows, while keeping the supremum handoff as a displayed certificate row rather than a detached completed object.

Since the carrier of Definition 8457.1 has no coordinate for quotient streams, selected limits, host equality, countable choice, trichotomy, detached suprema, or ambient completeness, none of those objects can be projected from the handoff. Every accepted Real read therefore passes through the stated finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealTailMajorant}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealTailMajorant}^{\uparrow}$ packet is generated from finite StreamName windows, dyadic tolerance rows, an explicit regular-Cauchy tail-majorant threshold, Cauchy tail-bound comparisons, RegSeqRat readback, a LocatedSequenceSupremum handoff, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealTailMajorant}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8457.1, Definition 8457.2, and Definition 8457.3 seed the finite located-real tail-majorant route over displayed StreamName windows, dyadic tolerance rows, explicit threshold rows, RegSeqRat readback, LocatedSequenceSupremum handoff, and the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealTailMajorant}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim quotient stream equality, selected limits, host real equality, countable choice, trichotomy, detached supremum objects, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier exactness, StreamName window readback, dyadic tolerance readback, explicit threshold exactness, tail-bound comparison, RegSeqRat readback, LocatedSequenceSupremum handoff, Real seal nonescape, provenance, and local naming for the displayed finite packet.

Chapter 8458

A Concrete Naming Certificate for $\mathsf{DualSpace}^{\uparrow}$

Following Bishop and Bridges on constructive normed spaces and Riesz's duality tradition, the $\mathsf{DualSpace}^{\uparrow}$ packet records the continuous dual of a displayed normed vector-space carrier as finite NameCert data. It sits over the vector-space carrier of chapter 47, the norm row of chapter 89, the linear-map surface of chapter 48, and the bounded-linear-functional boundary of chapter 5790. The packet names only displayed bounded scalar functional rows and their finite transport data; it does not import Hahn–Banach, choice, quotient duals, or full Banach duality.

Definition 8458.1 (Dual space carrier)**.** *A* $\mathsf{DualSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (V, N, L, B, E, H, C, P, A)$$

with the following visible rows:

1. *V is the source* $\mathsf{VecSpace}^{\uparrow}$ *row, including the vector addition, zero, inverse, scalar-action, and vector-classifier reads available to dual consumers.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row on the same source, exposing the finite norm comparison and norm-transport witnesses used to state boundedness.*
3. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row for a scalar-valued linear action on the displayed vector rows.*
4. *B is the* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row, recording the boundedness ledger for L against N with scalar endpoints read through the ambient scalar certificate named by the dependency packet.*
5. *E is the evaluation row, pairing an accepted functional row with an accepted vector row and returning the displayed scalar endpoint.*
6. *H records componentwise* hsame *transport for V, N, L, B, E, C, P, A.*
7. *C records displayed* Cont *replay from vector and norm reads through linearity, boundedness, and evaluation.*
8. *P is the* Pkg *provenance over* $\mathsf{DualSpace}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{BoundedLinearFunctional}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *A is the local* $\mathsf{NameCert}_{\mathsf{DualSpace}^{\uparrow}}$ *row.*

The classifier compares accepted dual packets only through these displayed rows. It has no coordinate for all algebraic linear functionals, a quotient by pointwise equality, a selected representative of a functional class, a Hahn–Banach extension principle, or an ambient Banach-dual theorem.

Theorem 8458.2 (Dual space NameCert obligations)**.** *For every accepted* $\mathsf{DualSpace}^{\uparrow}$ *carrier* $D = (V, N, L, B, E, H, C, P, A)$*, the local* $\mathsf{NameCert}_{\mathsf{DualSpace}^{\uparrow}}$ *surface consists exactly of source vector-space admission, norm compatibility, scalar-valued linear-map admission, bounded-linear-functional ledger exposure, evaluation-row exactness, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer of the packet receives no unbounded functional, no quotient dual carrier, no selected representative, no Hahn–Banach extension, and no full Banach-duality theorem.*

Proof. Project the carrier of Definition 8458.1. The rows $V, N, L, B, E, H, C, P, A$ are the full inventory, so every accepted read begins with the displayed vector-space and norm rows.

Read the functional rows next. The linear-map row L supplies only the scalar-valued linear action visible through $\mathsf{LinMap}^{\uparrow}$, and the boundedness row B records the finite norm ledger supplied by $\mathsf{BoundedLinearFunctional}^{\uparrow}$.

The evaluation row E is then exact because it pairs only an accepted bounded functional row with an accepted vector row from V. Transport and replay through H and C preserve those same coordinates, while P and A only record provenance and local naming.

Thus the NameCert obligations are precisely the displayed finite rows. Since no row stores an unbounded functional, quotient dual, selected representative, Hahn–Banach extension, or full Banach-duality object, none can be exported by the accepted packet. □

Falsifiable prediction: A purported $\mathsf{DualSpace}^{\uparrow}$ consumer that evaluates a functional without first exposing the $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, and $\mathsf{BoundedLinearFunctional}^{\uparrow}$ rows is rejected by the carrier of Definition 8458.1.

Independence witness: vecspace, norm, linearmap, boundedlinearfunctional: $\mathsf{DualSpace}^{\uparrow}$ is not bijective to any listed sibling. $\mathsf{VecSpace}^{\uparrow}$ lacks scalar-valued bounded functional rows; $\mathsf{Norm}^{\uparrow}$ lacks linear action and evaluation rows; $\mathsf{LinMap}^{\uparrow}$ lacks the norm-boundedness ledger; $\mathsf{BoundedLinearFunctional}^{\uparrow}$ supplies the bounded functional boundary but not the downstream dual-space packet provenance and local naming row.

Closure status for $\mathsf{NameCert}_{\mathsf{DualSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DualSpace}^{\uparrow}$ packet is generated from VecSpaceUp source rows, NormUp norm rows, LinearMapUp scalar-valued action rows, BoundedLinearFunctionalUp boundedness rows, an evaluation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DualSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8458.1, Definition 8458.2, the falsifiable prediction, and the independence witness seed the finite continuous-dual packet over displayed vector-space, norm, linear-map, bounded-linear-functional, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DualSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach, choice, quotient duals, all algebraic linear functionals, full Banach duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-functional ledger exactness, evaluation exactness, transport, replay, provenance, and local naming for BEDC.Derived.DualSpaceUp.

Chapter 8459

A Concrete Naming Certificate for $\mathsf{SouslinOperation}^{\uparrow}$

Following Suslin and Luzin on analytic sets, the $\mathsf{SouslinOperation}^{\uparrow}$ packet records the finite BEDC surface by which a tree-indexed family of Borel rows on Baire space is read as an analytic-set handoff. It sits between the Baire-space carrier of chapter 334, the Borel hierarchy of chapter 4020, the analytic-set consumer of chapter 8008, the topology and set-like rows of chapter 88 and chapter 3668, and the finite observation route of chapter 126. The packet names a displayed operation from Borel branch data to an analytic-set surface; it is not a host projection theorem, a completed choice sequence, a quotient equality of streams, or an ambient descriptive-set-theoretic universe.

Definition 8459.1 (Souslin-operation carrier)**.** *A* $\mathsf{SouslinOperation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (B, L, A, T, E, W, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BaireSpace}^{\uparrow}$ *branch row, naming the finite branch prefixes and their inspection order.*
2. *L is the* $\mathsf{BorelHierarchy}^{\uparrow}$ *code-family row, assigning Borel-code data to the displayed finite prefix nodes.*
3. *A is the* $\mathsf{AnalyticSet}^{\uparrow}$ *handoff row produced from the branch-indexed Borel family.*
4. *T is the* $\mathsf{Topology}^{\uparrow}$ *open-neighbourhood and closure-stability row used by the Borel and analytic reads.*
5. *E is the* $\mathsf{SetLike}^{\uparrow}$ *membership row, recording the displayed set-membership tests before the analytic handoff is accepted.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which branch observations and membership probes are read.*
7. *R is the operation ledger: it records branch-prefix compatibility, Borel-row stability along extensions, and the finite handoff from the displayed family to the analytic-set row.*
8. *H records componentwise* hsame *transport for $B, L, A, T, E, W, R, P, N$.*
9. *C records displayed* Cont *replay from a requested analytic-set read through Baire branches, Borel codes, topology, set-like membership, stream windows, and the operation ledger.*

10. *P is the* Pkg *provenance over* $\mathsf{SouslinOperation}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, $\mathsf{BorelHierarchy}^{\uparrow}$, $\mathsf{AnalyticSet}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{SetLike}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{SouslinOperation}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $B, L, A, T, E, W, R, H, C, P, N$. It has no coordinate for countable choice, arbitrary projection over a completed product, host equality of sets, quotient stream equality, or an unbounded Borel-code oracle.

Theorem 8459.2 (Souslin-operation NameCert obligations)**.** *For the carrier of Definition 8459.1, the local* $\mathsf{NameCert}_{\mathsf{SouslinOperation}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$S = (B, L, A, T, E, W, R, H, C, P, N),$$

Baire branch exposure through B, Borel family exposure through L, analytic-set handoff through A, topology and set-like membership exposure through T, E, finite stream observation through W, operation-ledger exactness through R, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.

Proof. Project the carrier of Definition 8459.1. The visible rows are exactly $B, L, A, T, E, W, R, H, C, P, N$, so every accepted read is either one of those projections or a route replaying them.

The branch and code side is read through B, L, W. The Baire row names the branch-prefix data, the Borel row attaches a code family to those prefixes, and the StreamName row records the finite observations used by the branch read.

The analytic side is read through A, T, E, R. The topology and set-like rows supply the membership and neighbourhood tests already exposed by the Borel family, while the operation ledger records the branch-extension compatibility needed before A can be exported.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no row contains countable choice, host set equality, quotient stream equality, or an unbounded Borel-code oracle, the listed rows exhaust the NameCert obligations. □

Theorem 8459.3 (Souslin-operation analytic-set handoff)**.** *Every accepted* $\mathsf{SouslinOperation}^{\uparrow}$ *packet exposes an* $\mathsf{AnalyticSet}^{\uparrow}$ *handoff only after the finite route*

$$\mathsf{BaireSpace}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{BorelHierarchy}^{\uparrow} \longmapsto \mathsf{Topology}^{\uparrow}, \mathsf{SetLike}^{\uparrow} \longmapsto \mathsf{AnalyticSet}^{\uparrow}$$

has been displayed through $B, W, L, T, E, R, H, C, P, N$. A consumer may use the analytic-set row A only as the output of that route, not as an external projection theorem or a selected infinite branch.

Proof. Begin with the branch data. The row B supplies the Baire prefixes and W supplies the finite observations of those prefixes; no completed branch is selected outside the displayed windows.

Next read the Borel family. The row L assigns the Borel-code data to the inspected prefixes, while T and E expose the topology-facing and membership-facing tests used by those codes.

The ledger R then binds extension compatibility and handoff exactness. It is the only row that relates the branch-indexed Borel family to the analytic-set export.

Finally A, H, C, P, N export and preserve the analytic-set handoff. Because the route never introduces countable choice, host projection, quotient stream equality, or ambient set equality, the consumer receives exactly the displayed $\mathsf{AnalyticSet}^{\uparrow}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{SouslinOperation}^{\uparrow}}$.

Constructive story: A $\mathsf{SouslinOperation}^{\uparrow}$ packet is generated from BaireSpace branch rows, BorelHierarchy code-family rows, an AnalyticSet handoff, Topology and SetLike membership rows, StreamName finite windows, an operation ledger, componentwise hsame transports, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SouslinOperation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8459.1, Definition 8459.2, and Definition 8459.3 seed the finite operation route from Borel branch data on Baire space to an analytic-set handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SouslinOperation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host projection theorems, countable choice, quotient stream equality, or ambient set equality.

Upgrade path: Obligation closure requires checked carrier admission, Baire branch exposure, Borel family stability, topology and set-like membership replay, StreamName window discipline, analytic-set handoff exactness, and non-escape for BEDC.Derived.SouslinOperationUp.

Chapter 8460

A Concrete Naming Certificate for $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$

The $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ packet realizes the hyperbolic observer-expansion route in chapter 9463 as one finite NameCert surface joining boundary shadows, cross-ratio readback, visual metrics, Busemann boundary data, and observer-expansion ledgers. It sits after the boundary-shadow packet of chapter 3813, the cross-ratio packet of chapter 3948, the visual-metric packet of chapter 3866, the Busemann boundary packet of chapter 3732, and the observer-expansion packet of chapter 4167. The packet is a finite boundary-shadow cross-ratio ledger; it is not a host hyperbolic boundary, a selected geodesic endpoint, a global compactification theorem, or ambient real-valued geometry.

Falsifiable prediction: An accepted $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ read is refuted if a consumer exports a cross-ratio comparison without first displaying boundary-shadow rows, visual-metric rows, Busemann boundary rows, observer-expansion ledger rows, transport, replay, provenance, and local naming.

Independence witness: hyperbolic-boundary-shadow, hyperbolic-cross-ratio, hyperbolic-visual-metric, hyperbolic-busemann-boundary, hyperbolic-observer-expansion: $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ is not bijective to any listed sibling because only this packet jointly records boundary-shadow incidence, four-point cross-ratio readback, visual-metric comparison, Busemann boundary calibration, observer-expansion routing, transport, replay, provenance, and local NameCert rows.

Definition 8460.1 (Boundary-shadow cross-ratio carrier)**.** *A* $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (S, Q, V, B, O, R, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$ *row, naming the boundary shadows and incidence data visible to the packet.*
2. *Q is the* $\mathsf{HyperbolicCrossRatio}^{\uparrow}$ *row, recording the finite four-boundary-point comparison readback.*
3. *V is the* $\mathsf{HyperbolicVisualMetric}^{\uparrow}$ *row, supplying the visual-metric comparison surface used by the same boundary data.*
4. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row, calibrating the shadow and visual-metric reads through Busemann boundary data.*

5. *O is the* $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$ *row, recording the observer-expansion ledger that consumes the boundary-shadow and metric comparison data.*
6. *R is the unification ledger, binding shadow incidence, cross-ratio order, visual-metric scale, Busemann calibration, and observer-expansion replay to the same displayed boundary packet.*
7. *H records componentwise* hsame *transport for S, Q, V, B, O, R, P, N.*
8. *C records displayed* Cont *replay from a boundary-shadow request through cross-ratio readback, visual-metric comparison, Busemann calibration, observer-expansion routing, and the unification ledger.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicVisualMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{HyperbolicObserverExpansion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowCrossRatio}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, Q, V, B, O, R, H, C, P, N$. It has no coordinate for selected boundary endpoints, global hyperbolic compactification, ambient real-valued geometry, quotient boundary equality, or host geodesic equality.

Theorem 8460.2 (Boundary-shadow cross-ratio NameCert obligations)**.** *For the carrier of Definition 8460.1, the local* $\mathsf{NameCert}_{\mathsf{BoundaryShadowCrossRatio}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$X = (S, Q, V, B, O, R, H, C, P, N),$$

boundary-shadow exposure through S, cross-ratio readback through Q, visual-metric comparison through V, Busemann boundary calibration through B, observer-expansion routing through O, unification-ledger exactness through R, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.

Proof. Project the carrier of Definition 8460.1. Its visible rows are exactly $S, Q, V, B, O, R, H, C, P, N$.

The geometric comparison side is read through S, Q, V, B. Boundary shadows provide the incidence surface, cross-ratio readback supplies the four-point comparison, the visual metric supplies scale, and the Busemann boundary row calibrates the same boundary data.

The observer side is read through O, R. The observer-expansion row consumes the boundary-shadow and comparison data, while the unification ledger records that all reads use the same displayed packet.

Finally H, C, P, N preserve, replay, source, and name the route. Since the carrier has no coordinate for selected endpoints, global compactification, ambient real-valued geometry, quotient boundary equality, or host geodesic equality, the listed rows exhaust the obligations. □

Theorem 8460.3 (Boundary-shadow cross-ratio observer handoff)**.** *Every accepted* $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ *packet hands an observer-expansion consumer the finite route*

$$\mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longmapsto \mathsf{HyperbolicCrossRatio}^{\uparrow}, \mathsf{HyperbolicVisualMetric}^{\uparrow}, \mathsf{HyperbolicBusemannBoundary}^{\uparrow} \longmapsto$$

The handoff must pass through $S, Q, V, B, O, R, H, C, P, N$ before any boundary-shadow cross-ratio comparison is consumed.

Proof. Start with the boundary-shadow row S. It fixes the displayed boundary incidence data before any comparison row is read.

Next read the comparison rows Q, V, B. The cross-ratio, visual-metric, and Busemann boundary rows provide compatible comparison surfaces for the same displayed shadows.

The ledger R then binds those surfaces to the observer-expansion row O. This is the step that prevents a cross-ratio read from floating free of the boundary-shadow and observer-expansion data.

Transport, replay, provenance, and local naming are carried by H, C, P, N. Therefore a consumer cannot replace the route by selected boundary endpoints, quotient boundary equality, host geodesic equality, global compactification, or ambient real-valued geometry. □

The Lean `TasteGate.lean` development for $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ must include explicit $\mathsf{Nontrivial\ BoundaryShadowCrossRatio}^{\uparrow}$ and $\mathsf{FieldFaithful\ BoundaryShadowCrossRatio}^{\uparrow}$ instances. These instances must preserve the boundary-shadow, cross-ratio, visual-metric, Busemann boundary, observer-expansion, unification-ledger, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundaryShadowCrossRatio}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$ packet is generated from boundary-shadow rows, cross-ratio readback, visual-metric comparison, Busemann boundary calibration, observer-expansion routing, a unification ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundaryShadowCrossRatio}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8460.1, Definition 8460.2, and Definition 8460.3 seed the finite boundary-shadow cross-ratio route for observer-expansion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundaryShadowCrossRatio}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, selected boundary endpoints, global compactification, quotient boundary equality, host geodesic equality, or ambient real-valued geometry.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exposure, cross-ratio readback, visual-metric comparison, Busemann boundary calibration, observer-expansion routing, unification-ledger exactness, nontriviality, and field faithfulness for BEDC.Derived.BoundaryShadowCrossRatioUp.

Chapter 8461

Bounded Variation Cauchy Completion NameCert Construction

Following Bishop and Bridges, the $\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}$ packet records the constructive-analysis route by which a regular rational Cauchy name is completed while a finite variation-budget ledger remains visible to BEDC consumers. It sits over the regular Cauchy readback of chapter 301, the terminal real-name seal of chapter 38, and the tail-threshold normalization surface of chapter 1299. The packet is a finite NameCert carrier for bounded-variation completion data; it is not a quotient of Cauchy names, not a selected limit operator, not a host equality principle for completed reals, and not an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Definition 8461.1 (Bounded-variation Cauchy completion carrier)**.** *A* $\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$V = (Q, T, L, E, H, C, P, N)$$

with the following displayed rows:

1. *Q is the source* $\mathsf{RegSeqRat}^{\uparrow}$ *row carrying the regular rational Cauchy name whose tail will be read by the completion consumer.*
2. *T is the* $\mathsf{CauchyTailThresholdNormalizer}^{\uparrow}$ *row selecting a finite dyadic tail window for each displayed unary tolerance request.*
3. *L is the finite* $\mathsf{DyadicRatCore}^{\uparrow}$ *variation-budget ledger, recording dyadic tail differences, partial variation sums, and the displayed bound attached to the normalized tail windows.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after Q, T, L have been consumed.*
5. *H records componentwise* hsame *transport for the source regular name, the normalized tail threshold, the variation-budget ledger, the terminal real seal, replay, provenance, and local naming rows.*
6. *C records displayed* Cont *replay from every finite completion request through*

$$Q, T, L \longmapsto E, H, P, N.$$

7. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyTailThresholdNorm}$ $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

8. N is the local $\mathsf{NameCert}_{\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}}$ *row.*

The classifier accepts exactly componentwise hsame*-stable packets of this form. In particular, replacing the regular name, changing the normalized tail threshold, or weakening the dyadic variation ledger changes the packet unless the corresponding row is transported by the displayed H row and replayed by C.*

Theorem 8461.2 (Bounded-variation Cauchy completion obligations)**.** *For every accepted* BoundedVariationCauch *carrier*

$$V = (Q, T, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed* BHist *packet;*
2. *classifier exposure for componentwise* hsame *transport of Q, T, L, E, H, C, P, N;*
3. *stability of the normalized dyadic tail rows under* hsame *and* Cont *replay;*
4. *exactness of the regular Cauchy readback through Q and of the terminal* $\mathsf{Real}^{\uparrow}$ *seal through E;*
5. *ledger descent for the finite variation budget, requiring every later tail window to read a suffix of the same dyadic ledger L rather than a detached variation bound;*
6. *package provenance and local naming through P, N.*

No obligation row exports quotient Cauchy equality, a selected representative, a selected limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier tuple in Definition 8461.1. The only analytic rows available before the terminal seal are the regular rational source Q, the tail-threshold normalizer T, and the dyadic variation-budget ledger L.

The classifier row is componentwise. Thus an accepted transport must preserve the same source name, normalized tail window, ledger, seal, replay, provenance, and local naming coordinates through hsame; the displayed continuation row C replays the same route for each finite completion request.

It remains to justify ledger descent. Use induction on the finite tail-window spine supplied by T. The base window reads the first displayed dyadic suffix of Q and the initial partial variation budget in L.

For the induction step, the next normalized tail window is a suffix of the previous displayed window. The ledger row L records the corresponding dyadic difference budget and partial variation sum, so the successor read can only decrease the remaining displayed budget or keep it equal under hsame transport. The continuation row C then hands the same suffix route to the terminal seal E.

Since each step uses only finite rows of the displayed packet, the argument invokes neither quotienting of Cauchy names nor a choice of representatives. The absent quotient, selected-limit, host-equality, countable-choice, and ambient-completeness data therefore cannot become NameCert obligations. □

Theorem 8461.3 (Bounded-variation Cauchy completion Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}$ *carrier must read the finite route*

$$Q, T, L \longmapsto E, H, P, N$$

before the completed real seal is public. The handoff therefore preserves the regular Cauchy source, normalized tail threshold, and finite variation-budget ledger as visible BEDC rows.

Proof. Start with the obligation theorem Definition 8461.2. It exposes the terminal seal E only after carrier admission, classifier transport, tail stability, readback exactness, and ledger descent have been recorded for the same tuple.

The source row Q supplies the regular rational Cauchy name, while T supplies the finite tail threshold used by a completion request. The ledger L is read before E, so a consumer cannot replace the displayed variation budget by an external supremum or a host-level completed-real statement.

Transport and replay preserve the handoff. The rows H, C, P, N name only the displayed route, and the carrier contains no coordinate for quotient Cauchy equality, selected representatives, selected limits, host real equality, countable choice, or ambient completeness. Hence every accepted Real-facing read remains attached to Q, T, L. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationCauchyCompletion}\uparrow}$.

Constructive story: A $\mathsf{BoundedVariationCauchyCompletion}^{\uparrow}$ packet is generated from a RegSeqRat regular Cauchy source row, a CauchyTailThresholdNormalizer tail-window row, a DyadicRatCore finite variation-budget ledger, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationCauchyCompletion}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8461.1, Definition 8461.2, and Definition 8461.3 seed the finite bounded-variation completion route from RegSeqRat through tail normalization and dyadic ledger descent to RealUp readback.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationCauchyCompletion}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient Cauchy equality, selected representatives, selected limits, host real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, classifier stability, tail-window stability, readback exactness, ledger descent, transport, replay, provenance, and local naming for BEDC.Derived.BoundedVariationCauchyCompletionUp.

Chapter 8462

A Concrete Naming Certificate for $\mathsf{NashEmbedding}^{\uparrow}$

Following Nash on isometric embeddings of Riemannian manifolds, the $\mathsf{NashEmbedding}^{\uparrow}$ packet records only the finite chartwise certificate surface needed to name an embedding candidate inside BEDC. It sits between the manifold chart carrier of chapter 96, the metric rows of chapter 133, the vector target surface of $\mathsf{VecSpace}^{\uparrow}$ and $\mathsf{EuclideanSpace}^{\uparrow}$, and the terminal scalar seals of chapter 38. The packet is not a host Nash theorem, not a selected global chart, not a quotient manifold equality, and not an ambient completeness principle.

Definition 8462.1 (Nash embedding carrier)**.** *A* $\mathsf{NashEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (M, G, A, E, D, R, H, C, P, L)$$

with the following displayed rows:

1. *M is the* $\mathsf{Manifold}^{\uparrow}$ *finite chart row, listing the inspected chart names, chart domains, and overlap rows used by the embedding read.*
2. *G is the* $\mathsf{RiemannianMetric}^{\uparrow}$ *row, exposing only the finite metric-component ledger over the displayed chart windows.*
3. *A is the chartwise atlas-to-target ledger, recording which chart rows are sent into the finite* $\mathsf{VecSpace}^{\uparrow}$ *and* $\mathsf{EuclideanSpace}^{\uparrow}$ *target rows.*
4. *E is the embedding-candidate row, naming the finite coordinate functions and point-separation obligations inspected in the displayed chart windows.*
5. *D is the* $\mathsf{Derivative}^{\uparrow}$ *comparison row, storing the finite derivative or metric-pullback comparisons used to test that E preserves the displayed metric rows of G.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row for every metric coefficient, coordinate coefficient, derivative comparison, and pullback comparison consumed by D.*
7. *H records componentwise* hsame *transport for chart rows, metric rows, target rows, embedding-candidate rows, derivative comparison rows, scalar seals, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from a chartwise embedding request through M, G, A, E, D, R, H.*
9. *P is the* Pkg *provenance over* $\mathsf{NashEmbedding}^{\uparrow}$, $\mathsf{Manifold}^{\uparrow}$, $\mathsf{RiemannianMetric}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{EuclideanSpace}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. L is the local $\mathsf{NameCert}_{\mathsf{NashEmbedding}^{\uparrow}}$ *row.*
The carrier has no coordinate for a host embedding operator, a global Nash existence theorem, quotient equality of manifolds, selected global charts, an unbounded coordinate family, or ambient Euclidean completeness.

Theorem 8462.2 (Nash embedding NameCert obligations)**.** *For every accepted* $\mathsf{NashEmbedding}^{\uparrow}$ *carrier* $N = (M, G, A, E, D, R, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{NashEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite chart row, metric-component admission, atlas-to-target admission, embedding-candidate admission, derivative or metric-pullback comparison admission, Real scalar sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No obligation can be discharged by reading a host Nash theorem, a global embedding operator, quotient manifold equality, selected global charts, or ambient Euclidean completeness outside those rows.

Proof. Project the carrier of Definition 8462.1. The available rows are exactly $M, G, A, E, D, R, H, C, P, L$, so every naming obligation must be assigned to one of those coordinates.

The geometric obligations are chartwise. The row M supplies the inspected chart windows, G supplies the finite metric ledger over those windows, A routes the same chart windows into the target rows, and E records the finite embedding-candidate data that downstream consumers may inspect.

The comparison obligations are scalar-sealed. The row D stores only derivative or metric-pullback comparisons over the displayed chart windows, and R seals the scalar coefficients as $\mathsf{Real}^{\uparrow}$ rows before the structural rows H, C, P, L transport, replay, source, and name the route. Since no other coordinate appears, the excluded host and quotient objects are not part of the local NameCert surface. □

Theorem 8462.3 (Nash embedding finite chart metric route)**.** *Every metric-facing consumer of an accepted* $\mathsf{NashEmbedding}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{Manifold}^{\uparrow},\ \mathsf{RiemannianMetric}^{\uparrow},\ \mathsf{VecSpace}^{\uparrow},\ \mathsf{EuclideanSpace}^{\uparrow},\ \mathsf{Derivative}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

through the displayed rows $M, G, A, E, D, R, H, C, P, L$ before treating the packet as an isometric-embedding witness. The route exports finite chartwise metric comparison data, not an ambient existence theorem or a globally selected coordinate system.

Proof. Start with the chart and metric rows. The rows M and G determine the only chart windows and metric coefficients that can be inspected by a consumer.

Next read the target and comparison rows. The row A routes the displayed chart windows into the finite vector and Euclidean target rows, E supplies the embedding-candidate ledger, and D records the derivative or metric-pullback comparisons against the metric row G.

Finally apply the scalar and structural rows. The row R seals every coefficient and comparison through $\mathsf{Real}^{\uparrow}$, while H, C, P, L keep transport, replay, provenance, and local naming attached to the same finite route. Thus a metric-facing consumer receives only chartwise comparison data and cannot replace it by a host Nash existence theorem, selected global chart, quotient manifold equality, or ambient completeness fact. □

Theorem 8462.4 (Nash embedding Euclidean seal nonescape)**.** *Every* $\mathsf{EuclideanSpace}^{\uparrow}$ *or* $\mathsf{VecSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{NashEmbedding}^{\uparrow}$ *packet receives the target rows only after the chart ledger, Riemannian metric ledger, embedding-candidate ledger, derivative or pullback comparison ledger,*

and Real scalar seal have all been exposed. The Euclidean target seal therefore cannot escape into a host embedding operator, quotient manifold equality, selected global charts, or ambient completeness.

Proof. Inspect Definition 8462.1. The target rows appear only through A and E, and both rows are downstream of the chart row M and the metric row G.

Use Definition 8462.3. It forces every target-facing read through D and R, so the Euclidean coordinate data are consumed only after derivative or pullback comparisons and Real scalar seals are displayed.

Then apply Definition 8462.2. The structural rows H, C, P, L preserve the same finite route and add no host operator, quotient equality, selected global chart, or completeness row. Hence the Euclidean target seal stays inside the local $\mathsf{NashEmbedding}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{NashEmbedding}^{\uparrow}}$.

Constructive story: A $\mathsf{NashEmbedding}^{\uparrow}$ packet is generated from finite ManifoldUp chart rows, RiemannianMetricUp metric-component rows, atlas-to-target rows, Euclidean and vector target rows, embedding-candidate rows, derivative or metric-pullback comparison rows, RealUp scalar seals, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NashEmbedding}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8462.1, Definition 8462.2, Definition 8462.3, and Definition 8462.4 seed the finite chartwise isometric-embedding certificate surface for NashEmbeddingUp.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NashEmbedding}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Nash's full embedding theorem, global smooth embedding existence, selected global charts, quotient manifold equality, ambient Euclidean completeness, Lean theorem checking, axiom purity, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite chart accountability, metric-component comparison, derivative or pullback exactness, Real scalar sealing, target nonescape, transport, replay, provenance, and local naming for BEDC.Derived.NashEmbeddingUp.

Chapter 8463

A Concrete Naming Certificate for $\mathsf{RationalIntervalSequence}^{\uparrow}$

Following Bishop and Bridges-style nested interval and Cauchy constructions, the $\mathsf{RationalIntervalSequence}^{\uparrow}$ packet records a finite inspected schedule of rational intervals before any Real or Completion consumer reads a limiting name. It sits over the dyadic endpoint ledger of chapter 291, the finite observation interface of chapter 126, the regular rational readback surface of chapter 301, and the terminal real-name seal of chapter 38. The packet is a schedule object: it exposes endpoints, nesting, widths, finite windows, readback, and seal handoff as displayed NameCert data, not as a selected completed limit.

Definition 8463.1 (Rational interval sequence carrier)**.** *A* $\mathsf{RationalIntervalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (E, L, U, N, W, S, R, Z, X, C, P, K)$$

with the following displayed rows:

1. *E is the finite endpoint table of rational lower and upper rows, each row read through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger before comparison;*
2. *L and U are the displayed lower-endpoint and upper-endpoint schedules, with $L_i \leq U_i$ recorded at every inspected window;*
3. *N is the nesting evidence row, recording $L_i \leq L_j \leq U_j \leq U_i$ whenever the displayed index j refines the displayed index i;*
4. *W is the dyadic width ledger, assigning each displayed interval a dyadic budget and recording the inspected shrinkage evidence used by later regular-readback rows;*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected indices, endpoint observations, and replay order;*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed nested endpoints and width budgets;*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal handoff row, available only after the endpoint table, nesting evidence, width ledger, finite windows, and regular rational readback have been displayed;*
8. *X records componentwise* hsame *transport for endpoints, nesting, widths, finite windows, readback, seal handoff, replay, provenance, and local naming rows;*

9. *C records displayed* Cont *replay from a tolerance request through W, then through S, N, E, L, U, then through R, and finally into Z;*
10. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalSequence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*
11. *K is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, L, U, N, W, S, R, Z, X, C, P, K$. It has no coordinate for a selected limit, quotient real equality, countable choice, trichotomy of real order, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Lean4 ✓ `BEDC.Derived.RationalIntervalSequenceUp.TasteGate.RationalIntervalSequenceTasteGate`
`single carrier alignment`

Theorem 8463.2 (Rational interval sequence nesting obligations)**.** *For every accepted* $\mathsf{RationalIntervalSequence}^{\uparrow}$ *carrier*

$$I = (E, L, U, N, W, S, R, Z, X, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{RationalIntervalSequence}^{\uparrow}}$ *surface includes exactly the finite nesting obligations displayed by N and W: each inspected interval has rational endpoints in E, L, U, each refined window recorded by S is nested inside the earlier displayed window, and each width comparison is read through the dyadic budget row W before the readback row R or Real seal row Z is visible.*

Proof. Project the carrier. The accepted packet displays endpoint rows E, L, U, nesting evidence N, width budgets W, finite windows S, regular readback R, Real seal handoff Z, and the structural rows X, C, P, K.

Read the nesting row before any readback. For each inspected refinement, N records the lower endpoint moving upward, the upper endpoint moving downward, and the refined interval remaining inside the earlier interval.

Use the width ledger next. The dyadic budget row W is the only route by which a tolerance request reaches the nested endpoints, so shrinkage evidence is finite and displayed before R or Z can be consumed.

The transport, replay, provenance, and local name rows then preserve the same finite route. Since no selected limit or quotient coordinate occurs in the carrier, the nesting obligations are exhausted by the displayed packet. □

Theorem 8463.3 (Rational interval sequence regular readback)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *readback exported by an accepted* $\mathsf{RationalIntervalSequence}^{\uparrow}$ *carrier is obtained from the displayed nested interval route*

$$E, L, U, N, W, S, R, Z, X, C, P, K.$$

The readback may use finite StreamName windows, dyadic endpoint comparisons, nesting evidence, and width budgets, but it exports no selected real limit, no quotient equality of real names, no countable-choice schedule, no trichotomy principle, and no ambient Real completeness theorem.

Proof. Begin with the finite observation row S. It names the inspected indices and endpoint observations, so a consumer never reads an unbounded interval family directly.

The endpoint and nesting rows E, L, U, N then supply the interval data inside those windows. The dyadic ledger W supplies the tolerance budget needed to treat the displayed endpoints as a regular rational approximation.

The readback row R is downstream of that route. It packages the regular rational data produced by the finite windows and dyadic widths, and the Real seal handoff Z remains terminal rather than a separate selected limit.

Finally replay through C and transport through X. Provenance P and the local NameCert row K keep the packet inside the displayed BEDC surface, so excluded quotient, choice, trichotomy, and completeness claims stay outside the public readback. □

Falsifiable prediction: Deleting the nesting row permits finite interval windows whose endpoints can be read by RegSeqRat without evidence that later windows refine earlier ones.

Independence witness: Nearest siblings: dyadicratcore, streamname, regseqrat, real, nestedinterval, and dyadic-nested-interval-selector; no bijection exists because this packet records a rational interval schedule with endpoint, nesting, width, readback, and Real-seal rows in one finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{RationalIntervalSequence}^{\uparrow}$ packet is generated from rational endpoint rows, lower and upper endpoint schedules, nesting evidence, a dyadic width ledger, finite StreamName windows, RegSeqRat readback, Real seal handoff, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8463.1, Definition 8463.2, and Definition 8463.3 specify the finite nested rational interval schedule and its regular rational readback route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient real equality, countable choice, trichotomy of real order, ambient Real completeness, Lean verification, or bridge checking for $\mathsf{RationalIntervalSequence}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, nesting exactness, dyadic width monotonicity, finite-window replay, regular-rational readback, Real-seal handoff, transport, provenance, and local NameCert obligations.

Chapter 8464

Nikodym Boundedness NameCert Construction

Following Nikodym and Dunford–Schwartz, the $\mathsf{NikodymBoundedness}^{\uparrow}$ packet records the finite NameCert surface by which a pointwise bounded family of countably additive measures exposes one displayed bound on the inspected variation rows. It sits over the measure carrier of chapter 92, the local regular rows of chapter 2263, the density handoff of chapter 3448, the bounded-family discipline of chapter 1835, and the terminal real-name seal of chapter 38. The packet is a finite reconstruction of the traditional boundedness route; it is not a host measure-completion theorem, a selector for subfamilies, or an ambient Banach-dual principle.

Definition 8464.1 (Nikodym boundedness carrier)**.** *A* $\mathsf{NikodymBoundedness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (M, A, F, W, T, B, D, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row, carrying the measurable-event surface and the displayed countable-additivity rows that the family is allowed to inspect.*
2. *A is the finite event-algebra window. It lists the measurable rows $E_1, \ldots, E_n$ on which the family is tested and records their transport under the* $\mathsf{Measure}^{\uparrow}$ *classifier.*
3. *F is the measure-family ledger, a finite schedule of signed or finite-variation* $\mathsf{Measure}^{\uparrow}$ *rows ν_i over the same displayed measurable surface.*
4. *W is the pointwise boundedness window. For every event row in A, it records a* $\mathsf{Real}^{\uparrow}$ *bound for the displayed family values $\nu_i(E_j)$.*
5. *T is the variation-window row, recording the finite disjoint decompositions of the displayed events and the variation sums that may be read from F.*
6. *B is the candidate uniform* $\mathsf{Real}^{\uparrow}$ *bound for the displayed variation rows.*
7. *D is the* $\mathsf{RadonNikodym}^{\uparrow}$ *density handoff row used only when a displayed member of F is read through a dominated local density.*
8. *R is the* $\mathsf{RadonMeasure}^{\uparrow}$ *regularity row for the locally finite event windows used by A, T, D.*
9. *H records componentwise* hsame *transport for $M, A, F, W, T, B, D, R, C, P, N$.*

10. *C records displayed* Cont *replay from a requested family-bound read through*

$$M, A, F, W, T, D, R \longmapsto B, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{NikodymBoundedness}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{RadonMeasure}^{\uparrow}$, $\mathsf{RadonNikodym}^{\uparrow}$, $\mathsf{UniformBoundedness}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{NikodymBoundedness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for a completed measure algebra, a choice-selected subfamily, a quotient of measures, a hidden dual Banach space, or a global countable-additivity principle beyond the displayed rows of M.

Lean4 ✓ `BEDC.Derived.NikodymBoundednessUp.NikodymBoundednessTasteGate single carrier alignment`

Theorem 8464.2 (Nikodym boundedness NameCert obligations)**.** *For every accepted* $\mathsf{NikodymBoundedness}^{\uparrow}$ *carrier*

$$K = (M, A, F, W, T, B, D, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{NikodymBoundedness}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the displayed measure source, event-algebra window, measure-family ledger, pointwise boundedness window, variation window, candidate bound, Radon–Nikodym density handoff, Radon regularity row, transport, replay, provenance, and local naming;*
2. *family coherence, requiring every member of F to read the same* $\mathsf{Measure}^{\uparrow}$ *event surface M and the same event-window row A;*
3. *pointwise boundedness admission, requiring W to supply only scheduled event reads and their* $\mathsf{Real}^{\uparrow}$ *bounds;*
4. *variation-window exactness, requiring T to build every exposed variation sum from the displayed finite decompositions and values in F;*
5. *Radon and Radon–Nikodym compatibility, requiring R and D to be local handoff rows rather than ambient completion or domination principles;*
6. *uniform-bound exposure through the single* $\mathsf{Real}^{\uparrow}$ *row B and the replay row C;*
7. *package provenance and local naming through P, N.*

No local obligation exports measure completion, countable additivity beyond the displayed rows of M, choice-selected subfamilies, quotient equality of measures, or ambient Banach-space duality.

Proof. Project the carrier of Definition 8464.1. The projection exposes exactly the measure source, event window, family ledger, pointwise boundedness window, variation window, bound row, Radon–Nikodym density handoff, Radon regularity row, transport, replay, provenance, and local naming.

Family coherence is read from F together with M and A. Every family member is evaluated only on events admitted by the same displayed $\mathsf{Measure}^{\uparrow}$ surface, and each event read is transported by the same classifier row. Thus no detached measurable universe or quotient of event algebras is available.

The boundedness data is local. The row W records pointwise $\mathsf{Real}^{\uparrow}$ bounds on the scheduled event reads, while T records the finite disjoint decompositions used to compute the displayed variation sums. The candidate bound B is downstream from those two rows and cannot be read before them.

The Radon rows are also local. The row R supplies regularity only for the displayed windows, and D supplies a Radon–Nikodym density handoff only for a displayed dominated member of the family. Neither row contains measure completion, a selected subfamily, or an ambient dual-space identification.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the classifier sees only the listed coordinates, the excluded host principles cannot become NameCert obligations. □

Theorem 8464.3 (Nikodym boundedness measure-family route)**.** *Every accepted* $\mathsf{NikodymBoundedness}^{\uparrow}$ *family-bound read factors through the displayed route*

$$\mathsf{Measure}^{\uparrow}, \mathsf{RadonMeasure}^{\uparrow}, \mathsf{RadonNikodym}^{\uparrow}, \mathsf{UniformBoundedness}^{\uparrow}, \mathsf{Real}^{\uparrow}.$$

Concretely, the read first opens the common measure source M and event window A, then inspects the family ledger F and pointwise bound window W, then computes only the variation rows listed in T, then uses the local Radon and Radon–Nikodym rows R, D when those rows are present, and only then exposes the uniform $\mathsf{Real}^{\uparrow}$ *bound B through H, C, P, N.*

Lean4 ✓ `BEDC.Derived.NikodymBoundednessUp.NikodymBoundednessMeasureFamilyRoute`

Proof. Start with the obligation theorem Definition 8464.2. It says that an accepted read may inspect only the displayed rows of the carrier.

The route begins at M, A, F, W. These rows name the measurable surface, the finite event window, the family members, and the pointwise $\mathsf{Real}^{\uparrow}$ bounds. This is the measure-family analogue of the finite bounded-family discipline carried by $\mathsf{UniformBoundedness}^{\uparrow}$.

The variation and regularity rows are downstream. The row T constructs variation reads from finite decompositions of the events in A, while R and D may be consulted only as local $\mathsf{RadonMeasure}^{\uparrow}$ and $\mathsf{RadonNikodym}^{\uparrow}$ handoffs attached to those displayed events and measures.

The endpoint is B. Because B is replayed through C after M, A, F, W, T, R, D, a consumer cannot replace the finite route by measure completion, a countable-choice selection of subfamilies, unrestricted countable additivity, or an ambient Banach-dual theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{NikodymBoundedness}^{\uparrow}}$.

Constructive story: A $\mathsf{NikodymBoundedness}^{\uparrow}$ packet is generated from a MeasureUp source, finite event-window rows, a measure-family ledger, pointwise RealUp bound windows, finite variation rows, local RadonMeasure and Radon-Nikodym handoffs, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{NikodymBoundedness}^{\uparrow}}$, seed)

Scope closed: Definition 8464.1, Definition 8464.2, and Definition 8464.3 seed the finite measure-family boundedness route through MeasureUp, RadonMeasureUp, RadonNikodymUp, UniformBoundednessUp, and RealUp rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{NikodymBoundedness}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close measure completion, countable additivity beyond the displayed rows, choice-selected subfamilies, ambient Banach-space duality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, family coherence, pointwise boundedness admission, variation-window exactness, local Radon and Radon–Nikodym compatibility, uniform RealUp bound exposure, transport, replay, provenance, and local naming for BEDC.Derived.NikodymBoundednessUp.

Chapter 8465

A Concrete Naming Certificate for $\mathsf{KraftPrefixCode}^{\uparrow}$

Following Kraft and McMillan, the $\mathsf{KraftPrefixCode}^{\uparrow}$ packet records a finite prefix-free binary code table together with the Kraft budget that makes instantaneous decoding visible as BEDC NameCert data. It sits beside the minimum-distance coding surface of chapter 241, the finite branch discipline of chapter 5910, the source-measure ledger of chapter 192, and the bounded program-code surface of chapter 5989. The packet names only displayed codewords, tree-frontier rows, length rows, Kraft-budget rows, refusal rows, transport, replay, provenance, and local naming; it is not a Shannon optimality theorem, a Huffman construction, an oracle for shortest descriptions, or a host probability-space completion.

Definition 8465.1 (KraftPrefixCode carrier)**.** *A* $\mathsf{KraftPrefixCode}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (C, F, L, B, D, H, T, P, N)$$

with the following displayed rows:

1. *C is the code-table row, listing finitely many source symbols together with their binary codeword histories.*
2. *F is the binary-tree prefix-frontier row, read through* $\mathsf{BinaryTree}^{\uparrow}$*, whose leaves are exactly the displayed codewords admitted by C.*
3. *L is the length-ledger row, recording each displayed codeword length as a finite natural-history budget.*
4. *B is the Kraft-budget row, recording the finite inequality that the sum of the displayed dyadic weights 2^{-L_i} is bounded by the unit budget.*
5. *D is the decoding-refusal row: if a requested bit history is not on the displayed frontier, or extends through two codewords, the packet records refusal rather than a decoded symbol.*
6. *H records componentwise* hsame *transport for code tables, prefix frontiers, length ledgers, Kraft budgets, refusal rows, replay rows, provenance rows, and local naming rows.*
7. *T records displayed* Cont *replay from a finite decoding request through the same C, F, L, B, D, H, P, N rows.*
8. *P is the* Pkg *provenance over* $\mathsf{KraftPrefixCode}^{\uparrow}$*,* $\mathsf{ErrorCode}^{\uparrow}$*,* $\mathsf{BinaryTree}^{\uparrow}$*,* $\mathsf{Entropy}^{\uparrow}$*,* $\mathsf{KolmogorovComplexity}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{KraftPrefixCode}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $C, F, L, B, D, H, T, P, N$. It has no coordinate for a selected optimal code, an infinite alphabet, a completed probability model, quotient code equality, or an unbounded decoder.

Theorem 8465.2 (KraftPrefixCode NameCert obligations)**.** *For every accepted* $\mathsf{KraftPrefixCode}^{\uparrow}$ *carrier*

$$K = (C, F, L, B, D, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{KraftPrefixCode}^{\uparrow}}$ *surface consists exactly of code-table exposure, binary-tree prefix-frontier exposure, length-ledger exposure, Kraft-budget exposure, decoding-refusal exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every entropy, error-code, or bounded-description consumer must expose $C, F, L, B, D, H, T, P, N$ before reading a finite prefix-code row.*

Lean4 ✓ `BEDC.Derived.KraftPrefixCodeUp.KraftPrefixCodeTasteGate single carrier alignment`

Proof. Project the carrier $K = (C, F, L, B, D, H, T, P, N)$. The analytic rows are the finite code table C, the prefix frontier F, the length ledger L, the Kraft budget B, and the decoding-refusal row D.

The binary-tree frontier makes prefix admission explicit. The length ledger and Kraft budget then read only the displayed leaves, so the packet supplies a finite budget row rather than an optimal coding theorem or a hidden probability-space argument.

The structural rows H, T, P, N transport, replay, source, and name the same finite route. Since the carrier has no row for selected optimality, infinite alphabets, quotient equality, or an unbounded decoder, the listed rows exhaust the NameCert surface. □

Theorem 8465.3 (KraftPrefixCode prefix disjointness)**.** *Every accepted* $\mathsf{KraftPrefixCode}^{\uparrow}$ *carrier*

$$K = (C, F, L, B, D, H, T, P, N)$$

forces the displayed codeword frontier F to be prefix-disjoint: two decoded source rows can share a bit history only when the same displayed frontier leaf is read. Consequently a finite decoding request cannot pass through two distinct codewords, and any request that would do so is routed to the refusal row D rather than to a second decoded symbol.

Proof. Read the code table C through the binary-tree frontier F. The accepted frontier records codewords as leaves, so a decoded request must terminate at one displayed leaf before any longer extension can be considered.

Compare two candidate decoded rows. If they read the same frontier leaf, componentwise hsame transport identifies the same displayed codeword row inside C. If one candidate attempts to extend through another leaf, the prefix-frontier row blocks that branch as a leaf boundary.

The refusal row D records precisely the blocked case. Transport H, replay T, provenance P, and local naming N preserve the same finite frontier order, so the packet never exports ambiguous instantaneous decoding. □

Falsifiable prediction: Every accepted $\mathsf{KraftPrefixCode}^{\uparrow}$ consumer that reads a finite prefix-code row without first displaying the code table, binary-tree frontier, length ledger, Kraft budget, refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row refutes the packet surface.

Independence witness: errorcode, binarytree, entropy, kolmogorov-complexity: $\mathsf{KraftPrefixCode}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries code-table rows, prefix-frontier rows, length ledgers, Kraft budgets, decoding-refusal rows, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{KraftPrefixCode}\uparrow}$.

Constructive story: A $\mathsf{KraftPrefixCode}^{\uparrow}$ packet is generated from finite code-table rows, binary-tree prefix-frontier rows, finite length ledgers, Kraft-budget rows, decoding-refusal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KraftPrefixCode}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8465.1, Definition 8465.2, and Definition 8465.3 seed the finite prefix-free coding interface over code tables, binary-tree frontiers, length ledgers, Kraft budgets, decoding refusal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KraftPrefixCode}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Shannon optimality, Huffman construction, selected shortest programs, infinite alphabets, quotient code equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, prefix-frontier exactness, length-ledger exposure, Kraft-budget exposure, decoding-refusal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.KraftPrefixCodeUp.

Chapter 8466

A Concrete Naming Certificate for $\mathsf{FiniteRealObserver}^{\uparrow}$

Following Bishop and Bridges on finite rational observations of real numbers, the $\mathsf{FiniteRealObserver}^{\uparrow}$ packet records the finite observation window through which a Real-facing reader inspects a regular Cauchy name. It sits beside the finite schedule of chapter 5916, the StreamName window of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal Real seal of chapter 38. The packet names a finite observation route; it is not a host real, not a quotient equality of names, not a selected limit, and not a completeness theorem.

Definition 8466.1 (Finite real observer carrier)**.** *A* $\mathsf{FiniteRealObserver}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (Q, L, W, R, D, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request row listing the real-name observations being asked for;*
2. *L is the list schedule row, read through a* $\mathsf{FiniteStream}^{\uparrow}$ *prefix surface for the requested observations;*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selected by Q and L;*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the selected window;*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the readback;*
6. *H records componentwise* hsame *transport for the request, list schedule, window, readback, tolerance, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from the request through the finite window and readback rows;*
8. *P is the* Pkg *provenance over* $\mathsf{FiniteRealObserver}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$*;*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteRealObserver}^{\uparrow}}$ *row.*

The carrier has no coordinate for an infinite observation trace, a host real, a quotient representative, a selected limit, or a Real equality principle outside the displayed finite route.

Theorem 8466.2 (Finite real observer window soundness)**.** *Every accepted* $\mathsf{FiniteRealObserver}^{\uparrow}$ *packet exposes its Real-facing read through the finite route*

$$Q, L, W, R, D, H, C, P, N.$$

Thus a $\mathsf{Real}^{\uparrow}$ *consumer may inspect the requested window only after the finite request row, list prefix row,* $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance rows have all been displayed.*

Proof. Project the carrier of Definition 8466.1. The request row Q and list row L determine the only finite observation schedule available to a consumer.

Next read W, R, D. The window is a $\mathsf{StreamName}^{\uparrow}$ row selected by the finite schedule, the readback is a $\mathsf{RegSeqRat}^{\uparrow}$ row attached to that window, and the tolerance ledger is a $\mathsf{DyadicRatCore}^{\uparrow}$ row consumed by the same readback.

Finally use H, C, P, N. Transport is componentwise, continuation replay follows the displayed finite route, provenance names the sibling surfaces, and the local NameCert row seals the packet. Since no other observation coordinate is present, a Real-facing read cannot bypass the displayed window route. □

Theorem 8466.3 (Finite real observer NameCert obligations)**.** *For the carrier of Definition 8466.1, the local* $\mathsf{NameCert}_{\mathsf{FiniteRealObserver}^{\uparrow}}$ *surface consists of carrier admission for* $O = (Q, L, W, R, D, H, C, P, N)$*, finite request admission, list prefix admission, StreamName window admission, RegSeqRat readback admission, DyadicRatCore tolerance admission, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

No obligation can be discharged by reading an ambient infinite stream, a host real, a quotient representative, a selected limit, or a completeness principle outside those rows.

Proof. Read the rows of the carrier. The finite request and list rows Q, L are the only schedule data, so every observation obligation begins there.

The analytic rows are then forced in order. The StreamName row W supplies the finite window, the RegSeqRat row R ties that window to a regular rational readback, and the DyadicRatCore row D supplies the displayed tolerance data.

The structural rows H, C, P, N transport, replay, source, and name exactly that route. The refused host objects are not coordinates of O, so they cannot satisfy a local naming obligation for $\mathsf{FiniteRealObserver}^{\uparrow}$. □

Theorem 8466.4 (Finite real observer Real readback route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *readback route that consumes an accepted* $\mathsf{FiniteRealObserver}^{\uparrow}$ *packet factors through chapter 5916, chapter 126, chapter 301, chapter 291, and chapter 38 before the terminal Real seal is read. In carrier terms, the rows* $Q, L, W, R, D, H, C, P, N$ *remain attached to one finite observation window throughout the readback.*

Proof. Start with window soundness, Definition 8466.2. It makes every Real-facing read expose Q, L, W, R, D before the structural rows are consumed.

Use the sibling chapters as the route sources. The finite stream chapter supplies the list prefix surface, StreamName supplies the finite window, RegSeqRat supplies regular readback, DyadicRatCore supplies the tolerance ledger, and Real supplies only the terminal seal reached through those rows.

The NameCert obligations of Definition 8466.3 then keep transport, replay, provenance, and local naming on the same packet. Hence the readback route is finite and displayed, not a host real, quotient equality, selected limit, or completeness claim. □

Falsifiable prediction: Any Real-facing read that omits the finite request row or list prefix row is not a FiniteRealObserverUp carrier read.

Independence witness: finite-stream, streamname, regseqrat, dyadicratcore, real: FiniteStreamUp supplies schedules without regular rational readback; StreamNameUp supplies windows without the full request and Real readback route; RegSeqRatUp supplies regular rational names without the observer schedule; DyadicRatCoreUp supplies tolerance rows without the Real-facing observation packet; RealUp supplies the seal boundary without the finite request ledger. None is bijective to $\mathsf{FiniteRealObserver}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteRealObserver}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteRealObserver}^{\uparrow}$ packet is generated from a finite request row, list prefix schedule, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteRealObserver}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8466.1, Definition 8466.2, Definition 8466.3, and Definition 8466.4 seed the finite observation-window bridge for Real and completion-phase readers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteRealObserver}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, Real completeness, quotient equality of names, selected limits, host real equality, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite request soundness, list-prefix accountability, StreamName window soundness, RegSeqRat readback, DyadicRatCore tolerance routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteRealObserverUp.

Chapter 8467

A Concrete Naming Certificate for $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$ packet records an explicit-subsequence-selector compactness surface for located real intervals. It sits after the real-name carrier of chapter 38, the regular rational readback of chapter 301, the finite stream interface of chapter 126, the selector discipline of chapter 5902, and the located interval sequence route of chapter 8094. The packet does not claim open-cover Heine–Borel compactness, quotient real equality, selected representatives, countable choice, or general sequential compactness without displayed selector data.

Definition 8467.1 (Sequentially compact real interval carrier)**.** *A* $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, S, Q, M, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the located real interval row, recording endpoint names, locator data, and the closed interval boundary read through* $\mathsf{Real}^{\uparrow}$*.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the input sequence of interval points and the finite windows inspected before a subsequence is accepted.*
3. *Q is the explicit selector row, naming the monotone subsequence index function and the finite evidence that each selected index is read from the input stream.*
4. *M is the Cauchy-modulus corridor row, recording the displayed tolerance schedule, interval-nesting or finite-net corridor, and the modulus data attached to the selected subsequence.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *handoff row, converting regular rational readback and terminal real-name sealing into the same interval packet.*
6. *H records componentwise* hsame *transport for interval, stream, selector, modulus, handoff, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a located interval and sequence request through the selector and Cauchy-modulus corridor.*
8. *P is the* Pkg *provenance over* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{CauchySubsequenceSelector}^{\uparrow}$*,* $\mathsf{LocatedCompactIntervalSequence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

9. N is the local $\mathsf{NameCert}_{\mathsf{SequentiallyCompactRealInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, Q, M, R, H, C, P, N$. It has no coordinate for open-cover compactness, quotient equality of real names, hidden selected representatives, countable choice, or a general sequential-compactness principle detached from the displayed selector row.

Theorem 8467.2 (Sequentially compact real interval NameCert obligations)**.** *For every accepted* $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$ *carrier*

$$K = (I, S, Q, M, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SequentiallyCompactRealInterval}^{\uparrow}}$ *surface consists of five finite obligations:*

1. *interval exposure: the located interval row I is displayed before any compactness read;*
2. *sequence exposure: the input sequence and inspected finite windows are exposed through S;*
3. *explicit selector exposure: the subsequence selector row Q displays the chosen index map and its monotonicity-facing data;*
4. *Cauchy-modulus corridor: the selected subsequence is routed through the modulus and finite corridor row M before convergence may be read;*
5. *Real-seal handoff: the regular rational readback and terminal real-name seal travel through R, H, C, P, N as the same local packet.*

Thus every accepted compactness consumer reads located interval data, sequence windows, an explicit selector, a Cauchy-modulus corridor, and a Real-facing seal in one finite route.

Proof. Project the carrier of Definition 8467.1. The rows $I, S, Q, M, R, H, C, P, N$ are the only accepted coordinates, so each consumer read begins with the located interval, sequence, selector, modulus corridor, and Real handoff rows.

Use the selector and located interval siblings next. The $\mathsf{CauchySubsequenceSelector}^{\uparrow}$ route supplies displayed selector data, while chapter 8094 supplies the located finite-window interval corridor consumed by M.

Finally read the regular rational and Real rows through R, H, C, P, N. These structural rows transport, replay, source, and name the same packet; they do not add open-cover compactness, quotient equality, hidden representatives, countable choice, or selector-free sequential compactness. □

Falsifiable prediction: An accepted $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$ consumer that reaches a Real seal or Cauchy subsequence without displaying $I, S, Q, M, R, H, C, P, N$ refutes the carrier surface.

Independence witness: real, regseqrat, streamname, cauchy-subsequence-selector, located-compact-interval-sequence: no listed sibling supplies the joint finite packet containing located interval data, stream windows, explicit subsequence selector rows, Cauchy-modulus corridors, regular rational readback, Real sealing, transport, replay, provenance, and local NameCert rows.

Closure status for $\mathsf{NameCert}_{\mathsf{SequentiallyCompactRealInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{SequentiallyCompactRealInterval}^{\uparrow}$ packet is generated from located real interval rows, stream-window sequence rows, explicit subsequence selector rows, Cauchy-modulus corridor rows, RegSeqRat and Real handoff rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SequentiallyCompactRealInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8467.1 and Definition 8467.2 seed the explicit-selector compactness route for located real intervals.

Formal verification: FormalStatus(NameCert$_{\mathsf{SequentiallyCompactRealInterval}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim open-cover Heine–Borel compactness, quotient real equality, selected representatives, countable choice, general sequential compactness without displayed selector data, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located interval exposure, sequence-window exposure, explicit selector exactness, Cauchy-modulus corridor preservation, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.SequentiallyCompactRealIntervalUp.

Chapter 8468

A Concrete Naming Certificate for $\mathsf{TailEquivalenceModulus}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{TailEquivalenceModulus}^{\uparrow}$ packet records the shared finite modulus carried by two tail-equivalent regular Cauchy names before either name is read at a $\mathsf{Real}^{\uparrow}$ seal. It sits between the finite stream windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the tail-equivalence classifier of chapter 5179, the reusable tail seal of chapter 8052, and the terminal real-name surface of chapter 38. The packet names the common modulus as displayed finite data; it is not quotient stream equality, a selected limit, countable choice over tails, trichotomy, host real equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8468.1 (Tail-equivalence modulus carrier)**.** *A* $\mathsf{TailEquivalenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S_0, S_1, R_0, R_1, D, E, K, A, H, C, P, N)$$

with the following displayed rows:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which the regular Cauchy names are inspected.*
2. R_0 *and* R_1 *are the corresponding* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows exposed by the windows.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording the displayed precision request, dyadic comparison budget, and slack left after the two regular radii are paid.*
4. E *is the* $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ *row witnessing that the two readbacks share a tail-equivalence comparison at the displayed precision.*
5. K *is the common finite modulus row assigning the precision in* D *to a single tail bound valid for both readbacks.*
6. A *is the* $\mathsf{Real}^{\uparrow}$ *seal handoff reached only after* $S_0, S_1, R_0, R_1, D, E, K$ *have been displayed.*
7. H *records componentwise* hsame *transport for the two window rows, two readback rows, dyadic ledger, equivalence row, common modulus, Real seal, replay, provenance, and local naming rows.*
8. C *records displayed* Cont *replay from a tail-equivalence request through* $S_0, S_1, R_0, R_1, D, E, K, A, H, P, N$.
9. P *is the* Pkg *provenance over* $\mathsf{TailEquivalenceModulus}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$, $\mathsf{RegularCauchyTailSeal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{TailEquivalenceModulus}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $S_0, S_1, R_0, R_1, D, E, K, A, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8468.2 (Tail-equivalence modulus NameCert obligations)**.** *For every accepted* $\mathsf{TailEquivalenceModulus}^{\uparrow}$ *carrier*

$$M = (S_0, S_1, R_0, R_1, D, E, K, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{TailEquivalenceModulus}^{\uparrow}}$ *surface consists exactly of two finite* $\mathsf{StreamName}^{\uparrow}$ *window admissions, two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, one* $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ *comparison row, one common finite modulus row, one* $\mathsf{Real}^{\uparrow}$ *seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8468.1. The accepted packet displays exactly the two window rows, two regular readbacks, dyadic ledger, tail-equivalence comparison, common modulus, Real seal, and structural rows.

The source side is exhausted by S_0, S_1, R_0, R_1. A consumer must inspect both finite stream windows and the corresponding regular rational readbacks before any common tail bound can be read.

The comparison side is exhausted by D, E, K. The dyadic ledger fixes the tolerance request, the tail-equivalence row records the displayed comparison between the readbacks, and the common modulus row assigns a single finite threshold to both names.

The endpoint and structural rows A, H, C, P, N seal, transport, replay, source, and name the same packet. Since quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, host real equality, and ambient completeness are absent from the carrier, they cannot appear as NameCert obligations. □

Theorem 8468.3 (Tail-equivalence modulus Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{TailEquivalenceModulus}^{\uparrow}$ *packet must read the finite route*

$$S_0, S_1 \longmapsto R_0, R_1 \longmapsto D \longmapsto E \longmapsto K \longmapsto A$$

before it may consume the terminal Real seal. The handoff exports the common tail modulus shared by the two regular Cauchy readbacks, not quotient equality of streams or a selected completion endpoint.

Proof. Begin with a Real-facing read. By Definition 8468.1, the read first reaches the two $\mathsf{StreamName}^{\uparrow}$ windows and their $\mathsf{RegSeqRat}^{\uparrow}$ readbacks.

The dyadic row D then fixes the tolerance budget for the comparison. The tail-equivalence row E is read only against that displayed budget, and the common modulus row K records the single tail bound shared by the two readbacks.

Only after K is visible does the terminal seal row A become available. The transport, replay, provenance, and local naming rows preserve this route without adding a quotient class, a selected representative, a selected limit, countable choice, trichotomy, host equality, or ambient completeness. □

Falsifiable prediction: Every accepted $\mathsf{TailEquivalenceModulus}^{\uparrow}$ read displays two $\mathsf{StreamName}^{\uparrow}$ windows, two $\mathsf{RegSeqRat}^{\uparrow}$ readbacks, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, one $\mathsf{RegularCauchyTailEquivalence}^{\uparrow}$ row, one common finite modulus row, one $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed

Cont replay, Pkg provenance, and local naming before a Real-facing equality consumer can read the seal.

Independence witness: streamname, regseqrat, dyadicratcore, regular-cauchy-tail-equivalence, regular-cauchy-tail-seal, real: $\mathsf{TailEquivalenceModulus}^{\uparrow}$ is not bijective to any listed sibling because it binds two windows, two regular readbacks, one dyadic tolerance ledger, one tail-equivalence row, one shared modulus row, one Real seal, transport, replay, provenance, and local naming into a single finite carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{TailEquivalenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{TailEquivalenceModulus}^{\uparrow}$ packet is generated from two StreamName windows, two RegSeqRat readbacks, one DyadicRatCore tolerance ledger, one RegularCauchyTailEquivalence comparison row, one common finite modulus row, one RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TailEquivalenceModulus}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8468.1, Definition 8468.2, and Definition 8468.3 seed the finite shared-modulus surface between tail-equivalent regular Cauchy readbacks and the terminal $\mathsf{Real}^{\uparrow}$ seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TailEquivalenceModulus}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked window admission, regular readback, dyadic tolerance accounting, tail-equivalence comparison, common-modulus preservation, Real seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.TailEquivalenceModulusUp.

Chapter 8469

A Concrete Naming Certificate for $\mathsf{LocatedRealIntervalChain}^{\uparrow}$

Following Bishop and Bridges on located interval constructions, the $\mathsf{LocatedRealIntervalChain}^{\uparrow}$ packet records a finite chain of located real intervals as the displayed route by which interval refinements feed the Real and Completion stack. It sits between the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the closed interval boundary of chapter 1591. The packet names a finite located interval-chain certificate only; it does not assert interval compactness, choose an infinite branch, quotient real names, invoke trichotomy, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8469.1 (Located real interval chain carrier)**.** *A* $\mathsf{LocatedRealIntervalChain}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (I, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite located interval-chain row. It lists the inspected interval cells, their endpoint order, their containment relation to the preceding cell, and the locatedness evidence available at each stage.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *diameter and endpoint-arithmetic ledger attached to the same cells.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for endpoint names, midpoint requests, and refinement stages.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row serving the stream windows and dyadic tolerances of S and D.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after the interval chain, dyadic ledger, stream window, and regular readback rows have been displayed.*
6. *H records componentwise* hsame *transport for the interval-chain row, dyadic ledger, stream windows, readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the finite route*

$$I, D \longmapsto S, R \longmapsto E, H, P, N.$$

8. *P is the* Pkg *provenance over* LocatedRealIntervalChain$^{\uparrow}$, ClosedBoundedInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

9. *N is the local* NameCert$_{\text{LocatedRealIntervalChain}^{\uparrow}}$ *row.*

The carrier exports only this displayed finite packet. It has no coordinate for a host interval intersection theorem, quotient equality of real names, a selected infinite branch, countable choice, trichotomy, or ambient completeness.

Theorem 8469.2 (Located real interval chain NameCert obligations)**.** *For every accepted* LocatedRealIntervalChain *carrier $L = (I, D, S, R, E, H, C, P, N)$, the local* NameCert$_{\text{LocatedRealIntervalChain}^{\uparrow}}$ *surface consists exactly of the following obligations:*

1. *interval-chain admission: the finite located interval list, endpoint order, containment rows, and locatedness witnesses are displayed by I before any readback is allowed;*

2. *dyadic exactness: every diameter and endpoint-arithmetic request is read through the* DyadicRatCore$^{\uparrow}$ *ledger D attached to the same finite chain;*

3. *finite observation: endpoint and refinement-stage requests pass through the common* StreamName$^{\uparrow}$ *window S and* RegSeqRat$^{\uparrow}$ *readback row R before the terminal* Real$^{\uparrow}$ *seal E is consumed;*

4. *structural stability: H, C, P, N transport, replay, source, and locally name only the displayed rows of the carrier.*

No located real interval-chain obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8469.1. The located chain, dyadic diameter ledger, stream windows, regular readback, Real seal, and structural rows are all coordinates of one finite packet.

The dyadic exactness obligation reads only the row D. Since D is attached to the same finite interval cells named by I, a consumer cannot replace the chain by a host interval family, an infinite selector, or an ambient order-completeness principle.

The observation obligation is downstream. The stream row S exposes the inspected endpoint and refinement windows, the regular rational row R supplies readback for those windows, and the seal row E is available only after I, D, S, R have been displayed.

Finally H, C, P, N preserve that route under transport, replay, provenance, and local naming. Because no carrier coordinate contains quotient equality, choice, trichotomy, interval intersection, or ambient completeness, none of those principles is exported by the local certificate. □

Theorem 8469.3 (Located real interval chain nested refinement)**.** *Let $L = (I, D, S, R, E, H, C, P, N)$ be an accepted* LocatedRealIntervalChain$^{\uparrow}$ *carrier. Every refinement read of the chain must expose the finite interval row I and the dyadic diameter ledger D before it consumes the stream window S, the regular rational readback R, or the terminal* Real$^{\uparrow}$ *seal E. Thus a nested refinement is a displayed finite chain route through* ClosedBoundedInterval$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, *and* Real$^{\uparrow}$, *not a host-selected infinite intersection or quotient real endpoint.*

Proof. Start with the carrier definition. The only interval-chain coordinate is I, and the only diameter and endpoint-arithmetic coordinate is D.

Apply the NameCert obligations of Definition 8469.2. They force every refinement request to read the displayed interval-chain row and its dyadic ledger before any observation window or Real-facing seal is available.

The readback rows S, R, E are therefore downstream of the finite nested route. Componentwise transport and replay preserve the same ordering through H and C, while P and N record only the

displayed source and local name. No coordinate remains from which a consumer could recover a selected infinite branch, quotient endpoint equality, trichotomy, choice, or ambient completeness. □

Theorem 8469.4 (Located real interval chain Real seal route)**.** *Every Real and Completion consumer of an accepted* $\mathsf{LocatedRealIntervalChain}^{\uparrow}$ *carrier reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the finite route*

$$\mathsf{ClosedBoundedInterval}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may transport and replay the displayed chain, but it cannot export interval compactness, countable choice, quotient equality of real names, selected completed endpoints, real trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Use Definition 8469.3. It places every refinement read behind the finite interval row I and dyadic ledger D.

Next use Definition 8469.2. Its finite-observation clause routes endpoint and refinement-stage reads through S and R before the seal row E can be consumed.

The sibling anchors identify the public surfaces of the route: closed bounded interval data supplies the interval boundary, $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the diameter and endpoint arithmetic, $\mathsf{StreamName}^{\uparrow}$ supplies finite observation windows, $\mathsf{RegSeqRat}^{\uparrow}$ supplies regular rational readback, and $\mathsf{Real}^{\uparrow}$ supplies only the terminal seal. Since the carrier contains no compactness theorem, quotient equality, choice selector, trichotomy, or ambient completeness coordinate, the consumer receives only this finite seal route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealIntervalChain}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealIntervalChain}^{\uparrow}$ packet is generated from a finite located interval-chain row, a DyadicRatCore diameter and endpoint-arithmetic ledger, StreamName finite windows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalChain}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8469.1, Definition 8469.2, Definition 8469.3, and Definition 8469.4 seed the finite located interval-chain route into the Real and Completion stack.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealIntervalChain}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close interval compactness, selected infinite intersections, quotient equality of real names, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires a Lean declaration for BEDC.Derived.LocatedRealIntervalChainUp covering carrier admission, dyadic exactness, nested refinement ordering, readback routing, Real seal nonescape, transport, replay, provenance, and local naming.

Chapter 8470

A Concrete Naming Certificate for $\mathsf{CauchyGluingLemma}^{\uparrow}$

Following Bishop–Bridges constructive analysis on regular Cauchy names, the $\mathsf{CauchyGluingLemma}^{\uparrow}$ packet records the finite lemma surface by which two compatible regular rational windows are glued before a completion-facing Real seal is exposed. It sits after the finite windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance agreement of chapter 291, the downstream gluing row of chapter 5899, and the terminal Real seal of chapter 38. The packet is a finite NameCert reconstruction of the usual constructive gluing lemma; it is not quotient stream equality, a selected common representative, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8470.1 (Cauchy gluing lemma carrier)**.** *A* $\mathsf{CauchyGluingLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S_0, S_1, W_0, W_1, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are compatible finite* $\mathsf{StreamName}^{\uparrow}$ *windows naming the two local regular Cauchy observations and their common overlap schedule.*
2. *W_0 and W_1 are the two local* $\mathsf{RegSeqRat}^{\uparrow}$ *readback windows whose rational tails are compared only on the displayed overlap.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-agreement row tying the two windows to the same dyadic request and the same finite overlap budget.*
4. *R is the downstream* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *row that consumes the two local windows, the shared tolerance ledger, and the scheduled overlap before any glued readback is public.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the stream schedules, regular readbacks, dyadic agreement, and gluing row have been replayed.*
6. *H records componentwise* hsame *transport for the two schedules, two readbacks, dyadic ledger, gluing row, Real seal, replay, provenance, and local name.*
7. *C records displayed* Cont *replay from a requested glued-window read through $S_0, S_1, W_0, W_1, D, R, E, H, P, N$.*
8. *P is the* Pkg *provenance over* $\mathsf{CauchyGluingLemma}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyGluing}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyGluingLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient stream equality, selected representatives, countable choice, host Real equality, hidden completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8470.2 (Cauchy gluing lemma NameCert obligations)**.** *For every accepted* $\mathsf{CauchyGluingLemma}^{\uparrow}$ *carrier*

$$G = (S_0, S_1, W_0, W_1, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyGluingLemma}^{\uparrow}}$ *surface consists exactly of carrier admission, overlap compatibility, regular-readback preservation, gluing handoff, Real-seal nonescape, transport, replay, provenance, and local naming. The carrier admission exposes the two* $\mathsf{StreamName}^{\uparrow}$ *schedules, two* $\mathsf{RegSeqRat}^{\uparrow}$ *windows, one* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-agreement ledger, one* $\mathsf{RegularCauchyGluing}^{\uparrow}$ *consumer row, one terminal* $\mathsf{Real}^{\uparrow}$ *seal, and the structural rows* H, C, P, N*. No local obligation is stored outside these rows.*

Proof. Project the carrier of Definition 8470.1. The rows $S_0, S_1, W_0, W_1, D, R, E, H, C, P, N$ are the only visible coordinates, so carrier admission and local naming are immediate projections.

Overlap compatibility is the row D read together with the scheduled windows S_0, S_1. Regular-readback preservation is the pair W_0, W_1 read through the same dyadic request, so the two local rational windows cannot be replaced by quotient stream equality or selected representatives.

The gluing handoff is the row R. By the sibling route of chapter 5899, R consumes the displayed schedules, readbacks, and tolerance ledger before exposing any glued regular-Cauchy read.

Finally E is downstream of that handoff. The structural rows H, C, P, N transport, replay, source, and name the same finite route, so a Real-facing consumer receives only the listed rows and none of the refused host or quotient principles. □

Theorem 8470.3 (Cauchy gluing lemma Real seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{CauchyGluingLemma}^{\uparrow}$ *carrier must pass through the displayed route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularCauchyGluing}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The consumer first reads the two finite stream windows, then the two regular rational readbacks, then the shared dyadic tolerance agreement, then the regular-Cauchy gluing row, and only then the terminal Real seal. The route exports no quotient stream equality, selected common representative, countable choice, host Real equality, hidden completion, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.CauchyGluingLemmaUp`

Proof. Let $G = (S_0, S_1, W_0, W_1, D, R, E, H, C, P, N)$ be accepted. Any Real-facing read must end at E, and E is available only after the carrier's displayed replay row C has passed through the earlier rows.

The earlier rows are ordered by their dependencies. The schedules S_0, S_1 name the finite observations, W_0, W_1 give the regular rational readbacks on those observations, and D records the shared dyadic tolerance agreement for the overlap.

The downstream gluing row R is then the only row that can turn the two local windows into one glued regular-Cauchy read. Since the terminal seal E is read after R, every Real-facing consumer factors through the displayed route.

The carrier contains no coordinate for the refused endpoints. Componentwise transport, replay, provenance, and local naming preserve the same route rather than adding a quotient, selector, choice principle, host equality, hidden completion, or ambient completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{CauchyGluingLemma}^{\uparrow}$ Real-facing read factors through two $\mathsf{StreamName}^{\uparrow}$ finite windows, two $\mathsf{RegSeqRat}^{\uparrow}$ readback windows, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance-agreement row, one $\mathsf{RegularCauchyGluing}^{\uparrow}$ handoff, one terminal $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, regularcauchygluing, real: no listed sibling is bijective to $\mathsf{CauchyGluingLemma}^{\uparrow}$ because this packet jointly carries two compatible finite windows, two regular readbacks, one dyadic agreement ledger, a downstream gluing row, a Real seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyGluingLemma}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyGluingLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8470.1, Definition 8470.2, and Definition 8470.3 seed the finite gluing-lemma route over two StreamName windows, two RegSeqRat readbacks, DyadicRatCore tolerance agreement, a RegularCauchyGluing handoff, a Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyGluingLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, host Real equality, hidden completion, ambient RealUp completeness, Lean theorem verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, overlap compatibility, regular-readback preservation, gluing handoff, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyGluingLemmaUp.

Constructive story: A $\mathsf{CauchyGluingLemma}^{\uparrow}$ packet is generated from two compatible finite StreamName windows, two RegSeqRat readback windows, one DyadicRatCore tolerance-agreement row, one RegularCauchyGluing handoff row, one Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8471

A Concrete Naming Certificate for $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$ packet records the finite criterion by which a displayed regular sequence over the real-completion route supplies a limit-facing read only after its StreamName windows, RegSeqRat readbacks, dyadic tolerance rows, sequential-completeness witness, and completion-operator handoff are visible. It sits after the terminal real-name seal of chapter 38, the finite window surface of chapter 126, the regular rational readback of chapter 301, the sequence-completeness interface of chapter 1515, and the completion-operator route of chapter 3379. The packet is a Bishop-style sequential limit criterion for the Real and Completion phase; it is not a proof of $\mathsf{Real}^{\uparrow}$ completeness, a quotient equality of streams, countable choice, trichotomy, selected representatives, or bridge checking.

Definition 8471.1 (Bishop sequential limit criterion carrier)**.** *A* $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, Q, O, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, exposing the finite sequence observations and tolerance requests opened by the limit read.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the displayed windows of S.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording requested radii, split tolerances, slack cells, endpoint observations, and comparison budgets.*
4. *Q is the* $\mathsf{SequentiallyCompleteMetric}^{\uparrow}$ *row that carries the sequence-completeness witness for the displayed metric-side sequence without importing an ambient completeness theorem.*
5. *O is the* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *route row, read only after S, R, D, Q have fixed the finite window and completion-boundary data.*
6. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached by the criterion after the sequential-completeness and completion-operator rows are displayed.*
7. *H records componentwise* hsame *transport for the window, readback, tolerance, sequential-completeness, completion-operator, real-seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay of the route*

$$S, R, D \longmapsto Q \longmapsto O \longmapsto E.$$

9. *P is the* Pkg *provenance over* BishopSequentialLimitCriterion$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, SequentiallyCompleteMetric$^{\uparrow}$, CauchyCompletionOperator$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{BishopSequentialLimitCriterion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, Q, O, E, H, C, P, N$. It has no coordinate for Real$^{\uparrow}$ *completeness, quotient stream equality, countable choice, trichotomy, selected representatives, selected limits outside the displayed packet, host real equality, or bridge checking.*

Theorem 8471.2 (Bishop sequential limit criterion NameCert obligations)**.** *For every accepted* BishopSequentialLimitCriterion$^{\uparrow}$ *carrier*

$$L = (S, R, D, Q, O, E, H, C, P, N),$$

the local NameCert$_{\text{BishopSequentialLimitCriterion}^{\uparrow}}$ *surface consists exactly of the following finite obligations:*

1. *carrier admission for the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, SequentiallyCompleteMetric row, CauchyCompletionOperator route, Real seal, componentwise transport, displayed replay, provenance, and local naming;*
2. *window-readback exactness, requiring R to read only the finite observations displayed by S;*
3. *tolerance exactness, requiring D to display the dyadic radii, split tolerances, endpoint observations, slack cells, and comparison budgets before any sequential-completeness or completion-operator consumer reads the route;*
4. *sequential-completeness handoff, requiring Q to receive only the displayed S, R, D evidence and not an ambient completeness theorem;*
5. *completion-operator compatibility, requiring O to be downstream of the same S, R, D, Q route;*
6. *Real seal nonescape, requiring E to be reached only after the displayed sequential and completion rows have been read;*
7. *structural stability, requiring H, C, P, N to transport, replay, source, and name only the displayed route.*

No Bishop sequential limit criterion obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8471.1. The accepted packet displays exactly the StreamName window row, regular readback, dyadic tolerance ledger, sequential-completeness row, completion-operator route, Real seal, and structural rows.

Window-readback and tolerance exactness are local to S, R, D. The readback row is attached to the displayed windows, and the dyadic ledger supplies all requested radii, endpoint observations, split tolerances, slack cells, and comparison budgets before the later rows may be consumed.

The sequential-completeness row Q receives only that displayed evidence. It names the sequence-completeness handoff for the given finite route rather than an external theorem that all real sequences have limits.

The completion-operator row O is downstream of the same route. It may read the completion boundary only after S, R, D, Q have fixed the finite window, readback, tolerance, and sequence-completeness data.

Finally E, H, C, P, N seal, transport, replay, source, and name the route. Since the carrier has no coordinate for $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, countable choice, trichotomy, selected representatives, selected limits outside the displayed packet, host real equality, or bridge checking, the listed rows exhaust the local NameCert surface. □

Theorem 8471.3 (Bishop sequential limit criterion Real-completion route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$ *packet factors through the finite route*

$$S \longmapsto R \longmapsto D \longmapsto Q \longmapsto O \longmapsto E \longmapsto H, C, P, N.$$

The consumer first reads the StreamName windows, then the RegSeqRat readback and DyadicRatCore tolerance ledger, then the SequentiallyCompleteMetric witness and CauchyCompletionOperator route, and only then the terminal Real seal and structural rows. The route exports no $\mathsf{Real}^{\uparrow}$ *completeness theorem, quotient stream equality, countable choice, trichotomy, selected representative, host real equality, or bridge checking.*

Proof. Begin with a $\mathsf{Real}^{\uparrow}$ or completion-facing read of an accepted carrier. Projection exposes the ordered rows $S, R, D, Q, O, E, H, C, P, N$ and no additional analytic coordinate.

The rows S, R, D provide the finite observational base. A consumer cannot start from a quotient stream or an unbounded host sequence because the readback and tolerance evidence are attached to the displayed windows.

The sequential-completeness row Q is read next. It consumes the finite window, readback, and dyadic ledger as a displayed sequence-completeness witness for this packet, not as a global completeness claim.

The completion-operator row O then provides the completion-facing handoff, and the terminal seal E is available only after that handoff. The structural rows preserve the same path under transport, replay, provenance, and local naming.

The excluded principles are absent from the carrier inventory. Therefore every Real or completion consumer factors through the displayed route and receives none of the listed escape data. □

Falsifiable prediction: An accepted $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$ consumer is refuted if it reaches a $\mathsf{Real}^{\uparrow}$ or completion-facing seal without displaying the StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, SequentiallyCompleteMetric row, CauchyCompletionOperator route, transport row, replay row, provenance row, and local naming row.

Independence witness: streamname, regseqrat, dyadicratcore, sequentially-complete-metric, cauchycompletionoperator, real: $\mathsf{BishopSequentialLimitCriterion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds finite sequence windows, regular rational readback, dyadic tolerance accounting, sequential-completeness handoff, completion-operator routing, Real sealing, componentwise transport, replay, provenance, and local naming as one criterion packet.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopSequentialLimitCriterion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopSequentialLimitCriterion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8471.1, Definition 8471.2, and Definition 8471.3 seed the Bishop sequential limit route through StreamName windows, RegSeqRat readback, DyadicRatCore tolerance data, SequentiallyCompleteMetric handoff, CauchyCompletionOperator routing, Real seal, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopSequentialLimitCriterion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, countable choice, trichotomy, selected representatives, selected limits outside the displayed packet, host real equality, Lean checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window-readback exactness, tolerance exactness, sequential-completeness handoff, completion-operator compatibility, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopSequentialLimitCriterionUp.

Constructive story: A BishopSequentialLimitCriterion$^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance rows, a SequentiallyCompleteMetric handoff, a CauchyCompletionOperator route, a terminal RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8472

A Concrete Naming Certificate for $\mathsf{FiniteCauchyTailHandoff}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real construction, the $\mathsf{FiniteCauchyTailHandoff}^{\uparrow}$ packet records the finite tail-window interface where regular rational names, finite stream requests, dyadic tolerance ledgers, and terminal real-name seals meet. It sits over the regular-rational readback of chapter 301, the finite request surface of chapter 126, the dyadic arithmetic rows of chapter 291, the real-name seal of chapter 38, the tail selector of chapter 458, and the modulus arithmetic of chapter 1485. The packet gives the L10 Real and Completion route a named handoff between tail evidence and Real sealing without quotient equality, selected limits, trichotomy, countable choice, or ambient completeness.

Definition 8472.1 (Finite Cauchy tail handoff carrier)**.** *A* $\mathsf{FiniteCauchyTailHandoff}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (R, W, D, M, S, Z, H, K, P, N)$$

with the following displayed rows:

1. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-rational readback row whose tail is being offered to a Real-facing consumer;*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite request window over which the tail is inspected;*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger carrying the displayed radius, precision, and comparison budget for the window;*
4. *M is the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *row computing the tail bound from the request window and dyadic ledger;*
5. *S is the* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *row selecting the finite tail segment licensed by M;*
6. *Z is the terminal* $\mathsf{Real}^{\uparrow}$ *seal that may consume the displayed tail handoff;*
7. *H records componentwise* hsame *transports for the regular readback, window, dyadic ledger, modulus arithmetic, tail selector, real seal, provenance, and local name;*
8. *K records displayed* Cont *routes from R, W, D through M, S to Z and from the structural rows back to the local certificate;*
9. *P is the* Pkg *provenance over* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyModulusArithmetic}^{\uparrow}$, $\mathsf{RegularCauchyTailSelector}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows;*

10. N is the local $\mathsf{NameCert}_{\mathsf{FiniteCauchyTailHandoff}^{\uparrow}}$ *row.*
The carrier has no coordinate for quotient stream equality, a host-selected Cauchy tail, a selected real limit, trichotomy, countable choice, or an ambient completeness principle.

Lean4 (statement) `BEDC.Derived.FiniteCauchyTailHandoffUp`

Theorem 8472.2 (Finite Cauchy tail handoff NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCauchyTailHandoff}^{\uparrow}$ *carrier* $T = (R, W, D, M, S, Z, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyTailHandoff}^{\uparrow}}$ *surface consists exactly of four public obligation rows: regular-rational tail source through* R*, finite window and dyadic budget through* W, D*, computed modulus and tail selector through* M, S*, and terminal real sealing through* Z*. The structural rows* H, K, P, N *preserve, replay, source, and locally name only those displayed rows, so no other tail witness or Real-facing evidence is available.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyTailHandoffUp.FiniteCauchyTailHandoffNameCertObligations`

Proof. Project the finite packet of Definition 8472.1. Its analytic rows are exactly the regular readback R, window W, dyadic ledger D, modulus arithmetic row M, tail selector S, and real seal Z.

The first obligation exposes the $\mathsf{RegSeqRat}^{\uparrow}$ tail source. The second obligation fixes the finite $\mathsf{StreamName}^{\uparrow}$ window and $\mathsf{DyadicRatCore}^{\uparrow}$ budget. The third obligation computes the displayed tail bound and selector through M, S. The fourth obligation seals the resulting handoff through Z.

The rows H, K, P, N transport, replay, package, and name the same packet. Since the carrier omits quotient equality, selected limits, choice schedules, trichotomy, and ambient completeness, the local certificate has no other public obligation row. □

Lean4 ✓ `BEDC.Derived.FiniteCauchyTailHandoffNameCertObligations`

Theorem 8472.3 (Finite Cauchy tail handoff Real seal route)**.** *Every Real-facing read of an accepted* $\mathsf{FiniteCauchyTailHandoff}^{\uparrow}$ *carrier reaches the* $\mathsf{Real}^{\uparrow}$ *seal* Z *only after passing through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R*, the common* $\mathsf{StreamName}^{\uparrow}$ *window* W*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger* D*, the* $\mathsf{CauchyModulusArithmetic}^{\uparrow}$ *row* M*, the* $\mathsf{RegularCauchyTailSelector}^{\uparrow}$ *row* S*, componentwise* hsame *transport* H*, displayed* Cont *replay* K*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{FiniteCauchyTailHandoff}^{\uparrow}}$ *row* N*. It cannot replace this finite route by quotient equality, host real equality, a selected limit, trichotomy, countable choice, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteCauchyTailHandoffUp.FiniteCauchyTailHandoffRealSealRoute`

Proof. Start with the NameCert obligations of Definition 8472.2. They place the tail source, window, dyadic ledger, modulus arithmetic, tail selector, and Real seal in one displayed finite packet.

The route to Z must therefore pass through R, W, D, M, S first. The Cont row K records that order, while the hsame row H can only transport the displayed components of the same carrier.

Finally, P and N provide provenance and local naming for that carrier. Because no omitted coordinate is present in Definition 8472.1, a Real-facing consumer cannot cite a quotient equality, host equality, selected limit, choice schedule, trichotomy branch, or ambient completeness witness as part of the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCauchyTailHandoff}^{\uparrow}}$**.**

Constructive story: A FiniteCauchyTailHandoff$^{\uparrow}$ packet is generated from a RegSeqRat readback, a StreamName window, a DyadicRatCore ledger, CauchyModulusArithmetic, RegularCauchyTailSelector, a RealUp seal, componentwise transport, continuation replay, package provenance, and local naming.

Theory closure: TheoryGate(NameCert$_{\text{FiniteCauchyTailHandoff}\uparrow}$, seed)

Scope closed: Definition 8472.1, Definition 8472.2, and Definition 8472.3 bind the finite tail-window route from regular rational readback to terminal Real sealing.

Formal verification: FormalStatus(NameCert$_{\text{FiniteCauchyTailHandoff}\uparrow}$, formalTarget)

Lean target: `BEDC.Derived.FiniteCauchyTailHandoffUp`

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient equality of streams, host real equality, selected limits, trichotomy, countable choice, ambient completeness, theorem checking, audit cleanliness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tail-window determinacy, Real seal non-escape, and structural route preservation for the same finite packet.

Chapter 8473

A Concrete Naming Certificate for $\mathsf{RegularCauchyRecursion}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{RegularCauchyRecursion}^{\uparrow}$ packet records the finite evaluator surface by which a regular rational Cauchy name is read through displayed precision windows, dyadic tolerance rows, and a recursion ledger before a $\mathsf{Real}^{\uparrow}$ seal is available. It sits over the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance core of chapter 291, the finite $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the $\mathsf{RegSeqRat}^{\uparrow}$ rational source rows of chapter 301, the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38, and the completion eliminator of chapter 3628. The chapter names a finite L10 evaluator route; it does not identify quotient streams, select limits, compare host functions by equality, invoke countable choice, or use ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8473.1 (Regular Cauchy recursion carrier)**.** *A* $\mathsf{RegularCauchyRecursion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (Q, S, D, E, L, H, C, P, N)$$

with the following displayed rows:

1. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row whose regular rational entries are the only values read by the evaluator.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row recording the finite observation windows used for each precision request.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row recording dyadic radii, comparison cells, and the requested error budget.*
4. *E is the evaluator and recursion ledger, recording each finite call, its source window, its dyadic tolerance, and its dependency on earlier ledger rows.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after Q, S, D, E have been displayed.*
6. *H records componentwise* hsame *transport for the rational source, window, tolerance, evaluator ledger, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay for each evaluator request through Q, S, D, E, L, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRecursion}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{CauchyCompletionRecursor}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRecursion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $Q, S, D, E, L, H, C, P, N$. No coordinate stores a quotient stream, a selected limit, host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.RegularCauchyRecursionUp.RegularCauchyRecursionTasteGate single carrier alignment`

Theorem 8473.2 (Regular Cauchy recursion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyRecursion}^{\uparrow}$ *carrier*

$$R = (Q, S, D, E, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyRecursion}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{RegSeqRat}^{\uparrow}$ *source row, finite* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, evaluator and recursion ledger, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every evaluator read must expose the source row Q, window row S, tolerance row D, and ledger row E before any Real-facing seal is visible.*

Proof. Project the carrier of Definition 8473.1. Its displayed coordinates are exactly $Q, S, D, E, L, H, C, P, N$, so local naming and carrier admission have no hidden analytic source.

Read the analytic rows in order. The rational source Q supplies only regular rational entries, the window row S fixes the finite observations, and the dyadic row D fixes the requested tolerance budget.

The evaluator ledger E is downstream of those rows. It records finite recursive calls and their dependencies, but it does not add a quotient stream, selected limit, host function equality, choice schedule, or completeness principle.

Finally read the structural rows H, C, P, N and the seal row L. Transport, replay, provenance, and local naming preserve the same finite route, so the listed rows exhaust the NameCert surface. □

Theorem 8473.3 (Regular Cauchy recursion evaluation handoff)**.** *Every Real-facing or completion-facing consumer of an accepted* $\mathsf{RegularCauchyRecursion}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{CauchyCompletionRecursor}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The evaluator ledger may be handed to the $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ *route only as displayed regular-Cauchy recursion data over Q, S, D, E, H, C, P, N. The handoff exports no quotient-stream equality, selected representative, selected limit, host function equality, countable choice, or ambient Real completeness.*

Proof. Start from the NameCert obligations of Definition 8473.2. They force every evaluator request to expose the regular rational source, finite windows, dyadic tolerance row, and evaluator ledger before the Real seal is read.

The completion recursor then receives only the displayed ledger. Its input is the finite route through Q, S, D, E together with transport, replay, provenance, and local naming; it is not a separate limit selector or quotient representative.

Since quotient streams, selected representatives, selected limits, host function equality, countable choice, and ambient Real completeness have no coordinate in the carrier, no downstream consumer can extract them from the handoff. □

Falsifiable prediction: An accepted $\mathsf{RegularCauchyRecursion}^{\uparrow}$ consumer that reads a $\mathsf{Real}^{\uparrow}$ seal or a $\mathsf{CauchyCompletionRecursor}^{\uparrow}$ handoff without displaying the $\mathsf{RegSeqRat}^{\uparrow}$ source row, $\mathsf{StreamName}^{\uparrow}$ windows, $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, evaluator ledger, transport, replay, provenance, and local naming evidence refutes the carrier surface.

Independence witness: dyadicratcore, streamname, regseqrat, real, cauchy-completion-recursor: no listed sibling supplies the whole packet $R = (Q, S, D, E, L, H, C, P, N)$, because each sibling contributes only a tolerance, window, rational-source, Real-seal, or completion-elimination surface while this chapter binds all five with an evaluator ledger, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRecursion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRecursion}^{\uparrow}$ packet is generated from a RegSeqRat source row, StreamName windows, DyadicRatCore tolerances, an evaluator and recursion ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyRecursion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8473.1, Definition 8473.2, and Definition 8473.3 seed the finite L10 regular-Cauchy evaluator route over rational-source rows, finite windows, dyadic tolerances, completion-recursion handoff, Real sealing, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyRecursion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient streams, selected limits, host function equality, countable choice, ambient Real completeness, Lean verification, axiom-clean audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-row exactness, window exposure, dyadic tolerance exactness, evaluator ledger replay, completion-recursion handoff, Real seal nonescape, transport, provenance, and local naming for BEDC.Derived.RegularCauchyRecursionUp.

Chapter 8474

A Concrete Naming Certificate for $\mathsf{FunctionSequence}^{\uparrow}$

Following Bishop and Bridges on displayed sequences of maps, the $\mathsf{FunctionSequence}^{\uparrow}$ packet records the finite route through which a reader inspects a sequence of functions before uniform, pointwise, compactness, or limit-continuity consumers read the resulting value rows. It sits beside the continuous-map carrier of chapter 130, the stream schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name carrier of chapter 38, the uniform-convergence route of chapter 3417, and the uniform-limit continuity surface of chapter 1751. The packet is a shared BEDC carrier for displayed sequences of maps; it is not a host sequence of functions, quotient equality of maps, selected representatives, countable choice, or ambient completeness.

Definition 8474.1 (Function sequence carrier)**.** *A* $\mathsf{FunctionSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, F, A, V, W, H, C, P, L)$$

with the following displayed rows:

1. *X is the source-carrier row naming the domain and codomain surfaces through which the displayed maps are read;*
2. *F is the indexed function-graph row, listing the inspected stage names and their graph rows through* $\mathsf{ContinuousMap}^{\uparrow}$ *or the relevant displayed map carrier;*
3. *A is the finite argument-window row, recording the source arguments inspected at the displayed stages;*
4. *V is the value readback row, routing each inspected value through* $\mathsf{RegSeqRat}^{\uparrow}$ *and the terminal* $\mathsf{Real}^{\uparrow}$ *seal when the codomain is Real-facing;*
5. *W is the uniform-window ledger, recording finite stage and argument windows for uniform, compact, or limit-continuity consumers;*
6. *H records componentwise* hsame *transport for the source carrier, indexed graph rows, argument windows, value readbacks, uniform-window ledger, replay, provenance, and local naming rows;*
7. *C records displayed* Cont *replay from a stage-and-argument request through X, F, A, V, W, H, P, L;*
8. *P is the* Pkg *provenance over* $\mathsf{FunctionSequence}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformConvergence}^{\uparrow}$, $\mathsf{UniformLimitContinuity}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows;*

9. L is the local $\mathsf{NameCert}_{\mathsf{FunctionSequence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for host function extensionality, quotient equality of maps, an infinite uninspected schedule, selected representatives, countable choice, pointwise-only convergence detached from the value readback row, or ambient completeness.

Theorem 8474.2 (Function sequence NameCert obligations)**.** *For every accepted* $\mathsf{FunctionSequence}^{\uparrow}$ *carrier* $S = (X, F, A, V, W, H, C, P, L)$*, the local* $\mathsf{NameCert}_{\mathsf{FunctionSequence}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source carrier, indexed function-graph rows, finite argument windows, value readback rows, uniform-window ledger, componentwise transport, displayed replay, provenance, and local naming; value readback through* A, V*; uniform-window exposure through* W*; and refusal of host function equality, quotient map equality, uninspected infinite schedules, selected representatives, countable choice, pointwise-only detached convergence, and ambient completeness.*

Proof. Project the carrier of Definition 8474.1. The source and analytic rows are X, F, A, V, W, and the structural rows are H, C, P, L.

The value readback obligation uses A and V. A consumer first chooses a displayed stage and argument window, then reads the value row through the regular rational and Real-facing surfaces supplied by the packet.

The uniform-window obligation uses W. Uniform convergence, compactness, and uniform-limit continuity consumers may request finite stage and argument windows, but the requested window remains attached to the same indexed graph rows and value readbacks.

Finally inspect H, C, P, L. These rows transport, replay, source, and name only the displayed packet. Since the refused host-side objects are not carrier coordinates, they cannot discharge a local NameCert obligation for $\mathsf{FunctionSequence}^{\uparrow}$. □

Theorem 8474.3 (Function sequence L10 route)**.** *Every accepted* $\mathsf{FunctionSequence}^{\uparrow}$ *read factors through the L10 route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{ContinuousMap}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}$$

whenever a Real-facing value is inspected. Uniform-convergence and uniform-limit-continuity consumers may read W *only after the source carrier* X*, indexed graph row* F*, argument window* A*, value readback row* V*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* L *remain visible.*

Proof. Start with the NameCert obligations of Definition 8474.2. They force any consumer to expose the source carrier, indexed graph rows, argument windows, value readback rows, and uniform-window ledger before the packet is named.

Read the L10 siblings in order. The stream schedule supplies the inspected stage row, the continuous-map carrier supplies the displayed graph row, the regular rational surface supplies the value readback, and the Real carrier supplies only the terminal seal reached through those rows.

For a uniform or limit-continuity consumer, the row W adds a finite stage-and-argument ledger without detaching the read from X, F, A, V. The structural rows H, C, P, L preserve the same packet under transport, replay, provenance, and local naming, so the route cannot become a host-level sequence of functions or a quotient equality of maps. □

Falsifiable prediction: A uniform-convergence or uniform-limit-continuity read that obtains a value row without displaying the indexed graph row and finite argument window is not a $\mathsf{FunctionSequence}^{\uparrow}$ carrier read.

Independence witness: continuous-map, streamname, regseqrat, real, uniform-convergence, uniform-limit-continuity: ContinuousMapUp names one displayed map without the sequence schedule; StreamNameUp supplies schedules without map graphs; RegSeqRatUp supplies regular rational readback without the source and map rows; RealUp supplies the terminal seal without the sequence ledger; UniformConvergenceUp and UniformLimitContinuityUp consume finite uniform windows but do not by themselves name the shared displayed sequence-of-maps carrier. None is bijective to $\mathsf{FunctionSequence}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{FunctionSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{FunctionSequence}^{\uparrow}$ packet is generated from a source-carrier row, indexed function-graph rows, finite argument windows, value readback rows, a uniform-window ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FunctionSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8474.1, Definition 8474.2, and Definition 8474.3 seed the shared displayed sequence-of-maps carrier for ContinuousMapUp, StreamNameUp, RegSeqRatUp, RealUp, UniformConvergenceUp, UniformLimitContinuityUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FunctionSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host function extensionality, quotient equality of maps, selected representatives, countable choice, pointwise-only detached convergence, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, value readback, uniform-window exposure, L10 route preservation, transport, replay, provenance, and local naming for BEDC.Derived.FunctionSequenceUp.

Chapter 8475

A Concrete Naming Certificate for $\mathsf{SobolevSlobodeckij}^{\uparrow}$

Following Triebel and Adams–Fournier on fractional Sobolev and Slobodeckij regularity, the $\mathsf{SobolevSlobodeckij}^{\uparrow}$ packet records the finite Gagliardo-seminorm surface by which a non-integer smoothness read is exposed before any function-space quotient or ambient completeness theorem can be cited. It sits beside the Sobolev-space carrier of chapter 5911, the fractional Sobolev packet of chapter 6051, the Holder-space boundary of chapter 7000, and the Besov-space scale packet of chapter 4204. The chapter names only displayed function windows, dyadic pair ledgers, exponent data, seminorm readbacks, structural transport, replay, provenance, and local naming evidence.

Definition 8475.1 (Sobolev-Slobodeckij carrier)**.** *A* $\mathsf{SobolevSlobodeckij}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (U, F, p, s, Q, G, R, B, H, C, P, N)$$

with the following displayed rows:

1. *U is the source* $\mathsf{SobolevSpace}^{\uparrow}$ *or* $\mathsf{FractionalSobolev}^{\uparrow}$ *row whose weak or fractional regularity window is being inspected.*
2. *F records the finite function-value windows used by the seminorm read.*
3. *p and s are rational exponent and smoothness rows, with $0 < s < 1$ recorded as displayed order data.*
4. *Q is the finite pair ledger naming the inspected point-pair or dyadic cell-pair requests.*
5. *G is the Gagliardo-seminorm ledger, recording the displayed difference quotient budget over Q, F, p, s.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the finite seminorm estimates.*
7. *B is the handoff row to* $\mathsf{HolderSpace}^{\uparrow}$ *or* $\mathsf{BesovSpace}^{\uparrow}$ *consumers when their scale boundary is read.*
8. *H, C, P, N record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{SobolevSlobodeckij}^{\uparrow}}$ *evidence.*

The classifier compares only $U, F, p, s, Q, G, R, B, H, C, P, N$. It has no coordinate for quotient function equality, almost-everywhere representatives, selected completions, unrestricted integration theory, or ambient Banach-space completeness.

Theorem 8475.2 (Sobolev-Slobodeckij NameCert obligations)**.** *For every accepted* $\mathsf{SobolevSlobodeckij}^{\uparrow}$ *carrier* $S = (U, F, p, s, Q, G, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{SobolevSlobodeckij}^{\uparrow}}$ *surface consists exactly of carrier admission, source Sobolev or fractional-Sobolev exposure, function-window exposure, exponent and smoothness-row exactness, pair-ledger coverage, Gagliardo-seminorm ledger exposure,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Holder/Besov handoff exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8475.1. The analytic rows are precisely U, F, p, s, Q, G, R, B, and the structural rows are H, C, P, N.

The source regularity is read from U, while the finite windows and pair requests are read from F and Q. The exponent rows p, s and the ledger G record the Gagliardo-seminorm budget over exactly those displayed requests.

The readback row R transports the finite estimates to regular rational data, and the handoff row B exposes only the Holder or Besov boundary named by the sibling chapters. Since every remaining operation is componentwise transport, replay, provenance, or naming, the listed rows exhaust the local NameCert obligations. □

Theorem 8475.3 (Sobolev-Slobodeckij Gagliardo-seminorm boundary)**.** *Every downstream regularity consumer of an accepted* $\mathsf{SobolevSlobodeckij}^{\uparrow}$ *packet must read the Gagliardo-seminorm ledger* G *through the displayed source row* U*, function windows* F*, exponent rows* p, s*, pair ledger* Q*, and regular rational readback* R *before it receives any seminorm bound. The exported bound is therefore a finite BEDC row over the displayed pair ledger, not a host integral, quotient representative, or completed function-space norm.*

Proof. Begin with the NameCert obligations of Definition 8475.2. They make U, F, p, s, Q, G, R visible before any consumer can cite a seminorm estimate.

The ledger G is indexed by the displayed pair requests in Q and by the finite function windows F. Thus a seminorm read cannot replace those rows by an ambient integral domain, an almost-everywhere representative, or an unrestricted quotient function.

The readback R supplies the regular rational boundary for the estimate. The structural rows H, C, P, N preserve the same displayed route, so every exported Gagliardo-seminorm bound is attached to the carrier surface. □

Theorem 8475.4 (Sobolev-Slobodeckij Holder and Besov handoff)**.** *Any* $\mathsf{HolderSpace}^{\uparrow}$ *or* $\mathsf{BesovSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{SobolevSlobodeckij}^{\uparrow}$ *packet must first read the same source row* U*, function windows* F*, exponent data* p, s*, pair ledger* Q*, Gagliardo-seminorm ledger* G*, and* $\mathsf{RegSeqRat}^{\uparrow}$ *readback* R*. The handoff row* B *then exposes a regularity-scale boundary compatible with chapter 7000 and chapter 4204; it does not export an independent Holder modulus, Besov decomposition, quotient function identity, or selected completion point.*

Proof. Project the accepted packet and apply Definition 8475.3. Every scale-facing consumer has already read the source, window, exponent, pair-ledger, seminorm, and readback rows.

The handoff row B has no data outside that route. It merely names the boundary by which the displayed Slobodeckij seminorm can be consumed by the Holder-space or Besov-space sibling surface.

Because quotient identities, selected representatives, completed function-space points, and independent scale decompositions are absent from the carrier, neither the Holder nor Besov consumer can receive such data from the handoff. □

Falsifiable prediction: An accepted $\mathsf{SobolevSlobodeckij}^{\uparrow}$ consumer that cites a Gagliardo-seminorm, Holder boundary, or Besov boundary without reading the displayed source row, finite windows, exponent rows, pair ledger, seminorm ledger, regular rational readback, structural transport, replay, provenance, and local naming refutes the carrier surface.

Independence witness: sobolev-space, fractional-sobolev, holder-space, besov-space: no listed sibling supplies the whole packet $S = (U, F, p, s, Q, G, R, B, H, C, P, N)$, because SobolevSpace supplies the weak-source row, FractionalSobolev supplies a broader non-integer smoothness surface, HolderSpace supplies a power-law target boundary, and BesovSpace supplies a scale packet while this chapter binds the Gagliardo-seminorm pair ledger as its own finite NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{SobolevSlobodeckij}^{\uparrow}}$.

Constructive story: A $\mathsf{SobolevSlobodeckij}^{\uparrow}$ packet is generated from a SobolevSpace or FractionalSobolev source row, finite function windows, rational exponent and smoothness rows, a finite pair ledger, a Gagliardo-seminorm ledger, RegSeqRat readback, HolderSpace or BesovSpace handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SobolevSlobodeckij}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8475.1, Definition 8475.2, Definition 8475.3, and Definition 8475.4 seed the finite Gagliardo-seminorm carrier and its Holder/Besov handoff boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SobolevSlobodeckij}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim quotient function equality, almost-everywhere representative selection, host integration completeness, Lean verification, bridge checking, or ambient Banach-space completeness.

Upgrade path: Obligation closure requires checked carrier admission, source exposure, function-window exposure, exponent and smoothness exactness, pair-ledger coverage, Gagliardo-seminorm ledger exactness, regular rational readback, handoff exposure, transport, replay, provenance, and local naming.

Chapter 8476

A Concrete Naming Certificate for $\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}$

Following Lebesgue and the Hardy–Littlewood differentiation tradition, the $\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}$ packet records the theorem-level finite route by which local differentiation rows are read after the basis, maximal, covering, measure, and real-name packets have all been displayed. It consumes the differentiation carrier of chapter 4153, the basis carrier of chapter 6706, the maximal-function boundary of chapter 3581, the finite Vitali covering ledger of chapter 2166, the measurable source rows of chapter 92, and the terminal real-name seal of chapter 38. The packet names one finite theorem route; it is not measure completion, a selected almost-everywhere representative, quotient function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8476.1 (Lebesgue differentiation theorem carrier)**.** *A* $\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (L, B, H, V, M, R, A, E, Q, C, P, N)$$

with the following displayed rows:

1. *L is the accepted* $\mathsf{LebesgueDifferentiation}^{\uparrow}$ *row, exposing the finite local differentiation certificate.*
2. *B is the accepted* $\mathsf{LebesgueDifferentiationBasis}^{\uparrow}$ *row, exposing basis cells, finite selection, finite overlap, local-average, tolerance, and seal rows.*
3. *H is the* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *domination row used before an exceptional-set or local-average verdict is consumed.*
4. *V is the* $\mathsf{FiniteVitaliCover}^{\uparrow}$ *ledger, recording finite disjoint subfamilies, cover cells, and overlap budgets used by B and L.*
5. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row for the inspected measurable requests and local-measure windows.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for local values, averages, radii, and error budgets.*
7. *A is the theorem-readback ledger, listing the finite route from basis admission through maximal domination and Vitali selection to the differentiation verdict.*
8. *E is the exclusion ledger, recording that the theorem route does not use measure completion, almost-everywhere representative selection, quotient function equality, countable choice, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

9. *Q records componentwise* hsame *transport for differentiation, basis, maximal, Vitali, measure, real, readback, exclusion, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from theorem requests through $L, B, H, V, M, R, A, E, Q, P, N$.*
11. *P is the* Pkg *provenance over* LebesgueDifferentiationTheorem$^{\uparrow}$, LebesgueDifferentiation$^{\uparrow}$, LebesgueDifferentiationB HardyLittlewoodMaximal$^{\uparrow}$, FiniteVitaliCover$^{\uparrow}$, Measure$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted theorem packets only through $L, B, H, V, M, R, A, E, Q, C, P, N$. It has no coordinate for measure completion, selected almost-everywhere representatives, quotient function equality, countable-choice schedules, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8476.2 (Lebesgue differentiation theorem NameCert obligations)**.** *For every accepted* LebesgueDifferentiationTheorem$^{\uparrow}$ *carrier*

$$T = (L, B, H, V, M, R, A, E, Q, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the differentiation row, basis row, maximal-domination row, finite Vitali-cover ledger, measure source row, Real seal row, theorem-readback ledger, exclusion ledger, transport, replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8476.1. The displayed rows $L, B, H, V, M, R, A, E, Q, C, P, N$ are the whole theorem-level packet.

The differentiation and basis rows are read first. The row L supplies the local differentiation certificate of chapter 4153, while B supplies the basis and finite-cover handoff of chapter 6706.

The maximal and covering rows then constrain the theorem read. The row H records the Hardy–Littlewood domination boundary, V records the finite Vitali ledger, and M, R keep the measurable source and Real seal visible before any differentiation verdict is consumed.

Finally A, E, Q, C, P, N record the theorem route, excluded endpoints, componentwise transport, replay, provenance, and local name. Since the excluded objects have no carrier coordinates, the NameCert obligations cannot use measure completion, selected almost-everywhere representatives, quotient function equality, countable choice, or ambient Real$^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted LebesgueDifferentiationTheorem$^{\uparrow}$ read must expose the LebesgueDifferentiation row, LebesgueDifferentiationBasis row, HardyLittlewoodMaximal row, FiniteVitaliCover ledger, Measure source row, Real seal row, theorem-readback ledger, exclusion ledger, hsame transport, Cont replay, Pkg provenance, and local NameCert before a theorem-level differentiation verdict is consumed.

Independence witness: lebesgue-differentiation, lebesgue-differentiation-basis, hardy-littlewood-maximal, finite-vitali-cover, measure, real: LebesgueDifferentiationTheorem$^{\uparrow}$ is not bijective to any listed sibling because it binds the theorem-level readback ledger and exclusion ledger to all six local rows before the verdict is named.

Closure status for $\mathsf{NameCert}_{\mathsf{LebesgueDifferentiationTheorem}^{\uparrow}}$**.**

Constructive story: A LebesgueDifferentiationTheorem$^{\uparrow}$ packet is generated from LebesgueDifferentiationUp rows, LebesgueDifferentiationBasisUp rows, HardyLittlewoodMaximalUp domination, FiniteVitaliCoverUp ledgers, MeasureUp source rows, RealUp seals, theorem-readback rows, exclusion rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{LebesgueDifferentiationTheorem}^{\uparrow}}$, seed)

Scope closed: Definition 8476.1 and Definition 8476.2 seed the theorem-level finite route through differentiation, basis, maximal, Vitali, measure, and real-name rows.

Formal verification: FormalStatus(NameCert$_{\text{LebesgueDifferentiationTheorem}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim measure completion, selected almost-everywhere representatives, quotient function equality, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, differentiation-row admission, basis-row admission, maximal-domination routing, finite Vitali-cover routing, Measure and Real sealing, exclusion-ledger exhaustion, transport, replay, provenance, and local naming for BEDC.Derived.LebesgueDifferentiationTheoremUp.

Chapter 8477

A Concrete Naming Certificate for $\mathsf{FreudenthalSuspension}^{\uparrow}$

Following Freudenthal and Hatcher on suspension and stable homotopy, the $\mathsf{FreudenthalSuspension}^{\uparrow}$ packet records the finite route by which a pointed homotopy object is suspended and handed to a stable-range connectivity consumer. It sits after the $\mathsf{Homotopy}^{\uparrow}$ deformation surface of chapter 156, the $\mathsf{SimplicialSet}^{\uparrow}$ face-and-degeneracy ledger of chapter 157, the $\mathsf{Homology}^{\uparrow}$ chain-read surface of chapter 98, and the S1Up circle certificate of chapter 58. The chapter names suspension cones, equator gluing, basepoint transport, homology-window, connectivity-handoff, replay, provenance, and local naming rows; it does not import a host suspension space, quotient topology, selected homotopy representatives, stable homotopy groups, or Freudenthal's theorem as an ambient oracle.

Definition 8477.1 (FreudenthalSuspension carrier)**.** *A* $\mathsf{FreudenthalSuspension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, S_-, S_+, E, G, H_*, K, T, R, P, N)$$

with the following displayed rows:

1. *X is the pointed source row, read through* $\mathsf{Homotopy}^{\uparrow}$ *and carrying only the displayed basepoint and deformation ledgers needed by the suspension read.*
2. *S_- and S_+ are the two cone rows. Each cone row records finite face, degeneracy, and endpoint data through* $\mathsf{SimplicialSet}^{\uparrow}$ *rather than through a quotient topological suspension.*
3. *E is the equator row, read through the S1Up circle certificate and the source basepoint ledger.*
4. *G is the gluing ledger that identifies the two cone boundaries along E by displayed* hsame *data.*
5. *H_* is the finite* $\mathsf{Homology}^{\uparrow}$ *read window used by the stable-range consumer.*
6. *K is the connectivity handoff row. It records only the displayed stable-range obligation surface, not a selected homotopy group element or a host Freudenthal isomorphism.*
7. *T records componentwise* hsame *transport for the source, cones, equator, gluing, homology window, connectivity handoff, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from a suspension query through $X, S_-, S_+, E, G, H_*, K, T$.*
9. *P is the* Pkg *provenance over* $\mathsf{FreudenthalSuspension}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{SimplicialSet}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, *S1Up,* BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FreudenthalSuspension}^{\uparrow}}$ *row.*

The carrier has no coordinate for a quotient suspension, a selected homotopy class, an ambient stable homotopy group, a classical connectivity theorem, open-cover compactness, or choice-selected cellular approximation.

Theorem 8477.2 (FreudenthalSuspension NameCert obligations)**.** *For every accepted* $\mathsf{FreudenthalSuspension}^{\uparrow}$ *carrier* $F = (X, S_-, S_+, E, G, H_*, K, T, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FreudenthalSuspension}^{\uparrow}}$ *surface consists exactly of source admission, two displayed cone admissions, equator admission through S1Up, cone-boundary gluing, finite homology-window readback, stable-range connectivity handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A downstream suspension consumer must read* X, S_-, S_+, E, G *before the homology window* H_* *is public and must read* H_* *before the connectivity handoff* K *is public.*

Proof. Project the carrier of Definition 8477.1. The source row X supplies only displayed homotopy data, while S_- and S_+ supply the two finite simplicial cone ledgers.

The equator row E is read through S1Up before the gluing ledger G is exposed. Thus the suspension boundary is a displayed cone-equator-cone route rather than a quotient-space construction.

The homology window H_* can be inspected only after the source, cone, equator, and gluing rows have been replayed. The connectivity handoff K is then a finite stable-range obligation row over that homology window, not an ambient stable homotopy theorem.

Transport through T, replay through R, provenance through P, and local naming through N preserve exactly these rows. Since the carrier stores no quotient suspension, selected homotopy class, host homotopy group, or classical connectivity theorem, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8477.3 (FreudenthalSuspension connectivity handoff)**.** *Every accepted* $\mathsf{FreudenthalSuspension}^{\uparrow}$ *connectivity consumer reaches its stable-range handoff only after the displayed* $\mathsf{Homotopy}^{\uparrow}$ *source row, the two* $\mathsf{SimplicialSet}^{\uparrow}$ *cone rows, the S1Up equator row, the cone-boundary gluing ledger, and the finite* $\mathsf{Homology}^{\uparrow}$ *read window have been exposed. Consequently the handoff exports a local NameCert obligation surface for suspension connectivity, not a proof of Freudenthal's suspension theorem, a selected homotopy class, a quotient suspension space, or a completed stable homotopy group.*

Proof. Start from Definition 8477.2. It places $X, S_-, S_+, E, G, H_*, K, T, R, P, N$ in the only accepted order available to the packet.

The homotopy, simplicial, circle, and homology siblings are therefore visible before K can be consumed. Each sibling contributes a displayed row: deformation data from $\mathsf{Homotopy}^{\uparrow}$, face and degeneracy data from $\mathsf{SimplicialSet}^{\uparrow}$, equator data from S1Up, and the finite chain-read window from $\mathsf{Homology}^{\uparrow}$.

Finally the structural rows T, R, P, N preserve that route under transport, replay, provenance, and local naming. With no carrier coordinate for quotient suspension spaces, selected homotopy classes, stable homotopy groups, or classical connectivity oracles, the connectivity handoff remains a finite BEDC obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{FreudenthalSuspension}^{\uparrow}}$**.**

Constructive story: A $\mathsf{FreudenthalSuspension}^{\uparrow}$ packet is generated from a pointed HomotopyUp source row, two SimplicialSetUp cone rows, an S1Up equator row, a cone-boundary gluing ledger, a HomologyUp read window, a stable-range connectivity handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FreudenthalSuspension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8477.1, Definition 8477.2, and Definition 8477.3 seed the Freudenthal suspension packet over Homotopy, SimplicialSet, Homology, S1, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FreudenthalSuspension}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Freudenthal's suspension theorem, quotient suspension topology, selected homotopy classes, stable homotopy groups, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, cone admission, equator gluing, homology-window readback, connectivity handoff, transport, replay, provenance, and local naming for BEDC.Derived.FreudenthalSuspensionUp.

Chapter 8478

A Concrete Naming Certificate for $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$ packet records a located metric subspace together with a finite oscillation gauge before any Real or Completion consumer reads the resulting function space. It sits over the metric source of chapter 57, the located-subset surface of chapter 1541, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, and the explicit modulus-continuity row of chapter 1631. The packet exposes oscillation control as finite located metric data, not as an external selector, quotient function equality, countable choice, host continuity, or ambient completeness.

Definition 8478.1 (Bishop located oscillation space carrier)**.** *A* $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (M, L, G, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row naming the finite metric requests and comparison budget visible to the packet.*
2. *L is the* $\mathsf{LocatedSet}^{\uparrow}$ *row for the inspected subspace, including the positive and negative locatedness tests allowed over the source row M.*
3. *G is the located oscillation gauge row. It records the displayed input cells, local radius requests, dyadic slack, and oscillation bounds served on the same support as M and L.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the sampled values and oscillation bounds carried by G.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after the metric source, located-set row, oscillation gauge, and regular rational readback have been displayed.*
6. *H records componentwise* hsame *transport for the metric source, located subset, oscillation gauge, regular readback, Real seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from each oscillation request through M, L, G, R, E, H.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{LocatedSet}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ModulusContinuity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, G, R, E, H, C, P, N$. It has no coordinate for selected representatives, quotient function equality, a detached continuity principle, countable choice, global compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8478.2 (Bishop located oscillation space NameCert obligations)**.** *For every accepted* $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$ *carrier*

$$O = (M, L, G, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, metric-source exposure through M, located-subset admission through L, oscillation-gauge exactness through G, regular rational readback through R, Real-seal nonescape through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Carrier admission is projection from Definition 8478.1. The packet displays exactly the metric source, located subset, oscillation gauge, regular readback, Real seal, transport, replay, provenance, and local name.

The source and located rows are read first. Row M fixes the metric comparison surface, and row L restricts every oscillation request to the located subset carried on that surface.

The oscillation obligation is the gauge row G. Its local radii and oscillation bounds are valid only on the same located support, and the readback row R exposes those bounds as regular rational data before the Real seal E can be consumed.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no row for selected representatives, quotient equality, detached continuity, countable choice, global compactness, or ambient Real completeness, none of those principles is exported by the local NameCert surface. □

Theorem 8478.3 (Bishop located oscillation space modulus route)**.** *Every* $\mathsf{ModulusContinuity}^{\uparrow}$ *consumer of an accepted* $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$ *carrier reads the finite route*

$$M, L, G \longmapsto R, E \longmapsto H, C, P, N.$$

The consumer receives a source metric row, a located subset row, a displayed oscillation gauge, regular rational readback, and a Real seal before any modulus-continuity handoff is visible. The route exports no external selector, host continuity theorem, quotient function equality, selected representative, countable-choice schedule, global compactness, or ambient completeness coordinate.

Proof. Project the carrier through Definition 8478.1. The only analytic rows available to a modulus consumer are M, L, G, R, E.

Use Definition 8478.2. It forces the metric source and located subset to be displayed before the oscillation gauge is read, and it forces the regular rational row and Real seal to be displayed before the handoff reaches a $\mathsf{ModulusContinuity}^{\uparrow}$ consumer.

The structural rows H, C, P, N preserve that same finite route. Therefore the modulus-facing read is a located oscillation handoff over displayed metric data, not a host continuity principle or a completion-side selector. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopLocatedOscillationSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopLocatedOscillationSpace}^{\uparrow}$ packet is generated from a MetricUp source row, a LocatedSetUp row, a located oscillation gauge, RegSeqRatUp readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{BishopLocatedOscillationSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8478.1, Definition 8478.2, and Definition 8478.3 seed the located metric oscillation route for Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopLocatedOscillationSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected representatives, quotient function equality, detached continuity, countable choice, global compactness, ambient Real$^{\uparrow}$ completeness, Lean theorem checking, or standard bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, metric-source exposure, located-subset admission, oscillation-gauge exactness, regular rational readback, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopLocatedOscillationSpaceUp.

Chapter 8479

A Concrete Naming Certificate for $\mathsf{RationalIntervalCoverage}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RationalIntervalCoverage}^{\uparrow}$ packet records coverage of a displayed rational interval by finitely many dyadic subintervals. It sits over the rational endpoint surface of chapter 37, the dyadic arithmetic core of chapter 291, the finite observation discipline of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet gives the Real and Completion route a named finite coverage carrier for interval arguments, not an open-cover compactness theorem, a quotient interval, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8479.1 (Rational interval coverage carrier)**.** *A* $\mathsf{RationalIntervalCoverage}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (A, B, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Rat}^{\uparrow}$ *endpoint row for the source closed interval, displaying rational endpoints $a \leq b$.*
2. *B is the finite list of rational subinterval rows whose endpoints lie in the source interval and whose successive endpoints meet at displayed rational boundaries.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *refinement ledger. It records dyadic radii, midpoint cuts, containment checks, and endpoint slack bounds for every subinterval named by B.*
4. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *observation schedule bounding which endpoint, midpoint, and containment rows may be inspected by a downstream consumer.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row carrying the displayed rational and dyadic endpoint data toward regular rational names.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, B, D, W, R have been displayed.*
7. *H records componentwise* hsame *transport for the rational endpoint, subinterval, dyadic ledger, stream-window, regular-rational, real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from an interval-coverage request through $A, B, D, W, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{RationalIntervalCoverage}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalCoverage}^{\uparrow}}$ *row naming exactly this finite interval-coverage packet.*

The classifier compares accepted packets only through $A, B, D, W, R, E, H, C, P, N$. It has no coordinate for open-cover compactness, quotient intervals, selected real representatives, countable choice, host equality of real endpoints, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8479.2 (Rational interval coverage NameCert obligations)**.** *For every accepted* $\mathsf{RationalIntervalCoverage}^{\uparrow}$ *carrier $I = (A, B, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RationalIntervalCoverage}^{\uparrow}}$ *surface consists exactly of carrier admission for the source rational interval, finite rational subinterval list, dyadic refinement ledger, bounded StreamName observation schedule, RegSeqRat readback, Real seal handoff, componentwise transport, displayed replay, provenance, and local naming. The obligation surface may cite* $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *sibling chapters, but it cannot replace the displayed finite rows by open-cover compactness, quotient interval equality, host real equality, countable choice, selected representatives, or ambient real completeness.*

Proof. Project the carrier of Definition 8479.1. The analytic rows visible to the local certificate are exactly the rational endpoint row A, the finite subinterval list B, the dyadic refinement ledger D, the finite observation schedule W, the regular-rational readback R, and the downstream real seal E.

The rational interval is covered only by reading the finite list B. For each listed subinterval, the dyadic ledger D supplies the displayed midpoint, containment, overlap, and slack checks needed to compare its endpoints with the source endpoints in A.

The rows W and R bound the consumer route. A Real or Completion-facing use must inspect only the scheduled finite endpoint and dyadic rows before the regular rational readback is available.

Finally H, C, P, N transport, replay, source, and name the same packet. Since none of the excluded principles is a carrier coordinate or a product of these projections, the listed rows exhaust the local NameCert obligation surface. □

Theorem 8479.3 (Rational interval coverage dyadic refinement)**.** *Let $I = (A, B, D, W, R, E, H, C, P, N)$ be an accepted* $\mathsf{RationalIntervalCoverage}^{\uparrow}$ *carrier. Every subinterval row in B refines the source rational interval by the finite route*

$$A \longmapsto B \longmapsto D \longmapsto W \longmapsto R \longmapsto E, H, C, P, N.$$

In particular, each endpoint comparison used by a downstream Real or Completion consumer is witnessed by a displayed dyadic budget in D before any $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *seal is read. The route exports no open-cover compactness, quotient interval, selected real representative, countable choice, host real equality, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Fix a listed subinterval in B. By Definition 8479.1, its endpoints are rational rows tied to the source endpoint row A and to the dyadic ledger D.

Read the dyadic ledger next. The containment and slack entries in D give a finite comparison budget for the left endpoint, the right endpoint, and the shared boundary rows visible in B.

The StreamName row W bounds which of these comparisons can be inspected. The RegSeqRat row R then packages exactly the displayed endpoint approximations, and the Real seal E remains downstream of that same finite route.

The structural rows H, C, P, N add no analytic principle beyond transport, replay, provenance, and naming. Thus every refinement claim factors through the displayed dyadic budget and cannot escape to open-cover compactness, quotient intervals, selected representatives, choice, host equality, or ambient completeness. □

Theorem 8479.4 (Rational interval coverage Real-completion nonescape)**.** *Any Real or Completion-facing use of an accepted* $\mathsf{RationalIntervalCoverage}^{\uparrow}$ *packet must expose the source rational interval, finite subinterval list, dyadic refinement ledger, bounded observation schedule, and regular-rational readback before reading the terminal* $\mathsf{Real}^{\uparrow}$ *seal. Consequently the packet is available to compact-interval and completion arguments only as finite dyadic interval-coverage evidence, not as open-cover compactness, quotient interval equality, host real equality, countable choice, selected representatives, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a Real or Completion-facing consumer of I. The carrier projection first exposes A, B, D, W, R; no real seal can be read before those rows have been displayed.

Apply Definition 8479.3. Each subinterval comparison reaching the consumer has already passed through the finite dyadic ledger and the bounded StreamName schedule.

The terminal row E is therefore a seal of the displayed regular rational readback, not an independent host real interval. Transport, replay, provenance, and local naming keep that route inside H, C, P, N.

Since the packet contains no open-cover object, quotient interval coordinate, selected representative, choice schedule, host equality proof, or ambient completeness row, none of those objects can be exported by a Real or Completion-facing use. □

Falsifiable prediction: An accepted $\mathsf{RationalIntervalCoverage}^{\uparrow}$ consumer that reaches a RealUp or completion-facing interval conclusion without reading rational endpoint rows, a finite subinterval list, a DyadicRatCore refinement ledger, StreamName windows, and a RegSeqRat readback refutes the carrier surface.

Independence witness: rat, dyadicratcore, streamname, regseqrat, real: $\mathsf{RationalIntervalCoverage}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source rational interval, finite subinterval list, dyadic refinement ledger, bounded observation schedule, regular-rational readback, Real seal handoff, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{RationalIntervalCoverage}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RationalIntervalCoverage}^{\uparrow}$ packet is generated from source rational endpoints, a finite rational subinterval list, dyadic midpoint and slack rows, bounded StreamName observations, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RationalIntervalCoverage}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8479.1, Definition 8479.2, Definition 8479.3, and Definition 8479.4 seed the finite dyadic interval-coverage route over $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RationalIntervalCoverage}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: The chapter does not claim open-cover compactness, quotient interval equality, host real equality, countable choice, selected real representatives, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite rational subinterval exposure, dyadic refinement exactness, bounded StreamName observation, RegSeqRat readback, Real seal handoff, and nonescape under BEDC.Derived.RationalIntervalCoverageUp.

Chapter 8480

A Concrete Naming Certificate for $\mathsf{DividedPowerAlgebra}^{\uparrow}$

Following Berthelot–Ogus and Grothendieck crystalline methods, the $\mathsf{DividedPowerAlgebra}^{\uparrow}$ packet records the finite law surface by which divided powers are named over a ring-module algebra context before any crystalline envelope or infinitesimal thickening consumer may read them. It sits over the coefficient ring of chapter 43, the underlying module rows of chapter 46, polynomial expression rows from chapter 50, tensor compatibility from chapter 87, and natural-number arity data from chapter 28. The packet names displayed multiplication, unit, ideal, divided-power operation, factorial-arity, polynomial-law, tensor-distribution, transport, replay, provenance, and local naming data; it does not export a host crystalline topos, quotient algebra equality, selected envelope, or unrestricted nilpotent completion.

Definition 8480.1 (Divided-power algebra carrier)**.** *A* $\mathsf{DividedPowerAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (R, A, I, \gamma, M, U, N, L, T, H, C, P, Z)$$

with the following displayed rows:

1. *R is the* $\mathsf{Ring}^{\uparrow}$ *coefficient row, carrying the addition, multiplication, zero, one, and distributivity data used by the algebra law checks.*
2. *A is the algebra-underlying* $\mathsf{Module}^{\uparrow}$ *row, exposing the finite additive and scalar rows on which the divided-power operations act.*
3. *I is the displayed ideal or augmentation row inside A, recorded as a finite membership and closure ledger.*
4. *γ is the finite divided-power operation table, with entries $\gamma_n(x)$ only for the natural-number arities and ideal elements listed by the request rows.*
5. *M and U record multiplication and unit compatibility for the algebra row over R.*
6. *N is the* $\mathsf{Nat}^{\uparrow}$ *arity ledger for zero, one, successor, and finite binomial-index reads.*
7. *L is the* $\mathsf{Poly}^{\uparrow}$ *law ledger, recording the displayed additivity, scalar, product, and composition law checks as polynomial identities over the listed arities.*
8. *T is the* $\mathsf{TensorProduct}^{\uparrow}$ *compatibility row for bilinear distribution and base-change reads.*
9. *H, C, P, Z record componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}_{\mathsf{DividedPowerAlgebra}^{\uparrow}}$ *evidence.*

The classifier compares accepted packets only through $R, A, I, \gamma, M, U, N, L, T, H, C, P, Z$. It has no coordinate for a host crystalline envelope, quotient algebra equality, selected completion, external factorial inverse, or ambient nilpotent thickening.

Theorem 8480.2 (Divided-power algebra NameCert obligations)**.** *For every accepted* $\mathsf{DividedPowerAlgebra}^{\uparrow}$ *carrier*

$$D = (R, A, I, \gamma, M, U, N, L, T, H, C, P, Z),$$

the local $\mathsf{NameCert}_{\mathsf{DividedPowerAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission for the coefficient ring, module-algebra row, ideal membership ledger, divided-power operation table, multiplication and unit rows, natural-number arity ledger, polynomial law ledger, tensor compatibility row, componentwise transport, displayed replay, provenance, and local naming. The law obligations require $\gamma_0(x)$, $\gamma_1(x)$, scalar compatibility, additivity, product compatibility, and iterated divided powers to be checked only through the displayed $R, A, I, \gamma, M, U, N, L, T$ rows.*

Proof. Project the carrier of Definition 8480.1. The algebraic source rows are $R, A, I, \gamma, M, U, N, L, T$, and the structural rows are H, C, P, Z.

The coefficient and module rows type every displayed operation. The ideal row I supplies the admitted inputs, while the arity ledger N restricts every divided-power read to the natural-number requests carried by the packet.

The law checks are then read from L and T. Polynomial rows record the displayed zero, unit, scalar, additivity, product, and composition equations, and the tensor row records the bilinear and base-change compatibility seen by downstream consumers.

Finally, H, C, P, Z transport, replay, source, and locally name exactly those rows. Since no carrier coordinate stores a crystalline envelope, quotient algebra equality, selected completion, external factorial inverse, or ambient nilpotent thickening, none of those objects can discharge a local NameCert obligation. □

Theorem 8480.3 (Divided-power law nonescape)**.** *Every consumer of an accepted* $\mathsf{DividedPowerAlgebra}^{\uparrow}$ *divided-power law must read the law through the finite route*

$$\mathsf{Ring}^{\uparrow},\ \mathsf{Module}^{\uparrow},\ I,\ \gamma,\ \mathsf{Nat}^{\uparrow} \longmapsto \mathsf{Poly}^{\uparrow},\ \mathsf{TensorProduct}^{\uparrow} \longmapsto H, C, P, Z.$$

In particular, additivity, scalar, product, and iteration laws cannot be justified by a host polynomial identity, a chosen divided-power envelope, quotient algebra equality, or an unlisted nilpotent-completion coordinate.

Proof. Start from Definition 8480.2. It forces every law-facing consumer to expose the coefficient ring, module-algebra row, ideal ledger, divided-power operation table, and natural-number arity ledger before a law row can be consumed.

The polynomial and tensor rows are the only law ledgers in the carrier. Thus a consumer may cite additivity, scalar compatibility, product compatibility, or iterated divided powers only after reading the displayed $\mathsf{Poly}^{\uparrow}$ and $\mathsf{TensorProduct}^{\uparrow}$ rows.

The structural rows preserve the same finite route. Transport, replay, provenance, and local naming do not add a crystalline envelope, quotient equality, selected completion, or hidden nilpotent coordinate, so the divided-power laws remain inside the displayed packet. □

Falsifiable prediction: Every accepted $\mathsf{DividedPowerAlgebra}^{\uparrow}$ consumer that cites a divided-power law must expose the Ring, Module, ideal, divided-power table, multiplication, unit, Nat arity, Polynomial law, TensorProduct compatibility, hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Independence witness: ring, module, polynomial, tensorproduct, nat: no listed sibling is bijective to $\mathsf{DividedPowerAlgebra}^{\uparrow}$, because this packet binds a coefficient ring, module-algebra row, ideal ledger, arity-indexed divided-power operations, polynomial laws, and tensor compatibility into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DividedPowerAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{DividedPowerAlgebra}^{\uparrow}$ packet is generated from RingUp coefficient rows, ModuleUp algebra rows, an ideal membership ledger, an arity-indexed divided-power operation table, multiplication and unit rows, a NatUp arity ledger, PolynomialUp law rows, TensorProductUp compatibility rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DividedPowerAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8480.1, Definition 8480.2, and Definition 8480.3 seed the finite divided-power law surface over ring, module, polynomial, tensor, and natural-number rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DividedPowerAlgebra}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host crystalline envelope, quotient algebra equality, selected completion, external factorial inverses, unrestricted nilpotent completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, ideal closure, divided-power table exactness, Nat arity coverage, polynomial law exactness, tensor compatibility, transport, replay, provenance, and local naming for BEDC.Derived.DividedPowerAlgebraUp.

Chapter 8481

A Concrete Naming Certificate for $\mathsf{SignedDistanceInterval}^{\uparrow}$

Following Bishop and Bridges constructive analysis of located intervals, the $\mathsf{SignedDistanceInterval}^{\uparrow}$ packet records the finite boundary-distance route by which a displayed point is compared with a displayed located interval before any Real-facing consumer reads a signed value. It sits over the bisection route of chapter 1711, the located-apartness comparison surface of chapter 6450, the metric route of chapter 1638, the regular rational readback of chapter 301, and the terminal seal of chapter 38. The packet names the interval boundary-distance carrier as finite BEDC data; it does not import host real equality, selected nearest endpoints, trichotomy, or ambient completeness.

Definition 8481.1 (Signed distance interval carrier)**.** *A* $\mathsf{SignedDistanceInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (X, A, B, O, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *X is the point row, recording the inspected* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{RegSeqRat}^{\uparrow}$ *name whose signed distance to the interval is requested.*
2. *A and B are the interval endpoint rows, recording the left and right located endpoint reads supplied by the located interval source.*
3. *O is the endpoint-order ledger, recording the finite route that certifies the displayed left endpoint is accepted before the displayed right endpoint.*
4. *S is the inside/outside sign row, recording whether the point read is routed through the interior window, the left exterior window, or the right exterior window.*
5. *D is the dyadic distance readback, carrying the finite tolerance, endpoint window, and signed rational comparison requested by the consumer.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback attached to X, A, B, O, S, D.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached only after the regular readback row R has been displayed.*
8. *H records componentwise* hsame *transport for the point row, endpoint rows, endpoint-order ledger, sign row, dyadic distance row, regular readback, Real seal, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of every signed-distance-interval consumer route through*

$$X, A, B, O, S, D, R \longmapsto E.$$

10. *P is the* Pkg *provenance over* $\mathsf{SignedDistanceInterval}^{\uparrow}$, $\mathsf{LocatedIntervalBisection}^{\uparrow}$, $\mathsf{LocatedRealApartness}^{\uparrow}$, $\mathsf{RealMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{SignedDistanceInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, A, B, O, S, D, R, E, H, C, P, N$. It has no coordinate for host real equality, a selected nearest endpoint, trichotomy, quotient representatives, ambient interval compactness, Lean verification, or bridge checking.

Theorem 8481.2 (Signed distance interval NameCert obligations)**.** *For every accepted* $\mathsf{SignedDistanceInterval}^{\uparrow}$ *carrier*

$$I = (X, A, B, O, S, D, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SignedDistanceInterval}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed point row, interval endpoint rows, endpoint-order ledger, inside/outside sign row, dyadic distance readback, regular rational readback, Real seal, transport, replay, provenance, and local naming rows;*
2. *endpoint-order stability, requiring every transported or replayed read to expose A, B, O before it treats the interval as an ordered located boundary;*
3. *sign-window exactness, requiring the row S to be read from the same point and endpoint rows X, A, B and to choose only the displayed interior, left exterior, or right exterior route;*
4. *dyadic and regular readback coherence, requiring D and R to read the same tolerance and signed boundary-distance observations before the Real seal E is exposed;*
5. *ledger refusal, requiring H, C, P, N to transport, replay, source, and name only the displayed rows, with no host equality, selected endpoint, trichotomy, Lean verification, or bridge credential.*

No signed-distance-interval NameCert obligation is stored outside these rows.

Proof. Carrier admission is projection from Definition 8481.1. The packet displays the point row, two endpoint rows, the endpoint-order ledger, the sign row, the dyadic distance readback, the regular rational readback, the Real seal, and the four structural rows.

Endpoint-order stability is componentwise. Any transported or replayed interval read keeps the same left endpoint row A, right endpoint row B, and order ledger O, so the boundary cannot be replaced by a host interval or by an unrecorded endpoint comparison.

The sign-window obligation is read from X, A, B. The row S names only the displayed interior route, left exterior route, or right exterior route, and therefore cannot install a trichotomy decision beyond the finite packet.

The dyadic row D and regular row R share the tolerance and signed boundary-distance observations. Since E appears only after these rows are displayed, every Real-facing value is sealed by the same finite readback route.

Finally, H, C, P, N only transport, replay, source, and name the carrier rows. The excluded host equality, nearest-endpoint selector, trichotomy, Lean-verification, and bridge data have no carrier coordinate, so the listed rows exhaust the local certificate surface. □

Theorem 8481.3 (Signed distance interval located handoff)**.** *Every accepted* $\mathsf{SignedDistanceInterval}^{\uparrow}$ *carrier*

$$I = (X, A, B, O, S, D, R, E, H, C, P, N)$$

hands its boundary-distance read to located interval consumers only through the displayed route

$$X, A, B, O, S, D, R, E.$$

The handoff consumes the located bisection endpoint rows, the located-apartness sign window, the Real metric comparison route, and the regular rational readback before any signed value is public. It exports no host interval equality, nearest endpoint, decidable side choice, quotient real representative, or ambient completeness theorem.

Proof. Project the accepted carrier. The endpoint rows A and B are the only interval-boundary coordinates, and the order ledger O is the only row that lets a consumer treat them as an ordered located interval.

The point row X is then compared with the displayed boundary through the sign row S. This row is downstream of the located-apartness comparison surface and records only the finite interior or exterior window selected by the packet.

The dyadic readback D and regular readback R pass the same signed boundary-distance observations to the Real seal E. Thus a bisection, located-apartness, or Real-metric consumer receives the displayed route rather than a host-side interval object.

Transport, replay, provenance, and local naming preserve this route under classification. Since none of the excluded host data occurs in I, the handoff cannot bypass the displayed rows. □

Theorem 8481.4 (Signed distance interval Real seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{SignedDistanceInterval}^{\uparrow}$ *carrier*

$$I = (X, A, B, O, S, D, R, E, H, C, P, N)$$

factors through the displayed route

$$X, A, B, O, S, D, R \longmapsto E.$$

The factorization exports the signed boundary-distance seal E only after the point row, endpoint rows, endpoint-order ledger, sign row, dyadic distance readback, and regular rational readback have been displayed. It exports no host real equality, selected nearest endpoint, trichotomy, quotient representative, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Proof. The carrier projection exposes E as the only Real-facing coordinate. Its replay row C names a route whose source rows are X, A, B, O, S, D, R.

Rows A, B, O bind the interval boundary, while X supplies the inspected point. The sign row S keeps the inside/outside decision inside the displayed finite window rather than in a host trichotomy.

The dyadic row D and regular row R then supply the only numeric readback consumed by the seal. Componentwise transport in H, replay in C, provenance in P, and naming in N preserve this order.

Therefore every Real-facing read factors through the displayed finite route. The excluded host equality, nearest-endpoint selection, quotient representative, completeness theorem, Lean-verification row, and bridge credential cannot escape through the seal because they are not coordinates of the packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{SignedDistanceInterval}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SignedDistanceInterval}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8481.1, Definition 8481.2, Definition 8481.3, and Definition 8481.4 seed the finite signed boundary-distance route from located interval rows through dyadic and regular readback to the Real seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SignedDistanceInterval}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host real equality, selected nearest endpoints, trichotomy, quotient representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint-order stability, sign-window exactness, dyadic and regular readback coherence, Real-seal nonescape, and ledger refusal for BEDC.Derived.SignedDistanceIntervalUp.

Constructive story: A $\mathsf{SignedDistanceInterval}^{\uparrow}$ packet is generated from point row, interval endpoint rows, endpoint-order ledger, inside/outside sign row, dyadic distance readback, RegSeqRat readback, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8482

A Concrete Naming Certificate for $\mathsf{BishopDiagonalRegularization}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{BishopDiagonalRegularization}^{\uparrow}$ packet records the finite diagonal regularization step used by Real and Completion consumers before they read a regular rational name. It sits beside the dyadic tolerance core of chapter 291, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the finite completion operator route of chapter 3379. The packet isolates diagonal repair as displayed NameCert data; it does not assert quotient stream equality, selected host limits, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8482.1 (Bishop diagonal regularization carrier)**.** *A* $\mathsf{BishopDiagonalRegularization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *M is the modulus-indexed diagonal choice row, recording which finite diagonal index is inspected for each precision request.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, exposing the finite observations used by the diagonal repair.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic bounds that compare the diagonal entry with the repaired regular name.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows and tolerance rows.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the repaired regular readback has been displayed.*
6. *H records componentwise* hsame *transport for the modulus choice, window, tolerance, readback, seal, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a precision request through M, W, D, R, E, H, P, N.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopDiagonalRegularization}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalRegularization}^{\uparrow}}$ *row.*

The classifier accepts only packets exhausted by $M, W, D, R, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected host limits, countable choice, host real equality, or ambient real completeness.

Lean4 ✓ `BEDC.Derived.BishopDiagonalRegularizationUp.BishopDiagonalRegularizationTasteGate`
`single carrier alignment`

Theorem 8482.2 (Bishop diagonal regularization NameCert obligations)**.** *For every accepted* $\mathsf{BishopDiagonalRegularization}^{\uparrow}$ *carrier* $G = (M, W, D, R, E, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalRegularization}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet; diagonal-window exactness through* M, W*; regularity repair through* D, R*;* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff through* R*; tolerance compatibility through* D*; Real-seal nonescape through* E*; componentwise transport through* H*; displayed replay through* C*; package provenance through* P*; and local naming through* N*.*

Proof. Project the carrier of Definition 8482.1. The accepted packet exposes precisely the modulus-indexed diagonal choice, finite stream windows, dyadic tolerances, regular rational readback, Real seal, and structural rows.

Read the analytic rows first. The diagonal-window exactness is confined to M, W, while regularity repair and tolerance compatibility are confined to D, R. Thus the $\mathsf{RegSeqRat}^{\uparrow}$ handoff is downstream of the displayed diagonal window and dyadic tolerance rows.

Finally inspect E, H, C, P, N. The Real seal is reached only after the repaired readback has been displayed, and the structural rows only transport, replay, source, and name the same packet. Since the excluded quotient, selected-limit, choice, host-equality, and completeness data are not coordinates of G, they cannot appear as local obligations. □

Theorem 8482.3 (Bishop diagonal regularization RegSeqRat handoff)**.** *Every Real-completion consumer of an accepted* $\mathsf{BishopDiagonalRegularization}^{\uparrow}$ *carrier must pass through the diagonal repair route*

$$M, W \longmapsto D \longmapsto R \longmapsto E, H, C, P, N$$

before reading either the $\mathsf{RegSeqRat}^{\uparrow}$ *row or the* $\mathsf{Real}^{\uparrow}$ *seal. The consumer receives a displayed repaired regular name, not a quotient stream, selected host limit, countable-choice schedule, or ambient completeness principle.*

Proof. Begin with the obligation surface of Definition 8482.2. It places the $\mathsf{RegSeqRat}^{\uparrow}$ readback row R after the modulus choice M, StreamName windows W, and dyadic tolerance ledger D.

The Real-completion consumer therefore reaches the regular readback only through the displayed diagonal repair route. The seal row E is later still, and H, C, P, N only transport, replay, source, and name that same finite route.

The carrier inventory has no coordinate for quotient stream equality, selected host limits, host natural-number search, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness. Hence a consumer that reads R or E must read the displayed diagonal repair packet rather than an external completion witness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalRegularization}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{BishopDiagonalRegularization}^{\uparrow}$ packet is generated from a modulus-indexed diagonal choice row, StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BishopDiagonalRegularization}^{\uparrow}}$, seed)

Scope closed: Definition 8482.1, Definition 8482.2, and Definition 8482.3 seed the finite diagonal regularization route over StreamName windows, DyadicRatCore tolerances, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BishopDiagonalRegularization}^{\uparrow}}$, encodedDef)
Lean4 (statement) `BEDC.Derived.BishopDiagonalRegularizationUp`

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected host limits, countable choice, host real equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal-window exactness, regularity repair, RegSeqRat handoff, tolerance compatibility, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopDiagonalRegularizationUp.

Chapter 8483

A Concrete Naming Certificate for $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$

The $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ packet realizes the compact-uniform-continuity route as one finite split ledger: compact finite windows and pointwise continuous-map rows are folded into a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ handoff before any $\mathsf{Real}^{\uparrow}$ consumer reads the target estimate. It sits over the compact metric source of chapter 129, the graph and pointwise-modulus surface of chapter 130, the tolerance-only handoff of chapter 369, the dyadic precision rows of chapter 291, the regular-rational readback of chapter 301, and the terminal real seal of chapter 38. The carrier records the finite $\mathsf{ProbeBundle}$ split from pointwise compact-cover moduli to one uniform-modulus read; it is not a host Heine–Cantor theorem, a selected Lebesgue number, an infinite cover, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8483.1 (Compact-uniform splitting ledger carrier)**.** *A* $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, F, U, B, D, Q, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, listing the finite compact windows and cover probes inspected by the ledger.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise row, recording the local modulus entries attached to the compact windows in K.*
3. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *tolerance-only output row.*
4. *B is the finite* $\mathsf{ProbeBundle}$ *split ledger, pairing each compact probe with its local radius, target tolerance request, and selected finite comparison row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *precision row for the dyadic tolerance cuts used by the split.*
6. *Q is the rational lower-bound and triangle-budget row that chooses the displayed minimum budget over the finite probe bundle.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational and dyadic estimates consumed by downstream Real-facing readers.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the source and target metric estimates.*

9. *H records componentwise* hsame *transport for compact, continuous-map, uniform-modulus, probe-bundle, dyadic, rational-budget, regular-readback, Real-seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay of the finite split*

$$K, F, B, D, Q \longmapsto U, R, E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformSplittingLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, U, B, D, Q, R, E, H, C, P, N$. It has no coordinate for an infinite cover, selected Lebesgue number, host compactness theorem, countable choice, external modulus oracle, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8483.2 (Compact-uniform splitting ledger NameCert obligations)**.** *For every accepted* $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ *carrier*

$$S = (K, F, U, B, D, Q, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformSplittingLedger}^{\uparrow}}$ *surface consists exactly of compact-source exposure through K, continuous-map pointwise exposure through F, finite* ProbeBundle *split exposure through B, dyadic precision exposure through D, rational lower-bound and metric-triangle budget exposure through Q, tolerance-only uniform-modulus output through U, regular-rational readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8483.1. The compact-continuous source rows are K, F, the finite splitting rows are B, D, Q, the output rows are U, R, E, and the structural rows are H, C, P, N.

The compact source and continuous-map rows determine the finite cover probes and local pointwise moduli. The ProbeBundle row then records the split from those local rows to a single tolerance request.

The dyadic and rational-budget rows record the precision and lower-bound comparisons used in the metric-triangle estimate. The regular readback and Real seal are downstream of those rows, while the uniform-modulus row is the only tolerance-only output.

Finally, transport, replay, provenance, and local naming preserve that displayed route. Since the carrier has no infinite cover, selected Lebesgue number, host compactness theorem, countable-choice row, external modulus oracle, quotient real equality, or ambient Real-completeness coordinate, those objects cannot discharge a local NameCert obligation. □

Theorem 8483.3 (Compact-uniform split nonescape)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ *packet must read the finite route*

$$\mathsf{CompactMetric}^{\uparrow},\ \mathsf{ContinuousMap}^{\uparrow},\ \mathsf{ProbeBundle},\ \mathsf{DyadicRatCore}^{\uparrow} \longmapsto Q,\ \mathsf{UniformModulus}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow} \longmapsto$$

Thus the tolerance-only uniform-modulus handoff and the Real-facing metric estimate cannot be justified by an infinite cover, a selected Lebesgue number, countable choice, quotient real equality, or ambient completeness.

Proof. Start with Definition 8483.2. It forces the compact metric source, continuous-map pointwise row, finite ProbeBundle split, dyadic precision row, and rational budget row to be displayed before a uniform-modulus or Real-facing read is available.

The uniform-modulus output is the row U. It is tolerance-only because the source point, local modulus, lower-bound fold, and triangle estimate have already been folded through B, D, Q.

The Real-facing read then passes through R and E. These rows read regular rational and Real seals downstream from the same split ledger, so they cannot introduce a selected cover, quotient real equality, or completeness theorem.

The structural rows keep the route finite and replayable. Hence every downstream consumer remains inside the displayed compact-uniform splitting ledger. □

Falsifiable prediction: Every accepted $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ read is refuted if it exports a $\mathsf{UniformModulus}^{\uparrow}$ or $\mathsf{Real}^{\uparrow}$ result without displaying the $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, finite ProbeBundle, $\mathsf{DyadicRatCore}^{\uparrow}$, rational lower-bound, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows.

Independence witness: compactmetric, continuousmap, uniformmodulus, dyadicratcore, real: $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ is not identical to any listed sibling because it binds compact finite-window data, pointwise continuous-map moduli, a finite ProbeBundle split, dyadic precision, rational lower-bound readback, a tolerance-only UniformModulus handoff, and a Real seal as one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformSplittingLedger}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformSplittingLedger}^{\uparrow}$ packet is generated from CompactMetric finite-window rows, ContinuousMap pointwise-modulus rows, a UniformModulus output row, finite ProbeBundle split rows, DyadicRatCore precision rows, rational lower-bound and triangle-budget rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformSplittingLedger}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8483.1, Definition 8483.2, and Definition 8483.3 seed the finite split from pointwise compact-cover moduli to one tolerance-only uniform-modulus handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformSplittingLedger}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim an infinite cover, selected Lebesgue number, host compactness theorem, countable choice, external modulus oracle, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, pointwise ContinuousMap exposure, ProbeBundle split exactness, dyadic precision, rational lower-bound and triangle-budget exactness, UniformModulus handoff, RegSeqRat readback, Real seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformSplittingLedgerUp.

Chapter 8484

A Concrete Naming Certificate for $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$ packet records the finite subsequence-extraction surface that is visible once a metric sequence exposes tolerance-indexed finite epsilon-net selector rows. It sits between the total-boundedness carrier of chapter 127, the finite center packet of chapter 1767, and the compact-metric consumer surface of chapter 129. Before any subsequence window is handed to $\mathsf{StreamName}^{\uparrow}$ (chapter 126), $\mathsf{RegSeqRat}^{\uparrow}$ (chapter 301), or the terminal $\mathsf{Real}^{\uparrow}$ seal (chapter 38), the packet makes the chosen finite-net rows, window bounds, replay rows, and nonescape clauses explicit as BEDC NameCert data.

Definition 8484.1 (Totally bounded subsequence carrier)**.** *A* $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (X, \sigma, E, P, C, D, W, H, R, S, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *source row carrying the point classifier, distance classifier, and metric-law ledger used by the sequence.*
2. *σ is the inspected metric sequence row, read as a finite-window* $\mathsf{StreamName}^{\uparrow}$ *schedule whose entries are admitted by X.*
3. *E is the positive tolerance row, read through* $\mathsf{Rat}^{\uparrow}$ *or* $\mathsf{DyadicRatCore}^{\uparrow}$ *before a center selector can be used.*
4. *P is the closed* $\mathsf{ProbeBundle}$ *of finite-net centers supplied by the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *surface.*
5. *C records, for every accepted center of P, the corresponding point-carrier admission in X.*
6. *D records the finite-net coverage ledger: for each inspected sequence entry, one accepted center of P and one displayed* $\mathsf{MetricDistanceWitness}$ *row bounded by E.*
7. *W records the subsequence-window selector. It names a finite source window, a center branch of P, and the entries of σ that remain in that branch for the next extraction stage.*
8. *H records componentwise* hsame *transport for $X, \sigma, E, P, C, D, W, R, S, N$.*
9. *R records displayed* Cont *replay from a subsequence request through the same metric, tolerance, finite-net, coverage, and window rows.*

10. *S is the* Pkg *provenance over* $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{TotallyBoundedSubsequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for countable choice, an infinite pigeonhole functional, an open-cover compactness proof, a selected limit, a host subsequence object, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8484.2 (Totally bounded subsequence finite-net selector)**.** *For every accepted* TotallyBoundedSubsequenc *carrier $Q = (X, \sigma, E, P, C, D, W, H, R, S, N)$, the finite-net selector row W can be read only after the metric source X, sequence row σ, positive tolerance E, center bundle P, center-carrier ledger C, and coverage-distance ledger D have been displayed. The selected branch remains a finite* ProbeBundle *branch with admitted centers and bounded metric-distance rows; it does not expose countable choice, an infinite pigeonhole functional, an open-cover compactness proof, a host subsequence object, or a selected* $\mathsf{Real}^{\uparrow}$ *limit.*

Proof. Project the carrier of Definition 8484.1. The selector coordinate W is placed after the metric, sequence, tolerance, finite center bundle, center admission, and coverage-distance rows.

The finite-net data are therefore prerequisites. A branch named by W can be inspected only through membership in P, admission in C, and the bounded distance rows recorded by D.

Transport and replay do not add a new selector source. The row H moves the same displayed coordinates componentwise, and R replays requests through the same ordered route. Since the carrier has no coordinate for countable choice, an infinite pigeonhole functional, open-cover compactness, host subsequences, or selected limits, none of those objects can be exported by the selector. □

Theorem 8484.3 (Totally bounded subsequence L10 handoff)**.** *Every* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$ *carrier must read the finite route*

$$X, \sigma, E \longmapsto P, C, D \longmapsto W, H, R, S, N$$

before it may treat a chosen subsequence window as real-name data. Thus the consumer receives only displayed metric rows, finite epsilon-net centers, bounded coverage witnesses, the subsequence-window selector, componentwise hsame *transport,* Cont *replay,* Pkg *provenance, and the local* NameCert *row. The handoff exports no countable-choice schedule, host-level subsequence, quotient stream equality, selected limit, open-cover compactness theorem, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness claim.*

Proof. Begin with a downstream consumer of Q. By Definition 8484.1, entry into the packet first exposes the metric source X, the inspected sequence σ, and the positive tolerance row E.

The finite-net selector is opened next. The closed bundle P names the centers, C admits those centers as points of X, and D supplies the bounded distance rows that locate inspected sequence entries in center branches.

Apply Definition 8484.2. The window selector W can only name branches already justified by P, C, D, and the structural rows H, R, S, N preserve the same route when the window is replayed toward $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$.

Therefore the L10 consumer sees exactly the displayed finite route. Because the carrier omits countable-choice schedules, host-level subsequence objects, quotient stream equality, selected limits, open-cover compactness proofs, and ambient completeness data, the handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedSubsequence}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedSubsequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8484.1, Definition 8484.2, and Definition 8484.3 seed the finite selector packet that routes total boundedness and finite epsilon-net coverage into subsequence windows before StreamName, RegSeqRat, or Real consumers read the result.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedSubsequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close compactness, sequential compactness, infinite pigeonhole extraction, countable choice, open-cover compactness, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, finite-net selector visibility, subsequence-window transport, L10 handoff, and ledger nonescape for BEDC.Derived.TotallyBoundedSubsequenceUp.

Constructive story: A $\mathsf{TotallyBoundedSubsequence}^{\uparrow}$ packet is generated from a MetricUp source row, an inspected finite-window sequence, a positive RatUp or DyadicRatCoreUp tolerance, a closed ProbeBundle of centers, center-carrier and coverage-distance ledgers, a subsequence-window selector, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8485

A Concrete Naming Certificate for $\mathsf{CauchyApproximationCategory}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{CauchyApproximationCategory}^{\uparrow}$ packet records the category-facing side of constructive completion as finite BEDC naming data. It sits beside the Cauchy approximation system of chapter 1920, the Cauchy approximation space of chapter 7574, the Bishop metric completion packet of chapter 4023, the finite stream interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real seal of chapter 38. The packet names objects and approximation-preserving arrows by displayed rows only; it does not introduce quotient completions, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or a host category of all Cauchy objects.

Definition 8485.1 (Cauchy approximation category carrier)**.** *A* $\mathsf{CauchyApproximationCategory}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (O, M, I, Q, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *O is the object row. Each object is a named finite Cauchy approximation packet whose visible coordinates are sourced from* $\mathsf{CauchyApproximationSystem}^{\uparrow}$ *or* $\mathsf{CauchyApproximationSpace}^{\uparrow}$ *rows.*
2. *M is the morphism approximation data row. A morphism carries displayed source and target object names, a finite window transformer, dyadic tolerance transport, and a regular-readback compatibility ledger.*
3. *I is the identity route. It records the reflexive window transformer, unchanged dyadic tolerance rows, unchanged* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and unchanged* $\mathsf{Real}^{\uparrow}$ *seal for each displayed object.*
4. *Q is the composition route. It records the finite pasting of two morphism approximation rows, including the composed window transformer, composed tolerance ledger, composed readback comparison, and Real-seal replay.*
5. *W is the finite-window row, reading every object and morphism request through* $\mathsf{StreamName}^{\uparrow}$ *windows before any regular readback or Real seal is opened.*
6. *R is the regular readback row, exposing the* $\mathsf{RegSeqRat}^{\uparrow}$ *observations used by objects, identities, and composites.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the finite windows, dyadic tolerances, regular readbacks, identity checks, and composition checks have been displayed.*

8. *H records componentwise* hsame *transport for $O, M, I, Q, W, R, E, C, P, N$ and for the displayed approximation comparisons.*
9. *C records displayed* Cont *replay for object admission, morphism approximation, identity replay, composition replay, finite-window access, regular readback, Real sealing, and transport.*
10. *P is the* Pkg *provenance over* $\mathsf{CauchyApproximationCategory}^{\uparrow}$, $\mathsf{CauchyApproximationSystem}^{\uparrow}$, $\mathsf{CauchyApproximationSpace}^{\uparrow}$, $\mathsf{BishopMetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyApproximationCategory}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, M, I, Q, W, R, E, H, C, P, N$. It has no coordinate for quotient Cauchy equality, selected representatives, chosen limits, large host category structure, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ *completeness, Lean verification, or bridge checking.*

Theorem 8485.2 (Cauchy approximation category NameCert obligations)**.** *For every accepted* $\mathsf{CauchyApproximationCategory}^{\uparrow}$ *carrier*

$$K = (O, M, I, Q, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyApproximationCategory}^{\uparrow}}$ *surface consists exactly of object admission through O; morphism approximation admission through M; identity-route exactness through I; composition-route exactness through Q; finite-window exposure through W; regular readback through R;* $\mathsf{Real}^{\uparrow}$ *sealing through E; componentwise* hsame *transport through H; displayed* Cont *replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8485.1. The object and morphism coordinates are O and M, and the only category-structure coordinates are the displayed identity and composition rows I and Q.

The finite analytic access is forced through W, R, E. A reader first opens StreamName windows, then the RegSeqRat readback tied to those windows, and only then the Real seal. The dyadic tolerance data are the displayed comparison rows carried by M, I, Q and packaged by P.

Identity exactness is constructive because I is a reflexive replay row. It preserves the same object, the same finite windows, the same dyadic tolerance rows, the same regular readback, and the same Real seal, so it introduces no representative choice or quotient equality.

Composition exactness is constructive because Q is a finite pasting row. Given two displayed morphism approximation rows, the composed window transformer and tolerance ledger are written as coordinates of the packet before any downstream readback is consumed.

Finally H, C, P, N transport, replay, source, and name the same finite sequence. Since the carrier contains no coordinate for selected limits, quotient completions, ambient Real completeness, countable choice, or host category structure, the listed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{CauchyApproximationCategory}^{\uparrow}$ read exposes object rows, morphism approximation rows, identity and composition routes, StreamName finite windows, RegSeqRat readback, RealUp seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: cauchy-approximation-system, cauchy-approximation-space, bishop-metric-completion, streamname, regseqrat, dyadicratcore, real: $\mathsf{CauchyApproximationCategory}^{\uparrow}$ is not bijective to any listed sibling because it binds approximation-preserving arrows with identity and composition rows before any completion-facing consumer reads a Real seal.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyApproximationCategory}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyApproximationCategory}^{\uparrow}$ packet is generated from object rows, morphism approximation rows, identity and composition routes, finite StreamName windows, RegSeqRat readback, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyApproximationCategory}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8485.1 and Definition 8485.2 seed the category-facing Cauchy approximation carrier over objects, approximation-preserving morphisms, identity and composition routes, finite windows, regular readback, Real seals, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyApproximationCategory}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, host category completeness, large-category universality, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, object and morphism approximation exactness, identity and composition route exactness, finite-window access, regular readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyApproximationCategoryUp.

Chapter 8486

A Concrete Naming Certificate for $\mathsf{RealModulusContinuity}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RealModulusContinuity}^{\uparrow}$ packet records the finite handoff by which a displayed continuity modulus on real names is read through regular rational data before any $\mathsf{Real}^{\uparrow}$ consumer treats the value as Real-facing. It sits after the continuity carrier of chapter 130, the local modulus packet of chapter 6998, the dyadic tolerance ledger of chapter 291, the finite stream-window surface of chapter 126, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet is a theorem-facing Real and Completion route; it is not a compactness theorem, a global uniform-continuity route, a quotient-real equality principle, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8486.1 (Real modulus continuity carrier)**.** *A* $\mathsf{RealModulusContinuity}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (F, \varepsilon, \mu, S, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *source row, recording the displayed real-valued map whose continuity modulus is being consumed.*
2. *ε is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive tolerance request for the target real-name read.*
3. *μ is the modulus row, recording the finite input-window budget licensed for the tolerance request ε.*
4. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used to inspect the source and image names under μ.*
5. *D is the dyadic tolerance ledger comparing the requested output precision with the source-window budget.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic comparisons.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal, available only after S, D, R have been displayed on the same packet route.*
8. *H records componentwise* hsame *transport for $F, \varepsilon, \mu, S, D, R, E$ and the local naming row.*
9. *C records displayed* Cont *replay through the continuity source, tolerance request, modulus row, windows, dyadic ledger, regular rational readback, real seal, provenance, and local naming rows.*

10. *P is the* Pkg *provenance over* $\mathsf{RealModulusContinuity}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BishopContinuityModulus}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, \varepsilon, \mu, S, D, R, E, H, C, P, N$. It has no coordinate for compact-domain uniformity, quotient stream equality, selected real representatives, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8486.2 (Real modulus continuity NameCert obligations)**.** *For the carrier of Definition 8486.1, the local* $\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$ *surface consists exactly of continuity-source exposure through F, tolerance-request exposure through ε, modulus-row exposure through μ, StreamName window exposure through S, dyadic comparison through D, RegSeqRat readback through R, terminal Real sealing through E, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The continuity source F, tolerance request ε, and modulus row μ are the only rows that determine which continuity request is being read.

Read the observation side next. The stream windows S are inspected under the budget named by μ, the dyadic ledger D compares those windows with the requested tolerance, and the regular rational row R supplies the readback data.

Finally apply the terminal seal and structural rows. The Real row E is reached only after S, D, R are displayed, while H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no further coordinates, the listed rows exhaust the NameCert surface. □

Theorem 8486.3 (Real modulus continuity RegSeqRat handoff)**.** *Every accepted* $\mathsf{RealModulusContinuity}^{\uparrow}$ *packet that exports a Real-facing continuity read must first factor through the displayed route*

$$\mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{BishopContinuityModulus}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The handoff supplies regular rational readback under an explicit modulus budget; it does not export compact-domain uniformity, quotient stream equality, selected limits, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from the NameCert obligations of Definition 8486.2. They place the continuity source, tolerance request, modulus row, stream windows, dyadic ledger, and regular rational readback in one finite certificate surface.

Use the sibling rows named in the statement. The continuity source is read through chapter 130, the local modulus through chapter 6998, the finite observations through chapter 126, the tolerance arithmetic through chapter 291, and the rational readback through chapter 301.

Thus the Real-facing consumer receives regular rational data only after the displayed modulus route has been replayed. None of the excluded compactness, quotient, choice, trichotomy, or completeness coordinates occurs in the carrier. □

Theorem 8486.4 (Real modulus continuity Real seal)**.** *Let $M = (F, \varepsilon, \mu, S, D, R, E, H, C, P, N)$ be an accepted* $\mathsf{RealModulusContinuity}^{\uparrow}$ *carrier. The terminal* $\mathsf{Real}^{\uparrow}$ *seal E is consumable only after the same packet has exposed $F, \varepsilon, \mu, S, D, R, H, C, P, N$. Consequently a Real consumer cannot read the continuity value while bypassing the modulus row, the finite stream windows, the dyadic tolerance ledger, or the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff.*

Proof. Project the carrier of Definition 8486.1. The terminal Real row E is listed after the modulus, window, dyadic, and readback rows, and it is transported and replayed only through the same structural packet.

Apply the RegSeqRat handoff theorem Definition 8486.3. It forces every Real-facing continuity read through the continuous-map, modulus, stream-window, dyadic, and regular-rational route before the terminal seal is used.

Finally inspect H, C, P, N. These rows preserve the same packet and add no alternate Real source. Therefore a consumer that reaches E without the listed rows has left the displayed $\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$ surface. □

Falsifiable prediction: Every accepted $\mathsf{RealModulusContinuity}^{\uparrow}$ consumer that reaches a $\mathsf{Real}^{\uparrow}$ continuity value without displaying a continuity source, modulus row, StreamName windows, DyadicRatCore tolerance ledger, and RegSeqRat readback refutes the carrier.

Independence witness: continuousmap, bishop-continuity-modulus, dyadicratcore, streamname, regseqrat, real: none is bijective to $\mathsf{RealModulusContinuity}^{\uparrow}$ because this carrier jointly binds a continuity source, tolerance request, modulus budget, finite windows, dyadic comparisons, regular rational readback, terminal real seal, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$.

Constructive story: A $\mathsf{RealModulusContinuity}^{\uparrow}$ packet is generated from a ContinuousMap source row, Bishop continuity modulus row, DyadicRatCore tolerance request, StreamName finite windows, RegSeqRat readback, terminal RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$, seed)

Scope closed: Definition 8486.1, Definition 8486.2, Definition 8486.3, and Definition 8486.4 seed the L10 Real and Completion continuity-modulus route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RealModulusContinuity}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not claim compact-domain uniform continuity, quotient stream equality, selected limits, countable choice, trichotomy, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, modulus exactness, StreamName window exposure, DyadicRatCore tolerance comparison, RegSeqRat readback, RealUp sealing, transport, replay, provenance, and local NameCert rows for BEDC.Derived.RealModulusContinuityUp.

Chapter 8487

A Concrete Naming Certificate for $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$

The $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ packet realizes the external-supply discipline of chapter 9395 as a finite audit-ledger route. It sits beside the external boundary packet of chapter 1065, the non-axiom boundary-form classifier of chapter 1066, the boundary-admission decision packet of chapter 1074, the composed audit-gate route of chapter 696, the GAP closure boundary of chapter 1006, and the external-supply audit route of chapter 1107. The packet records external supply as visible ledger data; it is not an axiom, not a theorem that the supply exists, and not an internal witness hidden inside a consumer.

Definition 8487.1 (External supply ledger route carrier)**.** *An* $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (B, F, A, G, R, H, C, P, N)$$

with the following displayed rows:

1. *B is the external-supply boundary row, naming the boundary and requested supply shape.*
2. *F is the* $\mathsf{NonAxiomBoundaryForm}^{\uparrow}$ *row, recording the admitted non-axiom form for the request.*
3. *A is the* $\mathsf{BoundaryAdmissionDecision}^{\uparrow}$ *row, recording the decision that selects the strongest permitted visible form.*
4. *G is the audit-gate composition row, recording the gate route through which the request is accepted, refused, or held open.*
5. *R is the* $\mathsf{GapClosureBoundary}^{\uparrow}$ *ledger row, recording the forward-binding memory that the requested supply has not been internalized as a theorem.*
6. *H records componentwise* hsame *transport for B, F, A, G, R and the local naming row.*
7. *C records displayed* Cont *replay through the boundary, boundary form, admission decision, audit gate, GAP ledger, provenance, and local naming rows.*
8. *P is the* Pkg *provenance over* $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$, $\mathsf{ExternalSupplyBoundary}^{\uparrow}$, $\mathsf{NonAxiomBoundaryForm}^{\uparrow}$, $\mathsf{BoundaryAdmissionDecision}^{\uparrow}$, $\mathsf{AuditGateComposition}^{\uparrow}$, $\mathsf{GapClosureBoundary}^{\uparrow}$, $\mathsf{ExternalSupplyAuditRoute}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, F, A, G, R, H, C, P, N$. It has no coordinate for an anonymous axiom, hidden host primitive, unrecorded supply witness, erased audit gate, or closed GAP memory.

Theorem 8487.2 (External supply ledger route NameCert obligations)**.** *For the carrier of Definition 8487.1, the local* $\mathsf{NameCert}_{\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}}$ *surface consists exactly of external boundary exposure through B, non-axiom boundary form exposure through F, boundary-admission decision through A, audit-gate composition through G, GAP closure-boundary ledger exposure through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The boundary row B states the requested supply shape, while F and A record the non-axiom form and admission decision that keep the request visible.

Read the audit side next. The gate row G records how the request is accepted, refused, or held open, and the GAP ledger row R records that the requested supply has not been smuggled into the theory as an internal theorem.

Finally inspect H, C, P, N. These rows only transport, replay, source, and name the same finite packet. Since the carrier has no anonymous supply coordinate, the listed rows exhaust the NameCert obligations. □

Theorem 8487.3 (External supply ledger non-axiom route)**.** *Every accepted* $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ *consumer must read the route*

$$\mathsf{ExternalSupplyBoundary}^{\uparrow} \longmapsto \mathsf{NonAxiomBoundaryForm}^{\uparrow} \longmapsto \mathsf{BoundaryAdmissionDecision}^{\uparrow} \longmapsto \mathsf{AuditGateCompositio}$$

before treating an external-supply request as audit-visible. The route records the boundary, form, decision, gate, and ledger; it does not assert that the requested supply exists.

Proof. Start from the NameCert obligations of Definition 8487.2. They bind boundary exposure, admitted boundary form, admission decision, audit-gate composition, and GAP ledger exposure into one finite packet.

Use the sibling chapters named in the statement. The external boundary identifies the request, the non-axiom form prevents axiom import, the admission decision chooses the visible form, the audit gate records the route by which the request is judged, and the GAP boundary preserves memory of the still-external supply.

Thus a consumer receives an audit ledger rather than a supplied theorem. Since no carrier coordinate stores a witness for the requested supply, the route cannot be read as existence of that supply. □

Theorem 8487.4 (External supply ledger audit memory)**.** *Let $L = (B, F, A, G, R, H, C, P, N)$ be an accepted* $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ *carrier. Any public read of the requested supply shape must keep the GAP ledger row R and audit-gate row G visible after B, F, A are displayed. Therefore the packet cannot be repacked as an internal theorem, anonymous axiom, hidden witness, or erased-boundary supply source.*

Proof. Project the carrier of Definition 8487.1. The requested supply appears only in the boundary row B and is governed by the form and decision rows F, A.

Apply the non-axiom route theorem Definition 8487.3. It forces every audit-visible read through the composed gate G and GAP ledger R before a consumer may treat the request as a ledgered external supply.

Finally read the structural rows H, C, P, N. They preserve the same boundary, gate, and ledger rows and add no internal witness coordinate. A public read that hides G or R is therefore outside the displayed NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ read is refuted if it names an external supply boundary without also displaying the non-axiom boundary form, boundary-admission decision, audit-gate composition, and GAP closure-boundary ledger.

Independence witness: external-supply-boundary, nonaxiomboundaryform, boundary-admission-decision, auditgatecomposition, gapclosureboundary: none is bijective to $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ because this carrier jointly records boundary name, admitted non-axiom form, admission decision, composed audit route, GAP memory, transport, replay, provenance, and local NameCert rows.

The Lean follow-up must provide explicit $\mathsf{Nontrivial\ ExternalSupplyLedgerRoute}^{\uparrow}$ and $\mathsf{FieldFaithful\ ExternalSupplyl}$ instances before any checked TasteGate marker can be attached to this chapter. Those instances must keep $B, F, A, G, R, H, C, P, N$ as distinct rows and must not internalize the requested supply as a theorem.

Closure status for $\mathsf{NameCert}_{\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}}$.

Constructive story: An $\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}$ packet is generated from an external-supply boundary row, non-axiom boundary-form row, boundary-admission decision row, audit-gate composition row, GAP closure-boundary ledger, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8487.1, Definition 8487.2, Definition 8487.3, and Definition 8487.4 seed the external-supply ledger route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ExternalSupplyLedgerRoute}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: ai

Not claimed: This chapter does not claim that requested external supply exists, that any external source is internalized, that a hidden witness is available, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-form exactness, admission-decision exposure, audit-gate composition, GAP ledger retention, transport, replay, provenance, and local NameCert rows for BEDC.Derived.ExternalSupplyLedgerRouteUp, followed by Nontrivial and FieldFaithful instances.

Chapter 8488

A Concrete Naming Certificate for YoulaKuceraParametrization$^{\uparrow}$

Following Youla and Kucera on stabilizing-controller parametrization, the YoulaKuceraParametrization$^{\uparrow}$ packet records the finite control-theory surface by which a displayed plant row, coprime-factor row, free stable-parameter row, closed-loop stability ledger, and controller readback are named before robust-control consumers read a controller family. It sits after the quadratic-control ledger of chapter 296, the algebraic Riccati row of chapter 307, the control Riccati route of chapter 5103, the bounded-gain route of chapter 4752, and the finite-horizon replay of chapter 348. The packet gives robust-control consumers a finite parametrization certificate; it is not an analytic theorem selecting all stabilizing controllers.

Definition 8488.1 (Youla-Kucera parametrization carrier)**.** *A* YoulaKuceraParametrization$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Y = (P, C, Q, S, K, T, R, V, H, E, G, N)$$

with the following displayed rows:

1. *P is the plant row, recording the finite state-space, matrix, vector-space, and real-gain data consumed by the control packet.*
2. *C is the coprime-factor row, displaying the numerator, denominator, Bezout, and normalization ledgers used by the parametrization read.*
3. *Q is the free stable-parameter row, naming the displayed stable parameter offered to the controller family.*
4. *S is the closed-loop stability ledger, recording the finite route by which the selected parameter is checked against the plant and coprime-factor rows.*
5. *K is the controller readback row, carrying the controller expression obtained from P, C, Q, S.*
6. *T is the transport row, recording componentwise* hsame *transport for plant, factor, parameter, stability, controller, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from a robust-control request through P, C, Q, S, K, T.*
8. *V is the verification ledger row read by* HInfinityControl$^{\uparrow}$, LQR$^{\uparrow}$, Riccati$^{\uparrow}$, ControlRiccati$^{\uparrow}$, *and* ModelPredictiveControl$^{\uparrow}$ *consumers when they compare the controller family with finite gain, quadratic, Riccati, and rollout data.*

9. *H is the host-refusal row, separating transfer-function syntax, quotient controller equality, spectral factorization, infinite-dimensional realization, and selected analytic stabilizers from BEDC evidence.*

10. *E is the exactness row, requiring controller readback to use the same displayed plant, factor, parameter, and stability rows.*

11. *G is the* Pkg *provenance over* $\mathsf{YoulaKuceraParametrization}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, $\mathsf{HInfinityControl}^{\uparrow}$, $\mathsf{ModelPredictiveControl}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{YoulaKuceraParametrization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $P, C, Q, S, K, T, R, V, H, E, G, N$. It has no coordinate for host transfer functions, quotient controller equality, spectral factorization, infinite-dimensional realization, or an analytic selector for all stabilizing controllers.

Theorem 8488.2 (Youla-Kucera parametrization NameCert obligations)**.** *For every accepted* $\mathsf{YoulaKuceraParametrization}^{\uparrow}$ *carrier*

$$Y = (P, C, Q, S, K, T, R, V, H, E, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{YoulaKuceraParametrization}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the displayed plant row, coprime-factor row, free stable-parameter row, closed-loop stability ledger, controller readback, transport, replay, verification ledger, refusal row, exactness row, provenance, and local naming;*

2. *factor exposure, requiring every controller read to display P and C before it consumes the free parameter Q;*

3. *stability-ledger exactness, requiring S and E to bind the same plant, factor, parameter, and controller rows;*

4. *robust-control handoff, requiring V to expose the finite* $\mathsf{LQR}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, $\mathsf{HInfinityControl}^{\uparrow}$, *and* $\mathsf{ModelPredictiveControl}^{\uparrow}$ *dependency rows before a consumer reads K as a controller-family output;*

5. *host-refusal preservation, requiring H, T, R, G, N to preserve the same finite route without adding selected analytic stabilizers, host transfer functions, quotient controller equality, spectral factorization, or infinite-dimensional realization.*

No Youla-Kucera parametrization obligation is stored outside $P, C, Q, S, K, T, R, V, H, E, G, N$.

Proof. Project the carrier of Definition 8488.1. The packet displays the plant, coprime-factor, free stable-parameter, stability-ledger, controller-readback, transport, replay, verification, refusal, exactness, provenance, and local naming rows.

Factor exposure is immediate from the order of the rows. A controller read reaches K only after the same plant row P, factor row C, parameter row Q, and stability ledger S have been displayed.

The exactness obligation is carried by E. It binds the controller readback to the displayed P, C, Q, S route, so componentwise transport or replay cannot replace the controller by a host-side transfer-function calculation.

The robust-control handoff is the row V. It names exactly the finite LQR, Riccati, control-Riccati, bounded-gain, and model-predictive-control dependency rows consumed by downstream control packets before K is public.

Finally, H, T, R, G, N keep the refusal and structural data attached to the same carrier. Since selected analytic stabilizers, quotient controller equality, spectral factorization, host transfer functions, and infinite-dimensional realizations have no coordinate in Y, the listed rows exhaust the local NameCert surface. □

Theorem 8488.3 (Youla-Kucera parametrization robust-control handoff)**.** *Every* $\mathsf{HInfinityControl}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, *or* $\mathsf{ModelPredictiveControl}^{\uparrow}$ *consumer of an accepted* $\mathsf{YoulaKuceraParametrization}^{\uparrow}$ *carrier*

$$Y = (P, C, Q, S, K, T, R, V, H, E, G, N)$$

must read the displayed route

$$P, C, Q, S, K, V, E$$

before treating K as a controller-family output. The handoff exports a finite parametrization surface, not a selected analytic stabilizing controller, host transfer-function equality, quotient controller equality, spectral factorization, or infinite-dimensional realization.

Proof. Start with the NameCert obligations of Definition 8488.2. They force every controller read to expose P, C, Q, S, K and then to pass through the verification ledger V and exactness row E.

Read the downstream control rows through V. The finite LQR, Riccati, control-Riccati, bounded-gain, and model-predictive-control rows are dependency rows for the same carrier, not replacement analytic control theorems.

The refusal row H remains attached under T, R, G, N. Thus the consumer receives only the displayed parametrization route and cannot bypass it through host transfer functions, quotient equality, spectral factorization, selected stabilizers, or infinite-dimensional realization. □

Closure status for $\mathsf{NameCert}_{\mathsf{YoulaKuceraParametrization}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{YoulaKuceraParametrization}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8488.1, Definition 8488.2, and Definition 8488.3 seed the finite parametrization route from plant and coprime-factor rows through a free stable-parameter row to controller readback and robust-control dependency rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{YoulaKuceraParametrization}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected analytic stabilizing controllers, host transfer functions, quotient controller equality, spectral factorization, infinite-dimensional realization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, factor exposure, stability-ledger exactness, robust-control handoff, host-refusal preservation, transport, replay, provenance, and local naming for BEDC.Derived.YoulaKuceraParametrizati

Constructive story: A $\mathsf{YoulaKuceraParametrization}^{\uparrow}$ packet is generated from a finite plant row, coprime-factor row, free stable-parameter row, closed-loop stability ledger, controller readback, componentwise hsame transport, displayed Cont replay, robust-control verification ledger, host-refusal row, exactness row, Pkg provenance, and local NameCert row.

Chapter 8489

A Concrete Naming Certificate for $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ packet records a constructive uniform-space completion as finite BEDC NameCert data. It sits after the finite observation discipline of chapter 126, the regular rational readback of chapter 301, the metric carrier of chapter 57, and the entourage completion surface of chapter 8414. The packet gives the L10 completion route a located Cauchy-filter basis, regular observation windows, dense embedding rows, separated classifier rows, and structural provenance without quotienting filters, selecting representatives, invoking countable choice, or importing host equality.

Definition 8489.1 (Bishop uniform-space completion carrier)**.** *A* $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, L, F, W, R, D, E, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{UniformSpace}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *row, exposing the finite entourage or metric requests that the completion consumer may inspect.*
2. *L is the located uniformity row, recording finite positive-radius or entourage-location evidence before any Cauchy-filter read is made.*
3. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *or* $\mathsf{CauchyFilter}^{\uparrow}$ *row, carrying the located Cauchy-filter base through displayed finite requests.*
4. *W is the regular finite observation-window row over* $\mathsf{StreamName}^{\uparrow}$*, and R is the matching* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare finite observations and filter requests.*
6. *E is the dense embedding row from the source carrier into the completion packet; it records graph membership before equality or separation is read.*
7. *S is the separated classifier row, comparing accepted completion names only through the displayed located Cauchy-filter base, observation windows, readback rows, tolerance ledger, and dense embedding row.*
8. *H records componentwise* hsame *transport for X, L, F, W, R, D, E, S and for the structural rows.*

9. *C records displayed* Cont *replay from a completion request through the located filter base, observation windows, readback, tolerance, dense embedding, and separated classifier.*

10. *P is the* Pkg *provenance over* $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CauchyFilterBasis}^{\uparrow}$, $\mathsf{CauchyFilter}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{EntourageCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopUniformSpaceCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for quotient filter equality, host uniform-space equality, selected limits, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8489.2 (Bishop uniform-space completion NameCert obligations)**.** *For every accepted* $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ *carrier* $U = (X, L, F, W, R, D, E, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopUniformSpace}}$ *surface consists of five rows:*

1. *source and located-uniformity admission, requiring X and L to display every entourage, metric, or positive-radius request before the completion route is read;*

2. *located Cauchy-filter basis exposure, requiring F to carry only finite filter-base requests over the displayed source and located rows;*

3. *regular finite observation, requiring W, R, D to expose StreamName windows, RegSeqRat readback, and DyadicRatCore tolerances for the same filter requests;*

4. *dense embedding and separated classifier exactness, requiring E and S to compare completion names through the displayed source graph, located Cauchy-filter base, observation windows, and tolerance ledger;*

5. *structural provenance, requiring H, C, P, N to transport, replay, source, and locally name the same packet without adding quotient filters, selected representatives, countable choice, host equality, or ambient completeness.*

Proof. Project the carrier of Definition 8489.1. The displayed mathematical rows are X, L, F, W, R, D, E, S, and the structural rows are H, C, P, N.

The source and located rows X, L precede every Cauchy-filter request. The filter-base row F is therefore read as a finite located basis rather than as a completed quotient object.

The observation rows W, R, D bind every inspected request to finite StreamName windows, regular rational readback, and dyadic tolerances. Dense embedding and separation are then read through E, S, so equality-sensitive completion reads remain attached to displayed evidence.

Finally H, C, P, N transport, replay, source, and name the same route. Since the carrier has no coordinate for quotient filters, selected limits, countable choice, host equality, or ambient completeness, the five listed rows exhaust the local certificate surface. □

Theorem 8489.3 (Bishop uniform-space completion dense image)**.** *Every accepted* $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ *carrier* $U = (X, L, F, W, R, D, E, S, H, C, P, N)$ *exports its source object to completion-facing consumers only through the dense embedding row E and the separated classifier row S. A consumer that reads a completion name must first expose the located source rows X, L, the Cauchy-filter basis F, the regular observation route W, R, D, and then the displayed embedding and separation rows. Thus the source image is dense in the completion packet as a finite NameCert route, not as a quotient completion, a choice-selected representative, host equality, or an ambient completeness theorem.*

Proof. Start from the NameCert obligations of Definition 8489.2. They force every completion-facing read to expose the source, located-uniformity, Cauchy-filter basis, observation, readback, and tolerance rows before any endpoint is consumed.

The dense embedding row E records the source graph inside the completion packet. Since E is downstream of X, L, F, W, R, D, an image read cannot be detached from the finite located Cauchy-filter evidence that produced it.

The separated classifier row S is the only comparison row for completion names. It reads through E and the same observation surface, so density is witnessed by the displayed route rather than by quotienting filters or selecting representatives.

Transport, replay, provenance, and local naming are carried by H, C, P, N. These rows preserve the same packet and add no host equality or ambient completeness data, giving the claimed dense-image handoff. □

Falsifiable prediction: Every accepted $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ consumer that reaches a completion name while omitting the located source rows, Cauchy-filter basis row, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance ledger, dense embedding row, separated classifier row, hsame transport, Cont replay, Pkg provenance, or local NameCert row refutes the carrier.

Independence witness: uniform-space, metric, cauchy-filter-basis, cauchy-filter, streamname, regseqrat, dyadicratcore, entourage-completion: no listed sibling is bijective to $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ because this packet jointly binds located uniform-space requests, Cauchy-filter bases, regular finite observation windows, dense embedding rows, separated classifier rows, transport, replay, provenance, and local naming as one completion-facing NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopUniformSpaceCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopUniformSpaceCompletion}^{\uparrow}$ packet is generated from a source uniform-space or metric row, located uniformity evidence, a located Cauchy-filter basis, StreamName observation windows, RegSeqRat readbacks, DyadicRatCore tolerances, a dense embedding row, a separated classifier row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopUniformSpaceCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8489.1, Definition 8489.2, and Definition 8489.3 seed the located uniform-space completion route over Cauchy-filter bases, regular finite observation windows, dense embedding rows, separated classifier rows, hsame transport, Cont replay, Pkg provenance, and local NameCert data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopUniformSpaceCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, host uniform-space equality, choice-selected representatives, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, located Cauchy-filter basis exposure, regular observation exactness, dense embedding exactness, separated classifier exactness, transport, replay, provenance, and local naming for BEDC.Derived.BishopUniformSpaceCompletionUp.

Chapter 8490

A Concrete Naming Certificate for $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$

The $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ packet realizes the observer-horizon branch of chapter 9463 as finite boundary-shadow, Busemann-cocycle, phase-distance, transport, provenance, and refusal rows. It sits after the boundary-shadow cross-ratio route of chapter 8460, the hyperbolic observer phase route of chapter 7112, the phase-transport budget of chapter 7134, the Gromov-boundary readback of chapter 6470, and the visual-flow shadow route of chapter 6609. The packet names a finite cocycle ledger for horizon-facing observer reads; it is not a global hyperbolic model, quotient boundary theorem, selected geodesic ray, physical observer, or analytic ergodic statement.

Falsifiable prediction: Every accepted $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ read is refuted if it reaches a phase-distance or horizon-cocycle conclusion without displaying the boundary-shadow, Busemann-cocycle, observer-horizon, transport, provenance, and refusal rows.

Independence witness: boundary-shadow-cross-ratio, hyperbolic-observer-phase, hyperbolic-phase-transport-budget, gromov-boundary, hyperbolic-visual-flow-shadow: none is bijective to $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ because this packet jointly carries an observer horizon row, Busemann-cocycle ledger, phase-distance readback, transport replay, provenance, refusal, and local NameCert naming.

Later Lean work must supply Nontrivial and FieldFaithful TasteGate instances before any positive discovery claim can be read from this packet. This chapter records the finite carrier and obligation surface only.

Definition 8490.1 (Hyperbolic observer horizon-cocycle carrier)**.** *A* $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (B, U, H, D, C, A, T, R, P, F, N)$$

with the following displayed rows:

1. *B is the boundary-shadow row, recording the visible shadow window seen by the observer.*
2. *U is the Busemann-cocycle row, recording the finite signed comparison between two displayed horizon reads.*
3. *H is the observer-horizon row, tying the boundary-shadow and Busemann rows to a displayed observer expansion route.*

4. *D is the phase-distance row, recording the finite readback consumed by phase-geometry consumers.*
5. *C is the cocycle-consistency ledger, requiring additivity and basepoint transport to be read only through displayed finite rows.*
6. *A is the apophatic refusal row, preventing the horizon far end from becoming an interior center, selected geodesic endpoint, or physical observer.*
7. *T records componentwise* hsame *transport for boundary-shadow, Busemann-cocycle, horizon, phase-distance, cocycle ledger, refusal, replay, provenance, and local naming rows.*
8. *R records displayed* Cont *replay from an observer request through B, U, H, D, C, A, T.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$, $\mathsf{BoundaryShadowCrossRatio}^{\uparrow}$, $\mathsf{HyperbolicObserverPhase}^{\uparrow}$, $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$, $\mathsf{HyperbolicVisualFlowShadow}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *F is the FieldFaithful readiness row, recording that later field-facing comparison must preserve the same finite phase-distance and Busemann-cocycle data.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, U, H, D, C, A, T, R, P, F, N$. It has no coordinate for a quotient visual boundary, selected geodesic ray, physical observer state, ambient hyperbolic manifold, analytic ergodic invariant, or hidden basepoint equality.

Theorem 8490.2 (Hyperbolic observer horizon-cocycle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ *carrier*

$$O = (B, U, H, D, C, A, T, R, P, F, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}}$ *surface consists exactly of the following finite obligation rows:*

1. *carrier admission for the boundary-shadow, Busemann-cocycle, observer-horizon, phase-distance, cocycle-ledger, refusal, transport, replay, provenance, FieldFaithful-readiness, and local naming rows;*
2. *boundary-shadow exposure, requiring every horizon read to display B before it consumes the cocycle row U;*
3. *Busemann-cocycle exactness, requiring U, C, T, R to preserve the same finite horizon comparison under basepoint transport and replay;*
4. *phase-distance handoff, requiring D and F to remain attached before any phase-geometry or field-facing consumer reads the packet;*
5. *apophatic refusal, requiring A, P, N to keep selected rays, physical observers, quotient boundary equality, ambient manifolds, and analytic ergodic invariants outside the certificate surface.*

No observer horizon-cocycle obligation is stored outside $B, U, H, D, C, A, T, R, P, F, N$.

Proof. Project the accepted carrier from Definition 8490.1. The packet displays the boundary-shadow, Busemann-cocycle, observer-horizon, phase-distance, cocycle-ledger, refusal, transport, replay, provenance, FieldFaithful-readiness, and local naming rows.

Boundary-shadow exposure comes first. A horizon read reaches the Busemann row only after the visible shadow window B has been displayed, so the horizon cannot be replaced by a hidden ideal-boundary representative.

Busemann-cocycle exactness is the joint role of U, C, T, R. The cocycle ledger C records the finite comparison, while transport and replay preserve the same basepoint-facing route.

The phase-distance handoff uses D and F. These rows keep the phase readback and later field-facing comparison attached to the same finite observer route.

Finally, the refusal row A and provenance rows P, N exclude selected rays, physical observer states, quotient boundary equality, ambient manifolds, and analytic ergodic invariants. Since none of those objects is a coordinate of O, the listed rows exhaust the local NameCert surface. □

Theorem 8490.3 (Hyperbolic observer horizon-cocycle phase handoff)**.** *Every phase-geometry consumer of an accepted* $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ *carrier*

$$O = (B, U, H, D, C, A, T, R, P, F, N)$$

must read the displayed route

$$B, U, H, D, C, A, T, R, P, F, N$$

before treating the packet as horizon-cocycle data. The handoff exports finite boundary-shadow, Busemann-cocycle, phase-distance, transport, provenance, refusal, and readiness rows, not quotient boundary equality, selected rays, physical observer states, ambient hyperbolic manifolds, or analytic ergodic invariants.

Proof. Use the obligation theorem Definition 8490.2. It places boundary-shadow exposure before Busemann-cocycle readback, then keeps the observer-horizon and phase-distance rows attached to the same finite route.

Read transport and replay next. Rows T and R preserve the displayed cocycle ledger C rather than introducing an unshown basepoint equality or quotient boundary representative.

Finally apply the refusal and readiness rows. The apophatic row A blocks selected-ray and physical-observer interpretations, while F records only later FieldFaithful readiness. Thus a phase consumer receives the finite horizon-cocycle packet and no stronger analytic or quotient endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8490.1, Definition 8490.2, and Definition 8490.3 seed the finite horizon-cocycle route from boundary-shadow and Busemann-cocycle rows through phase-distance, transport, provenance, refusal, readiness, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient visual-boundary equality, selected geodesic rays, physical observer states, ambient hyperbolic manifolds, analytic ergodic invariants, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, boundary-shadow exposure, Busemann-cocycle exactness, phase-distance handoff, apophatic refusal, Nontrivial TasteGate support, FieldFaithful TasteGate support, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicObserverHorizonCocycleUp.

Constructive story: A $\mathsf{HyperbolicObserverHorizonCocycle}^{\uparrow}$ packet is generated from boundary-shadow row, Busemann-cocycle row, observer-horizon row, phase-distance row, cocycle-consistency ledger, apophatic refusal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, FieldFaithful readiness, and a local NameCert row.

Chapter 8491

A Concrete Naming Certificate for $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$

Following Bishop and Bridges on constructive completion, the $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ packet records the finite handoff between regular Cauchy data and completion-facing consumers. It sits over the stream-window surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the completion-operator interface of chapter 3379. The packet is a finite enriched completion route, not a quotient completion, a selected limit, countable choice, host real equality, or an ambient completeness principle.

Definition 8491.1 (Regular Cauchy enriched completion carrier)**.** *A* $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S, R, D, M, A, O, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window ledger, naming the visible stream windows consumed by the completion route.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational approximants attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic error scale used by the regularity test.*
4. *M is the explicit modulus row, giving the finite bound by which later windows are read at a requested tolerance.*
5. *A is the enrichment row, retaining the companion annotations that make the completion consumer inspect a regular Cauchy schedule rather than a bare stream name.*
6. *O is the* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *handoff row, exposing the completion-operator call site without choosing a quotient representative or a host limit.*
7. *H records componentwise* hsame *transport for stream windows, rational readback, dyadic tolerances, modulus data, enrichment rows, completion-operator handoff, provenance, and local naming.*
8. *C records displayed* Cont *replay from a completion query through $S, R, D, M, A, O, H, P, N$.*

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, R, D, M, A, O, H, C, P, N$. It contains no coordinate for quotient real equality, a selected limit, countable choice, Dedekind completeness, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8491.2 (Regular Cauchy enriched completion NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ *carrier*

$$E = (S, R, D, M, A, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}}$ *surface consists exactly of stream-window exposure through S, regular rational readback through R, dyadic tolerance exposure through D, modulus exposure through M, enrichment retention through A, completion-operator handoff through O, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8491.1. Rows S, R, D, M, A, O are the completion-facing finite data, while H, C, P, N are the structural certificate rows.

The stream and rational parts are read through S and R. The dyadic tolerance and modulus parts are read through D and M, so every requested completion tolerance remains tied to a displayed finite bound.

The enrichment and completion-operator parts are then read through A and O. These rows expose the regular Cauchy schedule and the operator handoff, but they do not select a quotient representative or assert a host limit.

Finally H, C, P, N transport the displayed rows, replay the completion query, source the packet, and name it. Since no carrier coordinate contains choice, quotient real equality, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8491.3 (Regular Cauchy enriched completion modulus handoff)**.** *Every completion-facing read of an accepted* $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ *carrier factors the requested tolerance through the dyadic row D and the modulus row M before it reaches the* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *handoff row O. In particular, a consumer cannot bypass the displayed modulus to read the packet as an unbounded Cauchy stream or as an already completed* $\mathsf{Real}^{\uparrow}$ *object.*

Proof. Start with a completion query. The query first reads the finite stream windows through S and their rational values through R, so it has only displayed approximants at this stage.

The tolerance request then passes through D and M. Row D supplies the dyadic scale, and row M supplies the finite bound that makes later windows inspectable at that scale.

Only after those rows are present can the query reach O. The handoff to $\mathsf{CauchyCompletionOperator}^{\uparrow}$ therefore carries its modulus data with it, and no consumer can detach the handoff from the finite regularity evidence. □

Theorem 8491.4 (Regular Cauchy enriched completion non-escape)**.** *Every public read exported by an accepted* $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ *carrier factors through $S, R, D, M, A, O, H, C, P, N$. The packet cannot be used to extract quotient real equality, a selected limit, countable choice, Dedekind completeness, open-cover compactness, or an ambient completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Inspect the carrier inventory. The packet contains stream windows, regular rational readback, dyadic tolerance data, an explicit modulus, enrichment rows, a completion-operator handoff, transport, replay, provenance, and local naming.

Each public read is one of those rows or a replay through them. The completion-facing coordinate is O, and it is guarded by the preceding stream, rational, dyadic, modulus, and enrichment rows.

None of the excluded objects appears as a coordinate. Hence the carrier is a finite NameCert handoff for regular Cauchy completion data and not a source of quotient equality, selected limits, choice, compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, explicit modulus data, enrichment rows, CauchyCompletionOperator handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8491.1, Definition 8491.2, Definition 8491.3, and Definition 8491.4 seed the finite enriched completion handoff for regular Cauchy consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyEnrichedCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, selected limits, countable choice, Dedekind completeness, open-cover compactness, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular rational readback, dyadic tolerance exposure, modulus handoff, enrichment retention, completion-operator exactness, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyEnrichedCompletionUp.

Chapter 8492

A Concrete Naming Certificate for $\mathsf{HomotopyExtensionProperty}^{\uparrow}$

Following Borsuk and Dugundji on homotopy extension theory, the $\mathsf{HomotopyExtensionProperty}^{\uparrow}$ packet records the finite surface by which a homotopy already defined on a closed subcarrier is extended across a displayed cylinder window. It sits after the $\mathsf{DugundjiExtension}^{\uparrow}$ extension-operator route of chapter 2121, the $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$ neighbourhood-retraction route of chapter 6562, the $\mathsf{Homotopy}^{\uparrow}$ deformation ledger of chapter 156, the $\mathsf{ClosedMetricSubspace}^{\uparrow}$ admission route of chapter 7567, and the $\mathsf{ContinuousMap}^{\uparrow}$ graph row of chapter 130. The packet names the homotopy-extension property as displayed NameCert data; it does not import a host cofibration theorem, quotient cylinder equality, selected neighbourhood deformation, or ambient extension operator.

Definition 8492.1 (Homotopy extension property carrier)**.** *A* $\mathsf{HomotopyExtensionProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (A, X, I, F, G, D, R, W, T, C, P, N)$$

with the following displayed rows:

1. *A is the closed subcarrier row, read through* $\mathsf{ClosedMetricSubspace}^{\uparrow}$ *and retaining the admitted inclusion of the displayed subcarrier in the ambient metric carrier.*
2. *X is the ambient carrier row, recording only the parent metric, topology, and continuous-map data visible to the extension request.*
3. *I is the cylinder homotopy window, a finite interval-and-endpoint ledger for the displayed $A \times I$ and $X \times I$ read.*
4. *F is the initial continuous-map row on X, read through* $\mathsf{ContinuousMap}^{\uparrow}$*.*
5. *G is the subcarrier homotopy row on $A \times I$, read through* $\mathsf{Homotopy}^{\uparrow}$ *and compatible with F on the initial face.*
6. *D is the Dugundji or ANR handoff row. It records the displayed extension interface supplied by* $\mathsf{DugundjiExtension}^{\uparrow}$ *or* $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$*, not a host-selected extension.*
7. *R is the extension request row, binding A, X, I, F, G, D into one finite request for a homotopy over $X \times I$.*
8. *W is the extended homotopy window row, recording the candidate extension only through the same displayed cylinder, initial-face, and subcarrier rows.*

9. *T records componentwise* hsame *transport for closed-subcarrier, ambient, cylinder, initial-map, subcarrier-homotopy, handoff, request, window, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from an extension query through $A, X, I, F, G, D, R, W, T$.*
11. *P is the* Pkg *provenance over* $\mathsf{HomotopyExtensionProperty}^{\uparrow}$, $\mathsf{DugundjiExtension}^{\uparrow}$, $\mathsf{AbsoluteNeighborhoodRetract}^{\uparrow}$, $\mathsf{Homotopy}^{\uparrow}$, $\mathsf{ClosedMetricSubspace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{HomotopyExtensionProperty}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, X, I, F, G, D, R, W, T, C, P, N$. It has no coordinate for an ambient cofibration theorem, quotient cylinder equality, selected global deformation, host function-space topology, or choice-selected extension operator.

Lean4 ✓ `BEDC.Derived.HomotopyExtensionPropertyUp.HomotopyExtensionPropertyTasteGate single carrier alignment`

Theorem 8492.2 (Homotopy extension property NameCert obligations)**.** *For every accepted* $\mathsf{HomotopyExtensionProperty}^{\uparrow}$ *carrier*

$$E = (A, X, I, F, G, D, R, W, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HomotopyExtensionProperty}^{\uparrow}}$ *surface consists exactly of closed subcarrier admission through A; ambient carrier exposure through X; cylinder homotopy-window exposure through I; initial continuous-map exposure through F; subcarrier homotopy exposure through G; Dugundji or ANR handoff through D; extension request binding through R; extended-window readback through W; componentwise transport through T; displayed replay through C; provenance through P; and local naming through N.*

Proof. Project the carrier of Definition 8492.1. The rows A and X display the closed subcarrier inside the ambient carrier, while I fixes the finite cylinder window on which the homotopy-extension request is inspected.

The analytic rows are F, G, D, R, W. The initial map F and the subcarrier homotopy G must be compatible before the handoff row D can be read. The request row R then binds those rows, and W records only the resulting displayed extended window.

The structural rows T, C, P, N preserve the same request under transport, replay, provenance, and local naming. Since the carrier contains no host cofibration theorem, quotient cylinder equality, selected deformation, function-space topology, or choice-selected operator, the listed rows exhaust the local NameCert obligations. □

Theorem 8492.3 (Homotopy extension Dugundji and ANR handoff)**.** *Every Dugundji-facing or ANR-facing consumer of an accepted* $\mathsf{HomotopyExtensionProperty}^{\uparrow}$ *carrier must read the route*

$$A, X, I, F, G \longmapsto D \longmapsto R, W, T, C, P, N$$

before treating the packet as homotopy-extension evidence. The handoff may cite the extension surface of chapter 2121 or the neighbourhood-retract surface of chapter 6562, but it exports only finite BEDC rows and not a host cofibration theorem, selected neighbourhood deformation, quotient cylinder equality, or global extension operator.

Proof. Start with the NameCert obligations of Definition 8492.2. They force every consumer to expose A, X, I, F, G before the handoff row D can be public.

Read D through the sibling extension route. A Dugundji consumer receives a displayed extension-operator interface, while an ANR consumer receives a displayed neighbourhood-retraction interface; neither route replaces the closed subcarrier, cylinder, initial-map, or homotopy rows.

Finally use R, W, T, C, P, N. These rows bind the request, expose the extended window, and preserve the packet under transport, replay, provenance, and local naming. Thus the handoff remains a finite homotopy-extension property surface rather than an ambient cofibration or extension theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{HomotopyExtensionProperty}^{\uparrow}}$.

Constructive story: A $\mathsf{HomotopyExtensionProperty}^{\uparrow}$ packet is generated from a closed subcarrier row, ambient carrier row, cylinder homotopy-window row, initial continuous-map row, subcarrier homotopy row, Dugundji or ANR handoff row, extension request row, extended-window readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HomotopyExtensionProperty}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8492.1, Definition 8492.2, and Definition 8492.3 seed the homotopy-extension property route over closed-subcarrier, cylinder, homotopy, Dugundji, ANR, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HomotopyExtensionProperty}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close cofibration recognition, quotient cylinder equality, selected neighbourhood deformation, host function-space topology, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked closed-subcarrier admission, cylinder-window exposure, initial-map exposure, subcarrier-homotopy exposure, Dugundji or ANR handoff, request binding, extended-window readback, transport, replay, provenance, and local naming for BEDC.Derived.HomotopyExtensionPropertyUp.

Chapter 8493

A Concrete Naming Certificate for $\mathsf{HigmanLemma}^{\uparrow}$

Following Higman 1952 and Nash-Williams' well-quasi-order method, the $\mathsf{HigmanLemma}^{\uparrow}$ packet records finite word-embedding data over a well-quasi-ordered source as a NameCert carrier. It sits after the finite-product induction packet of chapter 6754, the finite list rows of chapter 36, the ordered comparison rows of chapter 53, and the candidate-boundary rows of chapter 892. The packet is a finite subsequence-embedding certificate for words; it is not a selected infinite subsequence theorem, not a quotient of streams, and not a host proof of MetaCIC normalization.

Definition 8493.1 (Higman lemma carrier)**.** *A* $\mathsf{HigmanLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\mathsf{Higman}(S, W, E, B, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the source well-quasi-order row, exposing only finite comparisons and bad-prefix refusals for the underlying alphabet.*
2. *W is the finite-word row, storing word windows as* $\mathsf{List}^{\uparrow}$ *packets over S.*
3. *E is the subsequence-embedding row, recording monotone index maps and pointwise source comparisons for a pair of displayed word windows.*
4. *B is the bad-sequence-prefix row, storing the finite obstruction prefix that must be reduced when no embedding row is displayed.*
5. *D is the Dickson-style product-order dependency row read through* $\mathsf{DicksonLemma}^{\uparrow}$ *for the finite vector of front letters and residual word lengths.*
6. *H records componentwise* hsame *transport for source, word, embedding, obstruction, dependency, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a bad-prefix read to a shorter residual-word read and then to an embedding read.*
8. *P is the* Pkg *provenance over* $\mathsf{HigmanLemma}^{\uparrow}$, $\mathsf{DicksonLemma}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HigmanLemma}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for countable choice, quotient word equality, a selected infinite subsequence, excluded-middle case selection, or an unconditional MetaCIC termination theorem.

Lean4 ✓ `BEDC.Derived.HigmanLemmaUp.TasteGate.HigmanLemmaTasteGate single carrier alignment`

Theorem 8493.2 (Higman lemma NameCert obligations)**.** *For every accepted* $\mathsf{HigmanLemma}^{\uparrow}$ *carrier* $\mathsf{Higman}(S, W, E, B, D, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HigmanLemma}^{\uparrow}}$ *surface consists exactly of source well-quasi-order exposure through* S*, finite-word exposure through* W*, subsequence-embedding exposure through* E*, bad-sequence-prefix exposure through* B*, Dickson dependency exposure through* D*, componentwise transport through* H*, continuation replay through* C*, provenance nonescape through* P*, and local naming through* N*.*

Proof. Project the displayed carrier. The source row S, word row W, embedding row E, obstruction row B, and dependency row D are the only mathematical rows available before the structural rows are read.

The source and word rows fix the alphabet and finite windows. The embedding row records only monotone index maps together with pointwise source comparisons, while the bad-prefix row records the finite obstruction prefix that remains when no such embedding is displayed.

The dependency row is read through chapter 6754. It supplies a finite product-order route for the front-letter and residual-length bookkeeping, but it does not add a selected infinite subsequence or a quotient word equality.

Finally H, C, P, N transport, replay, source, and name the same packet. Since the carrier has no coordinate for countable choice, excluded-middle selection, quotient words, or an unconditional MetaCIC termination theorem, the listed rows exhaust the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.HigmanLemmaUp.HigmanLemmaNameCertObligations`

Theorem 8493.3 (Higman lemma finite subsequence embedding route)**.** *Every downstream consumer of an accepted* $\mathsf{HigmanLemma}^{\uparrow}$ *packet that asks for a word-embedding certificate must read the finite route*

$$\mathsf{List}^{\uparrow} \to \mathsf{Poset}^{\uparrow} \to \mathsf{DicksonLemma}^{\uparrow} \to \mathsf{HigmanLemma}^{\uparrow} \to \mathsf{NameCert}.$$

The consumer receives finite word windows, source comparisons, monotone index data, bad-prefix reduction data, Dickson-style product bookkeeping, componentwise transport, replay, provenance, and local naming. It receives no selected infinite subsequence, no quotient stream equality, no countable-choice selector, and no global normalization theorem.

Proof. Start with the NameCert obligations of Definition 8493.2. They force a consumer to expose the source row S, word row W, embedding row E, obstruction row B, and dependency row D before it reads the local naming row.

The word row is a finite $\mathsf{List}^{\uparrow}$ window over the source comparison surface. The embedding row is a displayed monotone index map with pointwise comparisons, so it is a finite certificate rather than an infinite subsequence selection.

The dependency row routes the finite obstruction reduction through $\mathsf{DicksonLemma}^{\uparrow}$. This places the front-letter and residual-length bookkeeping on the same finite product-order surface already named by chapter 6754.

Finally the structural rows carry the route to normalization-facing consumers. A $\mathsf{MetaCICNormalizationFrontier}^{\uparrow}$ reader may consume the packet only as a finite residual-word evidence row, because P names no quotient stream equality, countable-choice selector, or global normalization theorem. □

Lean4 ✓ `BEDC.Derived.HigmanLemmaUp.HigmanLemmaSubsequenceEmbeddingRoute`

Theorem 8493.4 (Higman lemma normalization-frontier handoff)**.** *A normalization-frontier consumer may cite* HigmanLemma$^{\uparrow}$ *only after the finite word packet exposes* $S, W, E, B, D, H, C, P, N$ *and after the consumer has identified which residual-word window is being handed to the* MetaCICNormalizationFront *boundary. The handoff is a finite subsequence-embedding certificate for residual windows; it does not close subject reduction, confluence, strong normalization, quotient syntax equality, or host evaluator soundness.*

Proof. Read the finite subsequence route of Definition 8493.3. It already places the word windows, source comparisons, embedding data, bad-prefix reduction, Dickson dependency, and structural rows before any downstream handoff.

Now compare with the MetaCIC normalization frontier of chapter 892. That frontier separates candidate evidence, finished-normal evidence, and obstruction rows; the Higman packet may feed only the finite residual-word evidence side of that separation.

Thus the handoff preserves a finite certificate boundary. It can record that a residual-word window has an embedding route, but it cannot erase the MetaCIC obstruction rows or turn the finite combinatorial packet into a global normalization theorem. □

Lean4 ✓ `BEDC.Derived.HigmanLemmaUp.HigmanLemmaNormalizationFrontierHandoff`

Theorem 8493.5 (Higman lemma finite bad-prefix induction)**.** *Any accepted residual-word consumer of a* HigmanLemma$^{\uparrow}$ *packet may perform induction only on the displayed finite bad-prefix windows carried by* B *and routed through* D, C, P, N*. At each induction step the consumer must keep the* MetaCICNormalizationFrontier$^{\uparrow}$ *obstruction row visible, so the induction exports a shorter residual-word window or a finite embedding row, not a global normalization theorem.*

Lean4 ✓ `BEDC.Derived.HigmanLemmaUp.HigmanLemmaFiniteBadPrefixInduction`

Proof. Start with the carrier of Definition 8493.1. The only obstruction data available to a residual-word consumer is the finite bad-sequence-prefix row B, together with the Dickson dependency row D and the structural replay rows C, P, N.

Induction therefore has a finite displayed domain. The base case reads an already displayed embedding row E, while an induction step shortens only the bad-prefix window named by B and records the dependency through D.

Now compare the handoff of Definition 8493.4. A MetaCIC-facing consumer must preserve the normalization-frontier obstruction row while reading the residual-word evidence.

Thus the induction produces only a shorter displayed residual window or a finite embedding certificate. It cannot erase the obstruction row, select an infinite subsequence, or turn the finite Higman packet into global normalization. □

Falsifiable prediction: A claimed HigmanLemmaUp certificate fails if its word-embedding row lacks either a monotone index map or the pointwise source-comparison rows for the displayed finite word windows.

Independence witness: dickson-lemma, list, poset, metacicnormalizationfrontier: DicksonLemma$^{\uparrow}$ supplies finite product-order bookkeeping without word embedding rows; List$^{\uparrow}$ supplies finite word windows without bad-prefix reduction; Poset$^{\uparrow}$ supplies comparison rows without residual-word replay; and MetaCICNormalizationFrontier$^{\uparrow}$ consumes candidate-boundary evidence without being a word-embedding certificate. None is bijective to HigmanLemma$^{\uparrow}$ under NameCert-row preservation.

Closure status for $\mathsf{NameCert}_{\mathsf{HigmanLemma}^{\uparrow}}$.

Constructive story: A $\mathsf{HigmanLemma}^{\uparrow}$ packet is generated from a source well-quasi-order row, finite word rows, subsequence-embedding rows, bad-sequence-prefix rows, Dickson dependency rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HigmanLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8493.1, Definition 8493.2, Definition 8493.3, and Definition 8493.4 seed the finite word-embedding packet and its MetaCIC normalization-frontier handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HigmanLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, selected infinite subsequences, quotient word equality, excluded-middle case selection, subject reduction, confluence, strong normalization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source exposure, finite-word exposure, subsequence-embedding exposure, bad-prefix reduction, Dickson dependency routing, componentwise transport, replay, provenance, and local NameCert exactness for BEDC.Derived.HigmanLemmaUp.

Chapter 8494

A Concrete Naming Certificate for $\mathsf{HewittRealcompactification}^{\uparrow}$

Following Hewitt and Kelley on realcompact spaces, the $\mathsf{HewittRealcompactification}^{\uparrow}$ packet records the finite real-valued-function completion boundary seen by BEDC consumers before any ambient realcompactification theorem is available. It sits after the completely regular source of chapter 5161, the topology carrier of chapter 88, the continuous-map surface of chapter 130, the terminal real-name seal of chapter 38, and the bounded-probe comparison of chapter 2344. The packet names the displayed real-function handoff only; it does not claim z-ultrafilter choice, host compactification equality, selected points, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8494.1 (Hewitt realcompactification carrier)**.** *A* $\mathsf{HewittRealcompactification}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (C, T, F, R, B, Z, E, L, K, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{CompletelyRegularSpace}^{\uparrow}$ *source row, exposing the point-versus-closed-set real-valued separation surface.*
2. *T is the* $\mathsf{Topology}^{\uparrow}$ *row naming the open-set carrier on which the real-valued observations are read.*
3. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row listing the visible real-valued probes used by the completion boundary.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *value-seal row for the displayed probe evaluations.*
5. *B is the* $\mathsf{StoneCechCompactification}^{\uparrow}$ *comparison row, used only as a bounded-probe sibling surface.*
6. *Z is the zero-set and cozero-set ledger row recording the finite real-function tests seen by the packet.*
7. *E is the realcompactification envelope row, exposing the completion-facing request without selecting z-ultrafilters or points.*
8. *L records componentwise* hsame *transport for the source, topology, continuous-map, Real, Stone–Cech comparison, zero-set ledger, envelope, replay, provenance, and local naming rows.*
9. *K records displayed* Cont *replay from a real-function completion request through $C, T, F, R, B, Z, E, L, P, N$.*

10. *P is the* Pkg *provenance over* $\mathsf{HewittRealcompactification}^{\uparrow}$, $\mathsf{CompletelyRegularSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StoneCechCompactification}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HewittRealcompactification}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $C, T, F, R, B, Z, E, L, K, P, N$. It contains no coordinate for a selected z-ultrafilter, a chosen realcompactification point, host compactification equality, a full ring of all real-valued functions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8494.2 (Hewitt realcompactification NameCert obligations)**.** *For every accepted* HewittRealcompactificat *carrier*

$$H = (C, T, F, R, B, Z, E, L, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HewittRealcompactification}^{\uparrow}}$ *surface consists exactly of completely regular source exposure through C, topology exposure through T, continuous real-valued probe exposure through F, Real value sealing through R, Stone–Cech comparison through B, zero-set ledger exposure through Z, realcompactification-envelope exposure through E, componentwise transport through L, displayed replay through K, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8494.1. Rows C, T, F, R expose the completely regular source, its topology, the displayed continuous real-valued probes, and their Real value seals.

Rows B, Z, E then record only the comparison and envelope data. The Stone–Cech row is a sibling bounded-probe comparison, the zero-set ledger lists finite real-function tests, and the envelope row names the completion-facing request without adding a selected z-ultrafilter or point.

Finally L, K, P, N transport, replay, source, and name exactly those rows. Since no excluded object is a carrier coordinate, the listed rows exhaust the local NameCert obligations. □

Theorem 8494.3 (Hewitt realcompactification real-function handoff)**.** *Every completion-facing read of an accepted* $\mathsf{HewittRealcompactification}^{\uparrow}$ *carrier first exposes the route*

$$\mathsf{CompletelyRegularSpace}^{\uparrow} \longmapsto \mathsf{Topology}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

and only then reads the $\mathsf{StoneCechCompactification}^{\uparrow}$ *comparison row, the zero-set ledger, and the realcompactification envelope. Thus the packet exports a finite real-function handoff, not z-ultrafilter choice, host compactification equality, selected points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with a completion-facing query. The query must read C and T before any real-valued probe is visible, so the completely regular source and its topology remain explicit.

The probe stage is F and R. It displays the continuous real-valued observations and their Real value seals, but it does not supply an ambient function space or a completed realcompact host.

Only after those rows are present can the consumer read B, Z, E. The comparison, zero-set ledger, and envelope therefore remain downstream of displayed real-function data, and the structural rows L, K, P, N preserve that same order. □

Closure status for $\mathsf{NameCert}_{\mathsf{HewittRealcompactification}^{\uparrow}}$.

Constructive story: A $\mathsf{HewittRealcompactification}^{\uparrow}$ packet is generated from CompletelyRegularSpace source rows, Topology rows, ContinuousMap real-valued probes, Real value seals, a StoneCechCompactification comparison row, zero-set ledger rows, an envelope row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HewittRealcompactification}^{\uparrow}}$, seed)

Scope closed: Definition 8494.1, Definition 8494.2, and Definition 8494.3 seed the finite real-valued-function completion boundary for Hewitt realcompactification consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HewittRealcompactification}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close z-ultrafilter choice, host compactification equality, selected points, a full function-ring construction, Lean verification, bridge checking, or ambient $\mathrm{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, completely regular source exposure, topology exposure, continuous real-valued probe exactness, Real value sealing, Stone–Cech comparison nonescape, zero-set ledger exposure, envelope handoff, transport, replay, provenance, and local naming for BEDC.Derived.HewittRealcompactificationUp.

Chapter 8495

A Concrete Naming Certificate for $\mathsf{CompactOscillationTree}^{\uparrow}$

Following Bishop–Bridges compact uniform-continuity proofs, the $\mathsf{CompactOscillationTree}^{\uparrow}$ packet records the finite cover-refinement tree by which local oscillation windows are folded into a uniform-modulus handoff. It sits after the compact metric source of chapter 129, the continuous-map rows of chapter 130, the finite cover nerve of chapter 7597, the dyadic tolerance core of chapter 291, the regular rational readback of chapter 301, the Real seal of chapter 38, and the uniform-modulus consumer of chapter 369. The packet names only displayed finite tree data; it is not open-cover compactness, an external Lebesgue number selector, a host modulus function, quotient equality of maps, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8495.1 (Compact oscillation tree carrier)**.** *A* $\mathsf{CompactOscillationTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, F, V, D, Q, R, O, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row, exposing the finite compact-net cells and coverage witnesses.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *pointwise inspection row attached to the displayed compact source.*
3. *V is the* $\mathsf{FiniteCoverNerve}^{\uparrow}$ *cover-refinement row, listing finite parent-child cover incidences.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, recording the dyadic oscillation scale used at each node.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational lower-bound and oscillation-window values.*
6. *R is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for the displayed real-valued bounds.*
7. *O is the compact oscillation tree row. It records the finite rooted tree, node windows, child refinements, and leaf oscillation bounds.*
8. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported only after K, F, V, D, Q, R, O have been displayed.*
9. *H records componentwise* hsame *transport for source, pointwise map, cover refinement, dyadic tolerance, rational readback, Real seal, oscillation tree, uniform modulus, replay, provenance, and local naming.*
10. *C records displayed* Cont *replay from a compact-uniform query through $K, F, V, D, Q, R, O, U, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{CompactOscillationTree}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{FiniteCoverNerve}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactOscillationTree}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, F, V, D, Q, R, O, U, H, C, P, N$. It has no coordinate for arbitrary open-cover compactness, a selected Lebesgue number, a host modulus function, quotient equality of continuous maps, or ambient completeness.

Theorem 8495.2 (Compact oscillation tree NameCert obligations)**.** *For every accepted* $\mathsf{CompactOscillationTree}^{\uparrow}$ *carrier*

$$T = (K, F, V, D, Q, R, O, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactOscillationTree}^{\uparrow}}$ *surface consists exactly of compact-metric source exposure through K, continuous-map pointwise inspection through F, finite cover-refinement exposure through V, dyadic tolerance exposure through D, rational readback through Q, Real sealing through R, finite oscillation-tree exposure through O, uniform-modulus handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8495.1. The source rows K, F, V expose the compact finite net, the pointwise continuous-map checks, and the finite cover-refinement incidence data.

Rows D, Q, R attach the numerical readback. They display dyadic tolerances, rational oscillation-window values, and Real value seals before any uniform-modulus consumer can inspect the tree.

The tree row O is therefore read as finite combinatorial data over already displayed cover and tolerance rows. The handoff row U can only consume that finite route, while H, C, P, N transport, replay, source, and name it. □

Theorem 8495.3 (Compact oscillation tree uniform-modulus handoff)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *consumer of an accepted* $\mathsf{CompactOscillationTree}^{\uparrow}$ *carrier first reads the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{FiniteCoverNerve}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow} \longmapsto \mathsf{CompactO}$$

Thus the exported modulus is a finite cover-refinement and oscillation-window handoff, not an external compactness theorem, selected Lebesgue number, host modulus function, or ambient $\mathsf{Real}^{\uparrow}$ *completeness principle.*

Proof. Start with a compact-uniform query. It must expose the compact-metric row K and pointwise continuous-map row F before it can read any refinement data.

The finite cover route is then V, D, Q, R. These rows display the cover-refinement incidences, dyadic oscillation scales, rational lower-bound reads, and Real seals needed at the tree nodes.

Only after those rows are present can the query read O and then U. Componentwise transport, replay, provenance, and local naming preserve the same finite order, so no hidden compactness or host modulus coordinate is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactOscillationTree}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactOscillationTree}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, ContinuousMap pointwise checks, FiniteCoverNerve refinement rows, DyadicRatCore tolerances, RegSeqRat rational readback, Real seals, a finite oscillation tree, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CompactOscillationTree}^{\uparrow}}$, seed)

Scope closed: Definition 8495.1, Definition 8495.2, and Definition 8495.3 seed the finite cover-refinement and oscillation-window route for compact uniform-modulus consumers.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CompactOscillationTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected Lebesgue numbers, host modulus functions, quotient equality of continuous maps, Lean verification, bridge checking, or ambient $\mathrm{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-metric source exposure, continuous-map pointwise inspection, finite cover-refinement exactness, dyadic tolerance exposure, rational readback, Real sealing, oscillation-tree handoff, UniformModulus export, transport, replay, provenance, and local naming for BEDC.Derived.CompactOscillationTreeUp

Chapter 8496

A Concrete Naming Certificate for FiniteDimensionalNormedCompleteness$^{\uparrow}$

Following Bishop and Bridges constructive analysis, the FiniteDimensionalNormedCompleteness$^{\uparrow}$ packet names the finite-basis route by which a Cauchy sequence in a finite-dimensional normed space is sealed as Banach data. It sits after the normed-space carrier of chapter 1950, the vector-space rows of chapter 47, the coordinate and evaluation maps of chapter 48, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, the completion-operator route of chapter 3379, and the Banach-space packet of **??**. The chapter is a finite-dimensional certificate: it records a displayed basis window, coordinate Cauchy extraction, norm-stability rows, completion handoff, and Banach seal, rather than a general completeness theorem for arbitrary normed spaces.

Definition 8496.1 (Finite-dimensional normed completeness carrier)**.** *A* FiniteDimensionalNormedCompleteness$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (V, N, B, K, S, R, E, O, Z, H, C, P, L)$$

with the following displayed rows:

1. *V is the* VecSpace$^{\uparrow}$ *source row for the finite vector-space window.*
2. *N is the* NormedSpace$^{\uparrow}$ *row, exposing the norm and metric reads attached to the same vector rows.*
3. *B is the finite basis ledger, listing the displayed basis names and the coordinate-admission rows for inspected vectors.*
4. *K is the* LinMap$^{\uparrow}$ *coordinate-evaluation row from vectors to finitely many scalar coordinate names.*
5. *S is the coordinate Cauchy schedule, recording that each displayed coordinate stream is Cauchy through finite windows.*
6. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the coordinate streams and the norm-control estimates.*
7. *E is the* Real$^{\uparrow}$ *seal row for coordinate limits and norm estimates.*
8. *O is the* CauchyCompletionOperator$^{\uparrow}$ *handoff row, carrying the finite Cauchy evidence into the completion-facing route.*
9. *Z is the* BanachSpace$^{\uparrow}$ *seal row asserting that this finite-basis packet supplies the Banach-facing completeness read.*

10. *H records componentwise* hsame *transport for all rows of the packet.*
11. *C records displayed* Cont *replay through the finite-basis, coordinate, readback, completion, and seal rows.*
12. *P is the* Pkg *provenance over* FiniteDimensionalNormedCompleteness$^{\uparrow}$, VecSpace$^{\uparrow}$, NormedSpace$^{\uparrow}$, LinMap$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, CauchyCompletionOperator$^{\uparrow}$, BanachSpace$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *L is the local* NameCert$_{\text{FiniteDimensionalNormedCompleteness}^{\uparrow}}$ *row.*

The classifier accepts only packets whose completeness read is exhausted by $V, N, B, K, S, R, E, O, Z, H, C, P, L$. It has no coordinate for Hahn–Banach extension, arbitrary Banach-space completeness, quotient normed spaces, selected bases, countable choice, or an ambient host completion.

Lean4 ✓ `BEDC.Derived.FiniteDimensionalNormedCompletenessTasteGate single carrier alignment`

Theorem 8496.2 (Finite coordinate Cauchy extraction)**.** *For every accepted* FiniteDimensionalNormedCompletenes *carrier*

$$F = (V, N, B, K, S, R, E, O, Z, H, C, P, L),$$

any Cauchy read of the normed vector sequence factors through the finite basis ledger B and the coordinate-evaluation row K before it reaches the regular rational readback R or the real seal E. Thus the extracted evidence consists of finitely many coordinate Cauchy streams, their RegSeqRat readbacks, the displayed norm-control estimates, and the structural rows H, C, P, L.

Proof. Project the carrier of Definition 8496.1. The only route from the normed source rows V, N to scalar data passes through the finite basis ledger B and the coordinate-evaluation row K.

The coordinate Cauchy schedule S is read after those rows are displayed. It supplies one finite-window Cauchy record for each coordinate named by B, so the extraction is finite rather than a choice over an external basis.

The rows R and E then read the same coordinate streams as regular rational data and terminal real seals. The norm-control estimates remain attached to those scalar rows because H, C, P, L transport, replay, source, and name the displayed packet.

Since the carrier contains no selected basis, quotient normed space, arbitrary Banach-space completeness field, or choice schedule, no downstream consumer can replace the coordinate extraction by a stronger ambient principle. □

Theorem 8496.3 (Finite-dimensional Banach seal)**.** *Every accepted* FiniteDimensionalNormedCompleteness$^{\uparrow}$ *carrier supplies a Banach-facing completeness seal only through the displayed route*

$$V, N \longmapsto B, K, S \longmapsto R, E \longmapsto O \longmapsto Z \longmapsto H, C, P, L.$$

The row O hands finite coordinate Cauchy evidence to the completion-operator surface, and the row Z records the resulting BanachSpace$^{\uparrow}$ *seal for this finite-dimensional packet. No Hahn–Banach principle, quotient normed space, arbitrary Banach completeness theorem, selected basis operation, countable-choice schedule, or host completion endpoint is exported.*

Proof. Begin with Definition 8496.2. It forces the Cauchy read through the finite coordinate surface B, K, S before any scalar readback or real seal is available.

The norm-stability step uses the normed-space row N together with the scalar rows R, E. The displayed estimates say that convergence of the finitely many coordinate streams is enough for the

normed Cauchy route seen by this packet; the proof does not require a supremum over an unlisted basis family.

The completion handoff is the row O. It consumes exactly the finite Cauchy evidence already displayed, matching the operator discipline of chapter 3379.

Finally Z records the Banach-facing seal for this packet, while H, C, P, L keep the route attached under transport, replay, provenance, and local naming. The excluded analytic principles are absent from the carrier inventory, so the seal cannot export them. □

Falsifiable prediction: A purported finite-dimensional completeness read that reaches a Banach seal without displaying the finite basis ledger, coordinate Cauchy schedule, RegSeqRat readback, Real seal, and completion-operator handoff refutes this carrier surface.

Independence witness: normedspace, vecspace, linearmap, regseqrat, real, cauchycompletionoperator, banachspace: no listed sibling alone binds finite basis rows, coordinate Cauchy extraction, norm stability, completion handoff, and a Banach-facing seal into one NameCert packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormedCompleteness}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteDimensionalNormedCompleteness}^{\uparrow}$ packet is generated from vector-space, normed-space, finite-basis, coordinate-evaluation, coordinate Cauchy, RegSeqRat readback, Real seal, CauchyCompletionOperator handoff, Banach seal, transport, replay, provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormedCompleteness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8496.1, Definition 8496.2, and Definition 8496.3 seed the finite-basis completeness route from normed vector rows through coordinate Cauchy extraction and Banach sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteDimensionalNormedCompleteness}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FiniteDimensionalNormedCompletenessUp`

Bridge status: none

Not claimed: This chapter does not close Hahn–Banach extension, arbitrary Banach-space completeness, quotient normed spaces, selected bases, countable choice, host completion endpoints, theoremChecked Lean status, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite coordinate Cauchy extraction, norm-stability readback, completion-operator handoff, Banach sealing, transport, replay, provenance, and local naming for BEDC.Derived.FiniteDimensionalNormedCompletenessUp.

Chapter 8497

A Concrete Naming Certificate for CauchyCompletionErrorEstimator$^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy completion and explicit error bounds, the CauchyCompletionErrorEstimator$^{\uparrow}$ packet records the finite route by which a completion read carries an a posteriori dyadic error estimate. It sits beside the completion operator of chapter 3379, the dyadic tolerance core of chapter 291, the regular rational source rows of chapter 301, the finite stream-name windows of chapter 126, and the terminal real-name seal of chapter 38. The packet names error control as finite NameCert data; it does not choose a limit representative, import ambient completeness, assert host real equality, or hide the estimate behind quotient completion syntax.

Definition 8497.1 (Cauchy completion error estimator carrier)**.** *A* CauchyCompletionErrorEstimator$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (O, S, W, D, R, A, Z, H, C, P, N)$$

with the following displayed rows:

1. *O is the* CauchyCompletionOperator$^{\uparrow}$ *row whose completion output is being inspected.*
2. *S is the* RegSeqRat$^{\uparrow}$ *source row naming the regular rational approximation stream.*
3. *W is the* StreamName$^{\uparrow}$ *finite-window row through which the source tail is observed.*
4. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance ledger used to record the displayed error radius.*
5. *R is the* Real$^{\uparrow}$ *seal row for the completed value reached from the source data.*
6. *A is the a posteriori estimate row, read only after O, S, W, D, R have been displayed.*
7. *Z is the zero-tail or residual-bound row certifying that the displayed estimate bounds the remaining completion tail.*
8. *H records componentwise* hsame *transport for the operator, source, window, dyadic ledger, real seal, estimate row, residual-bound row, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay of the same finite route from an estimator request.*
10. *P records* Pkg *provenance over* CauchyCompletionErrorEstimator$^{\uparrow}$*,* CauchyCompletionOperator$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* StreamName$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. N is the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $O, S, W, D, R, A, Z, H, C, P, N$. It has no coordinate for selected limits, quotient completion equality, host real equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8497.2 (Cauchy completion error estimator NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}$ *carrier*

$$E = (O, S, W, D, R, A, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}}$ *surface consists exactly of completion-operator exposure for O, regular-rational source exposure for S, finite-window exposure for W, dyadic tolerance exposure for D, Real-seal exposure for R, a posteriori estimate exposure for A, residual-bound exposure for Z, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The operator, source, finite window, dyadic ledger, and Real seal are the only completion-facing rows available before an estimate can be read.

Next read A and Z. The estimate row supplies the displayed dyadic error radius, while the residual-bound row ties that radius to the remaining completion tail observed through the same source and window rows.

Finally H, C, P, N preserve the route under componentwise transport, replay it for estimator consumers, record provenance, and name the packet locally. Since the carrier contains no coordinate for selected limits, quotient equality, host real equality, countable choice, trichotomy, or ambient completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8497.3 (Cauchy completion error estimator a posteriori bound)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing read of an accepted* $\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}$ *carrier reaches an a posteriori error bound only through the finite route*

$$O, S, W, D, R, A, Z, H, C, P, N.$$

The dyadic ledger D and finite window W determine the displayed bound, the residual row Z certifies it against the source tail S, and the Real seal R receives the estimate only after those rows are visible. Thus the estimator exports a finite completion-error certificate rather than a selected completion limit, quotient representative equality, host real equality, countable-choice schedule, trichotomy split, or ambient completeness theorem.

Proof. Start with the carrier projection. The completion operator row O and regular rational source row S determine which completion read is being estimated, while W fixes the finite observation window.

Use the dyadic ledger row D. It supplies the displayed radius for the estimate, but it is still tied to the source and window rows rather than to an external real-valued oracle.

Now read A and Z after the Real seal row R is visible. The estimate row records the a posteriori bound, and the residual-bound row certifies that the remaining completion tail is covered by that dyadic radius.

The support rows H, C, P, N only transport, replay, source, and name this same route. Because the excluded ambient principles are not carrier coordinates, the exported bound remains a finite completion-error certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}$ packet is generated from a CauchyCompletionOperatorUp row, a RegSeqRatUp source row, a StreamNameUp finite-window row, a DyadicRatCoreUp tolerance ledger, a RealUp seal row, an a posteriori estimate row, a residual-bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8497.1, Definition 8497.2, and Definition 8497.3 seed the finite completion-error estimator packet over completion-operator, regular-rational, stream-window, dyadic-ledger, Real-seal, residual-bound, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCompletionErrorEstimator}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected completion limits, quotient representative equality, host real equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires Lean encoding of the carrier, NameCert obligation surface, a posteriori bound route, transport stability, replay stability, and nonescape for BEDC.Derived.CauchyCompletionErrorEstimatorUp.

Chapter 8498

A Concrete Naming Certificate for $\mathsf{CompactMetricRegularSequence}^{\uparrow}$

Following Bishop and Bridges on compact metric spaces, finite nets, and regular Cauchy real names, the $\mathsf{CompactMetricRegularSequence}^{\uparrow}$ packet records the finite route by which a compact metric source supplies regular sequence data before a completion-facing consumer reads a real-name seal. It sits over the compact metric source of chapter 129, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name boundary of chapter 38. It is the base compact-metric regular-sequence packet consumed by the compact regular Cauchy subsequence route of chapter 3913; it does not assert open-cover compactness, countable choice, a host-selected limit, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8498.1 (Compact metric regular sequence carrier)**.** *A* $\mathsf{CompactMetricRegularSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, S, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *source row carrying finite-net, located-distance, and compact inspection data.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row for the source sequence windows inspected by the compact metric consumer.*
3. *W is the finite window ledger pairing requested precisions with inspected compact-net cells and source sequence windows.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for compact mesh radii, window distances, and regular Cauchy budgets.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed windows and dyadic budgets.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, exposed only after the compact source, finite windows, dyadic tolerances, and regular rational readback have been displayed.*
7. *H records componentwise* hsame *transport for K, S, W, D, R, E and for the structural rows.*
8. *C records displayed* Cont *replay from compact inspection through finite windows, dyadic tolerance accounting, regular readback, and the Real seal.*

9. *P is the* Pkg *provenance over* $\mathsf{CompactMetricRegularSequence}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactMetricRegularSequence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $K, S, W, D, R, E, H, C, P, N$. It has no coordinate for a host-selected subsequence, open-cover compactness theorem, quotient stream representative, hidden real limit, countable choice, or ambient completion principle.

Theorem 8498.2 (Compact metric regular sequence NameCert obligations)**.** *For every accepted* $\mathsf{CompactMetricRegularSequence}^{\uparrow}$ *carrier $M = (K, S, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CompactMetricRegularSe}}$ *surface consists exactly of compact-metric source exposure through K, source-window exposure through S, finite-window ledger exposure through W, dyadic tolerance accounting through D,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R,* $\mathsf{Real}^{\uparrow}$ *seal handoff through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8498.1. The finite packet exposes exactly the compact metric source, source stream windows, inspected finite-window ledger, dyadic tolerance ledger, regular rational readback, Real seal, and structural rows.

Read the analytic rows in order. The row K supplies only displayed compact metric inspection data, while S and W record the finite source windows and compact-net cells inspected at each requested precision.

The handoff is then forced through D, R, E. Dyadic budgets are recorded in D, regular rational readback is recorded in R, and the Real seal E is reached only after those rows are visible. Finally H, C, P, N transport, replay, source, and name the same finite packet, so no additional NameCert obligation is available outside the displayed rows. □

Theorem 8498.3 (Compact metric regular sequence finite-net handoff)**.** *Every* $\mathsf{CompactMetricRegularSequence}^{\uparrow}$ *consumer that requests regular sequence data must first read the finite route*

$$\mathsf{CompactMetric}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}.$$

The compact metric source supplies finite-net cells, the stream row supplies inspected windows, the dyadic ledger supplies mesh and tail budgets, and the regular rational row supplies the displayed readback before any $\mathsf{Real}^{\uparrow}$ *seal is exposed.*

Proof. Begin with an accepted carrier $M = (K, S, W, D, R, E, H, C, P, N)$. The compact source row K is the only compact metric coordinate, and the source observations are read through S and the finite ledger W.

Use the finite-net data in K together with the displayed windows in W. For a requested precision, the consumer receives a compact-net cell and the source observations inspected in that cell rather than an unrecorded compactness theorem.

The dyadic and regular rows complete the handoff. The ledger D records the mesh radius and tail budget, and R repacks the inspected windows as $\mathsf{RegSeqRat}^{\uparrow}$ readback data. Transport and replay through H, C, P, N preserve this route, so the consumer reaches E only after the finite-net handoff has been displayed. □

Theorem 8498.4 (Compact metric regular sequence Cauchy readback)**.** *Every completion-facing consumer of an accepted* $\mathsf{CompactMetricRegularSequence}^{\uparrow}$ *carrier reads the Cauchy evidence through the displayed sequence*

$$K, S, W, D, R, E, H, C, P, N.$$

In particular, CompactMetricRegularSequence$^{\uparrow}$ *can feed the compact regular Cauchy subsequence packet of chapter 3913 only by exporting finite windows, dyadic budgets,* RegSeqRat$^{\uparrow}$ *readback,* hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *naming; it does not export a host-selected limit or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start from the finite-net handoff theorem, Definition 8498.3. It confines regular sequence data to the compact source, finite stream windows, dyadic budget ledger, and regular rational readback.

Apply the NameCert obligation theorem, Definition 8498.2. The obligation surface keeps $K, S, W, D, R, E, H, C, P, N$ jointly visible, so downstream completion consumers cannot discard the compact-net or dyadic-budget rows while retaining the readback.

Finally compare the downstream compact regular Cauchy subsequence route of Definition 3913.3. That packet may consume the displayed regular readback and Real seal boundary, but this carrier itself supplies only the finite-window Cauchy evidence named in the theorem. Host-selected limits, ambient completeness, quotient equality, and countable choice remain outside the exported surface. □

Closure status for NameCert$_{\text{CompactMetricRegularSequence}^{\uparrow}}$.

Constructive story: A CompactMetricRegularSequence$^{\uparrow}$ packet is generated from a CompactMetric finite-net source row, StreamName finite windows, a finite window ledger, DyadicRatCore tolerance rows, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CompactMetricRegularSequence}^{\uparrow}}$, seed)

Scope closed: Definition 8498.1, Definition 8498.2, Definition 8498.3, and Definition 8498.4 seed the compact-metric regular sequence route over CompactMetric, StreamName, DyadicRatCore, RegSeqRat, and RealUp rows.

Formal verification: FormalStatus(NameCert$_{\text{CompactMetricRegularSequence}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, countable choice, quotient stream equality, host sequence equality, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact finite-net exposure, source-window exposure, dyadic tolerance accounting, RegSeqRat readback exactness, RealUp seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompactMetricRegularSequenceUp.

Chapter 8499

A Concrete Naming Certificate for $\mathsf{DunfordPettisOperator}^{\uparrow}$

Following Dunford–Schwartz and Schaefer on completely continuous operators between Banach spaces, the $\mathsf{DunfordPettisOperator}^{\uparrow}$ packet records the finite BEDC operator carrier that sends weakly compact or weakly null inspection rows into compact-image and completely continuous handoff rows. It sits over the bounded-operator carrier of chapter 1644, the Banach endpoint certificates of chapter 90, the finite weak-test surface of chapter 3597, the weak-compactness request of chapter 6851, the compact-operator consumer of chapter 1952, and the Dunford–Pettis handoff row of chapter 6346. The chapter names an operator carrier; it does not import a host theorem asserting that every weakly compact row is compactly imaged, nor does it select weakly convergent subsequences or quotient operator equality.

Definition 8499.1 (Dunford–Pettis operator carrier)**.** *A* $\mathsf{DunfordPettisOperator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (X, Y, A, W, K, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *X is the source* $\mathsf{Banach}^{\uparrow}$ *row, naming the normed linear source and its displayed completeness data.*
2. *Y is the target* $\mathsf{Banach}^{\uparrow}$ *row, naming the codomain Banach carrier read by compact-image consumers.*
3. *A is the* $\mathsf{BoundedLinearOperator}^{\uparrow}$ *action row, carrying the bounded linear map from X to Y only as displayed operator data.*
4. *W is the* $\mathsf{WeakTopology}^{\uparrow}$ *finite-test row, listing the weak probes and tolerances through which bounded or weakly null input families are inspected.*
5. *K is the* $\mathsf{WeakCompactness}^{\uparrow}$ *request row, read as a compactness-facing demand on inspected input windows rather than as a completed weak-compactness theorem.*
6. *Q is the compact-image or completely-continuous handoff row consumed by* $\mathsf{CompactOperator}^{\uparrow}$ *and* $\mathsf{DunfordPettis}^{\uparrow}$ *readers.*
7. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for operator norms, weak probe values, compact-image radii, and tolerance ledgers.*

8. *H records componentwise* hsame *transport for the Banach endpoints, bounded operator action, weak tests, weak-compactness request, compact-image handoff, scalar readback, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay through the same operator packet for weak-compactness, compact-operator, and Dunford–Pettis consumers.*

10. *P is the* Pkg *provenance over* $\mathsf{DunfordPettisOperator}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{BoundedLinearOperator}^{\uparrow}$, $\mathsf{WeakTopology}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, $\mathsf{CompactOperator}^{\uparrow}$, $\mathsf{DunfordPettis}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{DunfordPettisOperator}^{\uparrow}}$ *row.*

The classifier accepts only packets exhausted by $X, Y, A, W, K, Q, R, H, C, P, N$. It has no coordinate for a host compactness theorem, a selected weakly convergent subsequence, quotient equality of operators, Banach–Alaoglu, countable choice, or ambient dual-space identification.

Lean4 (statement) `BEDC.Derived.DunfordPettisOperatorUp`

Theorem 8499.2 (Dunford–Pettis operator NameCert obligations)**.** *For the carrier of Definition 8499.1, the local* $\mathsf{NameCert}_{\mathsf{DunfordPettisOperator}^{\uparrow}}$ *surface consists exactly of source and target Banach admission, bounded-linear-operator action admission, finite weak-test visibility, weak-compactness request visibility, compact-image or completely-continuous handoff exactness, Real scalar readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the packet $T = (X, Y, A, W, K, Q, R, H, C, P, N)$. The Banach endpoint rows X, Y and the bounded-linear-operator row A supply the operator carrier before any compactness-facing consumer can read it.

The weak side is also displayed. The finite weak-test row W and the weak-compactness request row K are read before the handoff row Q, so the compact-image or completely-continuous conclusion remains attached to visible weak data.

The scalar row R supplies only the listed operator-norm, probe, radius, and tolerance readbacks. The structural rows H, C, P, N transport, replay, source, and name the same finite packet.

Since no coordinate stores a host compactness theorem, selected subsequence, quotient operator equality, Banach–Alaoglu principle, countable-choice schedule, or dual-space identification, the NameCert obligations are exactly the displayed rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordPettisOperator}^{\uparrow}}$.

Constructive story: A $\mathsf{DunfordPettisOperator}^{\uparrow}$ packet is generated from source and target Banach rows, a bounded-linear-operator action, weak-topology finite tests, a weak-compactness request, a compact-image or completely-continuous handoff, Real scalar readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DunfordPettisOperator}^{\uparrow}}$, seed)

Scope closed: Definition 8499.1 and Definition 8499.2 seed the finite operator carrier linking Banach endpoints, bounded linear action, weak tests, weak-compactness requests, and compact-image handoff rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DunfordPettisOperator}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.DunfordPettisOperatorUp`

Bridge status: none

Not claimed: This chapter does not close a host Dunford–Pettis theorem, selected weakly convergent subsequences, quotient equality of operators, Banach–Alaoglu, countable choice, ambient dual-space identification, theoremChecked Lean status, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Banach endpoint compatibility, bounded operator action, finite weak-test visibility, weak-compactness request visibility, compact-image handoff exactness, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.DunfordPettisOperatorUp.

Chapter 8500

A Concrete Naming Certificate for $\mathsf{DaugavetProperty}^{\uparrow}$

Following Kadets and Shvidkoy on the Daugavet property in Banach-space geometry, the $\mathsf{DaugavetProperty}^{\uparrow}$ packet records the finite row surface by which a Banach carrier exposes the rank-one norm equation to later operator and geometry consumers. It sits over the norm carrier of chapter 89, the Banach rows of chapter 90, the scalar-functional surface of chapter 5790, the linear-map carrier of chapter 48, and the James-space comparison packet of chapter 6468. The packet names a displayed rank-one equation ledger; it is not a host class of all rank-one operators, not a selected norming functional, not a quotient operator algebra, and not an ambient compactness or reflexivity theorem.

Definition 8500.1 (Daugavet property carrier)**.** *A* $\mathsf{DaugavetProperty}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (B, N, F, L, R, J, E, H, C, P, A)$$

with the following displayed rows:

1. *B is the* $\mathsf{Banach}^{\uparrow}$ *source row whose vector and completeness reads are visible to the packet.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row used to compare the identity-plus-operator norm with the operator norm.*
3. *F is the* $\mathsf{BoundedLinearFunctional}^{\uparrow}$ *row naming the scalar functional in the displayed rank-one factorization.*
4. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the vector action used by the same rank-one factorization.*
5. *R is the rank-one operator ledger, recording the finite factorization data read through F and L.*
6. *J is the* $\mathsf{JamesSpace}^{\uparrow}$ *comparison row, present only as a Banach-geometry sibling and not as a reflexivity theorem.*
7. *E is the equation row recording that the displayed rank-one read is judged against the norm equation $\|I + T\| = 1 + \|T\|$.*
8. *H records componentwise* hsame *transport for the Banach, norm, functional, linear-map, rank-one, James-space, equation, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the same finite rows.*
10. *P is the* Pkg *provenance over* $\mathsf{DaugavetProperty}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{BoundedLinearFunctional}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{JamesSpace}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. A is the local $\mathsf{NameCert}_{\mathsf{DaugavetProperty}^{\uparrow}}$ *row.*

The classifier accepts only packets whose Daugavet read is exhausted by $B, N, F, L, R, J, E, H, C, P, A$*. It has no coordinate for all bounded operators on the host space, a selected norming vector, a quotient operator class, weak compactness, reflexivity, or an ambient Banach-space theorem outside the displayed rows.*

Theorem 8500.2 (Daugavet property rank-one equation)**.** *For every accepted* $\mathsf{DaugavetProperty}^{\uparrow}$ *carrier*

$$D = (B, N, F, L, R, J, E, H, C, P, A),$$

any consumer read of the rank-one equation must first expose the Banach source row B*, the norm row* N*, the bounded-functional row* F*, the linear-map row* L*, and the rank-one ledger* R*. Only after those rows are visible may the equation row* E *be read as the finite statement that the displayed rank-one operator* T *satisfies* $\|I+T\| = 1+\|T\|$ *for the named Banach row. The* $\mathsf{JamesSpace}^{\uparrow}$ *row* J *remains a comparison surface, and the structural rows* H, C, P, A *transport, replay, source, and name the same packet.*

Proof. Project the carrier of Definition 8500.1. Rows B and N expose the Banach source and norm comparison data before any operator equation is available.

The rank-one stage is F, L, R. The bounded functional and linear-map rows name the displayed factorization, and the ledger R records that the operator read is finite and local to those rows.

Only then can the equation row E be consumed. It records the equality for the displayed rank-one operator and the displayed Banach norm, while J stays a sibling comparison row rather than a source of reflexivity or weak compactness.

Finally H, C, P, A keep the same finite route under transport, replay, provenance, and local naming. Since the carrier has no coordinate for a host operator space, selected norming data, quotient equality, or ambient Banach theorem, the consumer cannot export any of those endpoints. □

Closure status for $\mathsf{NameCert}_{\mathsf{DaugavetProperty}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DaugavetProperty}^{\uparrow}$ packet is generated from Banach source rows, Norm rows, bounded linear functional rows, LinearMap rows, rank-one operator ledgers, JamesSpace comparison rows, an equation row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{DaugavetProperty}^{\uparrow}}$, seed)

Scope closed: Definition 8500.1 and Definition 8500.2 seed the finite rank-one norm-equation route over displayed Banach, Norm, BoundedLinearFunctional, LinearMap, JamesSpace, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{DaugavetProperty}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a host space of all bounded operators, selected norming vectors, quotient operator equality, weak compactness, reflexivity, Lean verification, bridge checking, or an ambient Banach-space theorem.

Upgrade path: Obligation closure requires checked carrier admission, Banach source exposure, norm comparison exactness, bounded-functional and linear-map factorization, rank-one ledger stability, James-space comparison nonescape, equation readback, transport, replay, provenance, and local naming for BEDC.Derived.DaugavetPropertyUp.

Chapter 8501

A Concrete Naming Certificate for $\mathsf{DyadicRoundingInterval}^{\uparrow}$

Following Bishop and Bridges on constructive real approximation by rational intervals, the $\mathsf{DyadicRoundingInterval}^{\uparrow}$ packet records the finite lower–upper dyadic enclosure obtained from one displayed rounding request. It sits over the dyadic arithmetic source of chapter 291, the lower-grid route of chapter 1416, the upper-grid route of chapter 1690, the signed normal-form boundary of chapter 1865, the finite observation window of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names an interval produced by finite rounding rows, not a host order decision, quotient real equality, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8501.1 (Dyadic rounding interval carrier)**.** *A* $\mathsf{DyadicRoundingInterval}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (D, Q, F, U, S, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *source row carrying the dyadic arithmetic ledger and requested scale.*
2. *Q is the rounding request row naming the inspected value, precision, and outward-rounding direction as finite data.*
3. *F is the lower endpoint row read through the dyadic floor route of chapter 1416.*
4. *U is the upper endpoint row read through the dyadic ceiling route of chapter 1690.*
5. *S is the* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$ *row that keeps both endpoints in the same signed normal-form convention.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which the request is observed.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row served by the same window and endpoint pair.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, Q, F, U, S, W, R are displayed.*
9. *H records componentwise* hsame *transport for the dyadic source, request, endpoints, signed normal form, window, readback, Real seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay of the same finite route from a rounding-interval request.*

11. *P records* Pkg *provenance over* $\mathsf{DyadicRoundingInterval}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, *the floor and ceiling endpoint routes,* $\mathsf{SignedDyadicNormalForm}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRoundingInterval}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, Q, F, U, S, W, R, E, H, C, P, N$. It has no coordinate for host trichotomy, quotient real equality, selected representatives, a global rounding oracle, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8501.2 (Dyadic rounding interval NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRoundingInterval}^{\uparrow}$ *carrier*

$$I = (D, Q, F, U, S, W, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRoundingInterval}^{\uparrow}}$ *surface consists exactly of DyadicRatCore source exposure through D, rounding-request exposure through Q, lower endpoint exposure through F, upper endpoint exposure through U, signed normal-form exposure through S, finite-window exposure through W, RegSeqRat readback through R, Real seal exposure through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The dyadic source row D and rounding request row Q determine the displayed scale and the finite request; no host comparison service is available outside those rows.

Next read the two endpoint rows. The lower endpoint F is supplied by the floor route, the upper endpoint U by the ceiling route, and S forces both endpoints to share the signed normal-form convention before any stream or regular readback is consumed.

Finally W, R, E, H, C, P, N expose the observation window, regular rational readback, terminal Real seal, transport, replay, provenance, and local name. Since the carrier contains no coordinate for trichotomy, quotient equality, selected representatives, global rounding, choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8501.3 (Dyadic rounding interval containment route)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{DyadicRoundingInterval}^{\uparrow}$ *carrier must read the displayed route*

$$D, Q, F, U, S, W, R, E, H, C, P, N.$$

The consumer receives the lower endpoint F and upper endpoint U as one signed dyadic interval before reading R or E, and the interval is transported only componentwise through H and replayed only through C.

Proof. Begin with the carrier projection. The source and request rows D, Q identify one finite rounding query, so the endpoint rows are not independent witnesses from separate searches.

Read F, U, S next. The lower and upper endpoint rows form the displayed dyadic interval, and the signed normal-form row keeps them in the same endpoint convention before the observation window is served.

The regular and Real-facing rows are downstream. The StreamName window W and RegSeqRat readback R must be exposed before the terminal Real seal E can consume the interval, while H, C, P, N preserve only that same route. Hence containment is a finite interval route rather than an ambient order fact. □

Theorem 8501.4 (Dyadic rounding interval nonescape)**.** *No accepted* $\mathsf{DyadicRoundingInterval}^{\uparrow}$ *carrier exports a host rounding operator, a trichotomy decision for arbitrary real names, quotient*

equality of real representatives, a selected endpoint representative, countable-choice search, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. Any consumer that reaches the interval must remain inside the rows* $D, Q, F, U, S, W, R, E, H, C, P, N$.

Proof. Inspect the carrier coordinates. They contain dyadic source data, one request, two endpoint rows, signed normal form, window and readback rows, a Real seal, and structural rows for transport, replay, provenance, and naming.

None of the excluded principles is a coordinate of the carrier or a consequence of a structural row. Componentwise hsame transport preserves the displayed endpoint rows, Cont replay replays the same finite route, and Pkg provenance records only the named dependencies.

Therefore every interval-facing read stays inside $D, Q, F, U, S, W, R, E, H, C, P, N$. A consumer claiming host rounding, trichotomy, quotient equality, selected representatives, choice, or ambient completeness has left the accepted NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRoundingInterval}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicRoundingInterval}^{\uparrow}$ packet is generated from a DyadicRatCore source row, a rounding request, floor and ceiling endpoint rows, signed dyadic normal-form data, StreamName finite windows, RegSeqRat readback, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicRoundingInterval}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8501.1, Definition 8501.2, Definition 8501.3, and Definition 8501.4 seed the finite rounding-interval route over dyadic source, rounding request, lower endpoint, upper endpoint, signed normal form, finite window, regular readback, Real seal, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicRoundingInterval}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host rounding, trichotomy for arbitrary real names, quotient real equality, selected endpoint representatives, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires Lean encoding of the carrier, NameCert obligation surface, containment route, nonescape theorem, transport stability, replay stability, and provenance rows for BEDC.Derived.DyadicRoundingIntervalUp.

Chapter 8502

A Concrete Naming Certificate for $\mathsf{ClosedGraphCertificate}^{\uparrow}$

Following Banach's closed graph theorem tradition and the Bishop–Bridges reading of metric completeness, the $\mathsf{ClosedGraphCertificate}^{\uparrow}$ packet records graph-closedness as finite BEDC carrier data before it is consumed by the theorem-level route of chapter 1537. It sits over the metric observation surface of chapter 57, the complete-metric boundary of chapter 128, the metric-completion interface of chapter 1506, the Banach source row of chapter 90, and the finite StreamName, RegSeqRat, and Real readback route of chapter 126, chapter 301, and chapter 38. The certificate names the displayed graph-closedness surface itself, not the surrounding boundedness conclusion, open mapping theorem, bounded inverse theorem, quotient function space, or host-level graph equality.

Definition 8502.1 (Closed graph certificate carrier)**.** *A* $\mathsf{ClosedGraphCertificate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, Y, F, G, Q, S, R, E, H, C, P, N)$$

with the following visible rows:

1. *X is the source metric or Banach row, read through* $\mathsf{Met}^{\uparrow}$*,* $\mathsf{CompleteMetric}^{\uparrow}$*, or* $\mathsf{Banach}^{\uparrow}$ *observations.*
2. *Y is the target metric or Banach row, read through the same displayed complete-metric vocabulary.*
3. *F is the finite function-action row, containing the inspected source addresses and their displayed target addresses.*
4. *G is the graph-membership row, recording the finite source–target pairs accepted as graph data for F.*
5. *Q is the graph-closedness witness row, recording the sequential test: a scheduled source route converges in X, its graph targets converge in Y, graph membership persists along the schedule, and the target limit is accepted as the graph value for the source limit.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row selecting the finite source, target, graph, and convergence windows used by the test.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational metric and convergence estimates on the scheduled windows.*

8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for distance and bound reads consumed by metric or completion-facing consumers.*
9. *H records componentwise* hsame *transport for source, target, function action, graph membership, graph-closedness witness, schedule, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from metric and completion admission through graph inspection, sequential closure, and real-seal handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{ClosedGraphCertificate}^{\uparrow}$, $\mathsf{ClosedGraphTheorem}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}^{\uparrow}}$ *row.*

The carrier has no coordinate for a boundedness theorem, an open-mapping theorem, a bounded-inverse theorem, host graph equality, selected limits, quotient function spaces, or ambient completeness beyond the displayed rows X and Y.

Theorem 8502.2 (Closed graph certificate NameCert obligations)**.** *For an accepted* $\mathsf{ClosedGraphCertificate}^{\uparrow}$ *carrier $K = (X, Y, F, G, Q, S, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}^{\uparrow}}$ *surface consists exactly of carrier admission, source and target metric readback, function-action exposure, graph-membership exactness, sequential graph-closedness, finite schedule and rational readback, real-seal non-escape, componentwise transport, displayed replay, package provenance, and local naming. Each obligation is read through the finite route*

$$X, Y, F, G, Q, S, R, E, H, C, P, N.$$

Proof. Project the carrier of Definition 8502.1. The displayed rows are exactly $X, Y, F, G, Q, S, R, E, H, C, P, N$, so carrier admission and local naming are immediate readings of the packet.

Read the analytic rows first. The source and target rows X, Y supply metric or Banach observations, F supplies the inspected function action, and G supplies the graph-membership pairs accepted for that action.

The graph-closedness row Q then supplies the sequential test. It can be inspected only along the windows selected by S, the rational estimates read by R, and the real-facing seals in E.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since no further coordinate remains, the listed obligations exhaust the local $\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}^{\uparrow}}$ surface and no theorem-level boundedness conclusion is exported by the certificate alone. □

Theorem 8502.3 (Closed graph certificate sequential route)**.** *Every completion-facing or theorem-facing consumer of an accepted* $\mathsf{ClosedGraphCertificate}^{\uparrow}$ *carrier*

$$K = (X, Y, F, G, Q, S, R, E, H, C, P, N)$$

must read graph-closedness through the sequential route

$$X, Y, F, G, S, R, E, Q, H, C, P, N.$$

The route may feed the $\mathsf{ClosedGraphTheorem}^{\uparrow}$ *packet of chapter 1537, but it does not by itself assert local boundedness, continuity, a host graph equality, a quotient function-space equality, selected limits, or ambient completeness.*

Proof. Begin with the graph rows. The consumer sees the function-action row F and graph-membership row G only as displayed finite source–target observations.

Next read the sequential closure data. The schedule S selects the source and target windows, the readback row R supplies rational metric estimates, and the seal row E carries the metric values into a Real-facing read. The row Q accepts the limit graph value only along that same scheduled route.

Use the closed-graph theorem sibling only after this route is visible. chapter 1537 may consume the certificate as its graph-closedness input, while the certificate remains the smaller carrier-level surface named by Definition 8502.1.

Transport, replay, provenance, and local naming are then supplied by H, C, P, N. None of those structural rows adds a boundedness theorem, a quotient function-space object, or a selected host limit, so the sequential graph-closedness route is exactly the displayed finite route. □

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}\uparrow}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8502.1, Definition 8502.2, and Definition 8502.3 seed the finite graph-closedness certificate over displayed metric, completion, function-action, graph-membership, StreamName, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedGraphCertificate}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, local boundedness, continuity, open mapping, bounded inverse, quotient function-space equality, selected limits, or ambient completeness.

Upgrade path: Obligation closure requires checked carrier admission, graph-membership exactness, sequential graph-closedness, finite schedule readback, real-seal non-escape, classifier stability, and theorem-facing handoff for the same finite certificate.

Constructive story: The construction starts from displayed source and target metric rows, records finite graph membership, tests graph closure through scheduled sequential windows, and exports only the local certificate consumed by the closed-graph theorem route.

Chapter 8503

A Concrete Naming Certificate for $\mathsf{CatalanNumber}^{\uparrow}$

Following Stanley's enumerative combinatorics and Feller's Dyck-path ballot analysis, the $\mathsf{CatalanNumber}^{\uparrow}$ packet records Catalan data as finite prefix rows rather than as a completed counting theorem. It sits over the unary index carrier of chapter 28, the finite spine carrier of chapter 36, and the binary-tree induction surface of chapter 5910. The packet names one displayed Catalan object at a fixed size: a Dyck-prefix ledger, a matched binary-tree row, a finite count row, transport, replay, provenance, and local naming. It does not assert analytic generating-function identities, quotient equality of trees, or a host enumeration principle.

Definition 8503.1 (Catalan number carrier)**.** *A* $\mathsf{CatalanNumber}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (n, W, P, T, C, H, R, G, N)$$

with the following displayed rows:

1. *n is the* $\mathsf{Nat}^{\uparrow}$ *size row.*
2. *W is the finite* $\mathsf{List}^{\uparrow}$ *word row of left and right steps.*
3. *P is the Dyck-prefix ledger: every prefix of W has nonnegative balance, and the terminal balance is zero.*
4. *T is the* $\mathsf{BinaryTree}^{\uparrow}$ *row obtained by matching each left step with its closing right step.*
5. *C is the finite* $\mathsf{Nat}^{\uparrow}$ *count row naming the Catalan value attached to the displayed size row.*
6. *H records componentwise* hsame *transport for the size, word, prefix ledger, tree row, count row, replay, provenance, and local naming rows.*
7. *R records displayed* Cont *replay from a Dyck-prefix request to the tree row and count row.*
8. *G is the* Pkg *provenance over* $\mathsf{CatalanNumber}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, $\mathsf{BinaryTree}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{CatalanNumber}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for infinite paths, unbounded search, quotient tree equality, analytic generating functions, or an external cardinality theorem.

Theorem 8503.2 (Catalan number NameCert obligations)**.** *For every accepted* $\mathsf{CatalanNumber}^{\uparrow}$ *carrier* $K = (n, W, P, T, C, H, R, G, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CatalanNumber}^{\uparrow}}$ *surface consists exactly of size admission, finite word admission, Dyck-prefix balance, binary-tree matching, Catalan count naming, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from analytic or quotient enumeration principles.*

Proof. Project the carrier. The size row n is read through $\mathsf{Nat}^{\uparrow}$, while W is a finite $\mathsf{List}^{\uparrow}$ word row whose positions are the only inspected steps.

The Dyck-prefix ledger P supplies the balance checks. Since every prefix row is displayed and the terminal balance is zero, the packet never appeals to an infinite path or to unbounded search.

The tree row T is obtained only after the prefix ledger has been read. Matching a left step with its closing right step is therefore a finite operation over the displayed word, and the count row C names the resulting Catalan value at the same size row.

The structural rows H, R, G, N transport, replay, source, and name this finite route. Because the carrier has no coordinate for quotient tree equality, generating functions, or an external enumeration theorem, the local NameCert obligations are exhausted by the displayed rows. □

Theorem 8503.3 (Catalan Dyck-prefix induction route)**.** *Every accepted* $\mathsf{CatalanNumber}^{\uparrow}$ *packet admits the finite decomposition route*

$$W = L\,U\,R\,V$$

where the first left step L *is matched by the first return right step* R*, the interior word* U *and suffix word* V *are again displayed Dyck-prefix rows, and the associated* $\mathsf{BinaryTree}^{\uparrow}$ *read decomposes into the root node with left subtree from* U *and right subtree from* V*. The route is read only from the* $\mathsf{Nat}^{\uparrow}$ *size row, the* $\mathsf{List}^{\uparrow}$ *word row, the Dyck-prefix ledger, and the* $\mathsf{BinaryTree}^{\uparrow}$ *matching row.*

Proof. Begin with an accepted packet $K = (n, W, P, T, C, H, R, G, N)$. If W is empty, the terminal balance row in P gives the empty Dyck word and the binary-tree row T is the empty tree boundary.

For a nonempty accepted word, the first step must be a left step. A right step would make the first prefix balance negative, contradicting the displayed prefix ledger P.

Read along the finite $\mathsf{List}^{\uparrow}$ spine until the first return to balance zero. The ledger P displays each inspected balance, so the chosen return is a finite row inside the packet. The part between the first left step and this return has nonnegative shifted prefix balance, and the suffix after the return starts again at balance zero.

The matching row T reads the same decomposition as a binary tree. The interior word gives the left subtree, the suffix gives the right subtree, and the root is the displayed first matched pair. Transport by H and replay by R preserve the same finite decomposition for any transported packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CatalanNumber}^{\uparrow}}$.

Constructive story: A $\mathsf{CatalanNumber}^{\uparrow}$ packet is generated from a NatUp size row, a finite ListUp Dyck word row, a displayed prefix-balance ledger, a BinaryTreeUp matching row, a NatUp count row, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CatalanNumber}^{\uparrow}}$, seed)

Scope closed: Definition 8503.1, Definition 8503.2, and Definition 8503.3 seed the finite Dyck-prefix and binary-tree route for Catalan number packets.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CatalanNumber}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Catalan recurrence uniqueness, generating-function identities, quotient tree equality, host enumeration theorems, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Dyck-prefix balance, binary-tree matching, count-row naming, transport, replay, provenance, and local naming for BEDC.Derived.CatalanNumberUp.

Chapter 8504

A Concrete Naming Certificate for $\mathsf{FiniteModulusMesh}^{\uparrow}$

The $\mathsf{FiniteModulusMesh}^{\uparrow}$ packet realizes the compact-uniform-continuity route of chapter 9237 as finite mesh data. It consumes compact-net cells from chapter 129, continuous-map pointwise modulus rows from chapter 130, dyadic tolerance rows from chapter 291, Real readback from chapter 38, and the terminal uniform-modulus handoff of chapter 369. The packet names the mesh itself: compact cells, pointwise-radius witnesses, dyadic tolerances, a finite lower-bound fold, a triangle-estimate ledger, a tolerance-only $\mathsf{UniformModulus}^{\uparrow}$ output, transport, replay, provenance, and local naming.

Definition 8504.1 (Finite modulus mesh carrier)**.** *A* $\mathsf{FiniteModulusMesh}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (K, F, D, Q, L, T, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact-net cell row over the compact metric source.*
2. *F is the pointwise modulus row attached to the continuous-map data at the displayed cell centers.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row read by the mesh.*
4. *Q is the finite mesh incidence ledger pairing each compact-net cell with its local modulus and dyadic tolerance request.*
5. *L is the finite lower-bound fold over the displayed radius rows.*
6. *T is the triangle-estimate ledger that keeps source and target metric comparisons visible before the output row is exported.*
7. *U is the tolerance-only* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row.*
8. *H records componentwise* hsame *transport for compact cells, pointwise moduli, dyadic tolerances, incidence, lower-bound fold, triangle ledger, output, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay through the same mesh route.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusMesh}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusMesh}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, D, Q, L, T, U, H, C, P, N$. It has no coordinate for a selected subcover outside the packet, a host Lebesgue number, quotient metric equality, countable choice, or ambient compactness.

Theorem 8504.2 (Finite modulus mesh NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusMesh}^{\uparrow}$ *carrier* $M = (K, F, D, Q, L, T, U, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusMesh}^{\uparrow}}$ *surface consists exactly of compact-net cell admission, pointwise-modulus visibility, dyadic tolerance admission, finite incidence coverage, lower-bound fold exactness, triangle-estimate replay, uniform-modulus output admission, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, local naming, and non-escape from selector or completeness principles.*

Proof. Project the packet. The compact-net row K, pointwise-modulus row F, and dyadic tolerance row D are the only source rows available before the mesh ledger is opened.

The incidence ledger Q pairs each displayed cell with its local modulus and tolerance request. The fold row L is finite because it ranges only over the displayed incidence ledger.

The triangle ledger T records the source and target metric comparisons needed before the tolerance-only output row U can be exported. Thus the uniform-modulus handoff remains attached to compact-net, pointwise-modulus, dyadic, fold, and triangle evidence.

The rows H, C, P, N transport, replay, source, and name the same route. Since no carrier coordinate stores an external selector, host Lebesgue number, quotient metric equality, choice schedule, or ambient compactness theorem, the NameCert obligations are exactly the displayed rows. □

Theorem 8504.3 (Finite modulus mesh uniform handoff route)**.** *Every* $\mathsf{UniformModulus}^{\uparrow}$ *read exported by an accepted* $\mathsf{FiniteModulusMesh}^{\uparrow}$ *packet factors through*

$$K, F, D \longmapsto Q, L, T \longmapsto U, H, C, P, N.$$

In particular, a compact-uniform-continuity consumer cannot read the tolerance-only output before the compact-net cells, pointwise modulus rows, dyadic tolerance ledger, finite incidence ledger, lower-bound fold, and triangle-estimate ledger have all been displayed.

Proof. Start with an accepted carrier $M = (K, F, D, Q, L, T, U, H, C, P, N)$. Projection gives the compact-net cells, pointwise modulus rows, and dyadic tolerance row as the source stage.

The mesh stage is Q, L, T. The incidence ledger links cells to local moduli and tolerances, the lower-bound fold reads the finite radius rows, and the triangle ledger records the metric estimates used by the output route.

Only after this mesh stage does the carrier expose U. The structural rows H, C, P, N preserve, replay, source, and name the same route.

Therefore every accepted $\mathsf{UniformModulus}^{\uparrow}$ consumer sees the displayed finite mesh before it receives the tolerance-only handoff, and no external selector or compactness theorem is exported. □

Falsifiable prediction: An accepted $\mathsf{FiniteModulusMesh}^{\uparrow}$ read is refuted if a compact-uniform-continuity consumer exports a $\mathsf{UniformModulus}^{\uparrow}$ row without displaying compact-net cells, pointwise modulus rows, dyadic tolerance data, finite incidence coverage, lower-bound fold evidence, triangle-estimate replay, transport, provenance, and local naming.

Independence witness: compactmetric, continuousmap, dyadicratcore, real, uniformmodulus: none alone is bijective with $\mathsf{FiniteModulusMesh}^{\uparrow}$ because the packet jointly carries compact-net

cells, pointwise modulus rows, dyadic tolerances, Real-facing metric readback, finite fold data, triangle replay, a $\mathsf{UniformModulus}^{\uparrow}$ handoff, transport, replay, provenance, and local NameCert.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusMesh}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusMesh}^{\uparrow}$ packet is generated from compact-net cells, continuous-map pointwise modulus rows, dyadic tolerance rows, finite incidence coverage, a lower-bound fold, a triangle-estimate ledger, a UniformModulus output row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusMesh}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8504.1, Definition 8504.2, and Definition 8504.3 seed the finite compact-net, pointwise-modulus, dyadic-tolerance, fold, triangle, and uniform-modulus handoff route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusMesh}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected subcovers, host Lebesgue numbers, quotient metric equality, countable choice, ambient compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-net coverage, pointwise-modulus visibility, dyadic tolerance admission, fold exactness, triangle replay, uniform-modulus output, Nontrivial and FieldFaithful TasteGate instances, transport, provenance, and local naming for BEDC.Derived.FiniteModulusMeshUp.

Chapter 8505

A Concrete Naming Certificate for $\mathsf{FiniteTailOscillationBound}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ packet records the finite boundary by which a regular rational stream exposes a late-tail oscillation estimate before a Real or Completion consumer reads a seal. It sits after the finite stream names of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name surface of chapter 38, and the oscillation-modulus row of chapter 2224. The packet supplies a named finite tail-oscillation boundary without quotient stream equality, selected limits, ambient completeness, trichotomy, or countable choice.

Definition 8505.1 (Finite tail-oscillation bound carrier)**.** *A* $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, D, O, T, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected stream positions.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing the regular rational observations on those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare late observations.*
4. *O is the* $\mathsf{OscillationModulus}^{\uparrow}$ *row naming the finite oscillation schedule.*
5. *T is the tail-bound row, recording the displayed finite stage after which the D-bounded oscillation read is accepted.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only after S, R, D, O, T have been displayed.*
7. *H records componentwise* hsame *transport for the stream, readback, dyadic, oscillation, tail-bound, Real-seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the same finite route.*
9. *P records the* Pkg *provenance over* $\mathsf{FiniteTailOscillationBound}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{OscillationModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteTailOscillationBound}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, O, T, E, H, C, P, N$. It has no coordinate for ambient $\mathsf{Real}^{\uparrow}$ *completeness, quotient stream equality, selected limits, trichotomy, countable choice, or bridge checking.*

Theorem 8505.2 (Finite tail-oscillation bound NameCert obligations)**.** *For every accepted* FiniteTailOscillationBou *carrier*

$$B = (S, R, D, O, T, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteTailOscillationBound}^{\uparrow}}$ *surface consists exactly of finite stream-window exposure through S, regular rational readback through R, dyadic tolerance exposure through D, oscillation-modulus exposure through O, tail-bound exactness through T, Real-seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The only analytic rows available before the seal are the finite stream window S, the regular rational readback R, the dyadic tolerance ledger D, the oscillation-modulus row O, and the displayed tail-bound row T.

The tail-bound exactness is therefore finite. A consumer may inspect late observations only through the named windows and readback row, compare them only through the dyadic ledger, and spend only the oscillation schedule recorded by O.

Finally read E, H, C, P, N. The Real seal is downstream from the finite tail route, and the structural rows only transport, replay, source, and name that same route. Since no excluded endpoint is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8505.3 (Finite tail-oscillation bound Real route)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or Completion-facing read of an accepted* $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ *packet reaches the seal row E only through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{OscillationModulus}^{\uparrow} \longmapsto T \longmapsto \mathsf{Real}^{\uparrow}.$$

The read supplies a finite tail-oscillation boundary for regular Cauchy and Real-seal arguments; it does not identify quotient stream names, select a limit, invoke trichotomy or countable choice, or prove ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8505.2. They place the finite stream window, regular rational readback, dyadic tolerance ledger, oscillation schedule, and tail-bound row before the Real seal can be consumed.

The sibling dependencies give the displayed route. The StreamName row supplies finite windows, RegSeqRat supplies rational readback, DyadicRatCore supplies the tolerance comparisons, and OscillationModulus supplies the finite schedule that bounds the late tail.

The seal row E is therefore a downstream boundary, not an independent completeness theorem. Transport, replay, provenance, and local naming preserve the same finite route, so a Real or Completion consumer receives a named finite tail-oscillation boundary and none of the excluded quotient, choice, order, selected-limit, or completeness data. □

Theorem 8505.4 (Finite tail-oscillation bridge-consumer route)**.** *Any* $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ *consumer that also reads a* $\mathsf{FiniteModulusStaircase}^{\uparrow}$ *packet must factor the displayed tail-bound row through the staircase rows before the* $\mathsf{Real}^{\uparrow}$ *seal is consumed. Concretely, the consumer route has the finite form*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{OscillationModulus}^{\uparrow}, T \longmapsto \mathsf{FiniteModulusStaircase}^{\uparrow} \longmapsto E.$$

The staircase dependency is read through the carrier of Definition 8514.1; it does not supply a selected global modulus, infinite search, quotient stream equality, trichotomy, countable choice, selected limit, or ambient completeness theorem.

Proof. Start with the NameCert obligations of Definition 8505.2. They expose the tail-bound row T only after the finite window, regular readback, dyadic tolerance, and oscillation-modulus rows have been displayed.

Use the Real route theorem, Definition 8505.3. It places the seal row E downstream from the same finite tail-bound route, so a consumer cannot read E before the tail-bound row is fixed.

Now read the staircase carrier of Definition 8514.1. Its displayed rows place $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteModulusMesh}^{\uparrow}$, $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$, the staircase ledger, and the terminal handoff before its own Real-facing seal. A tail-bound consumer that imports this packet must therefore route T through those displayed staircase rows before consuming E.

The structural rows in both packets transport, replay, source, and name the same finite data. Since neither carrier contains a selected global modulus, infinite search, quotient equality, trichotomy, choice schedule, selected limit, or ambient completeness row, the bridge-consumer route is exactly the displayed finite staircase handoff. □

Falsifiable prediction: A $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ consumer that reaches a Real or Completion seal without displaying the StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, OscillationModulus schedule, tail-bound row, transport, replay, provenance, and local naming exits the accepted carrier.

Independence witness: streamname, regseqrat, dyadicratcore, oscillationmodulus, and real: no listed sibling is bijective with $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ because this packet jointly binds finite windows, rational readback, dyadic tolerances, an oscillation schedule, a tail-bound row, Real-seal exposure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteTailOscillationBound}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteTailOscillationBound}^{\uparrow}$ packet is generated from a StreamName finite-window row, RegSeqRat readback, DyadicRatCore tolerance ledger, OscillationModulus schedule, a finite tail-bound row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteTailOscillationBound}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8505.1, Definition 8505.2, Definition 8505.3, and Definition 8505.4 seed the finite tail-oscillation boundary over displayed stream-window, regular-rational, dyadic-tolerance, oscillation-modulus, staircase, tail-bound, Real, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteTailOscillationBound}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient stream equality, selected limits, trichotomy, countable choice, Lean verification, axiom-clean audit, or bridge checking for $\mathsf{FiniteTailOscillationBound}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular-readback exactness, dyadic-tolerance exactness, oscillation-schedule exposure, tail-bound exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteTailOscillationBoundUp.

Chapter 8506

A Concrete Naming Certificate for $\mathsf{FrobeniusNormalForm}^{\uparrow}$

Following Frobenius and the rational-canonical-form tradition, the $\mathsf{FrobeniusNormalForm}^{\uparrow}$ packet records the companion-block presentation of a displayed finite endomorphism as BEDC NameCert data. It sits between the matrix carrier of chapter 49, the linear-map surface of chapter 48, the polynomial rows of chapter 50, the invariant-factor packet of chapter 5843, the characteristic-polynomial route of chapter 6307, the block comparison boundary of chapter 6856, and the polynomial-matrix reduction route of chapter 2262. The packet names only the finite Frobenius companion-block certificate; it does not claim eigenvalue selection, algebraic closure, Jordan block decomposition, host similarity classification, or a detached canonical-form oracle.

Definition 8506.1 (Frobenius normal form carrier)**.** *A* $\mathsf{FrobeniusNormalForm}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, L, Q, S, R, B, A, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Mat}^{\uparrow}$ *presentation row for the displayed finite operator, including row-column windows and matrix multiplication requests.*
2. *L is the* $\mathsf{LinMap}^{\uparrow}$ *row naming the same endomorphism surface.*
3. *Q is the* $\mathsf{Poly}^{\uparrow}$ *row carrying the monic invariant-factor polynomials and the characteristic-polynomial ledger visible to the block read.*
4. *S is the* $\mathsf{SmithNormalForm}^{\uparrow}$ *dependency row for the polynomial-matrix reduction route that exposes the invariant factors.*
5. *R is the* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *handoff row, retaining the invariant-factor schedule used by the companion-block assembly.*
6. *B is the Frobenius companion-block row, listing one finite companion block for each displayed invariant factor in Q and the row-column positions used by the block sum.*
7. *A is the block-assembly exactness row, comparing the displayed* $\mathsf{Mat}^{\uparrow}$ *presentation with the companion-block presentation through the same* $\mathsf{LinMap}^{\uparrow}$ *endpoint.*
8. *T is the Cayley-Hamilton compatibility row, recording that the characteristic-polynomial ledger read through chapter 6307 is consumed only as a polynomial boundary for the displayed blocks.*

9. *H records componentwise* hsame *transport for the matrix, linear-map, polynomial, Smith-normal, rational-canonical, companion-block, exactness, Cayley-Hamilton, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from a Frobenius-form request through $M, L, Q, S, R, B, A, T, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{FrobeniusNormalForm}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, $\mathsf{SmithNormalForm}^{\uparrow}$, $\mathsf{RationalCanonicalForm}^{\uparrow}$, $\mathsf{CayleyHamilton}^{\uparrow}$, $\mathsf{JordanNormalForm}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FrobeniusNormalForm}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, L, Q, S, R, B, A, T, H, C, P, N$. It contains no coordinate for selected eigenvalues, algebraic closure, Jordan-chain splitting, quotient matrix equality, host similarity classification, non-displayed basis choice, or an ambient canonical-form theorem.

Theorem 8506.2 (Frobenius normal form NameCert obligations)**.** *For every accepted* $\mathsf{FrobeniusNormalForm}^{\uparrow}$ *carrier*

$$F = (M, L, Q, S, R, B, A, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrobeniusNormalForm}^{\uparrow}}$ *surface consists exactly of matrix exposure through M, linear-map exposure through L, invariant-factor polynomial exposure through Q, Smith-normal dependency routing through S, rational-canonical handoff through R, companion-block assembly through B, block exactness through A, Cayley-Hamilton compatibility through T, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8506.1. The finite operator source is M, L, the polynomial and reduction source is Q, S, and the canonical-form handoff is R.

The Frobenius block data are exactly B, A, T. The companion blocks are indexed by the displayed invariant-factor row, the exactness row compares the block matrix with the original matrix presentation, and the Cayley-Hamilton row is read only as a characteristic-polynomial compatibility boundary.

Finally H, C, P, N transport, replay, source, and name the same rows. Since no carrier coordinate contains eigenvalue selection, algebraic closure, Jordan-chain splitting, quotient equality, host similarity classification, non-displayed basis choice, or an ambient canonical-form theorem, the listed rows exhaust the NameCert surface. □

Theorem 8506.3 (Frobenius companion-block route)**.** *Every companion-block read exported by an accepted* $\mathsf{FrobeniusNormalForm}^{\uparrow}$ *packet factors through the finite route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{Poly}^{\uparrow}, \mathsf{SmithNormalForm}^{\uparrow}, \mathsf{RationalCanonicalForm}^{\uparrow} \longmapsto B, A, T \longmapsto \mathsf{FrobeniusNormalForm}^{\uparrow}.$$

The route exposes only invariant-factor polynomials, companion-block positions, block-assembly exactness, Cayley-Hamilton compatibility, transport, replay, provenance, and local naming.

Proof. Begin with the matrix and linear-map rows M, L. A companion-block consumer cannot read a Frobenius block before the endomorphism presentation and the polynomial row Q have been displayed.

Next use the Smith-normal and rational-canonical rows S, R. The invariant-factor schedule is obtained through the polynomial-matrix reduction route and then handed to the rational-canonical companion-block surface; it is not imported from a host classification oracle.

The rows B, A, T assemble and check the Frobenius blocks. Componentwise transport, replay, provenance, and local naming through H, C, P, N then preserve exactly this finite route, so the exported block read contains no Jordan-chain or spectral data. □

Theorem 8506.4 (Frobenius rational-canonical handoff)**.** *Any* $\mathsf{RationalCanonicalForm}^{\uparrow}$ *consumer that requests a Frobenius companion presentation from an accepted* $\mathsf{FrobeniusNormalForm}^{\uparrow}$ *packet must keep the invariant-factor schedule R, the polynomial row Q, the Smith-normal dependency S, the companion-block row B, and the exactness row A visible together. The handoff may compare with the Jordan packet of chapter 6856 only as a block-layout boundary, not as an algebraic-closure or eigenvector-selection source.*

Proof. Apply the NameCert obligations of Definition 8506.2. They require the rational-canonical handoff row, invariant-factor polynomial row, Smith-normal route, companion-block row, and exactness row to remain in the same accepted packet.

The rational-canonical chapter supplies the invariant-factor schedule, while the Frobenius packet records the companion-block presentation read from that schedule. Thus a consumer cannot detach the Frobenius blocks from Q, S, R without leaving the displayed NameCert surface.

The Jordan comparison is only a sibling boundary. Since the carrier has no eigenvalue or generalized-eigenvector coordinate, the handoff remains a rational-canonical companion-block route rather than a Jordan decomposition. □

Theorem 8506.5 (Frobenius finite nonescape)**.** *Every accepted* $\mathsf{FrobeniusNormalForm}^{\uparrow}$ *carrier exports a finite normal-form certificate over $M, L, Q, S, R, B, A, T, H, C, P, N$ and no other rows. In particular, a consumer cannot escape from the companion-block route to selected eigenvalues, algebraic closure, Jordan-chain splitting, quotient matrix equality, host similarity classification, non-displayed basis choice, or an ambient canonical-form theorem.*

Proof. The carrier predicate lists exactly twelve rows. The mathematical rows M, L, Q, S, R, B, A, T supply matrix presentation, endomorphism surface, invariant-factor polynomials, Smith-normal dependency, rational-canonical handoff, companion blocks, exactness, and Cayley-Hamilton compatibility.

The structural rows H, C, P, N then transport, replay, source, and name those rows without adding a further mathematical coordinate. Hence every consumer remains inside the finite packet.

All excluded data would require an extra row: eigenvalues or algebraic closure for spectral reads, Jordan chains for nilpotent splitting, quotient equality for host matrix comparison, or a selected basis outside the displayed carrier. Since the packet contains none of these rows, the export is nonescaping. □

Falsifiable prediction: A $\mathsf{FrobeniusNormalForm}^{\uparrow}$ consumer that exports companion blocks while omitting the Matrix, LinearMap, Polynomial, SmithNormalForm, RationalCanonicalForm, companion-block, exactness, Cayley-Hamilton, hsame, Cont, Pkg, or local NameCert rows refutes the carrier of Definition 8506.1.

Independence witness: matrix, linearmap, polynomial, smith-normal-form, rational-canonical-form, cayley-hamilton, jordan-normal-form: $\mathsf{FrobeniusNormalForm}^{\uparrow}$ is not bijective to any listed sibling because this packet alone binds invariant-factor polynomials to a finite Frobenius companion-block assembly with exactness, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FrobeniusNormalForm}^{\uparrow}}$.

Constructive story: A $\mathsf{FrobeniusNormalForm}^{\uparrow}$ packet is generated from Matrix rows, LinearMap rows, Polynomial invariant-factor rows, a SmithNormalForm dependency route, a RationalCanonicalForm handoff, finite companion-block assembly, block exactness, CayleyHamilton compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrobeniusNormalForm}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8506.1, Definition 8506.2, Definition 8506.3, Definition 8506.4, and Definition 8506.5 seed the finite Frobenius companion-block certificate over matrix, linear-map, polynomial, Smith-normal, rational-canonical, Cayley-Hamilton, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{FrobeniusNormalForm}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim selected eigenvalues, algebraic closure, Jordan-chain splitting, quotient matrix equality, host similarity classification, non-displayed basis choice, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, invariant-factor routing, companion-block assembly, rational-canonical handoff, Cayley-Hamilton compatibility, finite nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FrobeniusNormalFormUp.

Chapter 8507

A Concrete Naming Certificate for $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ packet records the finite limit-seal route by which regular Cauchy rational data are handed to a real-name consumer without selecting quotient representatives. It sits after the finite window discipline of chapter 126, the regular rational readback surface of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the choice-free completion route of chapter 4237. The packet is a finite NameCert limit boundary for completion-facing readers; it is not Real completeness, a quotient stream, a selected limit, countable choice, or host real equality.

Definition 8507.1 (RegularCauchyChoiceFreeLimit carrier)**.** *A* $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (S, R, D, C, E, H, T, P, N)$$

with the following displayed rows:

1. S *is the* $\mathsf{StreamName}^{\uparrow}$ *finite window schedule inspected by the limit request;*
2. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row attached to the scheduled windows;*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare readback windows;*
4. C *is the* $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$ *completion-facing route consumed before any limit seal is read;*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only through* S, R, D, C*;*
6. H *records componentwise* hsame *transport for the window, readback, dyadic, completion-route, seal, replay, provenance, and local naming rows;*
7. T *records displayed* Cont *replay for the same limit-seal route;*
8. P *is the* Pkg *provenance over* $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegularCauchyChoiceFreeCompletion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$*;*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}}$ *row.*

The classifier accepts only packets whose limit read is exhausted by $S, R, D, C, E, H, T, P, N$*. It has no coordinate for Real completeness, quotient stream equality, selected limits, countable-choice schedules, host real equality, or an ambient completion endpoint.*

Theorem 8507.2 (RegularCauchyChoiceFreeLimit NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ *carrier*

$$L = (S, R, D, C, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}}$ *surface consists exactly of finite-window exposure through* S*, regular rational readback through* R*, dyadic tolerance exposure through* D*, choice-free completion routing through* C*, terminal Real sealing through* E*, componentwise transport through* H*, displayed replay through* T*, provenance through* P*, and local naming through* N*.*

The obligation surface refuses Real completeness, quotient streams, selected limits, countable choice, host real equality, and ambient completion endpoints.

Proof. Project the carrier of Definition 8507.1. The displayed analytic rows are exactly the finite StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, completion route, and terminal Real seal.

Read those rows in order. The window schedule S bounds the observations, R supplies the regular rational readback, and D supplies the tolerance ledger before the completion-facing row C and Real seal E can be consumed.

Finally inspect the structural rows H, T, P, N. They transport, replay, source, and name the same finite packet. Since the excluded principles are absent from the carrier inventory, they cannot appear as local NameCert obligations. □

Theorem 8507.3 (RegularCauchyChoiceFreeLimit seal nonescape)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ *carrier*

$$L = (S, R, D, C, E, H, T, P, N)$$

must first read the finite route

$$S, R, D \longmapsto C \longmapsto E \longmapsto H, T, P, N.$$

The terminal seal exports only the displayed regular-Cauchy limit packet. It does not expose Real completeness, quotient streams, selected limits, countable choice, host real equality, or an ambient completion endpoint.

Proof. Start with the NameCert obligations of Definition 8507.2. They force every local read through the finite window, readback, dyadic tolerance, completion route, Real seal, and structural rows.

Use the sibling completion route of chapter 4237. The row C is consumed only after the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{DyadicRatCore}^{\uparrow}$ rows have been displayed, and it gives no quotient representative or selected limit.

Finally the $\mathsf{Real}^{\uparrow}$ seal row E is downstream of the same finite route. The transport, replay, provenance, and naming rows preserve that route rather than adding new analytic data, so no consumer can escape from the displayed limit packet to any refused endpoint. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ read exposes StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, RegularCauchyChoiceFreeCompletion routing, RealUp sealing, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any limit-facing consumer reads the seal.

Independence witness: streamname, regseqrat, dyadicratcore, real, regular-cauchy-choice-free-completion: none is bijective with $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ because this packet alone binds the finite window, regular readback, dyadic tolerance, choice-free completion route, and terminal limit seal while refusing quotient streams, selected limits, countable choice, and host real equality.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}$ packet is generated from StreamName windows, RegSeqRat readbacks, DyadicRatCore tolerance rows, RegularCauchyChoiceFreeCompletion route rows, RealUp seal rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8507.1, Definition 8507.2, and Definition 8507.3 seed the finite choice-free regular-Cauchy limit route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyChoiceFreeLimit}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Real completeness, quotient stream equality, selected limits, countable choice, host real equality, ambient completion endpoints, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window exposure, regular readback, dyadic tolerance stability, choice-free completion routing, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyChoiceFreeLimitUp.

Chapter 8508

A Concrete Naming Certificate for $\mathsf{NestedIntervalSequence}^{\uparrow}$

Following Cantor's nested-interval principle in the Bishop–Bridges constructive reading, the $\mathsf{NestedIntervalSequence}^{\uparrow}$ packet records a nested located interval sequence as finite BEDC certificate data before any Real or Completion consumer reads a limiting name. It sits over the located interval surface of chapter 394, the dyadic nested-interval sibling of chapter 328, the squeeze route of chapter 8247, the dyadic rational core of chapter 291, the finite observation interface of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names the interval-sequence surface itself: endpoint rows, nesting evidence, diameter budgets, finite-window readback, transport, replay, provenance, and local naming.

Definition 8508.1 (Nested interval sequence carrier)**.** *A* $\mathsf{NestedIntervalSequence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$N = (I, E, L, D, S, R, Z, H, C, P, A)$$

with the following displayed rows:

1. *I is the finite interval-row table, each row read as a located interval through* $\mathsf{LocatedInterval}^{\uparrow}$ *and carrying displayed lower and upper endpoint names.*
2. *E is the endpoint-comparison ledger, recording the endpoint order and endpoint equality tests available to the inspected interval rows.*
3. *L is the nesting ledger, recording that every later inspected interval lies inside every earlier inspected interval named by the common schedule.*
4. *D is the diameter-budget ledger, read through* $\mathsf{DyadicRatCore}^{\uparrow}$*, assigning each displayed interval a rational or dyadic shrinkage budget before any regular readback is allowed.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the inspected indices, endpoint requests, nesting checks, and replay order.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row obtained from the displayed endpoints, nesting ledger, and diameter budgets.*
7. *Z is the* $\mathsf{Real}^{\uparrow}$ *seal row available only after I, E, L, D, S, R have been displayed.*
8. *H records componentwise* hsame *transport for interval rows, endpoint comparison, nesting, diameter budgets, finite windows, readback, Real seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from a tolerance request through the diameter budget, then through the scheduled interval rows and nesting ledger, then through regular rational readback and the terminal Real seal.*

10. *P is the* Pkg *provenance over* $\mathsf{NestedIntervalSequence}^{\uparrow}$, $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{NestedIntervalSqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *A is the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, E, L, D, S, R, Z, H, C, P, A$. It has no coordinate for open-cover compactness, selected limits, countable choice, real-order trichotomy, quotient equality of real names, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8508.2 (Nested interval sequence NameCert obligation surface)**.** *For every accepted* $\mathsf{NestedIntervalSequence}^{\uparrow}$ *carrier*

$$N = (I, E, L, D, S, R, Z, H, C, P, A),$$

the local $\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}$ *surface consists exactly of interval-row admission, endpoint comparison, nesting-ledger exactness, diameter-budget readback, finite-window scheduling,* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff, terminal* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8508.1. The only displayed coordinates are $I, E, L, D, S, R, Z, H, C, P, A$, so interval admission, endpoint comparison, nesting evidence, diameter control, finite observation, readback, Real sealing, transport, replay, provenance, and local naming are all direct readings of the packet.

Read the interval data first. The row I supplies the located interval rows, E supplies endpoint comparison, and L supplies the displayed containment relation between later and earlier inspected intervals.

Read the shrinkage and observation rows next. The diameter ledger D is the only route by which a tolerance request reaches the interval sequence, and S is the only route by which a consumer selects the inspected windows. The handoff row R and seal row Z are downstream of those displayed rows.

Finally H, C, P, A preserve the same finite route under transport, replay, source, and local naming. Since the carrier has no coordinate for compactness, a selected limit, choice, trichotomy, quotient equality, or ambient completeness, the displayed rows exhaust the local NameCert obligation surface. □

Theorem 8508.3 (Nested interval sequence shrink induction)**.** *For an accepted* $\mathsf{NestedIntervalSequence}^{\uparrow}$ *carrier*

$$N = (I, E, L, D, S, R, Z, H, C, P, A),$$

finite prefix shrink data obtained from endpoint comparison rows E, nesting evidence L, diameter budgets D, $\mathsf{StreamName}^{\uparrow}$ *window rows S,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows R, and terminal* $\mathsf{Real}^{\uparrow}$ *seal rows Z is preserved by induction on the displayed finite windows. In particular, every displayed window prefix whose last interval has certified endpoints and diameter budget inherits the earlier-prefix containment and shrink ledger, and the successor window is obtained by consuming the next nesting row and next diameter row before transporting the result through H, C, P, and the local* $\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}$ *row.*

Proof. For the base window, read Definition 8508.1. A one-row prefix has endpoint comparison from E, its displayed diameter budget from D, its scheduled observation from S, and the downstream readback and seal rows R and Z.

For the successor step, assume the shrink ledger has been built for the displayed prefix named by S. The next window row supplies the next interval entry from I, the endpoint comparison row from E, the nesting row from L placing it inside the earlier displayed intervals, and the next diameter budget from D.

The successor ledger is then transported along the componentwise hsame row H and replayed through C. The provenance row P records that the construction used only the displayed $\mathsf{LocatedInterval}^{\uparrow}$, $\mathsf{NestedDyadicInterval}^{\uparrow}$, $\mathsf{NestedIntervalSqueeze}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, and $\mathsf{Real}^{\uparrow}$ surfaces, and the local $\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}$ row repacks the finite-window induction as a BEDC certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}$.

Constructive story: A $\mathsf{NestedIntervalSequence}^{\uparrow}$ packet is generated from located interval rows, endpoint-comparison rows, a nesting ledger, a DyadicRatCore diameter-budget ledger, StreamName finite windows, RegSeqRat readback, a terminal Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8508.1 and Definition 8508.2 seed the finite nested located interval sequence route into the regular-rational and Real-facing stack.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{NestedIntervalSequence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Heine–Borel compactness, open-cover compactness, selected limits, countable choice, trichotomy, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint comparison, nesting exactness, diameter-budget monotonicity, finite-window replay, regular-rational handoff, Real-seal nonescape, transport, provenance, and local naming for BEDC.Derived.NestedIntervalSequenceUp.

Chapter 8509

A Concrete Naming Certificate for $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$

Following the compact-uniform-continuity construction of chapter 9237, the $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$ packet records the finite $\mathsf{ProbeBundle}$ fold that turns bundled pointwise radii into one tolerance-only lower-bound history. It sits over the compact source data of chapter 60, the metric distance rows of chapter 57, the continuous pointwise modulus surface of chapter 59, the rational order readback of chapter 37, and the subordinate cover packet of chapter 596. The packet names only the finite lower-bound fold and its handoff to uniform-modulus consumers; it is not an infinite cover, a selected Lebesgue number, countable choice, a host compactness theorem, or an ambient real-completeness principle.

Definition 8509.1 (Finite modulus lower-bound ledger carrier)**.** *A* $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (K, M, F, Q, B, A, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row exposing the finite compact cover windows that supply the bundled probes.*
2. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used for source-ball and target-triangle comparisons in the compact-uniform route.*
3. *F is the* $\mathsf{Continuous}^{\uparrow}$ *pointwise-modulus row, assigning each bundled center its local positive rational precision history.*
4. *Q is the* $\mathsf{Rat}^{\uparrow}$ *order-readback row for positive rational histories and finite lower-bound comparisons.*
5. *B is the nonempty finite* $\mathsf{ProbeBundle}$ *row whose bundled entries carry centers, half-radius cover rows, local modulus rows, and subordinate radius histories.*
6. *A is the accumulator ledger produced by primitive recursion over B; each successor step compares the current accumulator with the next displayed half-radius history using Q.*
7. *U is the uniform-modulus handoff row, recording the tolerance-only precision history certified below every bundled half-radius ledger.*

8. *H records componentwise* hsame *transport for compact source, metric, continuous modulus, rational order, probe bundle, accumulator, handoff, replay, provenance, and local naming rows.*

9. *C records displayed* Cont *replay of the finite fold*

$$K, M, F, Q, B, A \longmapsto U, H, P, N.$$

10. *P is the* Pkg *provenance over* FiniteModulusLowerBoundLedger$^{\uparrow}$, Compact$^{\uparrow}$, Met$^{\uparrow}$, Continuous$^{\uparrow}$, Rat$^{\uparrow}$, SubordinateModulusCover$^{\uparrow}$, UniformModulus$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{FiniteModulusLowerBoundLedger}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, M, F, Q, B, A, U, H, C, P, N$. It has no coordinate for an infinite cover, a host minimum operator, selected Lebesgue number, countable choice, quotient real equality, or ambient completeness.

Theorem 8509.2 (Finite modulus lower-bound ledger fold obligation)**.** *For every accepted* FiniteModulusLowerBou *carrier*

$$L = (K, M, F, Q, B, A, U, H, C, P, N),$$

the local NameCert$_{\text{FiniteModulusLowerBoundLedger}^{\uparrow}}$ *surface consists exactly of compact-source exposure, metric-distance exposure, continuous pointwise-modulus exposure, rational order readback, nonempty finite* ProbeBundle *exposure, accumulator-step exactness, tolerance-only uniform-modulus handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8509.1. The compact, metric, continuous, rational, bundle, accumulator, handoff, and structural rows are exactly $K, M, F, Q, B, A, U, H, C, P, N$.

Read the source rows first. The compact row K and subordinate cover data inside B expose finitely many bundled centers and half-radius histories, while F exposes the pointwise continuous-modulus rows attached to those centers.

Run the fold through Q and A. At the initial and successor stages, the accumulator is compared with the displayed rational radius history for the next bundled probe, and the resulting lower-bound row is stored as finite BEDC history rather than as an external minimum.

The handoff row U is downstream of that fold and records only the tolerance-only precision certified below every bundled half-radius ledger. Transport, replay, provenance, and the local name preserve the same route through H, C, P, N, so no excluded compactness, choice, quotient, or completeness principle is exported. □

Closure status for NameCert$_{\text{FiniteModulusLowerBoundLedger}^{\uparrow}}$**.**

Constructive story: A FiniteModulusLowerBoundLedger$^{\uparrow}$ packet is generated from compact source rows, metric-distance rows, continuous pointwise-modulus rows, Rat order-readback rows, a nonempty finite ProbeBundle, a primitive-recursive accumulator ledger, a UniformModulus handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteModulusLowerBoundLedger}^{\uparrow}}$, seed)

Scope closed: Definition 8509.1 and Definition 8509.2 seed the finite rational lower-bound fold used by compact-uniform-continuity consumers.

Formal verification: FormalStatus(NameCert$_{\text{FiniteModulusLowerBoundLedger}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim an infinite cover, host minimum operator, selected Lebesgue number, countable choice, quotient real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, compact-source exposure, metric-distance exposure, continuous-modulus exposure, Rat order readback, finite ProbeBundle recursion, accumulator exactness, uniform-modulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusLowerBoundLedgerUp.

Chapter 8510

A Concrete Naming Certificate for $\mathsf{AumannIntegral}^{\uparrow}$

Following Aumann on integrals of set-valued maps, the $\mathsf{AumannIntegral}^{\uparrow}$ packet records the finite NameCert surface by which displayed selections of a correspondence expose a Banach-valued integral read. It sits after the set-valued map carrier of chapter 8121, the boundary discipline of chapter 6888, the measurable source of chapter 92, the integral readback of chapter 123, the convex-value row of chapter 208, the observable input surface of chapter 185, and the normed target of chapter 90. The packet names a finite integration object for displayed selection rows; it does not assert measurable-selection existence, quotient equality of selections, countable choice, or measure completion.

Definition 8510.1 (Aumann integral carrier)**.** *An* $\mathsf{AumannIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, R, X, F, G, S, K, I, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row carrying the measurable-event window on which all reads are tested.*
2. *R is the* $\mathsf{RandomVar}^{\uparrow}$ *observation row for the inspected source variables and their measurable preimage rows.*
3. *X is the* $\mathsf{SetValuedMap}^{\uparrow}$ *correspondence row, including the displayed source window and value-fibre addresses.*
4. *F is the* $\mathsf{ConvexSet}^{\uparrow}$ *value row, recording nonempty convex fibres only through finite membership and convex-combination tests.*
5. *G is the measurable-graph row that binds source observations in M, R to value candidates in X, F.*
6. *S is the finite selection ledger. Its entries are displayed rows*

$$(s_i, \gamma_i, \mu_i, \rho_i)_{i \in I_0}$$

where s_i is a named selection candidate, γ_i is its graph-admission witness through G, μ_i is its measurable-read witness through M, R, and ρ_i is its fibre-membership witness through F.

7. *K is the selection-integrability row. It records exactly which displayed selection candidates have accepted integral requests.*
8. *I is the* $\mathsf{Integral}^{\uparrow}$ *readback row, reducing every accepted selection integral to the finite integral data attached to K.*
9. *B is the* $\mathsf{Banach}^{\uparrow}$ *target row in which the displayed integral endpoints, addition reads, scalar reads, and norm comparisons are named.*
10. *H records componentwise* hsame *transport for $M, R, X, F, G, S, K, I, B$ and the structural rows.*
11. *C records displayed* Cont *replay of the route*

$$M, R, X, F, G \longmapsto S, K \longmapsto I, B.$$

12. *P is the* Pkg *provenance over* $\mathsf{AumannIntegral}^{\uparrow}$, $\mathsf{SetValuedMap}^{\uparrow}$, $\mathsf{AumannIntegralBoundary}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{ConvexSet}^{\uparrow}$, $\mathsf{RandomVar}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{AumannIntegral}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for producing selections, identifying selections modulo almost-everywhere equality, completing the measure space, or invoking a choice principle outside the displayed ledger.

Theorem 8510.2 (Aumann integral NameCert obligations)**.** *For every accepted* $\mathsf{AumannIntegral}^{\uparrow}$ *carrier*

$$A = (M, R, X, F, G, S, K, I, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AumannIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission for the measure row, random-variable row, set-valued map row, convex-value row, measurable graph row, finite selection ledger, selection-integrability row, integral readback row, Banach target row, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through N.*

Proof. Project the carrier of Definition 8510.1. The rows M, R, X, F provide the measurable source, observable input, correspondence, and convex-value data.

The analytic rows are G, S, K, I, B. The graph row admits only displayed graph tests, the finite ledger lists only selection candidates already present in the packet, the integrability row records which of those candidates are read by the integral row, and the Banach row names the endpoints and norm comparisons.

The structural rows H, C, P, N transport, replay, source, and name this same finite route. Since the carrier has no row for producing selections, identifying them by an ambient quotient, completing the measure space, or invoking countable choice, the listed rows exhaust the local certificate surface. □

Theorem 8510.3 (Aumann integral selection route)**.** *Every accepted* $\mathsf{AumannIntegral}^{\uparrow}$ *read that exports a Banach-valued integral endpoint factors through the finite route*

$$\mathsf{SetValuedMap}^{\uparrow}, \mathsf{AumannIntegralBoundary}^{\uparrow}, \mathsf{Measure}^{\uparrow}, \mathsf{RandomVar}^{\uparrow}, \mathsf{ConvexSet}^{\uparrow} \longmapsto S, K \longmapsto \mathsf{Integral}^{\uparrow}, \mathsf{Banach}^{\uparrow}.$$

The route may inspect displayed selection candidates and their integral readbacks, but it cannot infer the existence of an unlisted measurable selection or identify two selections by an ambient almost-everywhere quotient.

Proof. Begin with the source rows M, R, X, F, G. These rows expose the measurable window, the observed source variables, the set-valued graph, and the convex-value membership tests.

Next read the ledger rows S, K. The packet supplies only the listed selection candidates and only the integrability requests recorded for those candidates. Thus the route is a consumer of displayed selections, not a theorem producing selections.

Finally the rows I, B, H, C, P, N read the accepted integrals, place their endpoints in the Banach target, and replay the same route under transport and provenance. No step adds a measure completion row, a countable-choice row, or an almost-everywhere quotient row, so the exported endpoint remains inside the finite Aumann integral packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{AumannIntegral}\uparrow}$.

Constructive story: An $\mathsf{AumannIntegral}^{\uparrow}$ packet is generated from displayed measure, random-variable, set-valued-map, convex-value, measurable-graph, finite-selection, selection-integrability, integral-readback, Banach-target, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AumannIntegral}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8510.1, Definition 8510.2, and Definition 8510.3 seed the finite Aumann integral route through displayed selection ledgers and Banach integral readbacks.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AumannIntegral}\uparrow}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.AumannIntegralUp`

Bridge status: none

Not claimed: This chapter does not claim measurable-selection existence, quotient equality of selections, countable choice, measure completion, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, measurable graph exactness, finite selection ledger exactness, selection-integrability exactness, integral readback, Banach target preservation, transport stability, and replay stability for BEDC.Derived.AumannIntegralUp.

Chapter 8511

A Concrete Naming Certificate for $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$

Bishop–Bridges and Troelstra-style constructive continuity principles treat diagonal arguments over function spaces as finite evidence disciplines rather than as licenses to choose a discontinuity point. The $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$ packet records the boundary where a diagonal probe against a real-valued continuity claim must expose its source windows, rational readback, and replay rows before any obstruction is accepted. It sits beside the finite window route of chapter 126, the regular rational readback of chapter 301, the terminal Real seal of chapter 38, the continuous-map surface of chapter 130, and the Baire-space source discipline of chapter 334. The packet names a choice-free diagonal continuity barrier, not a completed counterexample extracted from countable choice or ambient completeness.

Definition 8511.1 (Bishop diagonal continuity barrier carrier)**.** *A* $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, R, A, F, U, W, D, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source-window row, recording the finite address requests used by the diagonal probe.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing regular rational values attached to those source windows.*
3. *A is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the regular rational readback has been displayed.*
4. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row whose claimed continuity is being inspected through the displayed windows.*
5. *U is the* $\mathsf{BaireSpace}^{\uparrow}$ *or source-window data row supplying the finite branch segment on which the diagonal probe is formed.*
6. *W is the diagonal probe-window row, pairing the inspected source window with the requested target tolerance.*
7. *D is the barrier ledger, recording that the diagonal read is an obstruction to an unexposed continuity route rather than a selected discontinuity point.*

8. *H records componentwise* hsame *transport for the source-window, regular readback, Real seal, continuous-map, source data, diagonal window, barrier ledger, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay from a continuity request through S, R, A, F, U, W, D, H.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{BaireSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, A, F, U, W, D, H, C, P, N$. It has no coordinate for countable choice, a selected discontinuity point, quotient function equality, or ambient Real completeness.

Theorem 8511.2 (Bishop diagonal continuity barrier NameCert obligations)**.** *For every accepted* $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$ *carrier*

$$B = (S, R, A, F, U, W, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{StreamName}^{\uparrow}$ *source windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{ContinuousMap}^{\uparrow}$ *row,* $\mathsf{BaireSpace}^{\uparrow}$ *or source-window row, diagonal probe windows, barrier ledger, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every barrier read must expose $S, R, A, F, U, W, D, H, C, P, N$ and no obligation is stored outside those rows.*

Proof. Project the carrier of Definition 8511.1. The analytic rows are exactly the source windows, regular rational readback, Real seal, continuous-map row, source data, diagonal probe windows, and barrier ledger.

The continuity-facing read is F, U, W, D. The source data row fixes the finite branch segment, the diagonal window records the inspected request, and the barrier ledger records only the failure of an unexposed continuity route.

The Real-facing read is S, R, A. The StreamName window and regular rational readback are displayed before the Real seal is consumed, so the packet cannot appeal to ambient Real completeness.

Finally H, C, P, N transport, replay, source, and name the same finite rows. Since no carrier coordinate contains countable choice, a selected discontinuity point, quotient function equality, or ambient Real completeness, the listed rows exhaust the NameCert surface. □

Theorem 8511.3 (Bishop diagonal continuity barrier choice-free route)**.** *Every accepted* BishopDiagonalContinuityB *read is a choice-free route*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{Real}^{\uparrow}, \mathsf{ContinuousMap}^{\uparrow}, \mathsf{BaireSpace}^{\uparrow} \longmapsto W, D \longmapsto \mathsf{hsame}, \mathsf{Cont}, \mathsf{Pkg}, \mathsf{NameCert}.$$

It may obstruct a continuity claim only through displayed source windows, regular rational readback, Real sealing, continuous-map inspection, source-window data, diagonal probe windows, transport, replay, provenance, and local naming. It does not export countable choice, a selected discontinuity point, quotient function equality, or ambient Real completeness.

Proof. Start with the NameCert obligations of Definition 8511.2. They require every accepted read to expose the source windows, regular readback, Real seal, continuous-map row, source data, diagonal window, and barrier ledger.

Read the diagonal stage through U, W, D. The source-window data and probe window are finite rows, so the obstruction is tied to a displayed request rather than to a choice-selected point.

Read the Real stage through S, R, A. The regular rational readback and terminal seal are consumed only after the finite StreamName windows are visible.

The structural rows H, C, P, N preserve the same route by transport, replay, provenance, and local naming. Because the carrier omits countable choice, selected discontinuity points, quotient function equality, and ambient Real completeness, the accepted barrier remains the stated choice-free finite packet. □

Falsifiable prediction: A $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$ consumer that exports a diagonal continuity obstruction without the $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, source-window, diagonal probe, hsame, Cont, Pkg, and local NameCert rows refutes the carrier of Definition 8511.1.

Independence witness: streamname, regseqrat, real, continuousmap, bairespace: BishopDiagonalContinuityBarrie is not bijective to any listed sibling because this packet alone binds source-window data, diagonal probe windows, barrier-ledger routing, transport, replay, provenance, and local naming around a choice-free continuity obstruction.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}$ packet is generated from StreamName source windows, RegSeqRat readback, a Real seal, a ContinuousMap row, BaireSpace or source-window data, diagonal probe windows, a barrier ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8511.1, Definition 8511.2, and Definition 8511.3 seed the choice-free diagonal continuity barrier over finite source windows, regular rational readback, Real seals, continuous-map inspection, source-window data, diagonal probe windows, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopDiagonalContinuityBarrier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim countable choice, selected discontinuity points, quotient function equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, source-window exposure, regular readback, continuous-map inspection, diagonal probe-window routing, barrier-ledger nonescape, transport, replay, provenance, and local naming for BEDC.Derived.BishopDiagonalContinuityBarrierUp.

Chapter 8512

A Concrete Naming Certificate for $\mathsf{CauchySequenceModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names, the $\mathsf{CauchySequenceModulus}^{\uparrow}$ packet records the finite tail-budget data by which a displayed sequence can be read as Cauchy before any Real or Completion consumer inspects its terminal seal. It sits over the effective Cauchy sequence route of chapter 1705, the regular Cauchy sequence packet of chapter 660, the finite stream-window interface of chapter 126, the regular rational readback of chapter 301, the finite tail handoff of chapter 8472, the lower-bound ledger of chapter 8509, and the terminal real-name seal of chapter 38. The packet names explicit tail-budget rows only; it does not assert quotient equality of Cauchy names, select a limit, invoke countable choice, decide trichotomy, or import ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8512.1 (Cauchy sequence modulus carrier)**.** *A* $\mathsf{CauchySequenceModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (E, R, W, Q, L, S, H, C, P, N)$$

with the following displayed rows:

1. *E is the* $\mathsf{EffectiveCauchySequence}^{\uparrow}$ *source row, exposing the effective Cauchy reading before a tail budget is exported.*
2. *R is the* $\mathsf{RegularCauchySequence}^{\uparrow}$ *regularity row, recording the regular Cauchy sequence discipline that the modulus serves.*
3. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, displaying the inspected sequence windows and index requests.*
4. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, binding the displayed stream windows to regular rational approximation data.*
5. *L is the finite tail-bound ledger row, storing the explicit threshold and tolerance histories used to compare later sequence windows.*
6. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after E, R, W, Q, L have been displayed.*
7. *H records componentwise* hsame *transport for source, regularity, window, readback, ledger, seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the finite route*

$$E, R, W, Q, L \longmapsto S, H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchySequenceModulus}^{\uparrow}$, $\mathsf{EffectiveCauchySequence}^{\uparrow}$, $\mathsf{RegularCauchySequence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchySequenceModulus}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $E, R, W, Q, L, S, H, C, P, N$. It has no coordinate for a selected limit, quotient stream equality, countable-choice tail selector, trichotomy, host real equality, or ambient completeness.

Theorem 8512.2 (Cauchy sequence modulus NameCert obligations)**.** *For every accepted* $\mathsf{CauchySequenceModulus}^{\uparrow}$ *carrier*

$$M = (E, R, W, Q, L, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CauchySequenceModulus}^{\uparrow}}$ *surface consists exactly of effective Cauchy source exposure, regular Cauchy sequence exposure, finite stream-window exposure, regular rational readback, finite tail-bound ledger exposure, Real-seal handoff, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8512.1. The accepted packet displays exactly the effective source, regular sequence, stream-window, readback, tail-ledger, Real-seal, and structural rows.

Read the source route first. The row E exposes the effective Cauchy sequence data, while R records the regular Cauchy discipline already used by chapter 660. The stream row W and readback row Q make the inspected finite windows and rational approximations visible before any tail budget is consumed.

The tail-budget row L is the only modulus ledger. It stores the displayed threshold and tolerance histories and then hands the resulting route to the seal row S; the seal is therefore downstream of E, R, W, Q, L, not a detached completeness or quotient principle.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no selected limit, quotient equality, countable-choice selector, trichotomy, host equality, or ambient completeness coordinate, the listed rows exhaust the local NameCert obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchySequenceModulus}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchySequenceModulus}^{\uparrow}$ packet is generated from an EffectiveCauchySequence source row, a RegularCauchySequence discipline row, finite StreamName windows, RegSeqRat readback, a finite tail-bound ledger, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{CauchySequenceModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8512.1 and Definition 8512.2 seed the explicit tail-budget carrier consumed by L10 Real and Completion routes.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{CauchySequenceModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient equality of Cauchy names, selected limits, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, effective Cauchy source exposure, regular Cauchy sequence exposure, finite stream-window exposure, RegSeqRat readback, finite tail-ledger exactness, Real-seal handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchySequenceModulusUp.

Chapter 8513

A Concrete Naming Certificate for $\mathsf{CompactUniformEquioscillation}^{\uparrow}$

Following Arzela–Ascoli equicontinuity and Chebyshev equioscillation practice, the $\mathsf{CompactUniformEquioscillation}^{\uparrow}$ packet records the finite compact-uniform surface on which oscillation bands are compared over a compact source before a uniform-modulus or approximation consumer reads them. It concretizes the compact-uniform-continuity route of chapter 9237 after the compact metric rows of chapter 129, the equicontinuity family rows of chapter 413, the Arzela–Ascoli family packet of chapter 412, the finite modulus handoff of chapter 5973, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names finite oscillation bands, compact-net windows, and equicontinuity rows; it does not assert host suprema, selected extrema, quotient equality of functions, open-cover compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8513.1 (CompactUniformEquioscillation carrier)**.** *A* $\mathsf{CompactUniformEquioscillation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (K, F, Q, B, O, D, S, R, U, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *finite-net row, exposing compact source centers, coverage radii, and located metric comparisons.*
2. *F is the* $\mathsf{EquicontinuityFamily}^{\uparrow}$ *row, recording the displayed family-wide modulus rows inspected on the compact source.*
3. *Q is the* $\mathsf{ArzelaAscoli}^{\uparrow}$ *family-control row, read only as finite boundedness and equicontinuity data.*
4. *B is the compact-uniform band row, naming the finite lower and upper comparison bands on each inspected net cell.*
5. *O is the equioscillation row, recording the finite alternation schedule, signed band gaps, and equality-of-oscillation comparisons between neighboring displayed cells.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used by the band-gap and oscillation comparisons.*
7. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row selecting compact-net cells, family observations, band comparisons, and alternation checks.*

8. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational band gaps, oscillation widths, and tolerance comparisons.*
9. *U is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row exported only after K, F, Q, B, O, D, S, R have been displayed.*
10. *H records componentwise* hsame *transport for compact nets, equicontinuity, family control, bands, equioscillation, dyadic tolerances, finite windows, regular readback, uniform-modulus handoff, replay, provenance, and local naming.*
11. *C records displayed* Cont *replay from a compact-uniform query through the finite net, family rows, band comparisons, equioscillation schedule, numerical readback, and uniform-modulus handoff.*
12. *P is the* Pkg *provenance over* $\mathsf{CompactUniformEquioscillation}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{EquicontinuityFamily}^{\uparrow}$, $\mathsf{ArzelaAscoli}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{UniformModulus}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, Q, B, O, D, S, R, U, H, C, P, N$. It has no coordinate for host extrema, selected maximizers, quotient function equality, countable choice, open-cover compactness, or ambient Real completeness.

Theorem 8513.2 (CompactUniformEquioscillation obligation surface)**.** *For every accepted* $\mathsf{CompactUniformEquios}$ *carrier*

$$E = (K, F, Q, B, O, D, S, R, U, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}$ *surface consists exactly of compact finite-net admission through K, equicontinuity-family exposure through F, Arzela–Ascoli family-control exposure through Q, compact-uniform band admission through B, finite equioscillation schedule exposure through O, dyadic tolerance visibility through D, finite-window scheduling through S, regular rational readback through R, uniform-modulus handoff through U, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8513.1. The compact source, family, and control rows are K, F, Q, so every band comparison is read after the compact-net and equicontinuity data are visible.

Rows B, O, D, S, R give the finite oscillation surface. The band row supplies the lower and upper comparison windows, the equioscillation row records the alternation and equal-width comparisons, and the dyadic, stream, and regular-rational rows expose the numerical checks before any consumer may use them.

The uniform-modulus handoff U is downstream of those displayed rows. Componentwise transport, replay, provenance, and local naming preserve the same finite route, so the packet exports no host extrema, selected maximizers, quotient function equality, countable-choice schedule, open-cover compactness theorem, or ambient completeness principle. □

Theorem 8513.3 (Compact-uniform equioscillation handoff)**.** *Every compact-uniform, Arzela–Ascoli, or Chebyshev-facing consumer of an accepted* $\mathsf{CompactUniformEquioscillation}^{\uparrow}$ *packet first reads*

$$K, F, Q \longmapsto B, O \longmapsto D, S, R \longmapsto U \longmapsto H, C, P, N.$$

Thus the consumer receives a finite compact-net and equicontinuity route together with displayed equioscillation bands before it may read the uniform-modulus handoff.

Proof. Start with the source and family rows. The compact metric row K, equicontinuity row F, and Arzela–Ascoli family-control row Q determine the finite family surface on which oscillation bands can be inspected.

Next read B and O. These rows bind the lower and upper band data to the displayed alternation schedule, so the equioscillation claim is a finite comparison ledger rather than a selected extremal point or host supremum.

Finally pass through D, S, R, U, H, C, P, N. The dyadic tolerance, stream window, and regular-rational readback rows expose the numerical comparisons before the uniform-modulus row is exported, while the structural rows keep the handoff inside the same local $\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}$.

Constructive story: A $\mathsf{CompactUniformEquioscillation}^{\uparrow}$ packet is generated from CompactMetric finite-net rows, EquicontinuityFamily rows, ArzelaAscoli family-control rows, compact-uniform band rows, finite equioscillation schedules, DyadicRatCore tolerances, StreamName windows, RegSeqRat readback, a UniformModulus handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8513.1, Definition 8513.2, and Definition 8513.3 seed the compact finite-net, equicontinuity-family, Arzela–Ascoli, band-comparison, equioscillation, rational-readback, and uniform-modulus route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompactUniformEquioscillation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host extrema, selected maximizers, quotient equality of functions, countable choice, open-cover compactness, Lean verification, bridge checking, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Upgrade path: Obligation closure requires checked carrier admission, compact-net exposure, equicontinuity-family exposure, Arzela–Ascoli family-control exposure, band exactness, equioscillation schedule exactness, dyadic tolerance visibility, finite-window replay, regular readback, UniformModulus handoff, transport, replay, provenance, and local naming for BEDC.Derived.CompactUniformEquioscillationUp.

Chapter 8514

A Concrete Naming Certificate for $\mathsf{FiniteModulusStaircase}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{FiniteModulusStaircase}^{\uparrow}$ packet records a finite staged route by which a modulus request is tightened through displayed rational tolerances before a Real or Completion consumer reads the final seal. It sits after the finite stream names of chapter 126, the regular rational readback of chapter 301, the dyadic core of chapter 291, the finite mesh surface of chapter 8504, the lower-bound ledger of chapter 8509, and the Real seal of chapter 38. The packet names only a finite staircase of modulus rows, monotone handoff between adjacent rows, transport, replay, provenance, and local naming; it is not an infinite modulus search, a selected global modulus, quotient stream equality, countable choice, trichotomy, or ambient completeness.

Definition 8514.1 (Finite modulus staircase carrier)**.** *A* $\mathsf{FiniteModulusStaircase}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, R, D, M, L, A, U, E, H, C, P, N)$$

with the following displayed rows:

1. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row naming the stream positions whose modulus requests are inspected.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposing rational observations on those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare adjacent requests.*
4. *M is the* $\mathsf{FiniteModulusMesh}^{\uparrow}$ *row exposing the finite mesh cells from which staged requests are drawn.*
5. *L is the* $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$ *row exposing the finite lower-bound fold available to every displayed stage.*
6. *A is the finite staircase ledger. Its initial row records the first displayed modulus request, and each successor row records a dyadic comparison against the previous request together with the lower-bound handoff read from L.*
7. *U is the terminal modulus handoff row, obtained only after every displayed staircase step in A has been read.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal boundary available only downstream from W, R, D, M, L, A, U.*

9. *H records componentwise* hsame *transport for stream windows, regular readback, dyadic tolerances, mesh cells, lower-bound rows, staircase steps, terminal handoff, Real seal, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay of the finite staircase route*

$$W, R, D, M, L \longmapsto A \longmapsto U, E, H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{FiniteModulusStaircase}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{FiniteModulusMesh}^{\uparrow}$, $\mathsf{FiniteModulusLowerBoundLedger}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteModulusStaircase}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, R, D, M, L, A, U, E, H, C, P, N$. It has no coordinate for an infinite search over moduli, selected global modulus, quotient stream equality, trichotomy, countable choice, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8514.2 (Finite modulus staircase NameCert obligations)**.** *For every accepted* $\mathsf{FiniteModulusStaircase}^{\uparrow}$ *carrier*

$$S = (W, R, D, M, L, A, U, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteModulusStaircase}^{\uparrow}}$ *surface consists exactly of finite stream-window exposure through W, regular rational readback through R, dyadic tolerance exposure through D, finite mesh exposure through M, lower-bound ledger exposure through L, staircase-step exactness through A, terminal modulus handoff through U, Real-seal exposure through E, componentwise transport through H, displayed continuation replay through C, package provenance through P, and local naming through N.*

Proof. Project the accepted carrier. The source rows available before the staircase opens are exactly the finite window, regular readback, dyadic tolerance, finite mesh, and lower-bound ledger rows W, R, D, M, L.

Read the staircase ledger A by finite induction over its displayed rows. The initial row records a visible modulus request, and each successor row records only the next visible request, the dyadic comparison against the previous request, and the lower-bound handoff already displayed by L.

The terminal row U is therefore downstream from a finite chain of visible comparisons, not from an external search. The Real seal E and the structural rows H, C, P, N transport, replay, source, and name that same finite route.

Since no excluded endpoint is a carrier coordinate, the listed rows exhaust the local NameCert surface. □

Theorem 8514.3 (Finite modulus staircase monotone handoff)**.** *Every terminal modulus handoff exported by an accepted* $\mathsf{FiniteModulusStaircase}^{\uparrow}$ *packet factors through the displayed staircase rows:*

$$\mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow}, \mathsf{FiniteModulusMesh}^{\uparrow}, \mathsf{FiniteModulusLowerBoundLedger}^{\uparrow} \longmapsto A \longmapsto U \longmapsto$$

Each successor row in A may tighten the current request only through the dyadic comparison and lower-bound handoff already present in the carrier. Thus a Real or Completion consumer receives a staged finite-modulus dependency rather than a one-shot modulus assertion.

Proof. Start with the obligations of Definition 8514.2. They place stream windows, regular readback, dyadic tolerances, finite mesh data, and lower-bound ledger data before the staircase ledger can be consumed.

Run finite induction along A. The base row supplies the first displayed request. At a successor row, the only available comparison is the dyadic one recorded by D, and the only lower-bound source is the ledger row L.

After the last displayed step, the terminal handoff U can be read. The seal row E and the structural rows preserve the same finite route, so no Real or Completion consumer can bypass the staircase by appealing to a selected global modulus, infinite search, quotient equality, choice schedule, or ambient completeness theorem. □

Falsifiable prediction: An accepted $\mathsf{FiniteModulusStaircase}^{\uparrow}$ read is refuted if a Real or Completion consumer exports a terminal modulus handoff without displaying the StreamName windows, RegSeqRat readback, DyadicRatCore comparisons, FiniteModulusMesh cells, FiniteModulusLowerBoundLedger fold, staircase rows, transport, replay, provenance, and local naming.

Independence witness: streamname, regseqrat, dyadicratcore, finite-modulus-mesh, finite-modulus-lower-bound-ledger, and real: none alone is bijective with $\mathsf{FiniteModulusStaircase}^{\uparrow}$ because the packet jointly binds finite windows, rational readback, dyadic comparisons, mesh rows, lower-bound rows, staged staircase steps, terminal handoff, Real-seal exposure, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteModulusStaircase}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteModulusStaircase}^{\uparrow}$ packet is generated from StreamName finite-window rows, RegSeqRat readback rows, DyadicRatCore tolerance rows, FiniteModulusMesh rows, FiniteModulusLowerBoundLedger rows, a finite staircase ledger, a terminal modulus handoff row, a Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteModulusStaircase}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8514.1, Definition 8514.2, and Definition 8514.3 seed the finite staged-modulus route over displayed stream-window, regular-readback, dyadic-tolerance, mesh, lower-bound, staircase, Real, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteModulusStaircase}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close an infinite modulus search, selected global modulus, quotient stream equality, selected limits, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, axiom-clean audit, or bridge checking for $\mathsf{FiniteModulusStaircase}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, regular-readback exactness, dyadic-comparison exactness, mesh exposure, lower-bound ledger exposure, staircase-step exactness, terminal handoff nonescape, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteModulusStaircaseUp.

Chapter 8515

A Concrete Naming Certificate for $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$

Following Bishop and Bridges on constructive Cauchy convergence, the $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ packet records the explicit finite threshold schedule by which a displayed regular rational stream becomes a Real-facing Cauchy name. It sits after the stream-window source of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal Real seal of chapter 38, and the completion route of chapter 3379. The packet names an explicit convergence modulus only; it does not choose a host limit, quotient stream representatives, countably many witnesses, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8515.1 (Modulus of Cauchy convergence carrier)**.** *A* $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, D, T, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *source row, carrying the inspected finite windows of the rational stream.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, naming the dyadic precision requests and their order comparison ledger.*
3. *T is the tail-threshold schedule. For each displayed tolerance request in D, it names a finite threshold index and the finite window in S on which all later inspected pairs are compared.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff row, reading the regular rational sequence through the same stream windows and tolerance requests.*
5. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row exposed only after the scheduled tail comparisons and the regular rational handoff have been read.*
6. *H records componentwise* hsame *transport for S, D, T, R, E and the structural rows.*
7. *C records displayed* Cont *replay of the route*

$$S, D \longmapsto T \longmapsto R \longmapsto E.$$

8. *P is the* Pkg *provenance over* $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{ModulusOfCauchyConvergence}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through these rows. It has no coordinate for selecting an infinite family of tail witnesses, passing to quotient Cauchy classes, choosing a completed Real representative, or invoking completeness outside the displayed completion route.

Theorem 8515.2 (Modulus of Cauchy convergence NameCert obligations)**.** *For every accepted* $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ *carrier*

$$M = (S, D, T, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ModulusOfCauchyConvergence}^{\uparrow}}$ *surface consists exactly of carrier admission for the stream source, dyadic tolerance row, tail-threshold schedule, regular rational handoff, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming through* N*.*

Proof. Project the carrier of Definition 8515.1. The rows S, D, T provide the only admissible source windows, tolerance requests, and threshold schedule.

The handoff rows R, E are read after that schedule is fixed. Thus a Real-facing consumer can inspect the regular rational row and the terminal seal only through the same finite tail data.

The structural rows H, C, P, N transport, replay, source, and name this finite route. Since no coordinate stores a choice functional, quotient class, selected host limit, or ambient completeness theorem, the listed rows exhaust the local certificate surface. □

Theorem 8515.3 (Modulus of Cauchy convergence tail witness)**.** *Every accepted tolerance request in a* $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ *packet is discharged by the displayed tail-threshold row* T*. More precisely, if a consumer asks for the dyadic tolerance named by a row of* D*, the packet returns the threshold and finite stream window named in* T*, and every later inspected pair used by the* $\mathsf{RegSeqRat}^{\uparrow}$ *handoff is routed through that same window.*

Proof. Begin with the requested dyadic tolerance. By carrier admission, it is a row of D, so the schedule coordinate T contains the corresponding threshold entry.

Read the stream source through S at the window named by that entry. The regular rational handoff row R is defined over the same source and tolerance rows, so it cannot replace the threshold with an unlisted one or ask for a stream value outside the displayed window.

Finally use the transport and replay rows H and C to carry the same threshold under equivalent packet presentations. The witness remains a finite tail row rather than a countable choice of witnesses. □

Theorem 8515.4 (Modulus of Cauchy convergence Real handoff)**.** *For an accepted* $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ *carrier* $M = (S, D, T, R, E, H, C, P, N)$*, every downstream* $\mathsf{Real}^{\uparrow}$ *or* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *consumer receives the stream source* S*, dyadic tolerance row* D*, tail-threshold schedule* T*, regular rational handoff* R*, Real seal* E*, and structural rows* H, C, P, N*. The handoff exports no selected host limit, quotient representative, countable-choice principle, or Real-completeness theorem beyond those displayed rows.*

Proof. Let a downstream consumer read the Real-facing output. The only available route to that output is the displayed replay row C, whose source is S, D, whose middle coordinate is T, and whose handoff rows are R, E.

The package row P records this same route as provenance for $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ and $\mathsf{CauchyCompletionOperator}^{\uparrow}$. It is not a limit selector, quotient map, or completeness principle.

Therefore every Real or completion read is still a read of the finite carrier coordinates. The excluded host limit, quotient representative, countable-choice row, and ambient completeness theorem are not carrier coordinates, so they cannot be exported by the handoff. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusOfCauchyConvergence}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusOfCauchyConvergence}^{\uparrow}$ packet is generated from a stream source, dyadic tolerance row, explicit tail-threshold schedule, regular rational handoff, Real seal, transport, replay, provenance, and local naming rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusOfCauchyConvergence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8515.1, Definition 8515.2, Definition 8515.3, and Definition 8515.4 seed the explicit modulus carrier, NameCert surface, tail witness route, and Real-facing handoff.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusOfCauchyConvergence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected host limits, quotient stream representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, tolerance exactness, tail-threshold coverage, regular rational handoff, Real seal preservation, transport stability, and replay stability for the finite modulus packet.

Chapter 8516

A Concrete Naming Certificate for $\mathsf{BishopRealFunctionSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{BishopRealFunctionSpace}^{\uparrow}$ packet records a finite L10 real-function surface whose inputs and outputs are read only through displayed real-name rows. It sits beside the general function-space packet of chapter 7964, the continuous-map carrier of chapter 130, the terminal real-name seal of chapter 38, the finite window route of chapter 126, the regular rational readback of chapter 301, and the dyadic tolerance core of chapter 291. The packet is a finite Bishop-style real-function certificate; it is not a host set of all functions, a quotient equality principle for maps, a completeness theorem for $\mathsf{Real}^{\uparrow}$, a function-extensionality axiom, a selected limit operator, or a countable-choice schedule.

Definition 8516.1 (Bishop real-function-space carrier)**.** *A* $\mathsf{BishopRealFunctionSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, T, G, W, R, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the source* $\mathsf{Real}^{\uparrow}$ *domain row, listing the displayed input real names on which the function packet may be inspected.*
2. *T is the target* $\mathsf{Real}^{\uparrow}$ *row, listing the displayed output real names returned by the inspected function windows.*
3. *G is the finite graph-window row, binding each inspected source window in D to the corresponding target window in T.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule for the source and target real names used by G.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached from the windows in W before any terminal target seal is consumed.*
6. *Q is the local Bishop continuity row, requiring each graph-window read to pass through the same displayed source window, target window, and regular readback route.*
7. *H records componentwise* hsame *transport for D, T, G, W, R, Q and the structural rows below.*
8. *C records displayed* Cont *replay from a real-function request through D, T, G, W, R, Q, H.*
9. *P is the* Pkg *provenance over* $\mathsf{BishopRealFunctionSpace}^{\uparrow}$, $\mathsf{RealFunctionSpace}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopRealFunctionSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, T, G, W, R, Q, H, C, P, N$. It has no coordinate for host function extensionality, quotient equality of maps, an ambient function-space completion, selected pointwise limits, countable choice, real trichotomy, or completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8516.2 (Bishop real-function-space NameCert obligations)**.** *For every accepted* BishopRealFunctionSpace *carrier $B = (D, T, G, W, R, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BishopRealFunctionSpace}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *source and target* $\mathsf{Real}^{\uparrow}$ *exposure through D and T;*
2. *finite graph-window exposure through G;*
3. $\mathsf{StreamName}^{\uparrow}$ *scheduling through W;*
4. $\mathsf{RegSeqRat}^{\uparrow}$ *readback through R;*
5. *Bishop continuity replay through Q over the same displayed windows;*
6. *componentwise* hsame *transport through H;*
7. *displayed* Cont *replay through C;*
8. Pkg *provenance through P and local naming through N.*

No accepted obligation row is stored outside $D, T, G, W, R, Q, H, C, P, N$.

Proof. Project the accepted carrier of Definition 8516.1. The Real-facing rows are D, T, the graph and observation rows are G, W, R, Q, and the structural rows are H, C, P, N.

The graph-window obligations are read before the terminal target row is available. A consumer first displays a source real-name row from D, then the graph-window row G, then the target real-name row T attached to that graph window.

The finite observation route is supplied by W, R, Q. The stream schedule W lists the inspected windows, the regular rational row R gives the readback, and the Bishop continuity row Q records that the same displayed source and target windows are used by the local continuity replay.

Finally H, C, P, N transport, replay, source, and name only this finite route. Since no other coordinate occurs in the carrier, the listed obligation rows exhaust the local certificate surface. □

Theorem 8516.3 (Bishop real-function-space nonescape)**.** *Every Real or Completion consumer of an accepted* $\mathsf{BishopRealFunctionSpace}^{\uparrow}$ *carrier factors through*

$$D, T, G, W, R, Q, H, C, P, N.$$

Thus a target $\mathsf{Real}^{\uparrow}$ *output row can be read only after the source* $\mathsf{Real}^{\uparrow}$ *domain row, graph-window row,* $\mathsf{StreamName}^{\uparrow}$ *schedule,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, Bishop continuity replay, componentwise transport, displayed replay, provenance, and local naming rows have been exposed. The packet exports no host function extensionality, quotient equality of maps, ambient function-space completion, selected pointwise limit, countable-choice schedule, real trichotomy, or completeness theorem for* $\mathsf{Real}^{\uparrow}$.

Proof. Begin with an accepted carrier and a Real- or Completion-facing consumer request. Carrier projection exposes only the rows named in Definition 8516.1.

The request reaches the target real-name row through the graph route. The source row D and graph-window row G identify the inspected input window, while the target row T records the output real-name window tied to that graph entry.

The L10 readback then passes through W, R, Q. The $\mathsf{StreamName}^{\uparrow}$ schedule and $\mathsf{RegSeqRat}^{\uparrow}$ row make the inspected finite windows visible, and the Bishop continuity row replays the same source and target windows instead of replacing them by a host function.

The structural rows H, C, P, N preserve, replay, source, and name the same packet. None of these rows introduces an equality principle for all functions, a quotient carrier, a selected limit, choice, trichotomy, or an ambient completeness coordinate. Hence every consumer read remains inside the displayed finite packet. □

Falsifiable prediction: Every accepted $\mathsf{BishopRealFunctionSpace}^{\uparrow}$ consumer that reaches a target $\mathsf{Real}^{\uparrow}$ output without displaying $D, T, G, W, R, Q, H, C, P, N$ refutes the carrier surface.

Independence witness: real-function-space, continuousmap, real, streamname, regseqrat, dyadicratcore: no listed sibling supplies the whole packet $B = (D, T, G, W, R, Q, H, C, P, N)$, because each sibling contributes only a general function-space, continuous-map, real-name, stream-window, regular-readback, or dyadic-tolerance face while this chapter binds them as one finite Bishop real-function route.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopRealFunctionSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopRealFunctionSpace}^{\uparrow}$ packet is generated from source and target RealUp rows, finite graph-window rows, StreamName windows, RegSeqRat readbacks, a Bishop continuity replay row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopRealFunctionSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8516.1, Definition 8516.2, and Definition 8516.3 seed the finite L10 real-function route over RealUp, StreamNameUp, RegSeqRatUp, ContinuousMapUp, RealFunctionSpaceUp, and DyadicRatCoreUp rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopRealFunctionSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host function extensionality, quotient equality of maps, ambient function-space completion, selected pointwise limits, countable choice, real trichotomy, $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, graph-window exactness, StreamName scheduling, RegSeqRat readback, Bishop continuity replay, transport, replay, provenance, and local naming for BEDC.Derived.BishopRealFunctionSpac

Chapter 8517

A Concrete Naming Certificate for $\mathsf{UltrametricSkeleton}^{\uparrow}$

Following the metric embedding and ultrametric skeleton literature, the $\mathsf{UltrametricSkeleton}^{\uparrow}$ packet records a finite tree-scale approximation to displayed metric data as NameCert rows rather than as a host-selected infinite tree. It sits over the metric source of chapter 57, the doubling control route of chapter 2035, the finite epsilon-net surface of chapter 1767, and the dyadic tolerance ledger of chapter 291. The packet gives compactness, finite-net, entropy, and embedding-facing consumers a named finite ultrametric approximation object; it does not import quotient metric equality, open-cover compactness, a selected infinite hierarchy, or ambient completeness.

Definition 8517.1 (Ultrametric skeleton carrier)**.** *An* $\mathsf{UltrametricSkeleton}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (M, E, T, D, B, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing only the displayed distance observations consumed by the skeleton.*
2. *E is the finite scale-net row, read through* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *at the displayed dyadic radii.*
3. *T is the cluster-tree row, recording the finite parent, child, and leaf incidence data induced by the scale-net inclusions.*
4. *D is the ultrametric distance ledger, assigning the displayed dyadic merge scale to each pair of retained leaves.*
5. *B is the distortion budget row, comparing source metric observations from M with ultrametric ledger entries from D.*
6. *H records componentwise* hsame *transport for the metric source, finite scale net, cluster tree, distance ledger, distortion budget, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay from a metric read through the scale-net row, cluster-tree row, ultrametric distance ledger, and distortion budget.*
8. *P is the* Pkg *provenance over* $\mathsf{UltrametricSkeleton}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{DoublingMetric}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $M, E, T, D, B, H, C, P, N$. It has no coordinate for a host quotient of metric spaces, a selected infinite cluster tree, open-cover compactness, a choice principle, or ambient metric completion.

Theorem 8517.2 (Ultrametric skeleton NameCert obligations)**.** *For every accepted* $\mathsf{UltrametricSkeleton}^{\uparrow}$ *carrier* $U = (M, E, T, D, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$ *surface consists exactly of metric-source exposure, finite scale-net exposure, cluster-tree incidence exposure, ultrametric distance ledger exposure, distortion-budget exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every embedding-facing or compactness-facing consumer must read the finite route*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{DoublingMetric}^{\uparrow},\quad \mathsf{FiniteEpsilonNet}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame},\quad \mathsf{Cont},\quad \mathsf{Pkg},\quad \mathsf{NameCert}.$$

No NameCert obligation is stored outside those rows.

Proof. Project the carrier of Definition 8517.1. The only analytic rows are the metric source M, finite scale-net row E, cluster-tree incidence row T, ultrametric distance ledger D, and distortion budget B.

Read the finite approximation rows in order. The metric source supplies displayed distances, the finite scale-net row supplies retained representatives at dyadic radii, the cluster-tree row supplies only finite incidence data, and the ultrametric ledger assigns the merge scale recorded by that finite tree.

The distortion obligation is then exactly the row B. Componentwise transport through H and replay through C preserve the same finite rows, while provenance P and local naming N cite the packet surface.

Since the carrier has no coordinate for host choice, quotient metric equality, a selected infinite tree, open-cover compactness, or ambient completeness, none of those principles can be exported by the local $\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$ obligations. □

Closure status for $\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$.

Constructive story: An $\mathsf{UltrametricSkeleton}^{\uparrow}$ packet is generated from a Metric source row, finite scale-net rows, a finite cluster-tree incidence ledger, an ultrametric distance ledger, a distortion budget, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$, seed)

Scope closed: Definition 8517.1 and Definition 8517.2 seed the finite ultrametric approximation surface over metric, doubling, finite-net, dyadic, transport, replay, provenance, and local naming rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{UltrametricSkeleton}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host choice, quotient metric equality, selected infinite trees, open-cover compactness, ambient completeness, Lean verification, axiom-purity audit, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite scale-net exposure, cluster-tree incidence exactness, ultrametric ledger exactness, distortion-budget compatibility, transport, replay, provenance, and local naming for BEDC.Derived.UltrametricSkeletonUp.

Chapter 8518

A Concrete Naming Certificate for $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$

Following Bishop–Bridges constructive total boundedness and Kelley's filter and net language, the $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$ packet records the finite route by which a totally bounded source and a Cauchy filter or net source produce a completion-facing regular readback. It sits after the finite-net surface of chapter 127, the Cauchy-filter surface of chapter 333, the complete-metric seal of chapter 128, and the basis-first completion handoff of chapter 4050. The packet names a finite compactness-completion bridge only; it does not select a limit, identify quotient filters, use countable choice, or import ambient completeness outside the displayed rows.

Definition 8518.1 (Totally bounded Cauchy net carrier)**.** *A* $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (B, C, F, D, W, R, S, H, K, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{TotallyBounded}^{\uparrow}$ *source row, exposing the finite-net coverage surface used by the inspected metric source.*
2. *C is the* $\mathsf{CauchyFilter}^{\uparrow}$ *or Cauchy-net source row, naming the directed observation route whose tails must be read through finite covers.*
3. *F is the finite net basis row, recording the selected cover indices, basis observations, and bundled centers displayed at each inspected tolerance.*
4. *D is the dyadic tolerance ledger row, storing the positive tolerance histories and refinement comparisons used by the finite basis.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window family through which Cauchy observations and finite-net choices are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row extracted from the same windows and dyadic tolerance data.*
7. *S is the* $\mathsf{CompleteMetric}^{\uparrow}/\mathsf{Real}^{\uparrow}$ *seal row reached only after B, C, F, D, W, R have been displayed.*
8. *H records componentwise* hsame *transport for the totally bounded source, Cauchy source, finite basis, tolerance ledger, windows, readback, seal, replay, provenance, and local naming.*
9. *K records displayed* Cont *replay from a Cauchy observation request through finite-net coverage, dyadic tolerance, stream-window inspection, regular rational readback, and the terminal seal.*

10. *P is the* Pkg *provenance over* TotallyBoundedCauchyNet$^{\uparrow}$, TotallyBounded$^{\uparrow}$, CauchyFilter$^{\uparrow}$, CauchyFilterBasisCom
CompleteMetric$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{TotallyBoundedCauchyNet}^{\uparrow}}$ *row.*

The carrier exports only the displayed finite completion route. It has no coordinate for quotient completion, a choice-selected subnet, host metric compactness, selected limit representatives, hidden tolerance comparison, or ambient completeness outside S.

Theorem 8518.2 (Totally bounded Cauchy net NameCert obligations)**.** *For every accepted* TotallyBoundedCauchyI *carrier*

$$T = (B, C, F, D, W, R, S, H, K, P, N),$$

the local NameCert$_{\text{TotallyBoundedCauchyNet}^{\uparrow}}$ *surface consists exactly of totally bounded source exposure, Cauchy filter or net source exposure, finite net basis exposure, dyadic tolerance-ledger exposure, StreamName window exposure, RegSeqRat readback, CompleteMetric or Real seal handoff, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8518.1. The source rows are B and C, the finite compactness rows are F, D, the observation rows are W, R, and the seal and structural rows are S, H, K, P, N.

Read the totally bounded row before the Cauchy observation is consumed. The finite basis F is licensed by the finite-net coverage surface, while the Cauchy row C fixes which directed tails or filter observations must be covered.

Next inspect D, W, R. The dyadic ledger records the tolerance budget, the stream windows display the finite observations, and the regular rational readback records the completion-facing value for the same inspected windows.

Finally consume S, H, K, P, N. The seal is downstream of the totally bounded source, Cauchy source, basis, tolerance, window, and readback rows, and the structural rows preserve exactly that route. Since no carrier coordinate stores quotient completion, a selected subnet, host compactness, selected limits, hidden tolerance comparison, or detached completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8518.3 (Totally bounded Cauchy net filter handoff)**.** *Every* CauchyFilterBasisCompletion$^{\uparrow}$ *or* CompleteMetric$^{\uparrow}$ *consumer of an accepted* TotallyBoundedCauchyNet$^{\uparrow}$ *packet must first read*

$$B, C, F, D, W, R, S, H, K, P, N.$$

Thus a completion-facing Cauchy read from a totally bounded source passes through displayed finite-net coverage, Cauchy filter or net source data, dyadic tolerance control, StreamName windows, RegSeqRat readback, the CompleteMetric or Real seal, transport, replay, provenance, and local naming before any downstream completion result is consumed.

Proof. Start with Definition 8518.2. It requires the totally bounded source row B and the Cauchy source row C before the finite basis, tolerance, window, and readback rows can be read.

For a CauchyFilterBasisCompletion$^{\uparrow}$ consumer, the row C supplies the filter or net source and F, D, W, R supply the basis, tolerance, window, and readback data needed for the basis-first route of chapter 4050.

For a CompleteMetric$^{\uparrow}$ consumer, the seal row S records only the displayed completion-facing handoff. The provenance row may cite the complete-metric vocabulary, but it does not add a selected limit, quotient filter, or choice-selected subnet.

The exclusions follow from Definition 8518.1. Any downstream completion read must traverse the finite rows of T, so no hidden compactness or quotient-completion principle can be recovered from the packet. □

Falsifiable prediction: A claimed $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$ completion read is rejected unless the totally bounded source, Cauchy source, finite net basis, dyadic tolerance ledger, StreamName windows, RegSeqRat readback, CompleteMetric or Real seal, transport, replay, provenance, and local NameCert rows are all displayed.

Independence witness: totallybounded, cauchyfilter, completemetric, cauchy-filter-basis-completion: none is bijective to $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$ because the packet jointly binds finite-net coverage, Cauchy filter or net source data, dyadic tolerance control, StreamName windows, RegSeqRat readback, completion seal, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{TotallyBoundedCauchyNet}^{\uparrow}}$.

Constructive story: A $\mathsf{TotallyBoundedCauchyNet}^{\uparrow}$ packet is generated from TotallyBounded source rows, CauchyFilter or Cauchy-net source rows, finite net basis data, dyadic tolerance ledgers, StreamName windows, RegSeqRat readback, a CompleteMetric or Real seal, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TotallyBoundedCauchyNet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8518.1, Definition 8518.2, and Definition 8518.3 seed the finite totally bounded Cauchy handoff to completion-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TotallyBoundedCauchyNet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected subnets, host compactness, selected limit representatives, countable choice, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked source admission, Cauchy source admission, finite net basis exactness, dyadic tolerance exactness, StreamName window exactness, RegSeqRat readback, CompleteMetric or Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.TotallyBoundedCauchyNetUp.

Chapter 8519

A Concrete Naming Certificate for $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$

The $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$ packet realizes the classifier-shift information principle of section 9462.2 as a finite gate for positiveDiscovery reads. It sits beside the classifier-channel shift ledger of chapter 6765, the pipeline discovery classifier of chapter 6931, the theorem-genome evolution packet of chapter 6358, and the theorem-DNA complexity scoring packet of chapter 7061. The packet accepts a discovery read only when classifier disagreement, witness flow, semantic certificate, public weight profile, refusal boundary, transport, replay, provenance, and local naming are displayed as one finite route.

Definition 8519.1 (Classifier-shift discovery gate carrier)**.** *A* $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (B, A, W, S, Q, R, T, C, P, N)$$

with the following displayed rows:

1. *B is the before-classifier row, naming the source scope and classifier relation before the inspected passage.*
2. *A is the after-classifier row, naming the same comparison surface after the inspected passage.*
3. *W is the witness-flow row, exposing a non-smoke path from source material to changed classifier judgment.*
4. *S is the semantic* $\mathsf{NameCert}$ *row, recording the certificate that licenses the changed classifier surface.*
5. *Q is the public weight-profile row used to distinguish positiveDiscovery from record growth or unchecked classifier movement.*
6. *R is the refusal row, recording failed, hidden, or ledger-incomplete claims that must remain visible.*
7. *T records componentwise* hsame *transport for classifier rows, witness flow, semantic certificate, weight profile, refusal, replay, provenance, and local naming.*
8. *C records displayed* Cont *replay from the before/after classifier comparison through witness flow, semantic certification, weight-profile reading, refusal inspection, and local naming.*

9. *P is the* Pkg *provenance over* ClassifierShiftDiscoveryGate$^{\uparrow}$, ClassifierChannelShiftLedger$^{\uparrow}$, PipelineDiscoveryClassif TheoremGenomeEvolution$^{\uparrow}$, TheoremDNAComplexityScoring$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}}$ *row.*

The carrier has no coordinate for prose-only discovery, record count alone, hidden classifier comparison, smoke witness flow, missing semantic certificate, hidden weight profile, refusal erasure, or a local name outside N.

Theorem 8519.2 (Classifier-shift discovery gate NameCert obligations)**.** *For every accepted* ClassifierShiftDiscovery *carrier*

$$G = (B, A, W, S, Q, R, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}}$ *surface consists exactly of before-classifier exposure, after-classifier exposure, non-smoke witness-flow exposure, semantic-certificate exposure, public weight-profile exposure, refusal-row exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the carrier of Definition 8519.1. The classifier comparison is carried by B, A, the evidence route by W, S, Q, R, and the structural preservation rows by T, C, P, N.

Read B and A first. A positiveDiscovery read cannot be formed before the before and after classifier rows are displayed over the same comparison surface.

Next inspect W, S, Q, R. The witness flow rules out smoke evidence, the semantic certificate licenses the changed classifier surface, the public weight profile records the positive reading, and the refusal row keeps rejected or incomplete claims visible.

Finally use T, C, P, N. These rows transport, replay, source, and name the same gate without adding hidden classifier comparison, hidden weights, or refusal erasure. The listed rows therefore exhaust the local NameCert obligations. □

Theorem 8519.3 (Classifier-shift discovery gate ledger route)**.** *Every positiveDiscovery read from an accepted* ClassifierShiftDiscoveryGate$^{\uparrow}$ *packet factors through the classifier-channel ledger, pipeline discovery classifier, theorem-genome evolution route, and theorem-DNA complexity scoring surface before the local gate name is consumed. If any of before/after disagreement, witness flow, semantic certificate, weight profile, refusal row, transport, replay, provenance, or local naming is absent, the read is rejected by the displayed carrier.*

Proof. Start with Definition 8519.2. It places the before and after classifier rows, witness flow, semantic certificate, weight profile, refusal row, transport, replay, provenance, and local naming inside the same accepted packet.

Read the sibling route named in the introduction. The classifier-channel ledger supplies the before/after comparison surface, the pipeline discovery classifier supplies the positiveDiscovery boundary, the theorem-genome evolution packet supplies the theorem-flow route, and the theorem-DNA complexity scoring surface supplies the public weight profile.

The refusal and structural rows keep the same route auditable. Since no carrier coordinate supplies prose-only discovery, record count alone, hidden comparison, smoke evidence, hidden weights, or refusal erasure, omitting any displayed row prevents the local gate name from being consumed as a positiveDiscovery read. □

Falsifiable prediction: A claimed positive discovery read is rejected unless before/after classifier disagreement, non-smoke witness flow, semantic NameCert row, classifier-gain row, weight profile, refusal row, transport, replay, provenance, and local naming are all displayed.

Independence witness: theorem-genome-evolution, pipeline-discovery-classifier, classifier-channel-shift-ledger, theorem-dna-complexity-scoring: none is bijective to $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$ because the gate jointly binds before/after classifier disagreement, witness flow, semantic certificate, weight profile, refusal, transport, replay, provenance, and local naming.

The Lean follow-up for $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$ must provide explicit $\mathsf{Nontrivial\ ClassifierShiftDiscoveryGate}^{\uparrow}$ and $\mathsf{FieldFaithful\ ClassifierShiftDiscoveryGate}^{\uparrow}$ instances in `lean4/BEDC/Derived/ClassifierShiftDiscoveryGate` The field-faithfulness witness must preserve $B, A, W, S, Q, R, T, C, P, N$ as distinct rows before a checked gate theorem can cite the packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}}$ **.**

Constructive story: A $\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}$ packet is generated from before-classifier rows, after-classifier rows, non-smoke witness flow, semantic NameCert evidence, public weight-profile rows, refusal rows, componentwise hsame transport, displayed Cont replay, package provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8519.1, Definition 8519.2, and Definition 8519.3 seed the finite gate for classifier-shift discovery reads.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClassifierShiftDiscoveryGate}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global discovery certification, hidden semantic novelty scoring, automated theorem proving, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked before/after classifier disagreement, witness-flow non-smoke exposure, semantic certificate exposure, public weight-profile exposure, refusal preservation, transport, replay, provenance, local naming, Nontrivial, and FieldFaithful rows for BEDC.Derived.ClassifierShiftDiscoveryGateUp.

Chapter 8520

A Concrete Naming Certificate for $\mathsf{DyadicIntervalHalving}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{DyadicIntervalHalving}^{\uparrow}$ packet records one inspected bisection step for a dyadic interval as finite NameCert data. It sits beside the dyadic arithmetic core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet supplies downstream nested interval, interval cover, and regular Cauchy completion consumers with a local halving row; it does not smuggle open-cover compactness, quotient real equality, trichotomy, an unbounded midpoint selector, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

The sibling route is deliberately local. $\mathsf{DyadicRatCore}^{\uparrow}$ supplies the endpoint arithmetic and width ledger, $\mathsf{StreamName}^{\uparrow}$ supplies the finite observation window, $\mathsf{RegSeqRat}^{\uparrow}$ supplies the regular rational readback boundary, and $\mathsf{Real}^{\uparrow}$ supplies the terminal seal only after the displayed dyadic row has been inspected.

Definition 8520.1 (Dyadic interval halving carrier)**.** *A* $\mathsf{DyadicIntervalHalving}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (I, D, M, L, R, W, Q, E, T, C, P, N)$$

with the following displayed rows:

1. *I is the input dyadic interval row, recording left endpoint, right endpoint, and the displayed nonnegative width witness.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row for endpoint comparison, midpoint formation, and dyadic denominator tracking.*
3. *M is the midpoint row computed from the displayed endpoints through D.*
4. *L is the left-child row with endpoints given by the input left endpoint and M.*
5. *R is the right-child row with endpoints given by M and the input right endpoint.*
6. *W is the width-halving row, exposing the equality of the two child widths with one displayed dyadic half of the input width.*
7. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row for reading endpoints, midpoint, and child widths.*
8. *E is the* $\mathsf{RegSeqRat}^{\uparrow}$ *rational readback row formed from Q and D.*
9. *T is the* $\mathsf{Real}^{\uparrow}$ *seal boundary row available only after I, D, M, L, R, W, Q, E have been displayed.*

10. *C records componentwise* hsame *transport for interval, arithmetic, midpoint, child, width, window, readback, seal, replay, provenance, and local naming rows.*
11. *P is the* Pkg *provenance over* $\mathsf{DyadicIntervalHalving}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}$ *row.*

The carrier exports exactly one dyadic halving step. It has no coordinate for an infinite branch, open-cover compactness, quotient real equality, trichotomy, selected midpoint choice beyond the displayed dyadic row, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.DyadicIntervalHalvingUp.DyadicIntervalHalvingTasteGate single carrier alignment`

Theorem 8520.2 (Dyadic interval halving NameCert obligations)**.** *For every accepted* $\mathsf{DyadicIntervalHalving}^{\uparrow}$ *carrier*

$$H = (I, D, M, L, R, W, Q, E, T, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}$ *surface consists exactly of input interval exposure, dyadic arithmetic exposure, midpoint exposure, left-child exposure, right-child exposure, width-halving exposure, finite-window scheduling, regular rational readback, terminal Real sealing, componentwise transport, package provenance, and local naming.*

Proof. Project the carrier of Definition 8520.1. The rows I and D expose the input interval and the dyadic arithmetic ledger before any child interval is read.

The midpoint and child rows are M, L, R. They are computed from the displayed dyadic endpoint data, and the width row W records the local halving equality for those two children.

The completion-facing route is downstream from the halving rows. The finite window Q is read before the regular rational row E, and the terminal Real seal T is available only after that readback. The rows C, P, N transport, source, and name the same finite route, so the listed rows exhaust the local certificate. □

Theorem 8520.3 (Dyadic interval halving nested route handoff)**.** *Every nested interval consumer of an accepted* $\mathsf{DyadicIntervalHalving}^{\uparrow}$ *carrier must read the handoff through*

$$I, D, M, L, R, W, Q, E, T, C, P, N.$$

The packet offers one displayed dyadic bisection step that can be appended to a finite nested route, but it does not choose an infinite branch, assert interval compactness, or identify quotient real names.

Proof. Begin with the displayed input interval row I and arithmetic row D. These rows determine the endpoint comparison and midpoint formation visible to a later nested-route consumer.

The child rows L and R are both present as finite data, with W recording the halved width relation. A consumer may retain either displayed child in its own finite route, but the carrier itself does not provide an infinite selector.

The rows Q, E, T then expose the observation, rational readback, and Real-facing boundary for that same one-step bisection. Since the structural rows C, P, N preserve only this finite packet, the handoff remains a local nested-route input rather than a compactness or quotient-real principle. □

Theorem 8520.4 (Dyadic interval halving Real seal boundary)**.** *The* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{DyadicIntervalHalving}^{\uparrow}$ *carrier is readable only after the dyadic endpoint row, midpoint row, child interval rows, width-halving row, finite observation row, and regular rational readback row have all been displayed. In particular, the seal does not create ambient real completeness, quotient equality of real names, trichotomy, or open-cover compactness.*

Proof. Read the carrier in the order prescribed by Definition 8520.1. The input endpoint row I, arithmetic row D, midpoint row M, child rows L, R, and width row W provide the whole dyadic halving surface.

The observation row Q and regular rational row E translate that finite surface into the completion-facing readback route. Only then is the row T exposed as the terminal $\mathsf{Real}^{\uparrow}$ seal boundary.

No remaining coordinate stores ambient completeness, quotient equality, trichotomy, or compactness. The seal therefore records only the displayed one-step dyadic interval readback. □

Theorem 8520.5 (Dyadic interval halving scoped bisection transport)**.** *Every accepted* $\mathsf{DyadicIntervalHalving}^{\uparrow}$ *bisection read transports componentwise through the displayed dyadic endpoint row, the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, the* $\mathsf{Real}^{\uparrow}$ *seal row,* hsame *transport,* Cont *replay,* Pkg *provenance, and the local* $\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}$ *row. The packet exports no open-cover compactness, quotient* $\mathsf{Real}^{\uparrow}$ *equality, trichotomy, unbounded midpoint selector, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Apply the NameCert obligations of Definition 8520.2. They expose the input interval row, dyadic arithmetic row, midpoint row, child rows, width-halving row, finite observation row, regular rational readback row, Real seal row, transport row, provenance row, and local naming row as one finite carrier.

Next use the nested route handoff of Definition 8520.3. It permits a consumer to append the displayed left or right child only as a one-step bisection input, with no infinite branch selector or compactness principle attached.

Finally apply the Real seal boundary of Definition 8520.4. Since the seal is readable only after the endpoint, midpoint, child, width, observation, and readback rows have been displayed, componentwise hsame transport and Cont replay preserve exactly that scoped route. The carrier has no coordinate for open-cover compactness, quotient real equality, trichotomy, an unbounded midpoint selector, or ambient completeness, so none is exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicIntervalHalving}^{\uparrow}$ packet is generated from one input dyadic interval row, DyadicRatCore arithmetic rows, a midpoint row, two child interval rows, a width-halving row, StreamName finite observations, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8520.1, Definition 8520.2, Definition 8520.3, and Definition 8520.4 seed the one-step dyadic interval bisection packet over arithmetic, observation, readback, seal, transport, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicIntervalHalving}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, quotient real equality, trichotomy, selected midpoint choice beyond the displayed dyadic row, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, dyadic arithmetic exposure, midpoint formation, child-row exposure, width-halving exactness, finite-window scheduling, regular rational readback, Real seal boundary control, transport, provenance, and local naming for BEDC.Derived.DyadicIntervalHalvingUp.

Chapter 8521

A Concrete Naming Certificate for $\mathsf{HyperbolicHorosphere}^{\uparrow}$

Following classical hyperbolic geometry, the $\mathsf{HyperbolicHorosphere}^{\uparrow}$ packet realizes the level-set side of the observer-expansion vision of chapter 9463 as finite NameCert data. It sits after the metric source of chapter 3474, the Busemann boundary route of chapter 3732, the terminal real-name seal of chapter 38, and the metric carrier of chapter 57. The packet names a displayed boundary point and Busemann level surface; it does not introduce a host ideal boundary quotient, a completed horoball compactification, a selected geodesic representative, or a physical observer trajectory.

Definition 8521.1 (Hyperbolic horosphere carrier)**.** *A* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (M, B, L, R, O, E, T, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *metric-read row for the source observations.*
2. *B is the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *boundary-point and Busemann-read row.*
3. *L is the displayed Busemann level row naming the horosphere slice.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *level-seal row used to compare the displayed Busemann value with L.*
5. *O is the observer-window row, recording which finite metric and Busemann observations are available.*
6. *E is the non-escape row excluding ideal-boundary quotient equality, completed horoball compactification, selected geodesic representatives, and physical observer motion.*
7. *T is the transport row preserving the boundary point, Busemann level, metric readback, observer window, and Real seal under componentwise readback.*
8. *H records componentwise* hsame *transport for metric, boundary, level, seal, window, non-escape, transport, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay through metric admission, Busemann boundary readback, level comparison, observer-window inspection, Real sealing, and non-escape.*
10. *P is the* Pkg *provenance over* $\mathsf{HyperbolicHorosphere}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

11. N is the local $\mathsf{NameCert}_{\mathsf{HyperbolicHorosphere}^{\uparrow}}$ *row.*
The carrier exports horosphere data only through $M, B, L, R, O, E, T, H, C, P, N$. It contains no coordinate for a host boundary quotient, a global foliation of hyperbolic space, a completed compactification, a selected geodesic ray, or an observer-substance reading.

Theorem 8521.2 (Hyperbolic horosphere NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *carrier*

$$S = (M, B, L, R, O, E, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicHorosphere}^{\uparrow}}$ *surface consists exactly of hyperbolic metric admission, Busemann boundary admission, displayed level exposure, Real seal comparison, observer-window exposure, non-escape refusal, componentwise transport, displayed replay, package provenance, and local naming.*

Proof. Project the carrier of Definition 8521.1. The metric row M and Busemann boundary row B expose the source and boundary data before any horosphere read is made.

The rows L and R form the level surface: L names the displayed Busemann level, while R gives the Real-facing comparison boundary for that level. The observer-window row O records the finite observations available to a consumer.

The refusal and structural rows E, T, H, C, P, N preserve this same route and exclude boundary quotients, compactification, selected geodesics, and observer-substance readings. Hence the displayed rows exhaust the local NameCert obligations. □

Theorem 8521.3 (Hyperbolic horosphere Busemann route)**.** *Every public read from an accepted* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *carrier to a Busemann-level statement factors through the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row M, the* $\mathsf{HyperbolicBusemannBoundary}^{\uparrow}$ *row B, the displayed level row L, the* $\mathsf{Real}^{\uparrow}$ *seal row R, and the observer-window row O before the transport, replay, provenance, and naming rows are consumed.*

Proof. Read the metric and Busemann source rows first. The metric read M supplies the finite hyperbolic distance observations, and B supplies the boundary point together with the Busemann readback route.

The level row L is interpreted only through the Real seal row R and the observer-window row O. This makes the horosphere a displayed level surface rather than a quotient boundary object.

The rows T, H, C, P, N then transport, replay, source, and name the same Busemann-level route. Since the carrier contains no global compactification or selected geodesic coordinate, every Busemann read must factor through the displayed rows. □

Theorem 8521.4 (Hyperbolic horosphere non-escape)**.** *An accepted* $\mathsf{HyperbolicHorosphere}^{\uparrow}$ *carrier cannot export host ideal-boundary quotient equality, completed horoball compactification, a selected geodesic representative, global horosphere foliation, or physical observer motion. All exported data are confined to*

$$M, B, L, R, O, E, T, H, C, P, N.$$

Proof. Inspect the carrier inventory of Definition 8521.1. The only geometric source rows are the metric row M, the Busemann boundary row B, the level row L, the Real seal row R, and the observer-window row O.

The non-escape row E records the excluded host readings, while T, H, C, P, N preserve only the displayed finite route. No carrier coordinate names a boundary quotient, compactification, selected geodesic, global foliation, or observer motion.

Therefore a consumer can extract only the finite horosphere rows and their replay/provenance data. The excluded host objects have no row from which they can be read. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicHorosphere}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicHorosphere}^{\uparrow}$ packet is generated from HyperbolicMetric metric rows, HyperbolicBusemannBoundary boundary and Busemann rows, a displayed Busemann level, RealUp level sealing, observer-window rows, non-escape refusal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicHorosphere}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8521.1, Definition 8521.2, Definition 8521.3, and Definition 8521.4 seed the finite horosphere certificate over metric, boundary, Busemann level, Real seal, observer-window, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicHorosphere}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close ideal-boundary quotient equality, completed horoball compactification, selected geodesic representatives, global horosphere foliations, physical observer motion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked metric admission, Busemann boundary admission, level-row exposure, Real seal comparison, observer-window exactness, non-escape, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicHorosphereUp.

Chapter 8522

A Concrete Naming Certificate for $\mathsf{MacShaneExtension}^{\uparrow}$

Following McShane's extension theorem, the $\mathsf{MacShaneExtension}^{\uparrow}$ packet records the finite BEDC certificate by which a displayed real-valued Lipschitz map on a located subcarrier of a displayed metric space is read as an ambient Lipschitz envelope. It consumes the $\mathsf{Met}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ carrier surfaces of chapter 57 and chapter 38, the $\mathsf{ContinuousMap}^{\uparrow}$ replay discipline of chapter 130, the $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ bound route of chapter 3812, and the $\mathsf{LocatedUniformSpace}^{\uparrow}$ located-uniform boundary of chapter 3814. The packet names a finite envelope certificate, not a host formula for arbitrary extrema or a quotient function over completed reals.

Definition 8522.1 (MacShaneExtension carrier)**.** *A* $\mathsf{MacShaneExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (X, A, d, f, L, E, S, R, U, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *ambient carrier row, exposing only the metric observations used by the envelope request.*
2. *A is the located source row, recording the admitted subcarrier points and the finite inclusion evidence read by ambient comparisons.*
3. *d is the* $\mathsf{LocatedUniformSpace}^{\uparrow}$ *compatibility row that keeps source and ambient distance reads on the same located-uniform route.*
4. *f is the* $\mathsf{Real}^{\uparrow}$ *source-value graph row for the displayed real-valued map on A.*
5. *L is the* $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ *bound row, recording the displayed Lipschitz constant and the finite tolerance handoff used by the envelope.*
6. *E is the MacShane envelope row, storing finite comparison data of the form source value plus bound times ambient distance, without selecting an arbitrary infimum operator.*
7. *S is the source-agreement row, requiring every source-admitted ambient read to return through A, d, f, L, E before it is identified with the original source read.*
8. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for source values, envelope comparisons, and ambient extension reads.*
9. *U is the* $\mathsf{ContinuousMap}^{\uparrow}$ *replay row that records the continuity-facing readback route after the Lipschitz handoff has been displayed.*

10. *H records componentwise* hsame *transport for the carrier, source, metric, graph, bound, envelope, agreement, Real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay from a precision request through $X, A, d, f, L, E, S, R, U, H, P, N$.*
12. *P is the* Pkg *provenance over* $\mathsf{MacShaneExtension}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$, $\mathsf{LocatedUniformSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{MacShaneExtension}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these thirteen rows. It has no coordinate for host choice, quotient real equality, arbitrary infimum operators, selected extrema, countable choice, trichotomy, or ambient completeness.

Theorem 8522.2 (MacShaneExtension NameCert obligations)**.** *For every accepted* $\mathsf{MacShaneExtension}^{\uparrow}$ *carrier $M = (X, A, d, f, L, E, S, R, U, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{MacShaneExtension}^{\uparrow}}$ *surface consists of the following finite obligation rows:*

1. *carrier admission for the ambient metric-space row, located source row, located-uniform distance row, source-value graph, Lipschitz handoff, envelope, agreement, Real seal, continuity replay, transport, provenance, and local naming rows;*
2. *domain compatibility, requiring every source-value read to pass through A and d before comparison with an ambient envelope read;*
3. *bound transport, requiring L to mediate every tolerance and distance-to-value estimate consumed by E;*
4. *envelope exactness, requiring E to store finite MacShane comparison data and no host choice, quotient real equality, selected extremum, or arbitrary infimum operator;*
5. *source-agreement nonescape, requiring S, R, U, H, C, P, N to preserve the displayed route without adding a host function object, a quotient function, or an ambient completeness witness.*

No local obligation is stored outside these five rows.

Proof. Carrier admission is projection from Definition 8522.1. The accepted packet displays exactly the ambient metric-space, located source, located-uniform distance, source graph, Lipschitz handoff, envelope, agreement, Real seal, continuity replay, and structural rows.

Read the domain and bound clauses next. The rows A and d provide the source admission and ambient distance route, while f and L provide the source value and the displayed Lipschitz constant. Thus an envelope comparison cannot be formed before the carrier has exposed the same finite metric and Real rows used by the source map.

Project the envelope row E. It stores finite MacShane comparisons derived from displayed source values and displayed distance bounds, so it can be replayed for a concrete ambient request without selecting a global extremum or quotient real representative.

Finally inspect S, R, U, H, C, P, N. Agreement, Real sealing, continuity replay, transport, provenance, and local naming only preserve the displayed rows. Therefore the NameCert surface is exactly the listed five-row obligation sketch, and no host choice, quotient real equality, arbitrary infimum operator, selected extremum, or ambient completeness principle is introduced. □

Theorem 8522.3 (MacShaneExtension Lipschitz envelope)**.** *Let $M = (X, A, d, f, L, E, S, R, U, H, C, P, N)$ be an accepted* $\mathsf{MacShaneExtension}^{\uparrow}$ *carrier. Every ambient envelope read exported by M factors through the finite route*

$$X, A, d \longmapsto f \longmapsto L \longmapsto E \longmapsto S, R, U \longmapsto H, C, P, N.$$

Along that route the displayed Lipschitz bound remains the only value-growth control used by the ambient read. The packet exports a finite Lipschitz-envelope certificate and no host choice, quotient real equality, arbitrary infimum operator, selected extremum, countable-choice selector, trichotomy branch, or ambient completeness witness.

Proof. Start with an ambient envelope request. The rows X, A, d expose the only metric-space, source-admission, and located-uniform distance information available to the read.

Read the source graph and bound handoff. The row f supplies the displayed Real source values, while L supplies the Lipschitz control that turns distance information into value estimates. This is the only route by which a bound can enter the envelope.

The envelope row E then records finite comparisons for the requested ambient input. The source-agreement and Real-seal rows S, R keep those comparisons tied to the source route, and the continuity replay row U exposes only the same Lipschitz-facing handoff to continuous-map consumers.

Transport, replay, provenance, and local naming preserve the route through H, C, P, N. Since no listed row stores host choice, quotient real equality, an arbitrary infimum operator, a selected extremum, countable choice, trichotomy, or ambient completeness, the exported object is exactly the finite Lipschitz-envelope certificate. □

Falsifiable prediction: An accepted $\mathsf{MacShaneExtension}^{\uparrow}$ consumer that reaches an ambient envelope read without first reading the ambient $\mathsf{Met}^{\uparrow}$ row, the located source row, the $\mathsf{Real}^{\uparrow}$ source graph, the $\mathsf{LipschitzContinuityHandoff}^{\uparrow}$ bound row, and the MacShane envelope row refutes the carrier surface.

Independence witness: metric-space, real, continuousmap, lipschitz-continuity-handoff, located-uniform-space: no listed sibling supplies the full thirteen-row packet $M = (X, A, d, f, L, E, S, R, U, H, C, P, N)$, because each sibling contributes only a metric carrier, Real seal, continuity replay, bound handoff, or located-uniform distance boundary while this chapter binds the finite MacShane envelope certificate into one local NameCert surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MacShaneExtension}^{\uparrow}}$.

Constructive story: A $\mathsf{MacShaneExtension}^{\uparrow}$ packet is generated from an ambient MetricSpaceUp row, a located source row, a LocatedUniformSpaceUp distance row, a RealUp source graph, a LipschitzContinuityHandoffUp bound row, a finite envelope row, a source-agreement row, a Real seal, ContinuousMapUp replay, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MacShaneExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8522.1, Definition 8522.2, and Definition 8522.3 seed the finite MacShane Lipschitz-envelope certificate over displayed metric-space, located-source, Real, continuity, Lipschitz-handoff, and located-uniform data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MacShaneExtension}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host choice, quotient real equality, arbitrary infimum operators, selected extrema, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, domain compatibility, bound transport, envelope exactness, source-agreement nonescape, and a Lean carrier/obligation formalization for BEDC.Derived.MacShaneExtensionUp.

Chapter 8523

A Concrete Naming Certificate for $\mathsf{ControllabilityRank}^{\uparrow}$

Following Kalman 1960 on controllability rank conditions, the $\mathsf{ControllabilityRank}^{\uparrow}$ packet records the finite rank-window certificate that sits between the reachability ledger of chapter 297 and the finite matrix-pencil consumers of chapter 8240. It names the displayed columns, dimension rows, rank-window comparisons, transport, replay, provenance, and local naming data used by finite-dimensional control reads. The packet is not a host reachable subspace, not a quotient state space, not a Kalman decomposition, and not an infinite-dimensional controllability theorem.

Definition 8523.1 (ControllabilityRank carrier)**.** *A* $\mathsf{ControllabilityRank}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (X, U, A, B, W, V, L, R, O, H, C, P, N)$$

with the following displayed rows:

1. *X is the finite state* $\mathsf{VecSpace}^{\uparrow}$ *row and U is the finite input* $\mathsf{VecSpace}^{\uparrow}$ *row.*
2. *A is the transition* $\mathsf{Mat}^{\uparrow}$ *row and B is the input* $\mathsf{Mat}^{\uparrow}$ *row, both read as* $\mathsf{LinMap}^{\uparrow}$ *data when the reachability columns are generated.*
3. *W is the finite rank-window row listing the displayed columns $B, AB, \ldots, A^{n-1}B$ and the row-reduction comparisons used to test whether the window spans the displayed state dimension.*
4. *V is the vector-space dimension row against which the rank window is measured.*
5. *L is the* $\mathsf{LinMap}^{\uparrow}$ *reachability-iterate ledger recording each multiplication and column append route.*
6. *R is the* $\mathsf{ControlControllability}^{\uparrow}$ *reachability ledger consumed by downstream controllability readers.*
7. *O is the* $\mathsf{ControlObservability}^{\uparrow}$ *dual-window row available to dual tests and observability-facing consumers.*
8. *H records componentwise* hsame *transport for state rows, input rows, matrix rows, reachability iterates, rank windows, dimension rows, dual windows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay from the plant rows through the reachability iterates into the rank-window certificate.*

10. *P is the* Pkg *provenance over* $\mathsf{ControllabilityRank}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ControlObservability}^{\uparrow}$, $\mathsf{HautusTest}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ControllabilityRank}^{\uparrow}}$ *row.*

The carrier exports only this finite rank-window surface. It has no coordinate for a host rank theorem detached from $W, V, L, R, O, H, C, P, N$, and it has no quotient subspace through which reachability could be identified externally.

Theorem 8523.2 (ControllabilityRank NameCert obligations)**.** *For every accepted* $\mathsf{ControllabilityRank}^{\uparrow}$ *carrier*

$$K = (X, U, A, B, W, V, L, R, O, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ControllabilityRank}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, finite rank-window exactness for W, matrix and vector-space readback through A, B, X, U, V, reachability-ledger exactness through L and R, dual-window exposure through O, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N. The certificate never escapes to a host rank predicate, a quotient state subspace, a Kalman decomposition, a spectral test outside the Hautus consumer row, or an infinite-dimensional controllability claim.*

Proof. Carrier admission is projection from Definition 8523.1. The accepted packet displays the finite state and input rows, transition and input matrices, rank-window row, dimension row, reachability iterates, controllability ledger, dual observability window, transport, replay, provenance, and local name.

Finite rank-window exactness is the row W measured against V. The matrix and vector-space readback rows A, B, X, U, V are already visible before W can be consumed, and the reachability-iterate ledger L records how each displayed column is generated.

The downstream control surface is R, O together with the $\mathsf{HautusTest}^{\uparrow}$ provenance named by P. A controllability consumer reads R, an observability or dual-test consumer reads O, and a Hautus consumer may inspect the same finite rank-window data without receiving an external spectral decomposition.

Finally transport and replay are exactly H and C. Since the carrier contains no host rank predicate, quotient state subspace, Kalman decomposition object, or infinite-dimensional theorem, the local NameCert obligations are exhausted by the finite packet K. □

Falsifiable prediction: An accepted $\mathsf{ControllabilityRank}^{\uparrow}$ packet is refuted by any downstream control consumer that reads a controllability rank result while bypassing the displayed rank-window row W, the dimension row V, the reachability-iterate ledger L, or the $\mathsf{ControlControllability}^{\uparrow}$ ledger R.

Independence witness: Nearest siblings: controlcontrollability, controlobservability, hautustest, matrix, linearmap, and vecspace; none is bijective to $\mathsf{ControllabilityRank}^{\uparrow}$ because this packet keeps the rank-window row, dimension readback, reachability-iterate ledger, dual-window row, Hautus provenance, transport, replay, provenance, and local NameCert row in one finite certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ControllabilityRank}^{\uparrow}}$.

Constructive story: A $\mathsf{ControllabilityRank}^{\uparrow}$ packet is generated from finite state and input rows, transition and input matrix rows, a finite rank-window row, a vector-space dimension row, reachability-iterate rows, controllability and observability ledger rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ControllabilityRank}^{\uparrow}}$, seed)

Scope closed: Definition 8523.1, Definition 8523.2, the displayed falsifiable prediction, and the displayed independence witness seed the finite Kalman rank-window certificate over matrix, vector-space, linear-map, controllability, observability, and Hautus rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{ControllabilityRank}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host reachable-subspace equality, quotient state-space rank, Kalman decomposition, spectral completeness, analytic trajectory semantics, infinite-dimensional controllability, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite rank-window exactness, matrix and vector-space readback, reachability-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.ControllabilityRankUp.

Chapter 8524

A Concrete Naming Certificate for $\mathsf{BeckChevalley}^{\uparrow}$

Following Beck and Chevalley on base-change coherence in categorical logic, the $\mathsf{BeckChevalley}^{\uparrow}$ packet records the finite NameCert surface by which a pullback square and its adjoint/Kan-extension data are allowed to expose a comparison map. It sits after the categorical carrier of chapter 61, the functorial transport surface of chapter 62, the natural-transformation component surface of chapter 63, the adjunction ledger of chapter 107, and the Kan-extension handoff of chapter 3927. The packet names only the displayed square, adjoint rows, Kan-extension route, comparison 2-cell, transport, replay, provenance, and local NameCert data; it does not assert a host indexed-category theorem, ambient exactness, or quotient equality of functor categories.

Definition 8524.1 (Beck–Chevalley carrier)**.** *A* $\mathsf{BeckChevalley}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A, C, L, R, K, T, H, E, P, N)$$

with the following displayed rows:

1. *A is the source* $\mathsf{Cat}^{\uparrow}$ *and target* $\mathsf{Cat}^{\uparrow}$ *square row, displaying the four corner categories and the four boundary functors of the pullback-shaped diagram.*
2. *C is the* $\mathsf{Pullback}^{\uparrow}$ *comparison row, recording that the square is consumed only as displayed finite square data.*
3. *L records the left-adjoint rows along the two vertical sides, including their unit and counit component ledgers.*
4. *R records the right-adjoint rows along the two horizontal sides, including their unit and counit component ledgers.*
5. *K is the* $\mathsf{KanExtension}^{\uparrow}$ *handoff row, exposing the extension candidate and its universal comparison route only after A, C, L, R have been read.*
6. *T is the* $\mathsf{NatTrans}^{\uparrow}$ *comparison 2-cell row between the two boundary composites around the square.*
7. *H records componentwise* hsame *transport for the square, adjoint rows, Kan-extension handoff, comparison 2-cell, replay, provenance, and local naming rows.*
8. *E records displayed* Cont *replay through*

$$A, C \longmapsto L, R \longmapsto K \longmapsto T \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{BeckChevalley}^{\uparrow}$, $\mathsf{Cat}^{\uparrow}$, $\mathsf{Functor}^{\uparrow}$, $\mathsf{NatTrans}^{\uparrow}$, $\mathsf{Adjunction}^{\uparrow}$, $\mathsf{KanExtension}^{\uparrow}$, $\mathsf{Pullback}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{BeckChevalley}^{\uparrow}}$ *row.*

The classifier accepts only packets whose comparison is exhausted by $A, C, L, R, K, T, H, E, P, N$. It has no coordinate for a host pullback theorem, an ambient indexed category, equality of functor categories, selected Kan-extension witnesses, or global exactness.

Theorem 8524.2 (Beck–Chevalley NameCert obligations)**.** *For every accepted* $\mathsf{BeckChevalley}^{\uparrow}$ *carrier $B = (A, C, L, R, K, T, H, E, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{BeckChevalley}^{\uparrow}}$ *surface consists exactly of square admission through A, pullback-shaped comparison through C, left-adjoint exposure through L, right-adjoint exposure through R, Kan-extension handoff through K, comparison 2-cell exposure through T, componentwise transport through H, displayed replay through E, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8524.1. The square rows A, C are read before any adjoint or Kan-extension data, so the packet exposes only displayed base-change geometry.

The adjoint rows L, R are then read as finite unit and counit ledgers. They do not create a host adjunction theorem; they only make the two sides of the square available to the later comparison.

Finally K, T, H, E, P, N provide the Kan-extension handoff, comparison 2-cell, transport, replay, provenance, and local naming. Since the carrier contains no coordinate for ambient functor-category equality, selected universal witnesses, or global exactness, no extra NameCert obligation is available outside the listed rows. □

Theorem 8524.3 (Beck–Chevalley square route)**.** *Every accepted* $\mathsf{BeckChevalley}^{\uparrow}$ *read factors the base-change comparison through the finite route*

$$\mathsf{Cat}^{\uparrow}, \mathsf{Functor}^{\uparrow}, \mathsf{Pullback}^{\uparrow} \longmapsto \mathsf{Adjunction}^{\uparrow} \longmapsto \mathsf{KanExtension}^{\uparrow} \longmapsto \mathsf{NatTrans}^{\uparrow}.$$

Thus a consumer may read the comparison 2-cell only after the square, adjoint rows, and Kan-extension handoff have been displayed, and only as a local NameCert route over $A, C, L, R, K, T, H, E, P, N$.

Proof. Start from the carrier rows A and C. They display the four corners, boundary functors, and pullback-shaped square data before any comparison 2-cell can be consumed.

Next read the adjoint and Kan-extension rows. The rows L and R expose the unit and counit ledgers needed by the base-change route, while K makes the extension handoff available only downstream of those rows.

The comparison 2-cell row T is therefore a terminal local read of the displayed route. The structural rows H, E, P, N only transport, replay, source, and name that same finite packet, so the route remains inside BEDC certificate data and does not import an ambient Beck–Chevalley theorem. □

Closure status for $\mathsf{NameCert}_{\mathsf{BeckChevalley}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BeckChevalley}^{\uparrow}$ packet is generated from displayed category and functor square rows, a pullback-shaped comparison row, left and right adjoint ledgers, a Kan-extension handoff, a comparison 2-cell, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BeckChevalley}^{\uparrow}}$, seed)

Scope closed: Definition 8524.1, Definition 8524.2, and Definition 8524.3 seed the finite base-change comparison surface over $A, C, L, R, K, T, H, E, P, N$.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BeckChevalley}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host indexed-category semantics, ambient exactness, equality of functor categories, selected Kan-extension witnesses, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked square admission, pullback-shaped comparison, adjoint exposure, Kan-extension handoff, comparison 2-cell exposure, transport, replay, provenance, and local naming for BEDC.Derived.BeckChevalleyUp.

Chapter 8525

A Concrete Naming Certificate for BoundedRegularCauchyCluster$^{\uparrow}$

Following Bishop and Bridges, the BoundedRegularCauchyCluster$^{\uparrow}$ packet records the bounded regular-Cauchy cluster route as finite NameCert data rather than as a completed real quotient or a chosen convergent subsequence. It sits on the L10 Real and Completion spine: bounded source evidence is read through the finite window interface of chapter 126, dyadic tail budgets through chapter 291, regular rational readback through chapter 301, displayed extraction through chapter 5125, and the terminal seal through chapter 38.

Definition 8525.1 (BoundedRegularCauchyCluster carrier)**.** *A* BoundedRegularCauchyCluster$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, D, R, E, X, H, C, P, N)$$

with the following visible rows:

1. *S is the bounded source row, recording the displayed lower and upper rational bounds for the inspected regular-Cauchy source.*
2. *W is the* StreamName$^{\uparrow}$ *finite-window row through which the source is observed.*
3. *D is the* DyadicRatCore$^{\uparrow}$ *tail-budget row used to compare requested tolerances with the displayed windows.*
4. *R is the* RegSeqRat$^{\uparrow}$ *readback row attached to W and D.*
5. *E is the* CauchySubsequenceExtractor$^{\uparrow}$ *row, exposing the finite extraction schedule consumed by cluster reads.*
6. *X is the terminal* Real$^{\uparrow}$ *seal reached only after the* RegSeqRat$^{\uparrow}$ *readback and the displayed extraction row have been read.*
7. *H records componentwise* hsame *transport for the source bounds, window row, tail-budget row, regular-rational readback, extraction row, and real seal.*
8. *C records the displayed* Cont *replay routes by which Real-facing and completion-facing consumers read the packet.*
9. *P is the* Pkg *provenance over* BoundedRegularCauchyCluster$^{\uparrow}$, StreamName$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, RegSeqRat$^{\uparrow}$, CauchySubsequenceExtractor$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchyCluster}^{\uparrow}}$ *row.*
The carrier exports no countable-choice selector, no quotient equality of Cauchy names, no host real equality, and no ambient completeness theorem for $\mathsf{Real}^{\uparrow}$*.*

Theorem 8525.2 (BoundedRegularCauchyCluster NameCert obligations)**.** *For every accepted* $\mathsf{BoundedRegularCauchyCluster}^{\uparrow}$ *carrier* $B = (S, W, D, R, E, X, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchyClust}}$ *surface consists exactly of carrier admission for the bounded source row,* $\mathsf{StreamName}^{\uparrow}$ *window row,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row,* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. The classifier is stable only through H, and the ledger admits no selected subsequence outside E, no quotient real equality, no countable choice, and no ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project an accepted read through Definition 8525.1. The bounded source, finite window, dyadic tail budget, regular-rational readback, extraction row, terminal real seal, transport, replay, provenance, and naming rows are all visible coordinates of the same packet.

Classifier stability is componentwise because the only transport coordinate is H. The continuation row C can replay the displayed source, readback, extraction, and Real-facing routes, but it has no coordinate for a selector or quotient object.

Thus the local certificate is exhausted by the displayed finite carrier. The excluded rows cannot be recovered from the packet because no coordinate stores them. □

Theorem 8525.3 (BoundedRegularCauchyCluster RegSeqRat handoff)**.** *Every cluster read accepted by a* $\mathsf{BoundedRegularCauchyCluster}^{\uparrow}$ *packet reaches the terminal* $\mathsf{Real}^{\uparrow}$ *seal only through the displayed* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R and the* $\mathsf{CauchySubsequenceExtractor}^{\uparrow}$ *row E. In particular, a Real-facing consumer must first read the bounded source row S, the* $\mathsf{StreamName}^{\uparrow}$ *window row W, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tail-budget row D, and the regular-rational readback row R before it may consume the extraction row E and the seal X.*

Proof. Read the carrier coordinates in order. The real seal X is stored as the terminal row of the same packet that contains S, W, D, R, E, and the displayed replay row C exposes no route to X that bypasses the regular-rational readback.

The extraction row E is not an independent choice functional. It is a finite row of the carrier, transported by H and replayed by C after the window and tail-budget rows have already fixed the RegSeqRat handoff.

Therefore every Real-facing cluster read factors through the displayed S, W, D, R, E, X route. The packet contains no quotient equality of streams, selected limit, countable-choice schedule, or ambient completeness row that could supply another route. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedRegularCauchyCluster}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BoundedRegularCauchyCluster}^{\uparrow}$ packet is generated from bounded source rows, finite StreamName windows, DyadicRatCore tail budgets, RegSeqRat readback, CauchySubsequenceExtractor rows, a Real seal, componentwise hsame transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{BoundedRegularCauchyCluster}^{\uparrow}}$, seed)

Scope closed: Definition 8525.1, Definition 8525.2, and Definition 8525.3 seed the bounded regular-Cauchy cluster route from finite windows and dyadic tail budgets to RegSeqRat readback, displayed subsequence extraction, and Real sealing.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{BoundedRegularCauchyCluster}^{\uparrow}}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close Real completeness, separability, quotient equality of Cauchy names, countable-choice subsequence selection, or bridge checking.

Upgrade path: Scoped closure requires Lean checking of carrier admission, classifier stability, RegSeqRat handoff exactness, and Real-seal nonescape for the same displayed packet.

Chapter 8526

A Concrete Naming Certificate for $\mathsf{FiniteCoverNerveUniformModulus}^{\uparrow}$

Following Bishop and Bridges on compact metric uniform continuity, the $\mathsf{FiniteCoverNerveUniformModulus}^{\uparrow}$ packet records the finite cover-nerve incidence and rational lower-bound handoff as concrete NameCert data. It consumes compact source rows from chapter 60, continuous-map rows from chapter 130, metric and rational comparison rows from chapter 57 and chapter 37, finite interval-cover rows from chapter 5105, finite Lebesgue-number rows from chapter 452, and hands the resulting ledger to chapter 369 before any $\mathsf{Real}^{\uparrow}$ readback in chapter 38.

Definition 8526.1 (FiniteCoverNerveUniformModulus carrier)**.** *A* $\mathsf{FiniteCoverNerveUniformModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (K, F, I, N, L, R, M, V, H, C, P, Q)$$

with the following visible rows:

1. *K is the* $\mathsf{Compact}^{\uparrow}$ *source row.*
2. *F is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row read on the compact source.*
3. *I is the* $\mathsf{FiniteIntervalCover}^{\uparrow}$ *row presenting the finite cover cells.*
4. *N is the finite nerve-incidence row, listing cover-cell adjacency and overlap witnesses as a bounded* BHist *table.*
5. *L is the* $\mathsf{FiniteLebesgueNumber}^{\uparrow}$ *row giving the displayed rational lower bound for the cover.*
6. *R is the* $\mathsf{Rat}^{\uparrow}$ *comparison ledger that keeps every chosen lower-bound read positive and below the relevant local radius.*
7. *M is the* $\mathsf{Met}^{\uparrow}$ *distance row used by the overlap and coverage tests.*
8. *V is the* $\mathsf{UniformModulus}^{\uparrow}$ *handoff row receiving the finite nerve and lower-bound ledger.*
9. *H records componentwise* hsame *transport for the compact source, continuous map, cover cells, nerve incidences, Lebesgue-number row, rational comparisons, metric rows, and uniform-modulus handoff.*
10. *C records the displayed* Cont *replay routes.*

11. *P is the* Pkg *provenance over* FiniteCoverNerveUniformModulus$^{\uparrow}$, Compact$^{\uparrow}$, ContinuousMap$^{\uparrow}$, Met$^{\uparrow}$, Rat$^{\uparrow}$, FiniteIntervalCover$^{\uparrow}$, FiniteLebesgueNumber$^{\uparrow}$, UniformModulus$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *Q is the local* NameCert$_{\text{FiniteCoverNerveUniformModulus}^{\uparrow}}$ *row.*

The carrier refuses open-cover compactness, selected subcovers, host minima, quotient real equality, and any Real$^{\uparrow}$ *seal not routed through the displayed uniform-modulus handoff.*

Theorem 8526.2 (FiniteCoverNerveUniformModulus NameCert obligations)**.** *For every accepted* FiniteCoverNerveUniformModulus$^{\uparrow}$ *carrier* $U = (K, F, I, N, L, R, M, V, H, C, P, Q)$*, the local* NameCert$_{\text{FiniteCoverNerveU}}$ *surface consists exactly of carrier admission for the compact source row, continuous-map row, finite interval-cover row, finite nerve-incidence row, finite Lebesgue-number row, rational comparison ledger, metric distance row, uniform-modulus handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming row. The classifier is stable only through H, and no obligation may be discharged by open-cover compactness, a selected subcover, a host minimum, quotient real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Project an accepted packet through Definition 8526.1. The compact, continuous, cover, nerve, Lebesgue-number, rational-comparison, metric, and uniform-modulus rows are all explicit coordinates.

The transport coordinate H preserves those rows componentwise. The replay coordinate C lets compact, continuous, metric, rational, cover, and uniform-modulus consumers read the same finite packet, but it does not create an open cover or a host minimum.

Consequently the local NameCert obligations are exactly the displayed finite rows. Since the excluded objects have no carrier coordinate, they cannot be used to discharge the certificate surface. □

Theorem 8526.3 (FiniteCoverNerveUniformModulus handoff)**.** *Every* UniformModulus$^{\uparrow}$ *read exported by an accepted* FiniteCoverNerveUniformModulus$^{\uparrow}$ *packet is handed the finite cover cells I, the nerve-incidence table N, the* FiniteLebesgueNumber$^{\uparrow}$ *lower-bound row L, the* Rat$^{\uparrow}$ *comparison ledger R, and the* Met$^{\uparrow}$ *distance row M before any Real-facing consumer may inspect a* Real$^{\uparrow}$ *seal. The handoff is finite and choice-free: it does not expose open-cover compactness, selected subcovers, host minima, quotient real equality, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Read the uniform-modulus handoff row V from the carrier. Its inputs are the finite cover row I, the nerve-incidence row N, the Lebesgue-number row L, the rational comparison ledger R, and the metric row M, all attached to the compact source K and continuous map F.

The hsame and Cont rows keep this handoff on the displayed packet. They transport and replay the finite incidence and lower-bound data, but they do not add a selector for subcovers or a minimum operation outside the carrier.

Thus the Real-facing boundary is downstream of the uniform-modulus handoff. Any consumer that reaches Real$^{\uparrow}$ must do so through the displayed finite route, not through quotient real equality or ambient completeness. □

Closure status for NameCert$_{\text{FiniteCoverNerveUniformModulus}^{\uparrow}}$**.**

Constructive story: A FiniteCoverNerveUniformModulus$^{\uparrow}$ packet is generated from compact source rows, continuous-map rows, finite interval-cover cells, finite nerve-incidence rows, finite Lebesgue-number lower bounds, rational comparison ledgers, metric rows, a UniformModulus handoff, componentwise hsame transport, continuation replay, provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{FiniteCoverNerveUniformModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8526.1, Definition 8526.2, and Definition 8526.3 seed the finite cover-nerve route from compact and continuous-map rows to a rational lower-bound UniformModulus handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{FiniteCoverNerveUniformModulus}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, selected subcovers, host minima, quotient real equality, Real completeness, or bridge checking.

Upgrade path: Scoped closure requires Lean checking of carrier admission, classifier stability, finite nerve incidence exactness, rational lower-bound handoff, and Real-facing nonescape for the same displayed packet.

Chapter 8527

A Concrete Naming Certificate for $\mathsf{Stabilizability}^{\uparrow}$

Following Kalman finite-dimensional control theory, the $\mathsf{Stabilizability}^{\uparrow}$ packet records the finite feedback data that lets a control consumer separate reachable stabilization evidence from unreachable stable residue. It sits after the state-space carrier of chapter 329, the reachability surface of chapter 297, the finite rank-window certificate of chapter 8523, and the optimization-facing corridors of chapter 296, chapter 307, chapter 5103, and chapter 4752. The chapter names the finite rows that make feedback stabilization inspectable without importing host spectral subspaces, analytic semigroups, or ambient asymptotic semantics.

Definition 8527.1 (Stabilizability carrier)**.** *A* $\mathsf{Stabilizability}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (X, U, A, B, R, M, F, D, L, H, T, P, N)$$

with the following displayed rows:

1. *X is the finite state-space source row consumed from* $\mathsf{StateSpaceModel}^{\uparrow}$*.*
2. *U is the finite input row used by the feedback surface.*
3. *A is the displayed transition row and B is the displayed input-map row.*
4. *R is the* $\mathsf{ControlControllability}^{\uparrow}$ *reachability ledger available to feedback consumers.*
5. *M is the* $\mathsf{ControllabilityRank}^{\uparrow}$ *rank-window row naming the finite columns and dimension comparisons used to separate controllable directions.*
6. *F is the unstable-mode witness row: it names exactly the finite residual rows whose uncontrolled transition must be checked before a feedback handoff can be accepted.*
7. *D is the decay ledger for the residual rows named by F after the displayed feedback row is attached.*
8. *L is the feedback row, read as finite input-on-state data rather than as an ambient operator selected outside the packet.*
9. *H is the componentwise* hsame *ledger for the state-space source, input row, transition row, input-map row, reachability ledger, rank-window row, unstable-mode witness, feedback row, and decay ledger.*

10. *T is the displayed* Cont *route for reachability readback, rank-window readback, feedback replay, and decay-ledger replay.*

11. *P is the* Pkg *provenance over* $\mathsf{Stabilizability}^{\uparrow}$, $\mathsf{StateSpaceModel}^{\uparrow}$, $\mathsf{ControlControllability}^{\uparrow}$, $\mathsf{ControllabilityRank}^{\uparrow}$, $\mathsf{LQR}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, $\mathsf{HInfinityControl}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}$ *row.*

The classifier identifies two accepted carriers only when the displayed state-space, input, transition, input-map, reachability, rank-window, unstable-mode, feedback, and decay rows agree componentwise through H, with the same continuation route, provenance, and local naming row.

Theorem 8527.2 (Stabilizability NameCert obligations)**.** *For every accepted* $\mathsf{Stabilizability}^{\uparrow}$ *carrier $S = (X, U, A, B, R, M, F, D, L, H, T, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}$ *surface has exactly six finite rows:*

1. *carrier admission for the displayed state-space, input, transition, input-map, reachability, rank-window, unstable-mode, feedback, and decay rows;*

2. *classifier admission through componentwise* hsame *transport over those displayed rows;*

3. *reachability readback saying that R and M are consumed only through* $\mathsf{ControlControllability}^{\uparrow}$ *and* $\mathsf{ControllabilityRank}^{\uparrow}$ *rows;*

4. *feedback admission saying that L is a displayed finite row attached to the same input and state coordinates as A and B;*

5. *residual stability readback saying that the only permitted decay claim is the finite ledger D over the unstable-mode witness F after the feedback row is attached;*

6. *provenance and local naming through the displayed* Cont, Pkg, *replay, and* $\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}$ *rows.*

No obligation row supplies a host spectral decomposition, an unrecorded state quotient, a selected optimal controller, a Riccati solution, or a robust performance theorem.

Proof. Project the carrier of Definition 8527.1. The rows $X, U, A, B, R, M, F, D, L$ are the only control-facing data, while H, T, P, N transport, replay, source, and name the same finite packet.

Reachability readback is forced through R and M. These rows point to $\mathsf{ControlControllability}^{\uparrow}$ and $\mathsf{ControllabilityRank}^{\uparrow}$, so a feedback consumer cannot substitute a hidden reachable subspace or an external rank theorem for the displayed finite ledgers.

The feedback and residual stability clauses are the rows L, F, D. Since L is attached to the same displayed input and state coordinates as A and B, and since D is the only decay ledger for the residual witness F, the local certificate exports feedback stabilizing data only through those rows. Repacking the projections with H, T, P, N gives the stated six-row surface. □

Theorem 8527.3 (Stabilizability feedback handoff)**.** *Every* $\mathsf{LQR}^{\uparrow}$, $\mathsf{Riccati}^{\uparrow}$, $\mathsf{ControlRiccati}^{\uparrow}$, *or* $\mathsf{HInfinityControl}^{\uparrow}$ *consumer of an accepted* $\mathsf{Stabilizability}^{\uparrow}$ *packet may read feedback-stabilizing data only through the displayed reachability ledger R, rank-window row M, unstable-mode witness F, feedback row L, decay ledger D, transport ledger H, continuation route T, provenance row P, and local naming row N. The handoff supplies no optimality claim, Riccati equation solution, robust gain bound, host spectral subspace, or ambient asymptotic theorem outside the finite packet of Definition 8527.1.*

Proof. Start with the obligation surface of Definition 8527.2. It exposes feedback only after the state-space, input, transition, input-map, reachability, rank-window, unstable-mode, and decay rows have been displayed.

The optimization-facing consumers read this as a boundary condition. An $\mathsf{LQR}^{\uparrow}$ or $\mathsf{Riccati}^{\uparrow}$ consumer may inspect the feedback and decay rows before forming an optimization ledger, while a $\mathsf{ControlRiccati}^{\uparrow}$ or $\mathsf{HInfinityControl}^{\uparrow}$ consumer may reuse the same finite handoff for control synthesis or robustness bookkeeping.

Because the carrier has no coordinate for an optimality claim, Riccati equation solution, robust gain bound, host spectral subspace, or ambient asymptotic theorem, no such object can be exported by the stabilizability handoff. □

Falsifiable prediction: Any LQR, Riccati, control Riccati, or robust-control consumer that reads $\mathsf{Stabilizability}^{\uparrow}$ while bypassing the displayed reachability ledger R, rank-window row M, unstable-mode witness F, feedback row L, or decay ledger D violates the local certificate boundary.

Independence witness: statespacemodel, controlcontrollability, controllability-rank, lqr, riccati, control-riccati, and h-infinity-control: none is bijective to $\mathsf{Stabilizability}^{\uparrow}$ because the stabilizability packet jointly carries state-space, input-map, reachability, rank-window, unstable-mode, feedback, decay, transport, replay, provenance, and local NameCert rows while excluding host spectral, optimality, and robustness semantics.

Closure status for $\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}$.

Constructive story: A $\mathsf{Stabilizability}^{\uparrow}$ packet is generated from finite state-space and input rows, transition and input-map rows, a controllability ledger, a controllability-rank row, an unstable-mode witness, a feedback row, a decay ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8527.1, Definition 8527.2, Definition 8527.3, the displayed falsifiable prediction, and the displayed independence witness seed the finite feedback-stabilization certificate over state-space, controllability, rank-window, LQR, Riccati, control Riccati, and robust-control rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{Stabilizability}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, host spectral decompositions, quotient reachable subspaces, optimal controllers, Riccati solutions, robust gain bounds, or ambient asymptotic stability.

Upgrade path: Obligation closure requires checked carrier admission, reachability readback, rank-window exactness, unstable-mode witness exactness, feedback-row admission, decay-ledger exactness, transport, replay, provenance, and local naming for BEDC.Derived.StabilizabilityUp.

Chapter 8528

A Concrete Naming Certificate for $\mathsf{PaleyWiener}^{\uparrow}$

Following Paley and Wiener on Fourier transforms of compactly supported functions, the $\mathsf{PaleyWiener}^{\uparrow}$ packet records the finite support-and-growth surface that a constructive Fourier-analysis consumer must inspect before it reads a band-limited or exponential-type conclusion. It sits beside the Fourier transform route of chapter 4025, the Schwartz-function test-window surface of chapter 3399, the tempered-distribution action row of chapter 2310, the regular rational readback route of chapter 301, and the terminal real-name seal of chapter 38. The packet names only finite support windows, displayed growth ledgers, Fourier handoff rows, test-function probes, distribution-facing action rows, scalar readback, transport, replay, provenance, and local naming; it does not assert Fourier inversion, a completed entire-function space, quotient equality of functions or distributions, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8528.1 (Paley–Wiener carrier)**.** *A* $\mathsf{PaleyWiener}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (K, F, G, S, T, R, E, H, C, Q, N)$$

with the following displayed coordinates:

1. *K is the compact support window row, naming the finite spatial support bounds and inspected test domains.*
2. *F is the* $\mathsf{FourierTransform}^{\uparrow}$ *handoff row, recording the transform-facing read of the supported source.*
3. *G is the growth ledger row, listing the finite exponential-type and polynomial-control bounds visible to the packet.*
4. *S is the* $\mathsf{SchwartzFunction}^{\uparrow}$ *probe row, exposing the rapidly decreasing test windows used to compare source and transform reads.*
5. *T is the* $\mathsf{TemperedDistribution}^{\uparrow}$ *action row, recording the distribution-facing interpretation of the same finite transform data.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *scalar readback row for the displayed bounds.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row for scalar comparisons.*
8. *H records componentwise* hsame *transport for support, Fourier handoff, growth, probes, distribution action, scalar readback, seal, provenance, and local name.*

9. *C records displayed* Cont *replay from support inspection through Fourier handoff, growth readback, distribution action, scalar sealing, and local naming.*
10. *Q is the* Pkg *provenance over* $\mathsf{PaleyWiener}^{\uparrow}$, $\mathsf{FourierTransform}^{\uparrow}$, $\mathsf{SchwartzFunction}^{\uparrow}$, $\mathsf{TemperedDistribution}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{PaleyWiener}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $K, F, G, S, T, R, E, H, C, Q, N$. It has no coordinate for host Fourier inversion, completed spaces of entire functions, quotient equality of functions or distributions, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8528.2 (Paley–Wiener NameCert obligations)**.** *For every accepted* $\mathsf{PaleyWiener}^{\uparrow}$ *carrier $P = (K, F, G, S, T, R, E, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{PaleyWiener}^{\uparrow}}$ *surface consists exactly of carrier admission for compact support windows, Fourier-transform handoff, finite growth ledgers, Schwartz-function probes, tempered-distribution action, regular rational readback, Real scalar sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any Fourier-analysis, distribution, or scalar-bound consumer of the packet must read through those rows before it cites a Paley–Wiener boundary.*

Proof. Project the carrier of Definition 8528.1. The support row K, transform row F, growth row G, Schwartz probe row S, distribution action row T, readback row R, and seal row E are the only analytic coordinates.

The Fourier-facing read is finite. It exposes the support window before the transform handoff, and it exposes the growth ledger before any scalar comparison can be sealed in $\mathsf{Real}^{\uparrow}$.

The test and distribution rows keep the route inside the displayed sibling certificates. The $\mathsf{SchwartzFunction}^{\uparrow}$ probes and $\mathsf{TemperedDistribution}^{\uparrow}$ action rows are read through S, T, not through a host function space or a quotient distribution.

Finally H, C, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for Fourier inversion, completed entire-function spaces, quotient equality, selected representatives, countable choice, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8528.3 (Paley–Wiener Fourier support handoff)**.** *Every Fourier-facing read of an accepted* $\mathsf{PaleyWiener}^{\uparrow}$ *carrier factors through the finite route*

$$\mathsf{FourierTransform}^{\uparrow} \longmapsto \mathsf{SchwartzFunction}^{\uparrow} \longmapsto \mathsf{TemperedDistribution}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

after the compact support row K and growth ledger G have been displayed. The handoff exports support-window and growth-bound data together with transport, replay, provenance, and local naming, but it exports no Fourier inversion theorem, completed entire-function space, quotient equality of functions or distributions, selected representative, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness row.*

Proof. Start from the accepted carrier $P = (K, F, G, S, T, R, E, H, C, Q, N)$. The support row K and Fourier handoff row F are upstream of every transform-facing read.

The growth ledger G is then read before scalar sealing. It records only finite exponential-type and polynomial-control bounds, and the scalar comparison passes through R and E.

Next expose the sibling analysis rows. The Schwartz probe row S supplies the test-window comparison, and the tempered-distribution action row T carries the same transform data toward distribution-facing consumers.

Finally replay the route through H, C, Q, N. Because no host inversion, completed function space, quotient equality, selected representative, countable choice, or ambient completeness coordinate appears in the carrier, the Fourier support handoff remains the displayed finite NameCert route. □

Falsifiable prediction: Every accepted $\mathsf{PaleyWiener}^{\uparrow}$ Fourier-facing read exposes compact support windows, Fourier handoff, growth ledger, SchwartzFunction probes, TemperedDistribution action, RegSeqRat readback, Real seal, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before any Paley–Wiener boundary is cited.

Independence witness: fourier-transform, schwartz-function, tempered-distribution, regseqrat, real: $\mathsf{PaleyWiener}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries compact support windows, Fourier handoff, growth ledgers, Schwartz probes, tempered-distribution action, scalar readback, sealing, transport, replay, provenance, and local naming while refusing inversion and completed entire-function data.

Closure status for $\mathsf{NameCert}_{\mathsf{PaleyWiener}^{\uparrow}}$.

Constructive story: A $\mathsf{PaleyWiener}^{\uparrow}$ packet is generated from compact support windows, FourierTransformUp handoff rows, finite growth ledgers, SchwartzFunctionUp probes, TemperedDistributionUp action rows, RegSeqRatUp scalar readback, RealUp sealing, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PaleyWiener}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8528.1, Definition 8528.2, and Definition 8528.3 seed the finite Paley–Wiener support and growth route over Fourier transform, Schwartz-function, tempered-distribution, scalar-readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PaleyWiener}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim Fourier inversion, completed entire-function spaces, quotient equality of functions or distributions, selected representatives, countable choice, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, support-window exactness, Fourier handoff, growth-ledger stability, Schwartz-probe and tempered-distribution action rows, scalar readback, transport, replay, provenance, and local naming for BEDC.Derived.PaleyWienerUp.

Chapter 8529

A Concrete Naming Certificate for $\mathsf{UniformCompletionIdempotence}^{\uparrow}$

Following Bishop and Bridges and Kelley on uniform-space completion, the $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ packet records the finite BEDC surface by which a completed uniform route is read back through the same uniform-completion boundary. It sits after the uniform-completion carrier of chapter 1473, the general completion-idempotence row of chapter 2381, the metric fixed-point row of chapter 3888, the separated-completion idempotence boundary of chapter 6970, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the terminal real-name seal of chapter 38. The packet is an idempotence certificate for a displayed uniform completion route; it is not quotient completion equality, a selected representative, countable choice, host equality, or ambient completeness.

Definition 8529.1 (Uniform completion idempotence carrier)**.** *A* $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (U, C, M, S, W, R, D, E, H, K, P, N)$$

with the following displayed rows:

1. *U is the first* $\mathsf{UniformCompletion}^{\uparrow}$ *boundary row whose completed route is being inspected.*
2. *C is the* $\mathsf{CompletionIdempotence}^{\uparrow}$ *row recording the repeated completion request as a finite idempotence surface.*
3. *M is the* $\mathsf{MetricCompletionIdempotence}^{\uparrow}$ *comparison row available when a metric presentation of the same uniform route is consumed.*
4. *S is the* $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ *row recording the separated classifier boundary for the completed object.*
5. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row through which completion-facing reads are inspected.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row exposed before any real-facing seal is consumed.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger controlling the finite comparison budget of the repeated read.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal reached only after U, C, M, S, W, R, D have been displayed.*

9. *H records componentwise* hsame *transport for the uniform boundary, idempotence rows, finite window, regular readback, dyadic ledger, real seal, replay, provenance, and local name.*
10. *K records displayed* Cont *replay of the same ordered route.*
11. *P records* Pkg *provenance over* $\mathsf{UniformCompletionIdempotence}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{MetricCompletionIdempotence}^{\uparrow}$, $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{UniformCompletionIdempotence}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8529.2 (Uniform completion idempotence NameCert obligations)**.** *For every accepted* $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ *carrier*

$$I = (U, C, M, S, W, R, D, E, H, K, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{UniformCompletionIdempotence}^{\uparrow}}$ *surface consists exactly of carrier admission for the uniform-completion boundary U, repeated-request exposure through C, metric-presentation compatibility through M, separated-boundary compatibility through S, shared finite-window exposure through W, regular rational readback through R, dyadic tolerance exposure through D, real-seal exposure through E, componentwise transport through H, displayed replay through K, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8529.1. The first four rows expose the uniform-completion boundary and the three idempotence witnesses that can be consumed by completion, metric, and separated presentations.

The finite analytic rows then force a single readback route. The window W, regular rational row R, and dyadic ledger D are displayed before the terminal seal E is available, so the repeated completion read cannot jump directly to a completed point.

Finally read H, K, P, N as structural rows for the same packet. They transport, replay, source, and locally name only the displayed route, and no coordinate remains from which quotient completion equality, selected representatives, countable choice, host equality, or ambient completeness could be exported. □

Theorem 8529.3 (Uniform completion idempotence unit handoff)**.** *Every unit-facing consumer of an accepted* $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ *carrier reads the second uniform-completion request through*

$$U, C, M, S, W, R, D, E, H, K, P, N$$

in that order. The consumer may use the $\mathsf{UniformCompletion}^{\uparrow}$ *boundary only together with the completion-idempotence, metric-idempotence, and separated-idempotence rows already displayed by the packet. It may not substitute quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness for that route.*

Proof. Begin with the NameCert obligations of Definition 8529.2. They place the uniform-completion boundary U before the idempotence rows C, M, S and before the finite readback rows W, R, D, E.

Use the sibling idempotence surfaces in order. The completion row C supplies the repeated-request boundary of chapter 2381; the metric row M supplies the metric fixed-point comparison of chapter 3888; and the separated row S supplies the separated classifier boundary of chapter 6970.

The regular and real-facing part of the handoff is still finite. The shared window comes from chapter 126, the regular readback from chapter 301, the tolerance ledger from chapter 291, and the terminal seal from chapter 38.

The structural rows H, K, P, N only transport, replay, source, and name that same ordered route. Hence a unit-facing consumer receives a displayed uniform-completion idempotence handoff rather than a quotient equality, representative selector, choice schedule, host equality, or detached completeness principle. □

Falsifiable prediction: An accepted $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ read is refuted if a second uniform-completion request reaches a $\mathsf{RegSeqRat}^{\uparrow}$ readback or $\mathsf{Real}^{\uparrow}$ seal without first exposing the $\mathsf{UniformCompletion}^{\uparrow}$ boundary, the $\mathsf{CompletionIdempotence}^{\uparrow}$, $\mathsf{MetricCompletionIdempotence}^{\uparrow}$, and $\mathsf{SeparatedCompletionIdempotence}^{\uparrow}$ rows, the $\mathsf{StreamName}^{\uparrow}$ window, the $\mathsf{DyadicRatCore}^{\uparrow}$ ledger, transport, replay, provenance, and local naming rows.

Independence witness: uniformcompletion, completion-idempotence, metric-completion-idempotence, separated-completion-idempotence, streamname, regseqrat, dyadicratcore, real: $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ is not bijective with any listed sibling because it jointly carries a uniform-completion boundary, three idempotence comparison rows, finite window and tolerance readback, a real seal, transport, replay, provenance, and local naming rows for the uniform fixed-point handoff.

Closure status for $\mathsf{NameCert}_{\mathsf{UniformCompletionIdempotence}^{\uparrow}}$.

Constructive story: A $\mathsf{UniformCompletionIdempotence}^{\uparrow}$ packet is generated from a UniformCompletion boundary row, CompletionIdempotence row, MetricCompletionIdempotence row, SeparatedCompletionIdempotence row, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{UniformCompletionIdempotence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8529.1, Definition 8529.2, and Definition 8529.3 seed the finite route by which a repeated uniform-completion request returns through the displayed uniform, completion-idempotence, metric-idempotence, separated-idempotence, readback, tolerance, and Real-seal rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{UniformCompletionIdempotence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not prove quotient completion equality, selected representatives, countable choice, host equality of completed points, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking for $\mathsf{UniformCompletionIdempotence}^{\uparrow}$.

Upgrade path: Obligation closure requires checked carrier admission, repeated uniform-completion request exactness, metric and separated compatibility, finite-window readback, dyadic tolerance, Real seal non-escape, transport, replay, provenance, and local naming for $\mathsf{UniformCompletionIdempotence}^{\uparrow}$.

Chapter 8530

A Concrete Naming Certificate for $\mathsf{RegularCauchyLiminf}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{RegularCauchyLiminf}^{\uparrow}$ packet records the finite lower-tail envelope available from a displayed regular Cauchy rational source before any Real-facing consumer reads a terminal value. It sits over the lower-envelope route of chapter 1553, the finite window discipline of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the upper-tail companion of chapter 8383. The packet names an L10 completion-facing lower-tail envelope; it does not import host infimum, quotient stream equality, countable choice, selected subsequences, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8530.1 (Regular Cauchy liminf carrier)**.** *A* $\mathsf{RegularCauchyLiminf}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (S, W, R, D, L, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source sequence row, recording the displayed regular Cauchy rational name whose lower tail is being inspected.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, listing the finite tail windows made visible to the lower-envelope request.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback row, binding the windows from W to regular rational values and tail tolerances.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, carrying dyadic precision, slack, and comparison budgets for the lower-envelope read.*
5. *L is the* $\mathsf{Liminf}^{\uparrow}$ *lower-envelope row, exposing the finite tail-lower surface available at the displayed precision.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after S, W, R, D, L have all been displayed.*
7. *H records componentwise* hsame *transport for the source, windows, readback, dyadic ledger, lower-envelope, Real-seal, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from a lower-tail request through*

$$S \longrightarrow W \longrightarrow R \longrightarrow D \longrightarrow L \longrightarrow E \longrightarrow H \longrightarrow P \longrightarrow N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLiminf}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Liminf}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLiminf}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, W, R, D, L, E, H, C, P, N$. It has no coordinate for quotient stream equality, a host-selected infimum value, a chosen cofinal subsequence, countable choice, or an ambient completeness theorem for $\mathsf{Real}^{\uparrow}$.

Theorem 8530.2 (Regular Cauchy liminf NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyLiminf}^{\uparrow}$ *carrier*

$$I = (S, W, R, D, L, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyLiminf}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed source sequence,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{Liminf}^{\uparrow}$ *lower-envelope row, terminal* $\mathsf{Real}^{\uparrow}$ *seal, componentwise transport, displayed continuation replay, package provenance, and local naming.*

Proof. Project the carrier rows of Definition 8530.1. The analytic rows S, W, R, D, L, E display the source name, finite windows, regular rational readback, dyadic tolerance ledger, lower-envelope request, and terminal Real seal in that order.

The structural rows H, C, P, N transport, replay, source, and name the same packet. They do not add a quotient stream, a selected cofinal subsequence, a host infimum, countable choice, or ambient Real completeness.

Since the classifier has no coordinate outside $S, W, R, D, L, E, H, C, P, N$, every local NameCert obligation is one of the listed rows, and every listed row is visible in the accepted carrier. □

Theorem 8530.3 (Regular Cauchy liminf Real seal route)**.** *Every terminal* $\mathsf{Real}^{\uparrow}$ *seal of an accepted* $\mathsf{RegularCauchyLiminf}^{\uparrow}$ *carrier is reached through displayed regular-Cauchy lower-tail data. More precisely, every Real or Completion-facing read factors through the finite route*

$$\mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{Liminf}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow},$$

with the same source sequence row S and the same displayed tail windows W governing the lower-envelope comparison.

Proof. Let a Real or Completion-facing consumer read an accepted carrier I. The terminal value is available only as the row E, and E is downstream of the source row S, window row W, readback row R, dyadic tolerance ledger D, and lower-envelope row L.

Replay the continuation row C. The consumer first opens the finite $\mathsf{StreamName}^{\uparrow}$ windows, then reads regular rational tail values through $\mathsf{RegSeqRat}^{\uparrow}$, and then consults the dyadic ledger before the lower-envelope row is available.

Componentwise transport H and provenance P preserve the same order. Therefore the Real seal cannot bypass the displayed regular-Cauchy tail rows or import a host infimum, quotient stream equality, countable choice, selected subsequence, or ambient completeness witness. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLiminf}^{\uparrow}$ Real-facing read exposes a source sequence, StreamName windows, RegSeqRat tail readbacks, a DyadicRatCore tolerance ledger, Liminf lower-envelope data, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before any lower-tail endpoint is visible.

Independence witness: liminf, regular-cauchy-limsup, limsup-liminf-gap, streamname, regseqrat, dyadicratcore, real: $\mathsf{RegularCauchyLiminf}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a regular Cauchy source, finite windows, rational tail readback, dyadic tolerances, lower-envelope data, Real sealing, transport, replay, provenance, and local NameCert in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLiminf}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLiminf}^{\uparrow}$ packet is generated from a regular Cauchy source sequence, StreamName windows, RegSeqRat tail readbacks, a DyadicRatCore tolerance ledger, a Liminf lower-envelope row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyLiminf}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8530.1, Definition 8530.2, and Definition 8530.3 seed the finite regular-Cauchy lower-tail envelope route through displayed windows, rational readback, dyadic tolerances, Liminf lower-envelope data, and terminal Real sealing.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyLiminf}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host infimum, quotient stream equality, selected subsequences, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window coverage, RegSeqRat readback, DyadicRatCore tolerance exposure, lower-envelope exactness, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyLiminfUp.

Chapter 8531

A Concrete Naming Certificate for $\mathsf{PrecompactMetricSpace}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{PrecompactMetricSpace}^{\uparrow}$ packet records finite-net precompactness as displayed BEDC rows before any compact or complete metric consumer reads a completion boundary. It sits after the metric carrier of chapter 57, the total-boundedness finite-net surface of chapter 2048, the compact metric boundary of chapter 129, the complete metric boundary of chapter 128, the terminal real-name surface of chapter 38, and the Cauchy-net route of chapter 8518. The packet names a finite-net route from metric data toward compact and complete consumers; it is not an open-cover compactness theorem, a selected completion point, a quotient of Cauchy names, or an ambient $\mathsf{Real}^{\uparrow}$ completeness principle.

Definition 8531.1 (Precompact metric space carrier)**.** *A* $\mathsf{PrecompactMetricSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (M, T, K, C, R, W, Q, H, A, G, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, exposing the metric observations and metric-law ledger used by every finite-net request.*
2. *T is the* $\mathsf{TotallyBoundedMetric}^{\uparrow}$ *finite-net row, displaying for each inspected positive tolerance a finite* ProbeBundle *of centers and coverage histories.*
3. *K is the* $\mathsf{CompactMetric}^{\uparrow}$ *compact-boundary row consumed only as a finite-net target surface.*
4. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *completion-boundary row reached only after the finite-net row has been exposed.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row for displayed distance and tolerance reads.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *or finite-window row through which Cauchy-facing consumers inspect the selected tolerance schedule.*
7. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the finite windows before any real seal is exported.*
8. *H records componentwise* hsame *transport for the metric source, finite-net, compact, complete, real-seal, window, readback, provenance, and local naming rows.*
9. *A records displayed* Cont *replay from finite-net inspection through compact and complete metric consumers.*

10. *G is the* Pkg *provenance over* $\mathsf{PrecompactMetricSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{TotallyBoundedMetric}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{PrecompactMetricSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, K, C, R, W, Q, H, A, G, N$. It has no coordinate for arbitrary open covers, selected completion points, quotient equality of Cauchy names, countable choice, host compactification, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8531.2 (Precompact metric space NameCert obligations)**.** *For every accepted* $\mathsf{PrecompactMetricSpace}^{\uparrow}$ *carrier*

$$P = (M, T, K, C, R, W, Q, H, A, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{PrecompactMetricSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the eleven displayed rows; metric-source admission through M; finite-net admission through T; compact-boundary admission through K; completion-boundary admission through C; real tolerance sealing through R; finite-window and regular-rational readback through W, Q; componentwise transport through H; displayed replay through A; provenance through G; and local naming through N.*

Proof. Project the carrier of Definition 8531.1. The analytic rows are the metric source M, finite-net row T, compact boundary K, complete boundary C, real seal R, finite window W, and regular readback Q.

The obligation order follows the finite-net route. A consumer first reads the metric source, then the displayed finite net, then any compact or complete metric boundary, and only then the window, readback, and real-seal rows.

The structural rows H, A, G, N transport, replay, source, and name that same route. Since no excluded object appears in the carrier, the obligation surface cannot export open-cover compactness, selected completion points, quotient Cauchy equality, countable choice, host compactification, or ambient real completeness. □

Theorem 8531.3 (Precompact metric space finite-net refinement)**.** *Let*

$$P = (M, T, K, C, R, W, Q, H, A, G, N)$$

be an accepted $\mathsf{PrecompactMetricSpace}^{\uparrow}$ *carrier. Any compact, complete, or real-facing consumer that reads P must first expose the finite-net route*

$$\mathsf{Met}^{\uparrow} \longrightarrow \mathsf{TotallyBoundedMetric}^{\uparrow} \longrightarrow \mathsf{CompactMetric}^{\uparrow}, \mathsf{CompleteMetric}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The row T refines every tolerance request into a displayed finite probe bundle before K, C, W, Q, or R can be consumed, and the structural rows H, A, G, N keep that refinement attached to the same packet.

Proof. Read M as the source metric row. It supplies only displayed distance observations and metric-law ledgers, so a compact or complete metric consumer has no access to a host completion boundary at this stage.

Next read T. The total-boundedness row supplies the finite probe bundles and coverage histories for the inspected tolerances. This is the only row that can feed the downstream compact and complete boundaries K and C.

Finally read W, Q, R and the structural rows H, A, G, N. The finite windows and regular readback carry the tolerance schedule to the real seal, while transport, replay, provenance, and local naming preserve the same finite-net route. Any consumer that bypasses T would use a coordinate absent from Definition 8531.1. □

Falsifiable prediction: An accepted $\mathsf{PrecompactMetricSpace}^{\uparrow}$ consumer that reaches $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, or $\mathsf{Real}^{\uparrow}$ data without displaying the finite-net row T refutes the carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{PrecompactMetricSpace}^{\uparrow}}$.

Constructive story: A $\mathsf{PrecompactMetricSpace}^{\uparrow}$ packet is generated from a MetricSpace source row, TotallyBoundedMetric finite-net row, CompactMetric boundary row, CompleteMetric boundary row, Real tolerance seal, finite-window row, RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PrecompactMetricSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8531.1, Definition 8531.2, and Definition 8531.3 seed the finite-net precompactness route over metric-source, total-boundedness, compact-boundary, complete-boundary, real-seal, finite-window, regular-readback, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PrecompactMetricSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected completion points, quotient equality of Cauchy names, countable choice, host compactification, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-net coverage admission, compact-boundary admission, completion-boundary admission, finite-window readback, real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PrecompactMetricSpaceUp.

Chapter 8532

A Concrete Naming Certificate for $\mathsf{CoarseSpace}^{\uparrow}$

Following Roe's large-scale geometry, $\mathsf{CoarseSpace}^{\uparrow}$ records controlled-set data over BEDC histories. It sits after the metric rows of chapter 57, the entourage discipline of chapter 2205, the metric-controlled specialization of chapter 6645, and the completion-facing uniform route of chapter 3560. The packet names large-scale control as finite carrier data; it does not identify small-scale uniform equivalence, quotient coarse maps, selected representatives, countable choice, or ambient completion.

Definition 8532.1 (CoarseSpace carrier)**.** *A* $\mathsf{CoarseSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$X = (U, \Delta, E, J, K, I, H, C, P, N)$$

with the following visible rows:

1. *U is the underlying history row carrying the displayed points or probes read by a coarse consumer.*
2. *Δ is the diagonal controlled-entourage row.*
3. *E is a finite list of controlled-entourage rows over the same* BHist *source.*
4. *J records the controlled-union ledger for finite unions of rows in E.*
5. *K records the controlled-composition ledger for composable rows in E.*
6. *I records the inverse or symmetry row when the presented coarse structure includes it.*
7. *H records componentwise* hsame *transport for the source row, diagonal row, controlled-entourage rows, union ledger, composition ledger, inverse row, replay routes, provenance, and local naming.*
8. *C records displayed* Cont *replay from a consumer request through the same controlled-entourage rows.*
9. *P is the* Pkg *provenance over* $\mathsf{CoarseSpace}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformEntourageSpace}^{\uparrow}$, $\mathsf{CoarseMetricSpace}^{\uparrow}$, $\mathsf{UniformSpaceCompletion}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CoarseSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed controlled rows and their structural provenance. It has no coordinate for quotient coarse categories, ambient bornologies, selected representatives, countable choice, or small-scale uniform equivalence.

Theorem 8532.2 (CoarseSpace NameCert obligations)**.** *For an accepted* $\mathsf{CoarseSpace}^{\uparrow}$ *carrier* $X = (U, \Delta, E, J, K, I, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{CoarseSpace}^{\uparrow}}$ *surface consists of carrier admission, the diagonal row* Δ*, controlled finite unions through* J*, controlled composition through* K*, inverse or symmetry exposure through* I *where present, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local NameCert naming through* N*. Every public controlled-entourage read must expose those rows before it can be consumed as large-scale coarse data.*

Proof. Carrier admission is the displayed finite packet. The diagonal, controlled-entourage list, union ledger, composition ledger, inverse row, transport rows, replay routes, package provenance, and local naming row are all visible coordinates of the same BHist surface.

The closure rows are finite. A union read uses J, a composition read uses K, and an inverse or symmetry read uses I only when that row is present in the carrier. Componentwise transport through H preserves the same rows rather than replacing them by an external coarse category.

The consumer routes are exhausted by C, P, N. Since no excluded object is a coordinate of the carrier, the NameCert surface cannot export quotient coarse maps, selected representatives, countable choice, ambient bornologies, or small-scale uniform equivalence. □

Theorem 8532.3 (CoarseSpace metric entourage handoff)**.** *Every metric-controlled* $\mathsf{CoarseSpace}^{\uparrow}$ *read factors through the displayed* $\mathsf{Met}^{\uparrow}$ *source and the existing* $\mathsf{CoarseMetricSpace}^{\uparrow}$ *specialization before the controlled-entourage rows are consumed. The handoff may also be read against* $\mathsf{UniformEntourageSpace}^{\uparrow}$ *and* $\mathsf{UniformSpaceCompletion}^{\uparrow}$ *as provenance for entourage and completion-facing consumers, but it does not assert that the large-scale controlled structure is equivalent to the small-scale uniform structure.*

Proof. Read the metric-controlled request through the provenance row P. Its metric side is the displayed $\mathsf{Met}^{\uparrow}$ source, and its large-scale specialization is the $\mathsf{CoarseMetricSpace}^{\uparrow}$ route already named as a dependency of the carrier.

The controlled-entourage rows of X are then consumed through $\Delta, E, J, K, I, H, C, P, N$. The $\mathsf{UniformEntourageSpace}^{\uparrow}$ and $\mathsf{UniformSpaceCompletion}^{\uparrow}$ references record where entourage and completion-facing readers may inspect compatible finite rows.

Nothing in the packet identifies those small-scale rows with the large-scale controlled structure. The handoff is therefore a factorization route for metric-controlled coarse reads, not a uniform-equivalence theorem. □

Falsifiable prediction: Every accepted $\mathsf{CoarseSpace}^{\uparrow}$ read displays the source row, diagonal controlled-entourage row, controlled-entourage packet, finite union ledger, composition ledger, available inverse or symmetry row, hsame transport, Cont replay, Pkg provenance, and local NameCert row before any large-scale control is exported.

Independence witness: metric, uniform-entourage-space, coarse-metric-space, uniform-space-completion: no listed sibling is bijective to $\mathsf{CoarseSpace}^{\uparrow}$ because this packet jointly carries diagonal, controlled union, controlled composition, optional inverse or symmetry, transport, replay, provenance, and local naming rows for an abstract controlled-set carrier.

Closure status for $\mathsf{NameCert}_{\mathsf{CoarseSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CoarseSpace}^{\uparrow}$ packet is generated from displayed source histories, a diagonal controlled-entourage row, finite controlled-entourage rows, controlled union and composition ledgers, an available inverse or symmetry row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CoarseSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8532.1, Definition 8532.2, and Definition 8532.3 seed the finite controlled-set surface and its metric-controlled handoff.

Formal verification: FormalStatus(NameCert$_{\mathsf{CoarseSpace}\uparrow}$, unformalized)

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient coarse categories, small-scale uniform equivalence, selected representatives, countable choice, ambient bornologies, completion, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, diagonal exposure, controlled union, controlled composition, inverse or symmetry transport, metric handoff, replay, provenance, and local naming for BEDC.Derived.CoarseSpaceUp.

Chapter 8533

A Concrete Naming Certificate for $\mathsf{CauchyCompletionCommutation}^{\uparrow}$

Following Bishop and Bridges and Mac Lane, the $\mathsf{CauchyCompletionCommutation}^{\uparrow}$ packet records the finite route by which a displayed binary product and a displayed Cauchy-completion read may be compared without choosing representatives or importing a quotient completion. It sits after the monad surface of chapter 378, the functor surface of chapter 423, the regular-sequence rational carrier of chapter 301, the stream-window carrier of chapter 126, the dyadic tolerance carrier of chapter 291, the real seal of chapter 38, and the product carrier of chapter 34. The packet names only finite product routing, completion routing, stream windows, dyadic tolerances, real readback, transport, replay, provenance, and local naming rows.

Definition 8533.1 (Cauchy completion commutation carrier)**.** *A* $\mathsf{CauchyCompletionCommutation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, R, U, V, W, G, D, E, H, C, P, N)$$

with the following displayed rows:

1. *A and B are the two input carrier rows whose finite product read is inspected.*
2. *R is the* $\mathsf{Prod}^{\uparrow}$ *product route, exposing pair formation and component projections before any completion read is consumed.*
3. *U is the completion-then-product route, reading* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *on A and B before the product row is formed.*
4. *V is the product-then-completion route, forming the displayed product row before the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *completion read is consumed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row, recording the finite prefixes used by both routes.*
6. *G is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, recording the regular rational-sequence witnesses visible through W.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row, displaying the dyadic precision budget used to compare the two finite routes.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, recording that the two reads are exported only as a real-valued finite tolerance comparison.*

9. *H records componentwise* hsame *transport for $A, B, R, U, V, W, G, D, E, C, P, N$.*
10. *C records displayed* Cont *replay through*

$$A, B \longmapsto R \longmapsto U, V \longmapsto W, G, D \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionCommutation}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionFun}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Prod}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionCommutation}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion, selected representatives, countable choice, host product equality, ambient real completeness, or a global theorem identifying products in an external category.

Theorem 8533.2 (Cauchy completion commutation NameCert obligations)**.** *For every accepted* $\mathsf{CauchyCompletionCommutation}^{\uparrow}$ *carrier $K = (A, B, R, U, V, W, G, D, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyComplet}}$ *surface consists exactly of product-route admission through R, completion-then-product admission through U, product-then-completion admission through V, stream-window exposure through W, regular rational readback through G, dyadic tolerance exposure through D, real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8533.1. The rows A, B, R display the finite product route before either completion path is compared.

Next read the two completion routes. The row U exposes completion before product formation, while V exposes product formation before completion. The shared stream-window row W, regular-sequence readback row G, and dyadic tolerance row D give the finite evidence by which the two routes can be compared.

Finally the real seal E exports only that finite tolerance comparison. The structural rows H, C, P, N transport, replay, source, and name the same packet, and the carrier contains no coordinate for representative choice or ambient product equality. Hence the listed rows exhaust the NameCert obligations. □

Theorem 8533.3 (Cauchy completion finite route commutation)**.** *Every accepted* $\mathsf{CauchyCompletionCommutation}^{\uparrow}$ *read factors the comparison of the two routes through the finite diagram*

$$\mathsf{Prod}^{\uparrow}, \mathsf{CauchyCompletionFunctor}^{\uparrow}, \mathsf{CauchyCompletionMonad}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{R}$$

Thus the completion-then-product route and the product-then-completion route can be compared only after product routing, completion routing, stream windows, regular rational readback, dyadic tolerance, and the real seal have all been displayed.

Proof. Start from the product row R. It exposes pair formation and projections as finite data, so both later routes consume the same displayed product interface.

Read U and V as two ordered uses of the completion surfaces. The comparison is not made at the level of host products; it is made only after both routes have supplied the same kind of stream windows and regular rational readbacks.

The dyadic row D supplies the common tolerance budget, and the real seal E exports the resulting finite comparison. Since H, C, P, N only preserve and name this route, every accepted read factors through the displayed finite diagram. □

Theorem 8533.4 (Cauchy completion commutation nonescape)**.** *An accepted* CauchyCompletionCommutation$^{\uparrow}$ *packet cannot be read as a quotient-completion theorem, a selected-representative construction, a countable-choice principle, host product equality, or ambient* Real$^{\uparrow}$ *completeness. Any consumer of the packet receives only the displayed finite route* $A, B, R, U, V, W, G, D, E, H, C, P, N$.

Proof. Inspect the carrier coordinates. None of $A, B, R, U, V, W, G, D, E, H, C, P, N$ contains a selector for Cauchy representatives, a quotient-equality rule, a countable-choice row, or a host product equality row.

The comparison rows stop at dyadic tolerance and the real seal. They can report that the two finite routes meet the displayed tolerance interface, but they cannot replace this report by a theorem of ambient completeness.

Therefore every consumer remains inside the named packet. Any request for quotient completion, representative selection, choice, host equality, or ambient real completeness leaves the accepted CauchyCompletionCommutation$^{\uparrow}$ carrier. □

Closure status for NameCert$_{\text{CauchyCompletionCommutation}^{\uparrow}}$**.**

Constructive story: A CauchyCompletionCommutation$^{\uparrow}$ packet is generated from two input carrier rows, a product route, completion-then-product and product-then-completion routes, StreamName windows, RegSeqRat readback, DyadicRatCore tolerance, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionCommutation}^{\uparrow}}$, seed)

Scope closed: Definition 8533.1, Definition 8533.2, Definition 8533.3, and Definition 8533.4 seed the finite product/completion route comparison over $A, B, R, U, V, W, G, D, E, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionCommutation}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close quotient completion, selected representatives, countable choice, host product equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked product routing, completion routing, stream-window exposure, regular rational readback, dyadic tolerance, real sealing, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionC

Chapter 8534

A Concrete Naming Certificate for HyperbolicPhaseVisualModulus$^{\uparrow}$

The HyperbolicPhaseVisualModulus$^{\uparrow}$ packet realizes the observer-expansion visual-modulus branch of chapter 9463 as finite NameCert data. It sits after the visual metric of chapter 3866, the observer phase route of chapter 6920, the Busemann-function readback of chapter 7534, the boundary-shadow surface of chapter 3813, the dyadic tolerance carrier of chapter 291, and the real seal of chapter 38. The packet names only finite observer phase rows, visual metric rows, Busemann rows, boundary-shadow windows, dyadic tolerance, real sealing, transport, replay, provenance, and local naming.

Definition 8534.1 (Hyperbolic phase visual-modulus carrier)**.** *A* HyperbolicPhaseVisualModulus$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (O, V, B, S, D, R, T, F, H, C, P, N)$$

with the following displayed rows:

1. *O is the* HyperbolicObserverPhaseRoute$^{\uparrow}$ *row, recording the observer phase route before a visual tolerance is read.*
2. *V is the* HyperbolicVisualMetric$^{\uparrow}$ *row, exposing the visual-metric comparison surface.*
3. *B is the* HyperbolicBusemannFunction$^{\uparrow}$ *row, recording the Busemann readback used to orient the observer phase.*
4. *S is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row, recording the finite boundary-shadow window consumed by the visual metric.*
5. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, displaying the dyadic modulus budget.*
6. *R is the* Real$^{\uparrow}$ *seal row, exporting the visual-modulus comparison only as a real-valued finite tolerance read.*
7. *T is the TasteGate row requiring* Nontrivial HyperbolicPhaseVisualModulus$^{\uparrow}$ *and* FieldFaithful HyperbolicPhaseVisu *instances before the packet can classify observer-expansion visual modulus data.*
8. *F is the refusal row, rejecting reads that turn the visual modulus into a global hyperbolic boundary oracle, selected geodesic representative, or ambient visual compactification.*
9. *H records componentwise* hsame *transport for $O, V, B, S, D, R, T, F, C, P, N$.*

10. *C records displayed* Cont *replay through*

$$O, V \longmapsto B, S \longmapsto D \longmapsto R \longmapsto T, F, H, P, N.$$

11. *P is the* Pkg *provenance over* HyperbolicPhaseVisualModulus$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicObserverPhase
HyperbolicBusemannFunction$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

12. *N is the local* NameCert$_{\text{HyperbolicPhaseVisualModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for a completed visual boundary, a global metric oracle, selected geodesic representatives, host hyperbolic compactification, or an ambient theorem identifying all observer phases.

Theorem 8534.2 (Hyperbolic phase visual-modulus NameCert obligations)**.** *For every accepted* HyperbolicPhaseVisualModulus$^{\uparrow}$ *carrier $M = (O, V, B, S, D, R, T, F, H, C, P, N)$, the local* NameCert$_{\text{HyperbolicPhaseVisua}}$ *surface consists exactly of observer-phase admission through O, visual-metric admission through V, Busemann readback through B, boundary-shadow exposure through S, dyadic tolerance exposure through D, real sealing through R, TasteGate nontriviality and field-faithfulness requests through T, refusal through F, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8534.1. The rows O, V, B, S expose the observer route, visual metric, Busemann readback, and boundary shadow as separate finite fields.

The tolerance and sealing rows then determine what can be exported. The dyadic row D gives the finite modulus budget, while R seals the result as a real-valued comparison rather than a boundary oracle.

Finally the TasteGate, refusal, and structural rows finish the certificate. The row T names the required Nontrivial and FieldFaithful instances, F blocks global-boundary readings, and H, C, P, N only transport, replay, source, and name the same packet. No further NameCert obligation is available outside the listed rows. □

Theorem 8534.3 (Hyperbolic phase visual-modulus boundary route)**.** *Every accepted* HyperbolicPhaseVisualModul *boundary read factors through*

HyperbolicObserverPhaseRoute$^{\uparrow}$, HyperbolicVisualMetric$^{\uparrow}$, HyperbolicBusemannFunction$^{\uparrow}$, HyperbolicBoundaryShadow

Thus the observer-expansion visual modulus is available only after the observer phase, visual metric, Busemann readback, boundary shadow, dyadic tolerance, and real seal have all been displayed.

Proof. Start with the observer-phase and visual-metric rows. They provide the phase route and visual comparison surface, but neither row alone carries a modulus exported to a consumer.

Next read the Busemann and boundary-shadow rows. These rows orient the boundary-facing comparison and supply the finite shadow window to which the modulus budget applies.

The dyadic tolerance row D and real seal R complete the boundary route. Since H, C, P, N preserve only this displayed path, every accepted boundary read factors through the stated finite diagram. □

Theorem 8534.4 (Hyperbolic phase visual-modulus expansion readback)**.** *An observer-expansion read of an accepted* HyperbolicPhaseVisualModulus$^{\uparrow}$ *packet exports only the row family $O, V, B, S, D, R, T, F, H, C, P,$ It cannot be read as a global hyperbolic visual-boundary oracle, a selected geodesic representative, a completed compactification, or a proof that all observer phases have the same ambient visual metric.*

Proof. Inspect the refusal and TasteGate rows. The row F blocks global-boundary and selected-representative readings, while T requires nontrivial and field-faithful Lean-side instances before the packet can classify visual-modulus data.

Readback therefore remains finite. The rows O, V, B, S, D, R give the observer route, visual metric, Busemann readback, boundary shadow, dyadic tolerance, and real seal, and the rows H, C, P, N transport, replay, source, and name only those data.

Hence no consumer can extract a completed compactification, global oracle, selected representative, or ambient equality of observer phases from the packet. The expansion readback is exactly the displayed row family. □

Falsifiable prediction: A packet missing D or R may still display observer-phase and boundary-shadow rows, but it cannot export a real-valued visual modulus.

Independence witness: hyperbolic-visual-metric, hyperbolic-observer-phase-route, hyperbolic-busemann-function, hyperbolic-boundary-shadow, real: no listed sibling is bijective with HyperbolicPhaseVisualMod because none preserves observer phase, visual metric, Busemann readback, boundary shadow, dyadic tolerance, real seal, TasteGate request, refusal, transport, replay, provenance, and local NameCert together.

The Lean-side boundary is expected to provide explicit Nontrivial HyperbolicPhaseVisualModulus$^{\uparrow}$ and FieldFaithful HyperbolicPhaseVisualModulus$^{\uparrow}$ instances. The field-faithfulness witness must keep $O, V, B, S, D, R, T, F, H, C, P, N$ as distinct rows before any classifier target for HyperbolicPhaseVisualModulus$^{\uparrow}$ can accept the packet.

Closure status for NameCert$_{\text{HyperbolicPhaseVisualModulus}^{\uparrow}}$.

Constructive story: A HyperbolicPhaseVisualModulus$^{\uparrow}$ packet is generated from observer phase, visual metric, Busemann readback, boundary shadow, dyadic tolerance, real seal, TasteGate request, refusal, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicPhaseVisualModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8534.1, Definition 8534.2, Definition 8534.3, and Definition 8534.4 seed the finite observer-expansion visual-modulus route over $O, V, B, S, D, R, T, F, H, C, P, N$.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicPhaseVisualModulus}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close a completed visual boundary, global metric oracle, selected geodesic representatives, host hyperbolic compactification, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked observer-phase admission, visual-metric admission, Busemann readback, boundary-shadow exposure, dyadic tolerance, real sealing, TasteGate nontriviality, field faithfulness, refusal, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicPhaseVisualModulusUp.

Chapter 8535

A Concrete Naming Certificate for $\mathsf{SteinitzExchange}^{\uparrow}$

Following Steinitz and the standard finite-dimensional linear algebra exchange argument, the $\mathsf{SteinitzExchange}^{\uparrow}$ packet records the finite route by which a displayed independent list, a displayed spanning list, and a selected exchange position are read as one NameCert surface. It sits after the vector-space carrier of chapter 47, the linear-map and matrix rows of chapter 48 and chapter 49, the rank accounting surface of chapter 3438, and the scalar source of chapter 45. The packet names only finite coordinate, independence, span, pivot, transport, replay, provenance, and local naming rows; it does not import a host basis choice, quotient vector equality, Zorn maximality, dimension comparison outside the displayed rank ledger, or ambient linear algebra.

Definition 8535.1 (Steinitz exchange carrier)**.** *A* $\mathsf{SteinitzExchange}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (F, V, L, S, M, R, Piv, B, H, C, P, N)$$

with the following displayed rows:

1. *F is the accepted* $\mathsf{Field}^{\uparrow}$ *scalar row.*
2. *V is the accepted* $\mathsf{VecSpace}^{\uparrow}$ *vector-space row over F.*
3. *L is the finite independent-list row whose entries are read through V.*
4. *S is the finite spanning-list row whose entries are read through V.*
5. *M is the* $\mathsf{Mat}^{\uparrow}$ *coordinate ledger recording the finite coefficient table from L into the span of S.*
6. *R is the* $\mathsf{RankNullity}^{\uparrow}$ *accounting row for the displayed coordinate map.*
7. *Piv is the pivot row naming the exchanged source position, target position, and nonzero scalar guard visible in the matrix ledger.*
8. *B is the basis-handoff row, recording the finite list obtained by replacing the target row of S by the selected row of L.*
9. *H records componentwise* hsame *transport for scalar, vector, list, matrix, rank, pivot, basis-handoff, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay through the same finite exchange route.*
11. *P is the* Pkg *provenance over* $\mathsf{SteinitzExchange}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{RankNullity}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

12. N is the local $\mathsf{NameCert}_{\mathsf{SteinitzExchange}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $F, V, L, S, M, R, Piv, B, H, C, P, N$. It has no coordinate for an ambient basis selector, quotient equality of vectors, a maximal independent set, or a dimension theorem outside the displayed finite ledger.

Theorem 8535.2 (Steinitz exchange NameCert obligations)**.** *For every accepted* $\mathsf{SteinitzExchange}^{\uparrow}$ *carrier*

$$E = (F, V, L, S, M, R, Piv, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SteinitzExchange}^{\uparrow}}$ *surface consists exactly of scalar-field exposure, vector-space exposure, independent-list exposure, spanning-list exposure, finite matrix-coordinate exposure, rank-nullity accounting, pivot exposure, basis-handoff exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer may read the exchange handoff only after the same F, V, L, S, M, R, Piv route has been displayed.*

Proof. Project the carrier E. The algebraic rows expose the scalar field, vector-space carrier, independent list, spanning list, finite coordinate matrix, rank ledger, pivot, and exchanged list in one packet.

The pivot row is downstream of the matrix and rank rows. Thus a consumer cannot obtain the exchanged list from a hidden basis choice or from a host dimension theorem; it must read the displayed nonzero scalar guard and the finite coordinate position in Piv.

The structural rows H, C, P, N transport, replay, source, and name the same finite route. Since the excluded ambient objects are not carrier coordinates, the NameCert obligations are exhausted by the displayed exchange packet. □

Theorem 8535.3 (Steinitz exchange basis handoff)**.** *Every* $\mathsf{SteinitzExchange}^{\uparrow}$ *consumer that exports a basis-exchange handoff to a* $\mathsf{LinMap}^{\uparrow}$*,* $\mathsf{Mat}^{\uparrow}$*, or* $\mathsf{RankNullity}^{\uparrow}$ *sibling must first read the shared finite route*

$$\mathsf{Field}^{\uparrow}, \mathsf{VecSpace}^{\uparrow}, L, S, M, R, Piv, B, H, C, P, N.$$

The handoff keeps the independent row L, spanning row S, coordinate matrix M, rank ledger R, and pivot row Piv attached to the same vector-space and field rows; it cannot split the exchanged basis row B from its finite coordinate witness.

Proof. Begin with the NameCert obligations of Definition 8535.2. They expose the exchange handoff only after the field, vector-space, independent-list, spanning-list, matrix, rank, and pivot rows have been displayed.

The sibling consumers read different faces of the same packet. A $\mathsf{LinMap}^{\uparrow}$ read uses the coordinate map, a $\mathsf{Mat}^{\uparrow}$ read uses the finite coefficient table, and a $\mathsf{RankNullity}^{\uparrow}$ read uses the rank ledger; none of these rows contains an independent basis selector.

Finally replay the structural rows H, C, P, N. They preserve the same finite exchange route under transport, continuation, provenance, and local naming, so the exported basis handoff remains the displayed Steinitz exchange packet rather than a host basis-choice principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{SteinitzExchange}^{\uparrow}}$**.**

Constructive story: A $\mathsf{SteinitzExchange}^{\uparrow}$ packet is generated from a displayed scalar field, vector-space row, independent list, spanning list, finite matrix-coordinate ledger, rank-nullity accounting row, pivot row, exchanged basis-handoff row, componentwise hsame transports, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SteinitzExchange}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8535.1, Definition 8535.2, and Definition 8535.3 seed the finite exchange surface over Field, VecSpace, LinearMap, Matrix, and RankNullity rows.

Formal verification: FormalStatus(NameCert$_{\text{SteinitzExchange}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, host basis selection, quotient vector equality, Zorn maximality, unrestricted dimension comparison, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite list exposure, matrix-coordinate exactness, rank-nullity handoff, pivot non-escape, basis-handoff transport, provenance, and local naming for BEDC.Derived.SteinitzExchangeUp.

Chapter 8536

A Concrete Naming Certificate for $\mathsf{HeytingAlgebra}^{\uparrow}$

Following Heyting and Brouwer, the $\mathsf{HeytingAlgebra}^{\uparrow}$ packet records the constructive algebraic reading of implication as a right adjoint to finite meet, rather than as Boolean complement or excluded middle. It sits beside the Boolean endpoint of chapter 3733, the meet–join surface of chapter 55, the order carrier of chapter 53, the point-free reading of chapter 5153, and the open-set discipline of chapter 88. The packet supplies the intuitionistic algebraic interface needed by Real and Completion chapters while refusing powerset, quotient, ultrafilter, prime-filter, and excluded-middle coordinates.

Definition 8536.1 (Heyting algebra carrier)**.** *A* $\mathsf{HeytingAlgebra}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$H = (L, \bot, \top, \mathsf{meet}, \mathsf{join}, \mathsf{imp}, H_s, C, P, N),$$

where:

1. *L is the bounded-lattice row, read through the displayed* $\mathsf{Lattice}^{\uparrow}$ *and* $\mathsf{Poset}^{\uparrow}$ *sibling obligations.*
2. *$\bot$ and $\top$ are the bottom and top endpoint rows, stable under the classifier inherited from the bounded-lattice surface.*
3. meet *and* join *are finite meet and join rows, transported only through componentwise* hsame *over the displayed lattice packet.*
4. imp *is the implication row, recording for displayed a, b, c the finite adjunction read that $a \wedge b \leq c$ exactly when $a \leq b \Rightarrow c$ inside the same classifier-stable order.*
5. *H_s records bounded-lattice stability, implication-adjunction stability, and refusal of Boolean complement as a required coordinate.*
6. *C is the displayed* Cont *replay row for the bounded-lattice and implication-adjunction data.*
7. *P is the* Pkg *provenance over* $\mathsf{HeytingAlgebra}^{\uparrow}$, $\mathsf{BooleanAlgebra}^{\uparrow}$, $\mathsf{Lattice}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{LocaleSpace}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{HeytingAlgebra}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, \bot, \top, \mathsf{meet}, \mathsf{join}, \mathsf{imp}, H_s, C, P, N$. It has no coordinate for Boolean complement, powerset representation, quotient order equality, excluded middle, prime filters, ultrafilters, or Stone duality.

Theorem 8536.2 (Heyting algebra NameCert obligations)**.** *For every accepted* $\mathsf{HeytingAlgebra}^{\uparrow}$ *carrier* $H = (L, \bot, \top, \mathsf{meet}, \mathsf{join}, \mathsf{imp}, H_s, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HeytingAlgebra}^{\uparrow}}$ *surface consists exactly of carrier admission, classifier exactness, bounded-lattice endpoint exposure, meet and join exposure, implication-adjunction exposure, transport stability, replay stability, provenance, and local naming.*

In particular, a consumer may read the implication row only after the bounded-lattice rows and the $\mathsf{Poset}^{\uparrow}/\mathsf{Lattice}^{\uparrow}$ *order comparison are visible. The certificate does not supply Boolean completeness, a complement operation, powerset membership, quotient classes, excluded middle, prime filters, ultrafilters, or Stone representation data.*

Proof. Project the carrier of Definition 8536.1. The finite packet exposes the bounded-lattice row L, endpoints, meet, join, implication, stability row, replay row, provenance row, and local naming row as separate coordinates.

The classifier is inherited only through the displayed order and lattice rows. Thus any accepted consumer must preserve the $\mathsf{Poset}^{\uparrow}$ comparison, the $\mathsf{Lattice}^{\uparrow}$ meet–join surface, and the endpoint rows before the implication row can be inspected.

The implication obligation is the adjunction row in H_s. It records the finite comparison between $a \wedge b \leq c$ and $a \leq b \Rightarrow c$ inside the same order, so implication is read as a constructive residual of meet.

Finally the structural rows C, P, N replay, source, and name the same finite packet. Since no complement, powerset, quotient, excluded-middle, prime-filter, ultrafilter, or Stone-duality coordinate occurs in the carrier, none can be exported by the local certificate. □

Theorem 8536.3 (Heyting algebra implication adjunction)**.** *Let* $H = (L, \bot, \top, \mathsf{meet}, \mathsf{join}, \mathsf{imp}, H_s, C, P, N)$ *be an accepted* $\mathsf{HeytingAlgebra}^{\uparrow}$ *packet whose* $\mathsf{Poset}^{\uparrow}$ *and* $\mathsf{Lattice}^{\uparrow}$ *histories are classifier-stable. For displayed rows* a, b, c *in the order carrier, the BEDC implication row is read by the finite adjunction relation*

$$a \wedge b \leq c \quad \textit{iff} \quad a \leq b \Rightarrow c$$

inside those classifier-stable histories. This read is an implication-adjunction certificate, not a Boolean complement, powerset, quotient, or excluded-middle coordinate.

Proof. Project the bounded-lattice rows from Definition 8536.1. The order comparison, meet row, join row, and endpoints are already supplied through the $\mathsf{Poset}^{\uparrow}$ and $\mathsf{Lattice}^{\uparrow}$ sibling histories, so the displayed expressions $a \wedge b \leq c$ and $a \leq b \Rightarrow c$ are read in the same classifier-stable order.

Next read the implication row and the stability row H_s. These rows record implication only as the right-adjoint comparison to finite meet. They do not add an independent complement operation or a classical truth-value discriminator.

Transport and replay preserve the same relation. Componentwise hsame and displayed Cont move the bounded-lattice and implication rows together, while P and N source and name the same finite packet.

Therefore the implication row is exactly the displayed adjunction relation over the accepted Poset and Lattice histories. Since the packet has no Boolean complement, powerset, quotient, or excluded-middle coordinate, those readings are refused rather than silently imported. □

Closure status for $\mathsf{NameCert}_{\mathsf{HeytingAlgebra}^{\uparrow}}$.

Constructive story: A $\mathsf{HeytingAlgebra}^{\uparrow}$ packet is generated from bounded-lattice rows, endpoint rows, meet and join rows, an implication-adjunction row, stability data, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HeytingAlgebra}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8536.1, Definition 8536.2, and Definition 8536.3 seed the finite constructive implication-algebra packet over PosetUp, LatticeUp, BooleanAlgebraUp, LocaleSpaceUp, TopologyUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{HeytingAlgebra}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Boolean completeness, classical powersets, prime filters, ultrafilters, Stone duality, quotient representations, excluded middle, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, bounded-lattice endpoint exposure, meet and join stability, implication-adjunction stability, transport, replay, provenance, and local naming for BEDC.Derived.HeytingAlgebraUp.

Chapter 8537

A Concrete Naming Certificate for $\mathsf{InhabitedLocatedCut}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{InhabitedLocatedCut}^{\uparrow}$ packet records a two-sided located-cut witness whose lower and upper rows are both inhabited before any $\mathsf{Real}^{\uparrow}$ seal is admitted. It sits beside the lower-row carrier of chapter 8086, the rounded-cut surface of chapter 6971, the two-sided located Dedekind cut of chapter 7256, the regular rational readback of chapter 301, and the terminal real-name surface of chapter 38. The packet exposes finite cut witnesses and readback rows for Real and Completion consumers; it does not assert Dedekind completeness, quotient cut equality, trichotomy, or selected host reals.

Definition 8537.1 (InhabitedLocatedCut carrier)**.** *An* $\mathsf{InhabitedLocatedCut}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, U, A, G, R, Q, W, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the lower-cut row, carrying the finite lower observations and downward-closed readback inspected by the packet.*
2. *U is the upper-cut row, carrying the finite upper observations and upward-closed readback paired with L.*
3. *A is the inhabited witness row. It displays at least one accepted lower observation and at least one accepted upper observation inside the same packet.*
4. *G is the locatedness modulus row. For every displayed interval request $a < b$ opened by the packet, G records the finite branch that witnesses a lower-side read below b or an upper-side read above a.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the displayed lower, upper, inhabited, and locatedness rows.*
6. *Q is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for endpoint comparison, gap narrowing, radius accounting, and finite budget replay.*
7. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule that fixes the finite observations of L, U, A, G, R, Q available to Real and Completion consumers.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, reached only after L, U, A, G, R, Q, W have been displayed.*

9. *H records componentwise* hsame *transport for lower rows, upper rows, inhabited witnesses, locatedness moduli, readbacks, dyadic ledgers, windows, Real seals, replay, provenance, and local naming.*

10. *C records displayed* Cont *replay through*

$$L, U, A, G \longmapsto R, Q, W \longmapsto E \longmapsto H, P, N.$$

11. *P is the* Pkg *provenance over* $\mathsf{InhabitedLocatedCut}^{\uparrow}$, $\mathsf{LocatedLowerCut}^{\uparrow}$, $\mathsf{RoundedCut}^{\uparrow}$, $\mathsf{LocatedDedekindCut}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{InhabitedLocatedCut}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, A, G, R, Q, W, E, H, C, P, N$. It has no coordinate for Dedekind completeness, arbitrary subset suprema, quotient cut equality, selected host reals, trichotomy, countable choice, or bridge checking.

Theorem 8537.2 (InhabitedLocatedCut NameCert obligations)**.** *For every accepted* $\mathsf{InhabitedLocatedCut}^{\uparrow}$ *carrier $I = (L, U, A, G, R, Q, W, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{InhabitedLocatedCut}^{\uparrow}}$ *obligation surface is exhausted by carrier admission, inhabited witness exposure, located-cut compatibility, classifier stability, and non-escape along the displayed rows. A consumer receives the lower and upper cut rows L, U, the inhabited witness row A, the locatedness modulus G, the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback R, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger Q, the* $\mathsf{StreamName}^{\uparrow}$ *window schedule W, the* $\mathsf{Real}^{\uparrow}$ *seal E, componentwise* hsame *transport H, displayed* Cont *replay C, provenance P, and local naming N, and no further analytic principle.*

Proof. Project the carrier of Definition 8537.1. Carrier admission exposes exactly the rows $L, U, A, G, R, Q, W, E, H$

The inhabited witness obligation is carried by A. It records one lower-side observation and one upper-side observation in the same finite packet, so the certificate never appeals to a detached existence principle.

Located-cut compatibility is carried by G together with L and U. Each displayed interval request is answered inside the finite row family, and the rows R, Q, W merely repack those answers as regular rational readback, dyadic tolerance accounting, and stream-window access.

Classifier stability and non-escape are structural. The rows H, C, P, N transport, replay, source, and name only the displayed data, while E seals only the already exposed route. Since no row contains completeness, quotient equality, selected host reals, trichotomy, arbitrary suprema, countable choice, or bridge data, none can be exported by the local NameCert. □

Theorem 8537.3 (InhabitedLocatedCut Real seal boundary)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{InhabitedLocatedCut}^{\uparrow}$ *packet factors through the displayed cut rows, locatedness row,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{StreamName}^{\uparrow}$ *window schedule, componentwise transport, continuation replay, provenance, and local naming rows before it can read the terminal seal:*

$$L, U, A, G \longmapsto R, Q, W \longmapsto H, C, P, N \longmapsto E.$$

The factorization gives Real and Completion consumers an inhabited located-cut witness without completing arbitrary cuts, quotienting cut equality, selecting host reals, or deciding trichotomy.

Proof. Start with the cut rows. The lower row L and upper row U provide the displayed two-sided cut surface, while A supplies the inhabited witness and G supplies the locatedness answers.

Next read the finite observation and tolerance rows. The regular readback R is computed from the displayed cut evidence, the dyadic ledger Q records endpoint and gap budgets, and the stream schedule W fixes which observations the consumer is allowed to inspect.

The structural rows then preserve the same route. Componentwise transport H, continuation replay C, provenance P, and local naming N can only replay the row family already exposed by the packet.

The seal E is terminal for this route. A consumer reaching E has therefore passed through the cut, locatedness, readback, tolerance, window, transport, replay, provenance, and naming rows, and cannot extract Dedekind completeness, arbitrary subset suprema, quotient cut equality, selected host reals, trichotomy, countable choice, or bridge checking from the packet. □

Falsifiable prediction: A $\mathsf{Real}^{\uparrow}$ consumer that reads an $\mathsf{InhabitedLocatedCut}^{\uparrow}$ seal while bypassing the inhabited witness row, locatedness modulus, regular rational readback, dyadic tolerance ledger, or StreamName window refutes the carrier of Definition 8537.1.

Independence witness: located-lower-cut, rounded-cut, located-dedekind-cut, regseqrat, real: no listed sibling is bijective with $\mathsf{InhabitedLocatedCut}^{\uparrow}$ because none carries lower and upper cut rows, inhabited witnesses, locatedness moduli, regular readback, dyadic tolerance, stream windows, real sealing, transport, replay, provenance, and local NameCert together.

Closure status for $\mathsf{NameCert}_{\mathsf{InhabitedLocatedCut}^{\uparrow}}$.

Constructive story: An $\mathsf{InhabitedLocatedCut}^{\uparrow}$ packet is generated from lower-cut rows, upper-cut rows, inhabited witness rows, locatedness modulus rows, RegSeqRat readbacks, DyadicRatCore tolerance ledgers, StreamName window schedules, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{InhabitedLocatedCut}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8537.1, Definition 8537.2, and Definition 8537.3 seed the inhabited located-cut witness packet for the Real and Completion route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{InhabitedLocatedCut}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter excludes Dedekind completeness, arbitrary subset suprema, quotient cut equality, selected host reals, trichotomy, countable choice, Lean verification, and bridge checking.

Upgrade path: Formal verification can encode carrier admission, inhabited witness exposure, located-cut compatibility, classifier stability, non-escape, readback factorization, tolerance accounting, StreamName scheduling, Real-seal ordering, transport, replay, provenance, and local naming for BEDC.Derived.InhabitedLocatedCutUp.

Chapter 8538

A Concrete Naming Certificate for $\mathsf{ModulusCofinalFilter}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy constructions, the $\mathsf{ModulusCofinalFilter}^{\uparrow}$ packet names the directed finite route by which a family of regular-Cauchy modulus rows is refined before a real-completion consumer reads a sealed real name. It sits between the regular-sequence carrier of chapter 301, the finite-window naming discipline of chapter 126, the real seal of chapter 38, the meet surface of chapter 462, and the uniform modulus surface of chapter 1741. The packet records directed cofinal refinement without quotient filters, host choice, or ambient completeness.

Definition 8538.1 (ModulusCofinalFilter carrier)**.** *A* $\mathsf{ModulusCofinalFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, M, D, W, R, S, E, H, C, Q, P, N)$$

with the following visible rows:

1. *I is the finite directed index spine for the displayed family of modulus rows.*
2. *M assigns a regular-Cauchy modulus history to each displayed index.*
3. *D records the finite common-refinement witnesses for pairs of displayed indices.*
4. *W records the* $\mathsf{StreamName}^{\uparrow}$ *window route through which each modulus row is read as finite stream data.*
5. *R records the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows attached to those windows.*
6. *S records the* $\mathsf{Real}^{\uparrow}$ *seal boundary reached only after the regular-Cauchy readback rows are exposed.*
7. *E records meet and comparison rows through* $\mathsf{CauchyModulusMeet}^{\uparrow}$ *and* $\mathsf{UniformCauchyModulus}^{\uparrow}$*.*
8. *H records componentwise* hsame *transport for the index spine, modulus rows, refinement witnesses, windows, readbacks, seals, and comparisons.*
9. *C records the displayed* Cont *replay routes used by stream, regular-sequence, real, meet, and uniform-modulus consumers.*
10. *Q records the refusal ledger for quotient-filter, host-choice, and ambient-completeness reads.*
11. *P is the* Pkg *provenance over the five sibling chapters named above,* BHist, hsame, Cont, *and the local naming rows.*

12. N is the local $\mathsf{NameCert}_{\mathsf{ModulusCofinalFilter}^{\uparrow}}$ *row.*

The carrier exports a directed cofinal finite-means corridor for regular-Cauchy modulus reasoning. It does not export a quotient filter, a selected host cofinal subsequence, a chosen real limit, or any ambient completeness principle.

Theorem 8538.2 (ModulusCofinalFilter regular-Cauchy handoff)**.** *Every accepted* $\mathsf{ModulusCofinalFilter}^{\uparrow}$ *packet hands a real-completion consumer only the displayed directed index spine, regular-Cauchy modulus rows, common-refinement witnesses,* $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks,* $\mathsf{Real}^{\uparrow}$ *seal boundary, and meet/uniform-modulus comparison ledger. The handoff is cofinal because every requested pair of displayed modulus rows has a visible refinement row in D before the consumer reaches S.*

Proof. Project the accepted packet through Definition 8538.1. The rows I, M, D, W, R, S, E are all visible coordinates of the same finite BHist carrier.

The window route W is read through chapter 126, and the regular-rational readback route R is read through chapter 301. These two rows keep the modulus family finite-windowed before any real seal is available.

The comparison ledger E records the meet and uniform-modulus faces using chapter 462 and chapter 1741. The seal row S is then read through chapter 38.

Since the refusal row Q has no quotient-filter, host-choice, selected-limit, or ambient-completeness coordinate, the completion consumer receives only the finite directed cofinal corridor displayed by the carrier. □

Theorem 8538.3 (ModulusCofinalFilter NameCert obligations)**.** *For every accepted* $\mathsf{ModulusCofinalFilter}^{\uparrow}$ *carrier $F = (I, M, D, W, R, S, E, H, C, Q, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{ModulusCofinalFilter}^{\uparrow}}$ *surface consists exactly of carrier admission, directed-index admission, regular-Cauchy modulus-row admission, common-refinement exactness, StreamName window routing, RegSeqRat readback routing, Real seal non-escape, meet and uniform-modulus comparison exactness, componentwise* hsame *transport, displayed* Cont *replay, refusal of quotient filters and host choice,* Pkg *provenance, and local naming.*

Proof. Carrier admission is the displayed finite packet. Directed-index admission reads I, modulus-row admission reads M, and common-refinement exactness reads D.

StreamName window routing, RegSeqRat readback routing, and Real seal non-escape are the rows W, R, S. They force every completion-facing read to pass through finite windows and regular-rational readbacks before the real seal is inspected.

Meet and uniform-modulus comparison exactness is the row E, transported componentwise by H and replayed only through C. Provenance and local naming are the rows P, N.

The refusal ledger Q accounts for the absent surfaces. Because no carrier coordinate stores quotient filters, a host-choice selector, a chosen real limit, or ambient completeness, none of those objects can be part of the local naming certificate. □

Falsifiable prediction: Every accepted $\mathsf{ModulusCofinalFilter}^{\uparrow}$ consumer must expose directed modulus rows, cofinal refinement witnesses, StreamName windows, RegSeqRat readbacks, the Real seal boundary, meet and uniform-modulus comparison rows, hsame transport, Cont replay, Pkg provenance, and local NameCert naming before any real-completion read is accepted.

Independence witness: streamname, regseqrat, real, cauchymodulusmeet, uniformcauchymodulus: no listed sibling is bijective to $\mathsf{ModulusCofinalFilter}^{\uparrow}$ because this packet jointly records directed cofinal refinement of regular-Cauchy modulus rows together with window, readback, seal, comparison, transport, replay, provenance, and refusal rows.

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusCofinalFilter}^{\uparrow}}$.

Constructive story: A $\mathsf{ModulusCofinalFilter}^{\uparrow}$ packet is generated from a finite directed index spine, regular-Cauchy modulus rows, cofinal refinement witnesses, StreamName windows, RegSeqRat readbacks, Real seal boundary, meet and uniform-modulus comparisons, componentwise hsame transport, displayed Cont replay, refusal rows, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ModulusCofinalFilter}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8538.1, Definition 8538.2, and Definition 8538.3 register the finite directed modulus-filter corridor used before real-completion consumers read a sealed real name.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ModulusCofinalFilter}^{\uparrow}}, \mathsf{formalTarget})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient filters, selected cofinal subsequences, host choice, ambient completeness, completed real construction, or bridge checking.

Upgrade path: Scoped closure requires Lean checking of carrier admission, cofinal refinement exactness, window routing, regular-rational readback, Real seal non-escape, comparison exactness, and refusal rows for BEDC.Derived.ModulusCofinalFilterUp.

Chapter 8539

A Concrete Naming Certificate for $\mathsf{PreuniformSpace}^{\uparrow}$

Following Weil and Bourbaki uniform-space terminology, the $\mathsf{PreuniformSpace}^{\uparrow}$ packet records a finite entourage surface before the full uniform-space closure rows are available. It sits between the mature uniform interface of chapter 339, the entourage-base carrier of chapter 1819, and the preuniform-base surface of chapter 8267. The packet names the L10 substrate where neighbourhood and completion-facing consumers may inspect displayed entourage data without receiving symmetry, composition, separatedness, quotient completion, or selected-limit structure.

Definition 8539.1 (PreuniformSpace carrier)**.** *A* $\mathsf{PreuniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (X, E, W, T, H, C, P, N)$$

with the following displayed rows:

1. *X is the carrier-point row, listing the finite point histories whose neighbourhood comparisons are being inspected.*
2. *E is the entourage-base row, read through* $\mathsf{EntourageBase}^{\uparrow}$ *and* $\mathsf{PreuniformBase}^{\uparrow}$ *as a finite family of displayed binary neighbourhood requests.*
3. *W is the finite neighbourhood-window row, recording the inspected point pairs, base indices, and local membership evidence available to the consumer.*
4. *T is the topology or metric handoff row, exposing only the finite neighbourhood data that may later be read by* $\mathsf{UniformSpace}^{\uparrow}$*, topological, metric, or completion-facing consumers.*
5. *H records componentwise* hsame *transport for the point row, entourage-base row, finite-window row, handoff row, provenance, and local naming row.*
6. *C records displayed* Cont *replay of the same preuniform route.*
7. *P is the* Pkg *provenance over* $\mathsf{PreuniformSpace}^{\uparrow}$*,* $\mathsf{PreuniformBase}^{\uparrow}$*,* $\mathsf{EntourageBase}^{\uparrow}$*,* $\mathsf{UniformSpace}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
8. *N is the local* $\mathsf{NameCert}_{\mathsf{PreuniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through X, E, W, T, H, C, P, N. It has no coordinate for a uniform-space symmetry law, a composition-refinement law, separatedness, quotient equality of Cauchy names, selected completions, countable choice, or host powersets.

Theorem 8539.2 (PreuniformSpace NameCert obligations)**.** *For every accepted* $\mathsf{PreuniformSpace}^{\uparrow}$ *carrier*

$$U = (X, E, W, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{PreuniformSpace}^{\uparrow}}$ *surface consists exactly of carrier-point exposure through* X*, entourage-base exposure through* E*, finite neighbourhood-window exposure through* W*, topology or metric handoff exposure through* T*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8539.1. The analytic rows are the point histories X, the displayed entourage-base row E, the finite neighbourhood windows W, and the handoff row T.

The obligation order is finite. A consumer first reads the point and entourage rows, then the inspected neighbourhood windows, and only then the topology or metric handoff surface. No row in this route asserts symmetry, composition refinement, separatedness, quotient completion, or selected limits.

The structural rows H, C, P, N transport, replay, source, and name the same displayed data. Since the excluded uniform and completion objects are absent from the carrier, the local naming surface is exhausted by the listed rows. □

Theorem 8539.3 (PreuniformSpace entourage-base route)**.** *Every neighbourhood read exported by an accepted* $\mathsf{PreuniformSpace}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{EntourageBase}^{\uparrow}, \mathsf{PreuniformBase}^{\uparrow} \longmapsto W \longmapsto T.$$

Thus a topology, metric, or completion-facing consumer receives finite preuniform neighbourhood data rather than a full $\mathsf{UniformSpace}^{\uparrow}$ *packet.*

Proof. Read the carrier $U = (X, E, W, T, H, C, P, N)$. The only row that names binary neighbourhood data is E, and it is explicitly the entourage-base row attached to the preuniform-base surface.

The finite-window row W restricts each consumer request to displayed point pairs, base indices, and membership evidence. The handoff row T may expose those finite neighbourhood reads to topology, metric, or completion-facing consumers, but it does not create uniform symmetry or composition data.

Finally replay the structural rows H, C, P, N. They preserve the same entourage-base route under componentwise transport and displayed continuation, so every exported neighbourhood read remains downstream of E and W. □

Theorem 8539.4 (PreuniformSpace uniform-consumer handoff)**.** *Any* $\mathsf{UniformSpace}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{PreuniformSpace}^{\uparrow}$ *carrier must first expose the point row* X*, the entourage-base row* E*, the finite neighbourhood window* W*, and the handoff row* T*. The handoff may be consumed as preuniform input for later uniform closure, but it does not itself export diagonal refinement, symmetry, composition, separatedness, quotient completion, countable choice, selected limits, or host powersets.*

Proof. Start with Definition 8539.2. It places every consumer-visible read inside the displayed rows X, E, W, T, H, C, P, N.

Use the entourage-base route of Definition 8539.3. The $\mathsf{UniformSpace}^{\uparrow}$ or completion-facing consumer can inspect only the preuniform neighbourhood data carried by E and filtered through W before reaching T.

The uniform laws named in the statement require carrier coordinates that the preuniform packet does not store. Therefore the handoff is a finite substrate for later uniform closure, not a proof of full uniform-space closure or a completion principle. □

Falsifiable prediction: An accepted $\mathsf{PreuniformSpace}^{\uparrow}$ consumer is refuted if it reaches $\mathsf{UniformSpace}^{\uparrow}$, topological, metric, or completion-facing data without displaying the carrier-point row, entourage-base row, finite neighbourhood-window row, handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{PreuniformSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{PreuniformSpace}^{\uparrow}$ packet is generated from displayed carrier-point rows, an entourage-base row, finite neighbourhood windows, a topology or metric handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PreuniformSpace}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8539.1, Definition 8539.2, Definition 8539.3, and Definition 8539.4 seed the finite preuniform route over point, entourage-base, preuniform-base, neighbourhood-window, handoff, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PreuniformSpace}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close full UniformSpace laws, separatedness, quotient completion, selected limits, countable choice, host powersets, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, entourage-base exposure, neighbourhood-window exactness, topology or metric handoff nonescape, transport, replay, provenance, and local naming for BEDC.Derived.PreuniformSpaceU

Chapter 8540

A Concrete Naming Certificate for $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy real names and cofinal subsequence readings, the $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ packet records the finite modulus row that lets a regular Cauchy name be read along a displayed cofinal reindexing schedule before its regular rational readback or $\mathsf{Real}^{\uparrow}$ seal is consumed. It sits between the finite stream schedule of chapter 7081, the regular cofinal route of chapter 6960, the general handoff of chapter 1568, the dyadic tolerance carrier of chapter 291, the regular rational row of chapter 301, and the terminal real-name seal of chapter 38. The packet names only a finite cofinal-modulus carrier; it does not quotient streams, choose representatives, import countable choice, identify host equality, or invoke ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8540.1 (RegularCauchyReindexingModulus carrier)**.** *A* $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (S, T, I, U, D, W, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the source* $\mathsf{StreamName}^{\uparrow}$ *schedule of the regular Cauchy name.*
2. *T is the target* $\mathsf{StreamName}^{\uparrow}$ *schedule whose finite requests are sent back to S.*
3. *I is the* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *cofinal route, including the monotone index map and its cofinal reachability witness.*
4. *U is the modulus row assigning to each displayed target request a source-side bound along I.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger read by the modulus row.*
6. *W is the* $\mathsf{StreamReindexing}^{\uparrow}$ *finite-window replay surface for the source and target schedules.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached only after T, I, U, D, W have been displayed.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal reached after the regular rational readback and cofinal-modulus route have been replayed.*
9. *H records componentwise* hsame *transport for the schedules, route, modulus, tolerance ledger, finite windows, readback, seal, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from target requests through I, U, D, W, R to the terminal seal E.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamReindexing}^{\uparrow}$, $\mathsf{RegularCauchyReindexing}^{\uparrow}$, $\mathsf{CauchyReindexing}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexingModulus}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient stream equality, selected representatives, countable choice, host equality of streams or reals, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8540.2 (RegularCauchyReindexingModulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ *carrier $M = (S, T, I, U, D, W, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRe}}$ *surface consists exactly of source and target* $\mathsf{StreamName}^{\uparrow}$ *admission,* $\mathsf{RegularCauchyReindexing}^{\uparrow}$ *cofinal-route exposure, modulus-row exposure,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance exposure,* $\mathsf{StreamReindexing}^{\uparrow}$ *finite-window replay,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback,* $\mathsf{Real}^{\uparrow}$ *sealing, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Every accepted read of the packet factors through

$$\mathsf{StreamName}^{\uparrow},\quad \mathsf{StreamReindexing}^{\uparrow},\quad \mathsf{RegularCauchyReindexing}^{\uparrow},\quad \mathsf{CauchyReindexing}^{\uparrow},\quad \mathsf{DyadicRatCore}^{\uparrow},\quad \mathsf{RegSe}$$

before the local NameCert *row is public. No accepted read exports quotient streams, a selected representative, countable choice, host equality, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8540.1. Its analytic rows are the two stream schedules S, T, the cofinal reindexing route I, the modulus row U, the dyadic tolerance ledger D, the finite-window replay W, the regular readback R, and the Real seal E.

The target schedule is read through the reindexing rows before the modulus is available. Thus U can only assign bounds along the displayed cofinal route, and the tolerance ledger D is consumed as finite $\mathsf{DyadicRatCore}^{\uparrow}$ data.

Next the $\mathsf{StreamReindexing}^{\uparrow}$ row W replays the finite windows and the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies the regular rational readback. The terminal $\mathsf{Real}^{\uparrow}$ seal E is therefore downstream of the same cofinal-modulus route.

Finally H, C, P, N transport, replay, source, and name the displayed packet. Since no row stores quotient equality, representatives, choice, host equality, trichotomy, or completeness, the listed rows exhaust the local NameCert obligation surface. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ read exposes source and target StreamName schedules, a regular cofinal route, a modulus row, DyadicRatCore tolerance, StreamReindexing finite windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local NameCert before the Real seal is consumed.

Independence witness: stream-reindexing, regular-cauchy-reindexing, cauchy-reindexing, dyadicratcore, regseqrat, real: $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a source schedule, target schedule, cofinal route, modulus row, tolerance ledger, finite-window replay, regular rational readback, Real seal, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyReindexingModulus}^{\uparrow}}$ **·**

Constructive story: A $\mathsf{RegularCauchyReindexingModulus}^{\uparrow}$ packet is generated from source and target StreamName schedules, a RegularCauchyReindexing cofinal route, a modulus row, DyadicRatCore tolerance, StreamReindexing finite-window replay, RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{RegularCauchyReindexingModulus}\uparrow}$, seed)

Scope closed: Definition 8540.1 and Definition 8540.2 seed the finite cofinal-modulus route over StreamReindexing, RegularCauchyReindexing, CauchyReindexing, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: FormalStatus(NameCert$_{\text{RegularCauchyReindexingModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient streams, selected representatives, countable choice, host equality, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cofinal-route exposure, modulus exactness, dyadic tolerance compatibility, finite-window replay, regular readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.RegularCauchyReindexingModulusUp.

Chapter 8541

A Concrete Naming Certificate for $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$

Following Marcinkiewicz and Stein on weak-to-strong interpolation, the $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$ packet records the finite endpoint data by which a sublinear or operator-facing request reads weak-type and strong-type rows before an interpolated $\mathsf{Real}^{\uparrow}$ norm-bound is exposed. It sits beside the analytic-strip interpolation route of chapter 5725 and the singular-integral kernel route of chapter 7928. The packet names only displayed endpoint rows, interpolation parameters, scalar ledgers, transport, replay, provenance, and local naming; it does not assert a host interpolation theorem, completed measure space, quotient function equality, selected distribution function, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8541.1 (Marcinkiewicz interpolation carrier)**.** *A* $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (W, S, T, \Theta, B, R, H, C, P, N)$$

with the following displayed rows:

1. *W is the weak-type endpoint row, carrying the source exponent, target threshold ledger, finite distribution-window data, and endpoint scalar bound inspected by the packet.*
2. *S is the strong-type endpoint row, carrying the second endpoint exponent, norm-window data, and endpoint scalar bound.*
3. *T is the operator or sublinear-action row shared by the endpoint data. It records the displayed action route only, not host equality of operators or functions.*
4. *Θ is the interpolation-parameter row, storing the inspected parameter, endpoint incidence, and convex-weight ledger used to combine W and S.*
5. *B is the interpolated* $\mathsf{Real}^{\uparrow}$ *norm-bound row. It is public only after W, S, T, Θ have all been displayed.*
6. *R is the scalar readback row for endpoint constants, threshold windows, exponent comparisons, and the interpolated bound.*
7. *H stores componentwise* hsame *transport for weak endpoint data, strong endpoint data, the operator row, interpolation parameter, scalar readback, bound row, replay, provenance, and local name.*
8. *C stores displayed* Cont *replay from an interpolation request through $W, S, T, \Theta, R, B, H, P, N$.*

9. *P is the* Pkg *provenance over* MarcinkiewiczInterpolation$^{\uparrow}$, RieszThorinInterpolation$^{\uparrow}$, CalderonZygmundOperator$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* NameCert$_{\text{MarcinkiewiczInterpolation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these displayed rows. It has no coordinate for a host distribution function, selected level set, quotient function representative, measure completion, countable choice, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8541.2 (Marcinkiewicz interpolation NameCert obligations)**.** *For every accepted* MarcinkiewiczInterpolat *carrier*

$$M = (W, S, T, \Theta, B, R, H, C, P, N),$$

the local NameCert$_{\text{MarcinkiewiczInterpolation}^{\uparrow}}$ *surface consists exactly of weak-type endpoint admission through W, strong-type endpoint admission through S, shared operator-action admission through T, interpolation-parameter admission through Θ, scalar readback through R, interpolated* Real$^{\uparrow}$ *norm-bound export through B, componentwise* hsame *transport through H, displayed* Cont *replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8541.1. The endpoint rows W and S are the only weak-type and strong-type coordinates available to the classifier, and the shared action row T is the only operator-facing coordinate.

The interpolation parameter is then forced by row order. The row Θ records the displayed endpoint incidence and convex-weight ledger, while R accounts for the scalar endpoint constants and threshold windows used by the bound row.

The bound row B is downstream of those endpoint, action, parameter, and scalar-readback rows. Finally H, C, P, N transport, replay, source, and name the same finite packet, so no excluded host distribution function, selected level set, quotient representative, measure completion, choice schedule, or ambient completeness object can appear as a local obligation. □

Theorem 8541.3 (Marcinkiewicz interpolation weak-strong window route)**.** *Every accepted interpolated-bound read for a* MarcinkiewiczInterpolation$^{\uparrow}$ *packet exposes the weak endpoint row W, strong endpoint row S, shared operator row T, interpolation parameter Θ, scalar readback row R, and terminal* Real$^{\uparrow}$ *bound row B before the interpolated estimate is visible. The route may cite the strip-interpolation sibling* RieszThorinInterpolation$^{\uparrow}$ *for endpoint comparison discipline and the singular-integral sibling* CalderonZygmundOperator$^{\uparrow}$ *for weak-type operator windows, but it exports only the displayed weak/strong window certificate.*

Proof. Start with the NameCert obligations of Definition 8541.2. They require the weak endpoint, strong endpoint, shared action, interpolation parameter, scalar readback, and bound rows to be displayed before a local name is available.

The RieszThorinInterpolation$^{\uparrow}$ sibling supplies the comparison pattern that keeps endpoint interpolation parameters explicit, while the CalderonZygmundOperator$^{\uparrow}$ sibling supplies a kernel-window example whose weak-type row can feed the endpoint surface. These are sibling routes, not imported host theorems.

The structural rows H, C, P, N preserve the same route. Since the carrier contains no coordinate for measure completion, selected distribution functions, quotient function equality, or ambient Real completeness, every interpolated-bound consumer remains inside the finite weak/strong window packet. □

Falsifiable prediction: Every accepted $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$ bound read is refuted if the weak endpoint row, strong endpoint row, shared operator row, interpolation parameter, scalar readback row, and terminal $\mathsf{Real}^{\uparrow}$ bound row are not all displayed in the same packet.

Independence witness: riesz-thorin-interpolation, calderon-zygmund-operator, real: none is bijective to $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$ because this packet jointly carries weak-type endpoint data, strong-type endpoint data, a shared operator-action row, an interpolation parameter, scalar readback, an interpolated Real bound, transport, replay, provenance, and local naming as one weak-to-strong interpolation certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{MarcinkiewiczInterpolation}^{\uparrow}}$.

Constructive story: A $\mathsf{MarcinkiewiczInterpolation}^{\uparrow}$ packet is generated from weak-type endpoint data, strong-type endpoint data, a shared operator-action row, an interpolation parameter, scalar readback rows, an interpolated RealUp norm-bound, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MarcinkiewiczInterpolation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8541.1, Definition 8541.2, and Definition 8541.3 seed the finite weak-to-strong interpolation carrier and its displayed endpoint-window route.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MarcinkiewiczInterpolation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host interpolation theorems, measure completion, quotient function equality, selected distribution functions, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked weak endpoint admission, strong endpoint admission, shared operator admission, interpolation-parameter admission, scalar readback, RealUp bound export, transport, replay, provenance, and local naming for BEDC.Derived.MarcinkiewiczInterpolationUp.

Chapter 8542

Finite Intersection Closed Intervals NameCert Construction

Following Bishop–Bridges constructive real analysis, the $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$ packet records the finite-intersection surface for located closed intervals inside the L10 Real and Completion route. It sits beside the Real carrier of chapter 38, the finite window source of chapter 126, the rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the located interval surface of chapter 394. The packet exposes a finite common-window witness for closed interval families; it is not open-cover compactness, arbitrary intersection compactness, trichotomy, a choice-selected point, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8542.1 (Finite intersection closed intervals carrier)**.** *A* $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (L, A, B, W, D, S, R, E, H, C, P, N)$$

with the following displayed rows:

1. *L is the located closed interval family row, listing finitely many interval names together with their located left and right endpoint rows.*
2. *A is the endpoint-compatibility row, recording the finite comparisons that make the listed intervals mutually admissible for a shared search window.*
3. *B is the bounded-window row, storing the finite common-window witness from which every interval row may be inspected.*
4. *W is the window-membership row, stating that each listed interval admits the same displayed window witness rather than a separately selected point.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare endpoint approximants inside the common window.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule used to request the finitely many precision windows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row from S into rational endpoint data.*
8. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the located endpoints and the finite common-window witness.*
9. *H records componentwise* hsame *transport for L, A, B, W, D, S, R, E and the structural rows.*
10. *C records displayed* Cont *replay from a finite-intersection request through $L, A, B, W, D, S, R, E, H, P, N$.*

11. *P is the* Pkg *provenance over* $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, A, B, W, D, S, R, E, H, C, P, N$. It contains no coordinate for open-cover compactness, arbitrary intersections, trichotomy, choice-selected points, quotient real equality, or ambient real completeness.

Theorem 8542.2 (Finite intersection closed intervals NameCert obligations)**.** *For every accepted* $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$ *carrier*

$$I = (L, A, B, W, D, S, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}}$ *surface consists exactly of located family admission through L, endpoint compatibility through A, common-window exposure through B, W, dyadic tolerance comparison through D, finite window scheduling through S, rational readback through R, Real sealing through E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8542.1. The accepted packet displays the located interval family, endpoint compatibility, common-window witness, tolerance ledger, window schedule, rational readback, Real seal, and structural rows as finite data.

The interval-facing obligations are exhausted by L, A, B, W, D, S, R, E. Endpoint compatibility is checked before the common window is read, and the dyadic, stream, regular-rational, and Real rows keep every precision request inside that finite window.

The structural obligations are exhausted by H, C, P, N. Transport, replay, provenance, and local naming preserve the same packet and do not introduce open-cover compactness, arbitrary intersection compactness, trichotomy, selected points, quotient equality, or ambient completeness. □

Theorem 8542.3 (Finite intersection closed intervals common-window handoff)**.** *Let $I = (L, A, B, W, D, S, R, E, H$ be an accepted* $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$ *carrier. Every nested-interval, compact-interval, or completion-facing consumer of I must receive the same common-window route*

$$L, A \longmapsto B, W \longmapsto D, S, R, E \longmapsto H, C, P, N.$$

Thus the consumer obtains a finite located closed-interval handoff, not open-cover compactness, arbitrary intersection compactness, trichotomy, a choice-selected point, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8542.2. They expose endpoint compatibility before any common-window witness can be read.

Use the displayed common-window rows B, W. A downstream consumer receives one finite window route for the listed interval family, so it cannot replace the witness by a selected point or an arbitrary intersection principle.

Finally read D, S, R, E, H, C, P, N as the precision and structural handoff. The dyadic tolerance, StreamName schedule, RegSeqRat readback, and Real seal remain attached to the same finite packet, while transport, replay, provenance, and local naming add no ambient compactness or completeness endpoint. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}$ packet is generated from located closed interval family rows, endpoint compatibility rows, a finite common-window witness, DyadicRatCore tolerance rows, StreamName windows, RegSeqRat readback, a Real seal, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8542.1, Definition 8542.2, and Definition 8542.3 seed the finite located closed-interval intersection route for L10 Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteIntersectionClosedIntervals}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim open-cover compactness, arbitrary intersection compactness, trichotomy, choice-selected points, quotient real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint compatibility, common-window handoff, dyadic tolerance, finite window scheduling, rational readback, Real sealing, structural replay, provenance, and local naming for the finite intersection closed intervals packet.

Chapter 8543

A Concrete Naming Certificate for $\mathsf{RiemannLocalization}^{\uparrow}$

Following Riemann on localization for trigonometric series, the $\mathsf{RiemannLocalization}^{\uparrow}$ packet records the finite BEDC naming surface for a local Fourier read. It sits after the Fourier data of chapter 124, the Dirichlet and Riemann kernel windows of chapter 2311, the finite observation rows of chapter 126, the regular rational readback of chapter 301, and the terminal Real-facing seal of chapter 38. The packet names a local kernel-window certificate; it does not claim global Fourier convergence, a host function, quotient real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8543.1 (Riemann localization carrier)**.** *A* $\mathsf{RiemannLocalization}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, K, W, T, R, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{Fourier}^{\uparrow}$ *data row naming the finite coefficient and partial-sum observations available to the local read.*
2. *K is the Dirichlet/Riemann kernel-window row, containing the displayed neighborhood, kernel truncation, and oscillation window around the inspected point.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window family for coefficient, point-neighborhood, and kernel-tail requests.*
4. *T is the tail-localization budget, recording the finite bound that separates the displayed neighborhood contribution from the refused exterior tail.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *and* $\mathsf{Real}^{\uparrow}$ *readback row handed to Real-facing consumers after the local kernel window is displayed.*
6. *H records componentwise* hsame *transport for Fourier data, kernel windows, stream windows, tail budgets, readback, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from Fourier inspection through kernel-window localization, tail-budget refusal, regular readback, and Real-facing handoff.*
8. *P is the* Pkg *provenance over* $\mathsf{RiemannLocalization}^{\uparrow}$, $\mathsf{Fourier}^{\uparrow}$, $\mathsf{DirichletKernel}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{RiemannLocalization}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $F, K, W, T, R, H, C, P, N$. It has no coordinate for a host function, unrestricted Fourier convergence theorem, quotient real equality, countable choice, or ambient Real completeness.

Theorem 8543.2 (Riemann localization NameCert obligations)**.** *For every accepted* $\mathsf{RiemannLocalization}^{\uparrow}$ *carrier $L = (F, K, W, T, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RiemannLocalization}^{\uparrow}}$ *surface consists exactly of carrier admission, local-kernel window exposure, tail refusal, componentwise transport, displayed replay, provenance, and ledger nonescape. Carrier admission displays the Fourier data row F, kernel-window row K, StreamName window family W, tail-localization budget T, regular rational and Real readback row R, transport row H, replay row C, provenance row P, and local naming row N. Local-kernel exposure requires the displayed neighborhood and kernel-tail budget before a public read is formed. Tail refusal records that exterior Fourier behavior remains outside the packet. Transport, replay, provenance, and ledger nonescape keep the read on the same finite carrier surface and refuse global Fourier convergence, host functions, quotient real equality, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8543.1. Its rows display exactly the Fourier observations, kernel-window data, stream windows, tail budget, regular readback, transport, replay, provenance, and local naming available to the packet.

The local-kernel obligation is the row K read together with W and T. A consumer first names the displayed neighborhood and kernel-tail budget, then forms the regular rational and Real-facing readback through R.

The remaining rows preserve that route. Componentwise transport H, replay C, provenance P, and naming N keep the packet inside the displayed BHist ledger, while the absence of coordinates for host functions, global convergence, quotient real equality, choice, or ambient completeness supplies the stated nonescape. □

Theorem 8543.3 (Riemann localization local-kernel window)**.** *Every public read from an accepted* $\mathsf{RiemannLocalization}^{\uparrow}$ *carrier*

$$L = (F, K, W, T, R, H, C, P, N)$$

depends only on the displayed neighborhood in K, the kernel-tail budget T, the finite StreamName windows W, the Fourier observations in F, the readback row R, and the structural rows H, C, P, N. If a consumer asks for global Fourier convergence, a host function value, quotient equality of Real names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness, the request is outside the* $\mathsf{RiemannLocalization}^{\uparrow}$ *packet.*

Proof. Read the accepted carrier. The only analytic coordinates are F, K, W, T, R, so the local read has no access to an exterior Fourier tail except through the displayed budget T.

Use the NameCert obligations of Definition 8543.2. They require every public read to pass through the local-kernel window, tail refusal, transport, replay, provenance, and local naming rows before it reaches a Real-facing consumer.

Thus the public value is a finite kernel-window readback, not a global convergence theorem or a host-side function evaluation. Since quotient real equality, countable choice, and ambient completeness are not carrier coordinates, they cannot be exported by the local-kernel window. □

Falsifiable prediction: A $\mathsf{RiemannLocalization}^{\uparrow}$ consumer that exports a local Fourier read without displaying Fourier data, a kernel-window neighborhood, StreamName windows, a tail-localization budget, RegSeqRat/Real readback, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: fourier, dirichlet-kernel, streamname, regseqrat, real: no listed sibling by itself carries Fourier observations, a Dirichlet/Riemann kernel window, finite stream windows, tail-localization refusal, regular rational and Real readback, transport, replay, provenance, and local NameCert data while refusing global Fourier convergence and host-function semantics.

Closure status for $\mathsf{NameCert}_{\mathsf{RiemannLocalization}\uparrow}$.

Constructive story: A $\mathsf{RiemannLocalization}^{\uparrow}$ packet is generated from Fourier data, a Dirichlet/Riemann kernel-window row, finite StreamName windows, a tail-localization budget, RegSeqRat and Real readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RiemannLocalization}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8543.1, Definition 8543.2, and Definition 8543.3 seed the local Fourier localization packet over displayed kernel windows, tail budgets, finite StreamName rows, RegSeqRat and Real readback, transport, replay, provenance, and local NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RiemannLocalization}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close global Fourier convergence, host function semantics, quotient real equality, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, local-kernel window exactness, tail-refusal determinacy, readback stability, transport stability, replay stability, provenance exposure, and ledger nonescape for BEDC.Derived.RiemannLocalizati

Chapter 8544

A Concrete Naming Certificate for $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$

Following Bishop–Bridges constructive analysis, the $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ packet records the finite interval estimate that reads endpoint values, dyadic finite-difference slopes, and a displayed derivative or mean-value route before a Real-facing consumer may use a slope bound. It sits after the terminal real-name surface of chapter 38, the dyadic arithmetic core of chapter 291, the regular rational readback rows of chapter 301, the finite-difference surface of chapter 5135, the derivative boundary of chapter 122, and the theorem-facing route of chapter 1912. The packet names a finite slope-bound carrier over one displayed interval; it is not host division in a completed field, not a selected interior derivative point, not quotient real equality, not trichotomy, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8544.1 (Bishop interval slope-bound carrier)**.** *A* $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (A_0, A_1, V_0, V_1, W, D, Q, M, K, H, C, P, N)$$

with the following displayed rows:

1. A_0, A_1 *are the* $\mathsf{Real}^{\uparrow}$ *endpoint-name rows for the interval endpoints.*
2. V_0, V_1 *are the* $\mathsf{Real}^{\uparrow}$ *endpoint-value rows for the inspected map at* A_0 *and* A_1*.*
3. W *is the finite* $\mathsf{StreamName}^{\uparrow}$ *endpoint-window row listing the rational endpoint approximants, interval-width requests, and value-window requests read by the estimate.*
4. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *finite-difference slope ledger. It records the displayed numerator budget, nonzero interval-width witness, denominator-window comparison, and dyadic upper-bound certificate for the slope request.*
5. Q *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row that turns the dyadic slope ledger into regular rational endpoint and slope observations.*
6. M *is the derivative or mean-value handoff row. It points to the* $\mathsf{Derivative}^{\uparrow}$, $\mathsf{DifferenceQuotient}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, *or* $\mathsf{MeanValueTheorem}^{\uparrow}$ *packet that justifies reading the displayed finite slope as theorem-facing data.*
7. K *is the classifier row. It compares two accepted packets only through the endpoint rows, endpoint-value rows, finite window, dyadic ledger, regular readback, handoff row, and structural rows.*

8. *H records componentwise* hsame *transport for endpoint names, endpoint values, slope windows, dyadic ledgers, regular readbacks, handoff rows, classifier rows, replay, provenance, and local naming.*
9. *C records displayed* Cont *replay for the same finite slope-bound route.*
10. *P is the* Pkg *provenance over* $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DifferenceQuotient}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{MeanValueTheorem}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopIntervalSlopeBound}^{\uparrow}}$ *row.*

The classifier has no coordinate for host real division, equality of ambient functions, a selected interior derivative point, trichotomy of endpoints, a quotient of real names, or an ambient completeness principle.

Theorem 8544.2 (Bishop interval slope-bound NameCert obligations)**.** *For every accepted* BishopIntervalSlopeBou *carrier*

$$B = (A_0, A_1, V_0, V_1, W, D, Q, M, K, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BishopIntervalSlopeBound}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *endpoint admission for A_0, A_1, V_0, V_1 through the* $\mathsf{Real}^{\uparrow}$ *boundary;*
2. *finite slope-ledger admission for W, D, Q, including the dyadic finite-difference numerator, nonzero interval-width witness, denominator-window comparison, and regular rational readback;*
3. *theorem-facing handoff through M, using only the displayed* $\mathsf{DifferenceQuotient}^{\uparrow}$, $\mathsf{FiniteDifference}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, *or* $\mathsf{MeanValueTheorem}^{\uparrow}$ *route;*
4. *classifier and stability transport through K, H, C over the same finite rows;*
5. *provenance and local naming through P, N.*

Every Real-facing or calculus-facing consumer of the slope bound must expose these rows before it may read the bound. The packet exports no host real division, selected interior point, quotient real equality, endpoint trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8544.1. The endpoint rows A_0, A_1, V_0, V_1 are the only real-name data visible to the packet, and the finite window W is the only place where endpoint approximants, interval-width requests, and value-window requests are listed.

Read the dyadic and regular rows next. The ledger D records the finite-difference numerator, the displayed nonzero interval-width witness, the denominator-window comparison, and the dyadic upper-bound certificate. The row Q reads this ledger back as regular rational endpoint and slope observations, so no host division in a completed field is introduced.

Now use the handoff row M. It can cite only the already displayed difference-quotient, finite-difference, derivative, or mean-value packet, so a theorem-facing consumer receives a finite slope-bound route rather than a selected interior derivative point or an ambient mean-value theorem.

Finally transport and name the packet through K, H, C, P, N. These rows compare, replay, source, and certify the same endpoint, window, dyadic, regular, and handoff data. Since the excluded objects are not carrier coordinates, the five obligation rows exhaust the local NameCert surface. □

Theorem 8544.3 (Bishop interval slope-bound classifier transport)**.** *Let B and B' be accepted* $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ *packets whose endpoint rows, endpoint-value rows, finite windows, dyadic*

slope ledgers, regular readback rows, and handoff rows are related by the displayed classifier rows. Then every accepted slope-bound read from B transports to a slope-bound read from B' through the same finite route

$$\mathsf{Real}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{DifferenceQuotient}^{\uparrow}, \mathsf{FiniteDifference}^{\uparrow}, \mathsf{Derivative}^{\uparrow}, \mathsf{Me}$$

The transported read does not add host real division, quotient equality of real names, a selected derivative point, endpoint trichotomy, or ambient completeness.

Proof. Use the classifier row K from Definition 8544.1. Its comparison fields mention only endpoint names, endpoint values, finite windows, dyadic ledgers, regular readbacks, handoff rows, and structural rows.

Apply the NameCert obligations of Definition 8544.2. The slope-bound read is available only after the endpoint, ledger, handoff, transport, provenance, and local naming rows have been exposed.

The componentwise transport row H and replay row C preserve that order. The provenance and local-name rows P, N certify the transported packet without adding any refused coordinate, so the transported read remains the same finite slope-bound route. □

Theorem 8544.4 (Bishop interval slope-bound mean-value handoff)**.** *Every theorem-facing read of an accepted* $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ *packet that cites a mean-value or derivative route must first pass through the dyadic finite-difference ledger and regular rational readback rows. In symbols, the handoff row M is readable only after W, D, Q have exposed the finite endpoint-window, slope-ledger, and readback data. Thus the packet uses chapter 1912 and the derivative chapters as downstream handoffs, not as hidden sources of host-level division or selected interior points.*

Proof. Start with the carrier and obligation surface. The rows W, D, Q are listed before M, and Definition 8544.2 makes the finite slope-ledger admission a separate obligation from the theorem-facing handoff.

The mean-value and derivative chapters can therefore inspect only the displayed endpoint, dyadic, and regular rational rows. They cannot replace the finite ledger with a completed real quotient or a selected interior witness, because neither object is present in the carrier.

The structural rows preserve this dependency order under transport and replay. Hence every theorem-facing handoff remains downstream of the finite dyadic slope ledger. □

Falsifiable prediction: Every accepted $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ slope-bound read factors through displayed endpoint Real rows, a finite endpoint-window row, a DyadicRatCore finite-difference slope ledger, RegSeqRat readback, a derivative or mean-value handoff row, classifier transport, displayed replay, package provenance, and local NameCert evidence.

Independence witness: real, dyadicratcore, regseqrat, finite-difference, derivative, mean-value-theorem: $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds interval endpoints, endpoint values, finite windows, dyadic slope budgets, regular readback, theorem-facing handoff, classifier transport, replay, provenance, and local naming in one finite slope-bound certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{BishopIntervalSlopeBound}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BishopIntervalSlopeBound}^{\uparrow}$ packet is generated from displayed interval endpoint names, endpoint-value rows, finite endpoint windows, a dyadic finite-difference slope ledger, regular rational readback, a derivative or mean-value handoff row, classifier transport, displayed continuation replay, package provenance, and local NameCert evidence.

Theory closure: TheoryGate(NameCert$_{\mathsf{BishopIntervalSlopeBound}\uparrow}$, seed)

Scope closed: Definition 8544.1, Definition 8544.2, Definition 8544.3, and Definition 8544.4 seed the finite interval slope-bound carrier, its five-row obligation surface, classifier transport, and theorem-facing handoff discipline.

Formal verification: FormalStatus(NameCert$_{\mathsf{BishopIntervalSlopeBound}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host real division, quotient real equality, endpoint trichotomy, a selected interior derivative point, a host mean-value theorem, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, dyadic slope-ledger admission, regular read-back, theorem-facing handoff, classifier transport, replay, provenance, and local naming for BEDC.Derived.BishopIntervalSlopeBoundUp.

Chapter 8545

A Concrete Naming Certificate for $\mathsf{StepFunctionApproximation}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Rudin's classical step-function approximations, the $\mathsf{StepFunctionApproximation}^{\uparrow}$ packet records a finite interval-partition approximation surface for Real-facing regular-rational routes. It sits beside the dyadic endpoint ledger of chapter 291, the finite window naming discipline of chapter 126, the regular rational readback of chapter 301, and the terminal Real seal of chapter 38. The packet names only displayed partitions, rational values, endpoint ledgers, readback windows, transport, replay, provenance, and local naming; it is not host function equality, arbitrary partition choice, quotient real equality, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8545.1 (Step-function approximation carrier)**.** *A* $\mathsf{StepFunctionApproximation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (I, V, D, W, Q, R, H, C, P, N)$$

with the following displayed rows:

1. *I is the finite interval partition row, listing adjacent bounded intervals by displayed endpoint names.*
2. *V is the rational value row assigning one rational value token to each interval cell of I.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint ledger, recording every endpoint, tolerance cell, and comparison budget used by the partition.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row that records which finite name windows are inspected before a cell value may be read.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row, exposing the regular rational route through the finite windows and dyadic endpoint ledger.*
6. *R is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the partition, rational values, endpoint ledger, windows, and regular readback have all been displayed.*
7. *H records componentwise* hsame *transport for $I, V, D, W, Q, R, C, P, N$.*
8. *C records displayed* Cont *replay through partition selection, endpoint inspection, window readback, regular rational comparison, and Real sealing.*
9. *P is the* Pkg *provenance over* $\mathsf{StepFunctionApproximation}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{StepFunctionApproximation}^{\uparrow}}$ *row naming the displayed approximation packet. The carrier has no coordinate for host-level function equality, arbitrary choice of partitions, quotient equality of reals, measure integration, or ambient completeness of* $\mathsf{Real}^{\uparrow}$.

Theorem 8545.2 (Step-function approximation NameCert obligations)**.** *For every accepted* StepFunctionApproxim *carrier $A = (I, V, D, W, Q, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{StepFunctionApproximation}^{\uparrow}}$ *surface consists exactly of finite partition admission through I, rational value admission through V, dyadic endpoint and tolerance exposure through D, finite StreamName window exposure through W, RegSeqRat readback through Q, Real sealing through R, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

No local obligation is stored outside those rows, and no accepted read can add host function equality, partition choice, quotient real equality, measure integration, or ambient Real completeness.

Proof. Project the carrier of Definition 8545.1. The rows I, V, D, W, Q, R expose the analytic data: a finite interval partition, one rational value per cell, dyadic endpoints and tolerances, finite StreamName windows, regular rational readback, and the terminal Real seal.

The structural rows then keep that data local. Componentwise hsame transport, displayed Cont replay, Pkg provenance, and the local NameCert row preserve the same finite packet without adding a host function or a quotient real.

Since the carrier lists every available coordinate, the named rows exhaust the local obligation surface. Requests for arbitrary partition choice, measure integration, or ambient $\mathsf{Real}^{\uparrow}$ completeness are refused before the packet can be exported to a Real-facing consumer. □

Theorem 8545.3 (Step-function approximation RegSeqRat handoff)**.** *Every accepted* $\mathsf{StepFunctionApproximation}^{\uparrow}$ *read that reaches a Real-facing consumer factors through*

$$\mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{StreamName}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow}.$$

The handoff exposes only the displayed interval partition, rational value rows, dyadic endpoint ledger, StreamName windows, RegSeqRat readback, Real seal, componentwise transport, replay, provenance, and local NameCert row.

Proof. Start with the partition and endpoint rows. The finite partition I can be read only together with the dyadic endpoint ledger D, so each cell boundary is carried by displayed rational and tolerance data.

Next read the StreamName and RegSeqRat rows. The window row W records the finite observation surface, and the readback row Q turns that surface into a regular rational route without invoking a host function or an unbounded choice of partitions.

Finally the Real seal R is available only downstream of I, V, D, W, Q. The transport, replay, provenance, and local naming rows preserve that same route, so any Real-facing handoff factors through the named finite surface and refuses quotient equality, measure integration, and ambient completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{StepFunctionApproximation}^{\uparrow}}$.

Constructive story: A $\mathsf{StepFunctionApproximation}^{\uparrow}$ packet is generated from a finite interval partition, rational value rows, a DyadicRatCore endpoint ledger, StreamName windows, RegSeqRat readback, a Real seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{StepFunctionApproximation}^{\uparrow}}$, seed)

Scope closed: Definition 8545.1, Definition 8545.2, and Definition 8545.3 seed the finite step-function approximation route over interval partitions, rational values, dyadic endpoints, StreamName windows, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\mathsf{StepFunctionApproximation}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host function equality, arbitrary choice of partitions, quotient real equality, measure integration, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked partition admission, rational value rows, dyadic endpoint exactness, StreamName window exposure, RegSeqRat readback, Real sealing, transport, replay, provenance, and local naming for BEDC.Derived.StepFunctionApproximationUp.

Chapter 8546

A Concrete Naming Certificate for HyperbolicSectorEnvelope$^{\uparrow}$

The HyperbolicSectorEnvelope$^{\uparrow}$ packet realizes the boundary-sector branch of chapter 9463 as finite NameCert data. It sits after the Poincare disk metric of chapter 6209, the hyperbolic metric row of chapter 3474, the visual boundary of chapter 4181, the Busemann projection of chapter 7552, and the observer-expansion packet of chapter 4167. The carrier names only finite sector endpoints, visual radius, observer window, boundary-shadow handoff, refusal, transport, replay, provenance, and local naming.

Definition 8546.1 (Hyperbolic sector-envelope carrier)**.** *A* HyperbolicSectorEnvelope$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (S_0, S_1, R, O, B, V, F, T, H, C, P, N)$$

with the following displayed rows:

1. *S_0 and S_1 are the two finite boundary-sector endpoint rows.*
2. *R is the visual-radius row delimiting the sector envelope seen by the observer.*
3. *O is the observer-window row naming the finite focus through which the sector is read.*
4. *B is the boundary-shadow handoff row tying the endpoints and visual radius to a displayed boundary-shadow surface.*
5. *V is the visual-boundary readback row reached only after S_0, S_1, R, O, B have been displayed.*
6. *F is the refusal row excluding hidden hyperbolic metric data, a completed visual boundary, Busemann projection as a host map, and selected geodesic sectors.*
7. *T is the TasteGate row requiring* Nontrivial HyperbolicSectorEnvelope$^{\uparrow}$ *and* FieldFaithful HyperbolicSectorEnvelope *instances for the displayed row inventory.*
8. *H records componentwise* hsame *transport for $S_0, S_1, R, O, B, V, F, T, C, P, N$.*
9. *C records displayed* Cont *replay through sector endpoints, visual radius, observer window, boundary shadow, visual-boundary readback, refusal, and naming.*
10. *P is the* Pkg *provenance over* HyperbolicSectorEnvelope$^{\uparrow}$, PoincareDiskMetric$^{\uparrow}$, HyperbolicMetric$^{\uparrow}$, HyperbolicVisualBoundary$^{\uparrow}$, HyperbolicBoundaryShadow$^{\uparrow}$, BusemannProjection$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for host hyperbolic metric equality, completed boundary sectors, selected geodesic representatives, ambient visual compactification, or a global Busemann projection map.

Theorem 8546.2 (Hyperbolic sector-envelope NameCert obligations)**.** *For every accepted* HyperbolicSectorEnvelop *carrier $E = (S_0, S_1, R, O, B, V, F, T, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorEnvelope}^{\uparrow}}$ *surface consists exactly of endpoint admission through S_0, S_1, visual-radius admission through R, observer-window admission through O, boundary-shadow handoff through B, visual-boundary readback through V, refusal through F, TasteGate nontriviality and field-faithfulness requests through T, componentwise* hsame *transport through H, displayed* Cont *replay through C, package provenance through P, and local naming through N.*

No accepted read may expose a boundary-sector handoff without displaying the visual-radius row, observer-window row, provenance row, and refusal row.

Proof. Project the carrier of Definition 8546.1. The endpoint rows, visual-radius row, and observer-window row are the only coordinates from which a sector envelope can be read.

The boundary-shadow and visual-boundary rows are downstream of those data. Thus a consumer cannot obtain a boundary-sector handoff until S_0, S_1, R, O, B, V have all been displayed.

Finally the refusal, TasteGate, transport, replay, provenance, and local naming rows close the certificate surface. Since the carrier contains no host metric equality, completed boundary sector, selected geodesic representative, ambient compactification, or global Busemann map, the listed obligations exhaust the accepted read. □

Theorem 8546.3 (Hyperbolic sector-envelope observer handoff)**.** *Every accepted* $\mathsf{HyperbolicSectorEnvelope}^{\uparrow}$ *observer read factors through*

$$\mathsf{PoincareDiskMetric}^{\uparrow}, \mathsf{HyperbolicMetric}^{\uparrow} \longrightarrow \mathsf{HyperbolicBoundaryShadow}^{\uparrow} \longrightarrow \mathsf{HyperbolicVisualBoundary}^{\uparrow} \longrightarrow \mathsf{Busem}$$

The handoff exposes only finite boundary-sector endpoints, visual radius, observer window, boundary-shadow readback, visual-boundary readback, refusal, TasteGate rows, componentwise transport, replay, provenance, and local NameCert data.

Proof. Begin with the displayed sector endpoints and visual radius. They delimit the finite sector envelope as observed data, not as a completed hyperbolic boundary subset.

Next use the boundary-shadow and visual-boundary rows. These rows route the sector envelope through the Poincare disk and hyperbolic metric surfaces while keeping the observer window visible.

The Busemann projection dependency is then read only as provenance-facing handoff data. Refusal and transport preserve the same finite packet, so the observer read cannot become a host metric theorem, selected geodesic sector, global visual compactification, or ambient Busemann map. □

Falsifiable prediction: An accepted sector-envelope read cannot expose a boundary-sector handoff without displaying the visual-radius row, observer-window row, provenance row, and refusal row.

Independence witness: hyperbolicmetric, poincare-disk-metric, hyperbolic-visual-boundary, busemann-projection, real: the sector-envelope carrier jointly binds sector endpoints, visual radius, observer window, provenance, and refusal rows absent from each listed sibling.

The Lean-side TasteGate surface for this carrier is expected to include explicit Nontrivial HyperbolicSectorEnvelop and FieldFaithful HyperbolicSectorEnvelope$^{\uparrow}$ instances. Field faithfulness keeps $S_0, S_1, R, O, B, V, F, T, H, C, P, N$ as distinct rows before a classifier target may accept the packet.

Closure status for NameCert$_{\text{HyperbolicSectorEnvelope}^{\uparrow}}$ **.**

Constructive story: A HyperbolicSectorEnvelope$^{\uparrow}$ packet is generated from boundary-sector endpoints, visual radius, observer window, boundary-shadow handoff, visual-boundary readback, refusal, TasteGate requests, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate(NameCert$_{\text{HyperbolicSectorEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 8546.1, Definition 8546.2, and Definition 8546.3 seed the finite observer-expansion sector-envelope route over endpoints, visual radius, observer window, boundary-shadow handoff, visual-boundary readback, refusal, TasteGate rows, transport, replay, provenance, and local naming.

Formal verification: FormalStatus(NameCert$_{\text{HyperbolicSectorEnvelope}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host hyperbolic metric equality, completed boundary sectors, selected geodesic representatives, ambient visual compactification, global Busemann projection, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked endpoint admission, visual-radius admission, observer-window admission, boundary-shadow handoff, visual-boundary readback, refusal, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicSectorEnvelopeUp.

Chapter 8547

A Concrete Naming Certificate for $\mathsf{RegularOpenSet}^{\uparrow}$

Kelley/Munkres-style grounding: a regular open set is read as an open set recovered from the interior of its closure, with its complement read through the regular closed comparison surface. The $\mathsf{RegularOpenSet}^{\uparrow}$ packet records that topology-facing object as finite BEDC data over the topology carrier of chapter 88, the closed-set boundary packet of chapter 4229, the regular-closed sibling of chapter 8221, and the metric boundary route of chapter 57. It names the displayed open-neighborhood, closure, interior, complement, transport, replay, provenance, and local certificate rows; it does not import a host powerset, detached open-set lattice, quotient equality, selected point, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8547.1 (RegularOpenSet carrier)**.** *A* $\mathsf{RegularOpenSet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (T, C, R, M, O, K, I, E, D, H, Q, P, N)$$

with the following displayed rows:

1. *T is the ambient* $\mathsf{Topology}^{\uparrow}$ *row naming the finite open-neighborhood and closure observations available to the packet.*
2. *C is the* $\mathsf{ClosedSet}^{\uparrow}$ *boundary row used when the complement or boundary of the open set is inspected.*
3. *R is the* $\mathsf{RegularClosedSet}^{\uparrow}$ *complement row, recording that the complement side is read by the regular-closed sibling surface.*
4. *M is the* $\mathsf{Met}^{\uparrow}$ *row used when closure or boundary requests are consumed through ball and distance data.*
5. *O is the open-neighborhood classifier for the named open part.*
6. *K is the closure row reached from O through T and, when needed, through the metric row M.*
7. *I is the interior-of-closure row, recording the return from K to an open row in the same topology.*
8. *E is the exactness row certifying that the displayed open row O is recovered as I.*
9. *D is the complement-compatibility row tying the outside of O to the* $\mathsf{ClosedSet}^{\uparrow}$ *boundary row C and the* $\mathsf{RegularClosedSet}^{\uparrow}$ *row R.*
10. *H records componentwise* hsame *transport for $T, C, R, M, O, K, I, E, D, Q, P, N$.*

11. *Q records displayed* Cont *replay for the route $O \to K \to I \to E$ and for the complement route through C, R, D.*
12. *P is the* Pkg *provenance over* $\mathsf{RegularOpenSet}^{\uparrow}$, $\mathsf{Topology}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{RegularClosedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularOpenSet}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $T, C, R, M, O, K, I, E, D, H, Q, P, N$. It has no coordinate for host powersets, detached open-set lattices, selected limit points, quotient equality of open names, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8547.2 (RegularOpenSet NameCert obligations)**.** *For every accepted* $\mathsf{RegularOpenSet}^{\uparrow}$ *carrier*

$$U = (T, C, R, M, O, K, I, E, D, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularOpenSet}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, topology exposure through T, closure-interior stability along $O \to K \to I \to E$, complement compatibility through C, R, D, metric boundary access through M, componentwise* hsame *transport through H, displayed* Cont *replay through Q,* Pkg *provenance through P, and local naming through N. The certificate refuses host powersets, detached open-set lattices, quotient equality, selected points, countable choice, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Carrier admission is projection from Definition 8547.1. The tuple displays the topology, closed-set, regular-closed, metric, open-neighborhood, closure, interior, exactness, complement, transport, replay, provenance, and local naming rows.

Topology exposure is forced by T and O. A consumer cannot read the named open part before the finite open-neighborhood observations in T have been exposed, and any closure request must pass through the same topology row before reaching K.

Closure-interior stability is the route $O \to K \to I \to E$. The exactness row E records that the interior of the displayed closure returns to the displayed open row, so the packet exports regular openness as a finite certificate row rather than as equality in a host powerset.

Complement compatibility is supplied by C, R, D. The complement side is read through the closed-set boundary row and regular-closed sibling row before it is matched with the open side, which blocks a detached open-set lattice or independent closed-set quotient from entering the certificate.

Finally, H, Q, P, N preserve, replay, source, and name the same finite route. Since no carrier coordinate stores selected points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, quotient equality, or a host powerset, those principles cannot be extracted from the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.RegularOpenSetUp.RegularOpenSetTasteGate single carrier alignment`

Closure status for $\mathsf{NameCert}_{\mathsf{RegularOpenSet}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularOpenSet}^{\uparrow}$ packet is generated from ambient TopologyUp observations, ClosedSetUp boundary data, RegularClosedSetUp complement data, MetricUp boundary reads, an open-neighborhood classifier, closure and interior rows, exactness, complement compatibility, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularOpenSet}^{\uparrow}}$, seed)

Scope closed: Definition 8547.1 and Definition 8547.2 seed the regular-open carrier and local NameCert obligation surface over $\mathsf{Topology}^{\uparrow}$, $\mathsf{ClosedSet}^{\uparrow}$, $\mathsf{RegularClosedSet}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, Pkg, and NameCert.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularOpenSet}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host powersets, detached open-set lattices, quotient equality, selected points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or any complete lattice theorem for regular open sets.

Upgrade path: Formal closure requires a Lean carrier and obligation package for the same topology, closed-boundary, regular-closed complement, metric, closure-interior, complement-compatibility, transport, replay, provenance, and local naming rows.

Chapter 8548

A Concrete Naming Certificate for GronwallFiniteOde$^{\uparrow}$

Following Gronwall and Bishop–Bridges constructive analysis, the GronwallFiniteOde$^{\uparrow}$ packet records the finite dyadic surface by which a displayed ordinary-differential-equation row is bounded before any Real-facing consumer reads an estimate. It sits after the ODE source of chapter 193, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the dyadic arithmetic ledger of chapter 291, the Gronwall envelope of chapter 2034, and the ODE comparison route of chapter 8036. The packet names a finite constructive bound surface; it is not host existence, a selected solution curve, quotient path equality, countable choice, or ambient completeness.

Definition 8548.1 (Gronwall finite ODE carrier)**.** *A* GronwallFiniteOde$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (M, T, L, E, R, D, B, H, C, P, N)$$

with the following rows.

1. *M is the finite mesh row, displaying the inspected time nodes and successor windows.*
2. *T is the time-window row that bounds the interval on which the displayed ODE source is read.*
3. *L is the Lipschitz row, exposing the dyadic local constant and the source window in which it is valid.*
4. *E is the Euler or Picard comparison row that records the finite stepwise approximation route.*
5. *R is the* RegSeqRat$^{\uparrow}$ *readback row for the rational approximation and error sequence.*
6. *D is the* DyadicRatCore$^{\uparrow}$ *ledger carrying every tolerance, mesh width, Lipschitz coefficient, and accumulated error bound.*
7. *B is the bound row. It displays the Gronwall majorant read by downstream ODE or Real consumers.*
8. *H records componentwise* hsame *transport for the mesh, time, Lipschitz, comparison, readback, dyadic, bound, replay, provenance, and local naming rows.*
9. *C records displayed* Cont *replay of the finite bound route.*
10. *P is the* Pkg *provenance over* GronwallFiniteOde$^{\uparrow}$*,* Ode$^{\uparrow}$*,* GronwallInequality$^{\uparrow}$*,* OdeComparison$^{\uparrow}$*,* RegSeqRat$^{\uparrow}$*,* DyadicRatCore$^{\uparrow}$*,* Real$^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{GronwallFiniteOde}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, T, L, E, R, D, B, H, C, P, N$. It has no coordinate for a host solution theorem, selected flow, quotient path equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8548.2 (Gronwall finite ODE NameCert obligations)**.** *For every accepted* $\mathsf{GronwallFiniteOde}^{\uparrow}$ *carrier $G = (M, T, L, E, R, D, B, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{GronwallFiniteOde}^{\uparrow}}$ *surface consists exactly of the following five rows:*

1. *carrier admission for the displayed tuple $M, T, L, E, R, D, B, H, C, P, N$;*
2. *mesh exposure, requiring every time step and successor window to be read through M and T;*
3. *bound stability, requiring the Lipschitz row L, comparison row E, dyadic ledger D, and bound row B to remain componentwise stable under* hsame *transport;*
4. *regular-Cauchy handoff, requiring every exported approximation and error bound to pass through R before any* $\mathsf{Real}^{\uparrow}$ *seal is read;*
5. *no-escape from host completeness, selected solution curves, quotient path equality, trichotomy, countable choice, or any estimate not already displayed in D and B.*

Proof. Project the carrier of Definition 8548.1. Carrier admission is exactly the displayed tuple $M, T, L, E, R, D, B, H, C, P, N$ and the local naming row N attached to it.

The mesh exposure row is forced by M and T. A consumer can inspect only the listed time nodes and their successor windows, so the route cannot appeal to a host interval theorem or an unbounded solution domain.

The bound-stability row then reads L, E, D, B, H. The Lipschitz data and the Euler or Picard comparison row determine which dyadic entries may be used, the ledger D records all tolerances and accumulated errors, the bound row B is the only majorant export, and H preserves these rows componentwise.

Finally the regular-Cauchy handoff uses R, while C and P replay and source the same finite route. Since no carrier coordinate names completeness, choice, selected solutions, quotient paths, or trichotomy, the five rows exhaust the local certificate. □

Theorem 8548.3 (Gronwall finite ODE dyadic bound surface)**.** *Every accepted* $\mathsf{GronwallFiniteOde}^{\uparrow}$ *packet exports an ODE estimate only through the dyadic bound row B after the mesh row M, time window T, Lipschitz row L, Euler or Picard comparison row E,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger D have been exposed. The packet exports no separate analytic estimate, selected solution curve, quotient equality of paths, countable-choice schedule, or ambient-completeness claim.*

Proof. Begin with an accepted carrier $G = (M, T, L, E, R, D, B, H, C, P, N)$. The only estimate-bearing coordinates are the comparison row E, dyadic ledger D, and bound row B.

Read the mesh and time rows first. They restrict the computation to the displayed finite windows, so an estimate consumer cannot widen the route by invoking a host ODE existence theorem.

Next read the Lipschitz and comparison rows. The row L supplies the local coefficient data, while E records the finite Euler or Picard comparison route whose accumulated error is written in D.

The exported bound is then exactly B, with R repacking the rational data before any $\mathsf{Real}^{\uparrow}$ consumer sees it. The structural rows H, C, P, N transport, replay, source, and name this same route, and no remaining coordinate can export another estimate surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{GronwallFiniteOde}^{\uparrow}}$.

Constructive story: A $\mathsf{GronwallFiniteOde}^{\uparrow}$ packet is generated from a finite mesh row, time-window row, Lipschitz row, Euler or Picard comparison row, RegSeqRat readback, DyadicRatCore ledger, dyadic bound row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{GronwallFiniteOde}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8548.1, Definition 8548.2, and Definition 8548.3 seed the finite dyadic ODE bound surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{GronwallFiniteOde}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host ODE existence, selected solution curves, quotient path equality, trichotomy, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Formalization requires a Lean carrier and checked NameCert obligations for the mesh, time-window, Lipschitz, comparison, readback, dyadic ledger, bound, transport, replay, provenance, and naming rows.

Chapter 8549

A Concrete Naming Certificate for ContinuousDependenceOde$^{\uparrow}$

Following Picard, Lindelof, Gronwall, and Coddington–Levinson, the ContinuousDependenceOde$^{\uparrow}$ packet records the constructive ODE stability route by which two nearby local flows are compared before a downstream Real-facing consumer reads the endpoint dependence. It sits beside the ODE source of chapter 193, the Picard–Lindelof route of chapter 1888, the Gronwall inequality surface of chapter 2034, the Lipschitz ledger of chapter 410, the complete-metric convergence boundary of chapter 128, and the sealed real-name row of chapter 38. The packet names a finite continuous-dependence carrier, not a global ODE solver, a selected solution curve, quotient equality of flows, or ambient Real$^{\uparrow}$ completeness.

Definition 8549.1 (Continuous dependence ODE carrier)**.** *A* ContinuousDependenceOde$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (I, J, F, G, L, M, R, E, H, C, P, N)$$

with the following visible rows:

1. *I and J are the two initial time-state cells whose nearby data are compared by the packet;*
2. *F and G are the two vector-field ledgers, each read through the displayed* LipschitzMap$^{\uparrow}$ *surface on the same local window;*
3. *L is the shared Lipschitz row that keeps the two local-flow routes inside the same comparison band;*
4. *M is the Picard–Lindelof handoff row, recording the displayed local-flow route consumed by the stability comparison;*
5. *R is the* GronwallInequality$^{\uparrow}$ *comparison row, bounding the difference envelope between the two local-flow routes;*
6. *E is the* CompleteMetric$^{\uparrow}$ *convergence row, reading the displayed Cauchy comparison only after the Gronwall route has been exposed;*
7. *H records componentwise* hsame *transport for the two initial cells, the two vector-field ledgers, the Lipschitz row, the Picard–Lindelof row, the Gronwall row, the complete-metric row, the replay row, the provenance row, and the local naming row;*
8. *C records displayed* Cont *replay of the same finite dependence route;*

9. *P is the* Pkg *provenance over* $\mathsf{ContinuousDependenceOde}^{\uparrow}$, $\mathsf{Ode}^{\uparrow}$, $\mathsf{PicardLindelof}^{\uparrow}$, $\mathsf{GronwallInequality}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{ContinuousDependenceOde}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host solution-space equality, a quotient of flows, a selected continuation, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8549.2 (Continuous dependence ODE NameCert obligations)**.** *For every accepted* $\mathsf{ContinuousDependenceOde}^{\uparrow}$ *carrier*

$$K = (I, J, F, G, L, M, R, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ContinuousDependenceOde}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, paired initial-cell exposure through I and J, paired vector-field exposure through F and G, Lipschitz stability through L, Picard–Lindelof handoff through M, Gronwall comparison through R, complete-metric convergence visibility through E, transport through H, replay through C, provenance through P, and local naming through N.*

Proof. Project the accepted carrier of Definition 8549.1. The packet displays two initial cells, two vector-field ledgers, one shared Lipschitz row, one Picard–Lindelof handoff, one Gronwall comparison row, one complete-metric row, and the structural transport and naming rows.

The dependence surface begins with the two initial cells. The carrier exposes them as displayed time-state data, so the comparison always starts from named local flow inputs rather than a host solution object.

The vector-field and Lipschitz rows fix the comparison band. The two ledgers are read through the same $\mathsf{LipschitzMap}^{\uparrow}$ surface, and the shared Lipschitz row L keeps the two flow routes inside one finite stability region.

The Picard–Lindelof handoff and Gronwall row then compare the two routes. The row M carries the local-flow route, while R bounds the resulting difference envelope before the complete-metric row E is read. The rows H, C, P, and N only transport, replay, source, and name this same finite dependence route, so no host equality or quotient flow can be exported. □

Theorem 8549.3 (Continuous dependence ODE Gronwall route)**.** *Every accepted* $\mathsf{ContinuousDependenceOde}^{\uparrow}$ *carrier factors its stability read through the displayed route*

$$\mathsf{Ode}^{\uparrow} \longmapsto \mathsf{LipschitzMap}^{\uparrow} \longmapsto \mathsf{PicardLindelof}^{\uparrow} \longmapsto \mathsf{GronwallInequality}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route first exposes the two initial cells and two vector-field ledgers, then the shared Lipschitz row, then the Picard–Lindelof handoff, then the Gronwall comparison row, then the complete-metric convergence row, and only then the Real-facing endpoint seal. The dependence read does not bypass those rows by invoking a host ODE solver, a selected solution curve, or a quotient equality of flows.

Proof. Start with an accepted carrier $K = (I, J, F, G, L, M, R, E, H, C, P, N)$. The two initial cells and two vector-field ledgers are the only source rows available to the packet.

The shared Lipschitz row L constrains the two local-flow routes on the same finite window. That constraint is the only entry into the comparison route and keeps the two flows within the same stability band.

Apply the Picard–Lindelof handoff through M. It carries the local existence-and-uniqueness route for each source row before the comparison is read. Then apply the Gronwall row R to the displayed difference envelope. That row bounds the comparison and hands the result to the complete-metric row E.

Finally read the Real seal only after E. The rows H, C, P, and N preserve the same finite route, so the dependence theorem stays constructive and local rather than becoming a host solution-space equality or a global continuation claim. □

Theorem 8549.4 (Continuous dependence ODE real-seal nonescape)**.** *Every accepted* $\mathsf{ContinuousDependenceOde}^{\uparrow}$ *packet exposes the terminal* $\mathsf{Real}^{\uparrow}$ *seal only after the two initial cells, two vector-field ledgers, Lipschitz row, Picard–Lindelof handoff, Gronwall comparison row, and complete-metric convergence row have been displayed. The consumer therefore sees continuous dependence as finite NameCert data, not as host function equality, quotient equality of flows, selected continuation, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8549.1. The displayed source rows are the two initial cells and the two vector-field ledgers; the comparison rows are the Lipschitz row, the Picard–Lindelof handoff, the Gronwall row, and the complete-metric row.

Use the NameCert obligations of Definition 8549.2. They keep the dependence route local and finite, with the Real seal reached only after the comparison rows have been opened.

Then apply the Gronwall route of Definition 8549.3. It prevents a consumer from bypassing the comparison band or the complete-metric handoff. The structural rows H, C, P, and N only transport, replay, source, and name the same finite packet, so no host equality or quotient flow can escape from the seal. □

Falsifiable prediction: Every accepted $\mathsf{ContinuousDependenceOde}^{\uparrow}$ packet exposes two initial cells, two vector-field ledgers, one Lipschitz row, one Picard–Lindelof handoff, one Gronwall row, one complete-metric row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the Real seal is read.

Independence witness: ode, picard-lindelof, gronwall-inequality, lipschitzmap, completemetric, real: none is bijective to $\mathsf{ContinuousDependenceOde}^{\uparrow}$ because this packet jointly carries paired initial cells, paired vector-field ledgers, a shared Lipschitz row, a Picard–Lindelof handoff, a Gronwall comparison row, a complete-metric row, and the transport/replay/provenance rows binding them into one continuous-dependence certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{ContinuousDependenceOde}^{\uparrow}}$.

Constructive story: A $\mathsf{ContinuousDependenceOde}^{\uparrow}$ packet is generated from paired initial cells, paired vector-field ledgers, one Lipschitz row, one Picard–Lindelof handoff, one Gronwall comparison row, one complete-metric row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ContinuousDependenceOde}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8549.1, Definition 8549.2, Definition 8549.3, and Definition 8549.4 bind the finite constructive ODE stability packet for paired local flows, Lipschitz control, Picard–Lindelof handoff, Gronwall comparison, complete-metric convergence, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ContinuousDependenceOde}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host ODE solver, selected continuation, quotient equality of flows, host function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked paired-cell admission, vector-field compatibility, Lipschitz stability, Picard–Lindelof handoff, Gronwall comparison, complete-metric convergence, transport, replay, provenance, and local naming for BEDC.Derived.ContinuousDependenceOdeUp.

Chapter 8550

A Concrete Naming Certificate for $\mathsf{BoundedGeometry}^{\uparrow}$

Following Roe's coarse geometry and Heinonen's metric-space treatment of uniform local covering, the $\mathsf{BoundedGeometry}^{\uparrow}$ packet records the finite metric surface where a displayed separation floor and a displayed local-cover budget are bound to the same metric carrier. It sits after the metric source of chapter 57, the positive-separation ledger of chapter 7444, the half-radius cover surface of chapter 6131, the cover-count ledger of chapter 8055, and the finite-net handoff of chapter 1767. The packet names bounded geometry only as finite BEDC rows; it is not local compactness, selected nets, host properness, countable choice, or an ambient compactness theorem.

Definition 8550.1 (Bounded geometry carrier)**.** *A* $\mathsf{BoundedGeometry}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (X, S, R, L, K, E, F, Q, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Met}^{\uparrow}$ *or* $\mathsf{Met}^{\uparrow}$ *source row, carrying the point-history classifier, distance rows, and metric-law ledger.*
2. *S is the* $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$ *separation row over the same source, including the displayed positive floor and its finite comparison schedule.*
3. *R is the local radius-budget row, recording the inspected positive radii and the scale conversion used by local cover requests.*
4. *L is the* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *local-cover row, read only as finite ball-cover data for the radii named by R.*
5. *K is the* $\mathsf{MetricEntropy}^{\uparrow}$ *cover-count row, recording the finite bound attached to the displayed local covers.*
6. *E is the* $\mathsf{FiniteEpsilonNet}^{\uparrow}$ *handoff row, exposing the actual center bundle and coverage-distance ledger consumed by downstream finite-net users.*
7. *F is the bounded-geometry budget ledger, binding the separation floor from S and the local cover count from K to one named metric source X.*
8. *Q records the scope-exactness check: every bounded-geometry read must use X, S, R, L, K, E, F from the same packet and the same classifier route.*

9. *H records componentwise* hsame *transport for the metric source, separation row, radius budget, local-cover row, entropy count, finite-net handoff, budget ledger, exactness row, replay, provenance, and local name.*
10. *C records displayed* Cont *replay from a bounded-geometry request through $X, S, R, L, K, E, F, Q, H$.*
11. *P is the* Pkg *provenance over* $\mathsf{BoundedGeometry}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{UniformlyDiscreteMetric}^{\uparrow}$, $\mathsf{DoublingMetricSpace}^{\uparrow}$, $\mathsf{MetricEntropy}^{\uparrow}$, $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{Rat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, ProbeBundle, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BoundedGeometry}^{\uparrow}}$ *row.*

The classifier compares accepted packets only by componentwise replay of these rows. It has no coordinate for arbitrary local compactness, selected maximal nets, host properness, quotient point equality, countable choice, or ambient completion.

Theorem 8550.2 (Bounded geometry NameCert obligations)**.** *For every accepted* $\mathsf{BoundedGeometry}^{\uparrow}$ *carrier*

$$B = (X, S, R, L, K, E, F, Q, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedGeometry}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric source; separation-floor visibility through S; local radius-budget visibility through R; finite local-cover visibility through L; cover-count visibility through K; finite-net handoff through E; joint budget exactness through F; same-packet scope exactness through Q; componentwise transport, displayed replay, provenance, and local naming through H, C, P, N; and refusal of local compactness, selected nets, host properness, quotient point equality, countable choice, ambient compactness, and ambient completeness as local certificate data.*

Proof. Carrier admission is projection from Definition 8550.1. The metric source X, separation row S, radius budget R, local-cover row L, entropy count K, finite-net handoff E, budget ledger F, and exactness row Q are the only analytic rows available before local naming.

Separation visibility is read through S. This exposes a positive floor over the same source X but does not decide point equality or supply a host discrete topology.

Local cover visibility is read through R, L, K, E. The radius row names the inspected scales, the doubling row supplies finite local covers, the entropy row records their finite count, and the finite-net row displays the centers and coverage distances.

The joint bounded-geometry claim is the row F. It binds the separation floor and cover-count budget to one source, while Q prevents a consumer from mixing a separation row from one metric packet with a cover budget from another.

Transport and replay are structural. The rows H, C, P, N preserve, replay, source, and name the same finite route, so no unlisted local compactness theorem, selected maximal net, host properness principle, quotient equality, countable-choice schedule, or ambient completion witness can be recovered from the local NameCert surface. □

Theorem 8550.3 (Bounded geometry finite-net handoff)**.** *Every* $\mathsf{FiniteEpsilonNet}^{\uparrow}$, $\mathsf{MetricEntropy}^{\uparrow}$, *or* $\mathsf{DoublingMetricSpace}^{\uparrow}$ *consumer of an accepted* $\mathsf{BoundedGeometry}^{\uparrow}$ *carrier must read the finite route*

$$\mathsf{Met}^{\uparrow},\quad \mathsf{UniformlyDiscreteMetric}^{\uparrow},\quad \mathsf{DoublingMetricSpace}^{\uparrow},\quad \mathsf{MetricEntropy}^{\uparrow},\quad \mathsf{FiniteEpsilonNet}^{\uparrow},\quad \mathsf{BHist},\quad \mathsf{hsame}$$

through the rows $X, S, R, L, K, E, F, Q, H, C, P, N$. The handoff exports a displayed separation floor, finite local-cover budget, center bundle, and coverage ledger over the same metric source; it

exports no selected maximal net, local compactness theorem, host properness assertion, quotient point equality, countable-choice schedule, or ambient compactness witness.

Proof. Begin with a finite-net consumer. The consumer reaches centers and coverage distances only through E, and E is downstream of the metric source X, separation row S, radius budget R, local-cover row L, cover-count row K, and joint budget ledger F.

For a metric-entropy consumer, the cover-count row K is visible only after the displayed local-cover route R, L has been read. The same-packet exactness row Q keeps that count attached to the separation floor in S and the source metric in X.

For a doubling consumer, the local-cover row L remains the finite ball-cover data named by the packet. It may pass its centers through E and its count through K, but it does not become an open-cover compactness or host properness principle.

The structural rows then package exactly this route. Componentwise transport H and replay C preserve X, S, R, L, K, E, F, Q, while P, N source and name the local certificate. Therefore each listed consumer remains inside the displayed finite route and cannot import selected nets, quotient point equality, countable choice, ambient compactness, or ambient completeness. □

Falsifiable prediction: An accepted $\mathsf{BoundedGeometry}^{\uparrow}$ consumer that reads a finite-net center bundle, local cover count, or bounded-geometry budget without displaying the common metric source, positive separation row, local radius budget, doubling cover row, entropy count row, finite-net handoff, budget ledger, scope exactness row, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: metric, uniformly-discrete-metric, doubling-metric-space, metric-entropy, finite-epsilon-net: no listed sibling is bijective with $\mathsf{BoundedGeometry}^{\uparrow}$ because this packet jointly carries a common metric source, positive separation floor, local radius budget, finite local-cover row, finite cover-count row, finite-net center handoff, budget ledger, same-packet exactness, transport, replay, provenance, and local naming in one finite surface.

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedGeometry}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedGeometry}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8550.1, Definition 8550.2, and Definition 8550.3 seed the finite bounded-geometry route over metric, uniformly discrete, doubling, metric-entropy, and finite-net rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedGeometry}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim local compactness, selected maximal nets, host properness, quotient point equality, countable choice, ambient compactness, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, separation-floor visibility, local-cover budget exactness, finite-net handoff, same-packet exactness, transport, replay, provenance, and local naming for BEDC.Derived.BoundedGeometryUp.

Constructive story: A $\mathsf{BoundedGeometry}^{\uparrow}$ packet is generated from MetricUp or MetricSpaceUp rows, a UniformlyDiscreteMetricUp separation floor, finite radius budgets, DoublingMetricSpaceUp local covers, MetricEntropyUp cover counts, FiniteEpsilonNetUp center and coverage rows, a joint bounded-geometry budget ledger, same-packet exactness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8551

A Concrete Naming Certificate for $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$

Following Riesz and Bishop–Bridges constructive functional analysis, the $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ packet records the finite separation surface by which a normed vector space, a displayed proper closed subspace, and a positive tolerance expose one witness row before any quotient-space or compactness principle is available. It sits over the norm carrier of chapter 89, the vector-space carrier of chapter 47, the Banach-facing dependency of chapter 90, the terminal real seal of chapter 38, and the complete-metric boundary of chapter 128. The packet names the finite Riesz separation witness as BEDC data; it is not Hahn–Banach, not a quotient normed-space construction, not a selected supremum or nearest point, and not full Banach-space compactness.

Definition 8551.1 (Riesz lemma finite-separation carrier)**.** *A* $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (X, V, Y, Q, U, T, B, D, S, L, H, C, P, N)$$

with the following displayed rows:

1. *X is the* $\mathsf{Norm}^{\uparrow}$ *source row, carrying the norm comparisons used by the separation read.*
2. *V is the* $\mathsf{VecSpace}^{\uparrow}$ *row over the same source, exposing the finite addition and scalar-window data needed before a vector witness can be named.*
3. *Y is the displayed proper closed subspace row, recorded as membership, closure, and properness evidence rather than as a quotient carrier.*
4. *Q is the same-source compatibility row binding X, V, Y to one classifier route.*
5. *U is the unit-normalization row for the inspected vector window.*
6. *T is the positive tolerance row, read through* $\mathsf{Real}^{\uparrow}$ *or a dyadic real-facing seal before the separation row is visible.*
7. *B is the ball-avoidance row, listing the finite comparisons between the witness window and the displayed subspace window.*
8. *D is the norm-distance observation row, routed through* $\mathsf{CompleteMetric}^{\uparrow}$ *only as metric evidence attached to X.*
9. *S is the finite separation witness row exported by the packet.*

10. *L is the* $\mathsf{Banach}^{\uparrow}$ *or* $\mathsf{CompleteMetric}^{\uparrow}$ *dependency row, visible only as a source of completion discipline and not as a compactness or choice principle.*
11. *H stores componentwise* hsame *transport for $X, V, Y, Q, U, T, B, D, S, L$.*
12. *C stores displayed* Cont *replay from a finite separation request through the analytic rows to the witness row.*
13. *P is the* Pkg *provenance over* $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Banach}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
14. *N is the local* $\mathsf{NameCert}_{\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these rows. It has no coordinate for Hahn–Banach extension, quotient normed spaces, selected suprema, nearest-point projection, countable choice, or full Banach-space compactness.

Theorem 8551.2 (Riesz lemma finite-separation NameCert obligations)**.** *For every accepted* $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ *carrier*

$$R = (X, V, Y, Q, U, T, B, D, S, L, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}}$ *surface consists exactly of carrier admission for Definition 8551.1; norm and vector-space source visibility through X, V; proper closed-subspace visibility through Y; same-source compatibility through Q; unit and tolerance visibility through U, T; finite avoidance and distance stability through B, D; witness export through S; completion-discipline visibility through L; componentwise transport, displayed replay, provenance, and local naming through H, C, P, N; and refusal of Hahn–Banach, quotient normed spaces, selected suprema, nearest-point projections, countable choice, and full Banach-space compactness as local certificate data.*

Proof. Project the rows of Definition 8551.1. The analytic source is finite: X exposes norm comparisons, V exposes vector-space operations on the inspected windows, Y exposes the closed proper subspace ledger, and Q keeps those rows attached to one classifier route.

The separation read then passes through U, T, B, D, S. The unit row and tolerance row are visible before the avoidance and distance rows, and the witness row S is exported only after those finite comparisons have been recorded.

It remains to read the structural rows. The completion row L is only a dependency witness, while H, C, P, N preserve componentwise equality, replay the displayed route, record provenance, and name the local certificate. Since the carrier contains no row for Hahn–Banach extension, quotient normed spaces, selected suprema, nearest-point projection, countable choice, or full Banach-space compactness, none of those objects can appear as a NameCert obligation. □

Falsifiable prediction: Every accepted $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ consumer that exports a separation witness without displaying the norm source, vector-space source, proper closed-subspace row, same-source compatibility row, unit-normalization row, tolerance row, avoidance row, distance row, completion-discipline row, transport, replay, provenance, and local NameCert row refutes the carrier surface.

Independence witness: norm, vecspace, banach, real, completemetric: no listed sibling is bijective with $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ because this packet jointly binds a normed vector source, proper closed-subspace evidence, unit normalization, positive tolerance, finite avoidance, distance

observation, completion discipline, witness export, transport, replay, provenance, and local naming while refusing Hahn–Banach, quotient normed spaces, selected suprema, and full Banach-space compactness.

Closure status for $\mathsf{NameCert}_{\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}}$.

Constructive story: A $\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}$ packet is generated from NormUp, VecSpaceUp, proper closed-subspace, same-source compatibility, unit-normalization, Real-facing tolerance, avoidance, distance-observation, separation-witness, BanachUp or CompleteMetricUp dependency, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8551.1 and Definition 8551.2 seed the finite Riesz separation packet over norm, vector-space, Banach, Real, complete-metric, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RieszLemmaFiniteSeparation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Hahn–Banach, quotient normed spaces, selected suprema, nearest-point projections, countable choice, full Banach-space compactness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, same-source compatibility, unit and tolerance visibility, avoidance and distance stability, witness nonescape, transport, replay, provenance, and local naming for BEDC.Derived.RieszLemmaFiniteSeparationUp.

Chapter 8552

A Concrete Naming Certificate for $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$

Following Frechet and Urysohn, the $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ packet records the completion-facing sequential-closure interface as finite BEDC NameCert data. It sits after the Frechet–Urysohn carrier of chapter 3642, the sequential-space interface of chapter 4112, the complete-metric service of chapter 128, the regular-sequence readback of chapter 5965, and the terminal real-name seal of chapter 38. The packet names the displayed sequential completion route; it does not assert quotient sequence equality, selected representatives, countable choice, ambient Real completeness, or a host completion theorem.

Definition 8552.1 (Frechet–Urysohn completion carrier)**.** *A* $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (U, S, M, R, E, A, H, C, P, N)$$

with the following displayed rows:

1. *U is the accepted* $\mathsf{FrechetUrysohn}^{\uparrow}$ *source row, carrying the topological sequential-closure route.*
2. *S is the* $\mathsf{SequentialSpace}^{\uparrow}$ *source row, exposing the sequence-indexed convergence interface read by the completion consumer.*
3. *M is the* $\mathsf{CompleteMetric}^{\uparrow}$ *service row, recording only displayed Cauchy-window admission, limit-service requests, and convergence-distance reads.*
4. *R is the* $\mathsf{RegularSequenceSpace}^{\uparrow}$ *readback row attached to the same displayed sequence windows.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after U, S, M, R have been displayed.*
6. *A is the completion-admission row tying the Frechet–Urysohn sequential closure read to the complete-metric service and regular-sequence readback.*
7. *H records componentwise* hsame *transport for source, sequential, complete-metric, regular-sequence, seal, admission, replay, provenance, and naming rows.*
8. *C records displayed* Cont *replay from each completion-facing request through $U, S, M, R, E, A, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$, $\mathsf{FrechetUrysohn}^{\uparrow}$, $\mathsf{SequentialSpace}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{RegularSequenceSpace}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{FrechetUrysohnCompletion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $U, S, M, R, E, A, H, C, P, N$. It has no coordinate for quotient sequence equality, selected subsequences, chosen completion representatives, countable choice, ambient Real completeness, or a host completion object.

Theorem 8552.2 (Frechet–Urysohn completion NameCert obligations)**.** *For every accepted* $\mathsf{FrechetUrysohnComple}$ *carrier*

$$F = (U, S, M, R, E, A, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FrechetUrysohnCompletion}^{\uparrow}}$ *surface consists exactly of Frechet–Urysohn source admission through U, sequential-source admission through S, complete-metric service exposure through M, regular-sequence readback through R, terminal Real-seal ordering through E, completion admission through A, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8552.1. The source, sequential, complete-metric, regular-sequence, Real-seal, and admission rows are the only rows visible before transport and provenance are read.

The source row U supplies the Frechet–Urysohn sequential-closure route, while S supplies the displayed sequence-indexed convergence interface. The completion-facing consumer cannot reach the complete-metric service row M or the regular-sequence readback row R without those two displayed sources.

The seal row E is downstream of U, S, M, R. The rows A, H, C, P, N then bind the completion request to the same route, transport it componentwise, replay it, source it, and name it locally.

Since the carrier has no quotient sequence, selected representative, choice, ambient completeness, or host completion coordinate, none of those objects can be an obligation of the local certificate. □

Theorem 8552.3 (Frechet–Urysohn completion sequential density)**.** *Every completion-facing sequential-density read exported by an accepted* $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ *packet factors through the displayed route*

$$\mathsf{FrechetUrysohn}^{\uparrow},\ \mathsf{SequentialSpace}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow},\ \mathsf{RegularSequenceSpace}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow} \longmapsto A, H, C, P, N.$$

Thus the packet distinguishes Frechet–Urysohn sequential closure from an ambient completeness theorem: it exposes the finite sequence windows, complete-metric service rows, regular-sequence readback, and terminal Real seal before a density consumer may read the completion-facing admission row.

Proof. Begin with the NameCert obligations of Definition 8552.2. They force any completion-facing read to display the Frechet–Urysohn source row U and the sequential-space row S before the complete-metric or regular-sequence rows are available.

Read M and R next. The complete-metric service supplies only displayed Cauchy-window and limit-service data, while the regular-sequence row records the finite sequence readback attached to the same displayed windows.

The terminal Real seal E is then consumed as a seal, not as a proof of ambient Real completeness. The admission and structural rows A, H, C, P, N preserve the route for the density consumer.

Therefore sequential density in this packet is a finite displayed handoff from Frechet–Urysohn closure to completion-facing readback. It is not quotient stream equality, a selected dense subsequence, a chosen completion representative, countable choice, or a general completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ completion-facing read factors through a FrechetUrysohn source row, a SequentialSpace row, a CompleteMetric service row, a RegularSequenceSpace readback row, a terminal RealUp seal, completion admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming.

Independence witness: frechet-urysohn, sequential-space, completemetric, regular-sequence-space, real: $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ is not bijective to any listed sibling because it binds sequential closure, completion service, regular-sequence readback, Real sealing, transport, replay, provenance, and naming as one completion-facing packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FrechetUrysohnCompletion}^{\uparrow}}$.

Constructive story: A $\mathsf{FrechetUrysohnCompletion}^{\uparrow}$ packet is generated from a FrechetUrysohn source row, a SequentialSpace source row, a CompleteMetric service row, a RegularSequenceSpace readback row, a terminal RealUp seal, completion admission, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FrechetUrysohnCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8552.1, Definition 8552.2, and Definition 8552.3 seed the completion-facing sequential-density route over Frechet–Urysohn, SequentialSpace, CompleteMetric, RegularSequenceSpace, Real-seal, admission, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FrechetUrysohnCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient sequence equality, selected subsequences, chosen completion representatives, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Frechet–Urysohn source exactness, SequentialSpace source routing, CompleteMetric service ordering, RegularSequenceSpace readback, Real-seal ordering, completion admission, transport, replay, provenance, and local naming for BEDC.Derived.FrechetUrysohnCompletionUp.

Chapter 8553

A Concrete Naming Certificate for $\mathsf{AbelUniformTheorem}^{\uparrow}$

Following Abel, Hardy, and Bishop–Bridges constructive analysis, the $\mathsf{AbelUniformTheorem}^{\uparrow}$ packet records the finite theorem endpoint by which Abel uniform convergence data are handed to Real-and-Completion consumers. It sits after the uniform Abel route of chapter 7086, the Abel boundary theorem of chapter 1922, the Abel mean boundary of chapter 7412, the uniform-limit packet of chapter 463, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The chapter packages the traditional theorem as a finite NameCert route; it does not introduce host power-series semantics, selected sums, quotient streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8553.1 (AbelUniformTheorem carrier)**.** *An* $\mathsf{AbelUniformTheorem}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (R, U, L, M, T, Q, E, H, C, P, N)$$

with the following displayed rows:

1. *R is the finite radius-window row listing the displayed radial cells and endpoint-approach windows inspected by the theorem consumer.*
2. *U is the* $\mathsf{AbelUniformConvergence}^{\uparrow}$ *boundary row, carrying the already named uniform Abel convergence surface over the same radius windows.*
3. *L is the* $\mathsf{AbelLimitTheorem}^{\uparrow}$ *endpoint row, recording the boundary-limit handoff after R and U have been accepted.*
4. *M is the* $\mathsf{AbelMeanBoundary}^{\uparrow}$ *mean-boundary row, exposing the finite Abel-mean compatibility data used by the endpoint theorem.*
5. *T is the* $\mathsf{UniformLimit}^{\uparrow}$ *tail ledger, assigning one displayed tail discipline to every radius cell in R before endpoint readback.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the synchronized Abel endpoint windows.*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after R, U, L, M, T, Q have been displayed.*
8. *H records componentwise* hsame *transport for radius windows, Abel uniform convergence data, Abel endpoint data, mean-boundary data, uniform-tail data, readback, seal, replay, provenance, and local naming.*

9. *C records displayed* Cont *replay from each theorem request through R, U, L, M, T, Q, E.*
10. *P is the* Pkg *provenance over* $\mathsf{AbelUniformTheorem}^{\uparrow}$, $\mathsf{AbelUniformConvergence}^{\uparrow}$, $\mathsf{AbelLimitTheorem}^{\uparrow}$, $\mathsf{AbelMeanBoundary}^{\uparrow}$, $\mathsf{UniformLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AbelUniformTheorem}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $R, U, L, M, T, Q, E, H, C, P, N$. It has no coordinate for host power-series semantics, selected sums, quotient streams, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8553.2 (AbelUniformTheorem NameCert obligations)**.** *For every accepted* $\mathsf{AbelUniformTheorem}^{\uparrow}$ *carrier*

$$A = (R, U, L, M, T, Q, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{AbelUniformTheorem}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, radius-window admission through R, Abel uniform convergence boundary admission through U, Abel endpoint admission through L, Abel mean-boundary compatibility through M, uniform-tail exactness through T, regular rational readback and Real seal nonescape through Q and E, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8553.1. Its theorem rows are R, U, L, M, T, Q, E, and its structural rows are H, C, P, N.

The radius and Abel boundary obligations are finite-row projections. The row R fixes the displayed radius windows, U imports the sibling $\mathsf{AbelUniformConvergence}^{\uparrow}$ surface over those windows, L records the Abel endpoint route, and M records the Abel mean-boundary compatibility data.

The tail and readback obligations are downstream. The $\mathsf{UniformLimit}^{\uparrow}$ row T binds one finite tail discipline to the displayed windows before the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q is available, and the terminal $\mathsf{Real}^{\uparrow}$ seal E is read only after R, U, L, M, T, Q have appeared.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface and exclude host power-series semantics, selected sums, quotient streams, countable choice, and ambient completeness. □

Theorem 8553.3 (AbelUniformTheorem real-seal handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$ *or completion-facing consumer of an accepted* $\mathsf{AbelUniformTheorem}^{\uparrow}$ *packet reads the endpoint only through the finite route*

$$\mathsf{AbelUniformConvergence}^{\uparrow},\ \mathsf{AbelLimitTheorem}^{\uparrow},\ \mathsf{AbelMeanBoundary}^{\uparrow},\ \mathsf{UniformLimit}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{Real}^{\uparrow}.$$

The consumer first receives displayed radius windows, the Abel uniform convergence boundary, the endpoint Abel limit row, the Abel mean-boundary row, and one uniform-tail ledger; only then may it consume the regular rational readback and terminal Real seal. The route exports no host power-series semantics, selected sum, quotient stream equality, countable-choice schedule, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted consumer read and project the carrier. The rows R, U, L, M expose the radius windows, Abel uniform convergence boundary, Abel endpoint theorem row, and Abel mean-boundary row before any real-seal read can occur.

Apply the uniform-tail row T. It fixes the displayed tail discipline for the same radius windows and prevents a consumer from choosing a separate endpoint schedule outside the packet.

Now pass through the $\mathsf{RegSeqRat}^{\uparrow}$ readback Q and the terminal $\mathsf{Real}^{\uparrow}$ seal E. These rows are downstream of R, U, L, M, T, so the Real-facing handoff cannot bypass the finite Abel theorem route.

The structural rows H, C, P, N preserve the same route componentwise and add no analytic coordinate. Thus the packet exposes exactly the finite real-seal handoff stated above and none of the excluded host or choice principles. □

Falsifiable prediction: Every accepted AbelUniformTheoremUp read exposes radius-window rows, an AbelUniformConvergenceUp boundary row, an AbelLimitTheoremUp endpoint row, an AbelMeanBoundaryUp compatibility row, a UniformLimitUp tail ledger, RegSeqRatUp readback, RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert before a Real-facing consumer can inspect the endpoint.

Independence witness: abel-uniform-convergence, abel-limit-theorem, abel-mean-boundary, uniformlimit, regseqrat, real: $\mathsf{AbelUniformTheorem}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries radius windows, the uniform Abel boundary, endpoint Abel theorem data, Abel mean-boundary compatibility, one uniform tail ledger, regular rational readback, terminal Real sealing, transport, replay, provenance, and local naming.

Closure status for $\mathsf{NameCert}_{\mathsf{AbelUniformTheorem}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AbelUniformTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8553.1, Definition 8553.2, and Definition 8553.3 seed the finite Real-and-Completion Abel theorem route over AbelUniformConvergence, AbelLimitTheorem, AbelMeanBoundary, UniformLimit, RegSeqRat, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AbelUniformTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close host power-series semantics, selected sums, quotient streams, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, radius-window admission, Abel uniform convergence boundary admission, Abel endpoint admission, Abel mean-boundary compatibility, uniform-tail exactness, readback, Real seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.AbelUniformTheoremUp.

Constructive story: An $\mathsf{AbelUniformTheorem}^{\uparrow}$ packet is generated from radius-window rows, an AbelUniformConvergence boundary row, an AbelLimitTheorem endpoint row, an AbelMeanBoundary compatibility row, a UniformLimit tail ledger, RegSeqRat readback, a RealUp seal, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8554

A Concrete Naming Certificate for $\mathsf{LocatedRealSupremum}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{LocatedRealSupremum}^{\uparrow}$ packet records the supremum surface for a bounded inhabited located real set as finite NameCert data rather than as a host-order primitive. It sits beside the dyadic arithmetic core of chapter 291, the finite observation schedule of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the located interval bisection surface of chapter 5546. The packet exports a finite L10 route for upper-bound evidence, lower-approach evidence, dyadic interval narrowing, regular readback, transport, replay, provenance, and local naming; it does not export quotient $\mathsf{Real}^{\uparrow}$ equality, trichotomy, countable choice, selected host suprema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8554.1 (Located real supremum carrier)**.** *A* $\mathsf{LocatedRealSupremum}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (A, U, L, D, I, Q, R, T, H, C, P, N)$$

with the following displayed rows:

1. *A is the inhabited located real-set row, recording the inspected set predicate, the displayed membership witness, and the locatedness modulus used by finite queries.*
2. *U is the upper-bound row, recording a rational or dyadic bound that every inspected member must stay below through displayed evidence.*
3. *L is the lower-approach row, recording for each displayed tolerance request the finite witness that approaches the bound from below.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *arithmetic row for dyadic comparison, tolerance splitting, and endpoint refinement.*
5. *I is the located interval row, read through the located interval bisection surface of chapter 5546, which keeps the narrowing interval visible before a supremum name is read.*
6. *Q is the* $\mathsf{StreamName}^{\uparrow}$ *finite observation schedule for the inspected bounds, approach witnesses, dyadic endpoints, and interval rows.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row assembled from D, I, Q.*
8. *T is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the upper-bound, lower-approach, interval, observation, and readback rows have all been displayed.*

9. *H records componentwise* hsame *transport for set, bound, approach, dyadic, interval, observation, readback, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from finite located queries to bound comparison, approach selection, interval narrowing, regular readback, and local NameCert exposure.*
11. *P is the* Pkg *provenance over* $\mathsf{LocatedRealSupremum}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{LocatedRealSupremum}^{\uparrow}}$ *row.*

The carrier contains no coordinate for quotient real equality, trichotomy, countable choice, a selected host supremum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness. Every supremum read must be recovered from the displayed finite upper-bound, lower-approach, dyadic, interval, observation, readback, seal, transport, replay, provenance, and naming rows.*

Theorem 8554.2 (Located real supremum NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealSupremum}^{\uparrow}$ *packet*

$$S = (A, U, L, D, I, Q, R, T, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{LocatedRealSupremum}^{\uparrow}}$ *obligations are exhausted by inhabited located-set exposure through A, upper-bound exposure through U, lower-approach exposure through L, dyadic arithmetic through D, located interval narrowing through I, finite observation through Q, regular rational readback through R, terminal real-name sealing through T, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8554.1. The rows A, U, L display the exact inhabited located-set evidence, upper-bound evidence, and lower-approach evidence before any real-name seal can be consumed.

Next read D, I, Q, R. The dyadic arithmetic row supplies tolerance splitting and endpoint comparison, the located interval row keeps the narrowing interval visible, the finite observation row lists the inspected queries, and the regular rational row records the completion-facing readback.

Finally read T, H, C, P, N. These rows seal the same finite route into $\mathsf{Real}^{\uparrow}$, transport it componentwise, replay the displayed construction, record its source package, and expose the local name. Since no other coordinate is present, the listed rows exhaust the NameCert obligations. □

Theorem 8554.3 (Located real supremum L10 finite route)**.** *Every public* $\mathsf{LocatedRealSupremum}^{\uparrow}$ *supremum read factors through the L10 route*

$$A, U, L, D, I, Q, R, T, H, C, P, N.$$

The route may cite dyadic arithmetic, stream-name observation, regular rational readback, real-name sealing, and located interval bisection only as displayed sibling dependencies. It refuses quotient $\mathsf{Real}^{\uparrow}$ *equality, trichotomy, countable choice, selected host suprema, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the upper-bound and lower-approach rows. The row U records that inspected members stay below the displayed bound, while L records the finite approach witnesses demanded by the located supremum read.

Transport this evidence through the L10 siblings. The dyadic row D supplies the comparison arithmetic of chapter 291; the observation row Q supplies the finite schedule of chapter 126; the readback row R supplies the regular rational surface of chapter 301; and the seal row T supplies

only the terminal real-name boundary of chapter 38. The located interval row I keeps the bisection dependency visible before the seal is read.

The structural rows H, C, P, N preserve exactly this displayed packet under transport, replay, provenance, and local naming. None of those rows contains quotient equality, trichotomy, countable choice, host supremum selection, or ambient completeness, so the public read remains a finite BEDC route. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealSupremum}^{\uparrow}}$.

Constructive story: A $\mathsf{LocatedRealSupremum}^{\uparrow}$ packet is generated from inhabited located-set evidence, upper-bound evidence, lower-approach evidence, DyadicRatCore arithmetic, located interval narrowing, StreamName finite observations, RegSeqRat readback, a RealUp seal boundary, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealSupremum}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8554.1, Definition 8554.2, and Definition 8554.3 seed the finite located real supremum packet over L10 arithmetic, observation, readback, seal, transport, replay, provenance, and naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealSupremum}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient real equality, trichotomy, countable choice, selected host suprema, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, upper-bound exposure, lower-approach exposure, dyadic arithmetic exposure, located interval narrowing, finite-window scheduling, regular rational readback, Real seal boundary control, transport, replay, provenance, and local naming for BEDC.Derived.LocatedRealSupremumUp.

Chapter 8555

A Concrete Naming Certificate for $\mathsf{DunfordIntegral}^{\uparrow}$

Following Dunford and Schwartz, the $\mathsf{DunfordIntegral}^{\uparrow}$ packet records vector-valued integration by finite weak scalar integral rows before any strong measurability or Bochner norm-integrability endpoint is available. It sits between the weak scalar route of chapter 6638, the simple-function norm route of chapter 6587, the dual observation windows of chapter 5192, and the displayed separable Banach carrier of chapter 8449. The packet is a finite weak-integration NameCert boundary: it names scalar probe integrals and comparison windows, not a completed measure-theoretic representation theorem.

Definition 8555.1 (Dunford integral carrier)**.** *A* $\mathsf{DunfordIntegral}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (M, I, X, V, L, W, A, B, S, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Measure}^{\uparrow}$ *source row naming the finite measurable partitions, measurable-event windows, and null-boundary comparisons visible to the packet.*
2. *I is the* $\mathsf{Integral}^{\uparrow}$ *scalar readback row for the finite scalar integrals inspected by the weak probes.*
3. *X is the* $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$ *row naming the displayed Banach carrier, dense-code windows, norm readbacks, and completion-facing service used by the packet.*
4. *V is the Banach-space and dual-pairing row. It lists the inspected vector windows, dual probes, scalar pairing requests, and finite tolerance comparisons.*
5. *L is the* $\mathsf{WeakStarTopology}^{\uparrow}$ *readback row for dual-probe observation windows and weak-star scalar comparisons.*
6. *W is the weak scalar integral row. Each entry records a displayed bounded dual probe, the scalar shadow it induces, and the scalar integral read through M, I, V, L.*
7. *A is the simple-function approximation window row. It records finite simple approximants, finite range data, measurable fibres, and the weak scalar comparisons used to test the approximants.*
8. *B is the* $\mathsf{BochnerIntegral}^{\uparrow}$ *comparison handoff row, available only when the displayed simple-function and norm-tail data are already present.*
9. *S is the* $\mathsf{PettisIntegral}^{\uparrow}$ *comparison handoff row, available only through the same weak scalar integral rows and dual-pairing windows.*

10. *R is the weak-star readback and scalar-budget ledger for the probe integrals, including finite tolerance requests and comparison bounds.*
11. *H records componentwise* hsame *transport for $M, I, X, V, L, W, A, B, S, R$ and the local structural rows.*
12. *C records displayed* Cont *replay from a weak integration request through the same scalar probes, approximation windows, comparison handoffs, readback ledger, transport, provenance, and local naming rows.*
13. *P is the* Pkg *provenance over* $\mathsf{DunfordIntegral}^{\uparrow}$, $\mathsf{PettisIntegral}^{\uparrow}$, $\mathsf{BochnerIntegral}^{\uparrow}$, $\mathsf{WeakStarTopology}^{\uparrow}$, $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$, $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
14. *N is the local* $\mathsf{NameCert}_{\mathsf{DunfordIntegral}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $M, I, X, V, L, W, A, B, S, R, H, C, P, N$. It has no coordinate for strong measurability, measure completion, Radon–Nikodym conclusions, quotient function equality, countable choice, selected representatives, or Lean verification.

Lean4 ✓ `BEDC.Derived.DunfordIntegralUp.DunfordIntegralTasteGate single carrier alignment`

Theorem 8555.2 (Dunford integral NameCert obligations)**.** *For every accepted* $\mathsf{DunfordIntegral}^{\uparrow}$ *carrier*

$$D = (M, I, X, V, L, W, A, B, S, R, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DunfordIntegral}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, measure source compatibility through M, scalar integral readback through I, Banach-space and dual-pairing visibility through X, V, weak-star probe visibility through L, weak scalar integral exposure through W, simple-function approximation-window exposure through A, Pettis and Bochner comparison handoffs through S and B, weak-star scalar-budget readback through R, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Every weak-integration-facing consumer must read those finite rows before using the Dunford handoff. It receives no strong measurability theorem, no measure completion, no Radon–Nikodym conclusion, no quotient function equality, no countable-choice schedule, no selected vector representative, and no Lean-checked theorem from this packet.

Proof. Project the carrier in Definition 8555.1. Carrier admission exposes exactly $M, I, X, V, L, W, A, B, S, R, H, C,$

The analytic rows M, I, X, V, L, W fix the measurable source, scalar integral readback, Banach carrier, dual-pairing window, weak-star observation row, and weak scalar integrals. Thus every probe integral is a displayed scalar shadow, not a hidden vector-valued representative.

The comparison rows A, B, S, R keep the handoffs finite. Simple-function approximation windows are visible in A, Bochner comparison can be read only through B, Pettis comparison can be read only through S, and weak-star scalar budgets remain in R.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the refused objects have no carrier coordinate, the displayed rows exhaust the local NameCert obligations. □

Theorem 8555.3 (Dunford integral Pettis–Bochner handoff)**.** *Every accepted* $\mathsf{DunfordIntegral}^{\uparrow}$ *packet mediates between Pettis and Bochner consumers only through the finite route*

$$M, I, X, V, L \longmapsto W, A, R \longmapsto S, B \longmapsto H, C, P, N.$$

The Pettis-facing read consumes weak scalar integral rows and dual-pairing windows, while the Bochner-facing read additionally consumes the simple-function approximation windows and norm-tail comparison handoff. The shared Dunford packet contributes no strong measurability theorem, measure completion, Radon–Nikodym conclusion, quotient function equality, countable choice, selected representative, or ambient Banach completeness beyond the displayed carrier rows.

Proof. Begin with the weak scalar rows. By Definition 8555.2, the measurable source, scalar integrals, Banach carrier, dual-pairing windows, and weak-star observations must be exposed before any comparison handoff is available.

For the Pettis-facing read, use the row S. It is downstream of the weak scalar integral row W and the scalar-budget ledger R, so it can hand off only the displayed scalar probe integrals and not a selected vector representative.

For the Bochner-facing read, use the rows A and B. They require simple-function approximation windows and norm-tail comparison data before the Bochner comparison can be consumed.

Finally replay the structural route through H, C, P, N. The same finite rows are transported and named on both sides, and none of the refused strong-measurement, completion, Radon–Nikodym, quotient, choice, representative-selection, or Lean-verification endpoints appears as a coordinate. □

Falsifiable prediction: Every public $\mathsf{DunfordIntegral}^{\uparrow}$ read factors through displayed $\mathsf{Measure}^{\uparrow}$, $\mathsf{Integral}^{\uparrow}$, $\mathsf{FiniteRealizedSeparableBanachSpace}^{\uparrow}$, $\mathsf{WeakStarTopology}^{\uparrow}$, weak scalar integral, simple-function approximation, Pettis handoff, Bochner handoff, weak-star readback, hsame, Cont, Pkg, and local NameCert rows. A public read that exports strong measurability, measure completion, Radon–Nikodym conclusions, quotient function equality, countable choice, selected representatives, or Lean verification from this packet refutes the carrier boundary.

Independence witness: pettis-integral, bochner-integral, weak-star-topology, finite-realized-separable-banach-space: $\mathsf{DunfordIntegral}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite weak scalar integral rows, simple-function approximation windows, Banach-space and dual-pairing rows, Pettis and Bochner comparison handoffs, weak-star readback, transport, replay, provenance, and local naming while refusing stronger measure-theoretic and quotient endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{DunfordIntegral}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DunfordIntegral}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8555.1, Definition 8555.2, and Definition 8555.3 seed the finite weak-integration packet over scalar probe integrals, simple-function approximation windows, dual-pairing rows, Pettis and Bochner handoffs, weak-star readback, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DunfordIntegral}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim strong measurability, measure completion, Radon–Nikodym conclusions, quotient function equality, countable choice, selected representatives, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak scalar integral exposure, approximation-window stability, Pettis and Bochner handoff nonescape, weak-star readback, transport, replay, provenance, and local naming for BEDC.Derived.DunfordIntegralUp.

Constructive story: A $\mathsf{DunfordIntegral}^{\uparrow}$ packet is generated from Measure, Integral, finite realized separable Banach, dual-pairing, WeakStarTopology, weak scalar integral, simple-function approximation, Pettis comparison, Bochner comparison, weak-star readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 8556

A Concrete Naming Certificate for $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$

Following Bishop–Bridges regular real analysis and Kelley on complete metric subspaces, the $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ packet records the constructive completeness of a closed bounded real interval as finite BEDC NameCert data. It sits after the interval carrier of chapter 1591, the complete-metric service of chapter 128, the real-name seal of chapter 38, the regular rational readback of chapter 301, the finite StreamName windows of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet names the interval-completeness route used by L10 completion consumers without importing open-cover compactness, selected limits, quotient equality of real names, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8556.1 (Closed bounded interval complete carrier)**.** *A* $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, A, Z, R, W, D, C, M, T, H, Q, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *interval row, recording the closed endpoint pair, boundedness witnesses, and membership classifier for the interval being completed.*
2. *A records the two endpoint* $\mathsf{Real}^{\uparrow}$ *seals, including the lower and upper endpoint names and their displayed endpoint-order evidence.*
3. *Z is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback row for the candidate interval sequence.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *terminal seal row reached by the readback after the tolerance and window rows have been exposed.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row, recording exactly the finite observations of endpoint and sequence names requested by the consumer.*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, recording dyadic radii, endpoint slack, interval-retention comparisons, and regular-Cauchy budget cells.*
7. *C is the* $\mathsf{CompleteMetric}^{\uparrow}$ *limit row for the displayed Cauchy request.*
8. *M records membership transport, carrying the interval-membership rows from the finite tail windows to the terminal Real seal.*

9. *T records componentwise* hsame *transport for the interval row, endpoint seals, readback, StreamName windows, tolerance ledger, complete-metric limit row, membership transport, replay, provenance, and local naming.*
10. *H records displayed* Cont *replay from a completion request through $B, A, Z, R, W, D, C, M, T$.*
11. *Q is the local interval-completeness replay row, tying the Cauchy tail request, dyadic tolerance budget, and membership transport to the same closed interval.*
12. *P is the* Pkg *provenance over* $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$, $\mathsf{ClosedBoundedInterval}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, A, Z, R, W, D, C, M, T, H, Q, P, N$. No coordinate stores open-cover compactness, a selected limit functional, quotient equality of real names, countable choice, trichotomy, or completeness for ambient $\mathsf{Real}^{\uparrow}$.

Theorem 8556.2 (Closed bounded interval complete NameCert obligations)**.** *For every accepted* $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ *carrier*

$$I = (B, A, Z, R, W, D, C, M, T, H, Q, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}}$ *surface consists exactly of carrier admission for the* $\mathsf{ClosedBoundedInterval}^{\uparrow}$ *row, endpoint* $\mathsf{Real}^{\uparrow}$ *seals,* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-Cauchy readback, terminal* $\mathsf{Real}^{\uparrow}$ *seal,* $\mathsf{StreamName}^{\uparrow}$ *finite windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger,* $\mathsf{CompleteMetric}^{\uparrow}$ *limit row, membership transport, componentwise* hsame *transport, displayed* Cont *replay, local replay, provenance, and local naming. Any completion-facing consumer must read those rows before treating a displayed regular Cauchy sequence in the closed bounded interval as having an interval member as its terminal seal.*

Proof. Project the carrier of Definition 8556.1. The accepted packet displays exactly the interval row, endpoint seals, regular-Cauchy readback, terminal seal, StreamName windows, dyadic tolerance ledger, complete-metric row, membership transport, and structural rows.

The analytic route begins with B, A, W, D, Z. These rows expose the interval endpoints, finite name observations, dyadic tolerance budget, and regular rational readback before any terminal Real seal can be consumed.

The completion-facing rows are downstream. The row C supplies the complete-metric limit surface, while M transports membership from finite retained tails to the terminal seal R using only the displayed interval and tolerance data.

Finally T, H, Q, P, N preserve, replay, source, and name the same finite route. Since the carrier contains no open-cover compactness row, selected-limit functional, quotient real-name equality, countable-choice schedule, trichotomy branch, or ambient $\mathsf{Real}^{\uparrow}$ completeness coordinate, none of those claims belongs to the local NameCert obligations. □

Falsifiable prediction: Every accepted $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ completion read is refuted if it reaches a terminal $\mathsf{Real}^{\uparrow}$ seal without displaying the closed interval row, endpoint Real seals, regular-Cauchy readback, StreamName windows, dyadic tolerance ledger, complete-metric limit row, membership transport, componentwise transport, replay, provenance, and local NameCert data.

Independence witness: closedboundedinterval, completemetric, real, regseqrat, streamname, dyadicratcore: $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ is not bijective to any listed sibling because it

jointly carries a closed interval row, endpoint seals, regular-Cauchy readback, finite name windows, dyadic tolerance ledger, complete-metric limit surface, membership transport, replay, provenance, and local naming as one interval-completeness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalComplete}\uparrow}$.

Constructive story: A $\mathsf{ClosedBoundedIntervalComplete}^{\uparrow}$ packet is generated from a ClosedBoundedIntervalUp row, endpoint RealUp seals, RegSeqRatUp regular-Cauchy readback, StreamNameUp finite windows, DyadicRatCoreUp tolerance ledger, CompleteMetricUp limit row, membership transport, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalComplete}\uparrow}, \mathsf{seed})$

Scope closed: Definition 8556.1 and Definition 8556.2 seed the finite interval-completeness route from closed bounded interval data to a Real-facing terminal seal.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ClosedBoundedIntervalComplete}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected limits, quotient equality of real names, countable choice, trichotomy, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, endpoint seal exactness, regular-Cauchy readback, finite StreamName window inspection, DyadicRatCore tolerance exactness, CompleteMetric limit handoff, membership transport, replay, provenance, and local naming for BEDC.Derived.ClosedBoundedIntervalCompleteUp.

Chapter 8557

Cauchy Interleaving Tree NameCert Construction

Following Bishop and Bridges, the $\mathsf{CauchyInterleavingTree}^{\uparrow}$ packet records the finite branch tree used when two regular Cauchy readback routes are inspected together before either route is sealed as a completed real. It sits beside the regular-Cauchy shuffle of chapter 1721, the finite stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance carrier of chapter 291, and the terminal real-name route of chapter 38. The packet names diagonal, subsequence, and alternating-window reads without quotient stream equality, countable choice, a selected limit, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8557.1 (Cauchy interleaving tree carrier)**.** *A* $\mathsf{CauchyInterleavingTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S_0, S_1, B, D, R, E, H, C, P, N)$$

with the following displayed coordinates:

1. S_0 *and* S_1 *are the two* $\mathsf{StreamName}^{\uparrow}$ *finite schedules whose windows are being interleaved.*
2. B *is the finite branch row, recording left, right, and paired requests in the inspected tree.*
3. D *is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger attached to every displayed branch.*
4. R *is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row reached after the branch schedule and dyadic tolerance ledger are exposed.*
5. E *is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only through the displayed* S_0, S_1, B, D, R *route.*
6. H *records componentwise* hsame *transport for the two schedules, branch row, dyadic ledger, regular readback, real seal, replay, provenance, and local naming rows.*
7. C *records displayed* Cont *replay of the same interleaving route.*
8. P *is the* Pkg *provenance over* $\mathsf{CauchyInterleavingTree}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. N *is the local* $\mathsf{NameCert}_{\mathsf{CauchyInterleavingTree}^{\uparrow}}$ *row.*

The carrier has no coordinate for a host sequence selector, quotient equality of Cauchy streams, countable choice, trichotomy, or a completed-real object outside the displayed seal row.

Lean4 (statement) `BEDC.Derived.CauchyInterleavingTreeUp`

Theorem 8557.2 (Cauchy interleaving tree regularity)**.** *For every accepted* $\mathsf{CauchyInterleavingTree}^{\uparrow}$ *carrier* $T = (S_0, S_1, B, D, R, E, H, C, P, N)$*, every branch read that reaches the* $\mathsf{RegSeqRat}^{\uparrow}$ *row* R *first exposes both stream schedules* S_0, S_1*, the finite branch row* B*, and the dyadic tolerance ledger* D*. Thus the regular rational readback is a finite interleaving certificate, not a selected subsequence, quotient stream equality, or host convergence assertion.*

Proof. Project the displayed carrier rows. The row R appears only after the two finite stream schedules, the branch row, and the dyadic tolerance ledger, so a regular-rational consumer cannot read R as an independent convergence object.

Now compare with the regular-Cauchy shuffle packet of chapter 1721. That sibling records an alternating read order; the present tree keeps the branch row visible so diagonal, subsequence, and paired-window reads share the same finite tolerance ledger.

The structural rows H, C, P, N preserve, replay, source, and name that route. Since no coordinate stores a selector or quotient equality, every regularity read factors through the displayed branch tree. □

Theorem 8557.3 (Cauchy interleaving tree real seal)**.** *Every* $\mathsf{Real}^{\uparrow}$ *seal exported by an accepted* $\mathsf{CauchyInterleavingTree}^{\uparrow}$ *packet factors through the route*

$$S_0, S_1, B, D, R \longmapsto E.$$

The seal may be consumed by Real and Completion arguments as a finite branch-structured readback of regular Cauchy data, but it does not assert ambient real completeness, quotient stream equality, countable choice, or a selected limiting subsequence.

Proof. Read the seal coordinate E in the carrier. Its only public input route is the finite pair of stream schedules, the branch row, the dyadic tolerance ledger, and the regular rational readback.

The replay row C and provenance row P keep the same order visible to downstream Real and Completion consumers. A consumer may therefore cite the packet as a branch-structured handoff from regular Cauchy data to a real-name seal.

No additional row chooses a limit, compares quotient streams, or discharges completeness. Hence the exported seal is exactly the displayed finite route. □

Falsifiable prediction: Every accepted $\mathsf{CauchyInterleavingTree}^{\uparrow}$ real-seal read exposes the branch row B before the $\mathsf{RegSeqRat}^{\uparrow}$ readback R and the terminal $\mathsf{Real}^{\uparrow}$ seal E.

Independence witness: regular-cauchy-shuffle, streamname, regseqrat, dyadicratcore, real: the regular-Cauchy shuffle records an alternating schedule without the branch tree; StreamName records finite windows without regular readback; RegSeqRat records regular rational data without a two-source branch row; DyadicRatCore records tolerance arithmetic without a real seal; and RealUp seals a name without the interleaving carrier. None is bijective to $\mathsf{CauchyInterleavingTree}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyInterleavingTree}^{\uparrow}}$**.**

Constructive story: A $\mathsf{CauchyInterleavingTree}^{\uparrow}$ packet is generated from two finite stream schedules, a branch row, a dyadic tolerance ledger, a regular rational readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingTree}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8557.1, Definition 8557.2, and Definition 8557.3 seed the finite branch tree used by diagonal, subsequence, and regular-Cauchy readback arguments.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyInterleavingTree}^{\uparrow}}, \mathsf{formalTarget})$

Lean target: `BEDC.Derived.CauchyInterleavingTreeUp`

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, countable choice, selected limits, ambient Real$^{\uparrow}$ completeness, Lean theorem verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, branch-row stability, dyadic tolerance compatibility, regular rational readback, real-seal delivery, transport, replay, provenance, and local naming for BEDC.Derived.CauchyInterleavingTreeUp

Chapter 8558

MetaCIC Residual Join Envelope NameCert Construction

The $\mathsf{MetaCICResidualJoinEnvelope}^{\uparrow}$ packet realizes the residual-join route of the visions hub as a finite MetaCIC NameCert envelope. It sits between the finite residual join window of chapter 8021, the confluence diamond ledger of chapter 6547, the local join ledger of chapter 4126, the residual-substitution boundary of chapter 2181, and the parallel-diamond frontier of chapter 4238. The packet records a bounded residual-window, candidate-normalization, local-join, replay, provenance, and handoff envelope without claiming full closed confluence, strong normalization, subject reduction, evaluator equality, or kernel consistency.

Definition 8558.1 (MetaCIC residual join envelope carrier)**.** *A* $\mathsf{MetaCICResidualJoinEnvelope}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$J = (W, R, L, C, D, H, T, P, N)$$

with the following displayed coordinates:

1. *W is the finite residual-window row, exposing the source term, two residual branches, and bounded context.*
2. *R is the retained residual-substitution premise row consumed from the sibling boundary.*
3. *L is the local join row, recording candidate common-reduct data inside the displayed window.*
4. *C is the candidate-normalization row, available only as a bounded witness for the displayed residual window.*
5. *D is the parallel-diamond handoff row, read only after W, R, L, C are visible.*
6. *H records componentwise* hsame *transport for the residual window, premise, local join, candidate-normalization, handoff, replay, provenance, and local naming rows.*
7. *T records displayed* Cont *replay of the residual-join route.*
8. *P is the* Pkg *provenance over* $\mathsf{MetaCICResidualJoinEnvelope}^{\uparrow}$*,* $\mathsf{FiniteResidualJoinWindow}^{\uparrow}$*,* $\mathsf{MetaCICConfluenceDia}$ $\mathsf{MetaCICLocalJoinLedger}^{\uparrow}$*,* $\mathsf{MetaCICResidualSubstitutionBoundary}^{\uparrow}$*,* $\mathsf{MetaCICParallelDiamondFrontier}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{MetaCICResidualJoinEnvelope}^{\uparrow}}$ *row.*

The carrier has no coordinate for unrestricted Church–Rosser, global strong normalization, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Lean4 (statement) `BEDC.Derived.MetaCICResidualJoinEnvelopeUp`

Theorem 8558.2 (MetaCIC residual join envelope diamond handoff)**.** *Every parallel-diamond handoff exported by an accepted* MetaCICResidualJoinEnvelope$^{\uparrow}$ *carrier* $J = (W, R, L, C, D, H, T, P, N)$ *factors through the finite route*

$$W, R, L, C \longmapsto D.$$

The handoff may feed the MetaCICParallelDiamondFrontier$^{\uparrow}$ *consumer as a bounded residual-join envelope, but it does not discharge the residual-substitution premise, prove unrestricted confluence, prove strong normalization, prove subject reduction, decide evaluator equality, or establish kernel consistency.*

Proof. Inspect the displayed carrier. The handoff row D is not public until the residual window W, retained premise R, local join row L, and candidate-normalization row C have all been read.

The sibling finite residual join window supplies only the bounded window shape, while the confluence diamond ledger and local join ledger record the local common-reduct data. The residual-substitution boundary remains a premise row, so the handoff cannot erase it.

The structural rows H, T, P, N transport, replay, source, and name the same finite route. Therefore the exported diamond-facing datum is the bounded envelope W, R, L, C, D and nothing stronger. □

Falsifiable prediction: Every accepted MetaCICResidualJoinEnvelope$^{\uparrow}$ handoff exposes the retained residual-substitution premise row R before the parallel-diamond row D is consumed.

Independence witness: finite-residual-join-window, metacic-confluence-diamond-ledger, metacic-local-join-ledger, metacic-residual-substitution-boundary, metacic-parallel-diamond-frontier: the finite residual join window records bounded residual data without the handoff envelope; the confluence diamond ledger records diamond-facing rows without this retained-premise packaging; the local join ledger records common-reduct data without the candidate-normalization row; the residual-substitution boundary records the premise without a handoff; and the parallel-diamond frontier consumes a conditional frontier rather than the residual-join envelope. None is bijective to MetaCICResidualJoinEnvelope$^{\uparrow}$.

The Lean-side TasteGate surface is expected to provide explicit `Nontrivial` and `FieldFaithful` instances for `BEDC.Derived.MetaCICResidualJoinEnvelopeUp`. Field faithfulness must keep W, R, L, C, D, H, T, P as distinct rows before any residual-diamond consumer reads the envelope.

Closure status for NameCert$_{\text{MetaCICResidualJoinEnvelope}^{\uparrow}}$.

Constructive story: A MetaCICResidualJoinEnvelope$^{\uparrow}$ packet is generated from a finite residual window, retained residual-substitution premise, local join row, candidate-normalization row, parallel-diamond handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{MetaCICResidualJoinEnvelope}^{\uparrow}}$, seed)

Scope closed: Definition 8558.1 and Definition 8558.2 seed the finite residual-window, local-join, candidate-normalization, and parallel-diamond handoff envelope.

Formal verification: FormalStatus(NameCert$_{\text{MetaCICResidualJoinEnvelope}^{\uparrow}}$, formalTarget)

Lean target: `BEDC.Derived.MetaCICResidualJoinEnvelopeUp`

Bridge status: none

Not claimed: This chapter does not close residual-substitution discharge, full closed confluence, strong normalization, subject reduction, evaluator equality, quotient term equality, kernel consistency, Lean theorem verification, or a public standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, residual-window exposure, retained-premise visibility, local-join accounting, candidate-normalization accounting, handoff nonescape, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICResidualJoinEnvelopeUp.

Chapter 8559

A Concrete Naming Certificate for MetaCICBoundedDiamondWindow$^{\uparrow}$

The MetaCICBoundedDiamondWindow$^{\uparrow}$ packet realizes the bounded-window handoff between candidate-mediated normalization in chapter 9383 and residual confluence visibility in chapter 9378. It sits beside the candidate normalization and confluence handoff of chapter 5547, the parallel-diamond frontier of chapter 4238, the proof-trace normal-form packet of chapter 5157, the finite-window confluence packet of chapter 6027, and the machine export boundary of chapter 5205. The packet records a finite audit window for candidate evidence, normal-form readback, residual-frontier rows, local diamond visibility, transport, replay, provenance, and local naming without claiming global strong normalization, unrestricted confluence, subject reduction, evaluator equality, quotient syntax equality, or kernel consistency.

Definition 8559.1 (MetaCIC bounded diamond window carrier)**.** *A* MetaCICBoundedDiamondWindow$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$D = (W, C, N, R, J, T, M, H, K, P, L)$$

with the following displayed rows:

1. *W is the bounded closed-term and redex-window row.*
2. *C is the candidate-evidence row consumed before any normalization handoff is read.*
3. *N is the normal-form readback row, compatible with the proof-trace normal-form sibling.*
4. *R is the residual-frontier row that records the two bounded branches and their retained obstruction surface.*
5. *J is the local diamond visibility row for candidate join data inside the same window.*
6. *T is the finite proof-trace row linking the normal-form and residual-frontier reads.*
7. *M is the machine export boundary row, recording which bounded evidence can be emitted without becoming a kernel oracle.*
8. *H records componentwise* hsame *transport for the window, candidate, normal-form, residual-frontier, local-join, proof-trace, and export-boundary rows.*
9. *K is the displayed* Cont *replay row for the bounded audit route.*

10. *P is the* Pkg *provenance over* MetaCICBoundedDiamondWindow$^{\uparrow}$, MetaCICCandidateNormalizationConfluenceHan MetaCICParallelDiamondFrontier$^{\uparrow}$, ProofTraceNormalForm$^{\uparrow}$, FiniteWindowConfluence$^{\uparrow}$, MachineExportBoundary$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *L is the local* NameCert$_{\text{MetaCICBoundedDiamondWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for a global strong-normalization theorem, global confluence theorem, subject reduction, evaluator equality, quotient syntax equality, kernel consistency, or unbounded machine export.

Theorem 8559.2 (MetaCIC bounded diamond window NameCert obligations)**.** *For every accepted* MetaCICBoundedDiamondWindow$^{\uparrow}$ *carrier $D = (W, C, N, R, J, T, M, H, K, P, L)$, the local* NameCert$_{\text{MetaCICBoundedDiamondWindow}^{\uparrow}}$ *surface consists exactly of bounded window exposure through W, candidate-evidence exposure through C, normal-form readback through N, residual-frontier exposure through R, local diamond visibility through J, proof-trace linkage through T, machine export boundary through M, componentwise* hsame *transport through H, displayed* Cont *replay through K, provenance through P, and local naming through L.*

Proof. Project the carrier of Definition 8559.1. The window row W fixes the closed-term and redex scope before any candidate or frontier evidence can be consumed.

Rows C, N, R, J, T form the handoff surface. Candidate evidence precedes the normalization readback, the residual frontier keeps both bounded branches visible, and the local diamond row records only the join data inside the same window.

Rows M, H, K, P, L preserve the boundary. Machine export remains mediated by the export boundary, while transport, replay, provenance, and local naming carry the same finite packet. Hence the listed rows exhaust the NameCert obligations and add no global normalization, global confluence, evaluator equality, quotient syntax equality, or kernel-consistency coordinate. □

Theorem 8559.3 (MetaCIC bounded diamond window nonescape)**.** *Every* MetaCICBoundedDiamondWindow$^{\uparrow}$ *consumer factors through*

$$W, C, N, R, J, T, M, H, K, P, L.$$

If a bounded window omits either candidate evidence or residual-frontier rows, it cannot certify both strong-normalization handoff and local diamond visibility. In particular, the packet cannot be consumed as a global strong-normalization theorem, unrestricted confluence theorem, subject-reduction theorem, evaluator oracle, quotient syntax equality, kernel-consistency certificate, or unbounded machine-export route.

Proof. Start with the obligation surface. It makes candidate evidence C and residual-frontier evidence R mandatory rows before the normal-form readback N and local diamond row J are public.

The sibling handoff and frontier chapters are consumed through the displayed packet. The candidate-normalization handoff supplies candidate-mediated normalization data, while the parallel-diamond and finite-window confluence siblings supply only bounded residual visibility.

The proof-trace and machine-export rows keep the route inspectable. They record which evidence is replayed and which bounded rows can be emitted, without adding a kernel oracle or an unbounded export channel. Thus a consumer missing C or R leaves the carrier, and the accepted packet cannot escape to any of the listed global claims. □

Falsifiable prediction: If a bounded window omits either candidate evidence or residual-frontier rows, it cannot certify both SN handoff and local diamond visibility.

Independence witness: metacic-candidate-normalization-confluence-handoff, metacic-parallel-diamond-frontier, proof-trace-normal-form, finite-window-confluence, machine-export-boundary: the candidate-normalization handoff omits the machine export boundary row; the parallel-diamond frontier retains residual confluence rows without the normal-form proof trace; the proof-trace normal form omits the residual-frontier join row; the finite-window confluence packet omits candidate evidence; and the machine export boundary omits the local diamond visibility row. None is row-bijective to $\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}$.

The future Lean TasteGate surface must provide `Nontrivial` and `FieldFaithful` instances for `BEDC.Derived.MetaCICBoundedDiamondWindowUp`. Field faithfulness must keep $W, C, N, R, J, T, M, H, K, P, L$ distinct before any normalization or confluence consumer reads the bounded window.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}$ packet is generated from a bounded closed-term redex window, candidate evidence, normal-form readback, residual-frontier rows, local diamond visibility, proof-trace linkage, machine export boundary, componentwise hsame transport, Cont replay, Pkg provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8559.1, Definition 8559.2, and Definition 8559.3 seed the bounded candidate-normalization and residual-diamond handoff window.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedDiamondWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim global strong normalization, unrestricted confluence, subject reduction, evaluator equality, quotient syntax equality, kernel consistency, Lean verification, axiom-clean audit, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, candidate evidence, normal-form readback, residual-frontier exposure, local diamond visibility, proof-trace linkage, machine export boundary, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICBoundedDiamondWindow

Chapter 8560

A Concrete Naming Certificate for MetaCICBoundedChurchRosserFragment$^{\uparrow}$

The MetaCICBoundedChurchRosserFragment$^{\uparrow}$ packet realizes the conditional confluence boundary of section 9378.3 as finite NameCert data. It sits beside the critical-path source of chapter 765, the typed parallel-diamond boundary of chapter 6433, the parallel-diamond frontier of chapter 4238, and the confluence audit packet of chapter 735. The packet records atom fragments, normal-source fragments, conditional diamond rows, obstruction retention, transport, replay, provenance, and local naming without claiming full Church–Rosser, residual-substitution discharge, subject reduction, quotient syntax equality, or kernel consistency.

Definition 8560.1 (MetaCIC bounded Church–Rosser fragment carrier)**.** *A* MetaCICBoundedChurchRosserFragme *carrier is a finite* BHist *packet*

$$M = (A, N, C, O, T, R, P, S, H)$$

with the following visible rows:

1. *A is the atom fragment row, retaining the unconditional atom joins already exposed by the checked confluence substrate;*
2. *N is the normal-source row, retaining the unconditional closed-normal fragments already exposed by the checked substrate;*
3. *C is the conditional-diamond row, recording the substitution-sensitive bridge to the parallel-diamond frontier;*
4. *O is the obstruction row, keeping the residual-substitution boundary visible rather than silently discharged;*
5. *T is the typed-window row, recording the finite confluence input window read by the audit map;*
6. *R is the residual-frontier row, tracking the residual-premise budget available to the bridge;*
7. *P is the* MetaCICParallelDiamondFrontier$^{\uparrow}$ *provenance row consumed by the fragment;*
8. *S is the* MetaCICTypedParallelDiamondBoundary$^{\uparrow}$ *source row, exposing the typed boundary before the conditional bridge is read;*
9. *H records componentwise* hsame *transport for the atom, normal-source, conditional-diamond, obstruction, typed-window, residual-frontier, provenance, source, and local naming rows.*

The carrier has no coordinate for full Church–Rosser, residual-substitution discharge, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency.

Theorem 8560.2 (MetaCIC bounded Church–Rosser fragment NameCert obligations)**.** *For every accepted* $\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}$ *carrier*

$$M = (A, N, C, O, T, R, P, S, H),$$

the local $\mathsf{NameCert}_{\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows, atom-fragment exposure through A, normal-source exposure through N, conditional-diamond exposure through C, obstruction retention through O, typed-window exposure through T, residual-frontier exposure through R, parallel-frontier provenance through P, typed-boundary source exposure through S, and componentwise transport through H.*

Proof. Project the carrier of Definition 8560.1. The packet displays the atom and normal-source fragments, the conditional diamond row, the obstruction row, the typed window, the residual frontier, the provenance row, the typed boundary source, and the transport row.

Atom and normal-source exposure are the unconditional part of the packet. Those rows record the checked fragments already available from the confluence substrate, so the packet can name them without turning them into a global confluence theorem.

The conditional-diamond row C and obstruction row O keep the residual-substitution boundary visible. The typed-window row T, residual-frontier row R, provenance row P, and source row S place that conditional bridge inside the same finite audit surface rather than outside it.

The structural row H only transports the displayed packet. Because the carrier has no coordinate for full Church–Rosser, residual-substitution discharge, subject reduction, quotient syntax equality, evaluator equality, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 8560.3 (MetaCIC bounded Church–Rosser fragment conditional route)**.** *Every accepted* $\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}$ *packet factors its confluence-facing read through the displayed route*

$$\mathsf{MetaCICCriticalPath}^{\uparrow} \longmapsto \mathsf{MetaCICTypedParallelDiamondBoundary}^{\uparrow} \longmapsto \mathsf{MetaCICParallelDiamondFrontier}^{\uparrow} \longmapsto \mathsf{Meta}$$

The route first opens the critical path, then the typed boundary, then the parallel frontier, and only then the audit packet. The fragment therefore names a bounded Church–Rosser boundary, not a full closed Church–Rosser theorem or a residual-substitution discharge.

Proof. Start with the critical-path surface. It supplies the finite source package from which the confluence audit map reads its candidate evidence.

Next read the typed parallel-diamond boundary. That boundary keeps the typed-window and residual-substitution rows visible before any conditional bridge is consumed.

Then read the parallel-diamond frontier. The frontier keeps the local-join and obstruction rows visible, so the route remains conditional rather than unconditional.

Finally consume the audit packet. The route reaches the confluence audit map only after the checked fragments and boundary rows have been displayed, so it cannot be reinterpreted as full Church–Rosser, residual-substitution discharge, or kernel consistency. □

Theorem 8560.4 (MetaCIC bounded Church–Rosser fragment nonescape)**.** *Every accepted* $\mathsf{MetaCICBoundedChurc}$ *consumer must keep the atom fragment, normal-source fragment, conditional-diamond row, obstruction row, typed-window row, residual-frontier row, provenance row, and typed-boundary source*

row visible before citing the packet as confluence evidence. No consumer may replace that route by full Church–Rosser, residual-substitution discharge, subject reduction, quotient syntax equality, or kernel consistency.

Proof. Project the accepted carrier of Definition 8560.1. The visible rows are atom, normal-source, conditional diamond, obstruction, typed-window, residual-frontier, provenance, source, and transport.

Apply the NameCert obligations of Definition 8560.2. They keep the unconditional fragments and the conditional bridge separate, so a consumer must display the boundary rows before the fragment may be cited.

Use the conditional route of Definition 8560.3. It forces the confluence-facing read through the critical-path, typed-boundary, frontier, and audit rows, and therefore prevents the packet from being cited as full Church–Rosser or a residual-substitution discharge. □

Falsifiable prediction: An accepted $\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}$ packet that is cited as confluence evidence must display atom-fragment, normal-source, conditional-diamond, obstruction, typed-window, residual-frontier, provenance, source, and transport rows.

Independence witness: metaciccriticalpath, metacic-parallel-diamond-frontier, metacic-typed-parallel-diamond-boundary, metacicconfluenceauditpacket: none is bijective to MetaCICBoundedChurchRosserFragm because this packet jointly carries the atom fragment, normal-source fragment, conditional-diamond row, obstruction row, typed-window row, residual-frontier row, provenance row, source row, and transport row that keep the conditional boundary finite. The Lean TasteGate.lean follow-up must provide Nontrivial and FieldFaithful instances for the same carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}$ packet is generated from atom fragments, normal-source fragments, a conditional-diamond row, an obstruction row, a typed-window row, a residual-frontier row, a parallel-frontier provenance row, a typed-boundary source row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8560.1, Definition 8560.2, Definition 8560.3, and Definition 8560.4 bind the finite conditional confluence boundary for atom fragments, normal-source fragments, typed windows, residual frontiers, obstruction retention, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICBoundedChurchRosserFragment}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim full Church–Rosser, residual-substitution discharge, subject reduction, quotient syntax equality, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked atom-fragment exposure, normal-source exposure, conditional-diamond routing, obstruction retention, typed-window exposure, residual-frontier exposure, transport, replay, provenance, and local naming for BEDC.Derived.MetaCICBoundedChurchRosserFragmentUp.

Chapter 8561

A Concrete Naming Certificate for $\mathsf{TightApartness}^{\uparrow}$

Following Bishop and Bridges, a tight apartness relation is read as positive separation evidence whose non-apartness boundary agrees with the displayed equality classifier. The $\mathsf{TightApartness}^{\uparrow}$ packet sits between the constructive apartness surface of chapter 1380, the positive-distance route of chapter 3505, and the terminal real-name seal of chapter 38. It gives equality-facing consumers a finite apartness boundary without importing trichotomy, quotient equality, selected points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8561.1 (Tight apartness carrier)**.** *A* $\mathsf{TightApartness}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, E, T, S, C, H, R, P, N)$$

with the following displayed rows:

1. *A is the apartness evidence row. It records the positive separation branch read from a* $\mathsf{LocatedApartness}^{\uparrow}$ *or* $\mathsf{MetricApartness}^{\uparrow}$ *source before any equality-facing conclusion is exported.*
2. *E is the equality/classifier row. It records the classifier boundary whose accepted equality branch is the only branch allowed to match non-apartness.*
3. *T is the tightness row. It states that a displayed failure to produce apartness at the inspected boundary routes to the classifier row E, rather than to trichotomy or host negation.*
4. *S is the symmetry and cotransitivity-facing stability row. It keeps the positive apartness evidence stable under endpoint swap and under finite cotransitivity witnesses.*
5. *C records displayed* Cont *replay from an apartness or equality-boundary request through A, E, T, S, H, R, P, N.*
6. *H records componentwise* hsame *transport for apartness evidence, classifier rows, tightness boundaries, stability rows, replay, provenance, and the local name.*
7. *R is the Real-facing readback row. It allows a downstream* $\mathsf{Real}^{\uparrow}$ *consumer to inspect the same positive gap or non-apartness boundary without receiving a completed real equality theorem.*
8. *P is the* Pkg *provenance over* $\mathsf{TightApartness}^{\uparrow}$*,* $\mathsf{LocatedApartness}^{\uparrow}$*,* $\mathsf{MetricApartness}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{TightApartness}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $A, E, T, S, C, H, R, P, N$. It has no coordinate for trichotomy, quotient equality, selected points, countable choice, or ambient real completeness.

Theorem 8561.2 (Tight apartness NameCert obligations)**.** *For every accepted* $\mathsf{TightApartness}^{\uparrow}$ *carrier* $K = (A, E, T, S, C, H, R, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{TightApartness}^{\uparrow}}$ *surface consists exactly of carrier admission, apartness-evidence visibility, classifier-boundary visibility, tightness of non-apartness against the classifier row, symmetry and cotransitivity-facing stability, displayed replay, componentwise transport, Real-facing readback, provenance, and local naming. Every obligation is checked along the finite route*

$$A \longmapsto E \longmapsto T \longmapsto S \longmapsto C, H, R, P, N.$$

No obligation row exports trichotomy, quotient equality, selected points, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8561.1. The row A is the only source of positive apartness evidence, and the row E is the only equality/classifier boundary available to an equality-facing consumer.

The tightness row T binds non-apartness to E. Since the carrier has no total comparison row, this boundary is a finite classifier handoff rather than a trichotomy decision or host negation principle.

The stability row S keeps the apartness branch attached under endpoint swap and finite cotransitivity-facing transport. The rows C, H, R, P, N then replay, transport, read back, source, and name the same finite route.

Thus the local NameCert surface is exhausted by the listed rows. The excluded trichotomy, quotient, selection, choice, and real-completeness data are not carrier coordinates. □

Theorem 8561.3 (Tight apartness Real handoff)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{TightApartness}^{\uparrow}$ *packet must first read the apartness evidence row A, the equality/classifier row E, the tightness row T, and the stability row S, and only then consume C, H, R, P, N. The handoff therefore exposes a finite apartness-based equality boundary compatible with chapter 1380 and chapter 3505, while keeping the terminal real-name seal of chapter 38 downstream of displayed evidence.*

Proof. Begin with an equality-facing Real request. The carrier permits no direct read of host real equality, so the request first opens the apartness evidence row A and the classifier row E.

Read tightness through T. A non-apartness boundary is accepted only as the displayed classifier boundary, while a positive branch remains the evidence row named by A.

Use S to preserve this route under symmetry and finite cotransitivity-facing witnesses. Finally C, H, R, P, N replay, transport, read back, source, and name the same packet for the Real-facing consumer.

The consumer therefore receives an apartness-based equality boundary and no trichotomy, quotient equality, selected point, countable-choice schedule, or ambient real-completeness theorem. □

Falsifiable prediction: Every accepted $\mathsf{TightApartness}^{\uparrow}$ read factors through apartness evidence, an equality/classifier row, a tightness boundary, symmetry and cotransitivity-facing stability, replay, transport, Real-facing readback, provenance, and local naming before any equality-facing consumer reads a conclusion.

Independence witness: located-apartness, metric-apartness, real: $\mathsf{TightApartness}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries positive apartness evidence, a non-apartness-to-classifier boundary, stability rows, Real-facing readback, transport, replay, provenance, and local naming as one tightness packet.

Closure status for $\mathsf{NameCert}_{\mathsf{TightApartness}^{\uparrow}}$.

Constructive story: A $\mathsf{TightApartness}^{\uparrow}$ packet is generated from apartness evidence, an equality/classifier row, a tightness boundary, symmetry and cotransitivity-facing stability, displayed Cont replay, componentwise hsame transport, Real-facing readback, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TightApartness}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8561.1, Definition 8561.2, and Definition 8561.3 seed the finite apartness-based equality boundary over located apartness, metric apartness, and Real-facing readback rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TightApartness}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim trichotomy, quotient equality, selected points, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, apartness-evidence visibility, classifier-boundary visibility, tightness of non-apartness, stability, replay, transport, Real-facing readback, provenance, and local naming for BEDC.Derived.TightApartnessUp.

Chapter 8562

A Concrete Naming Certificate for $\mathsf{CompletionExponentialLaw}^{\uparrow}$

Following Mac Lane and Bishop–Bridges, the $\mathsf{CompletionExponentialLaw}^{\uparrow}$ packet records the finite completion-law surface by which a completion functor distributes over an exponential-style function object only through displayed completion rows. It sits after the functor packet of chapter 423, the monad packet of chapter 378, the unit packet of chapter 1527, the multiplication packet of chapter 1829, and the universal-property packet of chapter 397. The chapter names a standard completion-law handoff as finite NameCert data; it is not host cartesian closedness, not quotient equality of completed maps, not a selected limit, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8562.1 (Completion exponential law carrier)**.** *A* $\mathsf{CompletionExponentialLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, M, U, T, E, W, R, D, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{CauchyCompletionFunctor}^{\uparrow}$ *exposure row, recording the completion functor read used by the law.*
2. *M is the* $\mathsf{CauchyCompletionMonad}^{\uparrow}$ *row, recording the shared monad surface consumed by the unit and multiplication faces.*
3. *U is the* $\mathsf{CauchyCompletionUnit}^{\uparrow}$ *row, naming the unit side of the exponential-law comparison.*
4. *T is the* $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$ *row, naming the multiplication side of the comparison.*
5. *E is the exponential-function window row, listing the displayed source and target function windows inspected by the packet.*
6. *W is the finite completion-window row, recording the common finite Cauchy windows through which both sides are read.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row used for rational regularity checks along the finite windows.*
8. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row used to compare the two completion reads.*
9. *H records componentwise* hsame *transport for F, M, U, T, E, W, R, D and the local structural rows.*
10. *C records displayed* Cont *replay from a completion-law request through the same functor, monad, unit, multiplication, window, readback, tolerance, transport, provenance, and local naming rows.*

11. *P is the* Pkg *provenance over* $\mathsf{CompletionExponentialLaw}^{\uparrow}$, $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$ $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

12. *N is the local* $\mathsf{NameCert}_{\mathsf{CompletionExponentialLaw}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $F, M, U, T, E, W, R, D, H, C, P, N$. It has no coordinate for host exponentials, quotient equality of completed maps, selected representatives, selected limits, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8562.2 (Completion exponential law NameCert obligations)**.** *For every accepted* CompletionExponentialL *carrier*

$$L = (F, M, U, T, E, W, R, D, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{CompletionExponentialLaw}^{\uparrow}}$ *surface consists exactly of the following five obligation rows:*

1. *carrier admission for the displayed packet L and its structural rows H, C, P, N;*
2. *completion-functor exposure through F, read as the functorial source already named by chapter 423;*
3. *unit and multiplication coherence through M, U, T, read through chapter 378, chapter 1527, and chapter 1829;*
4. *universal-property handoff through the* $\mathsf{CompletionUniversalProperty}^{\uparrow}$ *source of chapter 397;*
5. *Real, RegSeqRat, and Dyadic nonescape through W, R, D, requiring every Real-facing consumer to pass through finite completion windows, regular rational readback, and dyadic tolerance rows before a terminal* $\mathsf{Real}^{\uparrow}$ *seal is read.*

Every completion-law-facing consumer must read these rows before treating the law as a standard completion interface. It receives no host exponential object, no quotient equality of completed maps, no selected representative, no selected limit, no countable-choice schedule, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no Lean-checked bridge from this packet.*

Proof. Project the carrier in Definition 8562.1. The accepted packet exposes exactly $F, M, U, T, E, W, R, D, H, C, P,$

The completion rows F, M, U, T bind the law to the existing functor, monad, unit, and multiplication packets. The universal-property read is therefore a handoff through named completion rows, not an external mapping-space theorem.

The finite rows E, W, R, D keep the exponential comparison observable. Function windows, completion windows, regular rational readback, and dyadic tolerances are inspected before any Real-facing seal can be consumed.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the refused host exponentials, quotient equalities, selected limits, choice schedules, and ambient completeness objects have no carrier coordinate, the five rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every public $\mathsf{CompletionExponentialLaw}^{\uparrow}$ read factors through displayed $\mathsf{CauchyCompletionFunctor}^{\uparrow}$, $\mathsf{CauchyCompletionMonad}^{\uparrow}$, $\mathsf{CauchyCompletionUnit}^{\uparrow}$, $\mathsf{CauchyCompletionMultiplication}^{\uparrow}$, $\mathsf{CompletionUniversalProperty}^{\uparrow}$, finite completion-window, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, hsame, Cont, Pkg, and local NameCert rows. A public read that exports host exponentials, quotient equality of completed maps, selected representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean bridge verification from this packet refutes the carrier boundary.

Independence witness: cauchycompletionfunctor, cauchycompletionmonad, cauchycompletionunit, cauchycompletionmultiplication, completionuniversalproperty: $\mathsf{CompletionExponentialLaw}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the completion functor, monad, unit, multiplication, universal-property handoff, finite exponential windows, regular rational readback, dyadic tolerance, transport, replay, provenance, and local naming while refusing host exponential and quotient endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{CompletionExponentialLaw}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CompletionExponentialLaw}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8562.1 and Definition 8562.2 seed the finite completion-law packet over functor, monad, unit, multiplication, universal-property handoff, finite window, rational readback, dyadic tolerance, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CompletionExponentialLaw}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host exponentials, quotient equality of completed maps, selected representatives, selected limits, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, completion-functor exposure, unit and multiplication coherence, universal-property handoff, Real/RegSeqRat/Dyadic nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CompletionExponentialLawUp.

Constructive story: A $\mathsf{CompletionExponentialLaw}^{\uparrow}$ packet is generated from CauchyCompletionFunctor, CauchyCompletionMonad, CauchyCompletionUnit, CauchyCompletionMultiplication, CompletionUniversalProperty, finite completion-window, RegSeqRat, DyadicRatCore, Real, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 8563

A Concrete Naming Certificate for $\mathsf{TraceTheorem}^{\uparrow}$

Following Sobolev and Lions–Magenes trace theory, the $\mathsf{TraceTheorem}^{\uparrow}$ packet records the finite boundary-read surface by which a Sobolev-class object exposes boundary data to Real-facing and variational consumers. It sits beside the Sobolev embedding route of chapter 2217, the boundary-control estimate of chapter 2329, the compact Sobolev route of chapter 2218, and the scalar readback seal of chapter 38. The packet is a NameCert surface for boundary trace rows; it is not a host trace theorem, a selected representative, or a quotient boundary-function space.

8563.1 Carrier

Definition 8563.1 (Trace theorem carrier)**.** *A* $\mathsf{TraceTheorem}^{\uparrow}$ *carrier is a finite packet*

$$T = (D, S, E, P, K, B, R, H, C, N)$$

with the following displayed rows:

1. *D is the domain and boundary-admissibility row, read through the metric, compact, or bounded-domain surface used by the surrounding Sobolev certificates.*
2. *S is the* $\mathsf{SobolevEmbedding}^{\uparrow}$ *source row that exposes the Sobolev regularity, exponent ledger, weak-derivative data, and scalar* $\mathsf{Real}^{\uparrow}$ *readback before any boundary value is consumed.*
3. *E is the* $\mathsf{PoincareInequality}^{\uparrow}$ *control row, recording the norm or anchored-boundary estimate that prevents constants and detached representatives from escaping the packet.*
4. *P is the* $\mathsf{RellichKondrachov}^{\uparrow}$ *compact-window row when a compact trace window is present, and an explicit boundary marker when no compact-window read is used.*
5. *K is the finite boundary-test schedule: a list of carried boundary windows and scalar probes whose values are read through* $\mathsf{Real}^{\uparrow}$*.*
6. *B is the boundary trace row binding each displayed boundary probe to the Sobolev source row.*
7. *R, H, C, N record replay, componentwise transport, continuation, and local* $\mathsf{NameCert}_{\mathsf{TraceTheorem}^{\uparrow}}$ *evidence over the same finite rows.*

The classifier compares two trace packets only by inherited transport of these rows. It does not identify host functions, quotient boundary classes, selected traces, or all boundary representatives.

8563.2 Obligations

Theorem 8563.2 (TraceTheorem NameCert obligations)**.** *Every accepted* $\mathsf{TraceTheorem}^{\uparrow}$ *packet exposes exactly the carrier rows of Definition 8563.1: domain admission, Sobolev embedding source, Poincare control, optional Rellich–Kondrachov compact window, finite boundary-test schedule, boundary trace ledger, replay, transport, continuation, and local naming. A consumer may cite the packet only after the sibling rows* $\mathsf{SobolevEmbedding}^{\uparrow}$, $\mathsf{PoincareInequality}^{\uparrow}$, $\mathsf{RellichKondrachov}^{\uparrow}$, *and* $\mathsf{Real}^{\uparrow}$ *have been displayed in the active branch.*

Proof. Project the carrier row by row. The source coordinate S supplies the Sobolev embedding and scalar readback data before the boundary ledger is visible, while E supplies the Poincare control row that keeps the estimate anchored to displayed finite data.

If the compact boundary route is present, the P coordinate reads it through the Rellich–Kondrachov row. If that route is absent, the boundary marker records the absence explicitly, so no compactness theorem can be inferred from the carrier alone.

Finally read K, B, R, H, C, N. These rows expose finite boundary probes, the boundary ledger, replay, transport, continuation, and local naming evidence. Since no row contains a host restriction operator, quotient boundary-function equality, selected representative, unrestricted extension theorem, or ambient completeness proof, the packet exports only the listed NameCert obligations. □

Theorem 8563.3 (TraceTheorem boundary route)**.** *Every* $\mathsf{TraceTheorem}^{\uparrow}$ *boundary consumer factors through the finite route*

$$\mathsf{SobolevEmbedding}^{\uparrow} \longmapsto \mathsf{PoincareInequality}^{\uparrow} \longmapsto \mathsf{RellichKondrachov}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

whenever the compact branch is active, and through the same Sobolev, Poincare, and Real rows with an explicit compact-window absence marker otherwise. The route supplies finite boundary probe values and their transport ledger; it does not supply a full host trace theorem, a global extension operator, a quotient boundary space, selected representatives, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Begin with the source and control rows S and E. They force every boundary read to pass through the Sobolev embedding and Poincare control surfaces before the boundary ledger can be consumed.

For the compact branch, read P through the Rellich–Kondrachov row and then seal boundary probe values through $\mathsf{Real}^{\uparrow}$. For the non-compact branch, the absence marker blocks any inference of compact trace data while leaving the displayed Sobolev, Poincare, and Real rows available.

Transport and replay are componentwise through R, H, C, N. Therefore a consumer receives only the finite boundary-route certificate, not a host trace theorem or any unlisted analytic object. □

Closure status for $\mathsf{NameCert}_{\mathsf{TraceTheorem}^{\uparrow}}$.

Constructive story: A $\mathsf{TraceTheorem}^{\uparrow}$ packet is generated from a domain-boundary row, Sobolev embedding source, Poincare control row, optional Rellich–Kondrachov compact-window row, finite boundary-test schedule, boundary trace ledger, replay, componentwise transport, continuation, and local naming evidence.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{TraceTheorem}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8563.1, Definition 8563.2, and Definition 8563.3 name the finite boundary-trace carrier, its NameCert obligation surface, and its sibling dependency route through SobolevEmbedding, PoincareInequality, RellichKondrachov, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{TraceTheorem}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host trace theorem, selected boundary representative, quotient boundary-function equality, unrestricted extension operator, Lean verification, or bridge checking.

Upgrade path: Formalization requires a Lean carrier for BEDC.Derived.TraceTheoremUp and checked obligation plus boundary-route theorems over the displayed sibling rows.

Chapter 8564

A Concrete Naming Certificate for $\mathsf{BMOFiniteWindow}^{\uparrow}$

Following John and Nirenberg, the $\mathsf{BMOFiniteWindow}^{\uparrow}$ packet records the finite bounded-mean-oscillation surface by which a displayed function window exposes local average deviation, dyadic scale control, and Calderon–Zygmund handoff data before any quotient function space or measure completion is imported. It sits after the real readback surface of chapter 38, the dyadic scalar ledger of chapter 291, the maximal-function consumer of chapter 3581, the weight-window route of chapter 6590, and the singular-integral handoff of chapter 7928. The packet names only finite rows: inspected windows, displayed averages, oscillation bounds, dyadic budgets, maximal and weighted consumers, Calderon–Zygmund provenance, transport, replay, and local NameCert evidence.

Definition 8564.1 (BMO finite-window carrier)**.** *A* $\mathsf{BMOFiniteWindow}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (S, W, A, O, D, M, Q, Z, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite source row naming the displayed function or scalar sample family whose oscillation is inspected.*
2. *W is the finite window ledger of balls, intervals, or dyadic cubes on which averages are allowed to be read.*
3. *A records the* $\mathsf{Real}^{\uparrow}$ *average readback on each displayed window.*
4. *O records the mean-oscillation bound row comparing the local deviation from A with the displayed tolerance.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale and tolerance ledger for window inclusion, subdivision, and oscillation comparisons.*
6. *M is the* $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ *consumer row allowed to read the displayed average-deviation data.*
7. *Q is the* $\mathsf{MuckenhouptWeight}^{\uparrow}$ *compatibility row for weighted finite-window consumers.*
8. *Z is the* $\mathsf{CalderonZygmundOperator}^{\uparrow}$ *handoff row, recording which truncated singular-integral request may consume the oscillation packet.*
9. *H records componentwise* hsame *transport for source, window, average, oscillation, dyadic, consumer, handoff, replay, provenance, and local naming rows.*

10. *C records displayed* Cont *replay from window selection to average readback, oscillation comparison, and consumer handoff.*
11. *P is the* Pkg *provenance over* $\mathsf{BMOFiniteWindow}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$, $\mathsf{MuckenhouptWeight}^{\uparrow}$, $\mathsf{CalderonZygmundOperator}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
12. *N is the local* $\mathsf{NameCert}_{\mathsf{BMOFiniteWindow}^{\uparrow}}$ *row.*

The carrier has no coordinate for an equivalence class modulo constants, a completed BMO *normed space, a John–Nirenberg exponential-integrability theorem, selected representatives, ambient measure completion, quotient function equality, or a host singular-integral theorem.*

Theorem 8564.2 (BMO finite-window NameCert obligations)**.** *For every accepted* $\mathsf{BMOFiniteWindow}^{\uparrow}$ *carrier*

$$B = (S, W, A, O, D, M, Q, Z, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BMOFiniteWindow}^{\uparrow}}$ *surface consists exactly of source admission through S, finite-window exposure through W,* $\mathsf{Real}^{\uparrow}$ *average readback through A, mean-oscillation comparison through O,* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale accounting through D, maximal and weighted consumer exposure through M, Q, Calderon–Zygmund handoff through Z, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8564.1. The tuple displays the source, inspected windows, averages, oscillation comparison, dyadic ledger, maximal consumer, weighted compatibility, Calderon–Zygmund handoff, transport, replay, provenance, and local name.

The scalar rows are read first. The average row A is sealed through $\mathsf{Real}^{\uparrow}$, while the window and tolerance comparisons in D are read through $\mathsf{DyadicRatCore}^{\uparrow}$; no host completion or quotient representative is introduced by those reads.

The consumer rows then expose M, Q, Z. These rows name the allowed Hardy–Littlewood maximal, Muckenhoupt-weight, and Calderon–Zygmund consumers, so the local certificate is exhausted by the displayed finite-window route before H, C, P, N transport, replay, package, and name it. □

Theorem 8564.3 (BMO finite-window mean-oscillation induction)**.** *Any induction over accepted* $\mathsf{BMOFiniteWindow}^{\uparrow}$ *mean-oscillation reads proceeds only by extending the finite window ledger W with a displayed window whose* $\mathsf{Real}^{\uparrow}$ *average row A, oscillation comparison row O, and* $\mathsf{DyadicRatCore}^{\uparrow}$ *scale row D are already present. The induction step may transport the ledger by H and replay it by C, but it cannot infer an ambient* BMO *quotient class, an unrestricted supremum over all windows, or a completed norm from the finite packet.*

Proof. The base case is the empty or singleton displayed-window ledger, where the only readable data are the rows named in Definition 8564.1. The local NameCert obligations of Definition 8564.2 require average, oscillation, and dyadic rows before a window contributes to the packet.

For the extension step, append one displayed window to W. Its average is read through A, its deviation comparison through O, and its scale and tolerance budget through D; the rows H and C only preserve this already displayed data under transport and replay.

Thus the induction remains finite-window induction. Since neither the carrier nor the obligation surface contains a coordinate for quotient representatives, unrestricted window suprema, or completed norms, no such object is exposed by the induction. □

Theorem 8564.4 (BMO finite-window Calderon-Zygmund handoff)**.** *Every* $\mathsf{CalderonZygmundOperator}^{\uparrow}$ *consumer of an accepted* $\mathsf{BMOFiniteWindow}^{\uparrow}$ *packet must read the finite route*

$$S, W, A, O, D, M, Q, Z, H, C, P, N$$

through the displayed average, oscillation, dyadic, maximal, and weighted rows before the handoff row Z *is available. In particular, the consumer receives a finite oscillation certificate for inspected windows, not a principal-value theorem, a quotient function-space theorem, a completed measure-space theorem, or an ambient weak-type estimate.*

Proof. Start from the obligation theorem. The handoff row Z appears only after S, W, A, O, D, M, Q have been displayed in the same packet.

The maximal row M records the $\mathsf{HardyLittlewoodMaximal}^{\uparrow}$ route for local average control, and the weighted row Q records the $\mathsf{MuckenhouptWeight}^{\uparrow}$ compatibility route for weighted finite-window consumers. The dyadic ledger D and real average row A keep the scalar content inside $\mathsf{DyadicRatCore}^{\uparrow}$ and $\mathsf{Real}^{\uparrow}$ readback.

Therefore a Calderon–Zygmund consumer can inspect only the finite oscillation certificate carried by Z together with the preceding rows. The packet exposes no principal value, quotient function equality, completed measure space, or global weak-type estimate. □

Falsifiable prediction: A $\mathsf{CalderonZygmundOperator}^{\uparrow}$ request that cites a $\mathsf{BMOFiniteWindow}^{\uparrow}$ handoff without displayed average, oscillation, dyadic scale, maximal-consumer, and weighted-compatibility rows refutes the local carrier.

Independence witness: real, dyadicratcore, hardy-littlewood-maximal, muckenhoupt-weight, calderon-zygmund-operator: none is bijective to $\mathsf{BMOFiniteWindow}^{\uparrow}$ because this packet jointly carries source, finite-window, average, oscillation, dyadic, maximal-consumer, weighted-compatibility, Calderon–Zygmund handoff, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{BMOFiniteWindow}^{\uparrow}}$**.**

Constructive story: A $\mathsf{BMOFiniteWindow}^{\uparrow}$ packet is generated from a source row, finite inspected windows, RealUp average readback, mean-oscillation comparison, DyadicRatCoreUp scale accounting, HardyLittlewoodMaximalUp and MuckenhouptWeightUp consumer rows, CalderonZygmundOperatorUp handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BMOFiniteWindow}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8564.1, Definition 8564.2, Definition 8564.3, and Definition 8564.4 seed the finite bounded-mean-oscillation NameCert surface for inspected windows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BMOFiniteWindow}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim a completed BMO space, quotient equality modulo constants, John–Nirenberg exponential integrability, principal values, weak-type estimates, measure completion, Lean verification, or a standard bridge.

Upgrade path: Obligation closure requires checked source admission, finite-window exposure, Real average readback, oscillation comparison, dyadic scale accounting, maximal and weighted consumer exposure, Calderon–Zygmund handoff, transport, replay, provenance, and local naming for BEDC.Derived.BMOFiniteWindowUp.

Chapter 8565

A Concrete Naming Certificate for $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$

Following Bishop–Bridges diagonal arguments, the $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ packet records the finite route by which a displayed stream diagonal is read as completion-facing Cauchy data before a terminal Real seal is available. It sits after the stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name surface of chapter 38, and the completion operator of chapter 3379. The packet supplies a completion-facing diagonal route for compact-uniform Cauchy consumers; it is not a selected subsequence principle, not quotient stream equality, not countable choice, and not ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8565.1 (Stream diagonalization completion carrier)**.** *A* $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (S, R, D, E, O, W, B, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *row naming the finite stream windows and diagonal schedule inspected by the packet.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational values exposed along the diagonal windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row that compares diagonal windows at the requested finite depths.*
4. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after the stream, regular-rational, and dyadic rows have been displayed.*
5. *O is the* $\mathsf{CauchyCompletionOperator}^{\uparrow}$ *row that receives the diagonal data as a completion-facing operator request.*
6. *W is the finite diagonal-window ledger, recording the source window, target window, and diagonal cut inspected for each completion read.*
7. *B is the compact-uniform Cauchy consumer boundary, recording the finite compact source and uniform-modulus read that asks for the diagonal completion handoff.*
8. *H records componentwise* hsame *transport for S, R, D, E, O, W, B and the local structural rows.*

9. *C records displayed* Cont *replay from a compact-uniform Cauchy request through the same stream, rational, dyadic, Real, completion-operator, window, boundary, transport, provenance, and local naming rows.*
10. *P is the* Pkg *provenance over* $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionOperator}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
11. *N is the local* $\mathsf{NameCert}_{\mathsf{StreamDiagonalizationCompletion}^{\uparrow}}$ *row.*

The carrier compares accepted packets only through $S, R, D, E, O, W, B, H, C, P, N$. It has no coordinate for selected subsequences, quotient stream equality, selected limits, countable choice, host compactness, host completion operators, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8565.2 (Stream diagonalization completion NameCert obligations)**.** *For every accepted* $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ *carrier*

$$G = (S, R, D, E, O, W, B, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StreamDiagonalizationCompletion}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rows; finite StreamName diagonal exposure through S; regular rational readback through R; dyadic tolerance exposure through D; terminal Real sealing through E; completion-operator handoff through O; compact-uniform Cauchy consumer boundary through B; finite diagonal-window replay through W; componentwise transport through H; displayed replay through C; provenance through P; and local naming through N.*

Every compact-uniform Cauchy consumer must read those finite rows before using the diagonalization as completion data. It receives no selected subsequence, no quotient stream equality, no selected limit, no countable-choice schedule, no host compactness theorem, no host completion operator, no ambient $\mathsf{Real}^{\uparrow}$ *completeness theorem, and no Lean-checked bridge from this packet.*

Proof. Project the carrier in Definition 8565.1. Carrier admission exposes exactly $S, R, D, E, O, W, B, H, C, P, N$.

The analytic route starts with S, R, D. These rows display the stream windows, regular rational readbacks, and dyadic tolerance comparisons that make the diagonal finite.

The completion route then reads E, O, W, B. The Real seal is downstream of the finite stream data, the completion operator receives only that displayed diagonal route, and the compact-uniform consumer boundary records the request without adding host compactness.

The structural rows H, C, P, N transport, replay, source, and name the same packet. Since the refused selected-subsequence, quotient, limit-selection, choice, host-completion, and ambient-completeness objects have no coordinate, the displayed rows exhaust the local NameCert obligations. □

Falsifiable prediction: Every public $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ read factors through displayed $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CauchyCompletionOperator}^{\uparrow}$, finite diagonal-window, compact-uniform Cauchy consumer, hsame, Cont, Pkg, and local NameCert rows. A public read that exports selected subsequences, quotient stream equality, selected limits, countable choice, host compactness, host completion operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, or Lean bridge verification from this packet refutes the carrier boundary.

Independence witness: streamname, regseqrat, dyadicratcore, real, cauchycompletionoperator: $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries finite stream windows, regular rational readback, dyadic tolerance, terminal Real sealing, completion-operator handoff, compact-uniform Cauchy boundary, transport, replay, provenance, and local naming while refusing selected-subsequence and quotient endpoints.

Closure status for $\mathsf{NameCert}_{\mathsf{StreamDiagonalizationCompletion}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StreamDiagonalizationCompletion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8565.1 and Definition 8565.2 seed the finite diagonal-completion packet over StreamName, RegSeqRat, DyadicRatCore, Real, CauchyCompletionOperator, compact-uniform consumer, transport, replay, provenance, and local naming rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StreamDiagonalizationCompletion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim selected subsequences, quotient stream equality, selected limits, countable choice, host compactness, host completion operators, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, stream-window exposure, regular rational readback, dyadic tolerance exposure, Real sealing, completion-operator handoff, compact-uniform consumer boundary, transport, replay, provenance, and local naming for BEDC.Derived.StreamDiagonalizationCompletionUp.

Constructive story: A $\mathsf{StreamDiagonalizationCompletion}^{\uparrow}$ packet is generated from StreamName, RegSeqRat, DyadicRatCore, Real, CauchyCompletionOperator, finite diagonal-window, compact-uniform Cauchy consumer, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Chapter 8566

A Concrete Naming Certificate for $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$

Following Bishop and Bridges, Constructive Analysis, the $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ packet names the finite equivalence surface between Bishop regular Cauchy completion data and the sealed $\mathsf{Real}^{\uparrow}$ completion route. It sits over the dyadic tolerance ledger of chapter 291, the finite stream windows of chapter 126, the regular rational handoff of chapter 301, the admission criterion of chapter 1476, and the terminal real seal of chapter 38. The packet records an equivalence of displayed NameCert routes, not a quotient real construction, a selected limit, countable choice, or completeness as a primitive.

Definition 8566.1 (Bishop Cauchy completion equivalence carrier)**.** *A* $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$E = (D, S, R, K, L, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used by both directions of the comparison.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window schedule through which Cauchy observations are read.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational row exposed by those windows.*
4. *K is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *admission row that certifies the displayed Cauchy route before any real seal is read.*
5. *L is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached from the same D, S, R, K surface.*
6. *H stores componentwise* hsame *transport for the dyadic ledger, stream schedule, regular rational row, criterion row, real seal, replay, provenance, and local naming.*
7. *C stores displayed* Cont *replay from Bishop regular Cauchy data to the criterion row and from the criterion row back to the same finite real-seal read.*
8. *P is the* Pkg *provenance over* $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these nine rows. It contains no coordinate for quotient streams, selected host limits, countable choice, host real equality, or ambient completeness.

Theorem 8566.2 (Bishop Cauchy completion equivalence NameCert obligations)**.** *For every accepted* $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ *carrier* $E = (D, S, R, K, L, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}}$ *surface consists exactly of carrier admission, dyadic tolerance admission, finite-window readback, regular rational handoff, completion-criterion admission, real-seal handoff, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8566.1. The rows $D, S, R, K, L, H, C, P, N$ are the only classifier-visible coordinates.

The Bishop regular Cauchy side is read through D, S, R. The dyadic ledger supplies the tolerance scale, the stream schedule supplies finite windows, and the regular rational row supplies the Cauchy handoff available to the criterion row.

The completion side is read through K, L. The criterion row admits the displayed Cauchy route, and the real seal row is exposed only after that admission has been consumed.

The remaining rows preserve and name the same route. Since no quotient stream, selected limit, countable-choice row, host equality, or completeness coordinate appears in the carrier, the listed obligations exhaust the local NameCert surface. □

Theorem 8566.3 (Bishop Cauchy completion equivalence route)**.** *Every consumer of an accepted* $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{CauchyCompletionCriterion}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

together with the stored hsame *transport,* Cont *replay,* Pkg *provenance, and local* NameCert *row. The route may be read from the Bishop regular Cauchy side toward the real seal or from the real seal back to the displayed criterion surface, but both reads use the same finite rows* $D, S, R, K, L, H, C, P, N$*.*

Proof. Begin with an accepted carrier $E = (D, S, R, K, L, H, C, P, N)$. The source side contains exactly the dyadic ledger D, stream schedule S, and regular rational row R.

Apply the NameCert obligations of Definition 8566.2. They require the criterion row K to be the admission point between the displayed regular Cauchy data and the real seal row L.

The replay row C records both readings of the same finite route: from D, S, R to K, L, and from a real-seal read back to the criterion surface that licensed it. The transport row H and provenance row P keep the route componentwise stable, while N names the local certificate.

Thus a consumer cannot substitute a host quotient, a selected limit, or a second completion principle for the displayed rows. Both directions of the equivalence are reads of the same finite NameCert route. □

Theorem 8566.4 (Bishop Cauchy completion equivalence non-escape)**.** *The carrier of Definition 8566.1, the NameCert obligations of Definition 8566.2, and the route theorem Definition 8566.3 assemble one finite equivalence packet over* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* BHist*,* hsame*,* Cont*,* Pkg*, and* NameCert*.*

The packet exports exactly the rows

$$D, S, R, K, L, H, C, P, N.$$

It exports no quotient stream, selected host limit, countable-choice schedule, host real equality, ambient completeness, or primitive completion operator.

Proof. The carrier definition lists the full observation surface. The NameCert obligations bind each row to its displayed role: dyadic tolerance, finite windows, regular rational handoff, criterion admission, real seal, transport, replay, provenance, and naming.

The route theorem shows that both readings of the equivalence factor through the same finite surface. A Bishop regular Cauchy read reaches the seal only through D, S, R, K, L, and a real-seal read returns only to the same criterion route.

No further row remains from which to read quotient streams, selected limits, countable choice, host equality, ambient completeness, or a primitive completion operator. The displayed rows therefore exhaust the $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}}$.

Constructive story: A $\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}$ packet is generated from a dyadic tolerance ledger, finite stream windows, a regular rational Cauchy row, a completion-criterion admission row, a Real seal, componentwise transport, displayed replay, provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8566.1, Definition 8566.2, Definition 8566.3, and Definition 8566.4 bind the finite equivalence carrier, obligation surface, route, and refusal boundary.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BishopCauchyCompletionEquivalence}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient-real construction, selected limits, countable choice, host real equality, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a public consumer-factorization theorem for both readings of the dyadic, stream, regular rational, criterion, Real seal, and local NameCert route.

Chapter 8567

A Concrete Naming Certificate for $\mathsf{ProperUniformSpace}^{\uparrow}$

Following Bourbaki and Kelley on uniform spaces, the $\mathsf{ProperUniformSpace}^{\uparrow}$ packet records the finite BEDC surface in which uniform entourages admit displayed controlled-neighbourhood windows whose completion-facing reads stay inside a properness boundary. It sits beside the uniform carrier of chapter 339, the proper-metric specializations of **??** and chapter 3686, the uniform and metric completion packets of chapter 1473 and chapter 1506, and the naming spine of chapter 126, chapter 301, and chapter 38. The carrier names properness as uniform finite data; it is not a selected compactification, a quotient-completion equality, a host-limit selector, or an ambient completeness principle.

Definition 8567.1 (Proper uniform space carrier)**.** *A* $\mathsf{ProperUniformSpace}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P_{\mathrm{pus}} = (U, M, W, C, R, S, Q, H, T, K, N)$$

with the following displayed rows:

1. *U is the* $\mathsf{UniformSpace}^{\uparrow}$ *entourage row, carrying finite entourage membership, inverse, refinement, and composition data.*
2. *M is the* $\mathsf{ProperMetric}^{\uparrow}$ *or* $\mathsf{ProperMetricSpace}^{\uparrow}$ *metric specialization row used when a consumer requests the metric properness face.*
3. *W is the controlled-uniform-neighbourhood window row, recording the bounded entourage windows that replace host compact neighbourhoods.*
4. *C is the completion-boundary row, exposing the* $\mathsf{UniformCompletion}^{\uparrow}$ *route before the* $\mathsf{MetricCompletion}^{\uparrow}$ *specialization can be read.*
5. *R is the regular rational readback row through* $\mathsf{RegSeqRat}^{\uparrow}$*, tied to the same finite windows.*
6. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule that names every inspected uniform and completion-facing request.*
7. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after U, M, W, C, R, S have been displayed.*
8. *H records componentwise* hsame *transport for the uniform source, metric specialization, window, completion, readback, stream, seal, replay, provenance, and local naming rows.*
9. *T records displayed* Cont *replay from a proper-uniform request through the same rows.*

10. *K is the* Pkg *provenance over* $\mathsf{ProperUniformSpace}^{\uparrow}$, $\mathsf{UniformSpace}^{\uparrow}$, $\mathsf{ProperMetric}^{\uparrow}$, $\mathsf{ProperMetricSpace}^{\uparrow}$, $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{ProperUniformSpace}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these eleven rows. It has no coordinate for host compact neighbourhoods, selected completions, quotient uniform equality, countable choice, host real equality, or ambient completeness.

Theorem 8567.2 (Proper uniform space NameCert obligations)**.** *For every accepted* $\mathsf{ProperUniformSpace}^{\uparrow}$ *carrier* $P_{\mathrm{pus}} = (U, M, W, C, R, S, Q, H, T, K, N)$*, the local* $\mathsf{NameCert}_{\mathsf{ProperUniformSpace}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed eleven-row packet; uniform-source exactness for U; metric-specialization compatibility through M; controlled-window properness through W; completion-boundary routing through C; regular rational and stream readback through R, S; Real seal non-escape through Q; and structural transport, replay, provenance, and local naming through H, T, K, N.*

Proof. Project the carrier of Definition 8567.1. The uniform row, metric specialization, controlled window, completion boundary, regular readback, stream schedule, Real seal, and structural rows are exactly the visible coordinates.

Uniform-source exactness is rowwise. The row U supplies the entourage ledger, and every controlled neighbourhood request must pass through the displayed window row W before any completion-facing consumer can read it.

The metric face is only a specialization. The row M may expose $\mathsf{ProperMetric}^{\uparrow}$ or $\mathsf{ProperMetricSpace}^{\uparrow}$ data, but it does so downstream of the same uniform windows, so it cannot replace the uniform carrier by an unrelated metric completion.

Finally the rows C, R, S, Q, H, T, K, N preserve the displayed completion route. Since the carrier has no coordinate for selected completions, quotient equality, countable choice, host real equality, or ambient completeness, the listed obligations exhaust the local NameCert surface. □

Theorem 8567.3 (Proper uniform space completion route)**.** *Every completion-facing consumer of an accepted* $\mathsf{ProperUniformSpace}^{\uparrow}$ *carrier factors through the displayed route*

$$\mathsf{UniformSpace}^{\uparrow} \longmapsto W \longmapsto \mathsf{UniformCompletion}^{\uparrow} \longmapsto \mathsf{MetricCompletion}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The route may use the $\mathsf{ProperMetric}^{\uparrow}$ *or* $\mathsf{ProperMetricSpace}^{\uparrow}$ *face as a specialization, but it cannot bypass the uniform window row or replace the completion boundary by a selected host limit, quotient completion, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Start with a completion-facing consumer and project the accepted carrier. The only source row is the uniform entourage row U, and the only properness row available before completion is the controlled window row W together with the metric specialization row M.

Read the completion boundary next. The row C exposes the $\mathsf{UniformCompletion}^{\uparrow}$ route before any $\mathsf{MetricCompletion}^{\uparrow}$ specialization can be consumed, so a metric-completion read remains attached to the same uniform source and windows.

The naming spine is then forced by R, S, Q. Regular rational readback and stream scheduling are displayed before the terminal Real seal, while the transport, replay, provenance, and naming rows keep the consumer inside the same finite packet.

The excluded objects are absent from the carrier. Thus every completion-facing read follows the displayed route and cannot obtain a selected host limit, quotient completion, countable-choice schedule, or ambient completeness principle. □

Theorem 8567.4 (Proper uniform space L10 boundary)**.** *An accepted* $\mathsf{ProperUniformSpace}^{\uparrow}$ *packet supplies an L10 source object for properness arguments that do not start from the metric specialization. Any downstream route to* $\mathsf{UniformCompletion}^{\uparrow}$, $\mathsf{MetricCompletion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *must first expose the uniform entourage row* U *and controlled window row* W*, then preserve the same packet through* H, T, K, N*.*

Proof. Project the source rows of Definition 8567.1. The packet begins with $\mathsf{UniformSpace}^{\uparrow}$ data and a controlled-window row, so the properness source is uniform before it is metric.

Use Definition 8567.3. It places $\mathsf{UniformCompletion}^{\uparrow}$ ahead of the metric-completion specialization and binds both completion reads to the same stream and regular-rational naming spine.

The structural rows H, T, K, N preserve that source order under accepted comparison. Therefore the L10 boundary is a proper-uniform source object, while the metric face remains a downstream specialization rather than the only properness entry point. □

Closure status for $\mathsf{NameCert}_{\mathsf{ProperUniformSpace}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ProperUniformSpace}^{\uparrow}$ packet is generated from UniformSpace entourage data, a proper-metric specialization row, controlled uniform windows, UniformCompletion and MetricCompletion boundary rows, StreamName and RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ProperUniformSpace}^{\uparrow}}$, seed)

Scope closed: Definition 8567.1, Definition 8567.2, Definition 8567.3, and Definition 8567.4 seed the finite proper-uniform carrier, its NameCert obligations, the completion route, and the L10 boundary separating the uniform source from the metric specialization.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ProperUniformSpace}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected compactifications, quotient completion equality, host-limit selection, countable choice, host real equality, ambient completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, uniform-source exactness, metric-specialization compatibility, controlled-window properness, completion-boundary routing, naming-spine readback, transport, replay, provenance, and local NameCert exactness for BEDC.Derived.ProperUniformSpaceUp.

Chapter 8568

A Concrete Naming Certificate for $\mathsf{KatetovTongInsertion}^{\uparrow}$

Following Katetov, Tong, and Dowker, the $\mathsf{KatetovTongInsertion}^{\uparrow}$ packet records the finite normal-space insertion route by which a lower semicontinuous row and an upper semicontinuous row are separated by a displayed continuous real-valued function. It sits over the normal separation surface of chapter 1866, the Urysohn separation route of **??**, the extension handoff of chapter 1956, the continuous-map carrier of chapter 130, and the terminal real-name seal of chapter 38. The packet names a finite insertion certificate only; it does not import host choice, quotient function equality, selected pointwise suprema, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8568.1 (Katetov–Tong insertion carrier)**.** *A* $\mathsf{KatetovTongInsertion}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (N, L, U, S, T, C, E, A, H, Q, P, M)$$

with the following displayed rows:

1. *N is the* $\mathsf{NormalSpace}^{\uparrow}$ *source row whose separated closed-neighborhood data are inspected.*
2. *L is the lower-row ledger for the displayed lower semicontinuous boundary.*
3. *U is the upper-row ledger for the displayed upper semicontinuous boundary.*
4. *S records the strict pointwise separation budget between the L and U rows through terminal* $\mathsf{Real}^{\uparrow}$ *seals.*
5. *T is the local Urysohn/Tietze route that turns the separated neighborhood data into a continuous real-valued candidate.*
6. *C is the* $\mathsf{ContinuousMap}^{\uparrow}$ *row of the inserted function.*
7. *E records the endpoint inequalities saying that the inserted function lies between the lower and upper rows on every displayed probe.*
8. *A records finite approximation windows used to read the lower row, upper row, candidate map, and endpoint inequalities through the same* $\mathsf{Real}^{\uparrow}$ *seal.*
9. *H records componentwise* hsame *transport for the normal source, semicontinuity rows, separation budget, Urysohn/Tietze route, continuous map, endpoint inequalities, approximation windows, replay, provenance, and local name.*
10. *Q records displayed* Cont *replay for the same insertion route.*

11. *P is the* Pkg *provenance over* $\mathsf{KatetovTongInsertion}^{\uparrow}$, $\mathsf{NormalSpace}^{\uparrow}$, $\mathsf{UrysohnLemma}^{\uparrow}$, $\mathsf{TietzeExtension}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, *finite insertion ledgers,* BHist, hsame, Cont, *and* NameCert.
12. *M is the local* $\mathsf{NameCert}_{\mathsf{KatetovTongInsertion}^{\uparrow}}$ *row.*

The carrier exports no host choice principle, quotient equality of functions, untracked real-valued map, selected supremum construction, or ambient completeness theorem.

Theorem 8568.2 (Katetov–Tong insertion NameCert obligations)**.** *For every accepted* $\mathsf{KatetovTongInsertion}^{\uparrow}$ *carrier*

$$I = (N, L, U, S, T, C, E, A, H, Q, P, M),$$

the local $\mathsf{NameCert}_{\mathsf{KatetovTongInsertion}^{\uparrow}}$ *surface consists exactly of carrier admission, normal-source exposure, lower-row and upper-row visibility, strict real-valued separation, Urysohn/Tietze route discipline, continuous-map insertion, endpoint inequality exactness, approximation-window replay, componentwise transport, package provenance, and local naming. No insertion obligation is stored outside these rows.*

Proof. Project the carrier of Definition 8568.1. The rows $N, L, U, S, T, C, E, A, H, Q, P, M$ are the whole public surface, so carrier admission is exactly admission of those displayed coordinates.

The normal-source and separation obligations are read through N, L, U, S. The lower and upper rows are compared only through the displayed $\mathsf{Real}^{\uparrow}$ seals in S, and the route T records the Urysohn/Tietze separation data used to build the inserted function.

The inserted function itself is the $\mathsf{ContinuousMap}^{\uparrow}$ row C, with endpoint exactness recorded by E and finite readback windows recorded by A. Transport, replay, provenance, and local naming are then confined to H, Q, P, M, leaving no coordinate for host choice, quotient function equality, selected pointwise suprema, or ambient real completeness. □

Theorem 8568.3 (Katetov–Tong normal-space route)**.** *Every accepted* $\mathsf{KatetovTongInsertion}^{\uparrow}$ *packet factors any insertion consumer through the finite route*

$$\mathsf{NormalSpace}^{\uparrow} \longmapsto \mathsf{UrysohnLemma}^{\uparrow} \longmapsto \mathsf{TietzeExtension}^{\uparrow} \longmapsto \mathsf{ContinuousMap}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

Thus the consumer first exposes normal separation, then the local Urysohn/Tietze construction route, then the continuous inserted function and its real endpoint inequalities. It receives neither a host choice functional nor quotient equality of functions.

Proof. Start with the normal-space source row N and the separated lower and upper ledgers L, U, S. These rows provide the only closed-neighborhood and real-valued comparison data visible to the insertion request.

Read the route row T next. It records the local Urysohn and Tietze handoff through which the separated normal-space data can be turned into a continuous candidate without adding a host selector.

Finally read the continuous-map row C, the endpoint row E, and the approximation row A. The endpoint inequalities are checked through the same $\mathsf{Real}^{\uparrow}$ seal used by the lower and upper ledgers, while H, Q, P, M keep transport, replay, provenance, and naming attached to the same finite carrier. Hence every insertion consumer stays on the displayed normal-space route and cannot claim quotient function equality, a selected supremum, host choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Falsifiable prediction: Every accepted $\mathsf{KatetovTongInsertion}^{\uparrow}$ read exposes the $\mathsf{NormalSpace}^{\uparrow}$ source row, lower and upper semicontinuity ledgers, strict $\mathsf{Real}^{\uparrow}$ separation budget, Urysohn/Tietze

route row, $\mathsf{ContinuousMap}^{\uparrow}$ inserted function, endpoint inequality ledger, finite approximation windows, hsame transport, Cont replay, Pkg provenance, and local naming before any insertion consumer may inspect the real-valued function.

Independence witness: normalspace, urysohn-lemma, tietze-extension, continuousmap, real: $\mathsf{KatetovTongInsertion}^{\uparrow}$ is not bijective to any listed sibling because it jointly binds lower and upper semicontinuity ledgers, strict real-valued separation budgets, Urysohn/Tietze construction rows, inserted continuous-map rows, endpoint inequalities, finite approximation windows, componentwise transport, replay, provenance, and local NameCert rows while refusing host choice and quotient function equality.

Closure status for $\mathsf{NameCert}_{\mathsf{KatetovTongInsertion}^{\uparrow}}$.

Constructive story: A $\mathsf{KatetovTongInsertion}^{\uparrow}$ packet is generated from a normal-space source row, lower and upper semicontinuity ledgers, a strict real-valued separation budget, a Urysohn/Tietze route row, a continuous-map inserted function, endpoint inequalities, finite approximation windows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{KatetovTongInsertion}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8568.1, Definition 8568.2, and Definition 8568.3 seed the finite normal-space insertion certificate for L10 continuous real-valued consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{KatetovTongInsertion}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, host choice, quotient equality of functions, selected pointwise suprema, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, normal-source exposure, lower and upper row visibility, strict real-valued separation, Urysohn/Tietze route discipline, continuous-map insertion, endpoint exactness, approximation replay, transport, provenance, and nonescape for BEDC.Derived.KatetovTongInsertionUp.

Chapter 8569

A Concrete Naming Certificate for $\mathsf{RegularCauchyRateLattice}^{\uparrow}$

Following Bishop and Bridges on regular Cauchy moduli, this packet records finite meet, join, and refinement operations on displayed regular Cauchy rate ledgers. It sits beside the dyadic rational core of chapter 291, the finite window surface of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the rate-comparison packet of chapter 1818. The carrier names rate combination as finite ledger algebra; it is not a choice of a modulus functional, a selected limit, quotient stream equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8569.1 (Regular Cauchy rate lattice carrier)**.** *A* $\mathsf{RegularCauchyRateLattice}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (D, S, R, A, M, J, F, Q, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance and comparison row used by every rate entry.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row recording the inspected Cauchy schedules.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback attached to the same windows.*
4. *A is the displayed rate-ledger row listing finitely many regular Cauchy rate entries.*
5. *M is the meet row, storing the finite common-refinement rate.*
6. *J is the join row, storing the finite coarser public rate bound.*
7. *F is the refinement row, recording when one displayed rate ledger refines another.*
8. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after D, S, R, A, M, J, F have been displayed.*
9. *H records componentwise* hsame *transport for the rate ledger, operations, readback rows, seal, replay, provenance, and local name.*
10. *C records displayed* Cont *replay of the same finite rate-lattice route.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyRateLattice}^{\uparrow}$, $\mathsf{CauchyRateLattice}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateLattice}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, S, R, A, M, J, F, Q, H, C, P, N$. It has no coordinate for a selected modulus functional, quotient stream equality, countable choice, trichotomy, a chosen limit, or ambient completeness.

Theorem 8569.2 (Regular Cauchy rate lattice obligation surface)**.** *For every accepted* $\mathsf{RegularCauchyRateLattice}^{\uparrow}$ *carrier* $L = (D, S, R, A, M, J, F, Q, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyRateLattice}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed rate ledger; dyadic tolerance admission through D; finite window admission through S; regular rational readback through R; meet, join, and refinement exposure through M, J, F; terminal real sealing through Q; and structural transport, replay, provenance, and local naming through H, C, P, N.*

Every Real or Completion consumer that combines regular Cauchy rates through this packet must read the finite ledger row A, the $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row D, the* $\mathsf{StreamName}^{\uparrow}$ *window row S, and the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row R before the meet, join, refinement, or* $\mathsf{Real}^{\uparrow}$ *seal rows are public.*

Proof. Project the carrier of Definition 8569.1. The rate-facing data are exactly the finite ledger A, the dyadic tolerance row D, the stream window S, and the regular rational readback R.

The lattice operations are finite row operations. The meet row M records a displayed common refinement, the join row J records a displayed coarser public bound, and the refinement row F records the comparison route between rate ledgers.

The consumer-facing read is delayed until the same finite route has been displayed. The seal row Q is downstream of D, S, R, A, M, J, F, and the structural rows H, C, P, N only transport, replay, source, and name that route.

No remaining coordinate can choose a modulus functional, quotient streams, a limit, a trichotomy branch, or a completeness principle. The listed rows therefore exhaust the obligation surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyRateLattice}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyRateLattice}^{\uparrow}$ packet is generated from dyadic tolerance rows, finite StreamName windows, RegSeqRat readback, a displayed regular Cauchy rate ledger, meet, join, and refinement rows, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyRateLattice}^{\uparrow}}$, seed)

Scope closed: Definition 8569.1 and Definition 8569.2 seed the finite regular Cauchy rate-lattice carrier and its NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyRateLattice}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, selected modulus functionals, quotient stream equality, countable choice, trichotomy, selected limits, ambient $\mathsf{Real}^{\uparrow}$ completeness, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, rate-ledger exactness, meet, join, refinement, dyadic tolerance, finite-window, regular-rational, Real-seal, transport, replay, provenance, and local NameCert rows for BEDC.Derived.RegularCauchyRateLatticeUp.

Chapter 8570

A Concrete Naming Certificate for HyperbolicBoundaryCrossRatioDistortion$^{\uparrow}$

The HyperbolicBoundaryCrossRatioDistortion$^{\uparrow}$ packet records boundary cross-ratio distortion as finite hyperbolic phase data. It sits beside the cross-ratio route of chapter 3948, the visual metric route of chapter 3866, the Busemann-function route of chapter 7534, and the boundary-shadow route of chapter 3813. The carrier is a NameCert surface for distortion rows; it is not a host hyperbolic boundary, a Mobius classification theorem, a quotient boundary equality, an unbounded real-valued invariant, or a global geometry oracle.

Definition 8570.1 (Hyperbolic boundary cross-ratio distortion carrier)**.** *A* HyperbolicBoundaryCrossRatioDistortion *carrier is a finite* BHist *packet*

$$D = (X, V, B, S, E, T, R, P, H, C, L, N)$$

with the following displayed rows:

1. *X is the* HyperbolicCrossRatio$^{\uparrow}$ *row for the inspected boundary quadruple.*
2. *V is the* HyperbolicVisualMetric$^{\uparrow}$ *row supplying the visual-metric comparison window.*
3. *B is the* HyperbolicBusemannFunction$^{\uparrow}$ *row used to read boundary displacement through finite Busemann data.*
4. *S is the* HyperbolicBoundaryShadow$^{\uparrow}$ *row naming the shadow window where the distortion is inspected.*
5. *E is the terminal* Real$^{\uparrow}$ *seal row for the displayed distortion read.*
6. *T is the transport row connecting the cross-ratio, visual-metric, Busemann, and boundary-shadow reads.*
7. *R is the replay row recording that the same boundary quadruple and shadow window are used throughout the packet.*
8. *P is the provenance row over the hyperbolic boundary, metric, Busemann, shadow, and Real-seal sources.*
9. *H records componentwise* hsame *transport for all analytic and structural rows.*
10. *C records displayed* Cont *replay of the local distortion route.*

11. *L records that later Lean TasteGate realizations must include* `Nontrivial` *and* `FieldFaithful` *instances before the distortion row is accepted as non-vacuous and source-faithful.*

12. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $X, V, B, S, E, T, R, P, H, C, L, N$. It has no coordinate for global boundary compactness, host Mobius equivalence, quotient boundary equality, hidden field choice, selected geodesics, or ambient hyperbolic geometry.

Theorem 8570.2 (Hyperbolic boundary cross-ratio distortion obligations)**.** *For every accepted* $\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}$ *carrier $D = (X, V, B, S, E, T, R, P, H, C, L, N)$, every distortion read exposes the cross-ratio row X, visual metric row V, Busemann row B, boundary-shadow row S, Real-seal row E, transport row T, replay row R, provenance row P, componentwise transport row H, displayed continuation row C, TasteGate instance row L, and local naming row N.*

The read is accepted only as this finite packet. It cannot be replaced by host boundary equality, a Mobius-normal-form theorem, unbounded real comparison, selected geodesics, quotient boundary compactification, or an ambient global-geometry principle.

Proof. Project the carrier of Definition 8570.1. The analytic rows are the cross-ratio, visual-metric, Busemann, boundary-shadow, and Real-seal rows X, V, B, S, E.

The structural rows keep those analytic reads attached to one boundary packet. Transport T and replay R preserve the same boundary quadruple and shadow window, while provenance P, componentwise transport H, displayed continuation C, and local naming N record the NameCert route.

The instance row L is part of the acceptance surface. It requires later Lean TasteGate material to carry `Nontrivial` and `FieldFaithful` instances before the distortion read can be accepted as non-vacuous and source-faithful.

No coordinate remains for a host boundary quotient, Mobius classification theorem, selected geodesic, hidden field choice, or global hyperbolic principle. The listed rows therefore exhaust the local obligations. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}$ distortion read exposes cross-ratio, visual metric, Busemann, boundary-shadow, Real-seal, transport, replay, provenance, and local naming rows before the read is public.

Independence witness: hyperbolic-cross-ratio, hyperbolic-visual-metric, hyperbolic-busemann-function, hyperbolic-boundary-shadow: cross-ratio records boundary quadruple comparison without a distortion ledger; visual metric records a metric window without the quadruple distortion row; Busemann functions record boundary displacement without the cross-ratio row; and boundary shadows record finite shadow windows without Real-sealed distortion. None is bijective to $\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}$.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}}$**.**

Constructive story: A $\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}$ packet is generated from HyperbolicCrossRatio, HyperbolicVisualMetric, HyperbolicBusemannFunction, HyperbolicBoundaryShadow, RealUp seal, transport, replay, provenance, hsame, Cont, TasteGate instance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}}$, seed)

Scope closed: Definition 8570.1 and Definition 8570.2 seed the finite boundary cross-ratio distortion carrier and its NameCert obligation surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicBoundaryCrossRatioDistortion}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host boundary equality, Mobius classification, selected geodesics, quotient boundary compactification, global hyperbolic geometry, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, cross-ratio, visual-metric, Busemann, boundary-shadow, Real-seal, transport, replay, provenance, instance, and local NameCert exactness for BEDC.Derived.HyperbolicBoundaryCrossRatioDis

Chapter 8571

A Concrete Naming Certificate for $\mathsf{CauchyCompletionSeparator}^{\uparrow}$

Following Bourbaki and Kelley, the $\mathsf{CauchyCompletionSeparator}^{\uparrow}$ packet records the finite separator object that completion consumers read between regular Cauchy completion criteria and Hausdorff or separated completion boundaries. It sits after the Cauchy criterion surface of chapter 1476, the finite stream-name route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance core of chapter 291, the separated universal surface of chapter 2242, and the quotient-free separation route of chapter 3839. The packet names a displayed separator boundary for L10 completion arguments; it is not quotient completion equality, a selected limit, host sequence equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8571.1 (Cauchy completion separator carrier)**.** *A* $\mathsf{CauchyCompletionSeparator}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (K, W, R, D, U, Q, H, C, P, N)$$

with the following displayed rows:

1. *K is the* $\mathsf{CauchyCompletionCriterion}^{\uparrow}$ *row. It records the criterion that a completion-facing Cauchy name must satisfy before any separator is read.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *row. It exposes the finite observation window through which the criterion is inspected.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *row. It records the regular rational readback used by the separator at the displayed precision.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row. It supplies the dyadic tolerance ledger used to compare the two inspected completion names.*
5. *U is the* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *row. It records the separated universal-property boundary consumed after the criterion, window, readback, and tolerance rows have been displayed.*
6. *Q is the* $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ *row. It records the quotient-free regular Cauchy separation handoff used by downstream completion consumers.*
7. *H records componentwise* hsame *transport for $K, W, R, D, U, Q, C, P, N$.*
8. *C records displayed* Cont *replay of the route*

$$K, W, R, D \longmapsto U, Q \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{CauchyCompletionSeparator}^{\uparrow}$, $\mathsf{CauchyCompletionCriterion}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$, $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*

10. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparator}^{\uparrow}}$ *row.*

The carrier has no coordinate for quotient completion equality, selected representatives, selected limits, host sequence equality, countable-choice schedules, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8571.2 (Cauchy completion separator NameCert obligations)**.** *For every accepted* CauchyCompletionSepa *carrier $S = (K, W, R, D, U, Q, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparator}^{\uparrow}}$ *surface consists exactly of Cauchy criterion admission, finite StreamName window exposure, RegSeqRat readback, DyadicRatCore tolerance comparison, HausdorffCompletionUniversal separated-boundary routing, RegularCauchyCompletionSeparation handoff, componentwise transport, displayed continuation replay, package provenance, and local naming through the displayed rows $K, W, R, D, U, Q, H, C, P, N$.*

Proof. Project the carrier of Definition 8571.1. The Cauchy criterion row K is the only admission point, and the finite window W is the only route by which the criterion is inspected.

The regular rational row R and dyadic tolerance row D provide the displayed comparison data. A separator read therefore stays inside the finite regular Cauchy and dyadic ledgers before any separated completion boundary is consumed.

The rows U and Q then route the same inspected data to the Hausdorff universal boundary and the regular Cauchy separation handoff. Componentwise transport, continuation replay, provenance, and local naming through H, C, P, N preserve that route without adding quotient equality, selected limits, host equality, choice, trichotomy, or ambient completeness. □

Theorem 8571.3 (Cauchy completion separator Hausdorff route)**.** *Every completion consumer that reads an accepted* $\mathsf{CauchyCompletionSeparator}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{CauchyCompletionCriterion}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{RegSeqRat}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{HausdorffCompletionUniversal}^{\uparrow}, \mathsf{Regular}$$

Thus the separator can be consumed as a displayed Hausdorff or separated completion boundary, but not as quotient completion equality, selected-limit data, host sequence equality, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start from an accepted carrier $S = (K, W, R, D, U, Q, H, C, P, N)$. The source side is fixed by K, W, R, D: criterion admission, finite window exposure, regular rational readback, and dyadic tolerance comparison.

Read the separated boundary rows next. The $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ row U supplies the universal separated route, while the $\mathsf{RegularCauchyCompletionSeparation}^{\uparrow}$ row Q supplies the quotient-free separation handoff for regular Cauchy names.

Finally inspect the structural rows. The hsame transport row H, continuation row C, provenance row P, and local naming row N replay the same finite packet, so downstream completion consumers receive only the displayed separator route and no stronger host-side completion principle. □

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCompletionSeparator}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyCompletionSeparator}^{\uparrow}$ packet is generated from a CauchyCompletionCriterion row, StreamName finite window, RegSeqRat readback, DyadicRatCore tolerance ledger, HausdorffCompletionUniversal separated-boundary row, RegularCauchyCompletionSeparation handoff row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{CauchyCompletionSeparator}\uparrow}$, seed)

Scope closed: Definition 8571.1, Definition 8571.2, and Definition 8571.3 seed the finite separator surface between regular Cauchy completion criteria and Hausdorff or separated completion consumers.

Formal verification: FormalStatus(NameCert$_{\text{CauchyCompletionSeparator}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient completion equality, selected representatives, selected limits, host sequence equality, countable choice, trichotomy, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, criterion-window exactness, regular-rational readback, dyadic tolerance comparison, Hausdorff universal routing, regular Cauchy separation handoff, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCompletionSeparatorUp.

Chapter 8572

A Concrete Naming Certificate for $\mathsf{OpialLemma}^{\uparrow}$

Following Opial's weak-convergence lemma, the $\mathsf{OpialLemma}^{\uparrow}$ packet records the finite certificate surface by which a Hilbert-facing weak-limit row and a strict norm-distance separation ledger can be inspected without importing a host weak compactness selector. It sits after the Opial-condition packet of chapter 6322, the Hilbert carrier of chapter 91, the norm and metric surfaces of chapter 89 and chapter 57, the scalar readback of chapter 38, and the weak compactness interface of chapter 6851. The packet names weak-limit and separation data only as displayed NameCert rows; it exports no selected weak cluster point, quotient equality, classical trichotomy, or ambient fixed-point theorem.

Definition 8572.1 (Opial lemma carrier)**.** *An* $\mathsf{OpialLemma}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (H, N, M, R, W, S, B, A, D, T, C, P, K)$$

with the following displayed rows:

1. *H is the* $\mathsf{Hilbert}^{\uparrow}$ *source row, exposing only the inner-product, induced norm, and weak-observation surfaces visible to the packet.*
2. *N is the* $\mathsf{Norm}^{\uparrow}$ *row that reads norm distances for the displayed Hilbert endpoints.*
3. *M is the* $\mathsf{Met}^{\uparrow}$ *row induced by the norm-distance ledger.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar readback row for all displayed inequalities and strict-separation margins.*
5. *W is the* $\mathsf{WeakCompactness}^{\uparrow}$ *handoff row, naming the weak-observation window while refusing any selected weak compactness witness.*
6. *S is the bounded sequence row whose entries are read through H, N, M, R.*
7. *B is the candidate weak-limit row, displayed as a named endpoint of the same Hilbert carrier and not as the result of a choice principle.*
8. *A is the alternative endpoint row used for comparison against the candidate weak limit.*
9. *D is the strict separation ledger*

$$\liminf_n \|S_n - B\| < \liminf_n \|S_n - A\|$$

read through the norm, metric, and Real rows.

10. *T records componentwise* hsame *transport for the Hilbert, norm, metric, Real, weak compactness, sequence, weak-limit, alternative endpoint, and strict-separation rows.*
11. *C records displayed* Cont *replay from an Opial-lemma request through*

$$H, N, M, R, W, S, B, A, D \longmapsto T, P, K.$$

12. *P is the* Pkg *provenance over* $\mathsf{OpialLemma}^{\uparrow}$, $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*
13. *K is the local* $\mathsf{NameCert}_{\mathsf{OpialLemma}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these displayed rows. It has no coordinate for a host weak compactness selector, quotient equality of weak limits or Hilbert endpoints, classical trichotomy for arbitrary reals, a demiclosedness theorem, or a fixed-point theorem.

Theorem 8572.2 (Opial lemma NameCert obligations)**.** *For every accepted* $\mathsf{OpialLemma}^{\uparrow}$ *carrier*

$$L = (H, N, M, R, W, S, B, A, D, T, C, P, K),$$

the local $\mathsf{NameCert}_{\mathsf{OpialLemma}^{\uparrow}}$ *surface consists exactly of Hilbert source admission, norm-distance admission, metric-distance readback, Real scalar readback, weak-observation handoff, bounded-sequence exposure, candidate weak-limit exposure, alternative-endpoint exposure, strict-separation exposure, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Carrier admission is projection from Definition 8572.1. The packet exposes precisely the rows $H, N, M, R, W, S, B, A, D, T, C, P, K$, so every obligation must be read from that finite inventory.

The analytic source rows are read first. The $\mathsf{Hilbert}^{\uparrow}$ row is interpreted through chapter 91; its norm and metric observations are routed through chapter 89 and chapter 57; and every comparison value is sealed by the $\mathsf{Real}^{\uparrow}$ readback of chapter 38.

The weak side is then confined to W, S, B, A. The $\mathsf{WeakCompactness}^{\uparrow}$ handoff of chapter 6851 supplies only a finite weak-observation window, while the sequence, candidate weak-limit row, and alternative endpoint remain displayed coordinates of the same packet.

Finally D, T, C, P, K bind the strict-separation and structural obligations. The strict ledger records the displayed norm-distance inequality, and the transport, replay, provenance, and local naming rows preserve only the stated coordinates. Hence no host weak compactness selector, quotient equality, classical trichotomy, or ambient fixed-point theorem is exported. □

Theorem 8572.3 (Opial lemma weak-limit separation)**.** *Every* $\mathsf{OpialLemma}^{\uparrow}$ *consumer that reads a candidate weak limit from an accepted carrier must also read the Hilbert source row H, norm-distance row N, metric row M, Real scalar row R, weak compactness handoff W, bounded sequence row S, alternative endpoint row A, and strict-separation ledger D. The exported conclusion is only the displayed weak-limit distance separation inside the packet; it is not a selected weak cluster point, quotient equality of endpoint representatives, classical real trichotomy, or host fixed-point principle.*

Proof. Start with the candidate weak-limit read. By Definition 8572.2, the candidate row B is visible only together with the source rows H, N, M, R, W, S, A, D and the structural rows T, C, P, K.

The distance comparison is routed through the named siblings. The Hilbert source provides the endpoint surface, the norm and metric chapters provide the distance observations, and the Real chapter supplies the scalar comparison row in which the strict inequality is read.

The weak compactness handoff stays local. The row W refers to the finite weak-observation interface of chapter 6851, so the consumer may inspect the displayed weak-limit candidate but may not extract a selected weak compactness witness.

It remains to identify the export boundary. Since the carrier has no coordinate for quotient equality, classical trichotomy, demiclosedness, or fixed-point data, the public read is exactly the strict weak-limit separation ledger preserved by T, C, P, K. □

Falsifiable prediction: Every accepted $\mathsf{OpialLemma}^{\uparrow}$ read must display $\mathsf{Hilbert}^{\uparrow}$, $\mathsf{Norm}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{WeakCompactness}^{\uparrow}$, bounded-sequence, candidate weak-limit, alternative-endpoint, strict-separation, transport, replay, provenance, and local NameCert rows before any weak-limit separation is public. A read that exports a host weak compactness selector, quotient equality, classical trichotomy, demiclosedness, or a fixed-point theorem from this packet refutes the carrier boundary.

Independence witness: opial-condition, hilbert, norm, metric, real, weak-compactness: none is bijective with $\mathsf{OpialLemma}^{\uparrow}$ because this carrier jointly binds a Hilbert source, norm-distance ledger, metric readback, Real strict comparison, weak-observation handoff, bounded sequence, candidate weak-limit row, alternative endpoint row, strict-separation ledger, transport, replay, provenance, and local NameCert row.

Closure status for $\mathsf{NameCert}_{\mathsf{OpialLemma}^{\uparrow}}$.

Constructive story: An $\mathsf{OpialLemma}^{\uparrow}$ packet is generated from a Hilbert source, norm-distance and metric rows, Real scalar readback, weak compactness handoff, bounded sequence, candidate weak-limit row, alternative endpoint row, strict-separation ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{OpialLemma}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8572.1, Definition 8572.2, and Definition 8572.3 seed the finite Opial-lemma route from displayed weak-limit data to strict norm-distance separation.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{OpialLemma}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim a host weak compactness selector, quotient equality, classical trichotomy, demiclosedness, fixed-point existence, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, weak-limit row exposure, norm-distance and Real strict-separation exactness, weak compactness handoff stability, and BEDC.Derived.OpialLemmaUp formalization.

Chapter 8573

A Concrete Naming Certificate for $\mathsf{RealTailFilter}^{\uparrow}$

Following Bishop and Bridges, a Real-facing tail filter is read only after the regular rational source, finite stream windows, dyadic tolerance ledger, terminal Real seal, and same-real tail route have all been displayed. The $\mathsf{RealTailFilter}^{\uparrow}$ packet sits after the stream-name interface of chapter 126, the regular-rational readback of chapter 301, the dyadic tolerance core of chapter 291, the terminal real-name seal of chapter 38, and the regular real tail-equivalence route of chapter 5940. It records terminal tail-filter evidence for L10 Real and Completion consumers without quotient streams, selected limits, host equality, or ambient Real completeness.

Definition 8573.1 (Real tail filter carrier)**.** *A* $\mathsf{RealTailFilter}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (S, R, D, E, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row inspected by the tail request.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row produced from the same displayed windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that records the late-stage bound used by the tail request.*
4. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row available only after S, R, D have been displayed.*
5. *F is the terminal filter row, recording the eventual tail request, its finite witness window, and its refusal boundary for missing tolerance evidence.*
6. *H records componentwise* hsame *transport for the window, readback, tolerance, seal, filter, replay, provenance, and local naming rows.*
7. *C records displayed* Cont *replay of the same route from a tail request through S, R, D, E, F.*
8. *P records* Pkg *provenance over* $\mathsf{RealTailFilter}^{\uparrow}$*,* $\mathsf{StreamName}^{\uparrow}$*,* $\mathsf{RegSeqRat}^{\uparrow}$*,* $\mathsf{DyadicRatCore}^{\uparrow}$*,* $\mathsf{Real}^{\uparrow}$*,* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RealTailFilter}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these nine rows. It has no coordinate for quotient stream equality, a selected Cauchy representative, a chosen limit, host real equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8573.2 (Real tail filter NameCert obligations)**.** *For every accepted* $\mathsf{RealTailFilter}^{\uparrow}$ *carrier*

$$T = (S, R, D, E, F, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{RealTailFilter}^{\uparrow}}$ *surface consists exactly of finite-window exposure through* S*, regular-rational readback through* R*, dyadic tolerance exposure through* D*, terminal Real sealing through* E*, eventual tail-filter evidence through* F*, componentwise transport through* H*, displayed replay through* C*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8573.1. The analytic route starts with the finite window S, then reads the regular rational row R and the dyadic tolerance ledger D before any terminal Real seal is visible.

The filter row F is downstream of that route. It records only the eventual tail request and the finite witness window already controlled by S, R, D, E, so it cannot add a separate stream representative or a selected limit.

Finally read H, C, P, N. These rows transport, replay, source, and name the same finite packet. Since the classifier has no quotient, choice, host-equality, or ambient-completeness coordinate, the listed rows exhaust the local certificate surface. □

Theorem 8573.3 (Real tail filter eventual stability)**.** *Let*

$$T = (S, R, D, E, F, H, C, P, N)$$

be an accepted $\mathsf{RealTailFilter}^{\uparrow}$ *carrier. Any Real or Completion consumer that reads the terminal tail-filter row* F *must preserve the same* S, R, D, E *route at every later tail request whose finite witness window refines the displayed one. The consumer receives no quotient stream, selected representative, selected host limit, countable-choice schedule, host real equality, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, or bridge credential.*

Proof. Start from the NameCert obligations of Definition 8573.2. They force every tail-filter read to expose the finite window, regular-rational readback, dyadic tolerance ledger, and terminal Real seal before F is available.

For a later tail request, refinement is read through the same finite window discipline. The displayed tolerance ledger D is the only bound available to the consumer, so the request remains attached to the original S, R, D, E route.

The structural rows H, C, P, N preserve the route under transport and replay. Because the carrier lacks quotient, selector, host-limit, host-equality, choice, completeness, and bridge coordinates, eventual stability can export only the displayed tail-filter evidence. □

Falsifiable prediction: A $\mathsf{RealTailFilter}^{\uparrow}$ consumer that reaches terminal Real-facing tail-filter evidence after deleting S, R, D, or E refutes the carrier of Definition 8573.1.

Independence witness: Nearest siblings: StreamName, RegSeqRat, DyadicRatCore, Real, and RegularRealTailEquivalence. $\mathsf{RealTailFilter}^{\uparrow}$ is not bijective to any one sibling because it jointly carries finite windows, regular-rational readback, dyadic tolerance, terminal Real sealing, eventual tail-filter evidence, transport, replay, provenance, and local naming as one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{RealTailFilter}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RealTailFilter}^{\uparrow}$ packet is generated from StreamName finite windows, RegSeqRat readback, DyadicRatCore tolerance evidence, a terminal RealUp seal, eventual tail-filter evidence, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RealTailFilter}^{\uparrow}}$, seed)

Scope closed: Definition 8573.1, Definition 8573.2, and Definition 8573.3 seed the terminal Real-facing tail-filter route for L10 Real and Completion consumers.

Formal verification: FormalStatus(NameCert$_{\mathsf{RealTailFilter}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient stream equality, selected representatives, selected limits, countable choice, host real equality, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, NameCert obligation rows, tail-filter nonescape, eventual stability, transport, replay, provenance, and local naming for BEDC.Derived.RealTailFilterUp.

Chapter 8574

A Concrete Naming Certificate for $\mathsf{LocatedRealSubset}^{\uparrow}$

Following Bishop and Bridges on located subsets of constructive metric spaces, the $\mathsf{LocatedRealSubset}^{\uparrow}$ packet records a Real-facing subset by finite positive and negative distance reads rather than by a classical powerset predicate. It sits over the located-real interface of **??**, the terminal real-name seal of chapter 38, the regular rational readback of chapter 301, the finite stream windows of chapter 126, and the dyadic tolerance ledger of chapter 291. The packet gives downstream Real and Completion consumers a finite located-subset boundary without importing quotient subsets, selected representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8574.1 (Located real subset carrier)**.** *A* $\mathsf{LocatedRealSubset}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (D, W, R, L, I, O, H, C, P, N)$$

with the following displayed rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used to compare positive and negative distance reads.*
2. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window schedule through which a consumer reads only finite prefixes of a real name.*
3. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *regular rational readback row extracted from those windows.*
4. *L is the* $\mathsf{LocatedReal}^{\uparrow}$ *comparison row that exposes the local located-real separator used by the subset packet.*
5. *I is the inside row, listing displayed evidence that the current real-name window lies within the subset up to the recorded tolerance.*
6. *O is the outside row, listing displayed evidence that the current real-name window is apart from the subset up to the recorded tolerance.*
7. *H stores componentwise* hsame *transport for tolerance, window, regular-rational, located-real, inside, outside, provenance, and local naming rows.*
8. *C stores displayed* Cont *replay by which the same finite read moves from a real-name window to either the inside row or the outside row.*
9. *P is the* Pkg *provenance over* $\mathsf{LocatedRealSubset}^{\uparrow}$, $\mathsf{LocatedReal}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{LocatedRealSubset}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through these rows. It has no coordinate for a host powerset of $\mathsf{Real}^{\uparrow}$*, quotient subset equality, selected representatives, countable choice, open-cover compactness, or ambient Real completeness.*

Theorem 8574.2 (Located real subset NameCert obligations)**.** *For every accepted* $\mathsf{LocatedRealSubset}^{\uparrow}$ *carrier* $S = (D, W, R, L, I, O, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{LocatedRealSubset}^{\uparrow}}$ *surface consists exactly of dyadic tolerance admission, finite-window readback, regular-rational handoff, located-real comparison, inside-row exposure, outside-row exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8574.1. The rows $D, W, R, L, I, O, H, C, P, N$ are the only visible coordinates.

The Real-facing read starts with D, W, R, L. The dyadic ledger supplies the tolerance scale, the stream schedule supplies finite observation windows, the regular rational row supplies the readback, and the located-real row supplies the comparison boundary before any subset row is read.

The subset read is then split into I and O. Inside evidence and outside evidence are both displayed packet rows, so the packet records locatedness as a finite decision-facing boundary rather than as a host subset predicate.

The remaining rows preserve and name the same boundary. Since the carrier contains no host powerset, quotient subset equality, selected representative, choice schedule, compact-cover datum, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8574.3 (Located real subset L10 scope)**.** *Every consumer of an accepted* $\mathsf{LocatedRealSubset}^{\uparrow}$ *packet factors through the displayed L10 route*

$$\mathsf{DyadicRatCore}^{\uparrow},\ \mathsf{StreamName}^{\uparrow},\ \mathsf{RegSeqRat}^{\uparrow},\ \mathsf{LocatedReal}^{\uparrow},\ \mathsf{Real}^{\uparrow}$$

together with the inside row, outside row, componentwise hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local* $\mathsf{NameCert}$ *row. The route exposes finite located-subset reads for Real and Completion consumers, and it does not export open-cover compactness, quotient subsets, countable choice, selected representatives, or ambient Real completeness.*

Proof. Begin with an accepted carrier $S = (D, W, R, L, I, O, H, C, P, N)$. The source side is the finite Real-facing chain D, W, R, L together with the real seal read named by the package row.

Apply Definition 8574.2. A consumer can read subset information only through the displayed inside row I or the displayed outside row O, and both rows remain under the same tolerance, window, regular-rational, and located-real boundary.

The transport row H, replay row C, provenance row P, and naming row N keep that boundary stable for downstream consumers. No remaining coordinate supplies compactness by open covers, quotient subset equality, countable choice, selected representatives, or ambient completeness of $\mathsf{Real}^{\uparrow}$. □

Closure status for $\mathsf{NameCert}_{\mathsf{LocatedRealSubset}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LocatedRealSubset}^{\uparrow}$ packet is generated from a dyadic tolerance ledger, finite stream windows, regular rational readback, located-real comparison, inside and outside subset rows, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LocatedRealSubset}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8574.1, Definition 8574.2, and Definition 8574.3 bind the finite located-subset carrier, NameCert obligation surface, and Real-facing L10 dependency scope.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LocatedRealSubset}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close open-cover compactness, quotient subsets, countable choice, selected representatives, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Scoped closure requires a checked consumer-factorization route for the displayed dyadic, stream, regular rational, located-real, Real seal, inside, outside, transport, replay, provenance, and local NameCert rows.

Chapter 8575

A Concrete Naming Certificate for $\mathsf{CauchyBinet}^{\uparrow}$

Cauchy–Binet's classical finite matrix-minor identity gives the $\mathsf{CauchyBinet}^{\uparrow}$ packet its linear-algebra surface: a displayed product matrix minor is expanded as a finite sum over intermediate column subsets, with every determinant, permutation sign, and scalar multiplication read through already named rows. It sits after the finite matrix carrier of chapter 49, the determinant packet of chapter 84, the permutation-sign route of chapter 116, and the scalar ring source of chapter 43. The packet names only finite minor data and its ledger; it does not assert a host linear-algebra theorem, quotient matrix equality, infinite-dimensional determinant, selected basis completion, or ambient algebraic closure.

Definition 8575.1 (Cauchy–Binet carrier)**.** *A* $\mathsf{CauchyBinet}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (R, A, C, I, J, K, P_{\mathrm{row}}, P_{\mathrm{col}}, D_A, D_C, S, H, T, Q, N)$$

with the following displayed rows:

1. *R is the consumed* $\mathsf{Ring}^{\uparrow}$ *scalar row.*
2. *A and C are the two* $\mathsf{Mat}^{\uparrow}$ *factors over R, with compatible displayed inner dimension.*
3. *I and J are the displayed row and column index lists selecting the product minor.*
4. *K is the finite list of intermediate column subsets of the required cardinality.*
5. *P_{row} and P_{col} are* $\mathsf{Permutation}^{\uparrow}$ *rows used to order the selected rows, selected columns, and intermediate subsets before determinant signs are read.*
6. *D_A records the* $\mathsf{Determinant}^{\uparrow}$ *minors of A indexed by (I, K), and D_C records the* $\mathsf{Determinant}^{\uparrow}$ *minors of C indexed by (K, J).*
7. *S is the finite scalar sum row*
$$\sum_K \det(A_{I,K})\,\det(C_{K,J})$$
read through the ring operations and the determinant rows.
8. *H records componentwise* hsame *transport for the scalar, matrix, index-list, permutation, determinant, finite-sum, replay, provenance, and local naming rows.*

9. *T records displayed* Cont *replay from a product-minor request through*

$$R, A, C, I, J, K, P_{\mathrm{row}}, P_{\mathrm{col}}, D_A, D_C, S \longmapsto H, Q, N.$$

10. *Q is the* Pkg *provenance over* $\mathsf{CauchyBinet}^{\uparrow}$, $\mathsf{Ring}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{Determinant}^{\uparrow}$, $\mathsf{Permutation}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{CauchyBinet}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host matrix equality, quotient row spaces, infinite determinant algorithms, selected bases, exterior algebra, or ambient field closure.

Theorem 8575.2 (Cauchy–Binet minor expansion)**.** *For every accepted* $\mathsf{CauchyBinet}^{\uparrow}$ *carrier*

$$B = (R, A, C, I, J, K, P_{\mathrm{row}}, P_{\mathrm{col}}, D_A, D_C, S, H, T, Q, N),$$

the product-minor read of the displayed matrix product factors through exactly the finite route

$$\mathsf{Mat}^{\uparrow}, \mathsf{Permutation}^{\uparrow}, \mathsf{Determinant}^{\uparrow}, \mathsf{Ring}^{\uparrow} \longmapsto D_A, D_C, S \longmapsto H, T, Q, N.$$

The exported identity is the displayed finite sum of paired minors indexed by K; it is not a host theorem about all matrices and not an equality outside the named carrier rows.

Proof. Project the carrier of Definition 8575.1. The matrix rows A and C, the selected index rows I, J, K, and the permutation rows $P_{\mathrm{row}}, P_{\mathrm{col}}$ are visible before any determinant is read.

The determinant rows are then finite. The row D_A reads each minor of A selected by (I, K), and D_C reads each minor of C selected by (K, J). Both rows are routed through chapter 84 and keep the needed order data attached to the permutation packet of chapter 116.

Finally the scalar sum row S is read through the $\mathsf{Ring}^{\uparrow}$ source. Since S contains only the displayed products $\det(A_{I,K})\det(C_{K,J})$ and their finite sum, the exported expansion remains inside the named matrix, determinant, permutation, ring, transport, replay, provenance, and local NameCert rows. □

Theorem 8575.3 (Cauchy–Binet ledger refusal)**.** *Every accepted* $\mathsf{CauchyBinet}^{\uparrow}$ *packet refuses host matrix equality, quotient row or column spaces, infinite-dimensional determinants, selected basis completion, exterior-algebra semantics, ambient field closure, and any determinant algorithm not displayed by the consumed* $\mathsf{Determinant}^{\uparrow}$ *rows. A consumer requesting one of those objects must leave the carrier route*

$$R, A, C, I, J, K, P_{\mathrm{row}}, P_{\mathrm{col}}, D_A, D_C, S, H, T, Q, N.$$

Proof. Inspect the carrier in Definition 8575.1. Its analytic rows are the scalar ring, the two displayed matrices, the finite index lists, the finite intermediate-subset list, the permutation order rows, the determinant-minor rows, and the finite scalar sum.

The minor expansion of Definition 8575.2 uses only those rows and the structural transport, replay, provenance, and local naming rows. No coordinate stores a quotient row space, an ambient equality of matrices, a selected basis completion, an infinite determinant, exterior-algebra semantics, or field-closure data.

Therefore such requests cannot be answered by the packet. They are refused at the ledger boundary before a linear-algebra consumer can treat the finite minor expansion as a host-level theorem. □

Falsifiable prediction: An accepted $\mathsf{CauchyBinet}^{\uparrow}$ read is refuted if it exports a product-minor identity without first displaying the MatrixUp factors, selected index lists, intermediate subset list, PermutationUp order rows, DeterminantUp minor rows, RingUp finite-sum row, transport, replay, provenance, and local NameCert rows.

Independence witness: matrix, determinant, permutation, ring: none is bijective with $\mathsf{CauchyBinet}^{\uparrow}$ because this carrier jointly binds two matrix factors, selected product-minor indices, intermediate subset data, permutation ordering, paired determinant minors, finite scalar summation, transport, replay, provenance, and local NameCert naming.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyBinet}^{\uparrow}}$.

Constructive story: A $\mathsf{CauchyBinet}^{\uparrow}$ packet is generated from a RingUp scalar source, two MatrixUp factor rows, selected row and column index lists, a finite intermediate-subset list, PermutationUp order rows, DeterminantUp minor rows, a finite scalar-sum row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyBinet}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8575.1, Definition 8575.2, and Definition 8575.3 seed the finite Cauchy–Binet route over displayed Matrix, Determinant, Permutation, Ring, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyBinet}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, host matrix equality, quotient row spaces, infinite determinants, selected basis completion, exterior-algebra semantics, ambient field closure, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite subset enumeration, determinant-minor exactness, permutation-order stability, ring finite-sum exactness, ledger refusal, transport, provenance, and local naming for BEDC.Derived.CauchyBinetUp.

Chapter 8576

A Concrete Naming Certificate for $\mathsf{DarbouxFunction}^{\uparrow}$

Following Darboux and Bishop–Bridges constructive analysis, the $\mathsf{DarbouxFunction}^{\uparrow}$ packet records the intermediate-value surface of a real function on a displayed interval as finite BEDC rows. It sits beside the Real naming boundary of chapter 38, the graph-and-modulus route of chapter 130, the derivative consumer boundary of chapter 122, the tagged-sum interface of chapter 1960, and the Darboux integral route of chapter 1460. The packet names between-value witnesses for inspected interval windows without identifying host functions by quotient equality, choosing a global intermediate point, importing measure completion, or asserting ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8576.1 (DarbouxFunction carrier)**.** *A* $\mathsf{DarbouxFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, R, G, B, C, D, H, K, P, N)$$

with the following displayed rows:

1. *I is the interval-source row whose endpoints and inspected subinterval windows are read through* $\mathsf{Real}^{\uparrow}$*.*
2. *R is the* $\mathsf{Real}^{\uparrow}$ *codomain row for the endpoint values and requested between-value level.*
3. *G is the displayed function-graph row, read by* $\mathsf{ContinuousMap}^{\uparrow}$ *and derivative-facing consumers only through finite source and value windows.*
4. *B is the between-value witness ledger: for each inspected pair of interval windows and requested value row it records the finite local witness window certified between the two endpoint values.*
5. *C is the continuity consumer boundary, tying G and B to the* $\mathsf{ContinuousMap}^{\uparrow}$ *route without asserting global uniform continuity.*
6. *D is the derivative consumer boundary, exposing the Darboux read needed by* $\mathsf{Derivative}^{\uparrow}$ *consumers while withholding any selected primitive or differentiability proof.*
7. *H stores componentwise* hsame *transport for interval, codomain, graph, between-value, continuity, derivative, provenance, and local naming rows.*
8. *K stores displayed* Cont *replay for the same finite reads.*
9. *P is the* Pkg *provenance over* $\mathsf{DarbouxFunction}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Derivative}^{\uparrow}$, $\mathsf{RiemannIntegrable}^{\uparrow}$, $\mathsf{DarbouxIntegral}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. N is the local $\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for quotient equality of host functions, a selected global intermediate point, measure completion, or ambient Real completeness.

Lean4 ✓ `BEDC.Derived.DarbouxFunctionUp.DarbouxFunctionTasteGate single carrier alignment`

Theorem 8576.2 (DarbouxFunction NameCert obligations)**.** *For every accepted* $\mathsf{DarbouxFunction}^{\uparrow}$ *carrier* $F = (I, R, G, B, C, D, H, K, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}$ *surface consists exactly of interval-source admission, Real codomain readback, finite graph exposure, between-value witness-ledger exactness, continuity consumer boundary, derivative consumer boundary, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. No obligation exports a host function quotient, a selected intermediate point outside the inspected witness ledger, measure completion, or ambient Real completeness.*

Proof. Project the carrier of Definition 8576.1. The rows $I, R, G, B, C, D, H, K, P, N$ are the only visible coordinates, so every Darboux-function read must pass through the interval source, Real codomain, displayed graph, and between-value ledger before it reaches a consumer.

The between-value claim is finite. The ledger B records inspected interval windows and requested value rows, and it names only the corresponding local witness window. Thus the packet supplies a Darboux surface for the inspected row, not a global choice of intermediate point.

The consumer boundaries then separate the downstream uses. The row C permits continuous-map consumers to replay the graph-and-ledger route, while D permits derivative consumers to read the same Darboux boundary without importing differentiability, a primitive, or an integral value.

Finally H, K, P, N transport, replay, source, and name this same packet. Since no carrier coordinate contains quotient equality of host functions, a global selected point, measure completion, or ambient Real completeness, the listed rows exhaust the local $\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}$ surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}$**.**

Constructive story: A $\mathsf{DarbouxFunction}^{\uparrow}$ packet is generated from interval-source rows, Real codomain rows, displayed graph rows, between-value witness ledgers, continuity and derivative consumer boundaries, componentwise transport, displayed replay, provenance, and local naming.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8576.1 and Definition 8576.2 seed the finite Darboux-function carrier and its local NameCert obligation surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DarbouxFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close host function quotients, selected global intermediate points, measure completion, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, between-value witness-ledger exactness, continuity and derivative consumer boundaries, transport, replay, provenance, and local naming for BEDC.Derived.DarbouxFunctionUp.

Chapter 8577

A Concrete Naming Certificate for $\mathsf{LyndonWord}^{\uparrow}$

Following Lyndon and Schützenberger, the $\mathsf{LyndonWord}^{\uparrow}$ packet records a primitive finite word that is lexicographically smaller than every nontrivial proper suffix over a displayed totally ordered alphabet. It sits beside the concrete monoid carrier of chapter 40, the total-order comparison surface of chapter 54, the regular-language accepted-word ledger of chapter 351, and the context-free grammar derivation surface of chapter 356. The packet names only finite word, order, suffix-comparison, factorization, transport, replay, provenance, and local naming rows; it does not assert an infinite language quotient, a host free-monoid quotient, a selected global factorization oracle, or a bridge.

Definition 8577.1 (Lyndon word carrier)**.** *A* $\mathsf{LyndonWord}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (W, A, X, U, S, F, H, C, P, N)$$

with the following displayed rows:

1. *W is the finite word row, displayed as a list of alphabet letters and read through the monoid concatenation surface.*
2. *A is the alphabet total-order row, exposing the finite comparison route for letters.*
3. *X is the lexicographic comparison row induced from A on finite word spines.*
4. *U is the primitive-word row, recording that W is not displayed as a nontrivial power of a shorter word in the monoid packet.*
5. *S is the proper-suffix minimality row, listing each nonempty proper suffix of W and the lexicographic comparison certifying W as strictly smaller.*
6. *F is the factorization ledger, recording the finite Chen–Fox–Lyndon factor route visible to regular-language and context-free grammar consumers.*
7. *H stores componentwise* hsame *transport for W, A, X, U, S, F and the structural rows.*
8. *C stores displayed* Cont *replay for finite word induction, suffix enumeration, lexicographic comparison replay, primitive-word inspection, and factorization handoff.*
9. *P is the* Pkg *provenance over* $\mathsf{LyndonWord}^{\uparrow}$*,* $\mathsf{Monoid}^{\uparrow}$*,* $\mathsf{TotalOrder}^{\uparrow}$*,* $\mathsf{RegularLanguage}^{\uparrow}$*,* $\mathsf{ContextFreeGrammar}^{\uparrow}$*,* BHist*,* hsame*,* Cont*, and* $\mathsf{NameCert}$*.*

10. N is the local $\mathsf{NameCert}_{\mathsf{LyndonWord}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $W, A, X, U, S, F, H, C, P, N$. It has no coordinate for a host free monoid, quotient language equality, a selected factorization oracle, classical totality beyond the displayed total-order row, or a bridge field.

Theorem 8577.2 (Lyndon word NameCert obligations)**.** *For every accepted* $\mathsf{LyndonWord}^{\uparrow}$ *carrier $L = (W, A, X, U, S, F, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{LyndonWord}^{\uparrow}}$ *surface consists exactly of carrier admission for the finite word row, alphabet total-order row, lexicographic comparison row, primitive-word row, proper-suffix minimality row, factorization ledger, componentwise transport, displayed replay, provenance, and local naming. No Lyndon-word obligation is stored outside those finite rows.*

Proof. Project the carrier of Definition 8577.1. The word row W, total-order row A, lexicographic comparison row X, primitive row U, suffix-minimality row S, and factorization ledger F are the only mathematical coordinates.

Use finite word induction on W. The empty and one-letter cases expose no nontrivial suffix obligation, while the cons step reads the head-letter comparison from A and the tail comparison from the induction route through X.

Replay the suffix comparisons through S and C. Each nonempty proper suffix is a finite row, and its comparison with W is transported componentwise by H without adding a host word quotient.

Finally read P and N. Provenance and local naming mention only the displayed monoid, total-order, regular-language, context-free grammar, transport, and replay rows, so no selected oracle, quotient language equality, or bridge data can become a local NameCert obligation. □

Theorem 8577.3 (Lyndon word Chen–Fox–Lyndon factor route)**.** *Every regular-language or context-free grammar consumer of an accepted* $\mathsf{LyndonWord}^{\uparrow}$ *packet reads the Chen–Fox–Lyndon factor route through the finite ledger*

$$W, A, X, U, S, F, H, C, P, N.$$

The route first exposes the monoid word spine, then the alphabet total order and lexicographic suffix comparisons, then the primitive-word row, and only then the factorization ledger consumed by language-facing packets.

Proof. Begin with the finite word row W and the monoid surface of chapter 40. Word concatenation and nontrivial power inspection are read as displayed finite rows, so the primitive row U is not a host free-monoid assertion.

Next read the total-order and lexicographic rows through chapter 54. The proper suffixes listed in S are compared with W one by one, and finite word induction supplies the replay route for each suffix-comparison step.

The factorization ledger F is then available to chapter 351 and chapter 356. These consumers receive the displayed Lyndon factor route as finite word and derivation data, not as an external language quotient.

Finally transport and source the route through H, C, P, N. Since every row is displayed before the factor handoff, no selected global factorization oracle, quotient stream, host language equality, classical trichotomy beyond the displayed total order, or bridge field is exposed. □

Falsifiable prediction: Every accepted $\mathsf{LyndonWord}^{\uparrow}$ consumer that reads a factorization route must first display the finite word row, alphabet total-order row, lexicographic comparison row,

primitive-word row, proper-suffix minimality row, factorization ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert row.

Independence witness: monoid, totalorder, regularlanguage, contextfreegrammar: $\mathsf{LyndonWord}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries primitive finite word data, proper-suffix lexicographic minimality, and a language-facing factorization ledger as one certificate.

Closure status for $\mathsf{NameCert}_{\mathsf{LyndonWord}^{\uparrow}}$**.**

Constructive story: A $\mathsf{LyndonWord}^{\uparrow}$ packet is generated from a finite word row, alphabet total-order row, lexicographic comparison row, primitive-word row, proper-suffix minimality row, factorization ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{LyndonWord}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8577.1, Definition 8577.2, and Definition 8577.3 seed the finite Lyndon-word certificate over monoid words, total-order comparisons, suffix minimality, and language-facing factorization data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{LyndonWord}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close a host free-monoid quotient, infinite language equality, selected global factorization, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite word induction, primitive-word exactness, suffix-comparison replay, factorization ledger handoff, transport, provenance, and local naming for BEDC.Derived.LyndonWordUp.

Chapter 8578

A Concrete Naming Certificate for $\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}$

Following Bishop–Bridges constructive analysis and Troelstra–van Dalen on choice sequences and limited omniscience boundaries, the $\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}$ packet records the finite test boundary at which Ishihara-style branch inspection may be consumed by Real and Completion rows. It sits beside $\mathsf{IshiharaTrick}^{\uparrow}$ in chapter 1665, $\mathsf{LLPOBoundary}^{\uparrow}$ in chapter 1978, $\mathsf{WLPOBoundary}^{\uparrow}$ in chapter 4062, the stream-window surface $\mathsf{StreamName}^{\uparrow}$ in chapter 126, the regular rational readback $\mathsf{RegSeqRat}^{\uparrow}$ in chapter 301, the dyadic tolerance ledger $\mathsf{DyadicRatCore}^{\uparrow}$ in chapter 291, and the terminal real-name seal $\mathsf{Real}^{\uparrow}$ in chapter 38. The packet exposes a finite branch-inspection route without importing LPO, WLPO, trichotomy, selected limits, quotient stream equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8578.1 (Ishihara finite-test boundary carrier)**.** *An* $\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$I = (B, P, N, W, Q, D, E, H, C, S)$$

with the following rows:

1. *B is the branch-window row displaying the finite observation schedule inspected by the Ishihara-style argument;*
2. *P is the positive-test row naming the finite evidence that the inspected branch has crossed the displayed positive threshold;*
3. *N is the negative-test row naming the finite evidence that the inspected branch remains inside the displayed negative threshold;*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row through which the inspected sequence coordinates are read;*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the same finite window;*
6. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row carrying the threshold budget used by the two finite tests;*
7. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after B, P, N, W, Q, D have been displayed;*
8. *H is componentwise* hsame *transport for the branch, test, window, readback, tolerance, and seal rows;*
9. *C is displayed* Cont *replay for the same finite inspection route;*
10. *S is the local* $\mathsf{NameCert}_{\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}}$ *row.*

The classifier accepts only packets whose public read factors through the displayed finite branch window and exactly one of the two test rows before the Real or Completion consumer reads E. It has no coordinate for LPO, WLPO, trichotomy of real names, a selected completed limit, quotient equality of streams, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Theorem 8578.2 (Ishihara finite-test boundary NameCert obligations)**.** *For every accepted* IshiharaFiniteTestBoun *carrier $I = (B, P, N, W, Q, D, E, H, C, S)$, the local NameCert surface consists exactly of finite branch-window admission, positive-test admission, negative-test admission, StreamName window readback, RegSeqRat readback, DyadicRatCore tolerance budgeting, terminal Real-seal exposure, componentwise transport, displayed replay, and local naming. A Real or Completion consumer may use the packet only after the finite inspection rows B, W, Q, D and one displayed test row have been exposed; the consumer receives no LPO, WLPO, real trichotomy, selected limit, quotient stream equality, or ambient Real-completeness row.*

Lean4 (statement) `BEDC.Derived.IshiharaFiniteTestBoundaryUp`

Proof. Project the carrier of Definition 8578.1. The only branch-inspection data are the displayed window B, the positive-test row P, the negative-test row N, the stream window W, the regular rational readback Q, and the dyadic tolerance budget D.

The Ishihara-style use is therefore finite. A consumer first reads W, Q, D over the same branch window and then consumes either P or N as the displayed test outcome. The terminal Real seal E is downstream of that route.

Transport and replay through H and C preserve the same rows, and the local naming row S adds no omniscience coordinate. Since the carrier contains no LPO, WLPO, trichotomy, selected-limit, quotient-stream, or Real-completeness row, the listed rows exhaust the NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}}$.

Constructive story: An $\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}$ packet is generated from a finite branch-window row, positive and negative finite-test rows, a StreamName window, RegSeqRat readback, a DyadicRatCore tolerance budget, a terminal Real seal, componentwise transport, displayed replay, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8578.1 and Definition 8578.2 seed the finite branch-inspection boundary used by Real and Completion consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{IshiharaFiniteTestBoundary}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close LPO, WLPO, trichotomy, selected limits, quotient stream equality, ambient Real completeness, Lean-checked obligations, or a standard bridge.

Upgrade path: Obligation closure requires checked carrier admission, test-row exactness, window/readback/tolerance compatibility, Real-seal nonescape, transport stability, replay stability, and local naming for BEDC.Derived.IshiharaFiniteTestBoundaryUp.

Chapter 8579

A Concrete Naming Certificate for $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$

Following Bishop and Bridges, *Constructive Analysis*, the $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ packet records the finite pairing and unpairing interface used when a regular Cauchy construction must fold a finite precision window into one unary request and then recover the two visible sides. It sits over the $\mathsf{StreamName}^{\uparrow}$ windows of chapter 126, the dyadic tolerance ledger of chapter 291, the regular rational readback of chapter 301, the diagonal route of chapter 3782, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet is a finite NameCert for precision-window pairing; it is not a host pairing oracle, quotient equality of streams, selected real representatives, countable choice, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8579.1 (Regular Cauchy pairing-function carrier)**.** *A* $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (P, U, V, W, D, R, H, C, G, N)$$

with the following displayed rows:

1. *P is the unary pairing row. It records the finite code by which two precision requests are packed into one request index.*
2. *U and V are the first and second unpairing rows. They recover the two request windows from the displayed code P and do not read an ambient host pairing function.*
3. *W is the finite* $\mathsf{StreamName}^{\uparrow}$ *window row inspected after U and V expose the two sides of the paired request.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance-transport ledger. It records the dyadic radius, split budget, slack comparison cells, and common-scale data transported across the two unpaired request windows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the paired window and dyadic ledger.*
6. *H records componentwise* hsame *transport for the pairing code, unpairing rows, StreamName windows, dyadic tolerance transport, regular readback, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a finite precision request through $P, U, V, W, D, R, H, G, N$.*
8. *G is the* Pkg *provenance over* $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. N is the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPairingFunction}^{\uparrow}}$ *row naming the finite pairing-function surface. The classifier compares accepted packets only through $P, U, V, W, D, R, H, C, G, N$. It has no coordinate for hidden host pairing functions, quotient stream equality, selected Real representatives, countable-choice schedules, trichotomy, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8579.2 (Regular Cauchy pairing-function NameCert obligations)**.** *For every accepted* $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ *carrier*

$$K = (P, U, V, W, D, R, H, C, G, N),$$

the local $\mathsf{NameCert}_{\mathsf{RegularCauchyPairingFunction}^{\uparrow}}$ *surface consists exactly of carrier admission for the unary pairing row, the two unpairing rows, the finite StreamName window, the DyadicRatCore tolerance-transport ledger, the RegSeqRat readback, componentwise transport, displayed replay, package provenance, and local naming; pairing exactness for P; unpairing exactness for U, V; window exactness for W; tolerance transport for D; readback exactness for R; and ledger refusal for host pairing, quotient equality, selected representatives, countable choice, trichotomy, host real equality, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8579.1. The accepted tuple displays exactly $P, U, V, W, D, R, H, C, G, N$.

Pairing exactness is the row P. The two unpairing rows U and V consume the displayed code and recover the two finite precision windows before any StreamName or RegSeqRat readback is public.

Window and tolerance exactness are the rows W and D. The StreamName row reads only the unpaired finite windows, and the dyadic ledger transports the requested tolerance and common-scale data across those two windows.

The readback row R is downstream of the same route. The structural rows H, C, G, N transport, replay, source, and name the finite packet. Since the carrier contains no hidden host pairing function, quotient stream equality, selected representative, countable-choice schedule, trichotomy, host equality, or ambient completeness coordinate, the listed obligations exhaust the local NameCert surface. □

Theorem 8579.3 (Regular Cauchy pairing-window exactness)**.** *Every* $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{RegularCauchyDiagonalization}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ *packet must read the finite route*

$$P \longmapsto U, V \longmapsto W \longmapsto D \longmapsto R \longmapsto H, C, G, N.$$

Thus the public readback receives only a displayed unary pairing code, its two displayed unpairing rows, finite $\mathsf{StreamName}^{\uparrow}$ *windows,* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance transport, one* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and the local* NameCert *row.*

Proof. Start with the NameCert obligations of Definition 8579.2. They force every accepted consumer to expose P before U, V, to expose U, V before W, and to expose W before the dyadic transport ledger D.

The regular readback is then row-local. The row R consumes exactly the displayed window and tolerance rows; it cannot replace them by a host pairing function or by an unbounded search over request pairs.

Finally, H, C, G, N preserve and name the same finite route. The downstream diagonal and Real consumers therefore inherit the paired precision window as displayed BEDC data, with no quotient stream equality, selected representative, countable-choice schedule, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness exported by the packet. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ read displays one unary pairing row, two unpairing rows, one finite $\mathsf{StreamName}^{\uparrow}$ window row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance-transport ledger, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before a diagonal, completion, or Real-facing consumer may read the paired precision window.

Independence witness: streamname, regseqrat, dyadicratcore, regular-cauchy-diagonalization, real: $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a unary pairing row, two unpairing rows, a finite StreamName window, a DyadicRatCore tolerance-transport ledger, a RegSeqRat readback, and the structural transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyPairingFunction}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyPairingFunction}^{\uparrow}$ packet is generated from one unary pairing row, two unpairing rows, a finite StreamName window, a DyadicRatCore tolerance-transport ledger, a RegSeqRat readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyPairingFunction}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8579.1, Definition 8579.2, and Definition 8579.3 seed the finite precision-window pairing route used by RegSeqRat, diagonalization, completion, and Real consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyPairingFunction}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close quotient stream equality, selected representatives, countable choice, trichotomy, host real equality, ambient Real completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, pairing exactness, unpairing exactness, finite-window exactness, dyadic tolerance transport, readback exactness, transport stability, replay stability, provenance exhaustion, and local naming for BEDC.Derived.RegularCauchyPairingFunctionUp.

Chapter 8580

A Concrete Naming Certificate for $\mathsf{DyadicRationalBallBasis}^{\uparrow}$

Following Bishop–Bridges constructive metric-space practice, the $\mathsf{DyadicRationalBallBasis}^{\uparrow}$ packet records a finite dyadic ball basis for real-line and metric-completion consumers before any open-ball primitive is available. It sits after the dyadic arithmetic core of chapter 291, the finite observation windows of chapter 126, the regular rational readback of chapter 301, the terminal real-name seal of chapter 38, and the metric source interface of chapter 57. The finite ball-basis route also consumes the interval-cell refinement surface of chapter 5966 when a metric or Real consumer turns a dyadic center-radius row into a displayed interval cover. The packet gives Real, separability, and completion arguments a displayed basis element with center, radius, tolerance, readback, seal, transport, provenance, and local naming rows; it does not import host open balls, quotient real equality, located choice of centers, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8580.1 (Dyadic rational ball basis carrier)**.** *A* $\mathsf{DyadicRationalBallBasis}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (C, R, D, W, Q, E, H, P, N)$$

with the following displayed rows:

1. *C is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *center row, recording the dyadic rational center and its endpoint arithmetic.*
2. *R is the positive dyadic radius row, with the radius positivity and radius-comparison checks read through the same dyadic ledger as C.*
3. *D is the dyadic tolerance ledger for basis containment, refinement, and finite overlap reads.*
4. *W is the* $\mathsf{StreamName}^{\uparrow}$ *finite-window row used when a real or metric consumer inspects the center, radius, or tolerance schedule.*
5. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row attached to the inspected dyadic data before any completed real boundary is opened.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the center and radius comparisons, available only after C, R, D, W, Q are displayed.*
7. *H records componentwise* hsame *transport for the center, radius, tolerance, window, readback, seal, provenance, and local naming rows.*

8. *P records* Pkg *provenance over* $\mathsf{DyadicRationalBallBasis}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

9. *N is the local* $\mathsf{NameCert}_{\mathsf{DyadicRationalBallBasis}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $C, R, D, W, Q, E, H, P, N$. It has no coordinate for host open balls, selected dense enumerations, quotient real equality, trichotomy, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8580.2 (Dyadic rational ball basis NameCert obligations)**.** *For every accepted* $\mathsf{DyadicRationalBallBasis}^{\uparrow}$ *carrier*

$$B = (C, R, D, W, Q, E, H, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{DyadicRationalBallBasis}^{\uparrow}}$ *surface consists exactly of dyadic center admission through C, positive dyadic radius admission through R, tolerance-ledger admission through D, finite-window exposure through W, regular-rational readback through Q, real-seal exposure through E, componentwise transport through H, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8580.1. The analytic rows are the dyadic center C, positive radius R, tolerance ledger D, finite window W, regular readback Q, and Real seal E.

Read the rows in the displayed order. The center and radius rows are dyadic data, the tolerance row records containment and refinement bounds, the window row exposes the finite observations, and the readback row turns those observations into regular rational data before the seal is consumed.

Finally use the structural rows H, P, N. Transport, provenance, and local naming preserve that same finite route. Since no host open-ball, quotient-equality, dense-choice, trichotomy, choice, or ambient completeness coordinate appears in the carrier, none can be exported by the local certificate. □

Theorem 8580.3 (Dyadic rational ball basis Real coverage route)**.** *Every Real-facing or metric-facing consumer of an accepted* $\mathsf{DyadicRationalBallBasis}^{\uparrow}$ *carrier reads a basis element through the finite route*

$$C, R, D \longmapsto W, Q \longmapsto E.$$

The dyadic center, positive radius, and tolerance ledger expose the ball data before the $\mathsf{StreamName}^{\uparrow}$ *window,* $\mathsf{RegSeqRat}^{\uparrow}$ *readback, and* $\mathsf{Real}^{\uparrow}$ *seal are available. Thus a local metric-ball argument receives a displayed dyadic basis row, not a host open-ball primitive, selected representative, quotient real equality, countable-choice dense set, or ambient completeness theorem.*

Proof. Begin with the NameCert obligations of Definition 8580.2. They force every accepted read to expose the center, radius, and tolerance rows before any Real-facing endpoint can be inspected.

Next read the $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$ rows. The finite window W supplies the inspected observations, while Q supplies regular rational readback for the same dyadic center and radius data.

Finally open the $\mathsf{Real}^{\uparrow}$ seal E. Because E is downstream of C, R, D, W, Q and the structural rows only transport, source, and name the same packet, the coverage route remains a finite dyadic ball-basis certificate. No excluded host open-ball, quotient, selected-representative, choice, or completeness endpoint is present. □

Falsifiable prediction: A $\mathsf{DyadicRationalBallBasis}^{\uparrow}$ consumer that reaches $\mathsf{Real}^{\uparrow}$ or $\mathsf{Met}^{\uparrow}$ ball language without displaying C, R, D, W, Q refutes the carrier surface.

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicRationalBallBasis}^{\uparrow}}$.

Constructive story: A DyadicRationalBallBasis$^{\uparrow}$ packet is generated from a dyadic center row, positive dyadic radius row, dyadic tolerance ledger, StreamName window row, RegSeqRat readback row, Real seal row, componentwise hsame transport, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\text{DyadicRationalBallBasis}\uparrow}$, seed)

Scope closed: Definition 8580.1, Definition 8580.2, and Definition 8580.3 seed the finite dyadic ball-basis route over center, radius, tolerance, finite-window, readback, Real-seal, transport, provenance, and local naming rows.

Formal verification: FormalStatus(NameCert$_{\text{DyadicRationalBallBasis}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host open-ball primitives, quotient real equality, selected dense enumerations, trichotomy, countable choice, ambient Real$^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius admission, tolerance-ledger routing, StreamName window readback, RegSeqRat handoff, Real seal nonescape, transport, provenance, and local naming for BEDC.Derived.DyadicRationalBallBasisUp.

Chapter 8581

A Concrete Naming Certificate for $\mathsf{SylvesterEquation}^{\uparrow}$

Following Sylvester's matrix equation tradition, the $\mathsf{SylvesterEquation}^{\uparrow}$ packet records the finite equation route for a displayed linear matrix equation $AX - XB = C$. It sits after the finite matrix carrier of chapter 49, the linear-operator surface of chapter 48, the vector-space source of chapter 47, the scalar field route of chapter 45, and the characteristic-polynomial ledger of chapter 50. The packet names a candidate solution, a separation or solver ledger, and a residual row; it is not a host spectral theorem, a selected inverse of the Sylvester operator, quotient matrix equality, ambient Banach-space completeness, or an unbounded solver.

Definition 8581.1 (Sylvester equation carrier)**.** *A* $\mathsf{SylvesterEquation}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (A, B, C, X, S, R, H, T, P, N)$$

with the following displayed rows:

1. *A and B are* $\mathsf{Mat}^{\uparrow}$ *or* $\mathsf{LinMap}^{\uparrow}$ *rows over a shared* $\mathsf{Field}^{\uparrow}$ *and compatible* $\mathsf{VecSpace}^{\uparrow}$ *source and target rows.*
2. *C is the right-hand-side row for the equation $AX - XB = C$.*
3. *X is candidate solution data with the same displayed source and target shape as the matrix or linear-operator route requires.*
4. *S is a separation or solver ledger, read through the* $\mathsf{Poly}^{\uparrow}$ *sibling when spectral or characteristic-polynomial separation data is displayed and through the* $\mathsf{LinMap}^{\uparrow}$ *sibling when an operator route is displayed.*
5. *R is the residual row for $AX - XB = C$, recording the displayed left action, right action, subtraction, and comparison with C.*
6. *H records componentwise* hsame *transport for A, B, C, X, S, R and the structural rows.*
7. *T records displayed* Cont *replay from the input operator rows and candidate solution through the residual check.*
8. *P is the* Pkg *provenance over* $\mathsf{SylvesterEquation}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, $\mathsf{Field}^{\uparrow}$, $\mathsf{Poly}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{SylvesterEquation}^{\uparrow}}$ *row naming the displayed equation packet.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host spectral decomposition, selected inverses, quotient matrix equality, analytic norm estimates, ambient completeness, or a solver oracle.

Theorem 8581.2 (Sylvester equation NameCert obligations)**.** *For every accepted* $\mathsf{SylvesterEquation}^{\uparrow}$ *carrier*

$$K = (A, B, C, X, S, R, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{SylvesterEquation}^{\uparrow}}$ *surface consists exactly of matrix or linear-operator admission for* A *and* B*, right-hand-side admission for* C*, candidate-solution admission for* X*, separation or solver-ledger admission for* S*, residual-row admission for* R*, componentwise transport through* H*, displayed replay through* T*, provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8581.1. The equation data are precisely the two operator rows, the right-hand side, the candidate solution, the solver ledger, and the residual row.

The sibling anchors supply the allowed public surfaces. Matrix presentations read through chapter 49; operator presentations read through chapter 48; the common vector-space and scalar sources read through chapter 47 and chapter 45; and separation ledgers that use characteristic data read through chapter 50.

Finally H, T, P, N transport, replay, source, and name the same displayed route. Since the carrier contains no host spectral theorem, selected inverse, quotient equality, analytic completeness, or solver oracle, the listed rows exhaust the local NameCert obligations. □

Theorem 8581.3 (Sylvester equation linear-operator route)**.** *Every accepted* $\mathsf{SylvesterEquation}^{\uparrow}$ *packet exposes the residual computation only through the displayed operator route*

$$\mathsf{Mat}^{\uparrow}, \mathsf{LinMap}^{\uparrow}, \mathsf{VecSpace}^{\uparrow}, \mathsf{Field}^{\uparrow} \longmapsto A, B, C, X \longmapsto R \longmapsto H, T, P, N.$$

When the separation or solver ledger S *uses characteristic data, that ledger is read through* $\mathsf{Poly}^{\uparrow}$ *before any consumer treats the residual row* R *as a certified solution check. No accepted consumer obtains a solution from a host inverse of* $X \mapsto AX - XB$*, quotient matrix equality, an unbounded algorithm, or ambient spectral completeness.*

Proof. Start from the carrier projection. The residual row R is downstream of the displayed rows A, B, C, X and records only the equation check $AX - XB = C$ inside the accepted packet.

The separation or solver ledger S is also a packet row. If a consumer uses spectral or characteristic-polynomial separation data, the packet forces that read through the $\mathsf{Poly}^{\uparrow}$ sibling before R can be consumed as a solution check.

The structural rows H, T, P, N then preserve and name this route. Because no host inverse, quotient equality, unbounded solver, analytic norm estimate, or ambient completeness coordinate is present, the linear-operator route is exactly the displayed finite route. □

Falsifiable prediction: An accepted $\mathsf{SylvesterEquation}^{\uparrow}$ read is refuted if it exports a solution check for $AX - XB = C$ without first displaying the MatrixUp or LinearMapUp input rows, VecSpaceUp and FieldUp sources, the right-hand-side row, candidate solution row, separation or solver ledger, residual row, transport, replay, provenance, and local NameCert rows.

Independence witness: matrix, linearmap, vecspace, field, polynomial: $\mathsf{SylvesterEquation}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries two operator rows, a right-hand-side row, candidate solution data, a separation or solver ledger, a residual row for $AX - XB = C$, and the local NameCert evidence in one equation packet.

Closure status for $\mathsf{NameCert}_{\mathsf{SylvesterEquation}^{\uparrow}}$.

Constructive story: A $\mathsf{SylvesterEquation}^{\uparrow}$ packet is generated from two MatrixUp or LinearMapUp rows over shared VecSpaceUp and FieldUp sources, a right-hand-side row, candidate solution data, a PolynomialUp-backed separation or solver ledger when needed, a residual row for $AX - XB = C$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{SylvesterEquation}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8581.1, Definition 8581.2, and Definition 8581.3 seed the finite Sylvester equation route over Matrix, LinearMap, VecSpace, Field, Polynomial, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{SylvesterEquation}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, host spectral decomposition, selected Sylvester-operator inverses, quotient matrix equality, analytic norm estimates, ambient completeness, unbounded solver algorithms, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, operator-shape compatibility, candidate solution admission, separation-ledger exactness, residual-row exactness, transport, replay, provenance, and local naming for BEDC.Derived.SylvesterEquationUp.

Chapter 8582

A Concrete Naming Certificate for $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$

Following Jordan's finite-partition treatment of bounded variation and Rudin's real-analysis presentation of variation sums, the $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$ packet records only the displayed partition ledger read by a bounded-variation consumer. It sits between the variation packet of chapter 398, the real-function route of chapter 3654, the finite dyadic partition carrier of chapter 1863, the finite mesh and adjacency sibling of chapter 3496, and the terminal real-name seal of chapter 38. The packet keeps the classical bounded-variation read at finite means: it names one interval, one finite partition, endpoint readbacks, edge-difference budgets, and local provenance, not a supremum over all partitions, a variation measure, or host equality of functions.

Definition 8582.1 (BoundedVariationFinitePartition carrier)**.** *A* $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (I, \Pi, E, R, D, V, H, C, P, N)$$

with the following displayed rows:

1. *I is the interval row on which the inspected partition is read.*
2. *Π is the finite* $\mathsf{DyadicPartition}^{\uparrow}$ *row, listing the ordered dyadic subintervals and their endpoint adjacency ledger.*
3. *E records the* $\mathsf{Real}^{\uparrow}$ *endpoint rows attached to the displayed partition points.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the endpoint names used by the partition inspection.*
5. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *edge-difference budget, recording the adjacent endpoint comparisons and the finite partial-sum ledger for the inspected partition.*
6. *V is the* $\mathsf{BoundedVariation}^{\uparrow}$ *ledger row consumed by a bounded-variation classifier after I, Π, E, R, D have been displayed.*
7. *H records componentwise* hsame *transport for the interval, partition, endpoint, readback, budget, bounded-variation, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bounded-variation finite-partition request through I, Π, E, R, D, V.*
9. *P is the* Pkg *provenance over* $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{DyadicPartition}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

10. N is the local $\mathsf{NameCert}_{\mathsf{BoundedVariationFinitePartition}^{\uparrow}}$ *row.*
The classifier compares accepted carriers only through the displayed interval, finite partition, endpoint readback, edge-difference budget, bounded-variation ledger, transport, replay, provenance, and naming rows. It has no coordinate for total variation as a host supremum, a variation measure, quotient equality of functions, hidden partitions, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8582.2 (BoundedVariationFinitePartition NameCert obligations)**.** *For every accepted* $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$ *carrier*

$$Q = (I, \Pi, E, R, D, V, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{BoundedVariationFinitePartition}^{\uparrow}}$ *surface consists exactly of interval admission, finite dyadic partition admission, endpoint admission through* $\mathsf{Real}^{\uparrow}$*, regular-rational endpoint readback through* $\mathsf{RegSeqRat}^{\uparrow}$*, dyadic edge-difference budgeting through* $\mathsf{DyadicRatCore}^{\uparrow}$*, bounded-variation ledger handoff through* $\mathsf{BoundedVariation}^{\uparrow}$*, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8582.1. The interval row I fixes the domain of the inspected read, and the finite $\mathsf{DyadicPartition}^{\uparrow}$ row Π fixes the ordered adjacent cells whose endpoints may be queried.

Read the endpoint rows next. The $\mathsf{Real}^{\uparrow}$ row E gives the terminal endpoint seal, while the $\mathsf{RegSeqRat}^{\uparrow}$ row R supplies the regular-rational readback used to inspect those endpoint names at finite precision.

The dyadic budget row D then records the adjacent endpoint differences and their finite partial sums through $\mathsf{DyadicRatCore}^{\uparrow}$. Only after those rows are displayed can the bounded-variation ledger V be consumed as a $\mathsf{BoundedVariation}^{\uparrow}$ row.

Finally H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no row for a host supremum over all partitions, a variation measure, quotient equality of functions, hidden partition families, or ambient real completeness, the listed rows exhaust the local NameCert obligations. □

Theorem 8582.3 (BoundedVariationFinitePartition ledger handoff)**.** *Every bounded-variation consumer of an accepted* $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$ *carrier must read the ordered finite route*

$$\mathsf{DyadicPartition}^{\uparrow} \longrightarrow \mathsf{Real}^{\uparrow} \longrightarrow \mathsf{RegSeqRat}^{\uparrow} \longrightarrow \mathsf{DyadicRatCore}^{\uparrow} \longrightarrow \mathsf{BoundedVariation}^{\uparrow}$$

through $I, \Pi, E, R, D, V, H, C, P, N$. The handoff supplies exactly one finite partition ledger to chapter 398 and to the real-function surface of chapter 3654.

Proof. Start with a bounded-variation request. By Definition 8582.2, the request first enters the displayed interval and finite partition rows, so every edge is one of the adjacent cells listed by Π.

The endpoint and budget rows then determine the inspected variation contribution. Endpoint values are read through E and R, and each adjacent difference is budgeted by the $\mathsf{DyadicRatCore}^{\uparrow}$ row D.

The $\mathsf{BoundedVariation}^{\uparrow}$ ledger V is downstream of this route. It receives the displayed finite partition and its edge-difference budget, while H, C, P, N preserve the same route for transport, replay, provenance, and local naming.

Thus the consumer obtains one finite partition ledger rather than a global variation object. The displayed partition row consumes the finite mesh and adjacency sibling of chapter 3496; no row supplies a supremum over all partitions, a variation measure, host function equality, a hidden refinement family, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BoundedVariationFinitePartition}^{\uparrow}}$.

Constructive story: A $\mathsf{BoundedVariationFinitePartition}^{\uparrow}$ packet is generated from an interval row, a finite DyadicPartitionUp row, RealUp endpoint rows, RegSeqRatUp readback rows, a DyadicRatCoreUp edge-difference budget, a BoundedVariationUp ledger row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BoundedVariationFinitePartition}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8582.1, Definition 8582.2, and Definition 8582.3 seed the finite bounded-variation partition surface over interval rows, dyadic partitions, real endpoints, regular readbacks, dyadic edge budgets, bounded-variation handoff, and local provenance.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BoundedVariationFinitePartition}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim total variation as a host supremum, a variation measure, quotient equality of functions, hidden partition families, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite partition exposure, endpoint readback, dyadic edge-budget exactness, bounded-variation ledger handoff, transport, replay, provenance, and local naming for BEDC.Derived.BoundedVariationFinitePartitionUp.

Chapter 8583

A Concrete Naming Certificate for $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$ packet records the separated uniqueness surface for regular Cauchy rational names before any quotient completion is formed. It sits between the $\mathsf{RegSeqRat}^{\uparrow}$ readback row of chapter 301, the $\mathsf{StreamName}^{\uparrow}$ finite-window surface of chapter 126, the $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger of chapter 291, and the terminal $\mathsf{Real}^{\uparrow}$ seal of chapter 38. The packet names uniqueness by finite separation data, not by host real equality, quotient classes, selected limits, or ambient completeness.

Definition 8583.1 (RegularCauchyUniqueLimit carrier)**.** *A* $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$U = (Q, Q', W, W', D, S, E, H, C, P, N)$$

with the following rows:

1. *Q and Q' are* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows naming two regular rational Cauchy names inspected for the same prospective* $\mathsf{Real}^{\uparrow}$ *seal.*
2. *W and W' are synchronized* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows through which the two readbacks are observed.*
3. *D is the shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger storing the dyadic radii, denominator windows, and comparison budget used by both readbacks.*
4. *S is the separated comparison row asserting that every displayed finite tolerance window forces the two readbacks into the same separation class before the seal row is opened.*
5. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after Q, Q', W, W', D, S have been displayed.*
6. *H records componentwise* hsame *transport for the two readbacks, finite windows, tolerance ledger, separation row, seal row, replay, provenance, and local naming row.*
7. *C records displayed* Cont *replay from finite window requests through dyadic tolerance comparison and separated uniqueness.*
8. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
9. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueLimit}^{\uparrow}}$ *row naming the separated uniqueness packet and its permitted real-seal reads.*

The classifier compares accepted packets only through $Q, Q', W, W', D, S, E, H, C, P, N$. It has no coordinate for quotient stream equality, selected representatives, countable choice over tails, host equality of real numbers, metric-completeness data, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.RegularCauchyUniqueLimitUp`

Theorem 8583.2 (RegularCauchyUniqueLimit separation)**.** *Let $U = (Q, Q', W, W', D, S, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$ *carrier. Any* $\mathsf{Real}^{\uparrow}$*-facing consumer that reads both regular Cauchy names through U must first pass through the synchronized* $\mathsf{StreamName}^{\uparrow}$ *windows, the common* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, and the separated comparison row S. Consequently the consumer receives a unique terminal seal only through the displayed finite separation route.*

The route exports no quotient stream equality, selected limit, countable-choice tail selector, host real equality, metric-completeness datum, or ambient $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Project the carrier of Definition 8583.1. The only rows available to a real-facing consumer are the two regular rational readbacks, the two finite StreamName windows, the shared DyadicRatCore tolerance ledger, the separated comparison row, and the terminal seal row, together with transport, replay, provenance, and local naming.

The separation row S is downstream of the synchronized finite windows and the common dyadic budget. Thus a consumer cannot inspect the terminal $\mathsf{Real}^{\uparrow}$ seal before the two regular Cauchy names have been compared through the same displayed tolerance ledger.

The structural rows H, C, P, N transport and replay exactly that finite route. Since the carrier has no row for quotient stream equality, selected limits, countable choice, host real equality, metric completeness, or ambient completeness, separated uniqueness is read only from the displayed NameCert surface. □

Theorem 8583.3 (RegularCauchyUniqueLimit NameCert obligations)**.** *For every accepted* RegularCauchyUniqueLi *carrier $U = (Q, Q', W, W', D, S, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueLimit}^{\uparrow}}$ *surface consists exactly of the following obligation rows:*

1. *carrier admission for the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readbacks, two* $\mathsf{StreamName}^{\uparrow}$ *finite-window rows, shared* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger, separated comparison row, terminal* $\mathsf{Real}^{\uparrow}$ *seal row, transport, replay, provenance, and local naming row;*
2. *window synchronization, requiring W and W' to expose the same finite inspection schedule before D is read;*
3. *tolerance-ledger exactness, requiring the denominator and radius budget in D to be the only budget consumed by the separated comparison row S;*
4. *separation-to-seal exactness, requiring S to be displayed before the terminal* $\mathsf{Real}^{\uparrow}$ *row E is available;*
5. *ledger refusal, excluding quotient stream equality, selected limits, countable choice over tails, host real equality, metric completeness, and ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

No local NameCert obligation is stored outside these rows.

Proof. Carrier admission is tuple projection from Definition 8583.1. The accepted packet displays the two regular rational names Q, Q', synchronized finite windows W, W', shared dyadic tolerance ledger D, separated comparison row S, terminal seal E, and the structural rows H, C, P, N.

Window synchronization and tolerance-ledger exactness follow the displayed dependency order. The two finite windows are inspected before the shared dyadic ledger is consumed, and the separated comparison row can read only that ledger.

The seal exactness clause follows because E is downstream of S in the carrier. A consumer therefore cannot obtain a terminal real seal without first exposing the finite separated comparison route.

Finally, the carrier contains no row for quotient equality, selected limits, countable choice, host real equality, metric completeness, or ambient completeness. The listed rows therefore exhaust the local NameCert surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueLimit}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyUniqueLimit}^{\uparrow}$ packet is generated from two RegSeqRat readback rows, two synchronized StreamName finite-window rows, one DyadicRatCore tolerance ledger, a separated comparison row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueLimit}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8583.1, Definition 8583.2, and Definition 8583.3 seed the finite separated uniqueness route through RegSeqRat, StreamName, DyadicRatCore, and Real rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{RegularCauchyUniqueLimit}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.RegularCauchyUniqueLimitUp`

Bridge status: none

Not claimed: This chapter does not claim full RealUp completeness, quotient completion, selected representatives, countable choice over tails, host real equality, metric completeness, checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, window synchronization, tolerance-ledger exactness, separation-to-seal exactness, transport stability, replay stability, and ledger refusal for BEDC.Derived.RegularCauchyUniqueLimitUp.

Chapter 8584

A Concrete Naming Certificate for $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$

Following Bishop–Bridges nested interval practice, the $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ packet records the finite closed-interval route by which a displayed nested interval argument is handed to Real and Completion consumers without choosing a completed point. It sits over the nested interval source of chapter 320, the finite diagonal selector surface of chapter 389, and the interval-cell refinement route of chapter 5966. The packet reads endpoint and width data through $\mathsf{DyadicRatCore}^{\uparrow}$, finite observations through $\mathsf{StreamName}^{\uparrow}$, regular rational tails through $\mathsf{RegSeqRat}^{\uparrow}$, and the terminal completion-facing boundary through $\mathsf{Real}^{\uparrow}$; it does not assert Cantor-style completed intersections, point extraction, host real equality, choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8584.1 (Finite closed-interval nested-intersection carrier)**.** *A* $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (I, S, C, D, W, Q, E, H, T, P, N)$$

with the following displayed rows:

1. *I is the source* $\mathsf{NestedInterval}^{\uparrow}$ *packet, recording the retained closed-interval nesting rows and their finite containment ledger.*
2. *S is the* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *selector row, exposing the finite diagonal stage requested by the consumer.*
3. *C is the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row, recording the interval cells used to read the selected finite stage.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint and width row, carrying dyadic lower endpoints, upper endpoints, and width bounds for the selected cells.*
5. *W is the* $\mathsf{StreamName}^{\uparrow}$ *observation-window row through which the consumer inspects the finite interval data.*
6. *Q is the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-readback row, turning the displayed width bounds and endpoint windows into regular rational completion data.*
7. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row, available only after I, S, C, D, W, Q have been displayed.*
8. *H records componentwise* hsame *transport for the nested source, selector, cells, endpoints, widths, windows, tail readback, Real seal, provenance, and local naming rows.*

9. *T records the displayed continuity boundary*

$$\mathsf{Cont}(F) = \mathsf{Cont}(I, S, C, D, W, Q, E, H)$$

for the finite handoff from interval data to the Real-facing seal.

10. *P records*

$$\mathsf{Pkg}(F) = \mathsf{Pkg}(\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}, \mathsf{NestedInterval}^{\uparrow}, \mathsf{NestedIntervalIntersection}^{\uparrow}, \mathsf{DyadicIntervalI}$$

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $I, S, C, D, W, Q, E, H, T, P, N$. It has no coordinate for a completed infinite intersection, selected point, quotient real equality, choice schedule, host endpoint equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8584.2 (Finite closed-interval nested-intersection obligation surface)**.** *For every accepted* $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ *carrier*

$$F = (I, S, C, D, W, Q, E, H, T, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}$ *surface consists of the following finite obligations:*

1. *carrier admission for the source* $\mathsf{NestedInterval}^{\uparrow}$ *row I and the displayed selector row S;*
2. *classifier and window transport through the* $\mathsf{StreamName}^{\uparrow}$ *row W and componentwise* hsame *row H;*
3. *finite diagonal selector coverage through S and the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row C;*
4. *width-tail Cauchy handoff through the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-width row D and the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-readback row Q;*
5. $\mathsf{Real}^{\uparrow}$*-seal nonselection through E, which may be read only after I, S, C, D, W, Q are displayed;*
6. *provenance and local naming through* $\mathsf{Pkg}(F)$ *and* $\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}$.

Thus the packet supplies a finite closed-interval nested-intersection handoff, not Cantor-style completed intersection data, point extraction, host real equality, choice, quotient real equality, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.FiniteClosedIntervalNestedIntersectionUp.FiniteClosedIntervalNestedIntersectionObl`

Proof. Project the carrier of Definition 8584.1. The source interval row I, selector row S, interval-cell row C, endpoint-width row D, window row W, readback row Q, and Real seal row E are displayed before the structural rows are read.

Read the finite route in dependency order. The nested source and selector admit the requested finite diagonal stage; the interval-cell and dyadic endpoint-width rows expose the inspected closed interval; the window and regular-rational readback rows turn that finite stage into completion-facing tail data.

Finally apply the transport, continuity, package, and local naming rows H, T, P, N. These rows preserve and name the same displayed data. Since the carrier contains no completed intersection coordinate, selected point, host equality, choice schedule, quotient equality, or ambient completeness row, none can be exported by the local certificate. □

Theorem 8584.3 (Closed-interval nested Bolzano handoff)**.** *Any Bolzano–Weierstrass or bounded-sequence consumer reading an accepted* $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ *packet must pass through the displayed seal rows*

$$I, S, C, D, W, Q, E, H, T, P, N.$$

In particular, cluster-point or subsequence language is available only after the consumer has read the $\mathsf{NestedInterval}^{\uparrow}$ *source row* I*, the* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *selector row* S*, the* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *cell row* C*, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-width row* D*, the* $\mathsf{StreamName}^{\uparrow}$ *window row* W*, the* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-readback row* Q*, and the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* E*, followed by transport, continuity, provenance, and local naming. The handoff exports no selected subsequence, choice schedule, quotient equality, host cluster point, or ambient completeness.*

Lean4 ✓ `BEDC.Derived.FiniteClosedIntervalNestedIntersectionUp.ClosedIntervalNestedBolzanoHandoff`

Proof. Project the carrier rows of Definition 8584.1. A bounded-sequence or Bolzano-facing read first sees the same nested source, selector, interval-cell, endpoint-width, window, readback, and Real-seal rows used by the local obligation surface.

Apply Definition 8584.2. It orders the finite route so that the selected diagonal stage, dyadic cell data, endpoint-width bounds, stream windows, and regular-rational tail readback are displayed before the Real-facing seal is consumed.

Only downstream readers may attach cluster or bounded-sequence terminology to that route. A $\mathsf{BoundedRealSequence}^{\uparrow}$, $\mathsf{SequentialCompact}^{\uparrow}$, or Bolzano–Weierstrass-style consumer receives the displayed rows $I, S, C, D, W, Q, E, H, T, P, N$ as a handoff boundary, not a source of selected subsequences, countable choice, quotient equality, host cluster points, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Theorem 8584.4 (Finite closed-interval nested-intersection obligation-closure package)**.** *For every accepted* $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ *carrier*

$$F = (I, S, C, D, W, Q, E, H, T, P, N),$$

the carrier, obligation surface, and Bolzano handoff jointly expose the $\mathsf{NestedInterval}^{\uparrow}$ *row* I*,* $\mathsf{NestedIntervalIntersection}^{\uparrow}$ *row* S*,* $\mathsf{DyadicIntervalNet}^{\uparrow}$ *row* C*,* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint-width row* D*,* $\mathsf{StreamName}^{\uparrow}$ *window row* W*,* $\mathsf{RegSeqRat}^{\uparrow}$ *tail-readback row* Q*,* $\mathsf{Real}^{\uparrow}$ *seal row* E*, componentwise* hsame *transport* H*,* Cont *replay* T*,* Pkg *provenance* P*, and the local* $\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}$ *row* N*. The package supplies the finite L10 Real and Completion route only; it supplies no selected point, completed infinite intersection, host real equality, quotient real equality, choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the carrier of Definition 8584.1. Its displayed rows are exactly the nested source, diagonal selector, interval-cell, endpoint-width, observation-window, tail-readback, Real-seal, transport, continuity, provenance, and local naming rows.

Apply the obligation surface of Definition 8584.2. It orders these rows as carrier admission, classifier and window transport, finite selector coverage, endpoint-width tail readback, Real-seal nonselection, provenance, and local naming.

Apply the Bolzano handoff of Definition 8584.3. It states that any bounded-sequence or Bolzano-facing consumer must pass through the same displayed rows before using cluster-point or subsequence language.

Because the carrier has no coordinate for point selection, completed intersection data, host equality, quotient equality, a choice schedule, or ambient completeness, the obligation package closes only the finite displayed route to L10 Real and Completion consumers. □

Lean4 ✓ `BEDC.Derived.FiniteClosedIntervalNestedIntersectionUp.FiniteClosedIntervalNestedIntersectionObl`

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}$ packet is generated from a NestedInterval source row, NestedIntervalIntersection selector row, DyadicIntervalNet cell row, DyadicRatCore endpoint-width row, StreamName window row, RegSeqRat tail-readback row, Real seal row, componentwise hsame transport, continuity boundary, package provenance, and local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8584.1, Definition 8584.2, and Definition 8584.3 seed the finite closed-interval nested-intersection route over source, selector, cell, endpoint-width, window, readback, Real-seal, transport, continuity, provenance, local naming, and bounded-sequence handoff rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteClosedIntervalNestedIntersection}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Cantor-style completed intersections, point extraction, host real equality, quotient real equality, choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, selector coverage, interval-cell routing, endpoint-width tail readback, StreamName window transport, RegSeqRat handoff, Real seal nonselection, provenance, and local naming for BEDC.Derived.FiniteClosedIntervalNestedIntersectionUp.

Chapter 8585

A Concrete Naming Certificate for $\mathsf{HausdorffCompletionPullback}^{\uparrow}$

Following Bourbaki and Bishop–Bridges on separated uniform completions, the $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ packet records the finite BEDC surface where a Cauchy completion comparison becomes public only after Hausdorff separation has been displayed. It reads the stream, regular-rational, and dyadic source rows of chapter 126, chapter 301, and chapter 291; it refines the synchronized comparison of chapter 6954; it consumes the separated-uniform packets of chapter 2367 and chapter 2242; and it exports only the Real-facing route already named by chapter 38. The packet is a finite L10 NameCert object: it does not import quotient completions, selected representatives, countable choice, host equality, or ambient completeness of $\mathsf{Real}^{\uparrow}$.

Definition 8585.1 (Hausdorff completion pullback carrier)**.** *A* $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$P = (S, W, D, P_0, P_1, H_0, H_1, U, T, C, Q, N)$$

with the following displayed rows:

1. *S is the common* $\mathsf{StreamName}^{\uparrow}$ *source row whose finite windows are read by both completion routes.*
2. *W is the shared* $\mathsf{RegSeqRat}^{\uparrow}$ *regular-sequence readback row attached to those windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger used for positive-radius comparison.*
4. *P_0 and P_1 are the two completion projection rows, each landing in the separated completion surface over S, W, D.*
5. *H_0 and H_1 are the two Hausdorff separation witnesses, read from* $\mathsf{HausdorffUniformCompletion}^{\uparrow}$ *or* $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$ *before any pullback comparison is exported.*
6. *U is the uniform pullback row binding the two projected completion routes over the common source and tolerance ledger.*
7. *T records componentwise* hsame *transport for the source, window, dyadic ledger, projections, separation witnesses, uniform pullback row, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay of the separated pullback route.*

9. *Q is the* Pkg *provenance over* $\mathsf{HausdorffCompletionPullback}^{\uparrow}$, $\mathsf{CauchyCompletionPullback}^{\uparrow}$, $\mathsf{HausdorffUniformComp}$ $\mathsf{HausdorffCompletionUniversal}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* $\mathsf{NameCert}_{\mathsf{HausdorffCompletionPullback}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $S, W, D, P_0, P_1, H_0, H_1, U, T, C, Q, N$. It has no coordinate for quotient-completion equality, selected limits, host function equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.HausdorffCompletionPullbackUp`

Theorem 8585.2 (Hausdorff completion pullback NameCert obligations)**.** *For every accepted* $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ *carrier*

$$P = (S, W, D, P_0, P_1, H_0, H_1, U, T, C, Q, N),$$

the local $\mathsf{NameCert}_{\mathsf{HausdorffCompletionPullback}^{\uparrow}}$ *surface consists exactly of common source admission, regular-rational readback, dyadic tolerance control, two completion projections, two Hausdorff separation witnesses, uniform pullback comparison, transport, replay, provenance, and non-escape. In particular, a public separated-comparison read must display $S, W, D, P_0, P_1, H_0, H_1, U, T, C, Q, N$ before it may treat the two completion projections as meeting.*

Lean4 ✓ `BEDC.Derived.HausdorffCompletionPullbackUp.HausdorffCompletionPullbackTasteGate single carrier alignment`

Proof. Project the carrier of Definition 8585.1. The source rows S, W, D are the only finite input data available to the two completion projections, so every later comparison is already tied to the same stream window, regular sequence readback, and dyadic tolerance ledger.

Next inspect P_0 and P_1. These rows expose the two completion projections without giving a selected completed representative or a quotient-completion equality.

The Hausdorff rows H_0 and H_1 are then mandatory. They are the only coordinates that turn a Cauchy pullback comparison into a separated comparison, and they must be read before the uniform pullback row U can be exported.

Finally T, C, Q, N provide componentwise transport, displayed replay, provenance, and local naming for the same finite route. Since the carrier contains no coordinate for countable choice, host equality, detached limits, or ambient Real completeness, the listed rows exhaust the NameCert obligations. □

Theorem 8585.3 (Hausdorff completion pullback uniform route)**.** *Every* $\mathsf{Real}^{\uparrow}$*-facing consumer of an accepted* $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ *packet that compares the two exported projection rows must first read the common* $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{DyadicRatCore}^{\uparrow}$ *rows S, W, D, then the two projection rows P_0, P_1, then the two Hausdorff separation witnesses H_0, H_1, and only then the uniform pullback row U. The route cannot inspect quotient filters, selected representatives, host function equality, countable choice, or ambient Real completeness.*

Proof. Begin with the synchronized finite-window comparison supplied by chapter 6954. It fixes the common source window and regular-rational readback through which the two completion routes are allowed to meet.

The dyadic ledger D supplies the positive-radius scale used by the separated uniform-completion packets. Reading P_0 and P_1 without D would expose two completion projections but no finite uniform comparison scale.

Now read H_0 and H_1 from the Hausdorff completion siblings. These witnesses are the public separation boundary; they block any replacement of the finite route by quotient filters, chosen representatives, or host-level equality.

With the source, readback, dyadic scale, projections, and separation witnesses displayed, the uniform pullback row U is a BEDC replay row rather than an external completeness principle. Transport, replay, provenance, and local naming keep the export inside the finite carrier. □

Falsifiable prediction: Every accepted $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ comparison must display StreamName, RegSeqRat, DyadicRatCore, two completion projection rows, two Hausdorff separation witnesses, a uniform pullback row, hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Independence witness: cauchy-completion-pullback, hausdorff-uniform-completion, hausdorff-completion-universal, streamname, regseqrat, dyadicratcore, real: $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ is not bijective to any listed sibling because it binds the Cauchy pullback comparison to two explicit Hausdorff separation witnesses before the uniform pullback row becomes public.

Closure status for $\mathsf{NameCert}_{\mathsf{HausdorffCompletionPullback}^{\uparrow}}$.

Constructive story: A $\mathsf{HausdorffCompletionPullback}^{\uparrow}$ packet is generated from common StreamName, RegSeqRat, and DyadicRatCore source rows, two completion projection rows, two Hausdorff separation witnesses, a uniform pullback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionPullback}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8585.1, Definition 8585.2, and Definition 8585.3 seed the finite separated completion-pullback route over the L10 Real completion spine.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HausdorffCompletionPullback}^{\uparrow}}, \mathsf{theoremChecked})$

Lean target: `BEDC.Derived.HausdorffCompletionPullbackUp.HausdorffCompletionPullbackTasteGate\_single\_carrier\_al`

Bridge status: none

Not claimed: This chapter does not close quotient completions, selected limits, countable choice, host function equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, projection compatibility, Hausdorff separation witnesses, uniform pullback replay, transport, provenance, and non-escape for BEDC.Derived.HausdorffCompletionPullbackUp.

Chapter 8586

A Concrete Naming Certificate for $\mathsf{MetricCompletionAdmissibleEmbedding}^{\uparrow}$

Following Bishop and Bridges and Kelley on metric completion and dense isometric embeddings, the $\mathsf{MetricCompletionAdmissibleEmbedding}^{\uparrow}$ packet records the finite entry boundary by which a metric source is admitted into a displayed separated completion before extension consumers read it. It sits beside the metric-completion route of chapter 1506, the completion-embedding interface of chapter 1512, the Cauchy-filter basis of chapter 1501, the separated-metric comparison of chapter 1411, and the uniform-continuous extension handoff of chapter 769. Its finite readback rows pass through chapter 126, chapter 301, chapter 291, and chapter 38. The packet names an admissible dense embedding boundary; it is not a quotient completion, a selected representative, a host equality principle, countable choice, trichotomy, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8586.1 (Metric completion admissible embedding carrier)**.** *A* $\mathsf{MetricCompletionAdmissibleEmbedding}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, E, F, S, U, W, R, D, Z, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{MetricCompletion}^{\uparrow}$ *row, recording the completion-facing carrier, Cauchy admission surface, and completion readback boundary.*
2. *E is the* $\mathsf{CompletionEmbedding}^{\uparrow}$ *row, recording the source-to-completion graph before any completed point equality is read.*
3. *F is the* $\mathsf{CauchyFilterBasis}^{\uparrow}$ *row, exposing the finite filter-basis requests whose images are tested for density.*
4. *S is the* $\mathsf{SeparatedMetric}^{\uparrow}$ *row, exposing the zero-distance comparison that makes the embedding admissible into a separated target.*
5. *U is the* $\mathsf{UniformContinuousExtension}^{\uparrow}$ *row, naming the downstream extension handoff available only after the dense embedding rows are displayed.*
6. *W is the* $\mathsf{StreamName}^{\uparrow}$ *window row for the finite observations consumed by completion and extension readers.*
7. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for rational distance and modulus data.*

8. *D is the* DyadicRatCore$^{\uparrow}$ *tolerance row, recording the dyadic radii and comparison cells used by density and separatedness checks.*
9. *Z is the terminal* Real$^{\uparrow}$ *seal for the displayed distance and extension-readback values.*
10. *H records componentwise* hsame *transport for the completion, embedding, filter-basis, separated-metric, extension, window, rational readback, dyadic tolerance, real seal, replay, provenance, and local naming rows.*
11. *C records displayed* Cont *replay for source requests, completion admission, dense-window lookup, separated comparison, and extension handoff.*
12. *P is the* Pkg *provenance over* MetricCompletionAdmissibleEmbedding$^{\uparrow}$, MetricCompletion$^{\uparrow}$, CompletionEmbedding CauchyFilterBasis$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformContinuousExtension$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
13. *N is the local* NameCert$_{\text{MetricCompletionAdmissibleEmbedding}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, E, F, S, U, W, R, D, Z, H, C, P, N$. It has no coordinate for quotient completion classes, selected limits, host equality of completed points, countable choice, trichotomy, or ambient Real$^{\uparrow}$ *completeness.*

Lean4 (definition) `BEDC.Derived.MetricCompletionAdmissibleEmbeddingUp`

Theorem 8586.2 (Metric completion admissible embedding NameCert obligations)**.** *For every accepted* MetricCompletionAdmissibleEmbedding$^{\uparrow}$ *carrier*

$$A = (M, E, F, S, U, W, R, D, Z, H, C, P, N),$$

the local NameCert$_{\text{MetricCompletionAdmissibleEmbedding}^{\uparrow}}$ *surface consists exactly of carrier admission for the metric-completion row, completion-embedding graph, Cauchy-filter basis, separated-metric comparison, uniform-continuous extension handoff, StreamName window, RegSeqRat readback, DyadicRatCore tolerance ledger, Real seal, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Every extension-facing or completion-facing consumer must display $M, E, F, S, U, W, R, D, Z, H, C, P, N$ before reading the embedding as admissible.*

Proof. Project the accepted carrier. The analytic rows are $M, E, F, S, U, W, R, D, Z$, and the structural rows are H, C, P, N.

The embedding is read through the completion and filter-basis rows first. The rows M, E, F expose a completion-facing object, its graph from the source, and the finite basis requests that witness density for the read under inspection.

The separated and extension rows are downstream. The row S supplies the zero-distance comparison for the separated target, and U can be consumed only as a named handoff after the embedding and density rows have been displayed.

The numerical readback rows W, R, D, Z keep every distance, tolerance, and extension value inside the finite StreamName, RegSeqRat, DyadicRatCore, and Real seal route. Transport, replay, provenance, and local naming preserve the same displayed packet, so no quotient completion, selected limit, host equality, countable-choice row, trichotomy branch, or ambient Real completeness coordinate can be projected from the NameCert surface. □

Theorem 8586.3 (Metric completion admissible embedding handoff)**.** *Every* MetricCompletionAdmissibleEmbeddin *read handed to a* UniformContinuousExtension$^{\uparrow}$ *or completion-universal consumer must first expose the* MetricCompletion$^{\uparrow}$ *row,* CompletionEmbedding$^{\uparrow}$ *graph,* CauchyFilterBasis$^{\uparrow}$ *density requests,*

SeparatedMetric$^{\uparrow}$ *comparison, StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, Real seal, and local NameCert rows. The handoff supplies finite admissible-embedding data only; it does not assert quotient completion equality, selected representatives, countable choice, host equality of completed points, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Start with the NameCert obligations of Definition 8586.2. They require the completion, embedding, filter-basis, separatedness, extension, window, readback, tolerance, seal, transport, replay, provenance, and naming rows to remain visible before the packet is read as admissible.

For a uniform-continuous extension consumer, the row U is not an independent extension theorem. It is a handoff row tied to M, E, F, S, W, R, D, Z, so the consumer receives only the displayed dense embedding boundary.

For a completion-universal consumer, the same rows give the completion and density route without quotienting or selecting a completed representative. The structural rows H, C, P, N preserve that finite route, and the excluded global principles are absent from the carrier. □

Falsifiable prediction: Every MetricCompletionAdmissibleEmbedding$^{\uparrow}$ handoff to completion or extension consumers displays MetricCompletion$^{\uparrow}$, CompletionEmbedding$^{\uparrow}$, CauchyFilterBasis$^{\uparrow}$, SeparatedMetric$^{\uparrow}$, UniformContinuousExtension$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the admissible embedding is consumed.

Independence witness: metriccompletion, completionembedding, cauchyfilterbasis, separated-metric, uniform-continuous-extension, streamname, regseqrat, dyadicratcore, real: MetricCompletionAdmissibleEmb is not bijective to any listed sibling because it jointly carries a completion row, embedding graph, Cauchy-filter basis, separated comparison, extension handoff, finite windows, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and local naming.

Closure status for NameCert$_{\text{MetricCompletionAdmissibleEmbedding}^{\uparrow}}$.

Theory closure: TheoryGate(NameCert$_{\text{MetricCompletionAdmissibleEmbedding}^{\uparrow}}$, seed)

Scope closed: Definition 8586.1, Definition 8586.2, and Definition 8586.3 seed the finite admissible-embedding route from metric completion and completion embedding rows through Cauchy-filter bases, separated comparison, extension handoff, finite windows, rational readback, dyadic tolerance, Real sealing, transport, replay, provenance, and naming.

Formal verification: FormalStatus(NameCert$_{\text{MetricCompletionAdmissibleEmbedding}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.MetricCompletionAdmissibleEmbeddingUp`

Bridge status: none

Not claimed: This chapter does not claim quotient completions, selected representatives, host equality of completed points, countable choice, trichotomy, ambient Real$^{\uparrow}$ completeness, theorem-level Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, embedding-graph exactness, Cauchy-filter density routing, separated-comparison exposure, extension-handoff nonescape, finite-window readback, transport, replay, provenance, and local naming for BEDC.Derived.MetricCompletionAdmissibleEmbeddingUp.

Constructive story: A MetricCompletionAdmissibleEmbedding$^{\uparrow}$ packet is generated from a MetricCompletion row, CompletionEmbedding graph, CauchyFilterBasis requests, SeparatedMetric comparison, UniformContinuousExtension handoff, StreamName window, RegSeqRat readback, DyadicRatCore tolerance row, Real seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Chapter 8587

A Concrete Naming Certificate for $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$

Following Cauchy and Bishop–Bridges constructive analysis, the $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$ packet isolates the finite dyadic block-witness row used by the condensation route before theorem-level summability or completeness claims are read. It sits between the source-series carrier of chapter 1581, the finite block packet of chapter 7794, the theorem packet of chapter 3727, the dyadic arithmetic core of chapter 291, the stream schedule of chapter 126, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The witness packet records only the displayed finite block data for one dyadic window; it is not host summability, quotient equality of series, selected infinite sums, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8587.1 (Cauchy condensation dyadic block witness carrier)**.** *A* $\mathsf{CauchyCondensationDyadicBlockWitness}$ *carrier is a finite* BHist *packet*

$$B = (A, D, W, M, R, E, H, C, P, N)$$

with the following displayed rows:

1. *A is the positive decreasing* $\mathsf{RealSeries}^{\uparrow}$ *source row whose inspected tail supplies the block terms.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row naming the dyadic block bounds and precision scale used by the finite witness.*
3. *W is the finite block witness ledger, listing the displayed terms between the two dyadic endpoints and the associated condensed row.*
4. *M is the monotone endpoint comparison row, recording the decreasing-source inequalities needed to compare the finite block with its dyadic endpoint terms.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the rational data extracted from the displayed block window.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row reached only after A, D, W, M, R have stayed visible.*
7. *H records componentwise* hsame *transport for the source, dyadic endpoint, witness ledger, monotone comparison, readback, real seal, replay, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a condensation consumer request through the source tail, dyadic endpoints, finite witness ledger, monotone comparison, rational readback, and real-facing seal.*

9. *P is the* Pkg *provenance over* CauchyCondensationDyadicBlockWitness$^{\uparrow}$, CauchyCondensationPacket$^{\uparrow}$, CauchyCondensationTheorem$^{\uparrow}$, RealSeries$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

10. *N is the local* NameCert$_{\text{CauchyCondensationDyadicBlockWitness}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, D, W, M, R, E, H, C, P, N$. It has no coordinate for an infinite series sum, host convergence theorem, quotient stream equality, selected limiting value, countable choice, or ambient completeness.

Lean4 ✓ `BEDC.Derived.CauchyCondensationDyadicBlockWitnessUp.CauchyCondensationDyadicBlockWitnessTasteGa`
`single carrier alignment`

Theorem 8587.2 (Cauchy condensation dyadic block witness NameCert obligations)**.** *For every accepted* CauchyCondensationDyadicBlockWitness$^{\uparrow}$ *carrier $B = (A, D, W, M, R, E, H, C, P, N)$, the local* NameCert$_{\text{CauchyCondensationDyadicBlockWitness}^{\uparrow}}$ *surface consists exactly of carrier admission for the positive decreasing* RealSeries$^{\uparrow}$ *source row, dyadic endpoint exposure through* DyadicRatCore$^{\uparrow}$*, finite block witness ledger exposure, monotone endpoint comparison,* RegSeqRat$^{\uparrow}$ *readback,* Real$^{\uparrow}$ *sealing, componentwise* hsame *stability, displayed* Cont *replay,* Pkg *provenance, and local naming. A consumer therefore reads the block witness only through the finite route*

$$A, D, W, M, R \longmapsto E, H, C, P, N.$$

Proof. Project the accepted carrier of Definition 8587.1. The source row A names the positive decreasing series, and the dyadic endpoint row D fixes the finite block window inspected by the witness ledger W.

The monotone comparison row M is then read before any condensed term or endpoint estimate is consumed. It keeps the comparison local to the displayed block and prevents a consumer from replacing the witness ledger by an ambient summability statement.

The rational readback row R and real seal row E are reached only after A, D, W, M remain visible. Finally H, C, P, N transport, replay, source, and name that same finite route, so no quotient stream, selected limit, host convergence theorem, countable-choice selector, or completeness witness enters the local NameCert surface. □

Lean4 ✓ `BEDC.Derived.CauchyCondensationDyadicBlockWitnessUp.CauchyCondensationDyadicBlockWitnessNameCer`

Theorem 8587.3 (Cauchy condensation dyadic block witness Real handoff)**.** *Every* Real$^{\uparrow}$*-facing or completion-facing consumer of an accepted* CauchyCondensationDyadicBlockWitness$^{\uparrow}$ *carrier $B = (A, D, W, M, R, E, H, C, P, N)$ must first display the positive decreasing source row A, dyadic endpoint row D, finite block witness ledger W, monotone endpoint comparison row M, and* RegSeqRat$^{\uparrow}$ *readback row R. The handoff to* CauchyCondensationPacket$^{\uparrow}$ *and* CauchyCondensationTheorem$^{\uparrow}$ *may consume the seal row E only as this displayed finite block route. It does not assert host summability, equality of infinite series, selected sums, countable choice, or ambient* Real$^{\uparrow}$ *completeness.*

Proof. Begin with the NameCert obligations of Definition 8587.2. They require A, D, W, M, R to be displayed before the real-facing seal E is read.

The condensation packet and theorem siblings consume only that finite witness row. The packet of chapter 7794 records the surrounding condensation carrier, and chapter 3727 reads theorem-level block data only after the dyadic witness has kept its source, endpoint, ledger, comparison, and readback rows visible.

Finally the structural rows H, C, P, N preserve the same finite route by transport, replay, provenance, and local naming. Since the accepted carrier contains no coordinate for host summability, quotient equality of infinite series, selected sums, countable choice, or ambient completeness, the Real handoff remains a finite block-witness handoff. □

Lean4 ✓ `BEDC.Derived.CauchyCondensationDyadicBlockWitnessUp.CauchyCondensationDyadicBlockWitnessRealHan`

Theorem 8587.4 (Cauchy condensation dyadic block witness scoped route)**.** *Every accepted* $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$ *packet reads the CauchyCondensationTest,* $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows before any Real-facing handoff is public. Equivalently, the handoff route is scoped by the displayed source-series row A, dyadic endpoint row D, finite witness ledger W, monotone comparison row M, regular rational readback row R, Real seal row E, componentwise transport row H, continuation row C, provenance row P, and local naming row N.*

Proof. Begin with the carrier of Definition 8587.1. It lists $A, D, W, M, R, E, H, C, P, N$ as the whole packet surface and gives the Cauchy-condensation consumer no independent row beyond those displayed coordinates.

Use the NameCert obligations of Definition 8587.2. They force the source-series, dyadic endpoint, witness ledger, monotone comparison, and regular readback rows to remain visible before the Real seal is consumed.

Finally apply the Real handoff theorem Definition 8587.3. It routes every Real-facing or completion-facing read through the same finite block-witness rows, while H, C, P, N provide transport, replay, provenance, and local naming rather than a second summability surface. □

Theorem 8587.5 (Cauchy condensation dyadic block witness public certificate)**.** *The public* $\mathsf{NameCert}_{\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}}$ *surface is the package consisting of Definition 8587.1, Definition 8587.2, Definition 8587.3, and Definition 8587.4. Any public read of the dyadic block witness therefore factors through the displayed carrier rows $A, D, W, M, R, E, H, C, P, N$ and through no host summability theorem, equality of infinite series, selected sum, countable-choice schedule, or ambient Real-completeness datum.*

Proof. Package the carrier and the NameCert obligations first. The carrier names the rows $A, D, W, M, R, E, H, C, P, N$, and the obligations identify those rows as the local admission, readback, seal, transport, replay, provenance, and naming surface.

Next use the Real handoff theorem. It shows that a Real-facing or completion-facing consumer cannot inspect the seal row E before the source, dyadic endpoint, block witness, monotone comparison, and regular rational readback rows have been displayed.

Finally use the scoped-route theorem. It makes the dependency boundary public: every accepted read has already passed through the CauchyCondensationTest-facing route, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, and $\mathsf{NameCert}$ rows. The package therefore exports exactly the finite dyadic block-witness certificate and nothing from the excluded host or completeness surfaces. □

Falsifiable prediction: Every accepted $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$ read that exports a Real-facing block estimate without displaying the positive decreasing source, dyadic endpoints, finite witness ledger, monotone comparison, RegSeqRat readback, transport, replay, provenance, and local naming is outside the carrier surface.

Independence witness: cauchy-condensation-packet, cauchy-condensation-theorem, realseries, dyadicratcore, regseqrat: none is bijective to $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$ because this

packet jointly carries one finite dyadic block witness ledger, its positive decreasing source row, endpoint core, monotone comparison, rational readback, Real seal, transport, replay, provenance, and local naming while refusing theorem-level summability.

Closure status for $\mathsf{NameCert}_{\mathsf{CauchyCondensationDyadicBlockWitness}\uparrow}$ **.**

Constructive story: A $\mathsf{CauchyCondensationDyadicBlockWitness}^{\uparrow}$ packet is generated from a positive decreasing RealSeries source row, a DyadicRatCore endpoint row, a finite block witness ledger, a monotone endpoint comparison row, a RegSeqRat readback row, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CauchyCondensationDyadicBlockWitness}\uparrow}, \mathsf{scopedClosed})$

Scope closed: Definition 8587.1, Definition 8587.2, Definition 8587.3, Definition 8587.4, and Definition 8587.5 scope the finite dyadic block-witness route consumed by condensation packets and theorem-level Real handoffs.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CauchyCondensationDyadicBlockWitness}\uparrow}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host summability, equality of infinite series, selected sums, countable choice, Lean verification, bridge checking, or ambient Real completeness.

Upgrade path: Obligation closure requires checked carrier admission, dyadic endpoint exposure, block-witness ledger exactness, monotone comparison stability, regular readback nonescape, Real-seal nonescape, transport, replay, provenance, and local naming for BEDC.Derived.CauchyCondensationDyadicBlockWitnessUp.

Chapter 8588

A Concrete Naming Certificate for $\mathsf{OrthogonalArray}^{\uparrow}$

Following Rao and standard design theory, the $\mathsf{OrthogonalArray}^{\uparrow}$ packet records the finite incidence table whose every displayed projection of bounded strength has a balanced tuple count. It sits between the row-column-symbol discipline of chapter 6739, the sign-row orthogonality surface of chapter 7074, the finite table readback of chapter 49, the finite-set carrier of chapter 112, and the unary size ledger of chapter 28. The packet names only displayed finite design data; it is not a host classification theorem, a construction of all arrays, a quotient design equality, an infinite combinatorial principle, or an ambient coding-theory theorem.

Definition 8588.1 (Orthogonal-array carrier)**.** *An* $\mathsf{OrthogonalArray}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$O = (R, F, L, t, W, B, M, S, H, C, P, N)$$

with the following displayed rows:

1. R *is the* $\mathsf{Nat}^{\uparrow}$ *row-count ledger naming the visible run boundary.*
2. F *is the* $\mathsf{FinSet}^{\uparrow}$ *factor row, exposing the finite family of coordinates inspected by the design.*
3. L *is the* $\mathsf{FinSet}^{\uparrow}$ *level row, exposing the finite value set shared by the displayed factors.*
4. t *is the* $\mathsf{Nat}^{\uparrow}$ *strength row, naming the maximum projection size whose balance is recorded.*
5. W *is the projection-window ledger, listing the displayed factor subsets of size at most* t*.*
6. B *is the balanced tuple-count ledger: for each window in* W *and each displayed level tuple,* B *records the finite row count in which that tuple appears.*
7. M *is the* $\mathsf{Mat}^{\uparrow}$ *readback row for the run-by-factor table.*
8. S *records row and coordinate scans that connect* M *to the factor and level ledgers.*
9. H *records componentwise* hsame *transport for row counts, factors, levels, strength, projection windows, tuple counts, matrix readback, scans, provenance, and local naming.*
10. C *records displayed* Cont *replay from an orthogonal-array inspection request through* $R, F, L, t, W, B, M, S, H, P, N$
11. P *is the* Pkg *provenance over* $\mathsf{OrthogonalArray}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{FinSet}^{\uparrow}$, $\mathsf{Nat}^{\uparrow}$, $\mathsf{LatinSquare}^{\uparrow}$, $\mathsf{HadamardMatrix}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
12. N *is the local* $\mathsf{NameCert}_{\mathsf{OrthogonalArray}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through these finite rows. It has no coordinate for host array equality, selected isomorphism representatives, classification of parameters, infinite designs, or ambient coding-theory semantics.

Theorem 8588.2 (Orthogonal-array NameCert obligations)**.** *For every accepted* $\mathsf{OrthogonalArray}^{\uparrow}$ *carrier* $O = (R, F, L, t, W, B, M, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{OrthogonalArray}^{\uparrow}}$ *surface consists exactly of row-count admission through* R*, factor and level admission through* F, L*, strength admission through* t*, projection-window exposure through* W*, balanced tuple-count exposure through* B*, matrix readback through* M*, scan compatibility through* S*, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8588.1. The only size data are R and t, the only finite coordinate data are F, L, W, and the only displayed table data are B, M, S.

Read the matrix route next. The row-by-factor table is inspected through $\mathsf{Mat}^{\uparrow}$, while the factors and levels remain finite $\mathsf{FinSet}^{\uparrow}$ rows and the run count and strength remain $\mathsf{Nat}^{\uparrow}$ rows.

The balance obligation is then local to W and B. For each displayed projection window and level tuple, the tuple-count row records the visible count; no hidden host enumeration or quotient of arrays is available.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier contains no coordinate for parameter classification, selected isomorphism representatives, host equality, infinite designs, or coding-theory semantics, the listed rows exhaust the NameCert obligations. □

Theorem 8588.3 (Orthogonal-array projection balance)**.** *Every* $\mathsf{Mat}^{\uparrow}$*,* $\mathsf{FinSet}^{\uparrow}$*, or* $\mathsf{Nat}^{\uparrow}$ *consumer that reads balance from an accepted* $\mathsf{OrthogonalArray}^{\uparrow}$ *carrier must pass through*

$$R, F, L, t \longmapsto W \longmapsto B \longmapsto M, S \longmapsto H, C, P, N.$$

The exported datum is exactly a displayed projection-window balance ledger. It may be consumed beside $\mathsf{LatinSquare}^{\uparrow}$ *and* $\mathsf{HadamardMatrix}^{\uparrow}$ *finite-design rows, but it does not construct a Latin square, construct a Hadamard matrix, classify orthogonal arrays, select a representative up to isomorphism, or assert host matrix equality.*

Proof. Start from the NameCert obligations of Definition 8588.2. They force every balance read through the row-count, factor, level, strength, projection-window, tuple-count, matrix, scan, transport, replay, provenance, and naming rows.

The projection window is finite. The row W lists the inspected factor subsets, and the row B records the balanced tuple counts for those windows and displayed level tuples.

The matrix readback is downstream of that finite ledger. The row M supplies the visible table, while S connects table entries to the factor and level rows without adding host matrix equality or a quotient of designs.

The sibling design routes are only comparison anchors. $\mathsf{LatinSquare}^{\uparrow}$ supplies a row-column-symbol finite design surface, and $\mathsf{HadamardMatrix}^{\uparrow}$ supplies a sign-row orthogonality surface; this packet exports the projection-balance surface and no construction or classification theorem for either sibling. □

Closure status for $\mathsf{NameCert}_{\mathsf{OrthogonalArray}^{\uparrow}}$**.**

Constructive story: An $\mathsf{OrthogonalArray}^{\uparrow}$ packet is generated from Nat row-count and strength rows, FinSet factor and level rows, projection-window ledgers, balanced tuple-count rows, Matrix readback, scan compatibility, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate(NameCert$_{\mathsf{OrthogonalArray}\uparrow}$, seed)

Scope closed: Definition 8588.1, Definition 8588.2, and Definition 8588.3 seed the finite projection-balance carrier over displayed Matrix, FinSet, Nat, LatinSquare, and HadamardMatrix rows.

Formal verification: FormalStatus(NameCert$_{\mathsf{OrthogonalArray}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close parameter existence, classification, selected isomorphism representatives, Latin-square construction, Hadamard-matrix construction, quotient design equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, factor and level exactness, strength exposure, projection-window coverage, balanced tuple-count readback, matrix readback, scan compatibility, transport, replay, provenance, and local naming for BEDC.Derived.OrthogonalArrayUp.

Chapter 8589

A Concrete Naming Certificate for $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$

Following Aronszajn–Panitchpakdi on hyperconvex metric spaces and injective metric extension, the $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$ packet records the finite NameCert surface where a displayed metric source may be read as an injective metric object. It sits between the metric source of chapter 57, the hyperconvex ball-family route of chapter 4013, the complete-metric boundary of chapter 128, the terminal real-radius rows of chapter 38, and the envelope consumer of chapter 6810. The packet names the Aronszajn–Panitchpakdi injective surface itself rather than another envelope synonym: finite extension requests, hyperconvex ball witnesses, completion visibility, and real-radius seals are displayed before any public consumer can treat the source as injective.

Definition 8589.1 (Aronszajn–Panitchpakdi injective metric carrier)**.** *An* $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (M, B, E, K, R, H, C, P, N)$$

with the following displayed rows:

1. *M is the* $\mathsf{Met}^{\uparrow}$ *source row, including the inspected point classifier and finite distance observations.*
2. *B is the* $\mathsf{HyperconvexMetric}^{\uparrow}$ *ball-family row, exposing finite closed-ball requests, real radii, pairwise compatibility, and the finite intersection handoff.*
3. *E is the finite injective-extension row, recording the admissible one-step extension boundary over the same metric source rather than a selected host hull point.*
4. *K is the* $\mathsf{CompleteMetric}^{\uparrow}$ *seal row, keeping completion-facing reads downstream of the metric source, hyperconvex ball data, and finite extension boundary.*
5. *R is the* $\mathsf{Real}^{\uparrow}$ *radius and distance row used by the metric observations, closed-ball tests, extension budgets, and completion boundary.*
6. *H records componentwise* hsame *transport for M, B, E, K, R, C, P, N.*
7. *C records displayed* Cont *replay from metric observations through ball-family compatibility, finite extension admissibility, complete-metric sealing, and real-radius readback.*
8. *P is the* Pkg *provenance over* $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{HyperconvexMetric}^{\uparrow}$, $\mathsf{CompleteMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.

9. N is the local $\mathsf{NameCert}_{\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}}$ *row.*
The carrier has no coordinate for arbitrary ball-family intersections, a chosen injective hull point, a quotient completion representative, countable choice, a host extension function, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8589.2 (Aronszajn–Panitchpakdi injective metric obligations)**.** *For every accepted* AronszajnPanitchpakd *carrier $A = (M, B, E, K, R, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}}$ *surface consists exactly of carrier admission for the displayed packet, metric-source exposure through M, hyperconvex finite ball-family exposure through B, finite injective-extension exposure through E, complete-metric sealing through K, real-radius and distance readback through R, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8589.1. The rows $M, B, E, K, R, H, C, P, N$ are the complete displayed inventory available to an injective-metric consumer.

Read the Aronszajn–Panitchpakdi side through the hyperconvex row. The row B supplies only the finite ball-family surface of chapter 4013: displayed closed balls, real radii, pairwise compatibility, and a finite intersection handoff over the same metric source.

Read the injective side through E. It records finite one-step extension admissibility before any envelope consumer from chapter 6810 may use the packet, and it does not select a host hull point or a global extension function.

Finally inspect K, R, H, C, P, N. The complete-metric and real-radius rows seal the same finite route, while transport, replay, provenance, and local naming preserve it without adding arbitrary-family intersections, quotient completions, countable choice, or ambient real completeness. Hence the listed rows exhaust the local NameCert obligations. □

Theorem 8589.3 (Aronszajn–Panitchpakdi envelope-facing route)**.** *Every envelope-facing or completion-neighbour consumer of an accepted* $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$ *packet must read*

$$\mathsf{Met}^{\uparrow} \longmapsto \mathsf{HyperconvexMetric}^{\uparrow} \longmapsto \mathsf{CompleteMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}$$

through the displayed rows M, B, K, R, H, C, P, N and must read the finite injective-extension boundary E before it treats the packet as an $\mathsf{InjectiveEnvelopeMetric}^{\uparrow}$ *source.*

Proof. Start with the carrier and obligation theorem. The metric source M is displayed before the hyperconvex row B, and B is the only row that exposes compatible closed-ball data.

The finite extension boundary E is read before an envelope-facing consumer can use the packet as injective. The completion seal K and real-radius row R remain downstream of the same metric and ball-family rows, so they cannot add a chosen hull point or an arbitrary intersection witness.

The structural rows H, C, P, N transport, replay, source, and name that same route. Thus every envelope-facing read factors through the displayed Aronszajn–Panitchpakdi surface rather than through an ungrounded injective-envelope synonym. □

Falsifiable prediction: Every accepted $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$ consumer that treats a metric packet as injective without first reading the displayed MetricUp, HyperconvexMetricUp, CompleteMetricUp, RealUp, finite extension, transport, replay, provenance, and local naming rows refutes the carrier surface.

Independence witness: metric, hyperconvex-metric, completemetric, real, injective-envelope-metric: no listed sibling supplies the whole packet $A = (M, B, E, K, R, H, C, P, N)$, because this chapter binds the Aronszajn–Panitchpakdi injective surface before the envelope consumer reads it.

Closure status for $\mathsf{NameCert}_{\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}}$.

Constructive story: An $\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}$ packet is generated from a metric source row, a hyperconvex finite ball-family row, a finite injective-extension boundary, a complete-metric seal, real radius and distance rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8589.1, Definition 8589.2, and Definition 8589.3 seed the finite Aronszajn–Panitchpakdi injective metric surface over metric, hyperconvex, complete-metric, real-radius, finite-extension, and envelope-facing rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AronszajnPanitchpakdiInjectiveMetric}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim Lean verification, bridge checking, arbitrary-family intersections, selected injective hull points, quotient completions, countable choice, host extension functions, or ambient RealUp completeness.

Upgrade path: Obligation closure requires checked carrier admission, hyperconvex ball-family exposure, finite extension exposure, complete-metric sealing, Real radius readback, transport, replay, provenance, and local naming for BEDC.Derived.AronszajnPanitchpakdiInjectiveMetricUp.

Chapter 8590

A Concrete Naming Certificate for $\mathsf{FiniteLipschitzExtension}^{\uparrow}$

Following McShane, Whitney, and Bishop–Bridges constructive metric analysis, the $\mathsf{FiniteLipschitzExtension}^{\uparrow}$ packet records the finite certificate by which a Lipschitz extension request over a displayed finite subcarrier is read as a bounded ambient extension window. It sits between the reusable interface of chapter 3650, the McShane–Whitney envelope certificate of chapter 1941, the finite metric observations of chapter 3742, the regular rational readback of chapter 301, and the terminal real-name seal of chapter 38. The packet names a finite extension surface; it is not a host function-space construction, not a selected global formula, and not an appeal to countable choice or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8590.1 (Finite Lipschitz extension carrier)**.** *A* $\mathsf{FiniteLipschitzExtension}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (X, A, L, B, G, W, R, S, H, C, P, N)$$

with the following displayed rows:

1. *X is the ambient* $\mathsf{Met}^{\uparrow}$ *row naming the metric observations used by the finite extension request.*
2. *A is the displayed finite subcarrier row, including membership evidence, inclusion into X, and the finite enumeration exposed to downstream readers.*
3. *L is the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row over A, carrying the finite graph window and displayed Lipschitz constant.*
4. *B is the* $\mathsf{RegSeqRat}^{\uparrow}$ *bound row recording the rational tolerance and constant reads used by the extension certificate.*
5. *G is the candidate finite ambient graph row, exposed only as finitely many source and target observations.*
6. *W is the refinement-window row comparing requested finite ambient observations with the enumerated source window.*
7. *R is the restriction-agreement row, requiring every source-admitted candidate read to replay the source* $\mathsf{LipschitzMap}^{\uparrow}$ *row through A, L, B.*
8. *S is the* $\mathsf{Real}^{\uparrow}$ *seal row for source values, candidate values, and rational tolerance readback.*
9. *H records componentwise* hsame *transport for the metric, finite subcarrier, source map, bound, graph, window, restriction, real seal, provenance, and local name rows.*

10. *C records displayed* Cont *replay from a finite ambient extension request through* $X, A, L, B, G, W, R, S, H, P, N$.
11. *P is the* Pkg *provenance over* $\mathsf{FiniteLipschitzExtension}^{\uparrow}$, $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{McShaneExtension}^{\uparrow}$, $\mathsf{FiniteMetricSpace}^{\uparrow}$, $\mathsf{LipschitzMap}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteLipschitzExtension}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through these rows. It has no coordinate for host function equality, quotient function spaces, selected representatives, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 (statement) `BEDC.Derived.FiniteLipschitzExtensionUp`

Theorem 8590.2 (Finite Lipschitz extension NameCert obligations)**.** *For every accepted* $\mathsf{FiniteLipschitzExtension}^{\uparrow}$ *carrier* $F = (X, A, L, B, G, W, R, S, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{FiniteLipschitzExtension}^{\uparrow}}$ *surface consists exactly of carrier admission, finite subcarrier enumeration, source Lipschitz-map admission, rational bound readback, finite graph admission, refinement-window comparison, restriction-agreement exactness, real seal handoff, componentwise transport, displayed replay, provenance, and ledger non-escape. The finite route is*

$$X, A \longmapsto L \longmapsto B \longmapsto G, W \longmapsto R, S \longmapsto H, C, P, N.$$

No obligation is discharged by a host extension formula, an equality of ambient functions, or an unlisted completion principle.

Proof. Carrier admission is projection from Definition 8590.1. The displayed packet exposes exactly the rows $X, A, L, B, G, W, R, S, H, C, P, N$, so every local obligation must be read through that inventory.

The finite subcarrier and source-map clauses read A and L. A source value can enter the extension certificate only after the finite membership row has exposed its enumeration and the $\mathsf{LipschitzMap}^{\uparrow}$ row has supplied the displayed graph and bound data.

The rational bound, candidate graph, and window clauses read B, G, W. These rows keep the extension request finite: B supplies regular rational tolerances, G stores finite ambient graph observations, and W records the requested finite refinement window.

Restriction exactness is the row R, while the real-facing seal is the row S. The structural rows H, C, P, N preserve the same route componentwise and do not add host function equality, selected representatives, countable choice, or ambient completeness. Hence the listed finite route exhausts the local NameCert obligations. □

Theorem 8590.3 (Finite Lipschitz extension window factorization)**.** *Every* $\mathsf{LipschitzExtension}^{\uparrow}$, $\mathsf{McShaneExtension}^{\uparrow}$, $\mathsf{FiniteMetricSpace}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *or* $\mathsf{Real}^{\uparrow}$ *consumer of an accepted* $\mathsf{FiniteLipschitzExtension}^{\uparrow}$ *packet must factor its finite extension observation through*

$$A, L, B \longmapsto G, W \longmapsto R, S$$

before exporting the observation to transport, replay, provenance, and the local NameCert *row. The factorization exports the displayed finite graph and its restriction route, not a host function object, not a selected global McShane envelope, and not ambient* $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Start with a finite extension observation. The request first reads the finite subcarrier row A, because the source side of the observation is meaningful only against the displayed enumeration and inclusion route.

Next read L and B. The source $\mathsf{LipschitzMap}^{\uparrow}$ row supplies the finite graph and Lipschitz constant, while the $\mathsf{RegSeqRat}^{\uparrow}$ row supplies the rational tolerance budget used to compare source and ambient values.

The candidate graph and refinement rows G, W then determine the ambient window being exported. The restriction row R checks agreement over source-admitted points, and the real seal S is the only terminal real-facing handoff available to downstream consumers.

Finally the structural rows H, C, P, N replay and source that same factorization. The sibling certificates in chapter 3650 and chapter 1941 may consume the route, but this finite packet contributes only the displayed finite graph, refinement window, restriction, seal, transport, replay, provenance, and local naming rows. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteLipschitzExtension}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteLipschitzExtension}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8590.1, Definition 8590.2, and Definition 8590.3 seed the finite Lipschitz extension surface over displayed finite metric, Lipschitz-map, regular-rational, real, Lipschitz-extension, and McShane-extension rows.

Constructive story: A $\mathsf{FiniteLipschitzExtension}^{\uparrow}$ packet is generated from an ambient Metric row, a displayed finite subcarrier row, a source LipschitzMap row, a regular rational bound row, a finite ambient graph row, a refinement-window row, a restriction-agreement row, a Real seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteLipschitzExtension}^{\uparrow}}, \mathsf{unformalized})$

Lean target: `BEDC.Derived.FiniteLipschitzExtensionUp`

Bridge status: none

Not claimed: This chapter does not close host function equality, quotient function spaces, selected global envelopes, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, checked NameCert obligations, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite subcarrier enumeration, source Lipschitz admission, rational bound readback, finite graph admission, window comparison, restriction exactness, real seal handoff, transport, replay, provenance, and non-escape for BEDC.Derived.FiniteLipschitzExtensionUp.

Chapter 8591

A Concrete Naming Certificate for $\mathsf{FiniteCoverTree}^{\uparrow}$

Following Bishop and Bridges constructive compact metric practice, the $\mathsf{FiniteCoverTree}^{\uparrow}$ packet records a finite cover-refinement tree built from displayed ProbeBundle rows. It sits after the compact source of chapter 60, the metric observation rows of chapter 57, the compact metric finite-net surface of chapter 129, and the total-bounded finite-net carrier of chapter 127. The chapter names constructive finite routing data for compact-uniform and finite-cover consumers; it does not assert arbitrary open-cover compactness, selected subcovers, host equality of covers, countable choice, or ambient completeness.

Definition 8591.1 (Finite cover tree carrier)**.** *A* $\mathsf{FiniteCoverTree}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$T = (K, M, B, L, E, R, S, H, C, P, N)$$

with the following displayed rows:

1. *K is the compact source row, read only through finite compact-facing data.*
2. *M is the metric observation row used to compare inspected points with displayed centers.*
3. *B is the finite* ProbeBundle *row of centers, radii, membership witnesses, and refinement histories.*
4. *L is the level row recording the finite depth, parent pointer, and child list for each branch node.*
5. *E is the edge row recording that every child probe is a displayed refinement of its parent probe at the next requested tolerance.*
6. *R is the residual coverage row recording, for each branch node, which still-uncovered finite probe cells are routed to its children.*
7. *S is the stopping row recording leaves whose displayed probes already cover their local residual cells.*
8. *H records componentwise* hsame *transport for K, M, B, L, E, R, S and the structural rows.*
9. *C records displayed* Cont *replay through compact source, metric observation, probe bundle, refinement edges, residual coverage, and stopping leaves.*
10. *P is the* Pkg *provenance over* $\mathsf{FiniteCoverTree}^{\uparrow}$, $\mathsf{Compact}^{\uparrow}$, $\mathsf{Met}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{TotallyBounded}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteCoverTree}^{\uparrow}}$ *row.*
The classifier compares accepted packets only through $K, M, B, L, E, R, S, H, C, P, N$. No coordinate stores an arbitrary open cover, a selected finite subcover, a host powerset, quotient equality of covers, countable choice, trichotomy, or ambient completeness.

Theorem 8591.2 (Finite cover tree NameCert obligations)**.** *For every accepted* $\mathsf{FiniteCoverTree}^{\uparrow}$ *carrier*

$$T = (K, M, B, L, E, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteCoverTree}^{\uparrow}}$ *surface consists exactly of carrier admission, compact source exposure through K, metric observation through M, finite* $\mathsf{ProbeBundle}$ *exposure through B, finite branch indexing through L, refinement-edge readback through E, residual coverage through R, stopping leaves through S, and structural transport, replay, provenance, and local naming through H, C, P, N.*

Proof. Project the carrier rows in Definition 8591.1. The rows K, M, B supply the compact, metric, and finite probe data that a cover-tree consumer can inspect.

Next read L, E, R, S. These rows give a finite tree: each branch has a displayed level, displayed child refinements, a residual-coverage ledger, and stopping leaves for the covered cells.

Finally read H, C, P, N. Transport, replay, provenance, and local naming preserve only the displayed rows, so the local certificate contains no route to arbitrary open-cover compactness, selected subcovers, host powersets, quotient cover equality, countable choice, trichotomy, or ambient completeness. □

Theorem 8591.3 (Finite cover tree branch stability)**.** *Let $T = (K, M, B, L, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{FiniteCoverTree}^{\uparrow}$ *packet. Any transported branch read that preserves the finite* $\mathsf{ProbeBundle}$ *row B and the refinement-edge row E also preserves the residual coverage row R and the stopping row S. Thus a branch can be replayed only as a finite cover-tree route through displayed probe refinements, not as an arbitrary open-cover argument or a selected subcover theorem.*

Proof. Start with the finite probe row B and the edge row E. A branch read has no independent child selector; it reaches children only through the displayed refinement edges attached to the same finite probe bundle.

The residual coverage row R is indexed by the same branch levels and children as L and E. Preserving B and E therefore preserves the finite residual cells that each child is allowed to cover.

The stopping row S is downstream of R. Since H, C, P, N only transport, replay, source, and name this finite route, a transported branch cannot acquire an arbitrary open cover, selected subcover, host cover equality, or ambient compactness proof. □

Theorem 8591.4 (Finite cover tree sibling dependency)**.** *Every finite-cover consumer of an accepted* $\mathsf{FiniteCoverTree}^{\uparrow}$ *packet must first expose the compact source of chapter 60, the metric observation surface of chapter 57, and the total-bounded finite-net route of chapter 127. The tree then routes those rows through $B, L, E, R, S, H, C, P, N$ before any local cover-tree certificate is exported.*

Proof. Project the source rows K and M. They are the only rows through which compact and metric data enter the packet.

Read the finite-net dependency through B, L, E, R, S. The tree is finite because its probes, levels, refinement edges, residual coverage rows, and stopping leaves are all displayed before the local name is exported.

The structural rows H, C, P, N preserve the same dependency route. Therefore the sibling chapters are load-bearing sources of rows, and the exported certificate remains finite ProbeBundle cover-tree data. □

Theorem 8591.5 (Finite cover tree compact Cauchy cover handoff)**.** *Let $T = (K, M, B, L, E, R, S, H, C, P, N)$ be an accepted* $\mathsf{FiniteCoverTree}^{\uparrow}$ *packet. If a* $\mathsf{CompactCauchyCover}^{\uparrow}$ *packet consumes a branch read exported by T, then the consumer must first expose the finite* ProbeBundle *branch rows B, L, E, R, S from Definition 8591.1. Only after those rows have displayed the finite probes, branch levels, refinement edges, residual coverage, and stopping leaves may the* $\mathsf{CompactCauchyCover}^{\uparrow}$ *rows W, D, S, R, E be read as Cauchy-facing cover windows.*

Thus the handoff from finite cover refinements to chapter 1979 factors through the branch stability of Definition 8591.3 and the sibling dependency route of Definition 8591.4. It exports no arbitrary open-cover compactness, selected subcovers, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Proof. Project the accepted carrier by Definition 8591.1. The only branch rows available to a downstream cover consumer are B, L, E, R, S, together with the structural transport, replay, provenance, and local name rows.

Apply Definition 8591.3 to the branch read. Preserving the finite ProbeBundle row and refinement-edge row also preserves residual coverage and stopping leaves, so the exported branch cannot be reinterpreted as a hidden open cover or as a selected finite subcover.

Apply Definition 8591.4. The compact, metric, and total-bounded sources are consumed before the finite tree rows are exported, and chapter 1979 can then read its W, D, S, R, E window route only from this displayed finite branch data.

The excluded principles are absent from both packet inventories. Since neither the finite cover tree nor the compact Cauchy cover stores arbitrary open-cover compactness, selected subcovers, quotient stream equality, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness, the handoff cannot export any of them. □

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteCoverTree}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteCoverTree}^{\uparrow}$ packet is generated from compact-source rows, metric-observation rows, finite ProbeBundle rows, branch-level rows, refinement-edge rows, residual-coverage rows, stopping-leaf rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{FiniteCoverTree}^{\uparrow}}$, seed)

Scope closed: Definition 8591.1, Definition 8591.2, Definition 8591.3, Definition 8591.4, and Definition 8591.5 seed the finite compact-source, metric-observation, ProbeBundle, refinement-edge, residual-coverage, stopping-leaf, CompactCauchyCover handoff, transport, replay, provenance, and local naming surface.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{FiniteCoverTree}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close arbitrary open-cover compactness, selected subcovers, host powersets, quotient equality of covers, countable choice, trichotomy, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, refinement-edge exactness, residual-coverage stability, stopping-leaf nonescape, sibling dependency, and branch transport for BEDC.Derived.FiniteCoverTreeUp.

Chapter 8592

A Concrete Naming Certificate for $\mathsf{StieltjesMeasure}^{\uparrow}$

Following Stieltjes and the Bishop–Bridges constructive reading of bounded variation, the $\mathsf{StieltjesMeasure}^{\uparrow}$ packet records the finite measure surface by which a bounded-variation distribution source supplies half-open interval masses before any Lebesgue–Stieltjes or real-valued measure consumer reads them. It sits after the partition-variation source of chapter 398, the endpoint-jump ledger of chapter 3528, the regular rational readback of chapter 301, the dyadic endpoint core of chapter 291, and the terminal real-name seal of chapter 38; it is the finite Stieltjes surface consumed by chapter 6047. The packet names only displayed half-open interval cells, endpoint-jump ledgers, finite additivity over inspected cells, regular rational and dyadic readback, Real sealing, transport, replay, provenance, and local naming.

Definition 8592.1 (Stieltjes measure carrier)**.** *A* $\mathsf{StieltjesMeasure}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (B, S, A, J, K, R, D, E, H, C, P, N)$$

with the following displayed rows:

1. *B is the* $\mathsf{BoundedVariation}^{\uparrow}$ *distribution source, read only through displayed finite partition-variation data.*
2. *S is the* $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$ *endpoint-jump ledger that exposes the left and right boundary reads used by the interval cells.*
3. *A is the displayed half-open interval algebra generated by the inspected endpoints, with cells of the form $[a, b)$ and refinement witnesses for finite disjoint decompositions.*
4. *J is the endpoint-jump ledger assigning each displayed cell its boundary difference through the Stieltjes boundary packet.*
5. *K is the finite additivity row, checking only the inspected disjoint unions of cells in A.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the regular rational windows requested by the finite ledger.*
7. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *readback row for dyadic endpoint and tolerance data in the same inspected cells.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal for the accepted interval-mass read.*

9. *H records componentwise* hsame *transport for the bounded-variation source, boundary row, interval algebra, jump ledger, additivity row, readbacks, seal, replay, provenance, and local naming rows.*
10. *C records displayed* Cont *replay from bounded-variation partition reads through endpoint jumps, half-open interval cells, finite additivity, regular and dyadic readback, and the* $\mathsf{Real}^{\uparrow}$ *seal.*
11. *P is the* Pkg *provenance over* $\mathsf{StieltjesMeasure}^{\uparrow}$, $\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{StieltjesMeasure}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $B, S, A, J, K, R, D, E, H, C, P, N$. It has no coordinate for a host sigma-algebra, completed outer measure, quotient equality of distribution functions, selected extension theorem, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8592.2 (Stieltjes measure NameCert obligations)**.** *For every accepted* $\mathsf{StieltjesMeasure}^{\uparrow}$ *carrier*

$$M = (B, S, A, J, K, R, D, E, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{StieltjesMeasure}^{\uparrow}}$ *surface consists exactly of carrier admission for the bounded-variation source B, Stieltjes boundary exposure through S, half-open interval algebra visibility through A, endpoint-jump exactness through J, finite additivity over inspected cells through K, regular rational readback through R, dyadic endpoint readback through D, terminal real sealing through E, componentwise transport through H, displayed replay through C, package provenance through P, and local naming through N.*

Proof. Project the carrier of Definition 8592.1. The source and boundary rows B, S supply the only distribution data: the bounded-variation source gives finite partition variation, and the Stieltjes boundary row gives endpoint jumps for displayed cells.

Read the interval algebra and ledgers next. The half-open cells of A are the only cells inspected by the packet, J assigns their endpoint-jump reads, and K checks finite additivity only for the displayed disjoint decompositions.

Finally consume the readback rows R, D, E and the structural rows H, C, P, N. The regular rational and dyadic readbacks are sealed by $\mathsf{Real}^{\uparrow}$, while transport, replay, provenance, and local naming preserve exactly the same finite rows. No host sigma-algebra, completed outer measure, quotient distribution equality, selected extension, countable-choice schedule, or ambient completeness row remains. □

Theorem 8592.3 (Stieltjes measure bounded-variation handoff)**.** *Every* $\mathsf{LebesgueStieltjesMeasure}^{\uparrow}$ *or measure-facing consumer of an accepted* $\mathsf{StieltjesMeasure}^{\uparrow}$ *packet receives the bounded-variation distribution only through*

$\mathsf{BoundedVariation}^{\uparrow}$, $\mathsf{StieltjesMeasureBoundary}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Co

Concretely, the consumer must display the bounded-variation source B, boundary row S, half-open interval algebra A, endpoint-jump ledger J, finite additivity row K, regular rational readback R, dyadic readback D, and terminal seal E before any Stieltjes interval mass is public.

Proof. Start with the bounded-variation source of chapter 398. It supplies partition-variation data and not a completed measure or host function quotient.

Pass through the boundary and interval rows. The Stieltjes boundary chapter supplies endpoint-jump reads for inspected cells, while the carrier here restricts those reads to the half-open algebra A and checks finite additivity through K.

Then apply the regular rational, dyadic, and Real rows. The readbacks R, D expose the requested windows and endpoint tolerances before the terminal seal E is visible. Thus a Lebesgue–Stieltjes or measure-facing consumer can read only the finite handoff route stated above, with no hidden extension theorem, countable choice, or ambient completeness coordinate. □

Closure status for $\mathsf{NameCert}_{\mathsf{StieltjesMeasure}^{\uparrow}}$.

Constructive story: A $\mathsf{StieltjesMeasure}^{\uparrow}$ packet is generated from a BoundedVariation distribution source, a StieltjesMeasureBoundary endpoint-jump ledger, a displayed half-open interval algebra, finite additivity over inspected cells, RegSeqRat and DyadicRatCore readbacks, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{StieltjesMeasure}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8592.1, Definition 8592.2, and Definition 8592.3 seed the finite Stieltjes measure surface from bounded-variation endpoint jumps to half-open interval masses and Real-facing consumers.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{StieltjesMeasure}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim host sigma-additivity, sigma-algebra completion, completed outer measure, selected extension theorems, quotient equality of distribution functions, countable choice, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, Stieltjes boundary exposure, half-open interval visibility, endpoint-jump exactness, finite additivity, RegSeqRat and DyadicRatCore readback, Real-seal non-escape, transport and replay stability, provenance non-escape, and a Lean carrier formalization for BEDC.Derived.StieltjesMeasureUp.

Chapter 8593

A Concrete Naming Certificate for $\mathsf{CountableMetricName}^{\uparrow}$

Following Bishop and Bridges constructive analysis and represented-space computable analysis, the $\mathsf{CountableMetricName}^{\uparrow}$ packet names the finite interface by which a countably represented source is read as metric-name data without leaving the BEDC carrier discipline. It sits between the finite observation schedules of chapter 126, the metric carrier surface of chapter 57, the dyadic tolerance rows of chapter 291, the regular rational readback route of chapter 301, the terminal real-name seal of chapter 38, and the completion-facing countable metric route of chapter 4044. The finite observation windows used by the countable-name route are the finite request/list/window schedules of chapter 5916, so a $\mathsf{CountableMetricName}^{\uparrow}$ consumer reaches metric-name data only after that finite-prefix surface has been displayed. The packet records a named handoff from certified countable observations to metric-name data; it is not a quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8593.1 (Countable metric name carrier)**.** *A* $\mathsf{CountableMetricName}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (S, M, W, D, R, E, H, C, P, N)$$

with the following displayed rows:

1. *S is the represented source row, naming the countable source, its displayed enumeration window, and the admitted source tokens read by the metric-name request.*
2. *M is the metric row, exposing the source-side distance classifier, finite ball ledger, and equality boundary only through the displayed metric packet.*
3. *W is the family of finite* $\mathsf{StreamName}^{\uparrow}$ *windows used to inspect source tokens, distance requests, and metric-name prefixes.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance row for requested radii, comparison budgets, slack witnesses, and refusal rows.*
5. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed stream windows and dyadic tolerance data.*
6. *E is the* $\mathsf{Real}^{\uparrow}$ *seal row for the finite distance comparisons that survive regular rational readback.*
7. *H records componentwise* hsame *transport for the represented source, metric row, stream windows, dyadic tolerance, regular readback, Real seal, replay, provenance, and local naming rows.*

8. *C records displayed* Cont *replay from any metric-name request through $S, M, W, D, R, E, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{CountableMetricName}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{CountableMetricName}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, M, W, D, R, E, H, C, P, N$. It has no coordinate for quotient equality of streams, a selected completion limit, countable choice, host real equality, a hidden distance oracle, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Lean4 ✓ `BEDC.Derived.CountableMetricNameUp.CountableMetricNameTasteGate single carrier alignment`

Theorem 8593.2 (CountableMetricName obligation surface)**.** *For an accepted* $\mathsf{CountableMetricName}^{\uparrow}$ *packet $A = (S, M, W, D, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{CountableMetricName}^{\uparrow}}$ *surface consists exactly of carrier admission, represented-source exposure, metric-row exposure, finite stream-window scheduling, dyadic tolerance checking, regular rational readback, Real sealing, componentwise* hsame *transport, displayed* Cont *replay, provenance, and ledger non-escape.*

Proof. Carrier admission is Definition 8593.1: every row read by a consumer is one of $S, M, W, D, R, E, H, C, P, N$.

The source and metric obligations are finite because the represented source is inspected only through S and the metric classifier only through M. Stream-name data is reduced to the displayed windows W, tolerance data is reduced to D, and every numerical readback must pass through R before the Real seal E is consumed.

Transport, replay, and provenance are the remaining exposed routes. The rows H, C, and P force componentwise identity transport, continuation replay, and package ancestry to remain inside the same displayed packet, while N names exactly this finite surface.

There is no additional obligation for quotient stream equality, a selected limit, countable choice, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness, because none of those objects is a coordinate of the carrier. □

Theorem 8593.3 (CountableMetricName finite observation scope)**.** *Every legal consumer read of a* $\mathsf{CountableMetricName}^{\uparrow}$ *carrier factors through a finite observation route*

$$S \longmapsto W \longmapsto D \longmapsto R \longmapsto E$$

over the displayed metric row M, followed only by the transport, replay, provenance, and local naming rows H, C, P, N.

Proof. Inspect a consumer read of the carrier. A request first chooses a displayed source token from S and a finite metric-name prefix from the stream windows W; no unbounded source enumeration is exported.

The requested tolerance is then checked by the dyadic row D. Any distance or comparison data that survives the tolerance check is read back through the regular rational row R and sealed by E as a finite $\mathsf{Real}^{\uparrow}$ observation.

Finally, the read is transported and replayed only by H and C, with provenance recorded by P and the local NameCert row N. Since the route never leaves these displayed rows, it cannot recover quotient stream equality, a hidden representative, countable choice, host real equality, or ambient completeness. □

Theorem 8593.4 (CountableMetricName completion handoff)**.** *A* $\mathsf{CountableMetricName}^{\uparrow}$ *carrier exports to completion-facing consumers only the represented source row, metric row, finite stream*

windows, dyadic tolerance row, regular rational readback, Real seal, componentwise transport, replay, provenance, and local naming data. Any later $\mathsf{CountableMetricCompletion}^{\uparrow}$ *or* $\mathsf{Real}^{\uparrow}$ *consumer must rebuild completion or real-completeness claims from those displayed rows rather than reading a selected limit, quotient equality, countable-choice schedule, host real equality, or ambient completeness from the handoff.*

Proof. The handoff payload is the carrier tuple $S, M, W, D, R, E, H, C, P, N$. A completion-facing consumer may reuse the represented source row S, the metric row M, the finite windows W, the tolerance ledger D, the regular readback R, and the Real seal E.

The same consumer may also transport and replay the packet through H and C, and may cite P and N for provenance and local naming. These are finite BEDC rows, so they can be passed to the countable metric completion route without changing the classifier boundary.

Nothing in the packet selects a limit or identifies two streams by quotient equality. Consequently, any completion theorem, separated comparison, or Real completeness claim must be supplied by a later completion certificate; it is not exported by $\mathsf{CountableMetricName}^{\uparrow}$ itself. □

Closure status for $\mathsf{NameCert}_{\mathsf{CountableMetricName}^{\uparrow}}$.

Constructive story: A $\mathsf{CountableMetricName}^{\uparrow}$ packet is generated by a represented source row, a metric row, finite $\mathsf{StreamName}^{\uparrow}$ windows, a $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance row, a $\mathsf{RegSeqRat}^{\uparrow}$ readback row, a $\mathsf{Real}^{\uparrow}$ seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{CountableMetricName}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8593.1, Definition 8593.2, Definition 8593.3, and Definition 8593.4 bind the finite carrier and handoff surface for countable observations read as metric-name data.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{CountableMetricName}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close quotient stream equality, selected limits, countable choice, host real equality, hidden distance oracles, ambient $\mathsf{Real}^{\uparrow}$ completeness, or completion completeness.

Upgrade path: Scoped closure requires Lean-backed NameCert obligations for the represented source, metric row, finite windows, tolerance, readback, Real seal, transport, replay, and completion handoff.

Chapter 8594

A Concrete Naming Certificate for $\mathsf{RegularRealSeparationModulus}^{\uparrow}$

Following Bishop–Bridges constructive real analysis, the $\mathsf{RegularRealSeparationModulus}^{\uparrow}$ packet records the finite positive-gap data by which two regular rational real names are separated before a Real or Completion consumer reads an apartness conclusion. It sits after the regular tail-equivalence route of chapter 5940, the regular rational readback of chapter 301, the finite stream-window surface of chapter 126, the dyadic tolerance ledger of chapter 291, the terminal real-name seal of chapter 38, and the positive-separation boundary of chapter 304. The packet names a displayed modulus for a strict finite gap; it is not quotient real equality, trichotomy, a selected limit, countable choice, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8594.1 (Regular real separation modulus carrier)**.** *A* $\mathsf{RegularRealSeparationModulus}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (L, R, W, D, T, E, A, H, C, P, N)$$

with the following displayed rows:

1. *L and R are the two* $\mathsf{RegSeqRat}^{\uparrow}$ *readback rows whose regular rational windows are compared.*
2. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *finite-window row exposing the inspected tail request for both readbacks.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *positive-radius ledger. It records the radius ρ and denominator budget used by the comparison.*
4. *T is the* $\mathsf{RegularRealTailEquivalence}^{\uparrow}$ *refusal row. It states that the inspected tails do not collapse through the sibling tail-equivalence route at the displayed radius.*
5. *E is the pair of terminal* $\mathsf{Real}^{\uparrow}$ *seal rows made available only after L, R, W, D, T have been displayed.*
6. *A is the apartness handoff row to the sibling apartness-real certificate of chapter 304.*
7. *H records componentwise* hsame *transport for $L, R, W, D, T, E, A, C, P, N$.*
8. *C records displayed* Cont *replay of the route*

$$L, R, W, D \longmapsto T \longmapsto E, A \longmapsto H, P, N.$$

9. *P is the* Pkg *provenance over* $\mathsf{RegularRealSeparationModulus}^{\uparrow}$, $\mathsf{RegularRealTailEquivalence}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert *rows.*
10. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularRealSeparationModulus}^{\uparrow}}$ *row.*

The classifier reads only these rows. It has no coordinate for quotient real equality, host trichotomy, a selected real representative, countable-choice tail selection, or an ambient completeness witness.

Theorem 8594.2 (Regular real separation modulus NameCert obligations)**.** *For every accepted* $\mathsf{RegularRealSeparationModulus}^{\uparrow}$ *carrier* $M = (L, R, W, D, T, E, A, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{RegularRealSeparationM}}$ *surface consists exactly of regular rational readback admission for* L, R*, shared finite-window exposure for* W*, positive dyadic radius and denominator-budget exactness for* D*, tail-equivalence refusal through* T*, delayed real-seal access through* E*, apartness handoff through* A*, componentwise transport, displayed continuation replay, package provenance, and local naming through* H, C, P, N*.*

Proof. Project the carrier of Definition 8594.1. The only source rows are the two regular rational readbacks, the shared finite stream window, and the dyadic positive-radius ledger.

The row T is downstream of those source rows. It records that the displayed tails do not collapse through the regular tail-equivalence route at the radius supplied by D.

Only after T is displayed may the terminal real seals E and the apartness handoff A be read. The structural rows H, C, P, N transport, replay, source, and name exactly that finite route, so the certificate exports no quotient equality, trichotomy, selected representative, choice schedule, or ambient completeness datum. □

Theorem 8594.3 (Regular real separation modulus finite-gap route)**.** *Every Real or Completion consumer that reads an accepted* $\mathsf{RegularRealSeparationModulus}^{\uparrow}$ *carrier must pass through the finite route*

$$\mathsf{RegSeqRat}^{\uparrow}, \mathsf{StreamName}^{\uparrow}, \mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{RegularRealTailEquivalence}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{NameCert}.$$

The resulting apartness read is therefore a positive-gap conclusion over displayed regular rational windows, not a quotient-real comparison, a trichotomy branch, a selected-limit argument, or an ambient completeness principle.

Proof. Start from an accepted carrier $M = (L, R, W, D, T, E, A, H, C, P, N)$. The finite comparison begins with the two regular rational readbacks L, R, the shared window W, and the dyadic radius row D.

Read the tail-equivalence refusal next. Because T is the only row between the source windows and the real seals, any downstream apartness consumer must use the positive radius and denominator budget already displayed in D.

Finally, the terminal seals and apartness handoff are transported and replayed by H, C, P, N. Since the carrier contains no stronger host-side principle, the consumer receives only the finite positive-gap route named by the local certificate. □

Closure status for $\mathsf{NameCert}_{\mathsf{RegularRealSeparationModulus}^{\uparrow}}$**.**

Constructive story: A $\mathsf{RegularRealSeparationModulus}^{\uparrow}$ packet is generated from two RegSeqRat readback rows, one shared StreamName finite-window row, a DyadicRatCore positive-radius ledger, a RegularRealTailEquivalence refusal row, terminal Real seal rows, an apartness handoff, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularRealSeparationModulus}^{\uparrow}}$, seed)

Scope closed: Definition 8594.1, Definition 8594.2, and Definition 8594.3 seed the finite positive-gap route for regular rational real names.

Formal verification: FormalStatus(NameCert$_{\text{RegularRealSeparationModulus}\uparrow}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim quotient real equality, trichotomy, selected representatives, selected limits, countable choice, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, positive-radius exactness, tail-equivalence refusal, real-seal delay, apartness handoff, transport, replay, provenance, and local naming for BEDC.Derived.RegularRealSeparationModulusUp.

Chapter 8595

A Concrete Naming Certificate for HyperbolicSectorNerve$^{\uparrow}$

The HyperbolicSectorNerve$^{\uparrow}$ packet realizes the residual-sector boundary of chapter 9378 as finite MetaCIC NameCert data. It sits beside the confluence substitution boundary of chapter 3791, the local join ledger of chapter 4126, the residual checker of chapter 3827, and the parallel-diamond frontier of chapter 4238. The carrier names a finite residual-sector nerve: branches, candidate joins, retained obstructions, transport, replay, provenance, and local naming are explicit rows, while full Church–Rosser, unrestricted substitution compatibility, subject reduction, evaluator equality, and kernel consistency remain outside the packet.

Definition 8595.1 (Hyperbolic sector nerve carrier)**.** *A* HyperbolicSectorNerve$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (W, B, J, O, T, R, G, H, C, P, N)$$

with the following displayed rows:

1. *W is the typed residual-window row naming the finite source term window and its local context.*
2. *B is the residual-branch row recording the two finite reduction branches inspected inside W.*
3. *J is the candidate-join row recording the proposed common reducts visible at the inspected branch tips.*
4. *O is the obstruction-retention row naming the residual-substitution boundary still required before a full diamond can be consumed.*
5. *T is the transport row for branch, join, and obstruction data under componentwise* hsame*.*
6. *R is the replay row for the finite residual-sector route through W, B, J, O, T.*
7. *G is the TasteGate readiness row, reserving the later* Nontrivial *and* FieldFaithful *instance obligations for this finite carrier surface.*
8. *H records componentwise* hsame *transport for $W, B, J, O, T, R, G, C, P, N$.*
9. *C records displayed* Cont *replay through residual windows, branches, candidate joins, obstruction retention, transport, TasteGate readiness, provenance, and naming.*
10. *P is the* Pkg *provenance over* HyperbolicSectorNerve$^{\uparrow}$*, the MetaCIC confluence audit map, residual-substitution boundary rows, local-join rows, residual-checker rows, parallel-diamond frontier rows,* BHist*,* hsame*,* Cont*,* TasteGate*, and* NameCert*.*

11. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicSectorNerve}^{\uparrow}}$ *row.*
The carrier has no coordinate for a full parallel diamond, closed Church–Rosser, unrestricted substitution compatibility, subject reduction, evaluator equality, quotient equality of terms, or kernel consistency.

Theorem 8595.2 (Hyperbolic sector nerve NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ *carrier*

$$S = (W, B, J, O, T, R, G, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{HyperbolicSectorNerve}^{\uparrow}}$ *surface consists exactly of typed residual-window exposure through W, residual-branch exposure through B, candidate-join exposure through J, obstruction retention through O, transport through T, H, replay through R, C, TasteGate readiness through G, provenance through P, and local naming through N.*

Proof. Project the finite carrier. The rows W, B, J display the inspected residual sector: a typed window, two local branches, and candidate joins at the branch tips.

Read O before any diamond-facing consumer. This retained obstruction is the residual-substitution boundary named by the confluence audit map, so the carrier cannot turn the candidate joins into a full confluence theorem.

Finally read T, R, G, H, C, P, N. Transport and replay preserve the same finite sector, while the TasteGate readiness row records the later Nontrivial and FieldFaithful obligations without treating them as checked evidence. Since no stronger global row occurs in the carrier, the listed rows exhaust the local certificate. □

Theorem 8595.3 (Hyperbolic sector nerve audit-map concretization)**.** *Every confluence-audit read exported by an accepted* $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ *packet factors through finite residual-branch, candidate-join, obstruction-retention, transport, replay, provenance, and local NameCert rows. The read may feed a conditional parallel-diamond consumer, but it does not discharge residual-substitution compatibility, prove full Church–Rosser, prove subject reduction, decide evaluator equality, or establish kernel consistency.*

Proof. Start with W, B, J. These rows display only a finite local sector of the residual graph and its candidate joins.

Next inspect O. The obstruction row remains visible before the handoff is consumed, so the packet records the audit-map boundary instead of erasing it.

The rows T, R, H, C, P, N transport, replay, source, and name the same finite sector. Therefore the exported read is a concrete conditional-boundary packet, not an unrestricted confluence theorem or kernel metatheorem. □

Theorem 8595.4 (Hyperbolic sector nerve TasteGate readiness)**.** *The later Lean TasteGate file for* $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ *must provide* Nontrivial *and* FieldFaithful *instances at the displayed carrier surface*

$$W, B, J, O, T, R, G, H, C, P, N.$$

Nontriviality must exhibit an accepted packet with all finite residual-sector rows present. Field faithfulness must show that deleting any of the displayed branch, join, obstruction, transport, replay, provenance, or naming rows changes the readable carrier surface.

Proof. The readiness row G records the instance boundary but not the instance proof. It is downstream of W, B, J, O and upstream of the structural rows, so it cannot hide a missing residual-sector coordinate.

The nontriviality obligation is therefore tied to the existence of a displayed packet with all rows present. Field faithfulness is tied to componentwise comparison of those rows under H, C, P, N, ensuring that the future Lean surface cannot collapse the residual branch, candidate join, or obstruction-retention data into an empty marker. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ confluence-audit read exposes the obstruction-retention row O before any conditional parallel-diamond handoff is consumed.

Independence witness: metacic-confluence-substitution-boundary, metacic-local-join-ledger, metacic-confluence-residual-checker, metacic-parallel-diamond-frontier: none is bijective with $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ because this packet jointly carries a typed residual window, residual branches, candidate joins, obstruction retention, transport, replay, TasteGate readiness, provenance, and local naming as one finite nerve surface.

The Lean TasteGate file later supplies $\mathsf{Nontrivial}\ \mathsf{HyperbolicSectorNerve}^{\uparrow}$ and $\mathsf{FieldFaithful}\ \mathsf{HyperbolicSectorNerve}^{\uparrow}$ instances for the rows $W, B, J, O, T, R, G, H, C, P, N$. Those instances are obligations of the future Lean surface, not paper-side checked evidence.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicSectorNerve}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicSectorNerve}^{\uparrow}$ packet is generated from a typed residual window, residual-branch rows, candidate-join rows, obstruction-retention rows, transport rows, replay rows, TasteGate readiness, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorNerve}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8595.1, Definition 8595.2, Definition 8595.3, and Definition 8595.4 seed the finite residual-sector, candidate-join, obstruction-retention, transport, replay, TasteGate-readiness, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{HyperbolicSectorNerve}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close residual-substitution compatibility, full parallel diamond, closed Church–Rosser, subject reduction, evaluator equality, quotient equality of terms, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, residual-branch exposure, candidate-join exactness, obstruction retention, transport stability, replay stability, provenance exhaustion, local naming, and Nontrivial and FieldFaithful TasteGate instances for BEDC.Derived.HyperbolicSectorNerveUp.

Chapter 8596

A Concrete Naming Certificate for $\mathsf{HyperbolicAreaDefect}^{\uparrow}$

Following classical hyperbolic geometry and the Gauss–Bonnet area-defect formula, the $\mathsf{HyperbolicAreaDefect}^{\uparrow}$ packet records the finite boundary-triangle route by which a Poincare disk area element is read into an ideal-triangle area comparison. It sits after the Poincare disk area-element row of chapter 7916, the ideal-triangle boundary row of chapter 6544, the hyperbolic metric row of chapter 3474, and the scalar real seal of chapter 38. The packet names only the finite boundary-area defect surface; it is not a host integration theorem, a completed moduli space, selected geodesic representatives, or an ambient curvature theorem.

Definition 8596.1 (Hyperbolic area-defect carrier)**.** *A* $\mathsf{HyperbolicAreaDefect}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$\Delta = (A, T, M, R, B, H, C, P, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{PoincareDiskAreaElement}^{\uparrow}$ *row. It records the local disk area-element read used by the defect computation.*
2. *T is the* $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$ *row. It records the ordered boundary triangle whose defect is inspected.*
3. *M is the* $\mathsf{HyperbolicMetric}^{\uparrow}$ *row. It supplies the metric handoff tying the disk area element and boundary triangle to the same hyperbolic surface.*
4. *R is the* $\mathsf{Real}^{\uparrow}$ *scalar seal row for the displayed area-defect read.*
5. *B is the boundary-triangle ledger. It records that the three boundary vertices, side windows, metric read, area-element read, and scalar seal are consumed in the displayed order.*
6. *H records componentwise* hsame *transport for A, T, M, R, B, C, P, N.*
7. *C records displayed* Cont *replay of the route*

$$A, T, M \longmapsto B \longmapsto R \longmapsto H, P, N.$$

8. *P is the* Pkg *provenance over* $\mathsf{HyperbolicAreaDefect}^{\uparrow}$, $\mathsf{PoincareDiskAreaElement}^{\uparrow}$, $\mathsf{HyperbolicIdealTriangle}^{\uparrow}$, $\mathsf{HyperbolicMetric}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicAreaDefect}^{\uparrow}}$ *row.*

The classifier reads only the displayed area element, ideal-triangle boundary, metric, scalar seal, boundary ledger, transport, replay, provenance, and naming rows. It has no coordinate for host integration, selected geodesic representatives, quotient boundary configurations, or a global Gauss–Bonnet theorem.

Theorem 8596.2 (Hyperbolic area-defect NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicAreaDefect}^{\uparrow}$ *carrier* $\Delta = (A, T, M, R, B, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicAreaDefect}^{\uparrow}}$ *surface consists exactly of Poincare disk area-element admission through* A*, ideal-triangle admission through* T*, hyperbolic metric compatibility through* M*, boundary-triangle ledger visibility through* B*, delayed Real scalar sealing through* R*, componentwise transport through* H*, displayed continuation replay through* C*, package provenance through* P*, and local naming through* N*.*

Proof. Project the carrier of Definition 8596.1. The only geometric source rows are the Poincare disk area element, the ideal-triangle boundary data, and the hyperbolic metric handoff.

The boundary-triangle ledger B binds those source rows before any scalar seal is read. Thus a defect consumer cannot bypass the displayed boundary vertices, side windows, metric read, or area-element read.

The Real row R is downstream of that ledger, and H, C, P, N transport, replay, source, and name the same finite route. Since the carrier contains no row for host integration, selected geodesics, quotient boundary configurations, or a global curvature theorem, the listed obligations exhaust the local certificate surface. □

Theorem 8596.3 (Hyperbolic area-defect boundary-triangle route)**.** *Every accepted* $\mathsf{HyperbolicAreaDefect}^{\uparrow}$ *read factors through*

$$\mathsf{PoincareDiskAreaElement}^{\uparrow}, \mathsf{HyperbolicIdealTriangle}^{\uparrow}, \mathsf{HyperbolicMetric}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}, \mathsf{NameCert}.$$

The scalar defect is therefore consumed as a finite boundary-triangle area readback, not as an ambient integration theorem, selected ideal-triangle representative, quotient boundary configuration, completed moduli-space point, or host Gauss–Bonnet principle.

Proof. Begin with the source rows A, T, M. They display the local Poincare disk area element, the ordered ideal-triangle boundary data, and the hyperbolic metric handoff on the same inspected surface.

Next read the boundary-triangle ledger B. It records the order in which boundary vertices, side windows, metric data, and area-element data are exposed before a scalar value is sealed.

Finally, the Real row and structural rows R, H, C, P, N seal and replay that same ledger. No extra coordinate remains from which a host integration theorem, selected geodesic representative, quotient boundary object, completed moduli point, or global curvature theorem could be exported. □

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicAreaDefect}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicAreaDefect}^{\uparrow}$ packet is generated from a PoincareDiskAreaElement row, HyperbolicIdealTriangle row, HyperbolicMetric row, Real scalar seal row, boundary-triangle ledger, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicAreaDefect}^{\uparrow}}$, seed)

Scope closed: Definition 8596.1, Definition 8596.2, and Definition 8596.3 seed the finite boundary-triangle area-defect route through Poincare disk area-element, ideal-triangle, metric, and Real-seal rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicAreaDefect}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not claim host integration, selected geodesic representatives, quotient boundary configurations, completed moduli spaces, a global Gauss–Bonnet theorem, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked area-element admission, ideal-triangle admission, metric compatibility, boundary-triangle ledger visibility, scalar-seal delay, transport, replay, provenance, and local naming for BEDC.Derived.HyperbolicAreaDef

Chapter 8597

A Concrete Naming Certificate for $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$

Following Bishop and Bridges, the $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ packet records the finite squeeze route that ties regular Cauchy lattice operations to the terminal $\mathsf{Real}^{\uparrow}$ seal without using host trichotomy, quotient streams, or a selected limit. It sits beside the minimum and maximum surfaces of chapter 1528 and chapter 1502, the lattice-operation surface of chapter 5727, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the finite observation surface of chapter 126, and the terminal real-name seal of chapter 38. The packet names a constructive squeeze certificate, not a host order theorem, ambient completeness claim, or quotient-real comparison.

Definition 8597.1 (RegularCauchyLatticeSqueeze carrier)**.** *A* $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$S = (L, U, W, D, \ell, u, R, E, H, C, P, N)$$

with the following rows:

1. *L is the lower-window row, carrying the displayed minimum route read from the accepted regular Cauchy lattice surface.*
2. *U is the upper-window row, carrying the displayed maximum route read from the same finite surface.*
3. *W is the shared* $\mathsf{StreamName}^{\uparrow}$ *observation row exposing the finite windows used by both lattice routes.*
4. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger recording the displayed radius budget and comparison scale.*
5. *ℓ is the lower-route exactness row, forcing the lower window to pass through the same finite squeeze route as the minimum surface.*
6. *u is the upper-route exactness row, forcing the upper window to pass through the same finite squeeze route as the maximum surface.*
7. *R is the terminal* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the common squeeze route.*
8. *E is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row, available only after R has been displayed.*

9. *H records componentwise* hsame *transport for the lower and upper routes, the shared observation row, dyadic tolerance, exactness rows, readback, seal, provenance, and local naming.*
10. *C records displayed* Cont *replay from the squeeze request through $L, U, W, D, \ell, u, R, E, H, P, N$.*
11. *P is the* Pkg *provenance over* $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$, $\mathsf{RegularCauchyMinimum}^{\uparrow}$, $\mathsf{RegularCauchyMaximum}^{\uparrow}$ $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.
12. *N is the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $L, U, W, D, \ell, u, R, E, H, C, P, N$. It has no coordinate for host trichotomy, quotient stream equality, selected limits, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8597.2 (RegularCauchyLatticeSqueeze NameCert obligations)**.** *For every accepted* RegularCauchyLattice *carrier $S = (L, U, W, D, \ell, u, R, E, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}}$ *surface consists exactly of carrier admission for the lower-window row, upper-window row, shared StreamName observation row, DyadicRatCore tolerance ledger, lower-route exactness row, upper-route exactness row, RegSeqRat readback row, Real seal row, componentwise transport, displayed replay, provenance, and local naming.*

Proof. Project the accepted carrier. The rows $L, U, W, D, \ell, u, R, E, H, C, P, N$ are the entire public inventory of the squeeze packet.

The lower and upper routes are displayed first. The lower route row ℓ and the upper route row u force the shared observation row W and dyadic tolerance row D to be read before the common readback row R is available.

The readback row R is downstream of the same displayed squeeze route. The structural rows H, C, P, N transport, replay, source, and name exactly that finite route. Since the carrier contains no coordinate for trichotomy, quotient stream equality, selected limits, or ambient completeness, the listed rows exhaust the local NameCert surface. □

Theorem 8597.3 (RegularCauchyLatticeSqueeze lower-window route)**.** *Let $S = (L, U, W, D, \ell, u, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ *carrier. Any lower-window consumer must read the finite route*

$$L \longmapsto \ell \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

Thus the lower-window route exports only the displayed lower-window row, the lower-route exactness row, the shared observation row, the dyadic tolerance ledger, the regular readback, and the terminal real seal.

Proof. Start with Definition 8597.2. The lower-window row is available only after L has been displayed, and the exactness row ℓ is the next lower-route commitment.

The shared observation row W and dyadic ledger D are then consumed before the readback row R appears. The seal row E remains downstream of that lower route, so no host trichotomy, quotient comparison, or selected limit enters the packet. □

Theorem 8597.4 (RegularCauchyLatticeSqueeze upper-window route)**.** *Let $S = (L, U, W, D, \ell, u, R, E, H, C, P, N)$ be an accepted* $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ *carrier. Any upper-window consumer must read the finite route*

$$U \longmapsto u \longmapsto W \longmapsto D \longmapsto R \longmapsto E.$$

Thus the upper-window route exports only the displayed upper-window row, the upper-route exactness row, the shared observation row, the dyadic tolerance ledger, the regular readback, and the terminal real seal.

Proof. Start with the same NameCert obligations. The upper-window row is available only after U has been displayed, and the exactness row u is the next upper-route commitment.

The shared observation row W and dyadic ledger D are then consumed before the readback row R appears. The seal row E remains downstream of that upper route, so no quotient stream equality or ambient completeness is exported by the packet. □

Theorem 8597.5 (RegularCauchyLatticeSqueeze RealUp-seal nonescape)**.** *Let $S = (L, U, W, D, \ell, u, R, E, H, C, P$ be an accepted* $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ *carrier. Every* $\mathsf{Real}^{\uparrow}$ *consumer reaches the seal E only through the displayed lower-window route and upper-window route together with the common readback row R. The consumer therefore receives no host trichotomy, quotient stream equality, selected limit, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness coordinate.*

Proof. Apply the lower-window route theorem and the upper-window route theorem. Both force the consumer through the same shared observation row, dyadic tolerance ledger, and regular readback before the seal row is available.

The structural rows H, C, P, N preserve and name that shared route. Since the carrier has no excluded completeness coordinate, the terminal seal is a finite readback boundary rather than a host-order or quotient argument. □

Falsifiable prediction: Every accepted $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ read displays one lower-window row, one upper-window row, one shared $\mathsf{StreamName}^{\uparrow}$ observation row, one $\mathsf{DyadicRatCore}^{\uparrow}$ tolerance ledger, lower-route exactness, upper-route exactness, one $\mathsf{RegSeqRat}^{\uparrow}$ readback row, one $\mathsf{Real}^{\uparrow}$ seal row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert evidence before a minimum, maximum, or Real-facing consumer may read the squeeze route.

Independence witness: regularcauchymin, regularcauchymax, regseqrat, dyadicratcore, streamname, real: $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the lower-window, upper-window, shared observation, dyadic tolerance, lower exactness, upper exactness, regular readback, real sealing, transport, replay, provenance, and local naming rows.

Closure status for $\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}}$.

Constructive story: A $\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}$ packet is generated from lower-window and upper-window rows, a shared StreamName observation row, a DyadicRatCore tolerance ledger, lower-route and upper-route exactness rows, a RegSeqRat readback, a RealUp seal, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}}$, seed)

Scope closed: Definition 8597.1, Definition 8597.2, Definition 8597.3, Definition 8597.4, and Definition 8597.5 seed the finite squeeze route over minimum, maximum, StreamName, DyadicRatCore, RegSeqRat, and Real rows.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{RegularCauchyLatticeSqueeze}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close host trichotomy, quotient stream equality, selected limits, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, lower-route exactness, upper-route exactness, route stability, provenance, and non-escape for the regular squeeze TasteGate target.

Chapter 8598

A Concrete Naming Certificate for $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$

The $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ packet realizes the composable observer-phase transport route of chapter 9463 as finite observer-phase, phase-distance, boundary-shadow, transport-budget, transport, replay, provenance, and NameCert data. It sits beside the observer-phase packet of chapter 7112, the phase-distance shell packet of chapter 6017, the observer-phase groupoid packet of chapter 6146, the transport-budget packet of chapter 7134, and the boundary-shadow packet of chapter 3813. The packet names a finite cocycle reading; it is not a global hyperbolic space, a completed observer geometry, or a host transport theorem.

Definition 8598.1 (Hyperbolic phase expansion cocycle carrier)**.** *A* $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$Q = (O, D, B, T, G, R, H, C, P, N)$$

with the following rows:

1. *O is the observer-phase row.*
2. *D is the phase-distance row.*
3. *B is the boundary-shadow row.*
4. *T is the transport-budget row.*
5. *G is the observer-phase groupoid row that composes the displayed route.*
6. *R is the cocycle readback row, recorded only after the displayed transport and distance data have been inspected.*
7. *H records componentwise* hsame *transport for the observer-phase, phase-distance, boundary-shadow, transport-budget, groupoid, readback, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from the cocycle request through $O, D, B, T, G, R, H, P, N$.*
9. *P is the* Pkg *provenance over* $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$, $\mathsf{HyperbolicObserverPhase}^{\uparrow}$, $\mathsf{PhaseDistanceObserverExpansion}^{\uparrow}$, $\mathsf{HyperbolicBoundaryShadow}^{\uparrow}$, $\mathsf{HyperbolicPhaseTransportBudget}^{\uparrow}$, $\mathsf{ObserverPhaseGroupoid}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $O, D, B, T, G, R, H, C, P, N$. It has no coordinate for a completed boundary, host phase equality, quotient transport class, or ambient completeness.

Theorem 8598.2 (Hyperbolic phase expansion cocycle NameCert obligations)**.** *For every accepted* $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ *carrier* $Q = (O, D, B, T, G, R, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseExpansi}}$ *surface consists exactly of carrier admission for observer-phase, phase-distance, boundary-shadow, transport-budget, observer-phase groupoid, cocycle readback, componentwise transport, displayed replay, provenance, and local naming rows.*

Proof. Project the accepted carrier. The rows $O, D, B, T, G, R, H, C, P, N$ are the public inventory of the cocycle packet.

The observer-phase, distance, boundary-shadow, and transport-budget rows are displayed before the readback row R is available. The groupoid row G composes those rows into the finite cocycle route, while the structural rows H, C, P, N transport, replay, source, and name that same route.

Since the carrier contains no completed boundary, host phase equality, quotient transport class, or ambient completeness coordinate, the listed rows exhaust the local NameCert surface. □

Falsifiable prediction: Every accepted $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ read exposes observer-phase, phase-distance, boundary-shadow, transport-budget, observer-phase groupoid, cocycle readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows before any public cocycle consumer receives the packet.

Independence witness: hyperbolic-observer-phase, phase-distance-observer-expansion, observer-phase-groupoid, hyperbolic-phase-transport-budget, hyperbolic-boundary-shadow: HyperbolicPhaseExpansionCocyc is not bijective to any listed sibling because it jointly binds observer-phase, phase-distance, boundary-shadow, transport-budget, groupoid, readback, transport, replay, provenance, and local naming rows into one finite cocycle surface.

The Lean TasteGate follow-up for this packet must provide explicit Nontrivial $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ and FieldFaithful $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ instances before a checked carrier-alignment theorem can witness the public route.

Closure status for $\mathsf{NameCert}_{\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}}$.

Constructive story: A $\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}$ packet is generated from observer-phase, phase-distance, boundary-shadow, transport-budget, observer-phase groupoid, cocycle readback, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local NameCert rows.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}}$, seed)

Scope closed: Definition 8598.1, Definition 8598.2, the falsifiable prediction, and the independence witness seed the finite observer-phase expansion cocycle route.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{HyperbolicPhaseExpansionCocycle}^{\uparrow}}$, unformalized)

Bridge status: none

Not claimed: This chapter does not close completed boundary geometry, host phase equality, quotient transport classes, ambient completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, observer-phase exposure, phase-distance exposure, boundary-shadow exposure, transport-budget exposure, groupoid composition, cocycle readback, TasteGate nontriviality, field faithfulness, transport, replay, provenance, and local naming for the hyperbolic phase expansion cocycle target.

Chapter 8599

A Concrete Naming Certificate for $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$

Following Bishop and Bridges constructive analysis, the $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ packet records the finite handoff by which Cauchy-name data reaches completion-facing $\mathsf{Real}^{\uparrow}$ seals without importing a classical real-completeness principle. It sits beside the stream-name route of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, the terminal real seal of chapter 38, the countable metric name route of chapter 8593, the countable metric completion route of chapter 4044, and the finite-prefix request surface of chapter 5916. The packet names the displayed bridge from finite Cauchy observations to completion-facing real seals; it is not a quotient stream equality, selected limit operator, countable-choice schedule, trichotomy principle, or ambient $\mathsf{Real}^{\uparrow}$ completeness theorem.

Definition 8599.1 (Constructive Cauchy real completion bridge carrier)**.** *A* ConstructiveCauchyRealCompletionBric *carrier is a finite* BHist *packet*

$$B = (S, R, D, E, M, F, H, C, P, N)$$

with the following displayed rows:

1. *S is the finite* $\mathsf{StreamName}^{\uparrow}$ *window schedule for Cauchy-name observations, including the request prefixes consumed by the bridge.*
2. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from those displayed stream windows.*
3. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger for comparison scales, slack witnesses, and refusal rows.*
4. *E is the completion-facing* $\mathsf{Real}^{\uparrow}$ *seal reached only after S, R, D have been displayed.*
5. *M is the* $\mathsf{CountableMetricName}^{\uparrow}$ *row naming the metric-name data read by the bridge.*
6. *F is the finite* $\mathsf{FiniteStream}^{\uparrow}$ *prefix schedule that bounds every request before a Cauchy-name or metric-name read is consumed.*
7. *H records componentwise* hsame *transport for the stream, regular rational, dyadic, real-seal, metric-name, finite-prefix, continuation, provenance, and local naming rows.*
8. *C records displayed* Cont *replay from a bridge request through $F, S, R, D, E, M, H, P, N$.*

9. *P is the* Pkg *provenance over* ConstructiveCauchyRealCompletionBridge$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, Real$^{\uparrow}$, CountableMetricName$^{\uparrow}$, CountableMetricCompletion$^{\uparrow}$, FiniteStream$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert.

10. *N is the local* NameCert$_{\text{ConstructiveCauchyRealCompletionBridge}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $S, R, D, E, M, F, H, C, P, N$. It has no coordinate for quotient equality of Cauchy streams, selected limits, countable choice, trichotomy, hidden representatives, host real equality, or ambient Real$^{\uparrow}$ *completeness.*

Theorem 8599.2 (Constructive Cauchy real completion bridge NameCert obligations)**.** *For an accepted* ConstructiveCauchyRealCompletionBridge$^{\uparrow}$ *carrier $B = (S, R, D, E, M, F, H, C, P, N)$, the local* NameCert$_{\text{ConstructiveCauchyRealCompletionBridge}^{\uparrow}}$ *surface consists exactly of carrier admission, finite-prefix exposure through F, stream-window exposure through S, regular rational readback through R, dyadic tolerance checking through D, completion-facing* Real$^{\uparrow}$ *sealing through E, countable metric-name exposure through M, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through P, and local naming through N.*

Proof. Carrier admission is the displayed packet of Definition 8599.1. Every row read by a consumer is one of $S, R, D, E, M, F, H, C, P, N$.

The Cauchy side is finite because each request first passes through the prefix schedule F and then through the stream windows S. The regular rational row R and dyadic ledger D expose only the readback and tolerance data admitted by those windows.

The completion-facing side is the real seal E together with the metric-name row M. Transport, replay, provenance, and local naming are confined to H, C, P, N, so the NameCert obligations are exhausted by the displayed bridge rows. □

Theorem 8599.3 (Constructive Cauchy real completion bridge Cauchy seal)**.** *Every accepted* ConstructiveCauchyRealCompletionBridge$^{\uparrow}$ *read reaches a completion-facing* Real$^{\uparrow}$ *seal only through the finite route*

$$F \longmapsto S \longmapsto R \longmapsto D \longmapsto E$$

together with the countable metric-name row M and the structural rows H, C, P, N.

Proof. Start with the finite-prefix row F. It bounds the request before the bridge can inspect a Cauchy-name window, so the stream row S is never consumed as an unbounded choice of observations.

The regular rational row R reads the displayed windows, and the dyadic ledger D records the tolerance scale for the comparison. Only after these rows are displayed does the packet expose the completion-facing real seal E.

The metric-name row M is read beside the same route, not in place of it. The structural rows H, C, P, N preserve and replay the displayed route without adding a selected limit or quotient representative. □

Theorem 8599.4 (Constructive Cauchy real completion bridge nonescape)**.** *An accepted* ConstructiveCauchyRealCo *packet exports only the displayed rows $S, R, D, E, M, F, H, C, P, N$. Any selected limit, quotient stream equality, countable-choice schedule, trichotomy principle, hidden representative, host real equality, or ambient* Real$^{\uparrow}$ *completeness claim must be supplied by a later certificate; it is not a coordinate of this bridge.*

Proof. Inspect the carrier coordinates. The packet contains finite stream windows, regular rational readback, dyadic tolerances, a real seal, countable metric-name data, finite prefixes, transport, replay, provenance, and local naming.

None of those coordinates is a selector for a Cauchy-stream equivalence class, a choice function over requests, a trichotomy oracle, or a completeness theorem. The real row E is a displayed seal reached by the route of Definition 8599.3, not an ambient completeness principle.

Therefore every legal consumer remains inside the named packet. A downstream completion theorem may cite the bridge as input, but it must display its own completion or equality certificate. □

Theorem 8599.5 (Constructive Cauchy real completion bridge finite prefix)**.** *For an accepted* $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ *carrier* $B = (S, R, D, E, M, F, H, C, P, N)$*, every bridge request must first expose the finite* $\mathsf{FiniteStream}^{\uparrow}$ *row* F *before it may read a* $\mathsf{StreamName}^{\uparrow}$ *window, a* $\mathsf{CountableMetricName}^{\uparrow}$ *row, or a completion-facing* $\mathsf{Real}^{\uparrow}$ *seal. The prefix row is therefore part of carrier admission, not a detachable optimization.*

Proof. Project the carrier rows. The row F is the only coordinate that bounds request prefixes before a Cauchy-name or metric-name read is consumed.

Once F is displayed, the stream row S and metric-name row M may be read through the structural rows H, C, P, N. Without F, the request would have no finite BHist boundary and could not be replayed by Cont.

Thus finite-prefix routing is a named obligation of the packet. It is not supplied by $\mathsf{StreamName}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, or $\mathsf{CountableMetricCompletion}^{\uparrow}$ alone. □

Theorem 8599.6 (Constructive Cauchy real completion bridge stream window)**.** *Every accepted Cauchy-name read in* $B = (S, R, D, E, M, F, H, C, P, N)$ *passes from the finite prefix row* F *into the displayed* $\mathsf{StreamName}^{\uparrow}$ *window row* S *before regular rational readback through* R*. No consumer may replace* S *by an unbounded stream, a hidden representative, or a host sequence.*

Proof. The carrier definition names S as the finite stream-window schedule for Cauchy observations. It is downstream from F and upstream from R.

Readback through $\mathsf{RegSeqRat}^{\uparrow}$ is therefore a projection of displayed stream windows, not a direct call to an ambient sequence object. Transport and replay keep the same F, S, R route visible through H and C.

Consequently the bridge exposes windowed stream data only. Any unbounded stream or hidden representative would be outside the named $\mathsf{NameCert}$ surface. □

Theorem 8599.7 (Constructive Cauchy real completion bridge dyadic tolerance)**.** *For every accepted bridge read, the* $\mathsf{DyadicRatCore}^{\uparrow}$ *row* D *must display the tolerance scale, slack witness, and refusal data used to compare the regular rational readback* R *with the completion-facing seal* E*. A read that omits* D *is not an accepted* $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ *comparison.*

Proof. The row D is the packet's tolerance ledger. It records comparison scales after R has read the displayed stream windows and before E is consumed.

The dyadic row also contains the refusal data for comparisons that the bridge cannot certify. This keeps tolerance checking within $\mathsf{DyadicRatCore}^{\uparrow}$ instead of moving it to host real equality or a trichotomy oracle.

Therefore a valid comparison route must expose R, D, E in that order, with H, C, P, N preserving the same local certificate rows. □

Theorem 8599.8 (Constructive Cauchy real completion bridge real seal)**.** *The* $\mathsf{Real}^{\uparrow}$ *row* E *of an accepted* $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ *packet is reached only after the finite-prefix, stream-window, regular rational, and dyadic-tolerance rows* F, S, R, D *have been displayed. The row* E *is a completion-facing seal for that route, not a proof of ambient real completeness.*

Proof. Use the carrier route recorded in Definition 8599.3. The row E occurs after F, S, R, D and is transported with the same componentwise hsame row.

Because E is a displayed packet row, continuation replay can revisit the route through C and provenance can name it through P. The local $\mathsf{NameCert}$ row N then records the seal as part of this bridge.

No coordinate of E selects limits, identifies quotient streams, or supplies global completeness. Those claims require a separate certificate beyond the bridge packet. □

Theorem 8599.9 (Constructive Cauchy real completion bridge countable metric)**.** *The countable metric-name row* M *is exposed beside the Cauchy route* F, S, R, D, E *and before any consumer may treat the packet as input to* $\mathsf{CountableMetricCompletion}^{\uparrow}$*. The bridge names metric-read data; it does not itself certify countable metric completion.*

Proof. Project M from the carrier. It is the $\mathsf{CountableMetricName}^{\uparrow}$ row read by the bridge, while $\mathsf{CountableMetricCompletion}^{\uparrow}$ appears in provenance as a downstream completion route.

The metric-name row is transported and replayed with H and C, so consumers can inspect the finite route by which metric data was made available. This is weaker than constructing a completed metric object.

Thus M supplies countable metric-name exposure only. Completion existence, quotient classes, and selected representatives remain outside the local bridge coordinates. □

Theorem 8599.10 (Constructive Cauchy real completion bridge transport and replay)**.** *For accepted packets* $B = (S, R, D, E, M, F, H, C, P, N)$*, the componentwise* hsame *row* H *and displayed* Cont *row* C *preserve the route* F, S, R, D, E, M *together with provenance* P *and local naming* N*. Transport or replay cannot introduce a selected limit, quotient stream equality, countable-choice schedule, or ambient* $\mathsf{Real}^{\uparrow}$ *completeness theorem.*

Proof. Read H first. Its componentwise domain is the displayed stream, rational, dyadic, real-seal, metric-name, finite-prefix, continuation, provenance, and local naming rows.

Read C next. Continuation replay follows a bridge request through the same rows $F, S, R, D, E, M, H, P, N$, so replay is a finite route over BHist data rather than a new analytic principle.

The provenance row P and local $\mathsf{NameCert}$ row N record the sources and name of that route. Since no listed coordinate contains selected limits, quotient stream equality, choice schedules, or ambient completeness, transport and replay cannot export them. □

Falsifiable prediction: Every accepted ConstructiveCauchyRealCompletionBridgeUp read displays $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{Real}^{\uparrow}$, $\mathsf{CountableMetricName}^{\uparrow}$, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before the completion-facing seal is consumed.

Independence witness: streamname, regseqrat, dyadicratcore, real, countable-metric-name, countable-metric-completion, finite-stream: $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries the finite-prefix schedule, Cauchy stream windows, rational readback, dyadic tolerance, real seal, countable metric-name row, transport, replay, provenance, and local naming in one bridge packet.

Closure status for $\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}}$.

Constructive story: A $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$ packet is generated from finite prefix schedules, StreamName windows, RegSeqRat readback, DyadicRatCore tolerances, Real seals, CountableMetricName rows, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8599.1, Definition 8599.2, Definition 8599.3, and Definition 8599.4 seed the finite bridge from Cauchy-name data to completion-facing Real seals.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not claim selected limits, quotient stream equality, countable choice, trichotomy, hidden representatives, host real equality, ambient $\mathsf{Real}^{\uparrow}$ completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-prefix routing, stream-window exposure, regular rational readback, dyadic tolerance checking, Real sealing, countable metric-name exposure, transport, replay, provenance, and local naming for $\mathsf{ConstructiveCauchyRealCompletionBridge}^{\uparrow}$.

Chapter 8600

A Concrete Naming Certificate for $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$

Following Brouwer on spreads and choice sequences, the $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ packet records a finite prefix law whose accepted nodes may be inspected by L10 Real and Completion consumers without quotient streams, selected branches, or countable choice. It sits beside the finite observation surface of chapter 5916, the StreamName window discipline of chapter 126, and the List prefix carrier of chapter 36. The packet isolates the constructive law: a displayed finite prefix is admitted only through a finite BHist row, and every public read stays inside the same prefix-closed route.

Definition 8600.1 (Brouwerian spread-law carrier)**.** *A* $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$L = (F, S, A, E, W, H, C, P, N)$$

with the following displayed rows:

1. *F is the* $\mathsf{FiniteStream}^{\uparrow}$ *observation row, listing the finite source windows currently inspected.*
2. *S is the* $\mathsf{StreamName}^{\uparrow}$ *schedule row that names the requested window positions.*
3. *A is the* $\mathsf{List}^{\uparrow}$ *prefix row, storing the finite words and parent-prefix inclusions read by the law.*
4. *E is the admissibility row: every displayed prefix is either admitted by the law or remains on the refusal side of the same finite ledger.*
5. *W is the extension row, recording for each admitted prefix the displayed one-step or bounded finite continuation still admitted by E.*
6. *H records componentwise* hsame *transport for finite streams, schedules, prefixes, admissibility rows, extension rows, replay, provenance, and local naming.*
7. *C records displayed* Cont *replay from a prefix request through F, S, A, E, W.*
8. *P is* Pkg *provenance over* $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$, $\mathsf{FiniteStream}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{List}^{\uparrow}$, BHist, hsame, Cont, *and* $\mathsf{NameCert}$ *rows.*
9. *N is the local* $\mathsf{NameCert}_{\mathsf{BrouwerianSpreadLaw}^{\uparrow}}$ *row.*

The classifier compares accepted carriers only through $F, S, A, E, W, H, C, P, N$. It has no coordinate for a completed infinite branch, quotient stream equality, countable-choice selector, fan compactness, or ambient $\mathsf{Real}^{\uparrow}$ *completeness.*

Theorem 8600.2 (Brouwerian spread-law NameCert obligations)**.** *For every accepted* $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ *carrier* $L = (F, S, A, E, W, H, C, P, N)$*, the local* $\mathsf{NameCert}_{\mathsf{BrouwerianSpreadLaw}^{\uparrow}}$ *surface consists exactly of finite-stream exposure through* F*, schedule exposure through* S*, List prefix exposure through* A*, admissibility classification through* E*, extension visibility through* W*, componentwise* hsame *transport through* H*, displayed* Cont *replay through* C*,* Pkg *provenance through* P*, and local naming through* N*. Every public read of the law factors through the finite route*

$$F, S, A \longmapsto E \longmapsto W \longmapsto H, C, P, N.$$

Proof. Project the carrier of Definition 8600.1. The only source rows available to a consumer are the finite stream windows, StreamName schedule, and List prefix ledger.

Read the admissibility and extension rows next. The row E classifies displayed prefixes in the finite ledger, while W records only continuations still admitted by that same displayed law.

Finally use H, C, P, N to preserve and name the route. Since no carrier coordinate stores a completed branch, quotient stream, countable-choice selector, fan compactness witness, or ambient completion principle, these rows exhaust the NameCert obligations. □

Theorem 8600.3 (Brouwerian spread-law prefix closure)**.** *Let* $L = (F, S, A, E, W, H, C, P, N)$ *be an accepted* $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ *carrier. If a consumer reads an admitted prefix from* A *and* E*, then every displayed predecessor prefix in the same List spine is read through the same finite stream row* F*, schedule row* S*, admissibility row* E*, extension row* W*, transport row* H*, replay row* C*, provenance row* P*, and local naming row* N*.*

Proof. Start with the List prefix row A. It stores the displayed parent-prefix inclusions for the finite words currently visible to the law.

Use the admissibility row E. An admitted prefix can be read only as part of the same finite ledger, so predecessor prefixes are classified by the same law rather than by a second hidden predicate.

The finite-stream and StreamName rows keep the observation schedule fixed. The extension row W then witnesses only continuations whose predecessors remain in the displayed List spine.

Transport, replay, provenance, and local naming through H, C, P, N preserve that packet. Therefore prefix restriction stays inside the accepted $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ carrier and exports no selected infinite branch. □

Theorem 8600.4 (Brouwerian spread-law finite-window handoff)**.** *Every L10 consumer of an accepted* $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ *packet reaches finite observation data only through the displayed route*

$$\mathsf{FiniteStream}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{List}^{\uparrow} \longmapsto \mathsf{BrouwerianSpreadLaw}^{\uparrow}.$$

The handoff supplies prefix-law evidence for finite windows; it does not select an infinite choice sequence, identify quotient streams, or assert compactness or completeness.

Proof. Apply the NameCert obligations of Definition 8600.2. They force the consumer to expose F, S, A, E, W before any public read of the law is available.

Apply prefix closure from Definition 8600.3. A later finite window cannot bypass the predecessor-prefix route, because the same List spine and admissibility row remain visible.

The excluded objects are not carrier coordinates. Thus the L10 handoff is a finite prefix-law route from finite streams and StreamName windows into a displayed Brouwerian law, with no quotient stream, selected branch, countable choice, fan compactness, or ambient $\mathsf{Real}^{\uparrow}$ completeness. □

Closure status for $\mathsf{NameCert}_{\mathsf{BrouwerianSpreadLaw}^{\uparrow}}$.

Constructive story: A $\mathsf{BrouwerianSpreadLaw}^{\uparrow}$ packet is generated from finite stream windows, StreamName schedules, List prefix rows, admissibility and extension rows, componentwise hsame transport, Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{BrouwerianSpreadLaw}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8600.1, Definition 8600.2, Definition 8600.3, and Definition 8600.4 seed the constructive finite-prefix law surface over FiniteStreamUp, StreamNameUp, ListUp, BHist, hsame, Cont, Pkg, and NameCert rows.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{BrouwerianSpreadLaw}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close selected infinite branches, quotient stream equality, countable choice, fan compactness, ambient RealUp completeness, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, finite-window exposure, prefix admissibility, extension visibility, prefix closure, structural nonescape, and L10 handoff coverage for BEDC.Derived.BrouwerianSpreadLawUp.

Chapter 8601

A Concrete Naming Certificate for $\mathsf{PartiallyOrderedGroup}^{\uparrow}$

Following Bourbaki on ordered algebraic structures and Fuchs on partially ordered groups, the $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ packet records the finite NameCert surface for a group equipped with a translation-invariant partial order. It sits between the group carrier of chapter 41, the order surface of chapter 1378, the poset carrier of chapter 53, the monoid source of chapter 40, and the local NameCert transport rows used throughout the concrete-instance layer. The packet names order-compatible multiplication and inversion data; it does not assert totality, lattice operations, Archimedean comparison, ordered completion, or host equality of group functions.

Definition 8601.1 (Partially ordered group carrier)**.** *A* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$G = (A, O, P, M, I, K, H, C, Q, N)$$

with the following displayed rows:

1. *A is the* $\mathsf{Group}^{\uparrow}$ *row, naming multiplication, inverse, neutral element, and the finite group-law surface.*
2. *O is the* $\mathsf{Order}^{\uparrow}$ *row on the same carrier, recording reflexive, antisymmetric, and transitive comparison data.*
3. *P is the* $\mathsf{Poset}^{\uparrow}$ *readback row, exposing the order as a partial-order classifier rather than a preorder-only relation.*
4. *M is the* $\mathsf{Monoid}^{\uparrow}$ *source row for the multiplication law before inverses are inspected.*
5. *I records order transport under left and right multiplication by displayed group elements.*
6. *K records positive-cone data: neutral membership, multiplication closure, inverse reflection, and reconstruction of the order from the cone.*
7. *H records componentwise* hsame *transport for A, O, P, M, I, K and the structural rows below.*
8. *C records displayed* Cont *replay from group-law reads to order reads, translation reads, positive-cone reads, provenance, and local naming.*
9. *Q is the* Pkg *provenance over* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$, $\mathsf{Group}^{\uparrow}$, $\mathsf{Order}^{\uparrow}$, $\mathsf{Poset}^{\uparrow}$, $\mathsf{Monoid}^{\uparrow}$, BHist, hsame, Cont, Pkg, *and* NameCert.
10. *N is the local* $\mathsf{NameCert}_{\mathsf{PartiallyOrderedGroup}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $A, O, P, M, I, K, H, C, Q, N$. It has no coordinate for total order, lattice meet or join, Archimedean law, ordered completion, quotient representative, or host-level group function equality.

Theorem 8601.2 (Partially ordered group NameCert obligations)**.** *For every accepted* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ *carrier $G = (A, O, P, M, I, K, H, C, Q, N)$, the local* $\mathsf{NameCert}_{\mathsf{PartiallyOrderedGroup}^{\uparrow}}$ *surface consists exactly of carrier admission for G, group exposure through A, order exposure through O, poset readback through P, monoid multiplication exposure through M, translation-invariance accountability through I, positive-cone accountability through K, componentwise* hsame *transport through H, displayed* Cont *replay through C,* Pkg *provenance through Q, local naming through N, and nonescape excluding totality, lattice operations, Archimedean comparison, ordered completion, quotient representatives, and host group-function equality.*

Proof. Carrier admission is projection from Definition 8601.1. The algebraic rows are A and M, while the order rows are O and P.

The compatibility rows are separate. Translation invariance is read from I, and positive-cone stability is read from K; neither row is forced by merely naming a group or a poset.

Finally H, C, Q, N transport, replay, source, and name the same finite packet. Since the carrier has no further coordinate, the listed rows exhaust the local NameCert surface and block the excluded stronger structures. □

Theorem 8601.3 (Partially ordered group positive cone stability)**.** *In an accepted* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ *packet, the positive-cone row K is stable under multiplication and reconstructs the displayed order row O only through the group row A, monoid row M, and poset row P. A consumer may read positive elements and cone multiplication, but not total comparison, lattice operations, or completion data.*

Proof. Read K as a displayed carrier row. It records neutral membership, multiplication closure, inverse reflection, and reconstruction of the order from the cone.

The reconstruction is not detached from algebra. It uses the group operation from A, the multiplication law from M, and the partial-order classifier exposed through O and P.

Thus cone stability remains a finite positive-cone obligation inside the packet. It does not add totality, meets, joins, Archimedean comparison, or completion rows. □

Theorem 8601.4 (Partially ordered group order translation)**.** *Every accepted order comparison in a* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ *packet is stable under displayed left and right translation only through the row I together with A, O, P, M, H, C, Q, N. Translation stability is part of the NameCert route and is not a host-level equality of group functions.*

Proof. Start with a comparison in O and its partial-order readback in P. The group and monoid rows A, M provide the displayed multiplication data used for translation.

The row I records the actual compatibility obligation: translating comparable elements on the left or right preserves the displayed order relation. Transport and replay keep this route visible through H and C.

Provenance and local naming record the route as part of the $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ certificate. No coordinate identifies host functions or supplies comparison data outside the finite packet. □

Theorem 8601.5 (Partially ordered group nonescape)**.** *An accepted* $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ *packet exports only the displayed rows $A, O, P, M, I, K, H, C, Q, N$. Any total order, lattice-ordered group structure, Archimedean principle, ordered completion theorem, quotient representative, or host equality of group operations must be supplied by another certificate.*

Proof. Inspect the carrier inventory. It contains group data, order data, poset readback, monoid multiplication, translation accountability, positive-cone accountability, transport, replay, provenance, and local naming.

None of these rows is a total-order selector, a lattice operation, an Archimedean comparison principle, a completion theorem, a quotient representative, or a host function equality. The translation and cone rows are compatibility obligations internal to the finite packet.

Therefore every legal consumer remains inside $A, O, P, M, I, K, H, C, Q, N$. Stronger ordered-algebra or completion claims require their own displayed NameCert rows. □

Falsifiable prediction: Every accepted $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ consumer displays the GroupUp row, OrderUp row, PosetUp readback, MonoidUp multiplication row, order-translation row, positive-cone row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and local naming before using order-compatible group structure.

Independence witness: group, order, poset, monoid: none is bijective because $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ jointly carries group laws, partial-order readback, monoid multiplication, translation-invariance accountability, positive-cone stability, transport, replay, provenance, and local naming in one packet.

Closure status for $\mathsf{NameCert}_{\mathsf{PartiallyOrderedGroup}^{\uparrow}}$.

Constructive story: A $\mathsf{PartiallyOrderedGroup}^{\uparrow}$ packet is generated from a GroupUp row, an OrderUp row, a PosetUp readback row, a MonoidUp multiplication row, translation-invariance accountability, positive-cone accountability, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{PartiallyOrderedGroup}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8601.1, Definition 8601.2, Definition 8601.3, Definition 8601.4, and Definition 8601.5 seed the finite order-compatible group certificate.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{PartiallyOrderedGroup}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Origin: human

Not claimed: This chapter does not close total orders, lattice-ordered groups, Archimedean comparison, ordered completions, quotient representatives, host group-function equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, group exposure, order exposure, poset readback, monoid multiplication exposure, translation-invariance accountability, positive-cone accountability, transport, replay, provenance, and local naming for BEDC.Derived.PartiallyOrderedGroupUp.

Chapter 8602

A Concrete Naming Certificate for $\mathsf{ModulusCauchyCompression}^{\uparrow}$

Following Bishop and Bridges on moduli for Cauchy constructions, this packet records a finite BEDC compression of regular-Cauchy tail schedules. It sits beside the stream-name surface of chapter 126, the regular rational readback of chapter 301, the dyadic tolerance ledger of chapter 291, and the real-name seal of chapter 38. The chapter names a displayed compression ledger for finite requests; it does not claim selected limits, quotient stream equality, countable choice, or ambient completeness.

Definition 8602.1 (Modulus Cauchy compression carrier)**.** *A* $\mathsf{ModulusCauchyCompression}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$K = (Q, D, S, R, H, C, P, N)$$

with the following displayed rows:

1. *Q is the finite request budget row for the compressed modulus surface.*
2. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *tolerance ledger that keeps the dyadic bounds visible.*
3. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row that exposes the finite tail schedule.*
4. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row obtained from the displayed windows.*
5. *H records componentwise* hsame *transport for Q, D, S, R, C, P, N.*
6. *C records displayed* Cont *replay from the request budget through the window row, dyadic ledger, and regular rational readback.*
7. *P is the* Pkg *provenance over* $\mathsf{ModulusCauchyCompression}^{\uparrow}$, BHist, hsame, Cont, $\mathsf{DyadicRatCore}^{\uparrow}$, $\mathsf{StreamName}^{\uparrow}$, $\mathsf{RegSeqRat}^{\uparrow}$, *and* $\mathsf{NameCert}$.
8. *N is the local* $\mathsf{NameCert}_{\mathsf{ModulusCauchyCompression}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through Q, D, S, R, H, C, P, N. It has no coordinate for selected limits, quotient stream equality, countable choice, ambient completeness, or a host real-space seal.

Theorem 8602.2 (Modulus Cauchy compression classifier transport)**.** *If two accepted* $\mathsf{ModulusCauchyCompression}^{\uparrow}$ *carriers agree row by row up to* hsame*, then the displayed classifier sees the same request budget, dyadic tolerance ledger, stream window, regular rational readback, replay, provenance, and local naming. The packet therefore transports only a finite NameCert surface inside* BHist.

Proof. Project the carrier of Definition 8602.1. The visible data are exactly the request budget row Q, the dyadic ledger D, the stream window S, the regular rational readback R, and the structural rows H, C, P, N.

Because hsame transport is recorded componentwise, the classifier cannot distinguish two packets that agree on those rows. The packet has no separate coordinate for a selected limit or a quotient stream, so the visible route is stable under transport. □

Theorem 8602.3 (Modulus Cauchy compression tail stability)**.** *Every accepted* $\mathsf{ModulusCauchyCompression}^{\uparrow}$ *carrier exposes its tail schedule through the same* $\mathsf{StreamName}^{\uparrow}$ *row before any* $\mathsf{RegSeqRat}^{\uparrow}$ *readback is consumed. The finite request budget Q therefore reaches the regular rational surface only after the dyadic and window rows have been displayed.*

Proof. The carrier definition places the request budget Q beside the dyadic ledger D and the stream window S. The readback row R is downstream of that displayed window data, so a consumer must read the finite tail schedule before it can read a regular rational output.

This is a stability statement about the route, not a completeness claim. The packet keeps the schedule finite, the window explicit, and the readback routed through $\mathsf{StreamName}^{\uparrow}$ and $\mathsf{RegSeqRat}^{\uparrow}$. □

Theorem 8602.4 (Modulus Cauchy compression ledger exactness)**.** *The* $\mathsf{DyadicRatCore}^{\uparrow}$ *ledger in an accepted* $\mathsf{ModulusCauchyCompression}^{\uparrow}$ *carrier records exactly the tolerance data needed for the compressed request budget. No additional dyadic witness, hidden choice row, or quotient equality row is available to the ledger.*

Proof. Inspect the definition. The row D is the unique tolerance ledger, and it is read together with the request budget Q and window row S.

Since the packet has only the rows listed in Definition 8602.1, the ledger cannot be supplemented by a hidden choice function or by a quotient stream equality. The exactness claim is only that the displayed dyadic data are the whole local ledger. □

Theorem 8602.5 (Modulus Cauchy compression RealUp handoff)**.** *An accepted* $\mathsf{ModulusCauchyCompression}^{\uparrow}$ *packet hands its displayed route to* $\mathsf{Real}^{\uparrow}$ *consumers only through the finite chain*

$$\mathsf{DyadicRatCore}^{\uparrow} \longmapsto \mathsf{StreamName}^{\uparrow} \longmapsto \mathsf{RegSeqRat}^{\uparrow} \longmapsto \mathsf{Real}^{\uparrow}.$$

The handoff does not add ambient completeness, selected limits, or bridge checking.

Proof. The carrier definition places the real-facing consumption downstream of the dyadic ledger, the stream windows, and the regular rational readback. A $\mathsf{Real}^{\uparrow}$ consumer therefore sees the same finite route before any endpoint seal is exposed.

Because the packet is a finite BHist object with explicit hsame, Cont, Pkg, and NameCert rows, the handoff remains local. The chapter does not claim ambient completeness or bridge checking; it only records the displayed route into the real-facing surface. □

Closure status for $\mathsf{NameCert}_{\mathsf{ModulusCauchyCompression}^{\uparrow}}$**.**

Constructive story: A $\mathsf{ModulusCauchyCompression}^{\uparrow}$ packet is generated from a finite request budget, a DyadicRatCore tolerance ledger, a StreamName window row, a RegSeqRat readback row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: TheoryGate($\mathsf{NameCert}_{\mathsf{ModulusCauchyCompression}^{\uparrow}}$, seed)

Scope closed: Definition 8602.1, Definition 8602.2, Definition 8602.3, Definition 8602.4, and Definition 8602.5 seed the finite compression route from regular-Cauchy tails to RegSeqRat and RealUp.

Formal verification: FormalStatus($\mathsf{NameCert}_{\mathsf{ModulusCauchyCompression}^{\uparrow}}$, unformalized)

Lean target: `BEDC.Derived.ModulusCauchyCompressionUp`

Bridge status: none

Not claimed: This chapter does not close selected limits, quotient stream equality, countable choice, ambient completeness, or bridge checking.

Upgrade path: The next grade requires checked carrier admission, exact tail compression, and a verified RealUp handoff for ModulusCauchyCompression$^{\uparrow}$.

Chapter 8603

A Concrete Naming Certificate for $\mathsf{FiniteElementMethod}^{\uparrow}$

Following Ciarlet's finite element method, the $\mathsf{FiniteElementMethod}^{\uparrow}$ packet records the finite mesh, local stiffness, assembly ledger, boundary row, and solution-readback surface that a constructive PDE-discretization consumer must inspect before it treats a variational problem as a computable finite system. It sits beside the PDE carrier of chapter 194, the matrix source of chapter 49, the linear-map source of chapter 48, and the vector-space source of chapter 47. The packet names only displayed finite element data; it does not assert analytic existence, host function equality, mesh convergence, hidden quadrature exactness, selected basis functions outside the ledger, or ambient completeness.

Definition 8603.1 (Finite element method carrier)**.** *A* $\mathsf{FiniteElementMethod}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$F = (M, V, L, A, B, R, S, H, C, P, N)$$

with the following displayed rows:

1. *M is the finite mesh row, naming cells, face incidences, boundary tags, and refinement provenance visible to the packet;*
2. *V is the local finite-element space row, naming the cellwise degrees of freedom, shape-function table, and local basis readback;*
3. *L is the local stiffness row, storing the finitely inspected bilinear-form entries on each cell;*
4. *A is the assembly ledger row, recording how local stiffness entries are routed into the global* $\mathsf{Mat}^{\uparrow}$ *row;*
5. *B is the boundary and load row, recording boundary constraints and source terms as displayed finite data;*
6. *R is the* $\mathsf{LinMap}^{\uparrow}$ *readback row associated with the assembled matrix and load data;*
7. *S is the solve-facing row, exposing the finite system interface without claiming an analytic PDE solution;*
8. *H records componentwise* hsame *transport for mesh, local space, stiffness, assembly, boundary, readback, solve-facing, provenance, and local naming rows;*
9. *C records displayed* Cont *replay from mesh inspection through local stiffness, assembly, readback, and solve-facing consumption;*

10. *P is the* Pkg *provenance over* $\mathsf{FiniteElementMethod}^{\uparrow}$, $\mathsf{Pde}^{\uparrow}$, $\mathsf{Mat}^{\uparrow}$, $\mathsf{LinMap}^{\uparrow}$, $\mathsf{VecSpace}^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{FiniteElementMethod}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $M, V, L, A, B, R, S, H, C, P, N$. It has no coordinate for host finite-element spaces, selected global basis functions outside V, analytic weak solutions, exact integration not displayed by L, quotient mesh equality, or convergence of a mesh family.

Theorem 8603.2 (Finite element method NameCert obligations)**.** *For every accepted* $\mathsf{FiniteElementMethod}^{\uparrow}$ *carrier*

$$F = (M, V, L, A, B, R, S, H, C, P, N),$$

the local $\mathsf{NameCert}_{\mathsf{FiniteElementMethod}^{\uparrow}}$ *surface consists exactly of carrier admission for finite meshes, local finite-element spaces, local stiffness tables, assembly ledgers, boundary and load rows, linear-map readback, solve-facing exposure, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming. Any PDE, matrix, or linear-map consumer of the packet must read through those rows before it cites a finite element method boundary.*

Proof. Project the carrier of Definition 8603.1. The mesh row M, local-space row V, stiffness row L, assembly row A, boundary row B, readback row R, and solve-facing row S are the only numerical-analysis coordinates.

The $\mathsf{Pde}^{\uparrow}$ sibling supplies the displayed relation-and-boundary discipline, while the $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ siblings supply the finite algebraic readback. The packet therefore exposes the finite element route as data moving from local cells to an assembled matrix, not as a host theorem about weak solutions.

Finally H, C, P, N transport, replay, source, and name the same finite packet. Since the carrier has no coordinate for hidden basis selection, analytic existence, unstated quadrature exactness, quotient mesh equality, or mesh-family convergence, the listed rows exhaust the local NameCert surface. □

Theorem 8603.3 (Finite element method local stiffness assembly)**.** *Every assembled algebraic read exported by an accepted* $\mathsf{FiniteElementMethod}^{\uparrow}$ *packet factors through the finite route*

$$M, V, L \longmapsto A \longmapsto R.$$

The local stiffness row is inspected cell by cell, the assembly ledger records each displayed placement into the global matrix row, and the linear-map readback consumes only the assembled rows already visible in the packet. No consumer may replace this route by host integration, an unstated global basis, a quotient mesh comparison, or an analytic PDE solution.

Proof. Start with the accepted carrier $F = (M, V, L, A, B, R, S, H, C, P, N)$. The local stiffness row L is meaningful only over the finite mesh M and local-space row V.

The assembly ledger A records the finite placement of each local entry into the matrix-facing surface. Thus the $\mathsf{Mat}^{\uparrow}$ and $\mathsf{LinMap}^{\uparrow}$ reads consume A and R rather than a hidden host assembly operation.

The structural rows H, C, P, N keep the same route under transport, replay, provenance, and local naming. Hence the assembled algebraic read is exactly the displayed finite route from mesh and local data to the assembled matrix readback. □

Theorem 8603.4 (Finite element method nonescape)**.** *Every accepted* $\mathsf{FiniteElementMethod}^{\uparrow}$ *consumer must keep the mesh row, local finite-element space row, local stiffness table, assembly ledger, boundary and load row, linear-map readback, solve-facing row, transport, replay, provenance, and local naming visible before citing the packet as finite element method data. The packet exports no analytic solution theorem, convergence theorem, host weak-form equality, selected global basis outside the displayed row, hidden quadrature, or ambient completeness principle.*

Proof. Apply the NameCert obligations of Definition 8603.2. They expose the finite mesh, local space, stiffness, assembly, boundary, readback, solve-facing, transport, replay, provenance, and naming rows.

Then use the local assembly theorem Definition 8603.3. It forces any algebraic consumer through the displayed mesh-to-matrix route before the finite system interface is read.

The excluded analytic and host-level objects are absent from the carrier. Therefore no downstream consumer can cite this packet as analytic PDE solvability, convergence, unstated basis selection, hidden integration exactness, quotient mesh equality, or ambient completion. □

Falsifiable prediction: Every accepted $\mathsf{FiniteElementMethod}^{\uparrow}$ finite-system read exposes mesh, local finite-element space, local stiffness, assembly, boundary and load, linear-map readback, solve-facing, hsame transport, Cont replay, Pkg provenance, and local NameCert rows before the finite element method boundary is consumed.

Independence witness: pde, matrix, linearmap, vecspace: $\mathsf{FiniteElementMethod}^{\uparrow}$ is not bijective to any listed sibling because it jointly carries a finite mesh, local finite-element spaces, local stiffness tables, assembly ledgers, boundary rows, linear-map readback, solve-facing exposure, transport, replay, provenance, and local naming as one discretization packet.

Closure status for $\mathsf{NameCert}_{\mathsf{FiniteElementMethod}^{\uparrow}}$.

Constructive story: A $\mathsf{FiniteElementMethod}^{\uparrow}$ packet is generated from a finite mesh row, local finite-element space row, local stiffness table, assembly ledger, boundary and load row, LinearMapUp readback, solve-facing row, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{FiniteElementMethod}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8603.1, Definition 8603.2, Definition 8603.3, and Definition 8603.4 seed the finite mesh, local stiffness, assembly, boundary, algebraic readback, transport, replay, provenance, and local naming surface.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{FiniteElementMethod}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim analytic PDE solvability, weak-solution uniqueness, mesh convergence, hidden quadrature exactness, quotient mesh equality, host function equality, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, mesh exposure, local-space exposure, stiffness-table exactness, assembly-ledger routing, boundary and load readback, linear-map handoff, nonescape, transport, replay, provenance, and local naming for BEDC.Derived.FiniteElementMethodUp.

Chapter 8604

A Concrete Naming Certificate for MetaCICNormalizationRedexFrontier$^{\uparrow}$

The MetaCICNormalizationRedexFrontier$^{\uparrow}$ packet realizes the candidate-mediated route of chapter 9383 as finite NameCert data. It sits beside the critical-path source of chapter 765, the normalization frontier of chapter 892, the parallel-diamond frontier of chapter 4238, and the typed example coverage matrix of chapter 923. The packet records typed terms, candidate evidence, residual budgets, beta windows, strong-normalization handoff, transport, replay, provenance, and local naming without claiming unconditional normalization for every closed MetaCIC term.

Definition 8604.1 (MetaCIC normalization redex-frontier carrier)**.** *A* MetaCICNormalizationRedexFrontier$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$R = (T, C, E, B, W, S, D, H, Q, P, N)$$

with the following visible rows:

1. *T is the typed-term frontier row, naming the closed term, type, context boundary, and visible redex windows;*
2. *C is the candidate-evidence row consumed by the candidate-mediated strong-normalization route;*
3. *E is the candidate-set or closed-candidate evidence row, when the route is exposed through a packaged candidate surface;*
4. *B is the residual-budget row, bounding the redex windows inspected before the strong-normalization handoff is cited;*
5. *W is the beta-window row, recording the finite beta steps and local residual reads relevant to the frontier;*
6. *S is the strong-normalization handoff row, readable only after T, C, E, B, W have been displayed;*
7. *D is the typed-example coverage row, showing which example or coverage matrix row witnesses the packet when a concrete term is used;*
8. *H records componentwise* hsame *transport for typed-term, candidate, evidence, budget, beta-window, handoff, coverage, provenance, and local naming rows;*
9. *Q records displayed* Cont *replay from typed-term inspection through candidate evidence, redex budgeting, beta-window reading, and strong-normalization handoff;*

10. *P is the* Pkg *provenance over* MetaCICNormalizationRedexFrontier$^{\uparrow}$, MetaCICCriticalPath$^{\uparrow}$, MetaCICNormalization MetaCICParallelDiamondFrontier$^{\uparrow}$, TypedExampleCoverageMatrix$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert*;*
11. *N is the local* NameCert$_{\text{MetaCICNormalizationRedexFrontier}^{\uparrow}}$ *row.*

The carrier has no coordinate for global closed-term normalization without candidate evidence, unrestricted subject reduction, full confluence, quotient syntax equality, evaluator equality, or kernel consistency.

Theorem 8604.2 (MetaCIC normalization redex-frontier NameCert obligations)**.** *For every accepted* MetaCICNormalizationRedexFrontier$^{\uparrow}$ *carrier*

$$R = (T, C, E, B, W, S, D, H, Q, P, N),$$

the local NameCert$_{\text{MetaCICNormalizationRedexFrontier}^{\uparrow}}$ *surface consists exactly of carrier admission for typed-term frontiers, candidate evidence, packaged candidate-set or closed-candidate evidence, residual budgets, beta windows, strong-normalization handoff, typed-example coverage, componentwise* hsame *transport, displayed* Cont *replay,* Pkg *provenance, and local naming.*

Proof. Project the carrier of Definition 8604.1. The typed frontier, candidate evidence, packaged evidence, residual budget, beta window, strong-normalization handoff, and coverage row are the only MetaCIC coordinates.

The audit map of chapter 9383 requires the candidate layer to remain visible. Rows C and E record that layer, while B and W keep the inspected redex frontier finite before S is read.

The sibling rows place the frontier in the existing MetaCIC lattice: critical path for the proof route, normalization frontier for the candidate handoff, parallel-diamond frontier for confluence-facing interaction, and typed example coverage for concrete witnesses. Since the carrier has no coordinate for unconditional normalization, subject reduction, full confluence, quotient syntax equality, evaluator equality, or kernel consistency, the listed rows exhaust the local NameCert obligations. □

Theorem 8604.3 (MetaCIC normalization redex-frontier candidate handoff)**.** *Every strong-normalization read exported by an accepted* MetaCICNormalizationRedexFrontier$^{\uparrow}$ *packet factors through*

$$T, C, E, B, W \longmapsto S.$$

The typed term frontier is inspected first, the candidate evidence and packaged evidence remain displayed, the residual budget and beta window bound the redex read, and only then may the strong-normalization handoff row be consumed.

Proof. Start with the accepted carrier $R = (T, C, E, B, W, S, D, H, Q, P, N)$. The row S is downstream of the typed-term, candidate, packaged-evidence, budget, and beta-window rows.

The candidate-mediated route prevents a consumer from erasing C or E from the citation. The residual budget and beta window keep the redex frontier finite, so the route is a displayed packet rather than a global evaluator theorem.

Transport, replay, provenance, and local naming preserve the same dependency order through H, Q, P, N. Therefore every strong-normalization handoff read factors through T, C, E, B, W before S is available. □

Theorem 8604.4 (MetaCIC normalization redex-frontier nonescape)**.** *Every accepted* MetaCICNormalizationRedex *consumer must keep the typed-term frontier, candidate evidence, packaged evidence, residual budget, beta window, strong-normalization handoff, coverage row, transport, replay, provenance, and*

local naming visible before citing the packet as normalization evidence. It cannot cite the packet as unconditional closed-term normalization, subject reduction, full confluence, quotient syntax equality, evaluator equality, or kernel consistency.

Proof. Use the NameCert obligations of Definition 8604.2. They expose the typed-term, candidate, evidence, budget, beta-window, handoff, coverage, transport, replay, provenance, and naming rows.

Then apply the candidate handoff theorem Definition 8604.3. It forces the strong-normalization read through the candidate-mediated redex frontier before any endpoint can be consumed.

The stronger metatheorems are absent from the carrier. Thus no consumer can replace this packet by global normalization, subject reduction, full confluence, quotient syntax equality, evaluator equality, or kernel consistency. □

Falsifiable prediction: Every accepted $\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}$ normalization read exposes MetaCICCriticalPath, MetaCICNormalizationFrontier, MetaCICParallelDiamondFrontier, and TypedExampleCoverageMatrix rows together with typed-term, candidate, evidence, residual-budget, beta-window, strong-normalization handoff, transport, replay, provenance, and local naming data.

Independence witness: metaciccriticalpath, metacicnormalizationfrontier, metacic-parallel-diamond-frontier, typedexamplecoveragematrix: none is bijective to $\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}$ because this packet jointly carries typed-term redex windows, candidate evidence, packaged candidate rows, residual budgets, beta-window reads, strong-normalization handoff, coverage, transport, replay, provenance, and local naming. The Lean TasteGate surface must provide Nontrivial and FieldFaithful instances for the same carrier rows before this packet can be treated as a checked derived target.

Closure status for $\mathsf{NameCert}_{\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}}$.

Constructive story: A $\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}$ packet is generated from a typed-term frontier, candidate evidence, packaged candidate-set or closed-candidate evidence, residual budget, beta window, strong-normalization handoff, typed-example coverage, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8604.1, Definition 8604.2, Definition 8604.3, and Definition 8604.4 seed the candidate-mediated redex-frontier route over typed terms, candidate evidence, residual budgets, beta windows, strong-normalization handoff, coverage, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{MetaCICNormalizationRedexFrontier}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not claim unconditional closed-term normalization, subject reduction, full confluence, quotient syntax equality, evaluator equality, kernel consistency, Lean verification, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, typed-term exposure, candidate-evidence exposure, packaged-evidence routing, residual-budget exactness, beta-window readback, strong-normalization handoff, typed-example coverage, transport, replay, provenance, local naming, Nontrivial TasteGate evidence, and FieldFaithful TasteGate evidence for BEDC.Derived.MetaCICNormalizationRedexFrontierUp.

Chapter 8605

Dyadic Barycentric Refinement NameCert Construction

Following Bishop and Bridges, the $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ packet records dyadic barycentric subdivision as finite listed cell data rather than as an open-cover compactness principle. It sits after the dyadic arithmetic core of chapter 291, the finite StreamName windows of chapter 126, the regular rational readback route of chapter 301, the terminal Real seal of chapter 38, and the finite interval-cell consumer of chapter 5966. The packet gives Real, Completion, and compact-interval arguments a displayed finite subdivision surface; it does not export open-cover compactness, selected subcovers, quotient streams, countable choice, trichotomy, host real equality, or ambient $\mathsf{Real}^{\uparrow}$ completeness.

Definition 8605.1 (Dyadic barycentric refinement carrier)**.** *A* $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$B = (D, I, M, K, S, R, Q, H, C, P, N)$$

with the following rows:

1. *D is the* $\mathsf{DyadicRatCore}^{\uparrow}$ *endpoint row. It records dyadic addition, halving, midpoint, successor, and radius comparisons used by the subdivision.*
2. *I is the parent-cell row consumed from* $\mathsf{DyadicIntervalNet}^{\uparrow}$*. It lists the displayed closed dyadic cells before refinement.*
3. *M is the midpoint row. For each listed parent cell it records the dyadic barycenter and the two displayed child endpoints produced by bisection.*
4. *K is the finite child-cell row. It lists the child cells, their parent pointers, adjacency witnesses, endpoint inheritance, and mesh-decrease witnesses.*
5. *S is the* $\mathsf{StreamName}^{\uparrow}$ *window row exposed when a parent endpoint, barycenter, or child endpoint is read.*
6. *R is the* $\mathsf{RegSeqRat}^{\uparrow}$ *readback row for the dyadic endpoints and the tolerance schedule induced by the child-cell radii.*
7. *Q is the terminal* $\mathsf{Real}^{\uparrow}$ *seal row reached only after the displayed parent, midpoint, child-cell, window, and readback rows have been inspected.*
8. *H records componentwise* hsame *transport for D, I, M, K, S, R, Q and the structural rows.*

9. *C records displayed* Cont *replay of the finite route*

$$D, I, M, K \longmapsto S, R \longmapsto Q, H, P, N.$$

10. *P is the* Pkg *provenance over* DyadicBarycentricRefinement$^{\uparrow}$, DyadicRatCore$^{\uparrow}$, DyadicIntervalNet$^{\uparrow}$, StreamName$^{\uparrow}$, RegSeqRat$^{\uparrow}$, Real$^{\uparrow}$, BHist, hsame, Cont, *and* NameCert *rows.*

11. *N is the local* NameCert$_{\text{DyadicBarycentricRefinement}^{\uparrow}}$ *row.*

The classifier compares accepted packets only through $D, I, M, K, S, R, Q, H, C, P, N$. It has no coordinate for an arbitrary open cover, a selected finite subcover, quotient stream equality, a chosen limit point, countable choice, trichotomy, or completed real compactness.

Theorem 8605.2 (Dyadic barycentric refinement NameCert obligations)**.** *For the carrier of Definition 8605.1, the local* NameCert$_{\text{DyadicBarycentricRefinement}^{\uparrow}}$ *surface consists exactly of carrier admission for*

$$B = (D, I, M, K, S, R, Q, H, C, P, N),$$

dyadic endpoint arithmetic through D, parent-cell exposure through I, barycenter exposure through M, child-cell listing through K, finite observation windows through S, regular rational readback through R, the terminal Real seal through Q, componentwise transport through H, displayed replay through C, provenance through P, and local naming through N.

Proof. Project the carrier definition. The rows D, I, M, K are the only subdivision-facing data: endpoints and midpoint arithmetic live in D, M, while the parent and child finite-cell ledgers live in I, K.

The observation and Real-facing rows are downstream. Endpoint and barycenter reads pass through S, the induced dyadic tolerance schedule passes through R, and the terminal real-name boundary is exposed only by Q.

Finally replay H, C, P, N. Transport, continuation replay, provenance, and local naming preserve exactly the displayed finite route, so the certificate exports subdivision data only through the listed rows. □

Theorem 8605.3 (Dyadic barycentric refinement RegSeqRat handoff)**.** *Every downstream consumer of an accepted* DyadicBarycentricRefinement$^{\uparrow}$ *carrier that inspects a parent endpoint, barycenter, child endpoint, or child-cell tolerance must read*

$$D, I, M, K \longmapsto S, R \longmapsto Q, H, C, P, N.$$

The DyadicRatCore$^{\uparrow}$ *row D supplies the dyadic arithmetic, the* StreamName$^{\uparrow}$ *row S exposes the finite endpoint windows, and the* RegSeqRat$^{\uparrow}$ *row R exposes the rational tolerance readback. Neither row may be skipped or replaced by quotient stream equality, selected limits, countable choice, or open-cover compactness.*

Proof. Begin with a downstream endpoint or tolerance read. The carrier gives the consumer only the parent cells in I, barycenters in M, child cells in K, and dyadic arithmetic in D before any named readback row is available.

The read then passes through S and R. The StreamName row supplies finite observation windows for the relevant endpoint names, while the RegSeqRat row supplies the regular rational schedule attached to the child-cell radii.

Finally replay Q, H, C, P, N. The Real seal is reached only after the displayed finite handoff, and the structural rows preserve that handoff componentwise, excluding quotient stream equality, selected limits, choice, and open-cover compactness. □

Theorem 8605.4 (Dyadic barycentric refinement Real seal non-escape)**.** *For every accepted* $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ *carrier* $B = (D, I, M, K, S, R, Q, H, C, P, N)$*, the terminal* $\mathsf{Real}^{\uparrow}$ *seal row* Q *is reachable only after the finite subdivision route*

$$D, I, M, K \longmapsto S, R$$

has been displayed. Any Real, Completion, compact-interval, or $\mathsf{DyadicIntervalNet}^{\uparrow}$ *consumer that reaches* Q *remains inside the same routed packet* $D, I, M, K, S, R, Q, H, C, P, N$ *and cannot escape to host real equality, real trichotomy, ambient* $\mathsf{Real}^{\uparrow}$ *completeness, selected subcovers, quotient equality, selected limits, or countable choice.*

Proof. Project the accepted packet. The carrier places Q downstream of endpoint arithmetic, parent cells, barycenter rows, child-cell rows, StreamName windows, and RegSeqRat readback.

Thus a Real-facing consumer must first traverse D, I, M, K, S, R. These rows display the finite subdivision cells, endpoint reads, and tolerance schedule before any Real-facing boundary is available.

Once Q is reached, the structural rows H, C, P, N only preserve the same displayed route. Since no excluded equality, selection, trichotomy, choice, compactness, or completeness row is present in the carrier, the Real seal cannot be used as an escape from the finite dyadic barycentric refinement packet. □

Closure status for $\mathsf{NameCert}_{\mathsf{DyadicBarycentricRefinement}^{\uparrow}}$.

Constructive story: A $\mathsf{DyadicBarycentricRefinement}^{\uparrow}$ packet is generated from dyadic endpoint arithmetic, parent interval cells, barycenter rows, finite child cells, StreamName windows, RegSeqRat readback, Real seals, componentwise hsame transport, displayed Cont replay, Pkg provenance, and a local NameCert row.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{DyadicBarycentricRefinement}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8605.1, Definition 8605.2, Definition 8605.3, and Definition 8605.4 seed the finite dyadic barycentric refinement carrier over dyadic endpoints, parent cells, barycenters, child cells, StreamName windows, RegSeqRat readback, Real seals, transport, replay, provenance, and local naming.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{DyadicBarycentricRefinement}^{\uparrow}}, \mathsf{formalTarget})$
Lean4 (statement) `BEDC.Derived.DyadicBarycentricRefinementUp`

Bridge status: none

Not claimed: This chapter does not close open-cover compactness, selected subcovers, quotient stream equality, countable choice, trichotomy, host real equality, Lean theorem checking, or bridge checking.

Upgrade path: Obligation closure requires checked carrier admission, barycenter arithmetic, child-cell coverage, StreamName and RegSeqRat readback routing, Real seal ordering, provenance, and local naming for BEDC.Derived.DyadicBarycentricRefineme

Chapter 8606

A Concrete Naming Certificate for $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$

Following Atiyah and Bott, the $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$ packet records a fixed-point formula as a finite local-index and trace ledger over an already displayed endomap. It consumes the Lefschetz trace surface of $\mathsf{LefschetzFixedPoint}^{\uparrow}$ (chapter 6557), the local index accounting route of $\mathsf{FixedPointIndex}^{\uparrow}$ (chapter 7376), compact-source rows from $\mathsf{CompactMetric}^{\uparrow}$ (chapter 129), self-map rows from $\mathsf{ContinuousMap}^{\uparrow}$ (chapter 130), and homology handoff rows from $\mathsf{Homology}^{\uparrow}$ (chapter 98). The packet is not a new ambient fixed-point theorem; it is the local formula surface that lets downstream readers see exactly which fixed-locus, index-weight, and trace rows are being composed.

Definition 8606.1 (Atiyah–Bott fixed point formula carrier)**.** *An* $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$ *carrier is a finite* BHist *packet*

$$A = (X, F, L, I, T, K, M, H, C, P, N)$$

with the following displayed rows:

1. *X is the compact-source row, read through* $\mathsf{CompactMetric}^{\uparrow}$*, naming the inspected finite source surface and its compact-metric probes.*
2. *F is the continuous self-map row, read through* $\mathsf{ContinuousMap}^{\uparrow}$*, whose fixed-locus and induced homology action are being inspected.*
3. *L is the fixed-locus row, listing the displayed fixed components, point windows, or refusal rows that the formula is allowed to inspect.*
4. *I is the local index-weight ledger, read through* $\mathsf{FixedPointIndex}^{\uparrow}$*, assigning each displayed fixed-locus row its finite index or weight datum.*
5. *T is the trace row, read through* $\mathsf{LefschetzFixedPoint}^{\uparrow}$*, recording the finite alternating trace or Lefschetz accounting datum.*
6. *K is the homology handoff row, read through* $\mathsf{Homology}^{\uparrow}$*, exposing the induced homology action needed by the trace computation.*
7. *M is the formula-match row comparing the sum of displayed local index-weights with the trace ledger through* $\mathsf{Real}^{\uparrow}$ *or the finite scalar row already named by the dependencies.*
8. *H records componentwise* hsame *transport for compact source, self-map, fixed-locus, index-weight, trace, homology handoff, formula-match, replay, provenance, and naming rows.*

9. *C records displayed* Cont *replay from X, F into L, K, from L into I, from K into T, and from I, T into M.*
10. *P is the* Pkg *provenance over* $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$, $\mathsf{LefschetzFixedPoint}^{\uparrow}$, $\mathsf{FixedPointIndex}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, $\mathsf{Homology}^{\uparrow}$, BHist, hsame, Cont, *and local naming rows.*
11. *N is the local* $\mathsf{NameCert}_{\mathsf{AtiyahBottFixedPoint}^{\uparrow}}$ *row.*

The carrier exports only these rows. It has no coordinate for transversality, smooth manifold structure, elliptic complexes, analytic index theory, host cohomology isomorphisms, or a global fixed-point existence theorem outside the displayed BEDC packets.

Theorem 8606.2 (Atiyah–Bott fixed point NameCert obligations)**.** *For an accepted* $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$ *carrier $A = (X, F, L, I, T, K, M, H, C, P, N)$, the local* $\mathsf{NameCert}_{\mathsf{AtiyahBottFixedPoint}^{\uparrow}}$ *surface consists exactly of carrier admission for the compact source, continuous self-map, fixed-locus, local index-weight ledger, trace row, homology handoff, formula-match row, componentwise transport, displayed replay, provenance, and local naming rows. Every formula read must pass through* $\mathsf{CompactMetric}^{\uparrow}$ *and* $\mathsf{ContinuousMap}^{\uparrow}$ *before the fixed-locus row is inspected, through* $\mathsf{FixedPointIndex}^{\uparrow}$ *before local weights are read, through* $\mathsf{Homology}^{\uparrow}$ *and* $\mathsf{LefschetzFixedPoint}^{\uparrow}$ *before the trace row is read, and through M before the local-index sum is compared with the trace ledger.*

Proof. Project the carrier of Definition 8606.1. Its rows already separate the compact source, self-map, fixed locus, index weights, trace ledger, homology handoff, and formula match.

Read the fixed-locus route first. The source row X and self-map row F expose the only fixed components that the packet may inspect, while L records whether those components are displayed or refused.

Read the two formula sides separately. The local side passes from L to the $\mathsf{FixedPointIndex}^{\uparrow}$ row I, and the trace side passes from the homology handoff K to the $\mathsf{LefschetzFixedPoint}^{\uparrow}$ trace row T.

Finally use M, H, C, P, N. The match row compares only the displayed local weights and trace ledger, while transport, replay, provenance, and naming preserve the same finite rows. No unlisted analytic or host topological datum can enter the local NameCert surface. □

Theorem 8606.3 (Atiyah–Bott fixed point index route)**.** *Every* $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$ *formula read factors through the route*

$$X, F \longmapsto L, \qquad L \longmapsto I, \qquad X, F, K \longmapsto T, \qquad I, T \longmapsto M.$$

Thus the local index-weight sum and the Lefschetz trace ledger meet only at the displayed formula-match row. A consumer cannot bypass the fixed-locus row, replace $\mathsf{FixedPointIndex}^{\uparrow}$ *with an ambient analytic index theorem, replace* $\mathsf{LefschetzFixedPoint}^{\uparrow}$ *with a host trace theorem, or infer global fixed-point existence from the local equality ledger.*

Proof. Begin with the compact-source and continuous self-map rows. They determine the fixed-locus row L as the only admissible source of local fixed components for this packet.

The local branch then reads I through $\mathsf{FixedPointIndex}^{\uparrow}$. This supplies the index-weight ledger for the displayed components and no analytic index object outside the row.

The trace branch reads K through $\mathsf{Homology}^{\uparrow}$ and then T through $\mathsf{LefschetzFixedPoint}^{\uparrow}$. This supplies the finite trace accounting datum and no host trace theorem outside the dependency packets.

At the final step, M compares the two displayed formula sides. Since every route into M has already passed through L, I, K, T, the consumer receives a local formula ledger rather than a global fixed-point theorem or an ambient Atiyah–Bott analytic package. □

Closure status for $\mathsf{NameCert}_{\mathsf{AtiyahBottFixedPoint}^{\uparrow}}$.

Theory closure: $\mathsf{TheoryGate}(\mathsf{NameCert}_{\mathsf{AtiyahBottFixedPoint}^{\uparrow}}, \mathsf{seed})$

Scope closed: Definition 8606.1, Definition 8606.2, and Definition 8606.3 seed the local fixed-locus, index-weight, trace, homology handoff, transport, replay, provenance, and NameCert rows over $\mathsf{LefschetzFixedPoint}^{\uparrow}$, $\mathsf{FixedPointIndex}^{\uparrow}$, $\mathsf{CompactMetric}^{\uparrow}$, $\mathsf{ContinuousMap}^{\uparrow}$, and $\mathsf{Homology}^{\uparrow}$.

Formal verification: $\mathsf{FormalStatus}(\mathsf{NameCert}_{\mathsf{AtiyahBottFixedPoint}^{\uparrow}}, \mathsf{unformalized})$

Bridge status: none

Not claimed: This chapter does not close Lean verification, bridge checking, transversality, smooth manifold structure, elliptic index theory, host cohomology isomorphisms, or global fixed-point existence.

Upgrade path: Obligation closure requires checked carrier admission, fixed-locus exposure, local index-weight exactness, trace and homology handoff, formula-match transport, replay, provenance, and no-host-theorem boundaries for BEDC.Derived.AtiyahBottFixedPointUp.

Constructive story: An $\mathsf{AtiyahBottFixedPoint}^{\uparrow}$ packet is generated from compact-source rows, a continuous self-map row, fixed-locus rows, local index-weight rows, Lefschetz trace rows, homology handoff rows, componentwise transport, displayed replay, provenance, and local NameCert data.

Chapter 8607

A Concrete Naming Certificate for MirandaTheoremFiniteCube$^{\uparrow}$

Following Miranda and the standard finite-dimensional intermediate-value tradition, the MirandaTheoremFiniteCube packet records the finite cube sign-change interface by which opposite-face sign data is read before any zero-facing consumer may act. It sits beside the labelled simplex route of chapter 2003, the finite obstruction ledger of chapter 3745, the compact carrier of chapter 60, the displayed map surface of chapter 130, and the terminal Real seal of chapter 38. The chapter names only finite cube, face-sign, compactness, continuity, degree, and readback rows; it does not assert a host zero theorem, selected root, quotient real equality, open-cover compactness, countable choice, or ambient Real$^{\uparrow}$ completeness.

Definition 8607.1 (Miranda theorem finite-cube carrier)**.** *A* MirandaTheoremFiniteCube$^{\uparrow}$ *carrier is a finite* BHist *packet*

$$M = (Q, F, S, C, D, L, W, R, E, H, T, P, N)$$

with the following displayed rows:

1. *Q is the finite cube row, listing the coordinate faces, opposite-face pairs, finite cell incidence table, and dyadic subdivision windows used by the certificate.*
2. *F is the face-sign row. For each coordinate it records the negative-face and positive-face sign reads of the displayed map.*
3. *S is the sign-stability row, preserving those face signs under the finite refinements, StreamName windows, and componentwise* hsame *transports used by the packet.*
4. *C is the* Compact$^{\uparrow}$ *source row for the named cube, read only as the displayed compact carrier required by the finite certificate.*
5. *D is the* BrouwerDegree$^{\uparrow}$ *obstruction row, consumed only as the finite boundary ledger attached to the sign-change data.*
6. *L is the* SpernerLemma$^{\uparrow}$ *labelled-cell handoff row, recording the finite labelled subdivision through which a sign conflict is localized.*
7. *W is the* StreamName$^{\uparrow}$ *finite-window row opened for coordinates, face probes, and retained cells.*
8. *R is the* RegSeqRat$^{\uparrow}$ *regular readback row attached to those windows and dyadic cell tolerances.*
9. *E is the terminal* Real$^{\uparrow}$ *seal row for the displayed candidate cell, available only after Q, F, S, C, D, L, W, R have been read.*

10. *H records componentwise* hsame *transport for all displayed rows.*
11. *T records displayed* Cont *replay through the* $\mathsf{ContinuousMap}^{\uparrow}$ *source surface.*
